Challenge/Response Limitations in the Java Servlet API 2.3 Environment ........................................................... 5-25
Filters and The Role of the weblogic.security.services.Authentication Class ...................................................... 5-25
How to Develop a Challenge Identity Asserter ........................ 5-25
Implement the ChallengeIdentityAsserterV2 Interface .............. 5-26
Implement the ProviderChallengeContext Interface ............... 5-26
Invoke the weblogic.security.services Challenge Identity Methods .......................................................... 5-27
Invoke the weblogic.security.services App ChallengeContext Methods ......................................................... 5-28
6. Principal Validation Providers

Principal Validation Concepts .................................................. 6-1
Principal Validation and Principal Types ................................. 6-2
How Principal Validation Providers Differ From Other Types of Security Providers 6-2
Security Exceptions Resulting from Invalid Principals .................. 6-2
The Principal Validation Process .............................................. 6-3
Do You Need to Develop a Custom Principal Validation Provider? ........ 6-4
How to Use the WebLogic Principal Validation Provider .................. 6-5
How to Develop a Custom Principal Validation Provider .................. 6-5
Implement the PrincipalValidator SSPI .................................... 6-6

7. Authorization Providers

Authorization Concepts ......................................................... 7-1
Access Decisions ................................................................. 7-2
Using the Java Authorization Contract for Containers .................... 7-2
The Authorization Process ..................................................... 7-2
Do You Need to Develop a Custom Authorization Provider? .......... 7-5
Does Your Custom Authorization Provider Need to Support Application Versioning? 7-5

How to Develop a Custom Authorization Provider ....................... 7-5
Create Runtime Classes Using the Appropriate SSPIs ................. 7-6
Implement the AuthorizationProvider SSPI ............................... 7-6
Implement the DeployableAuthorizationProviderV2 SSPI ............... 7-7
Implement the AccessDecision SSPI ........................................ 7-9
Example: Creating the Runtime Class for the Sample Authorization Provider 7-11
Policy Consumer SSPI ......................................................... 7-17
Required SSPI Interfaces ..................................................... 7-18
Implement the PolicyConsumerFactory SSPI Interface .................. 7-18
Implement the PolicyConsumer SSPI Interface ............................. 7-18
Implement the PolicyCollectionHandler SSPI Interface .................. 7-20
Supporting an Updated Policy Collection ................................. 7-21
The PolicyConsumerMBean .................................................. 7-21
PolicyStoreMBean ............................................................ 7-21
Examining the Format of a XACML Policy File .............................. 7-23
Using WLST to Add a Policy to the PolicyStoreMBean .................. 7-23
Using WLST to Read a PolicySet as a String .............................. 7-25
Bulk Authorization Providers ................................................. 7-26
Generate an MBean Type Using the WebLogic MBeanMaker ............... 7-27
Create an MBean Definition File (MDF) .................................... 7-27
Use the WebLogic MBeanMaker to Generate the MBean Type ............ 7-28
Use the WebLogic MBeanMaker to Create the MBean JAR File (MJF) .... 7-31
Install the MBean Type Into the WebLogic Server Environment .......... 7-32
Configure the Custom Authorization Provider Using the Administration Console 7-33
Managing Authorization Providers and Deployment Descriptors .......... 7-34
Enabling Security Policy Deployment ....................................... 7-35
Provide a Mechanism for Security Policy Management ..................... 7-36
Option 1: Develop a Stand-Alone Tool for Security Policy Management .... 7-36
Option 2: Integrate an Existing Security Policy Management Tool into the Administration Console ......................... 7-36

8. Adjudication Providers

The Adjudication Process ...................................................... 8-1
Do You Need to Develop a Custom Adjudication Provider? ................ 8-1
How to Develop a Custom Adjudication Provider .......................... 8-3
Create Runtime Classes Using the Appropriate SSPIs ...................... 8-3
Developing Security Providers for WebLogic Server

Implement the AdjudicationProviderV2 SSPI ........................................ 8-3
Implement the AdjudicatorV2 SSPI .................................................. 8-4
Bulk Adjudication Providers ......................................................... 8-4
Generate an MBean Type Using the WebLogic MBeanMaker ............... 8-5
Create an MBean Definition File (MDF) ......................................... 8-6
Use the WebLogic MBeanMaker to Generate the MBean Type .......... 8-6
Use the WebLogic MBeanMaker to Create the MBean JAR File (MJF) . 8-9
Install the MBean Type Into the WebLogic Server Environment ........ 8-10

Configure the Custom Adjudication Provider Using the Administration Console . 8-11

9. Role Mapping Providers

Role Mapping Concepts ................................................................. 9-1
Security Roles ............................................................................ 9-2
Dynamic Security Role Computation .......................................... 9-2
The Role Mapping Process .......................................................... 9-3
Do You Need to Develop a Custom Role Mapping Provider? .......... 9-6
Does Your Custom Role Mapping Provider Need to Support Application Versioning? 9-6

How to Develop a Custom Role Mapping Provider ......................... 9-6
Create Runtime Classes Using the Appropriate SSPIs .................... 9-6
Implement the RoleProvider SSPI .................................................. 9-7
Implement the DeployableRoleProviderV2 SSPI .......................... 9-8
Implement the RoleMapper SSPI .................................................... 9-9
Implement the SecurityRole Interface .......................................... 9-11
Example: Creating the Runtime Class for the Sample Role Mapping Provider 9-12

Role Consumer SSPI ................................................................. 9-20
Required SSPI Interfaces ........................................................... 9-21
Implement the RoleConsumerFactory SSPI Interface ................... 9-21
Implement the RoleConsumer SSPI Interface ........................................... 9-21
Implement the RoleCollectionHandler SSPI Interface ............................... 9-23
Supporting an Updated Role Collection ..................................................... 9-24
The RoleConsumerMBean ........................................................................... 9-24
PolicyStoreMBean ....................................................................................... 9-24
Examining the Format of a XACML Policy File ............................................ 9-26
Using WLST to Add a Policy to the PolicyStoreMBean ............................... 9-26
Using WLST to Read a PolicySet as a String .............................................. 9-28
Bulk Role Mapping Providers ...................................................................... 9-29
Generate an MBean Type Using the WebLogic MBeanMaker ..................... 9-30
Create an MBean Definition File (MDF) ...................................................... 9-30
Use the WebLogic MBeanMaker to Generate the MBean Type .................. 9-31
Use the WebLogic MBeanMaker to Create the MBean JAR File (MJF) ....... 9-34
Install the MBean Type Into the WebLogic Server Environment .................. 9-35
Configure the Custom Role Mapping Provider Using the Administration Console 9-36
Managing Role Mapping Providers and Deployment Descriptors ................. 9-36
Enabling Security Role Deployment ............................................................ 9-38
Provide a Mechanism for Security Role Management ............................... 9-38
Option 1: Develop a Stand-Alone Tool for Security Role Management ........ 9-38
Option 2: Integrate an Existing Security Role Management Tool into the Administration Console ................................. 9-39

10. Auditing Providers

Auditing Concepts ....................................................................................... 10-1
Audit Channels ............................................................................................ 10-2
Auditing Events From Custom Security Providers ..................................... 10-2
The Auditing Process ................................................................................... 10-2
Implementing the ContextHandler MBean ................................................... 10-5
11. Credential Mapping Providers

Credential Mapping Concepts ................................................. 11-1
The Credential Mapping Process ........................................... 11-2
Do You Need to Develop a Custom Credential Mapping Provider? ....... 11-3
  Does Your Custom Credential Mapping Provider Need to Support Application
  Versioning? ................................................................. 11-4
How to Develop a Custom Credential Mapping Provider ................. 11-4
  Create Runtime Classes Using the Appropriate SSPIs .................. 11-5
  Implement the CredentialProviderV2 SSPI ........................... 11-5
  Implement the DeployableCredentialProvider SSPI .................. 11-6
  Implement the CredentialMapperV2 SSPI ............................... 11-6
  Generate an MBean Type Using the WebLogic MBeanMaker .......... 11-8
  Create an MBean Definition File (MDF) ............................... 11-9
  Use the WebLogic MBeanMaker to Generate the MBean Type ...... 11-9
  Use the WebLogic MBeanMaker to Create the MBean JAR File (MJF) . 11-13
  Install the MBean Type Into the WebLogic Server Environment ...... 11-14
  Provide a Mechanism for Credential Map Management ............... 11-15
  Option 1: Develop a Stand-Alone Tool for Credential Map Management . 11-16
  Option 2: Integrate an Existing Credential Map Management Tool into the Administration Console ........................................... 11-16

12. Auditing Events From Custom Security Providers

Security Services and the Auditor Service ................................ 12-1
How to Audit From a Custom Security Provider .......................... 12-3
  Create an Audit Event .................................................. 12-3
  Implement the AuditEvent SSPI ........................................ 12-3
Implement an Audit Event Convenience Interface ...................... 12-4
Audit Severity .............................................................. 12-7
Audit Context .............................................................. 12-8
Example: Implementation of the AuditRoleEvent Interface ............. 12-8
Obtain and Use the Auditor Service to Write Audit Events ............. 12-10
Example: Obtaining and Using the Auditor Service to Write Role Audit Events . 12-11
Auditing Management Operations from a Provider’s MBean .......... 12-12
Example: Auditing Management Operations from a Provider’s MBean . 12-13
Best Practice: Posting Audit Events from a Provider’s MBean .......... 12-16

13. Servlet Authentication Filters

Authentication Filter Concepts ........................................... 13-1
Why Filters are Needed ................................................... 13-2
Servlet Authentication Filter Design Considerations .................... 13-2
How Filters Are Invoked .................................................. 13-3
Do Not Call Servlet Authentication Filters From Authentication Providers . 13-4

CHAPTER 1

Introduction and Roadmap

The following sections describe the content and organization of this document:

- “Document Scope” on page 1-1
- “Documentation Audience” on page 1-1
- “Guide to this Document” on page 1-2
- “Related Information” on page 1-3
- “New and Changed Features in this Release” on page 1-4

Document Scope

This document provides security vendors and application developers with the information needed to develop new security providers for use with WebLogic Server.

Documentation Audience

This document is written for independent software vendors (ISVs) who want to write their own security providers for use with WebLogic Server. It is assumed that most ISVs reading this documentation are sophisticated application developers who have a solid understanding of security concepts, and that no basic security concepts require explanation. It is also assumed that security vendors and application developers are familiar with WebLogic Server and with Java (including Java Management eXtensions (JMX)).
Guide to this Document

This document provides security vendors and application developers with the information needed to develop new security providers for use with the WebLogic Server.

The document is organized as follows:

- **Chapter 2, “Introduction to Developing Security Providers for WebLogic Server,”** which prepares you to learn more about developing security providers for use with WebLogic Server. It specifies the audience and prerequisites for this guide, and provides an overview of the development process.

- **Chapter 3, “Design Considerations,”** which explains the general architecture of a security provider and provides background information you should understand about implementing SSPIs and generating MBean types. This section also includes information about using optional management utilities and discusses how security providers interact with WebLogic resources. Lastly, this section suggests ways in which your custom security providers might work with databases that contain information security providers require.

- **Chapter 4, “Authentication Providers,”** which explains the authentication process (for simple logins) and provides instructions about how to implement each type of security service provider interface (SSPI) associated with custom Authentication providers. This topic also includes a discussion about JAAS LoginModules.

- **Chapter 5, “Identity Assertion Providers,”** which explains the authentication process (for perimeter authentication using tokens) and provides instructions about how to implement each type of security service provider interface (SSPI) associated with custom Identity Assertion providers.

- **Chapter 6, “Principal Validation Providers,”** which explains how Principal Validation providers assist Authentication providers by signing and verifying the authenticity of principals stored in a subject, and provides instructions about how to develop custom Principal Validation providers.

- **Chapter 7, “Authorization Providers,”** which explains the authorization process and provides instructions about how to implement each type of security service provider interface (SSPI) associated with custom Authorization providers.

- **Chapter 8, “Adjudication Providers,”** which explains the adjudication process and provides instructions about how to implement each type of security service provider interface (SSPI) associated with custom Adjudication providers.
• Chapter 9, “Role Mapping Providers,” which explains the role mapping process and provides instructions about how to implement each type of security service provider interface (SSPI) associated with custom Role Mapping providers.

• Chapter 10, “Auditing Providers,” which explains the auditing process and provides instructions about how to implement each type of security service provider interface (SSPI) associated with custom Auditing providers. This topic also includes information about how to audit from other types of security providers.

• Chapter 11, “Credential Mapping Providers,” which explains the credential mapping process and provides instructions about how to implement each type of security service provider interface (SSPI) associated with custom Credential Mapping providers.

• Chapter 12, “Auditing Events From Custom Security Providers,” which explains how to add auditing capabilities to the custom security providers you develop.

• Chapter 13, “Servlet Authentication Filters,” which explains the Servlet authentication filter process and provides instructions about how to implement each type of security service provider interface (SSPI) associated with Servlet authentication filters.

• Chapter 14, “Versionable Application Providers,” which explains the concept of versionable applications and provides instructions about how to implement each type of security service provider interface (SSPI) associated with custom Versionable Application providers.

• Chapter 15, “CertPath Providers,” which explains the certificate lookup and validation process and provides instructions about how to implement each type of security service provider interface (SSPI) associated with custom CertPath provider.

• Appendix A, “MBean Definition File (MDF) Element Syntax,” which describes all the elements and attributes that are available for use in a valid MDF. An MDF is an XML file used to generate the MBean types, which enable the management of your custom security providers.

Related Information

The Oracle corporate Web site provides all documentation for WebLogic Server. Other WebLogic Server documents that may be of interest to security vendors and application developers working with security providers are:

• Understanding WebLogic Security

• Securing WebLogic Server
Introduction and Roadmap

New and Changed Features in this Release

For a comprehensive listing of the new WebLogic Server features introduced in this release, see “What’s New in WebLogic Server” in Release Notes.
Introduction to Developing Security Providers for WebLogic Server

The following sections prepare you to learn more about developing security providers:

- “Prerequisites for This Guide” on page 2-1
- “Overview of the Development Process” on page 2-1

Prerequisites for This Guide

Prior to reading this guide, you should review the following sections in Understanding WebLogic Security:

- “Security Providers”
- “WebLogic Security Framework”

Additionally, WebLogic Server security includes many unique terms and concepts that you need to understand. These terms and concepts—which you will encounter throughout the WebLogic Server security documentation—are defined in the “Terminology” and the “Security Fundamentals” sections of Understanding WebLogic Security, respectively.

Overview of the Development Process

This section is a high-level overview of the process for developing new security providers, so you know what to expect. Details for each step are discussed later in this guide.

The main steps for developing a custom security provider are:
Designing the Custom Security Provider

The design process includes the following steps:

1. Review the descriptions of the WebLogic security providers to determine whether you need to create a custom security provider.

   Descriptions of the WebLogic security providers are available under “WebLogic Security Providers” in Understanding WebLogic Security and in later sections of this guide under the “Do You Need to Create a Custom <Provider_Type> Provider?” headings.

2. Determine which type of custom security provider you want to create.

   The type may be Authentication, Identity Assertion, Principal Validation, Authorization, Adjudication, Role Mapping, Auditing, Credential Mapping, Versionable Application, or CertPath, as described in “Types of Security Providers” in Understanding WebLogic Security. Your custom security provider can augment or replace the WebLogic security providers that are already supplied with WebLogic Server.

3. Identify which security service provider interfaces (SSPIs) you must implement to create the runtime classes for your custom security provider, based on the type of security provider you want to create.

   The SSPIs for the different security provider types are described in “Security Services Provider Interfaces (SSPIs)” on page 3-2 and summarized in “SSPI Quick Reference” on page 3-9.

4. Decide whether you will implement the SSPIs in one or two runtime classes.

   These options are discussed in “Understand the SSPI Hierarchy and Determine Whether You Will Create One or Two Runtime Classes” on page 3-7.
5. Identify which required SSPI MBeans you must extend to generate an MBean type through which your custom security provider can be managed. If you want to provide additional management functionality for your custom security provider (such as handling of users, groups, security roles, and security policies), you also need to identify which optional SSPI MBeans to implement.

The SSPI MBeans are described in “Security Service Provider Interface (SSPI) MBeans” on page 3-10 and summarized in “SSPI MBean Quick Reference” on page 3-19.

6. Determine how you will initialize the database that your custom security provider requires. You can have your custom security provider create a simple database, or configure your custom security provider to use an existing, fully-populated database.

These two database initialization options are explained in “Initialization of the Security Provider Database” on page 3-44.

7. Identify any database “seeding” that your custom security provider will need to do as part of its interaction with security policies on WebLogic resources. This seeding may involve creating default groups, security roles, or security policies.

For more information, see “Security Providers and WebLogic Resources” on page 3-27.

Creating Runtime Classes for the Custom Security Provider by Implementing SSPIs

In one or two runtime classes, implement the SSPIs you have identified by providing implementations for each of their methods. The methods should contain the specific algorithms for the security services offered by the custom security provider. The content of these methods describe how the service should behave.

Procedures for this task are dependent on the type of security provider you want to create, and are provided under the “Create Runtime Classes Using the Appropriate SSPIs” heading in the sections that discuss each security provider in detail.

Generating an MBean Type to Configure and Manage the Custom Security Provider

Generating an MBean type includes the following steps:

1. Create an MBean Definition File (MDF) for the custom security provider that extends the required SSPI MBean, implements any optional SSPI MBeans, and adds any custom
Introduction to Developing Security Providers for WebLogic Server

attributes and operations that will be required to configure and manage the custom security provider.

Information about MDFs is available in “Understand the Basic Elements of an MBean Definition File (MDF)” on page 3-12, and procedures for this task are provided under the “Create an MBean Definition File (MDF)” heading in the sections that discuss each security provider in detail.

2. Run the MDF through the WebLogic MBeanMaker to generate intermediate files (including the MBean interface, MBean implementation, and MBean information files) for the custom security provider’s MBean type.

Information about the WebLogic MBeanMaker and how it uses the MDF to generate Java files is provided in “Understand What the WebLogic MBeanMaker Provides” on page 3-17, and procedures for this task are provided under the “Use the WebLogic MBeanMaker to Generate the MBean Type” heading in the sections that discuss each security provider in detail.

3. Edit the MBean implementation file to supply content for any methods inherited from implementing optional SSPI MBeans, as well as content for the method stubs generated as a result of custom attributes and operations added to the MDF.

4. Run the modified intermediate files (for the MBean type) and the runtime classes for your custom security provider through the WebLogic MBeanMaker to generate a JAR file, called an MBean JAR File (MJF).

Procedures for this task are provided under the “Use the WebLogic MBeanMaker to Create the MBean JAR File (MJF)” heading in the sections that discuss each security provider in detail.

5. Install the MBean JAR File (MJF) into the WebLogic Server environment.

Procedures for this task are provided under the “Install the MBean Type into the WebLogic Server Environment” heading in the sections that discuss each security provider in detail.

Writing Console Extensions

Console extensions allow you to add JavaServer Pages (JSPs) to the WebLogic Server Administration Console to support additional management and configuration of custom security providers. Console extensions allow you to include Administration Console support where that support does not yet exist, as well as to customize administrative interactions as you see fit.
To get complete configuration and management support through the WebLogic Server Administration Console for a custom security provider, you need to write a console extension when:

- You decide not to implement an optional SSPI MBean when you generate an MBean type for your custom security provider, but still want to configure and manage your custom security provider via the Administration Console. (That is, you do not want to use the WebLogic Server Command-Line Interface instead.)

Generating an MBean type (as described in “Generating an MBean Type to Configure and Manage the Custom Security Provider” on page 2-3) is the Oracle-recommended way for configuring and managing custom security providers. However, you may want to configure and manage your custom security provider completely through a console extension that you write.

- You implement optional SSPI MBeans for custom security providers that are not custom Authentication providers.

When you implement optional SSPI MBeans to develop a custom Authentication provider, you automatically receive support in the Administration Console for the MBean type’s attributes (inherited from the optional SSPI MBean). Other types of custom security providers, such as custom Authorization providers, do not receive this support.

- You add a custom attribute that cannot be represented as a simple data type to your MBean Definition File (MDF), which is used to generate the custom security provider’s MBean type.

The Details tab for a custom security provider will automatically display custom attributes, but only if they are represented as a simple data type, such as a string, MBean, boolean or integer value. If you have custom attributes that are represented as atypical data types (for example, an image of a fingerprint), the Administration Console cannot visualize the custom attribute without customization.

- You add a custom operation to your MBean Definition File (MDF), which is used to generate the custom security provider’s MBean type.

Because of the potential variety involved with custom operations, the Administration Console does not know how to automatically display or process them. Examples of custom operations might be a microphone for a voice print, or import/export buttons. The Administration Console cannot visualize and process these operations without customization.

Some other (optional) reasons for extending the Administration Console include:
Introduction to Developing Security Providers for WebLogic Server

- Corporate branding—when, for example, you want your organization’s logo or look and feel on the pages used to configure and manage a custom security provider.

- Consolidation—when, for example, you want all the fields used to configure and manage a custom security provider on one page, rather than in separate tabs or locations.

For more information about console extensions, see *Extending the Administration Console*.

**Configuring the Custom Security Provider**

**Note:** The configuration process can be completed by the same person who developed the custom security provider, or by a designated administrator.

The configuration process consists of using the WebLogic Server Administration Console to supply the custom security provider with configuration information. If you generated an MBean type for managing the custom security provider, “configuring” the custom security provider in the Administration Console also means that you are creating a specific instance of the MBean type.

For more information about configuring security providers using the Administration Console, see *Securing WebLogic Server*.

Certain types of security providers need to provide administrators with a way to manage the security data associated with them. For example, an Authorization provider needs to supply administrators with a way to manage security policies. Similarly, a Role Mapping provider needs to supply administrators with a way to manage security roles, and a Credential Mapping provider needs to supply administrators with a way to manage credential maps.

For the WebLogic Authorization, Role Mapping, and Credential Mapping providers, there are already management mechanisms available for administrators in the WebLogic Server Administration Console. However, do you not inherit these mechanisms when you develop a custom version of one of these security providers; you need to provide your own mechanisms to manage security policies, security roles, and credential maps. These mechanisms must read and write the appropriate security data to and from the custom security provider’s database, but may or may not be integrated with the Administration Console.

For more information, refer to one of the following sections:
Overview of the Development Process

- “Provide a Mechanism for Security Policy Management” on page 7-36 (for custom Authorization providers)
- “Provide a Mechanism for Security Role Management” on page 9-38 (for custom Role Mapping providers)
- “Provide a Mechanism for Credential Map Management” on page 11-15 (for custom Credential Mapping providers)
Introduction to Developing Security Providers for WebLogic Server
Design Considerations

Careful planning of development activities can greatly reduce the time and effort you spend developing custom security providers. The following sections describe security provider concepts and functionality in more detail to help you get started:

- “General Architecture of a Security Provider” on page 3-1
- “Security Services Provider Interfaces (SSPIs)” on page 3-2
- “Security Service Provider Interface (SSPI) MBeans” on page 3-10
- “Security Data Migration” on page 3-21
- “Management Utilities Available to Developers of Security Providers” on page 3-26
- “Security Providers and WebLogic Resources” on page 3-27
- “Initialization of the Security Provider Database” on page 3-44
- “Differences In AttributeValidators” on page 3-47

General Architecture of a Security Provider

Although there are different types of security providers you can create (see “Types of Security Providers” in Understanding WebLogic Security), all security providers follow the same general architecture. Figure 3-1 illustrates the general architecture of a security provider, and an explanation follows.
Design Considerations

Figure 3-1  Security Provider Architecture

Note: The SSPIs and the runtime classes (that is, implementations) you will create using the SSPIs are shown on the left side of Figure 3-1 and are .java files.

Like the other files on the right side of Figure 3-1, MyFooMBean begins as a .xml file, in which you will extend (and optionally implement) SSPI MBeans. When this MBean Definition File (MDF) is run through the WebLogic MBeanMaker utility, the utility generates the .java files for the MBean type, as described in “Generating an MBean Type to Configure and Manage the Custom Security Provider” on page 2-3.

Figure 3-1 shows the relationship between a single runtime class (MyFooProviderImpl) and an MBean type (MyFooMBean) you create when developing a custom security provider. The process begins when a WebLogic Server instance starts, and the WebLogic Security Framework:

1. Locates the MBean type associated with the security provider in the security realm.
2. Obtains the name of the security provider’s runtime class (the one that implements the “Provider” SSPI, if there are two runtime classes) from the MBean type.
3. Passes in the appropriate MBean instance, which the security provider uses to initialize (read configuration data).

Therefore, both the runtime class (or classes) and the MBean type form what is called the “security provider.”

Security Services Provider Interfaces (SSPIs)

As described in “Overview of the Development Process” on page 2-1, you develop a custom security provider by first implementing a number of security services provider interfaces (SSPIs) to create runtime classes. This section helps you:
Additionally, this section provides an SSPI Quick Reference that indicates which SSPIs can be implemented for each type of security provider.

**Understand Two Important Restrictions**

Security providers must adhere to the following restrictions:

- A custom security provider's runtime class implementation must not contain any code that requires a security check to be performed by the WebLogic Security Framework. Doing so causes infinite recursion, because the security providers are the components of the WebLogic Security Framework that actually perform the security checks and grant access to WebLogic resources.

- No local (where local refers to the same server, cluster, or domain) Java Platform, Enterprise Edition (Java EE) Version 5 services are available for use within a security provider’s implementation. Any attempt to use them is unsupported. For example, this prohibits calling an EJB in the current domain from your security provider.

  Java EE services in other domains are accessible and can be used within a security provider.

**Understand the Purpose of the “Provider” SSPIs**

Each SSPI that ends in the suffix "Provider" (for example, CredentialProvider) exposes the services of a security provider to the WebLogic Security Framework. This allows the security provider to be manipulated (initialized, started, stopped, and so on).
As shown in Figure 3-2, the SSPIs exposing security services to the WebLogic Security Framework are provided by WebLogic Server, and all extend the `SecurityProvider` interface, which includes the following methods:

**initialize**

```java
public void initialize(ProviderMBean providerMBean, SecurityServices securityServices)
```

The `initialize` method takes as an argument a `ProviderMBean`, which can be narrowed to the security provider’s associated MBean instance. The MBean instance is created from the MBean type you generate, and contains configuration data that allows the custom security provider to be managed in the WebLogic Server environment. If this configuration data is available, the `initialize` method should be used to extract it.

The `securityServices` argument is an object from which the custom security provider can obtain and use the Auditor Service. For more information about the Auditor Service and auditing, see Chapter 10, “Auditing Providers” and Chapter 12, “Auditing Events From Custom Security Providers.”

**getDescription**

```java
public String getDescription()
```

This method returns a brief textual description of the custom security provider.

**shutdown**

```java
public void shutdown()
```

This method shuts down the custom security provider.
Because they extend SecurityProvider, a runtime class that implements any SSPI ending in "Provider" must provide implementations for these inherited methods.

**Understand the Purpose of the Bulk Access Providers**

This release of WebLogic Server includes bulk access versions of the following Authorization, Adjudication, and Role Mapping provider SSPI interfaces:

- BulkAuthorizationProvider
- BulkAccessDecision
- BulkAdjudicationProvider
- BulkAdjudicator
- BulkRoleProvider
- BulkRoleMapper

The bulk access SSPI interfaces allow Authorization, Adjudication, and Role Mapping providers to receive multiple decision requests in one call rather than through multiple calls, typically in a 'for' loop. The intent of the bulk SSPI variants is to allow provider implementations to take advantage of internal performance optimizations, such as detecting that many of the passed-in Resource objects are protected by the same policy and will generate the same decision result.

See “Bulk Authorization Providers” on page 7-26, “Bulk Adjudication Providers” on page 8-4, and “Bulk Role Mapping Providers” on page 9-29 for additional information.

**Determine Which “Provider” Interface You Will Implement**

Implementations of SSPIs that begin with the prefix "Deployable" and end with the suffix "Provider" (for example, DeployableRoleProviderV2) expose the services of a custom security provider into the WebLogic Security Framework as explained in “Understand the Purpose of the “Provider” SSPIs” on page 3-3. However, implementations of these SSPIs also perform additional tasks. These SSPIs also provide support for security in deployment descriptors, including the servlet deployment descriptors (web.xml, weblogic.xml), the EJB deployment descriptors (ejb-jar.xml, weblogic-ejb.jar.xml) and the EAR deployment descriptors (application.xml, weblogic-application.xml).

Authorization providers, Role Mapping providers, and Credential Mapping providers have deployable versions of their “Provider” SSPIs.
Note: If your security provider database (which stores security policies, security roles, and credentials) is read-only, you can implement the non-deployable version of the SSPI for your Authorization, Role Mapping, and Credential Mapping security providers. However, you will still need to configure deployable versions of these security provider that do handle deployment.

The **DeployableAuthorizationProviderV2** SSPI

An Authorization provider that supports deploying security policies on behalf of Web application or Enterprise JavaBean (EJB) deployments needs to implement the **DeployableAuthorizationProviderV2** SSPI instead of the **AuthorizationProvider** SSPI. (However, because the **DeployableAuthorizationProviderV2** SSPI extends the **AuthorizationProvider** SSPI, you actually will need to implement the methods from both SSPIs.) This is because Web application and EJB deployment activities require the Authorization provider to perform additional tasks, such as creating and removing security policies. In a security realm, at least one Authorization provider must support the **DeployableAuthorizationProviderV2** SSPI, or else it will be impossible to deploy Web applications and EJBs.

Note: For more information about security policies, see “Security Policies” in Securing WebLogic Resources Using Roles and Policies.

The **DeployableRoleProviderV2** SSPI

A Role Mapping provider that supports deploying security roles on behalf of Web application or Enterprise JavaBean (EJB) deployments needs to implement the **DeployableRoleProviderV2** SSPI instead of the **RoleProvider** SSPI. (However, because the **DeployableRoleProviderV2** SSPI extends the **RoleProvider** SSPI, you will actually need to implement the methods from both SSPIs.) This is because Web application and EJB deployment activities require the Role Mapping provider to perform additional tasks, such as creating and removing security roles. In a security realm, at least one Role Mapping provider must support this SSPI, or else it will be impossible to deploy Web applications and EJBs.

Note: For more information about security roles, see “Users, Groups, and Security Roles” in Securing WebLogic Resources Using Roles and Policies.

The **DeployableCredentialProvider** SSPI

Note: The **DeployableCredentialProvider** interface is deprecated in this release of WebLogic Server.
A Credential Mapping provider that supports deploying security policies on behalf of Resource Adapter (RA) deployments needs to implement the DeployableCredentialProvider SSPI instead of the CredentialProvider SSPI. (However, because the DeployableCredentialProvider SSPI extends the CredentialProvider SSPI, you will actually need to implement the methods from both SSPIs.) This is because Resource Adapter deployment activities require the Credential Mapping provider to perform additional tasks, such as creating and removing credentials and mappings. In a security realm, at least one Credential Mapping provider must support this SSPI, or else it will be impossible to deploy Resource Adapters.

**Notes:** For more information about credentials, see “Credential Mapping Concepts” on page 11-1. For more information about security policies, see “Security Policies” in Securing WebLogic Resources Using Roles and Policies.

**Understand the SSPI Hierarchy and Determine Whether You Will Create One or Two Runtime Classes**

Figure 3-3 uses a Credential Mapping provider to illustrate the inheritance hierarchy that is common to all SSPIs, and shows how a runtime class you supply can implement those interfaces. In this example, Oracle supplies the SecurityProvider interface, and the CredentialProviderV2 and CredentialMapperV2 SSPIs. Figure 3-3 shows a single runtime class called MyCredentialMapperProviderImpl that implements the CredentialProviderV2 and CredentialMapperV2 SSPIs.
However, Figure 3-3 illustrates only one way you can implement SSPIs: by creating a single runtime class. If you prefer, you can have two runtime classes (as shown in Figure 3-4): one for the implementation of the SSPI ending in “Provider” (for example, `CredentialProviderV2`), and one for the implementation of the other SSPI (for example, the `CredentialMapperV2` SSPI).

When there are separate runtime classes, the class that implements the SSPI ending in “Provider” acts as a factory for generating the runtime class that implements the other SSPI. For example, in Figure 3-4, `MyCredentialMapperProviderImpl` acts as a factory for generating `MyCredentialMapperImpl`. 
SSPI Quick Reference

Table 3-1 maps the types of security providers (and their components) with the SSPIs and other interfaces you use to develop them.

Table 3-1  Security Providers, Their Components, and Corresponding SSPIs

<table>
<thead>
<tr>
<th>Type/Component</th>
<th>SSPIs/Interfaces</th>
</tr>
</thead>
<tbody>
<tr>
<td>Authentication provider</td>
<td>AuthenticationProviderV2</td>
</tr>
<tr>
<td>LoginModule (JAAS)</td>
<td>LoginModule</td>
</tr>
</tbody>
</table>

Note: If you decide to have two runtime implementation classes, you need to remember to include both runtime implementation classes in the MBean JAR File (MJF) when you generate the security provider’s MBean type. For more information, see “Generating an MBean Type to Configure and Manage the Custom Security Provider” on page 2-3.

**Note:** The SSPIs you use to create runtime classes for custom security providers are located in the `weblogic.security.spi` package. For more information about this package, see the *WebLogic Server API Reference Javadoc*.

**Security Service Provider Interface (SSPI) MBeans**

As described in “Overview of the Development Process” on page 2-1, the second step in developing a custom security provider is generating an MBean type for the custom security provider. This section helps you:
Understand Why You Need an MBean Type

In addition to creating runtime classes for a custom security provider, you must also generate an MBean type. The term MBean is short for managed bean, a Java object that represents a Java Management eXtensions (JMX) manageable resource.

Note: JMX is a specification created by Sun Microsystems that defines a standard management architecture, APIs, and management services. For more information, see the Java Management Extensions White Paper.

An MBean type is a factory for instances of MBeans, the latter of which you or an administrator can create using the WebLogic Server Administration Console. Once they are created, you can configure and manage the custom security provider using the MBean instance, through the Administration Console.

Note: All MBean instances are aware of their parent type, so if you modify the configuration of an MBean type, all instances that you or an administrator may have created using the Administration Console will also update their configurations. (For more information, see “Understand the SSPI MBean Hierarchy and How It Affects the Administration Console” on page 3-15.)

Determine Which SSPI MBeans to Extend and Implement

You use MBean interfaces called SSPI MBeans to create MBean types. There are two types of SSPI MBeans you can use to create an MBean type for a custom security provider:

- Required SSPI MBeans, which you must extend because they define the basic methods that allow a security provider to be configured and managed within the WebLogic Server environment.
Optional SSPI MBeans, which you can implement because they define additional methods for managing security providers. Different types of security providers are able to use different optional SSPI MBeans.

For more information, see “SSPI MBean Quick Reference” on page 3-19.

**Understand the Basic Elements of an MBean Definition File (MDF)**

An MBean Definition File (MDF) is an XML file used by the WebLogic MBeanMaker utility to generate the Java files that comprise an MBean type. All MDFs must extend a required SSPI MBean that is specific to the type of the security provider you have created, and can implement optional SSPI MBeans.

Listing 3-1 shows a sample MBean Definition File (MDF), and an explanation of its content follows. (Specifically, it is the MDF used to generate an MBean type for the WebLogic Credential Mapping provider. Note that the DeployableCredentialProvider interface is deprecated in this release of WebLogic Server.)

**Note:** A complete reference of MDF element syntax is available in Appendix A, “MBean Definition File (MDF) Element Syntax.”

**Listing 3-1  DefaultCredentialMapper.xml**

```xml
<?xml version="1.0" ?>
<!DOCTYPE MBeanType SYSTEM "commo.dtd">

<MBeanType
    Name = "DefaultCredentialMapper"
    DisplayName = "DefaultCredentialMapper"
    Package = "weblogic.security.providers.credentials"
    Extends = "weblogic.management.security.credentials.DeployableCredentialMapper"
    Implements = "weblogic.management.security.credentials.UserPasswordCredentialMapEditor,
               weblogic.management.security.credentials.UserPasswordCredentialMapExtendedReader,
               weblogic.management.security.ApplicationVersioner,
               weblogic.management.security.Import,
               weblogic.management.security.Export"

```

Design Considerations
PersistPolicy = "OnUpdate"
Description = "This MBean represents configuration attributes for the WebLogic Credential Mapping provider." >

<MBeanAttribute
Name = "ProviderClassName"
Type = "java.lang.String"
Writeable = "false"
Default = "+weblogic.security.providers.credentials.DefaultCredentialMapperProviderImpl;" 
Description = "The name of the Java class that loads the WebLogic Credential Mapping provider."
/>

<MBeanAttribute
Name = "Description"
Type = "java.lang.String"
Writeable = "false"
Default = "Provider that performs Default Credential Mapping;"
Description = "A short description of the WebLogic Credential Mapping provider."
/>

<MBeanAttribute
Name = "Version"
Type = "java.lang.String"
Writeable = "false"
Default = "1.0;"
Description = "The version of the WebLogic Credential Mapping provider."
/>

The bold attributes in the <MBeanType> tag show that this MDF is named DefaultCredentialMapper and that it extends the required SSPI MBean called
D e s i g n C o ns i de ra t i o n s

DeployableCredentialMapper. It also includes additional management capabilities by
implementing the UserPasswordCredentialMapEditor optional SSPI MBean.

The ProviderClassName, Description, and Version attributes defined in the
<MBeanAttribute> tags are required in any MDF used to generate MBean types for security

providers because they define the security provider’s basic configuration methods, and are
inherited from the base required SSPI MBean called Provider (see Figure 3-5). The
ProviderClassName attribute is especially important. The value for the ProviderClassName
attribute is the Java filename of the security provider’s runtime class (that is, the implementation
of the appropriate SSPI ending in “Provider”). The example runtime class shown in Listing 3-1
is DefaultCredentialMapperProviderImpl.java.
While not shown in Listing 3-1, you can include additional attributes and operations in an MDF
using the <MBeanAttribute> and <MBeanOperation> tags. Most custom attributes will
automatically appear in the Provider Specific tab for your custom security provider in the
WebLogic Server Administration Console. To display custom operations, however, you need to
write a console extension. (See “Writing Console Extensions” on page 2-4.)

Custom Providers and Classpaths
Classes loaded from WL_HOME\server\lib\mbeantypes are not visible to other JAR and EAR
files deployed on WebLogic Server. If you have common utility classes that you want to share,
you must place them in the system classpath.
Note: WL_HOME\server\lib\mbeantypes is the default directory for installing MBean types.
Beginning with 9.0, security providers can be loaded from
...\domaindir\lib\mbeantypes as well. JAR files loaded from the
...\domaindir\lib\mbeantypes directory can be shared across applications. They
do not need to be explicitly placed in the system classpath.

Throwing Exceptions from MBean Operations
Your custom provider MBeans must throw only JDK exception types or
weblogic.management.utils exception types. Otherwise, JMX clients may not include the
code necessary to receive your exceptions.

3-14

z

For typed exceptions, you must throw only the exact types from the throw clause of your
MBean’s method, as opposed to deriving and throwing your own exception type from that
type.

z

For nested exceptions, you must throw only JDK exception types or
weblogic.management.utils exceptions.

Developing Security Providers for WebLogic Server


For runtime exceptions, you must throw or pass through only JDK exceptions.

Specifying Non-Clear Text Values for MBean Attributes

As described in Table A-2, you can use the Encrypted attribute to specify that the value of an MBean attribute should not be displayed as clear text. For example, you encrypt the value of the MBean attribute when getting input for a password. The following code fragment shows an example of using the Encrypted attribute:

```xml
<MBeanAttribute
Name        = "PrivatePassPhrase"
Type        = "java.lang.String"
Encrypted   = "true"
Default     = "&quot;&amp;quot;"
Description = "The Keystore password."
/>```

Understand the SSPI MBean Hierarchy and How It Affects the Administration Console

All attributes and operations that are specified in the required SSPI MBeans that your MBean Definition File (MDF) extends (all the way up to the Provider base SSPI MBean) automatically appear in a WebLogic Server Administration Console page for the associated security provider. You use these attributes and operations to configure and manage your custom security providers.

Note: For Authentication security providers only, the attributes and operations that are specified in the optional SSPI MBeans your MDF implements are also automatically supported by the Administration Console. For other types of security providers, you must write a console extension in order to make the attributes and operations inherited from the optional SSPI MBeans available in the Administration Console. For more information, see “Writing Console Extensions” on page 2-4.

Figure 3-5 illustrates the SSPI MBean hierarchy for security providers (using the WebLogic Credential Mapping MDF as an example), and indicates what attributes and operations will appear in the Administration Console for the WebLogic Credential Mapping provider.
Implementing the hierarchy of SSPI MBeans in the DefaultCredentialMapper MDF (shown in Figure 3-5) produces the page in the Administration Console that is shown in Figure 3-6. (A partial listing of the DefaultCredentialMapper MDF is shown in Listing 3-1.)

**Figure 3-6  DefaultCredentialMapper Administration Console Page**

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Migration</th>
</tr>
</thead>
<tbody>
<tr>
<td>Common</td>
<td>Provider Specific</td>
</tr>
</tbody>
</table>

This page displays basic information about this Credential Mapping Provider.

- **Description:** WebLogic Credential Mapping Provider
  The description of your Credential Mapping Provider
  More info...

- **Version:** 1.0
  The version of your Credential Mapping Provider
  More info...

- **Name:** DefaultCredentialMapper
  The name of your Credential Mapping Provider
  More info...
The Name, Description, and Version fields come from attributes with these names inherited from the base required SSPI MBean called Provider and specified in the DefaultCredentialMapper MDF. Note that the DisplayName attribute in the DefaultCredentialMapper MDF generates the value for the Name field, and that the Description and Version attributes generate the values for their respective fields as well. The Credential Mapping Deployment Enabled field is displayed (on the Provider Specific page) because of the CredentialMappingDeploymentEnabled attribute in the DeployableCredentialMapper required SSPI MBean, which the DefaultCredentialMapper MDF extends. Notice that this Administration Console page does not display a field for the DefaultCredentialMapper implementation of the UserPasswordCredentialMapEditor optional SSPI MBean.

Understand What the WebLogic MBeanMaker Provides

The WebLogic MBeanMaker is a command-line utility that takes an MBean Definition File (MDF) as input and outputs files for an MBean type. When you run the MDF you created through the WebLogic MBeanMaker, the following occurs:

- Any attributes inherited from required SSPI MBeans—as well as any custom attributes you added to the MDF—cause the WebLogic MBeanMaker to generate complete getter/setter methods in the MBean type’s information file. (The MBean information file is not shown in Figure 3-7.) For more information about the MBean information file, see “About the MBean Information File” on page 3-18.

  Necessary developer action: None. No further work must be done for these methods.

- Any operations inherited from optional SSPI MBeans cause the MBean implementation file to inherit their methods, whose implementations you must supply from scratch.

  Necessary developer action: Currently, the WebLogic MBeanMaker does not generate method stubs for these inherited methods, so you will need to supply the appropriate implementations.

- Any custom operations you added to the MDF will cause the WebLogic MBeanMaker to generate method stubs.

  Necessary developer action: You must provide implementations for these methods. (However, because the WebLogic MBeanMaker generates the stubs, you do not need to look up the Java method signatures.)

This is illustrated in Figure 3-7.
About the MBean Information File

The MBean information file contains a compiled definition of the data in the MBean Definition File in a form that JMX Model MBeans require. The format of this file is a list of attributes, operations, and notifications, each of which also has a set of descriptor tags that describe that entity. In addition, the MBean itself also has a set of descriptor tags. An example of this format is as follows:

MBean + tags
attribute1 + tags, attribute2 + tags ...
operation1 + tags, operation2 + tags ...
novation1 + tags, notification2 + tags ...

If desired, you can access this information at runtime by calling the standard JMX server getMBeanInfo method to obtain the ModelMBeanInfo.

Note: Be sure to reference the JMX specification to determine how to interpret the returned structure.
SSPI MBean Quick Reference

Based on the list of SSPIs you need to implement as part of developing your custom security provider, locate the required SSPI MBeans you need to extend in Table 3-2. Using Table 3-3 through Table 3-5, locate any optional SSPI MBeans you also want to implement for managing your security provider.

Table 3-2 Required SSPI MBeans

<table>
<thead>
<tr>
<th>Type</th>

</tr>
</tbody>
</table>

Note: The optional Authorization SSPI MBeans shown in Table 3-4 are located in the weblogic.management.security.authorization package.
Several of the WebLogic security providers have been developed to support security data migration. This means that administrators can export users and groups (for the WebLogic Authentication provider), security policies (for the WebLogic Authorization provider), security roles (for the WebLogic Role Mapping provider), or credential mappings (for the Credential Mapping provider) from one security realm, and then import them into another security realm. Administrators can migrate security data for each of these WebLogic security providers individually, or migrate security data for all the WebLogic security providers at once (that is, security data for the entire security realm).

The migration of security data may be helpful to administrators when:

- Transitioning from development mode to production mode
- Proliferating production mode security configurations to security realms in new WebLogic Server domains
- Moving data to a new security realm in the same WebLogic Server domain or in a different WebLogic Server domain.
- Moving from one security realm to a new security realm in the same WebLogic Server domain, where one or more of the WebLogic security providers will be replaced with custom security providers. (In this case, administrators need to copy security data for the security providers that are not being replaced.)
The following sections provide more information about security data migration:

- “Migration Concepts” on page 3-22
- “Adding Migration Support to Your Custom Security Providers” on page 3-23
- “Administration Console Support for Security Data Migration” on page 3-25

### Migration Concepts

Before you start to work with security data migration, you need to understand the following concepts:

- “Formats” on page 3-22
- “Constraints” on page 3-22
- “Migration Files” on page 3-23

### Formats

A format is simply a data format that specifies how security data should be exported or imported. Currently, WebLogic Server does not provide any standard, public formats for developers of security providers. Therefore, the format you use is entirely up to you. Keep in mind, however, that for data to be exported from one security provider and later imported to another security provider, both security providers must understand how to process the same format. **Supported formats** are the list of data formats that a given security provider understands how to process.

**Notes:** Because the data format used for the WebLogic security providers is unpublished, you cannot currently migrate security data from a WebLogic security provider to a custom security provider, or vice versa. Additionally, security vendors wanting to exchange security data with security providers from other vendors will need to collaborate on a standard format to do so.

### Constraints

**Constraints** are key/value pairs used to specify options to the export or import process. Constraints allow administrators to control which security data is exported or imported from the security provider’s database. For example, an administrator may want to export only users (not groups) from an Authentication provider’s database, or a subset of those users. **Supported constraints** are the list of constraints that administrators may specify during the migration process for a particular security provider. For example, an Authentication provider’s database can be used to import users and groups, but not security policies.
Migration Files

**Export files** are the files to which security data is written (in the specified format) during the export portion of the migration process. **Import files** are the files from which security data is read (also in the specified format) during the import portion of the migration process. Both export and import files are simply temporary storage locations for security data as it is migrated from one security provider’s database to another.

**Caution:** The migration files are not protected unless you take additional measures to protect them. Because migration files may contain sensitive data, take extra care when working with them.

Adding Migration Support to Your Custom Security Providers

If you want to develop custom security providers that support security data migration like the WebLogic security providers do, you need to extend the `weblogic.management.security.ImportMBean` and `weblogic.management.security.ExportMBean` optional SSPI MBeans in the MBean Definition File (MDF) that you use to generate MBean types for your custom security providers, then implement their methods. These optional SSPI MBeans include the attributes and operations described in Table 3-6 and Table 3-7, respectively.

<table>
<thead>
<tr>
<th>Attributes/Operations</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SupportedExportFormats</td>
<td>A list of export data formats that the security provider supports.</td>
</tr>
<tr>
<td>SupportedExportConstraints</td>
<td>A list of export constraints that the security provider supports.</td>
</tr>
<tr>
<td>exportData</td>
<td>Exports provider-specific security data in a specified format.</td>
</tr>
<tr>
<td>format</td>
<td>A parameter on the <code>exportData</code> operation that specifies the format to use for exporting provider-specific data.</td>
</tr>
</tbody>
</table>
Design Considerations

</tr>
<tr>
<td>constraints</td>
<td>A parameter on the <code>importData</code> operation that specifies the constraints to be used when importing provider-specific data.</td>
</tr>
</tbody>
</table>
Note: For more information, see the WebLogic Server API Reference Javadoc for the ImportMBean interface.

Administration Console Support for Security Data Migration

Unlike other optional SSPI MBeans you may extend in the MDF for your custom security providers, the attributes and operations inherited from the ExportMBean and ImportMBean optional SSPI MBeans automatically appear in a WebLogic Server Administration Console page for the associated security provider, under a Migration tab (see Figure 3-8 for an example). This allows administrators to export and import security data for each security provider individually.

Notes: If a security provider does not have migration capabilities, the Migration tab for that security provider will not appear in the Administration Console.

For instructions about how to migrate security data for individual security providers using the Administration Console, see “Migrating Security Data”.

Figure 3-8 Migration Tab for the WebLogic Authentication Provider

This page allows you to import users and/or groups from a file to the Default Authentication provider’s database.

Import Format: [Default/Plain]

The format for importing the Default Authentication provider specific data. More Info...

Import File on Server: [Default/Domain/Default/Server]

The full path to the filename used to write data. More info...

Supported Import Constraints: None

The list of constraints to be used when importing data. More info...

Import Constraints (key=value): [ ]

The constraints to be used when importing data. More info...

Additionally, if any of the security providers configured in your security realm have migration capabilities, the Migration tab at the security realm level (see Figure 3-9 for an example) allows
administrators to export or import security data for all the security providers configured in the security realm at once.

**Notes:** The Migration tab at the security realm level always appears in the Administration Console, whether or not any security providers with migration capabilities are configured in the security realm. However, it is only operational if one or more security providers have migration capabilities.

For instructions about how to migrate security data for all security providers at once, see “Migrating Security Data” in *Securing WebLogic Server*.

![Migration Tab for a Security Realm](image)

Note: Administrators can also use the WebLogic Scripting Tool (WLST) (rather than the Administration Console) to migrate security data when you extend the `ExportMBean` and `ImportMBean` optional SSPI MBeans. For more information, see *WebLogic Scripting Tool*.

As always, if you add additional attributes or operations to your MDF, you must write a console extension in order to make them available in the Administration Console.

**Management Utilities Available to Developers of Security Providers**

The `weblogic.management.utils` package contains additional management interfaces and exceptions that developers might find useful, particularly when generating MBean types for their...
custom security providers. Implementation of these interfaces and exceptions is not required to
develop a custom security provider (unless you inherit them by implementing optional SSPI
MBeans in your custom security provider’s MDF).

**Note:** The interfaces and classes are located in this package (rather than in
`weblogic.management.security`) because they are general purpose utilities; in other
words, these utilities can also be used for non-security MBeans. The various types of
MBeans are described in “Overview of WebLogic Server Subsystem MBeans” in
*Developing Custom Management Utilities with JMX*.

The `weblogic.management.utils` package contains the following utilities:

- Common exceptions.
- Interfaces that provide methods for handling large lists of data.
- An interface containing configuration attributes that are required to communicate with an
  external LDAP server.

For more information, see the *WebLogic Server API Reference Javadoc* for the
`weblogic.management.utils` package.

### Security Providers and WebLogic Resources

A **WebLogic resource** is a structured object used to represent an underlying WebLogic Server
entity that can be protected from unauthorized access. Developers of custom Authorization, Role
Mapping, and Credential Mapping providers need to understand how these security providers
interact with WebLogic resources and the security policies used to secure those resources.

**Note:** Security policies replace the access control lists (ACLs) and permissions that were used
to protect WebLogic resources in previous releases of WebLogic Server.

The following sections provide information about security providers and WebLogic resources:

- “The Architecture of WebLogic Resources” on page 3-28
- “Types of WebLogic Resources” on page 3-29
- “WebLogic Resource Identifiers” on page 3-30
- “Creating Default Groups for WebLogic Resources” on page 3-31
- “Creating Default Security Roles for WebLogic Resources” on page 3-32
- “Creating Default Security Policies for WebLogic Resources” on page 3-32
Design Considerations

- “Single-Parent Resource Hierarchies” on page 3-35
- “ContextHandlers and WebLogic Resources” on page 3-37

Note: For more information, see Securing WebLogic Resources Using Roles and Policies.

The Architecture of WebLogic Resources

The Resource interface, located in the weblogic.security.spi package, provides the definition for an object that represents a WebLogic resource, which can be protected from unauthorized access. The ResourceBase class, located in the weblogic.security.service package, is an abstract base class for more specific WebLogic resource types, and facilitates the model for extending resources. (See Figure 3-10 and “Types of WebLogic Resources” on page 3-29 for more information.)

Figure 3-10 Architecture of WebLogic Resources

The ResourceBase class includes the Oracle-provided implementations of the getId, getKeys, getValues, and toString methods. For more information, see the WebLogic Server API Reference Javadoc for the ResourceBase class.
This architecture allows you to develop security providers without requiring that they be aware of any particular WebLogic resources. Therefore, when new resource types are added, you should not need to modify the security providers.

**Types of WebLogic Resources**

As shown in Figure 3-10, certain classes in the `weblogic.security.service` package extend the `ResourceBase` class, and therefore provide you with implementations for specific types of WebLogic resources. WebLogic resource implementations are available for:

- Administrative resources
- Application resources
- COM resources
- Control resources
- EIS resources
- EJB resources
- JDBC resources
- JMS resources
- JNDI resources
- Remote resources
- Server resources
- URL resources
- Web Service resources
- Work Context resources
Design Considerations

Notes: For more information about each of these WebLogic resources, see Securing WebLogic Resources Using Roles and Policies and the WebLogic Server API Reference Javadoc for the weblogic.security.service package.

WebLogic Resource Identifiers

Each WebLogic resource (described in “Types of WebLogic Resources” on page 3-29) can be identified in two ways: by its toString() representation or by an ID obtained using the getID() method.

The toString() Method

If you use the toString() method of any WebLogic resource implementation, a description of the WebLogic resource will be returned in the form of a String. First, the type of the WebLogic resource is printed in pointy-brackets. Then, each key is printed, in order, along with its value. The keys are comma-separated. Values that are lists are comma-separated and delineated by open and close curly braces. Each value is printed as is, except that commas (,), open braces ({), close braces (}), and back slashes (\) are each escaped with a back slash. For example, the EJB resource:

EJBResource ("myApp", "MyJarFile", "myEJB", "myMethod", "Home", new String[] {"argumentType1", "argumentType2"});

will produce the following toString output:

type=ejb, app=myApp, module="MyJarFile", ejb=myEJB, method="myMethod", methodInterface="Home", methodParams={argumentType1, argumentType2}

The format of the WebLogic resource description provided by the toString() method is public (that is, you can construct one without using a Resource object) and is reversible (meaning that you can convert the String form back to the original WebLogic resource).

Note: Listing 3-2 illustrates how to use the toString() method to identify a WebLogic resource.

Resource IDs and the getID() Method

The getID() method on each of the defined WebLogic resource types returns a 64-bit hashcode that can be used to uniquely identify the WebLogic resource in a security provider. The resource ID can be effectively used for fast runtime caching, using the following algorithm:
1. Obtain a WebLogic resource.

2. Get the resource ID for the WebLogic resource using the getID method.

3. Look up the resource ID in the cache.

4. If the resource ID is found, then return the security policy.

5. If the resource ID is not found, then:
   a. Use the toString() method to look up the WebLogic resource in the security provider database.
   b. Store the resource ID and the security policy in cache.
   c. Return the security policy.

Note: Listing 3-3 illustrates how to use the getID() method to identify a WebLogic resource in Authorization provider, and provides a sample implementation of this algorithm. Because it is not guaranteed stable across multiple runs, you should not use the resource ID to store information about the WebLogic resource in a security provider database. Instead, Oracle recommends that you store any resource-to-security policy and resource-to-security role mappings in their corresponding security provider database using the WebLogic resource’s toString() method.

Notes: For more information about security provider databases, see “Initialization of the Security Provider Database” on page 3-44. For more information about the toString method, see “The toString() Method” on page 3-30.

Creating Default Groups for WebLogic Resources

When writing a runtime class for a custom Authentication provider, there are several default groups that you are required to create. Table 3-8 provides information to assist you with this task.

Table 3-8 Default Groups and Group Membership

<table>
<thead>
<tr>
<th>Group Name</th>
<th>Group Membership</th>
</tr>
</thead>
<tbody>
<tr>
<td>Administrators</td>
<td>Empty, or an administrative user.</td>
</tr>
<tr>
<td>Deployers</td>
<td>Empty</td>
</tr>
<tr>
<td>Monitors</td>
<td>Empty</td>
</tr>
</tbody>
</table>
Creating Default Security Roles for WebLogic Resources

When writing a runtime class for a custom Role Mapping provider, there are several default global roles that you are required to create. Table 3-9 provides information to assist you with this task.

Table 3-9  Default Global Roles and Group Associations

<table>
<thead>
<tr>
<th>Global Role Name</th>
<th>Group Association</th>
</tr>
</thead>
<tbody>
<tr>
<td>Admin</td>
<td>Administrators group</td>
</tr>
<tr>
<td>AdminChannelUser</td>
<td>AdminChannelUsers, Administrators, Deployers, Operators, Monitors, and AppTesters</td>

<td>Deployers group</td>
</tr>
<tr>
<td>Monitor</td>
<td>Monitors group</td>
</tr>
<tr>
<td>Operator</td>
<td>Operators group</td>
</tr>
<tr>
<td>AppTester</td>
<td>AppTesters group</td>
</tr>
</tbody>
</table>

Note: For more information about global and scoped security roles, see “Users, Groups, and Security Roles” in Securing WebLogic Resources Using Roles and Policies.

Creating Default Security Policies for WebLogic Resources

When writing a runtime class for a custom Authorization provider, there are several default security policies that you are required to create. These default security policies initially protect...
the various types of WebLogic resources. Table 3-10 provides information to assist you with this task.

Table 3-10  Default Security Policies for WebLogic Resources

<table>
<thead>
<tr>
<th>WebLogic Resource Constructor</th>
<th>Security Policy</th>
</tr>
</thead>
<tbody>
<tr>
<td>new AdminResource(null, null, null)</td>
<td>Admin global role</td>
</tr>
<tr>
<td>new AdminResource(&quot;Configuration&quot;, null, null)</td>
<td>Admin, Deployer, Monitor, or Operator global roles</td>
</tr>
<tr>
<td>new AdminResource(&quot;FileDownload&quot;, null, null)</td>
<td>Admin or Deployer global role</td>
</tr>
<tr>
<td>new AdminResource(&quot;FileUpload&quot;, null, null)</td>
<td>Admin or Deployer global role</td>
</tr>
<tr>
<td>New AdminResource(&quot;ViewLog&quot;, null, null)</td>
<td>Admin or Deployer global role</td>
</tr>
<tr>
<td>new ControlResource(null, null, null)</td>
<td>weblogic.security.WLSPrincipals.getEveryoneGroupname() group</td>
</tr>
<tr>
<td>new EISResource(null, null, null)</td>
<td>weblogic.security.WLSPrincipals.getEveryoneGroupname() group</td>
</tr>
<tr>
<td>new EJBResource(null, null, null, null, null, null)</td>
<td>weblogic.security.WLSPrincipals.getEveryoneGroupname() group</td>
</tr>
<tr>
<td>new JDBCResource(null, null, null, null, null)</td>
<td>weblogic.security.WLSPrincipals.getEveryoneGroupname() group</td>
</tr>
<tr>
<td>new JNDIResource(null, null, null)</td>
<td>weblogic.security.WLSPrincipals.getEveryoneGroupname() group</td>
</tr>
<tr>
<td>new JMSResource(null, null, null)</td>
<td>weblogic.security.WLSPrincipals.getEveryoneGroupname() group</td>
</tr>
<tr>
<td>new ServerResource(null, null, null)</td>
<td>Admin or Operator global roles</td>
</tr>
<tr>
<td>new URLResource(null, null, null, null, null)</td>
<td>weblogic.security.WLSPrincipals.getEveryoneGroupname() group</td>
</tr>
</tbody>
</table>
Design Considerations

Note: Application and COM resources should not have default security policies (that is, they should not grant permission to anyone by default).

Table 3-10  Default Security Policies for WebLogic Resources (Continued)

<table>
<thead>
<tr>
<th>WebLogic Resource Constructor</th>
<th>Security Policy</th>

</tr>
<tr>
<td>new WorkContext(null, null)</td>
<td>weblogic.security.WLSPrincipals.getEveryoneGroupname().getGroup()</td>
</tr>
</tbody>
</table>

Looking Up WebLogic Resources in a Security Provider’s Runtime Class

Listing 3-2 illustrates how to look up a WebLogic resource in the runtime class of an Authorization provider. This algorithm assumes that the security provider database for the Authorization provider contains a mapping of WebLogic resources to security policies. It is not required that you use the algorithm shown in Listing 3-2, or that you utilize the call to the getParentResource method. (For more information about the getParentResource method, see “Single-Parent Resource Hierarchies” on page 3-35.)

Listing 3-2  How to Look Up a WebLogic Resource in an Authorization Provider: Using the toString Method

```java
Policy findPolicy(Resource resource) {
    Resource myResource = resource;
    while (myResource != null) {
        String resourceText = myResource.toString();
        Policy policy = lookupInDB(resourceText);
        if (policy != null) return policy;
        myResource = myResource.getParentResource();
    }
    return null;
}
```
You can optimize the algorithm for looking up a WebLogic resource by using the getID method for the resource. (Use of the toString method alone, as shown in Listing 3-2, may impact performance due to the frequency of string concatenations.) The getID method may be quicker and more efficient because it is a hash operation that is calculated and cached within the WebLogic resource itself. Therefore, when the getID method is used, the toString value only needs to be calculated once per resource (as shown in Listing 3-3).

Listing 3-3  How to Look Up a WebLogic Resource in an Authorization Provider: Using the getID Method

```java
Policy findPolicy(Resource resource) {
    Resource myResource = resource;
    while (myResource != null) {
        long id = myResource.getID();
        Policy policy = lookupInCache(id);
        if (policy != null) return policy;
        String resourceText = myResource.toString();
        Policy policy = lookupInDB(resourceText);
        if (policy != null) {
            addToCache(id, policy);
            return policy;
        }
        myResource = myResource.getParentResource();
    }
    return null;
}
```

Note: The getID method is not guaranteed between service packs or future WebLogic Server releases. Therefore, you should not store getID values in your security provider database.

**Single-Parent Resource Hierarchies**

The level of granularity for WebLogic resources is up to you. For example, you can consider an entire Web application, a particular Enterprise JavaBean (EJB) within that Web application, or a single method within that EJB to be a WebLogic resource.
Design Considerations

WebLogic resources are arranged in a hierarchical structure ranging from most specific to least specific. You can use the `getParentResource` method for each of the WebLogic resource types if you like, but it is not required.

The WebLogic security providers use the single-parent resource hierarchy as follows: If a WebLogic security provider attempts to access a specific WebLogic resource and that resource cannot be located, the WebLogic security provider will call the `getParentResource` method of that resource. The parent of the current WebLogic resource is returned, and allows the WebLogic security provider to move up the resource hierarchy to protect the next (less-specific) resource. For example, if a caller attempts to access the following URL resource:

```
type=<url>, application=myApp, contextPath="/mywebapp", uri=foo/bar/my.jsp
```

and that exact URL resource cannot be located, the WebLogic security provider will progressively attempt to locate and protect the following resources (in order):

```
type=<url>, application=myApp, contextPath="/mywebapp", uri=/foo/bar/*
type=<url>, application=myApp, contextPath="/mywebapp", uri=/foo/*
type=<url>, application=myApp, contextPath="/mywebapp", uri=* .jsp
```

**Note:** For more information about the `getParentResource` method, see the WebLogic Server API Reference Javadoc for any of the predefined WebLogic resource types or the Resource interface.

**Pattern Matching for URL Resources**

Sections SRV.11.1 and SRV.11.2 of the Java Servlet 2.3 Specification describe the servlet container's pattern matching rules. These rules are used for URL resources as well. The following examples illustrate some important concepts with regard to URL resource pattern matching.

**Example 1**

For the URL resource `type=<url>, application=myApp, contextPath="/mywebapp", uri=/foo/my.jsp, httpMethod=GET`, the resource hierarchy used is as follows. (Note lines 3 and 4, which contain URL patterns that may be different from what is expected.)

1. `type=<url>, application=myApp, contextPath="/mywebapp", uri=/foo/my.jsp, httpMethod=GET`
2. `type=<url>, application=myApp, contextPath="/mywebapp", uri=/foo/my.jsp`
3. type=<url>, application=myApp, contextPath=/mywebapp, uri=/foo/my.jsp/*, httpMethod=GET
4. type=<url>, application=myApp, contextPath=/mywebapp, uri=/foo/my.jsp/*
5. type=<url>, application=myApp, contextPath=/mywebapp, uri=/foo/*, httpMethod=GET
6. type=<url>, application=myApp, contextPath=/mywebapp, uri=/foo/*
7. type=<url>, application=myApp, contextPath=/mywebapp, uri=*.jsp, httpMethod=GET
8. type=<url>, application=myApp, contextPath=/mywebapp, uri=*.jsp
9. type=<url>, application=myApp, contextPath=/mywebapp, uri=*/, httpMethod=GET
10. type=<url>, application=myApp, contextPath=/mywebapp, uri=*
11. type=<url>, application=myApp, contextPath=/mywebapp, uri=*
12. type=app, application=myApp
13. type=url

**Example 2**

For the URL resource type=<url>, application=myApp, contextPath=/mywebapp, uri=/foo, the resource hierarchy used is as follows. (Note line 2, which contains a URL pattern that may be different from what is expected.)

1. type=<url>, application=myApp, contextPath=/mywebapp, uri=/foo
2. type=<url>, application=myApp, contextPath=/mywebapp, uri=/foo/*
3. type=<url>, application=myApp, contextPath=/mywebapp, uri=*
4. type=<url>, application=myApp, contextPath=/mywebapp
5. type=url, application=myApp
6. type=app, application=myApp
7. type=url

**ContextHandlers and WebLogic Resources**

A ContextHandler is a high-performing WebLogic class that obtains additional context and container-specific information from the resource container, and provides that information to security providers making access or role mapping decisions. The ContextHandler interface
Design Considerations

provides a way for an internal WebLogic resource container to pass additional information to a WebLogic Security Framework call, so that a security provider can obtain contextual information beyond what is provided by the arguments to a particular method. A ContextHandler is essentially a name/value list and as such, it requires that a security provider know what names to look for. (In other words, use of a ContextHandler requires close cooperation between the WebLogic resource container and the security provider.) Each name/value pair in a ContextHandler is known as a **context element**, and is represented by a `ContextElement` object.

**Note:** For more information about the `ContextHandler` interface and `ContextElement` class, see the WebLogic Server API Reference Javadoc for the `weblogic.security.service` package.

Resource types have different context elements whose values you can inspect as part of developing a custom provider. That is, not all containers pass all context elements.

**Table 3-11** lists the available ContextHandler entries.

<table>
<thead>
<tr>
<th>Context Element Name</th>
<th>Description and Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>com.bea.contextelement.servlet.HttpServletRequest</td>

<td>The <a href="">ds:KeyInfo</a> element to be used for subject confirmation with holder-of-key SAML assertions. org.w3c.dom.Element</td>
</tr>
</tbody>
</table>

Listing 3-4 illustrates how you can access HttpServletRequest and HttpServletResponse context element objects via a URL (Web) resource’s ContextHandler. For example, you might
use this code in the `isAccessAllowed()` method of your `AccessDecision` SSPI implementation. (For more information, see “Implement the AccessDecision SSPI” on page 7-9.)

**Listing 3-4  Example: Accessing Context Elements in the URL Resource ContextHandler**

```java
static final String SERVLETREQUESTNAME =
    "com.bea.contextelement.servlet.HttpServletRequest";
if (resource instanceof URLResource) {
    HttpServletRequest req =
        (HttpServletRequest)handler.getValue(SERVLETREQUESTNAME);
}
```

**Note:** You might also want to access these context elements in the `getRoles()` method of the `RoleMapper` SSPI implementation or the `getContext()` method of the `AuditContext` interface implementation. (For more information, see “Implement the RoleMapper SSPI” on page 9-9 and “Audit Context” on page 12-8, respectively.)

**Providers and Interfaces that Support Context Handlers**

The ContextHandler interface provides a way to pass additional information to a WebLogic Security Framework call, so that a security provider or interface can obtain additional context information beyond what is provided by the arguments to a particular method.

Table 3-12 describes the context handler support.

**Table 3-12  Methods and Classes that Support Context Handlers**

<table>
<thead>
<tr>
<th>Methods</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>AccessDecision.isAccessAllowed()</code></td>
<td>The <code>isAccessAllowed()</code> method accepts a ContextHandler object that can optionally be used by an Access Decision to obtain additional information that may be used in making the authorization decision. If the caller is unable to provide additional information, a null value should be specified.</td>
</tr>
</tbody>
</table>
### Table 3-12 Methods and Classes that Support Context Handlers

<table>
<thead>
<tr>
<th>Method/Event</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AdjudicatorV2.adjudicate()</td>
<td>An implementation of the AdjudicatorV2 SSPI interface is the part of an Adjudication provider that is called after all the Access Decisions’ isAccessAllowed methods have been called and returned successfully (that is, without throwing exceptions). The AdjudicatorV2 SSPI accepts the resource and ContextHandler as additional arguments. When the AuthorizationManager calls the Adjudicator, it passes the same resource and ContextHandler as it passed to AccessDecision. This allows the Adjudicator to have all of the information that is available to AccessDecision.</td>
</tr>
<tr>
<td>AuditAttnEventV2.getContext()</td>
<td>Because the JAAS LoginModule.login() method and the IdentityAsserter.assertIdentity() method have access to the ContextHandler, the AuditAttnEventV2 interface also gets this data so it can audit relevant information. The getContext() method is inherited from <code>weblogic.security.spi.AuditContext</code>. The <code>getContext()</code> method gets a ContextHandler object from which additional audit information can be obtained.</td>
</tr>
<tr>
<td>AuditCertPathBuilderInterface.getContext(), AuditCertPathValidatorEvent.getContext()</td>
<td>The <code>getContext()</code> method gets an optional ContextHandler object that may specify additional data on how to look up and validate the CertPath.</td>
</tr>
<tr>
<td>AuditConfigurationEvent.getContext()</td>
<td>The AuditConfigurationEvent.getContex() method gets a ContextHandler object from which additional audit information can be obtained.</td>
</tr>
<tr>
<td>AuditContext.getContext()</td>
<td>The AuditContext.getContex() method gets a ContextHandler object from which additional audit information can be obtained.</td>
</tr>
<tr>
<td>AuditCredentialMappingEvent.getContext()</td>
<td>The <code>getContext()</code> method gets an optional ContextHandler object that may specify additional information about the credential mapping audit event.</td>
</tr>
<tr>
<td>CertPathBuilderParameterSpi.getContext and CertPathValidatorParameterSpi.getContext</td>
<td>The CertPathBuilderParameterSpi and CertPathValidatorParameterSpi interfaces include a <code>getContext()</code> method to get a ContextHandler that may pass in extra parameters that can be used for building and validating the Cert Path.</td>
</tr>
</tbody>
</table>
The ChallengeIdentityAsserterV2 methods accept a ContextHandler object that can optionally be used by the Identity assertion provider to obtain additional information that may be used in asserting the challenge identity.

The CredentialMapperV2.getCredentials() and CredentialMapper.getCredential() methods include a ContextHandler parameter with optional extra data.

The IdentityAsserterV2 provider allows the Security Framework to pass a ContextHandler in the assertIdentity method. The ContextHandler object can optionally be used to obtain additional information that may be used in asserting the identity. For example, the ContextHandler allows users to extract extra information from the HttpServletRequest and to set cookies in the HttpServletResponse.

A ContextHandler can be passed to the JAAS CallbackHandler parameter. A CallbackHandler is a variable-argument data structure that is passed to the login() method. Adding the ContextHandler in this manner allows users to extract extra information from the HttpServletRequest and to set cookies in the HttpServletResponse, for example. The implementation includes LoginModules used both for authentication and identity assertion.

The EJB and Servlet containers must add the ContextHandler to the CallbackHandler when calling the Principal Authenticator. Specifically, they must instantiate and pass a weblogic.security.auth.callback.ContextHandlerCallback to the invokeCallback method of a CallbackHandler to retrieve the ContextHandler related to this security operation. If no ContextHandler is associated with this operation, javax.security.auth.callback.UnsupportedCallbackException is thrown.
Initialization of the Security Provider Database

**Note:** Prior to reviewing this section, be sure you have read “Security Provider Databases” in the Understanding WebLogic Security.

At minimum, you must initialize security providers’ databases with the default users, groups, security policies, security roles, or credentials that your Authentication, Authorization, Role Mapping, and Credential Mapping providers expect. You will need to initialize a given security provider’s database before the security provider can be used, and should think about how this will work as you are writing the runtime classes for your custom security providers. The method you use to initialize a security provider’s database depends upon many factors, including whether or not an externally administered database will be used to store the user, group, security policy, security role, or credential information, and whether or not the database already exists or needs to be created.

The following sections explain some best practices for initializing a security provider database:

- **Best Practice: Create a Simple Database If None Exists**
- **Best Practice: Configure an Existing Database**
Initialization of the Security Provider Database

- Best Practice: Delegate Database Initialization

Best Practice: Create a Simple Database If None Exists

The first time an Authentication, Authorization, Role Mapping, or Credential Mapping provider is used, it attempts to locate a database with the information it needs to provide its security service. If the security provider fails to locate the database, you can have it create one and automatically populate it with the default users, groups, security policies, security roles, and credentials. This option may be useful for development and testing purposes.

Both the WebLogic security providers and the sample security providers follow this practice. The WebLogic Authentication, Authorization, Role Mapping, and Credential Mapping providers store the user, group, security policy, security role, and credential information in the embedded LDAP server. If you want to use any of these WebLogic security providers, you will need to follow the “Configuring the Embedded LDAP Server” instructions in Securing WebLogic Server.

Best Practice: Configure an Existing Database

If you already have a database (such as an external LDAP server), you can populate that database with the users, groups, security policies, security roles, and credentials that your Authentication, Authorization, Role Mapping, and Credential Mapping providers require. (Populating an existing database is accomplished using whatever tools you already have in place for performing these tasks.)

Once your database contains the necessary information, you must configure the security providers to look in that database. You accomplish this by adding custom attributes in your security provider’s MBean Definition File (MDF). Some examples of custom attributes are the database’s host, port, password, and so on. After you run the MDF through the WebLogic MBeanMaker and complete a few other steps to generate the MBean type for your custom security provider, you or an administrator use the WebLogic Server Administration Console to set these attributes to point to the database.

Note: For more information about MDFs, MBean types, and the WebLogic MBeanMaker, see “Generating an MBean Type to Configure and Manage the Custom Security Provider” on page 2-3.

As an example, Listing 3-5 shows some custom attributes that are part of the WebLogic LDAP Authentication provider’s MDF. These attributes enable an administrator to specify information about the WebLogic LDAP Authentication provider’s database (an external LDAP server), so it can locate information about users and groups.
Listing 3-5  LDAPAuthenticator.xml

...  

<MBeanAttribute
Name = "UserObjectClass"
Type = "java.lang.String"
Default = "&quot;person&quot;"
Description = "The LDAP object class that stores users."
/>

<MBeanAttribute
Name = "UserNameAttribute"
Type = "java.lang.String"
Default = "&quot;uid&quot;"
Description = "The attribute of an LDAP user object that specifies the name of the user."
/>

<MBeanAttribute
Name = "UserDynamicGroupDNAttribute"
Type = "java.lang.String"
Description = "The attribute of an LDAP user object that specifies the distinguished names (DNs) of dynamic groups to which this user belongs. If such an attribute does not exist, WebLogic Server determines if a user is a member of a group by evaluating the URLs on the dynamic group. If a group contains other groups, WebLogic Server evaluates the URLs on any of the descendents of the group."
/>

<MBeanAttribute
Name = "UserBaseDN"
Type = "java.lang.String"
Default = "&quot;ou=people, o=example.com&quot;"
Description = "The base distinguished name (DN) of the tree in the LDAP directory that contains users."
/>

<MBeanAttribute
Name = "UserSearchScope"
Type = "java.lang.String"
Default = "&quot;subtree&quot;"
LegalValues = "subtree,onelevel"
Description = "Specifies how deep in the LDAP directory tree to search for Users. Valid values are &lt;code&gt;subtree&amp;lt;/code&amp;gt; and &lt;code&gt;onelevel&amp;lt;/code&amp;gt;."
Best Practice: Delegate Database Initialization

If possible, initialization calls between a security provider and the security provider’s database should be done by an intermediary class, referred to as a database delegator. The database delegator should interact with the runtime class and the MBean type for the security provider, as shown in Figure 3-11.

Figure 3-11 Positioning of the Database Delegator Class

A database delegator is used by the WebLogic Authentication and Credential Mapping providers. The WebLogic Authentication provider, for example, calls into a database delegator to initialize the embedded LDAP server with default users and groups, which it requires to provide authentication services for the default security realm.

Use of a database delegator is suggested as a convenience to application developers and security vendors who are developing custom security providers, because it hides the security provider’s database and centralizes calls into the database.

Differences In Attribute Validators

A validator is an interface that is implemented by a class that can validate various types of expressions. In this release of WebLogic Server, the inheritance rules for security provider attribute validator methods differ from the rules that existed in 8.1.

In 8.1, a derived MBean had only to customize an attribute validator method in its MBean implementation file to make it take effect. As of version 9.0, the derived MBean must also...
explicitly declare the attribute validator in its MDF file to make it take effect. Otherwise, the customized method code is ignored.

Consider the following example of the base class of all identity assert MBean implementations, `weblogic.management.security.authentication.IdentityAsserterImpl`.

IdentityAsserterImpl extends the authentication provider MBean implementation and gives the authenticator's MBean implementation access to its configuration attributes.

In 8.1, you could do the following:

1. Write an Identity Asserter provider called IdentityAsserter1. In its MDF file, indicate that it extends `weblogic.management.security.authentication.IdentityAsserter`.

2. Use the WebLogic MBeanMaker to generate the MBean type. The implementation file created by the MBeanMaker, typically named `IdentityAsserter1Impl.java`, extends `weblogic.management.security.authentication.IdentityAsserterImpl`.

   Therefore, the MBean inherits the `activeTypes` attribute, which has an attribute validator method. The `validateActiveTypes(String[] activeTypes)` method ensures that `activeTypes` includes only supported types.

3. Modify the implementation file and specify a different implementation for the `validateActiveTypes` method. For example, it could further restrict the active types or loosen the rules.

4. In 8.1, IdentityAsserter1's `validateActiveTypes` implementation is used.

   As of version 9.0, the base IdentityAsserter's `validateActiveTypes` implementation is used instead. That is, IdentityAsserter1's `validateActiveTypes` implementation is silently ignored.

To work around this difference in version 9.0 and later, redefine the attribute validator in IdentityAsserter1's MDF file in an MBeanOperation subelement.

**Differences In Attribute Validators for Custom Validators**

The difference in inheritance rules for security provider attribute validators also applies to custom validators. You could have a provider declare an attribute with a custom validator. Then you could derive another provider from that one and write another implementation of the validator. In 8.1, the derived provider's validator would be used. As of version 9.0, the base provider's validator is used instead, and the derived one is silently ignored.
Authentication is the mechanism by which callers prove that they are acting on behalf of specific users or systems. Authentication answers the question, “Who are you?” using credentials such as username/password combinations.

In WebLogic Server, Authentication providers are used to prove the identity of users or system processes. Authentication providers also remember, transport, and make that identity information available to various components of a system (via subjects) when needed. During the authentication process, a Principal Validation provider provides additional security protections for the principals (users and groups) contained within the subject by signing and verifying the authenticity of those principals. (For more information, see Chapter 6, “Principal Validation Providers.”)

The following sections describe Authentication provider concepts and functionality, and provide step-by-step instructions for developing a custom Authentication provider:

- “Authentication Concepts” on page 4-2
- “The Authentication Process” on page 4-10
- “Do You Need to Develop a Custom Authentication Provider?” on page 4-11
- “How to Develop a Custom Authentication Provider” on page 4-12

Note: An Identity Assertion provider is a specific form of Authentication provider that allows users or system processes to assert their identity using tokens. For more information, see Chapter 5, “Identity Assertion Providers.”
Authentication Concepts

Before delving into the specifics of developing custom Authentication providers, it is important to understand the following concepts:

- “Users and Groups, Principals and Subjects” on page 4-2
- “LoginModules” on page 4-4
- “Java Authentication and Authorization Service (JAAS)” on page 4-6

Users and Groups, Principals and Subjects

A user is similar to an operating system user in that it represents a person. A group is a category of users, classified by common traits such as job title. Categorizing users into groups makes it easier to control the access permissions for large numbers of users. For more information about users and groups, see “Users, Groups, and Security Roles” in Securing WebLogic Resources Using Roles and Policies.

Both users and groups can be used as principals by application servers like WebLogic Server. A principal is an identity assigned to a user or group as a result of authentication. The Java Authentication and Authorization Service (JAAS) requires that subjects be used as containers for authentication information, including principals. Each principal stored in the same subject represents a separate aspect of the same user’s identity, much like cards in a person’s wallet. (For example, an ATM card identifies someone to their bank, while a membership card identifies them to a professional organization to which they belong.) For more information about JAAS, see “Java Authentication and Authorization Service (JAAS)” on page 4-6.

Note: Subjects replace WebLogic Server 6.x users.

Figure 4-1 illustrates the relationships among users, groups, principals, and subjects.
As part of a successful authentication, principals are signed and stored in a subject for future use. A Principal Validation provider signs principals, and an Authentication provider's LoginModule actually stores the principals in the subject. Later, when a caller attempts to access a principal stored within a subject, a Principal Validation provider verifies that the principal has not been altered since it was signed, and the principal is returned to the caller (assuming all other security conditions are met).

Note: For more information about Principal Validation providers and LoginModules, see Chapter 6, “Principal Validation Providers” and “LoginModules” on page 4-4, respectively.

Any principal that is going to represent a WebLogic Server user or group needs to implement the WLSUser and WLSGroup interfaces, which are available in the weblogic.security.spi package.

Providing Initial Users and Groups
Authentication providers need a list of users and groups before they can be used to perform authentication in a running WebLogic Server. Some Authentication providers let the administrator configure an external database (for example, add the users and groups to an LDAP server or a DBMS) and then configure the provider to use that database. These providers don't have to worry about how the users and groups are populated because the administrator does that first, using the external database's tools.

However, some Authentication providers create and manage their own list of users and groups. This is the case for the ManageableSampleAuthenticator provider. These providers need to worry
about how their initial set of users and groups is populated. One way to handle this is for the
provider's "initialize" method to notice that the users and groups don't exist yet, and then populate
the list with an initial set of users and groups.

Note that some providers have a separate list of users and groups for each security realm, and
therefore need to create an initial set of users and groups the first time the list is used in a new
realm. For example, the ManageableSampleAuthenticator provider creates a separate properties
file of users and groups for each realm. Its initialize method gets the realm name, determines
whether the properties file for that realm exists and, if not, creates one, populating it with its initial
set of users and groups.

**LoginModules**

A LoginModule is a required component of an Authentication provider, and can be a component
of an Identity Assertion provider if you want to develop a separate LoginModule for perimeter
authentication.

LoginModules are the work-horses of authentication: all LoginModules are responsible for
authenticating users within the security realm and for populating a subject with the necessary
principals (users/groups). LoginModules that are not used for perimeter authentication also verify
the proof material submitted (for example, a user’s password).

**Note:** For more information about Identity Assertion providers and perimeter authentication,
see Chapter 5, “Identity Assertion Providers.”

If there are multiple Authentication providers configured in a security realm, each of the
Authentication providers’ LoginModules will store principals within the same subject. Therefore,
if a principal that represents a WebLogic Server user (that is, an implementation of the WLSUser
interface) named “Joe” is added to the subject by one Authentication provider’s LoginModule,
any other Authentication provider in the security realm should be referring to the same person
when they encounter “Joe”. In other words, the other Authentication providers’ LoginModules
should not attempt to add another principal to the subject that represents a WebLogic Server user
(for example, named “Joseph”) to refer to the same person. However, it is acceptable for a another
Authentication provider’s LoginModule to add a principal of a type other than WLSUser with the
name “Joseph”.

**The LoginModule Interface**

LoginModules can be written to handle a variety of authentication mechanisms, including
username/password combinations, smart cards, biometric devices, and so on. You develop
LoginModules by implementing the javax.security.auth.spi.LoginModule interface,
which is based on the Java Authentication and Authorization Service (JAAS) and uses a subject as a container for authentication information. The LoginModule interface enables you to plug in different kinds of authentication technologies for use with a single application, and the WebLogic Security Framework is designed to support multiple LoginModule implementations for multipart authentication. You can also have dependencies across LoginModule instances or share credentials across those instances. However, the relationship between LoginModules and Authentication providers is one-to-one. In other words, to have a LoginModule that handles retina scan authentication and a LoginModule that interfaces to a hardware device like a smart card, you must develop and configure two Authentication providers, each of which include an implementation of the LoginModule interface. For more information, see “Implement the JAAS LoginModule Interface” on page 4-15.

**Note:** You can also obtain LoginModules from third-party security vendors instead of developing your own.

**LoginModules and Multipart Authentication**

The way you configure multiple Authentication providers (and thus, multiple LoginModules) can affect the overall outcome of the authentication process, which is especially important for multipart authentication. First, because LoginModules are components of Authentication providers, they are called in the order in which the Authentication providers are configured. Generally, you configure Authentication providers using the WebLogic Server Administration Console. (For more information, see “Specifying the Order of Authentication Providers” on page 4-33.) Second, the way each LoginModule’s control flag is set specifies how a failure during the authentication process should be handled. Figure 4-2 illustrates a sample flow involving three different LoginModules (that are part of three Authentication providers), and illustrates what happens to the subject for different authentication outcomes.
Figure 4-2  Sample LoginModule Flow

<table>
<thead>
<tr>
<th>WebLogic Authentication Provider</th>
<th>User Authenticated?</th>
<th>Principal Created?</th>
<th>Control Flag Setting</th>
<th>Subject</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Yes</td>
<td>Yes, p1</td>
<td>Required</td>
<td>p1</td>
</tr>
<tr>
<td>Custom Authentication Provider #1</td>
<td>No</td>
<td>No</td>
<td>Optional</td>
<td>N/A</td>
</tr>
<tr>
<td>Custom Authentication Provider #2</td>
<td>Yes</td>
<td>Yes, p2</td>
<td>Required</td>
<td>p2</td>
</tr>
</tbody>
</table>

If the control flag for Custom Authentication Provider #1 had been set to Required, the authentication failure in its User Authentication step would have caused the entire authentication process to have failed. Also, if the user had not been authenticated by the WebLogic Authentication provider (or custom Authentication provider #2), the entire authentication process would have failed. If the authentication process had failed in any of these ways, all three LoginModules would have been rolled back and the subject would not contain any principals.

Note:  For more information about the LoginModule control flag setting and the LoginModule interface, see the *Java Authentication and Authorization Service (JAAS) 1.0 LoginModule Developer’s Guide* and the Java 2 Enterprise Edition, v1.4.1 API Specification Javadoc for the LoginModule interface, respectively.

Java Authentication and Authorization Service (JAAS)

Whether the client is an application, applet, Enterprise JavaBean (EJB), or servlet that requires authentication, WebLogic Server uses the Java Authentication and Authorization Service (JAAS) classes to reliably and securely authenticate to the client. JAAS implements a Java version of the Pluggable Authentication Module (PAM) framework, which permits applications to remain independent from underlying authentication technologies. Therefore, the PAM framework allows the use of new or updated authentication technologies without requiring modifications to your application.

WebLogic Server uses JAAS for remote fat-client authentication, and internally for authentication. Therefore, only developers of custom Authentication providers and developers of remote fat client applications need to be involved with JAAS directly. Users of thin clients or
developers of within-container fat client applications (for example, those calling an Enterprise JavaBean (EJB) from a servlet) do not require the direct use or knowledge of JAAS.

How JAAS Works With the WebLogic Security Framework

Generically, authentication using the JAAS classes and WebLogic Security Framework is performed in the following manner:

1. A client-side application obtains authentication information from a user or system process. The mechanism by which this occurs is different for each type of client.

2. The client-side application can optionally create a CallbackHandler containing the authentication information.
   a. The client-side application passes the CallbackHandler to a local (client-side) LoginModule using the LoginContext class. (The local LoginModule could be UsernamePasswordLoginModule, which is provided as part of WebLogic Server.)
   b. The local LoginModule passes the CallbackHandler containing the authentication information to the appropriate WebLogic Server container (for example, RMI, EJB, servlet, or IIOP).

Note: A CallbackHandler is a highly-flexible JAAS standard that allows a variable number of arguments to be passed as complex objects to a method. There are three types of CallbackHandlers: NameCallback, PasswordCallback, and TextInputCallback, all of which reside in the javax.security.auth.callback package. The NameCallback and PasswordCallback return the username and password, respectively. TextInputCallback can be used to access the data users enter into any additional fields on a login form (that is, fields other than those for obtaining the username and password). When used, there should be one TextInputCallback per additional form field, and the prompt string of each TextInputCallback must match the field name in the form. WebLogic Server only uses the TextInputCallback for form-based Web application login. For more information about CallbackHandlers, see the Java 2 Enterprise Edition, v1.4.1 API Specification Javadoc for the CallbackHandler interface.

For more information about the LoginContext class, see the Java 2 Enterprise Edition v1.4.2 Specification Javadoc for the LoginContext class.

For more information about the UsernamePasswordLoginModule, see the WebLogic Server API Reference Javadoc for the UsernamePasswordLoginModule class.
If you do not want to use a client-side LoginModule, you can specify the username and password in other ways: for example, as part of the initial JNDI lookup.

3. The WebLogic Server container calls into the WebLogic Security Framework. If there is a client-side CallbackHandler containing authentication information, this is passed into the WebLogic Security Framework.

4. For each of the configured Authentication providers, the WebLogic Security Framework creates a CallbackHandler using the authentication information that was passed in. (These are internal CallbackHandlers created on the server-side by the WebLogic Security Framework, and are not related to the client’s CallbackHandler.)

5. The WebLogic Security Framework calls the LoginModule associated with the Authentication provider (that is, the LoginModule that is specifically designed to handle the authentication information).

   **Note:** For more information about LoginModules, see “LoginModules” on page 4-4.

   The LoginModule attempts to authenticate the client using the authentication information.

6. If the authentication is successful, the following occurs:

   a. Principals (users and groups) are signed by a Principal Validation provider to ensure their authenticity between programmatic server invocations. For more information about Principal Validation providers, see Chapter 6, “Principal Validation Providers.”

   b. The LoginModule associates the signed principals with a subject, which represents the user or system process being authenticated. For more information about subjects and principals, see “Users and Groups, Principals and Subjects” on page 4-2.

   **Note:** For authentication performed entirely on the server-side, the process would begin at step 3, and the WebLogic Server container would call the `weblogic.security.services.authentication.login` method prior to step 4.

**Example: Standalone T3 Application**

Figure 4-3 illustrates how the JAAS classes work with the WebLogic Security Framework for a standalone, T3 application, and an explanation follows.
For this example, authentication using the JAAS classes and WebLogic Security Framework is performed in the following manner:

1. The T3 application obtains authentication information (username, password, and URL) from a user or system process.
2. The T3 application creates a CallbackHandler containing the authentication information.

   a. The T3 application passes the CallbackHandler to the UsernamePasswordLoginModule using the LoginContext class.

   Note: The `weblogic.security.auth.login.UsernamePasswordLoginModule` implements the standard JAAS `javax.security.auth.spi>LoginModule` interface and uses client-side APIs to authenticate a WebLogic client to a WebLogic Server instance. It can be used for both T3 and IIOP clients. Callers of this LoginModule must implement a CallbackHandler to pass the username (NameCallback), password (PasswordCallback), and a URL (URLCallback).

   b. The `UsernamePasswordLoginModule` passes the CallbackHandler containing the authentication information (that is, username, password, and URL) to the WebLogic Server RMI container.
Authentication Providers

4. For each of the configured Authentication providers, the WebLogic Security Framework creates a CallbackHandler containing the username, password, and URL that was passed in. (These are internal CallbackHandlers created on the server-side by the WebLogic Security Framework, and are not related to the client’s CallbackHandler.)

5. The WebLogic Security Framework calls the LoginModule associated with the Authentication provider (that is, the LoginModule that is specifically designed to handle the authentication information).

   The LoginModule attempts to authenticate the client using the authentication information.

6. If the authentication is successful, the following occurs:

   a. Principals (users and groups) are signed by a Principal Validation provider to ensure their authenticity between programmatic server invocations.

   b. The LoginModule associates the signed principals with a subject, which represents the user or system being authenticated.

   c. The WebLogic Security Framework returns the authentication status to the T3 client application, and the T3 client application retrieves the authenticated subject from the WebLogic Security Framework.

The Authentication Process

Figure 4-4 shows a behind-the-scenes look of the authentication process for a fat-client login. JAAS runs on the server to perform the login. Even in the case of a thin-client login (that is, a browser client) JAAS is still run on the server.
Figure 4-4  The Authentication Process

Notes: Only developers of custom Authentication providers will be involved with this JAAS process directly. The client application could either use JNDI initial context creation or JAAS to initiate the passing of the username and password.

When a user attempts to log into a system using a username/password combination, WebLogic Server establishes trust by validating that user’s username and password, and returns a subject that is populated with principals per JAAS requirements. As Figure 4-4 also shows, this process requires the use of a LoginModule and a Principal Validation provider, which are discussed in detail in “LoginModules” on page 4-4 and Chapter 6, “Principal Validation Providers,” respectively.

After successfully proving a caller’s identity, an authentication context is established, which allows an identified user or system to be authenticated to other entities. Authentication contexts may also be delegated to an application component, allowing that component to call another application component while impersonating the original caller.

Do You Need to Develop a Custom Authentication Provider?

The default (that is, active) security realm for WebLogic Server includes a WebLogic Authentication provider.

Note: In conjunction with the WebLogic Authorization provider, the WebLogic Authentication provider replaces the functionality of the File realm that was available in 6.x releases of WebLogic Server.
The WebLogic Authentication provider supports delegated username/password authentication, and utilizes an embedded LDAP server to store user and group information. The WebLogic Authentication provider allows you to edit, list, and manage users and group membership.

WebLogic Server also provides the following additional Authentication providers that you can use instead of or in conjunction with the WebLogic Authentication provider in the default security realm:

- A set of LDAP Authentication providers that access external LDAP stores (Open LDAP, Netscape iPlanet, Microsoft Active Directory, and Novell NDS).
- A set of Database Base Management System (DBMS) authentication providers that access user, password, group, and group membership information stored in databases for authentication.
- A Windows NT Authentication provider that uses Windows NT users and groups for authentication purposes.
- An LDAP X509 Identity Assertion provider.

By default, these additional Authentication providers are available but not configured in the WebLogic default security realm.

If you want to perform additional authentication tasks, then you need to develop a custom Authentication provider.

**Note:** If you want to perform perimeter authentication using a token type that is not supported out of the box (for example, a new, custom, or third party token type), you might need to develop a custom Identity Assertion provider. For more information, see Chapter 5, “Identity Assertion Providers.”

**How to Develop a Custom Authentication Provider**

If the WebLogic Authentication provider does not meet your needs, you can develop a custom Authentication provider by following these steps:

1. “Create Runtime Classes Using the Appropriate SSPIs” on page 4-13
2. “Generate an MBean Type Using the WebLogic MBeanMaker” on page 4-25
3. “Configure the Custom Authentication Provider Using the Administration Console” on page 4-31
Create Runtime Classes Using the Appropriate SSPIs

Before you start creating runtime classes, you should first:

- “Understand the Purpose of the “Provider” SSPIs” on page 3-3
- “Understand the SSPI Hierarchy and Determine Whether You Will Create One or Two Runtime Classes” on page 3-7

When you understand this information and have made your design decisions, create the runtime classes for your custom Authentication provider by following these steps:

- “Implement the AuthenticationProviderV2 SSPI” on page 4-13
- “Implement the JAAS LoginModule Interface” on page 4-15

For an example of how to create a runtime class for a custom Authentication provider, see “Example: Creating the Runtime Classes for the Sample Authentication Provider” on page 4-18.

Implement the AuthenticationProviderV2 SSPI

**Note:** The AuthenticationProvider SSPI is deprecated in this release of WebLogic Server. Use the AuthenticationProviderV2 SSPI instead.

To implement the AuthenticationProviderV2 SSPI, provide implementations for the methods described in “Understand the Purpose of the “Provider” SSPIs” on page 3-3 and the following methods:

getLoginModuleConfiguration

```java
public AppConfigurationEntry getLoginModuleConfiguration()
```

The `getLoginModuleConfiguration` method obtains information about the Authentication provider’s associated LoginModule, which is returned as an `AppConfigurationEntry`. The `AppConfigurationEntry` is a Java Authentication and Authorization Service (JAAS) class that contains the classname of the LoginModule; the LoginModule’s control flag (which was passed in via the Authentication provider’s associated MBean); and a configuration options map for the LoginModule (which allows other configuration information to be passed into the LoginModule).

For more information about the `AppConfigurationEntry` class (located in the `javax.security.auth.login` package) and the control flag options for LoginModules, see the *Java 2 Enterprise Edition, v1.4.1 API Specification Javadoc* for the `AppConfigurationEntry` class and the `Configuration` class. For more information about LoginModules, see “LoginModules” on page 4-4. For more information about security providers and MBeans, see “Understand Why You Need an MBean Type” on page 3-11.
getAssertionModuleConfiguration

public AppConfigurationEntry getAssertionModuleConfiguration()

The getAssertionModuleConfiguration method obtains information about an Identity Assertion provider’s associated LoginModule, which is returned as an AppConfigurationEntry. The AppConfigurationEntry is a JAAS class that contains the classname of the LoginModule; the LoginModule’s control flag (which was passed in via the Identity Assertion provider’s associated MBean); and a configuration options map for the LoginModule (which allows other configuration information to be passed into the LoginModule).

Notes: The implementation of the getAssertionModuleConfiguration method can be to return null, if you want the Identity Assertion provider to use the same LoginModule as the Authentication provider.

The assertIdentity() method of an Identity Assertion provider is called every time identity assertion occurs, but the LoginModules may not be called if the Subject is cached. The -Dweblogic.security.identityAssertionTTL flag can be used to affect this behavior (for example, to modify the default TTL of 5 minutes or to disable the cache by setting the flag to -1).

It is the responsibility of the Identity Assertion provider to ensure not just that the token is valid, but also that the user is still valid (for example, the user has not been deleted).

To use the EJB <run-as-principal> element with a custom Authentication provider, use the getAssertionModuleConfiguration() method. This method performs the identity assertion that validates the principal specified in the <run-as-principal> element.

getPrincipalValidator

public PrincipalValidator getPrincipalValidator()

The getPrincipalValidator method obtains a reference to the Principal Validation provider’s runtime class (that is, the PrincipalValidator SSPI implementation). In most cases, the WebLogic Principal Validation provider can be used (see Listing 4-1 for an example of how to return the WebLogic Principal Validation provider). For more information about Principal Validation providers, see Chapter 6, “Principal Validation Providers.”

getIdentityAsserter

public IdentityAsserterV2 getIdentityAsserter()
The AuthenticationProviderV2 getIdentityAsserter method obtains a reference to the new Identity Assertion provider’s runtime class (that is, the IdentityAsserterV2 SSPI implementation).

In most cases, the return value for this method will be null (see Listing 4-1 for an example). For more information about Identity Assertion providers, see Chapter 5, “Identity Assertion Providers.”

For more information about the AuthenticationProviderV2 SSPI and the methods described above, see the *WebLogic Server API Reference Javadoc.*

**Implement the JAAS LoginModule Interface**

To implement the JAAS `javax.security.auth.spi.LoginModule` interface, provide implementations for the following methods:

- **initialize**

  ```java
  public void initialize (Subject subject, CallbackHandler callbackHandler, Map sharedState, Map options)
  ```

  The `initialize` method initializes the LoginModule. It takes as arguments a subject in which to store the resulting principals, a `CallbackHandler` that the Authentication provider will use to call back to the container for authentication information, a map of any shared state information, and a map of configuration options (that is, any additional information you want to pass to the LoginModule).

  A `CallbackHandler` is a highly-flexible JAAS standard that allows a variable number of arguments to be passed as complex objects to a method. For more information about `CallbackHandlers`, see the *Java 2 Enterprise Edition, v1.4.1 API Specification Javadoc* for the `CallbackHandler` interface.

- **login**

  ```java
  public boolean login() throws LoginException
  ```

  The `login` method attempts to authenticate the user and create principals for the user by calling back to the container for authentication information. If multiple LoginModules are configured (as part of multiple Authentication providers), this method is called for each LoginModule in the order that they are configured. Information about whether the login was successful (that is, whether principals were created) is stored for each LoginModule.

- **commit**

  ```java
  public boolean commit() throws LoginException
  ```
Authentication Providers

The commit method attempts to add the principals created in the login method to the subject. This method is also called for each configured LoginModule (as part of the configured Authentication providers), and executed in order. Information about whether the commit was successful is stored for each LoginModule.

abort

public boolean abort() throws LoginException

The abort method is called for each configured LoginModule (as part of the configured Authentication providers) if any commits for the LoginModules failed (in other words, the relevant REQUIRED, REQUISITE, SUFFICIENT and OPTIONAL LoginModules did not succeed). The abort method will remove that LoginModule’s principals from the subject, effectively rolling back the actions performed. For more information about the available control flag settings, see the Java 2 Enterprise Edition, v1.4.1 API Specification Javadoc for the LoginModule interface.

logout

public boolean logout() throws LoginException

The logout method attempts to log the user out of the system. It also resets the subject so that its associated principals are no longer stored.

Note: The LoginModule.logout method is never called for the WebLogic Authentication providers or custom Authentication providers. This is simply because once the principals are created and placed into a subject, the WebLogic Security Framework no longer controls the lifecycle of the subject. Therefore, the developer-written, user code that creates the JAAS LoginContext to login and obtain the subject should also call the LoginContext.logout method. When the user code runs in a Java client that uses JAAS directly, that code has the option of calling the LoginContext.logout method, which clears the subject. When the user code runs in a servlet, the servlet has the ability to logout a user from a servlet session, which clears the subject.

For more information about the JAAS LoginModule interface and the methods described above, see the Java Authentication and Authorization Service (JAAS) 1.0 Developer’s Guide, and the Java 2 Enterprise Edition, v1.4.2 API Specification Javadoc for the LoginModule interface.

Throwing Custom Exceptions from LoginModules

You may want to throw a custom exception from a LoginModule you write. The custom exception can then be caught by your application and appropriate action taken. For example, if a PasswordChangeRequiredException is thrown from your LoginModule, you can catch that
exception within your application, and use it to forward users to a page that allows them to change their password.

When you throw a custom exception from a LoginModule and want to catch it within your application, you must ensure that:

1. The application catching the exception is running on the server. (Fat clients cannot catch custom exceptions.)
2. Your servlet has access to the custom exception class at both compile time and deploy time. You can do this using either of the following methods, depending on your preference:
   - “Method 1: Make Custom Exceptions Available via the System and Compiler Classpath” on page 4-17
   - “Method 2: Make Custom Exceptions Available via the Application Classpath” on page 4-17

Method 1: Make Custom Exceptions Available via the System and Compiler Classpath

1. Write an exception class that extends LoginException.
2. Use the custom exception class in your classes that implement the LoginModule and AuthenticationProvider interfaces.
3. Put the custom exception class in both the system and compiler classpath when compiling the security provider’s runtime class.
4. “Generate an MBean Type Using the WebLogic MBeanMaker.”

Method 2: Make Custom Exceptions Available via the Application Classpath

1. Write an exception class that extends LoginException.
2. Use the custom exception class in your classes that implement the LoginModule and AuthenticationProvider interfaces.
3. Put the custom exception’s source in the classpath of the application’s build, and include it in the classpath of the application’s JAR/WAR file.
4. “Generate an MBean Type Using the WebLogic MBeanMaker.”
5. Add the custom exception class to the MJF (MBean JAR File) generated by the WebLogic MBeanMaker.
6. Include the MJF when compiling your application.
Example: Creating the Runtime Classes for the Sample Authentication Provider

Listing 4-1 shows the SimpleSampleAuthenticationProviderImpl.java class, which is one of two runtime classes for the sample Authentication provider. This runtime class includes implementations for:

- The three methods inherited from the SecurityProvider interface: initialize, getDescription and shutdown (as described in “Understand the Purpose of the “Provider” SSPIs” on page 3-3.)

- The four methods in the AuthenticationProviderV2 SSPI: the getLoginModuleConfiguration, getAssertionModuleConfiguration, getPrincipalValidator, and getIdentityAsserter methods (as described in “Implement the AuthenticationProviderV2 SSPI” on page 4-13).

Note: The bold face code in Listing 4-1 highlights the class declaration and the method signatures.

```java
package examples.security.providers.authentication.simple;
import java.util.HashMap;
import javax.security.auth.login.AppConfigurationEntry;
import javax.security.auth.login.AppConfigurationEntry.LoginModuleControlFlag;
import weblogic.management.security.ProviderMBean;
import weblogic.security.provider.PrincipalValidatorImpl;
import weblogic.security.spi.AuthenticationProviderV2;
import weblogic.security.spi.IdentityAsserterV2;
import weblogic.security.spi.PrincipalValidator;
import weblogic.security.spi.SecurityServices;
import weblogic.security.principal.WLSGroupImpl;
import weblogic.security.principal.WLSUserImpl;

public final class SimpleSampleAuthenticationProviderImpl implements AuthenticationProviderV2
{
    private String description;
    private SimpleSampleAuthenticatorDatabase database;
    private LoginModuleControlFlag controlFlag;

    public void initialize(ProviderMBean mbean, SecurityServices services)
    {
        System.out.println("SimpleSampleAuthenticationProviderImpl.initialize");
        SimpleSampleAuthenticatorMBean myMBean =
```
How to Develop a Custom Authentication Provider

```java
SimpleSampleAuthenticatorMBean mbean;
    description = myMBean.getDescription() + "\n" + myMBean.getVersion();
database = new SimpleSampleAuthenticatorDatabase(mMyBean);

    String flag = myMBean.getControlFlag();
    if (flag.equalsIgnoreCase("REQUIRED")) {
        controlFlag = LoginModuleControlFlag.REQUIRED;
    } else if (flag.equalsIgnoreCase("OPTIONAL")) {
        controlFlag = LoginModuleControlFlag.OPTIONAL;
    } else if (flag.equalsIgnoreCase("REQUISITE")) {
        controlFlag = LoginModuleControlFlag.REQUISITE;
    } else if (flag.equalsIgnoreCase("SUFFICIENT")) {
        controlFlag = LoginModuleControlFlag.SUFFICIENT;
    } else {
        throw new IllegalArgumentException("invalid flag value" + flag);
    }

public String getDescription()
{
    return description;
}

public void shutdown()
{
    System.out.println("SimpleSampleAuthenticationProviderImpl.shutdown");
}

private AppConfigurationEntry getConfiguration(HashMap options)
{
    options.put("database", database);
    return new
        AppConfigurationEntry(
            "examples.security.providers.authentication.Simple.Simple.SampleLogi
        nModuleImpl",
            controlFlag,
            options
        );
}

public AppConfigurationEntry getLoginModuleConfiguration()
{
    HashMap options = new HashMap();
    return getConfiguration(options);
}

public AppConfigurationEntry getAssertionModuleConfiguration()
{
    HashMap options = new HashMap();
    options.put("IdentityAssertion","true");
```
Listing 4-2 shows the `SampleLoginModuleImpl.java` class, which is one of two runtime classes for the sample Authentication provider. This runtime class implements the JAAS LoginModule interface (as described in “Implement the JAAS LoginModule Interface” on page 4-15), and therefore includes implementations for its `initialize`, `login`, `commit`, `abort`, and `logout` methods.

Note: The bold face code in Listing 4-2 highlights the class declaration and the method signatures.

Listing 4-2 SimpleSampleLoginModuleImpl.java

```java
package examples.security.providers.authentication.simple;

import java.io.IOException;
import java.util.Enumeration;
import java.util.Map;
import java.util.Vector;
import javax.security.auth.Subject;
import javax.security.auth.callback.Callback;
import javax.security.auth.callback.CallbackHandler;
import javax.security.auth.callback.NameCallback;
import javax.security.auth.callback.PasswordCallback;
import javax.security.auth.callback.UnsupportedCallbackException;
import javax.security.auth.login.LoginException;
import javax.security.auth.login.FailedLoginException;
import javax.security.auth.spi.LoginModule;
import weblogic.management.utils.NotFoundException;
import weblogic.security.spi.WLSGroup;
import weblogic.security.spi.WLSUser;
```
import weblogic.security.principal.WLSGroupImpl;
import weblogic.security.principal.WLSUserImpl;

final public class SimpleSampleLoginModuleImpl implements LoginModule
{
    private Subject subject;
    private CallbackHandler callbackHandler;
    private SimpleSampleAuthenticatorDatabase database;

    // Determine whether this is a login or assert identity

        throwLoginException("Authentication Failed: User " + userName + ". Password not supplied");
    }
    String passwd = new String(password);
    System.out.println(" \tpasswordHave\t= " + passwd);
    return passwd;
}
Generate an MBean Type Using the WebLogic MBeanMaker

Before you start generating an MBean type for your custom security provider, you should first:

- “Understand Why You Need an MBean Type” on page 3-11
- “Determine Which SSPI MBeans to Extend and Implement” on page 3-11
- “Understand the Basic Elements of an MBean Definition File (MDF)” on page 3-12
- “Understand the SSPI MBean Hierarchy and How It Affects the Administration Console” on page 3-15
- “Understand What the WebLogic MBeanMaker Provides” on page 3-17

When you understand this information and have made your design decisions, create the MBean type for your custom Authentication provider by following these steps:

1. “Create an MBean Definition File (MDF)” on page 4-25
2. “Use the WebLogic MBeanMaker to Generate the MBean Type” on page 4-26
3. “Use the WebLogic MBeanMaker to Create the MBean JAR File (MJF)” on page 4-30
4. “Install the MBean Type Into the WebLogic Server Environment” on page 4-30

Note: All instructions provided in this section assume that you are working in a Windows environment.

Create an MBean Definition File (MDF)

To create an MBean Definition File (MDF), follow these steps:

1. Copy the MDF for the sample Authentication provider to a text file.
   
   Note: The MDF for the sample Authentication provider is called SimpleSampleAuthenticator.xml.

2. Modify the content of the <MBeanType> and <MBeanAttribute> elements in your MDF so that they are appropriate for your custom Authentication provider.

3. Add any custom attributes and operations (that is, additional <MBeanAttribute> and <MBeanOperation> elements) to your MDF.
4. Save the file.

Note: A complete reference of MDF element syntax is available in Appendix A, “MBean Definition File (MDF) Element Syntax.”

Use the WebLogic MBeanMaker to Generate the MBean Type

Once you create your MDF, you are ready to run it through the WebLogic MBeanMaker. The WebLogic MBeanMaker is currently a command-line utility that takes as its input an MDF, and outputs some intermediate Java files, including an MBean interface, an MBean implementation, and an associated MBean information file. Together, these intermediate files form the MBean type for your custom security provider.

The instructions for generating an MBean type differ based on the design of your custom Authentication provider. Follow the instructions that are appropriate to your situation:

- “No Optional SSPI MBeans and No Custom Operations” on page 4-26
- “Optional SSPI MBeans or Custom Operations” on page 4-27

No Optional SSPI MBeans and No Custom Operations

If the MDF for your custom Authentication provider does not implement any optional SSPI MBeans and does not include any custom operations, follow these steps:

1. Create a new DOS shell.
2. Type the following command:

   ```
   java -DMDF=xmlfile -Dfiles=filesdir -DcreateStubs=true
   weblogic.management.commo.WebLogicMBeanMaker
   ```
   
   where the -DMDF flag indicates that the WebLogic MBeanMaker should translate the MDF into code, xmlFile is the MDF (the XML MBean Description File) and filesdir is the location where the WebLogic MBeanMaker will place the intermediate files for the MBean type.

   Whenever xmlfile is provided, a new set of output files is generated.

   Each time you use the -DcreateStubs=true flag, it overwrites any existing MBean implementation file.

   Note: As of version 9.0 of WebLogic Server, you can also provide a directory that contains multiple MDF’s by using the -DMDFDIR <MDF directory name> option. In prior versions of WebLogic Server, the WebLogic MBeanMaker processed only one MDF
at a time. Therefore, you had to repeat this process if you had multiple MDFs (in other words, multiple Authentication providers).

3. Proceed to “Use the WebLogic MBeanMaker to Create the MBean JAR File (MJF)” on page 4-30.

Optional SSPI MBeans or Custom Operations

If the MDF for your custom Authentication provider does implement some optional SSPI MBeans or does include custom operations, consider the following:

- Are you creating an MBean type for the first time? If so, follow these steps:
  1. Create a new DOS shell.
  2. Type the following command:

     ```
     java -DMDF=xmlfile -Dfiles=filesdir -DcreateStubs=true
     weblogic.management.commo.WebLogicMBeanMaker
     ```

     where the -DMDF flag indicates that the WebLogic MBeanMaker should translate the MDF into code, xmlFile is the MDF (the XML MBean Description File) and filesdir is the location where the WebLogic MBeanMaker will place the intermediate files for the MBean type.

     Whenever xmlfile is provided, a new set of output files is generated.

     Each time you use the -DcreateStubs=true flag, it overwrites any existing MBean implementation file.

     **Note:** As of version 9.0 of WebLogic Server, you can also provide a directory that contains multiple MDF's by using the -DMDFDIR <MDF directory name> option. In prior versions of WebLogic Server, the WebLogic MBeanMaker processed only one MDF at a time. Therefore, you had to repeat this process if you had multiple MDFs (in other words, multiple Authentication providers).

3. If you implemented optional SSPI MBeans in your MDF, follow these steps:

   a. Locate the MBean implementation file.

      The MBean implementation file generated by the WebLogic MBeanMaker is named MBeanNameImpl.java. For example, for the MDF named SampleAuthenticator, the MBean implementation file to be edited is named SampleAuthenticatorImpl.java.

   b. For each optional SSPI MBean that you implemented in your MDF, implement each method. Be sure to also provide implementations for any methods that the optional SSPI MBean inherits.
4. If you included any custom attributes/operations in your MDF, implement the methods using the method stubs.

5. Save the file.

6. Proceed to “Use the WebLogic MBeanMaker to Create the MBean JAR File (MJF)” on page 4-30.

- Are you updating an existing MBean type? If so, follow these steps:

1. Copy your existing MBean implementation file to a temporary directory so that your current method implementations are not overwritten by the WebLogic MBeanMaker.

2. Create a new DOS shell.

3. Type the following command:

   ```java
   java -DMDF=xmlfile -Dfiles=filesdir -DcreateStubs=true
   weblogic.management.commo.WebLogicMBeanMaker
   ```

   where the `-DMDF` flag indicates that the WebLogic MBeanMaker should translate the MDF into code, `xmlfile` is the MDF (the XML MBean Description File) and `filesdir` is the location where the WebLogic MBeanMaker will place the intermediate files for the MBean type.

   Whenever `xmlfile` is provided, a new set of output files is generated.

   Each time you use the `-DcreateStubs=true` flag, it overwrites any existing MBean implementation file.

   **Note:** As of version 9.0 of WebLogic Server, you can also provide a directory that contains multiple MDF's by using the `-DMDFDIR <MDF directory name>` option. In prior versions of WebLogic Server, the WebLogic MBeanMaker processed only one MDF at a time. Therefore, you had to repeat this process if you had multiple MDFs (in other words, multiple Authentication providers).

4. If you implemented optional SSPI MBeans in your MDF, follow these steps:

   a. Locate and open the MBean implementation file.

      The MBean implementation file generated by the WebLogic MBeanMaker is named `<MBeanName>Impl.java`. For example, for the MDF named `SampleAuthenticator`, the MBean implementation file to be edited is named `SampleAuthenticatorImpl.java`.

   b. Open your existing MBean implementation file (which you saved to a temporary directory in step 1).
c. Synchronize the existing MBean implementation file with the MBean implementation file generated by the WebLogic MBeanMaker.

Accomplishing this task may include, but is not limited to: copying the method implementations from your existing MBean implementation file into the newly-generated MBean implementation file (or, alternatively, adding the new methods from the newly-generated MBean implementation file to your existing MBean implementation file), and verifying that any changes to method signatures are reflected in the version of the MBean implementation file that you are going to use (for methods that exist in both MBean implementation files).

d. If you modified the MDF to implement optional SSPI MBeans that were not in the original MDF, implement each method. Be sure to also provide implementations for any methods that the optional SSPI MBean inherits.

5. If you modified the MDF to include any custom operations that were not in the original MDF, implement the methods using the method stubs.

6. Save the version of the MBean implementation file that is complete (that is, has all methods implemented).

7. Copy this MBean implementation file into the directory where the WebLogic MBeanMaker placed the intermediate files for the MBean type. You specified this as filesdir in step 3. (You will be overriding the MBean implementation file generated by the WebLogic MBeanMaker as a result of step 3.)

8. Proceed to “Use the WebLogic MBeanMaker to Create the MBean JAR File (MIF)” on page 4-30.

About the Generated MBean Interface File

The MBean interface file is the client-side API to the MBean that your runtime class or your MBean implementation will use to obtain configuration data. It is typically used in the initialize method as described in “Understand the Purpose of the “Provider” SSPIs” on page 3-3.

Because the WebLogic MBeanMaker generates MBean types from the MDF you created, the generated MBean interface file will have the name of the MDF, plus the text “MBean” appended to it. For example, the result of running the SimpleSampleAuthenticator MDF through the WebLogic MBeanMaker will yield an MBean interface file called SimpleSampleAuthenticatorMBean.java.
Use the WebLogic MBeanMaker to Create the MBean JAR File (MJF)

Once your have run your MDF through the WebLogic MBeanMaker to generate your intermediate files, and you have edited the MBean implementation file to supply implementations for the appropriate methods within it, you need to package the MBean files and the runtime classes for the custom Authentication provider into an MBean JAR File (MJF). The WebLogic MBeanMaker also automates this process.

To create an MJF for your custom Authentication provider, follow these steps:

1. Create a new DOS shell.
2. Type the following command:

   ```
   java -DMJF=jarfile -Dfiles=filesdir
   weblogic.management.commo.WebLogicMBeanMaker
   ```

   where the -DMJF flag indicates that the WebLogic MBeanMaker should build a JAR file containing the new MBean types, jarfile is the name for the MJF and filesdir is the location where the WebLogic MBeanMaker looks for the files to JAR into the MJF.

   Compilation occurs at this point, so errors are possible. If jarfile is provided, and no errors occur, an MJF is created with the specified name.

   **Notes:** When you create a JAR file for a custom security provider, a set of XML binding classes and a schema are also generated. You can choose a namespace to associate with that schema. Doing so avoids the possibility that your custom classes will conflict with those provided by Oracle. The default for the namespace is vendor. You can change this default by passing the -targetNamespace argument to the WebLogicMBeanMaker or the associated WLMBeanMaker ant task.

   If you want to update an existing MJF, simply delete the MJF and regenerate it. The WebLogic MBeanMaker also has a -DIncludeSource option, which controls whether source files are included into the resulting MJF. Source files include both the generated source and the MDF itself. The default is false. This option is ignored when -DMJF is not used.

   The resulting MJF can be installed into your WebLogic Server environment, or distributed to your customers for installation into their WebLogic Server environments.

Install the MBean Type Into the WebLogic Server Environment

To install an MBean type into the WebLogic Server environment, copy the MJF into the WL_HOME/server/lib/mbeantypes directory, where WL_HOME is the top-level installation...
directory for WebLogic Server. This “deploys” your custom Authentication provider—that is, it makes the custom Authentication provider manageable from the WebLogic Server Administration Console.

**Note:** \( WL_{\text{HOME}}\server\lib\mbeantypes \) is the default directory for installing MBean types. (Beginning with 9.0, security providers can be loaded from \( ...\domaindir\lib\mbeantypes \) as well.) However, if you want WebLogic Server to look for MBean types in additional directories, use the \(-D\text{weblogic.alternateTypesDirectory}=<\text{dir}>\) command-line flag when starting your server, where \(<\text{dir}>\) is a comma-separated list of directory names. When you use this flag, WebLogic Server will always load MBean types from \( WL_{\text{HOME}}\server\lib\mbeantypes \) first, then will look in the additional directories and load all valid archives present in those directories (regardless of their extension). For example, if \(-D\text{weblogic.alternateTypesDirectory} = \text{dirX}, \text{dirY} \), WebLogic Server will first load MBean types from \( WL_{\text{HOME}}\server\lib\mbeantypes \) first, then any valid archives present in \text{dirX} and \text{dirY}. If you instruct WebLogic Server to look in additional directories for MBean types and are using the Java Security Manager, you must also update the \text{weblogic.policy} file to grant appropriate permissions for the MBean type (and thus, the custom security provider). For more information, see "Using the Java Security Manager to Protect WebLogic Resources" in Programming WebLogic Security.

You can create instances of the MBean type by configuring your custom Authentication provider (see “Configure the Custom Authentication Provider Using the Administration Console” on page 4-31), and then use those MBean instances from a GUI, from other Java code, or from APIs. For example, you can use the WebLogic Server Administration Console to get and set attributes and invoke operations, or you can develop other Java objects that instantiate MBeans and automatically respond to information that the MBeans supply. We recommend that you back up these MBean instances.

### Configure the Custom Authentication Provider Using the Administration Console

Configuring a custom Authentication provider means that you are adding the custom Authentication provider to your security realm, where it can be accessed by applications requiring authentication services.

Configuring custom security providers is an administrative task, but it is a task that may also be performed by developers of custom security providers. This section contains information that is important for the person configuring your custom Authentication providers:
Managing User Lockouts

As part of using a custom Authentication provider, you need to consider how you will configure and manage user lockouts. You have two choices for doing this:

- “Rely on the Realm-Wide User Lockout Manager” on page 4-32
- “Implement Your Own User Lockout Manager” on page 4-32

Rely on the Realm-Wide User Lockout Manager

The WebLogic Security Framework provides a realm-wide User Lockout Manager that works directly with the WebLogic Security Framework to manage user lockouts.

Note: Both the realm-wide User Lockout Manager and a WebLogic Server 6.1 PasswordPolicyMBean (at the Realm Adapter level) may be active. For more information, see the WebLogic Server 6.1 API Reference Javadoc for the PasswordPolicyMBean interface.

If you decide to rely on the realm-wide User Lockout Manager, then all you must do to make it work with your custom Authentication provider is use the WebLogic Server Administration Console to:

1. Ensure that User Lockout is enabled. (It should be enabled by default.)
2. Modify any parameters for User Lockout (as necessary).

Notes: Changes to the User Lockout Manager do not take effect until you reboot the server. Instructions for using the Administration Console to perform these tasks are described in “Protecting User Accounts” in Securing WebLogic Server.

Implement Your Own User Lockout Manager

If you decide to implement your own User Lockout Manager as part of your custom Authentication provider, then you must:
1. Disable the realm-wide User Lockout Manager to prevent double lockouts from occurring. (When you create a new security realm using the WebLogic Server Administration Console, a User Lockout Manager is always created.) Instructions for performing this task are provided in “Protecting User Accounts” in Securing WebLogic Server.

2. Because you cannot borrow anything from the WebLogic Security Framework’s realm-wide implementation, you must also perform the following tasks:
   
a. Provide the implementation for your User Lockout Manager. Note that there is no security service provider interface (SSPI) provided for User Lockout Managers.

b. Modify an MBean by which the User Lockout Manager can be managed.

c. If you plan to manage your User Lockout Manager from the console, incorporate the User Lockout Manager into the Administration Console using console extensions. For more information, see Extending the Administration Console.

Specifying the Order of Authentication Providers
As described in “LoginModules and Multipart Authentication” on page 4-5, the order in which you configure multiple Authentication providers (and thus LoginModules) affects the outcome of the authentication process.

You can configure Authentication providers in any order. However, if you need to reorder your configured Authentication providers, follow the steps described in “Changing the Order of Authentication Providers” in Securing WebLogic Server.
Identity Assertion Providers

An Identity Assertion provider is a specific form of Authentication provider that allows users or system processes to assert their identity using tokens (in other words, perimeter authentication). Identity Assertion providers enable perimeter authentication and support single sign-on. You can use an Identity Assertion provider in place of an Authentication provider if you create a LoginModule for the Identity Assertion provider, or in addition to an Authentication provider if you want to use the Authentication provider’s LoginModule.

If you want to allow the Identity Assertion provider to be configured separately from the Authentication provider, write two providers. If your Identity Assertion provider and Authentication provider cannot work independently, then write one provider.

The following sections describe Identity Assertion provider concepts and functionality, and provide step-by-step instructions for developing a custom Identity Assertion provider:

- “Identity Assertion Concepts” on page 5-1
- “The Identity Assertion Process” on page 5-7
- “Do You Need to Develop a Custom Identity Assertion Provider?” on page 5-8
- “How to Develop a Custom Identity Assertion Provider” on page 5-10

Identity Assertion Concepts

Before you develop an Identity Assertion provider, you need to understand the following concepts:
Identity Assertion Providers

- “Identity Assertion Providers and LoginModules” on page 5-2
- “Identity Assertion and Tokens” on page 5-3
- “Passing Tokens for Perimeter Authentication” on page 5-6
- “Common Secure Interoperability Version 2 (CSlv2)” on page 5-6

Identity Assertion Providers and LoginModules

When used with a LoginModule, Identity Assertion providers support single sign-on. For example, an Identity Assertion provider can generate a token from a digital certificate, and that token can be passed around the system so that users are not asked to sign on more than once.

The LoginModule that an Identity Assertion provider uses can be:

- Part of a custom Authentication provider you develop. For more information, see Chapter 4, “Authentication Providers.”
- Part of the WebLogic Authentication provider Oracle developed and packaged with WebLogic Server. For more information, see “Do You Need to Develop a Custom Authentication Provider?” on page 4-11.
- Part of a third-party security vendor’s Authentication provider.

Unlike in a simple authentication situation (described in “The Authentication Process” on page 4-10), the LoginModules that Identity Assertion providers use do not verify proof material such as usernames and passwords; they simply verify that the user exists.

The LoginModules in this configuration must:

- Populate the Subject with required Principals, such as those of type WLSGroup.
- Must trust that the user has submitted sufficient proof to login and not require a password or some other proof material.

You must implement the `AuthenticationProviderV2.getAssertionModuleConfiguration` method in your custom Authentication provider, as described in “Implement the AuthenticationProviderV2 SSPI” on page 5-11. This method is called for identity assertion, such as when an X.509 certificate is being used, and to process the run-as tag in deployment descriptors. Other single signon strategies use it as well.

**Note:** For more information about LoginModules, see “LoginModules” on page 4-4.
Identity Assertion and Tokens

You develop Identity Assertion providers to support the specific types of tokens that you will be using to assert the identities of users or system processes. You can develop an Identity Assertion provider to support multiple token types, but you or an administrator configure the Identity Assertion provider so that it validates only one “active” token type. While you can have multiple Identity Assertion providers in a security realm with the ability to validate the same token type, only one Identity Assertion provider can actually perform this validation.

Note: “Supporting” token types means that the Identity Assertion provider’s runtime class (that is, the IdentityAsserter SSPI implementation) can validate the token type its assertIdentity method. For more information, see “Implement the IdentityAsserter V2 SSPI” on page 5-12.

The following sections will help you work with new token types:

- “How to Create New Token Types” on page 5-3
- “How to Make New Token Types Available for Identity Assertion Provider Configurations” on page 5-4

How to Create New Token Types

If you develop a custom Identity Assertion provider, you can also create new token types. A token type is simply a piece of data represented as a string. The token types you create and use are completely up to you. The token types currently defined for the WebLogic Identity Assertion provider include, but are not limited to: X.509,CSI.PrincipalName, CSI.ITTAanonymous, CSI.X509CertChain, CSI.DistinguishedName, AUTHORIZATION_NEGOTIATE, SAML.Assertion64, SAML.Assertion.DOM, SAML.Assertion, and WWW-AUTHENTICATE_NEGOTIATE.

To create new token types, you create a new Java file and declare any new token types as variables of type String, as shown in Listing 5-1. The PerimeterIdentity AsserterTokenTypes.java file defines the names of the token types Test 1, Test 2, and Test 3 as strings.

Listing 5-1  PerimeterIdentity Asserter TokenTypes.java

```java
package sample.security.providers.authentication.perimeterATN;

public class PerimeterIdentity AsserterTokenTypes {
```
public final static String TEST1_TYPE = "Test 1";
public final static String TEST2_TYPE = "Test 2";
public final static String TEST3_TYPE = "Test 3";
}

Note: If you are defining only one new token type, you can also do it right in the Identity Assertion provider’s runtime class, as shown in Listing 5-4, “SampleIdentityAsserterProviderImpl.java,” on page 5-14.

How to Make New Token Types Available for Identity Assertion Provider Configurations

When you or an administrator configure a custom Identity Assertion provider (see “Configure the Custom Identity Assertion Provider Using the Administration Console” on page 5-24), the Supported Types field displays a list of the token types that the Identity Assertion provider supports. You enter one of the supported types in the Active Types field, as shown in Figure 5-1.

Figure 5-1 Configuring the Sample Identity Assertion Provider

The content for the Supported Types field is obtained from the SupportedTypes attribute of the MBean Definition File (MDF), which you use to generate your custom Identity Assertion provider’s MBean type. An example from the sample Identity Assertion provider is shown in Listing 5-2. (For more information about MDFs and MBean types, see “Generate an MBean Type Using the WebLogic MBeanMaker” on page 5-17.)

Listing 5-2 SampleIdentityAsserter MDF: SupportedTypes Attribute

```xml
<MBeanType>
   ...
   <MBeanAttribute
      Name = "SupportedTypes"
```
Similarly, the content for the Active Types field is obtained from the `ActiveTypes` attribute of the MBean Definition File (MDF). You or an administrator can default the `ActiveTypes` attribute in the MDF so that it does not have to be set manually with the WebLogic Server Administration Console. An example from the sample Identity Assertion provider is shown in Listing 5-3.

Listing 5-3  SampleIdentityAsserter MDF: ActiveTypes Attribute with Default

```xml
<MBeanAttribute
  Name= "ActiveTypes"
  Type= "java.lang.String[]"
  Default = "new String[] { "SamplePerimeterAtnToken" }"
/>
...  
</MBeanType>
```

While defaulting the `ActiveTypes` attribute is convenient, you should only do this if no other Identity Assertion provider will ever validate that token type. Otherwise, it would be easy to configure an invalid security realm (where more than one Identity Assertion provider attempts to validate the same token type). Best practice dictates that all MDFs for Identity Assertion providers turn off the token type by default; then an administrator can manually make the token type active by configuring the Identity Assertion provider that validates it.

**Note:** If an Identity Assertion provider is not developed and configured to validate and accept a token type, the authentication process will fail. For more information about configuring an Identity Assertion provider, see “Configure the Custom Identity Assertion Provider Using the Administration Console” on page 5-24.
Identity Assertion Providers

Passing Tokens for Perimeter Authentication

An Identity Assertion provider can pass tokens from Java clients to servlets for the purpose of perimeter authentication. Tokens can be passed using HTTP headers, cookies, SSL certificates, or other mechanisms. For example, a string that is base 64-encoded (which enables the sending of binary data) can be sent to a servlet through an HTTP header. The value of this string can be a username, or some other string representation of a user’s identity. The Identity Assertion provider used for perimeter authentication can then take that string and extract the username.

If the token is passed through HTTP headers or cookies, the token is equal to the header or cookie name, and the resource container passes the token to the part of the WebLogic Security Framework that handles authentication. The WebLogic Security Framework then passes the token to the Identity Assertion provider, unchanged.

WebLogic Server is designed to extend the single sign-on concept all the way to the perimeter through support for identity assertion. Identity assertion allows WebLogic Server to use the authentication mechanism provided by perimeter authentication schemes such as the Security Assertion Markup Language (SAML), the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO), or enhancements to protocols such as Common Secure Interoperability (CSI) v2 to achieve this functionality.

Common Secure Interoperability Version 2 (CSIv2)

WebLogic Server provides support for an Enterprise JavaBean (EJB) interoperability protocol based on Internet Inter-ORB (IIOP) (GIOP version 1.2) and the CORBA Common Secure Interoperability version 2 (CSIv2) specification. CSIV2 support in WebLogic Server:

- Interoperates with the Java 2 Enterprise Edition (J2EE) version 1.4 reference implementation.
- Allows WebLogic Server IIOP clients to specify a username and password in the same manner as T3 clients.
- Supports Generic Security Services Application Programming Interface (GSSAPI) initial context tokens. For this release, only usernames and passwords and GSSUP (Generic Security Services Username Password) tokens are supported.

Note: The CSIV2 implementation in WebLogic Server passed Java 2 Enterprise Edition (J2EE) Compatibility Test Suite (CTS) conformance testing.

The external interface to the CSIV2 implementation is a JAAS LoginModule that retrieves the username and password of the CORBA object. The JAAS LoginModule can be used in a
WebLogic Java client or in a WebLogic Server instance that acts as a client to another J2EE application server. The JAAS LoginModule for the CSIv2 support is called UsernamePasswordLoginModule, and is located in the weblogic.security.auth.login package.

CSIv2 works in the following manner:

1. When creating a Security Extensions to Interoperable Object Reference (IOR), WebLogic Server adds a tagged component identifying the security mechanisms that the CORBA object supports. This tagged component includes transport information, client authentication information, and identity token/authorization token information.

2. The client evaluates the security mechanisms in the IOR and selects the mechanism that supports the options required by the server.

3. The client uses the SAS protocol to establish a security context with WebLogic Server. The SAS protocol defines messages contained within the service context of requests and replies. A context can be stateful or stateless.

For information about using CSIv2, see “Common Secure Interoperability Version 2” in Understanding WebLogic Security. For more information about JAAS LoginModules, see “LoginModules” on page 4-4.

The Identity Assertion Process

In perimeter authentication, a system outside of WebLogic Server establishes trust via tokens (as opposed to the type of authentication described in “The Authentication Process” on page 4-10, where WebLogic Server establishes trust via usernames and passwords). Identity Assertion providers are used as part of perimeter authentication process, which works as follows (see Figure 5-2):

1. A token from outside of WebLogic Server is passed to an Identity Assertion provider that is responsible for validating tokens of that type and that is configured as “active”.

2. If the token is successfully validated, the Identity Assertion provider maps the token to a WebLogic Server username, and sends that username back to WebLogic Server, which then continues the authentication process as described in “The Authentication Process” on page 4-10. Specifically, the username is sent via a Java Authentication and Authorization Service (JAAS) CallbackHandler and passed to each configured Authentication provider’s LoginModule, so that the LoginModule can populate the subject with the appropriate principals.
Identity Assertion Providers

Figure 5-2  Perimeter Authentication

As Figure 5-2 also shows, perimeter authentication requires the same components as the authentication process described in “The Authentication Process” on page 4-10, but also adds an Identity Assertion provider.

Do You Need to Develop a Custom Identity Assertion Provider?

The WebLogic Identity Assertion providers support certificate authentication using X509 certificates, SPNEGO tokens, SAML assertion tokens, and CORBA Common Secure Interoperability version 2 (CSIv2) identity assertion.

The LDAP X509 Identity Assertion provider receives an X509 certificate, looks up the LDAP object for the user associated with that certificate, ensures that the certificate in the LDAP object matches the presented certificate, and then retrieves the name of the user from the LDAP object for the purpose of authentication.

The Negotiate Identity Assertion provider is used for SSO with Microsoft clients that support the SPNEGO protocol. The Negotiate Identity Assertion provider decodes SPNEGO tokens to obtain Kerberos tokens, validates the Kerberos tokens, and maps Kerberos tokens to WebLogic users. The Negotiate Identity Assertion provider utilizes the Java Generic Security Service (GSS) Application Programming Interface (API) to accept the GSS security context via Kerberos. The Negotiate Identity Assertion provider is for Windows NT Integrated Login.

The SAML Identity Assertion provider handles SAML assertion tokens when WebLogic Server acts as a SAML destination site. The SAML Identity Assertion provider consumes and validates SAML assertion tokens and determines if the assertion is to be trusted (using either the proof
Do You Need to Develop a Custom Identity Assertion Provider?

material available in the SOAP message, the client certificate, or some other configuration indicator).

The default WebLogic Identity Assertion provider validates the token type, then maps X509 digital certificates and X501 distinguished names to WebLogic usernames. It also specifies a list of trusted client principals to use for CSIv2 identity assertion. The wildcard character (*) can be used to specify that all principals are trusted. If a client is not listed as a trusted client principal, the CSIv2 identity assertion fails and the invoke is rejected.

**Note:** To use the WebLogic Identity Assertion provider for X.501 and X.509 certificates, you have the option of using the default user name mapper that is supplied with the WebLogic Server product (weblogic.security.providers.authentication.DefaultUserNameMapperImpl) or providing your own implementation of the weblogic.security.providers.authentication.UserNameMapper interface. This interface maps a X.509 certificate to a WebLogic Server user name according to whatever scheme is appropriate for your needs. You can also use this interface to map from an X.501 distinguished name to a user name. You specify your implementation of this interface when you use the Administration Console to configure an Identity Assertion provider.

The WebLogic Identity Assertion provider supports the following token types:

- **AU>Type**—for a WebLogic AuthenticatedUser used as a token.
- **X509_TYPE**—for an X509 client certificate used as a token.
- **CSI_PRINCIPAL_TYPE**—for a CSIv2 principal name identity used as a token.
- **CSI_ANONYMOUS_TYPE**—for a CSIv2 anonymous identity used as a token.
- **CSI_X509_CERTCHAIN_TYPE**—for a CSIv2 X509 certificate chain identity used as a token.
- **CSI_DISTINGUISHED_NAME_TYPE**—for a CSIv2 distinguished name identity used as a token.
- **AUTHORIZATION_NEGOTIATE**—for a SPNEGO internal token used as a token.
- **SAML_ASSERTION_B64_TYPE**—for a Base64 encoded SAML assertion used as a token.
- **SAML_ASSERTION_DOM_TYPE**—for a SAML DOM element used as a token.
- **SAML_ASSERTION_TYPE**—for a SAML string XML form used as a token.
- **SAML_SSO_CREDENTIAL_TYPE**—for a SAML string consisting of the TARGET parameter concatenated with the assertion itself and used as a token.
How to Develop a Custom Identity Assertion Provider

If the WebLogic Identity Assertion provider does not meet your needs, you can develop a custom Identity Assertion provider by following these steps:

1. “Create Runtime Classes Using the Appropriate SSPIs” on page 5-10
2. “Generate an MBean Type Using the WebLogic MBeanMaker” on page 5-17
3. “Configure the Custom Identity Assertion Provider Using the Administration Console” on page 5-24
4. Consider whether you need to implement Challenge Identity Assertion, as described in “Challenge Identity Assertion” on page 5-24.

Create Runtime Classes Using the Appropriate SSPIs

Before you start creating runtime classes, you should first:

- “Understand the Purpose of the “Provider” SSPIs” on page 3-3
- “Understand the SSPI Hierarchy and Determine Whether You Will Create One or Two Runtime Classes” on page 3-7

When you understand this information and have made your design decisions, create the runtime classes for your custom Identity Assertion provider by following these steps:

- “Implement the AuthenticationProviderV2 SSPI” on page 5-11
- “Implement the IdentityAsserterV2 SSPI” on page 5-12

Note: If you want to create a separate LoginModule for your custom Identity Assertion provider (that is, not use the LoginModule from your Authentication provider), you also need to implement the JAAS LoginModule interface, as described in “Implement the JAAS LoginModule Interface” on page 4-15.
For an example of how to create a runtime class for a custom Identity Assertion provider, see “Example: Creating the Runtime Class for the Sample Identity Assertion Provider” on page 5-13.

**Implement the AuthenticationProviderV2 SSPI**

**Note:** The AuthenticationProvider SSPI is deprecated in this release of WebLogic Server. Use the AuthenticationProviderV2 SSPI instead.

To implement the AuthenticationProviderV2 SSPI, provide implementations for the methods described in “Understand the Purpose of the “Provider” SSPIs” on page 3-3 and the following methods:

`getLoginModuleConfiguration`

```java
public AppConfigurationEntry getLoginModuleConfiguration()
```

The `getLoginModuleConfiguration` method obtains information about the Authentication provider’s associated LoginModule, which is returned as an `AppConfigurationEntry`. The `AppConfigurationEntry` is a Java Authentication and Authorization Service (JAAS) class that contains the classname of the LoginModule; the LoginModule’s control flag (which was passed in via the Authentication provider’s associated MBean); and a configuration options map for the LoginModule (which allows other configuration information to be passed into the LoginModule).

For more information about the `AppConfigurationEntry` class (located in the `javax.security.auth.login` package) and the control flag options for LoginModules, see the *Java 2 Enterprise Edition, v1.4.2 API Specification Javadoc* for the `AppConfigurationEntry` class and the `Configuration` class. For more information about LoginModules, see “LoginModules” on page 4-4. For more information about security providers and MBeans, see “Understand Why You Need an MBean Type” on page 3-11.

`getAssertionModuleConfiguration`

```java
public AppConfigurationEntry getAssertionModuleConfiguration()
```

The `getAssertionModuleConfiguration` method obtains information about an Identity Assertion provider’s associated LoginModule, which is returned as an `AppConfigurationEntry`. The `AppConfigurationEntry` is a JAAS class that contains the classname of the LoginModule; the LoginModule’s control flag (which was passed in via the Identity Assertion provider’s associated MBean); and a configuration options map for the LoginModule (which allows other configuration information to be passed into the LoginModule).
The LoginModules in this configuration must populate the Subject with required Principals, such as those of type WLSGroup, and must trust that the user has submitted sufficient proof to login and not require a password or some other proof material.

**Notes:** The `assertIdentity()` method of an Identity Assertion provider is called every time identity assertion occurs, but the LoginModules may not be called if the Subject is cached. The `weblogic.security.identityAssertionTTL` flag can be used to affect this behavior (for example, to modify the default TTL of 5 minutes or to disable the cache by setting the flag to -1).

It is the responsibility of the Identity Assertion provider to ensure not just that the token is valid, but also that the user is still valid (for example, the user has not been deleted).

#### `getPrincipalValidator`

```java
public PrincipalValidator getPrincipalValidator()
```

The `getPrincipalValidator` method obtains a reference to the Principal Validation provider’s runtime class (that is, the `PrincipalValidator` SSPI implementation). For more information, see Chapter 6, “Principal Validation Providers.”

#### `getIdentityAsserter`

```java
public IdentityAsserterV2 getIdentityAsserter()
```

The `getIdentityAsserter` method obtains a reference to the Identity Assertion provider’s runtime class (that is, the `IdentityAsserterV2` SSPI implementation). For more information, see “Implement the IdentityAsserterV2 SSPI” on page 5-12.

**Note:** When the LoginModule used for the Identity Assertion provider is the same as that used for an existing Authentication provider, implementations for the methods in the `AuthenticationProviderV2` SSPI (excluding the `getIdentityAsserter` method) for Identity Assertion providers can just return `null`. An example of this is shown in Listing 5-4, “SampleIdentityAsserterProviderImpl.java,” on page 5-14.

For more information about the `AuthenticationProvider` SSPI and the methods described above, see the *WebLogic Server API Reference Javadoc*.

### Implement the IdentityAsserterV2 SSPI

**Note:** The IdentityAsserterV2 SSPI includes additional token types and a `handler` parameter to the `assertIdentity` method that can optionally be used to obtain additional information when asserting the identity. Although the IdentityAsserter SSPI is still supported, you should consider using the IdentityAsserterV2 SSPI instead.

To implement the IdentityAsserterV2 SSPI, provide implementations for the following method:
assertIdentity

```java
public CallbackHandler assertIdentity(String type, Object token,
        ContextHandler handler) throws IdentityAssertionException;
```

The `assertIdentity` method asserts an identity based on the token identity information that is supplied. In other words, the purpose of this method is to validate any tokens that are not currently trusted against trusted client principals. The `type` parameter represents the token type to be used for the identity assertion. Note that identity assertion types are case **insensitive**. The `token` parameter contains the actual identity information. The `handler` parameter is a `ContextHandler` object that can optionally be used to obtain additional information that may be used in asserting the identity. The `CallbackHandler` returned from the `assertIdentity` method is passed to all configured Authentication providers’ LoginModules to perform principal mapping, and should contain the asserted username. If the `CallbackHandler` is `null`, this signifies that the anonymous user should be used.

A `CallbackHandler` is a highly-flexible JAAS standard that allows a variable number of arguments to be passed as complex objects to a method. For more information about `CallbackHandlers`, see the Java 2 Enterprise Edition, v1.4.1 API Specification Javadoc for the `CallbackHandler` interface.

**Notes:** The `assertIdentity()` method of an Identity Assertion provider is called every time identity assertion occurs, but the LoginModules may not be called if the Subject is cached. The `-Dweblogic.security.identityAssertionTTL` flag can be used to affect this behavior (for example, to modify the default TTL of 5 minutes or to disable the cache by setting the flag to -1).

It is the responsibility of the Identity Assertion provider to ensure not just that the token is valid, but also that the user is still valid (for example, the user has not been deleted).

For more information about the `IdentityAsserterV2` SSPI and the method described above, see the WebLogic Server API Reference Javadoc.

**Example: Creating the Runtime Class for the Sample Identity Assertion Provider**

Listing 5-4 shows the `SampleIdentityAsserterProviderImpl.java` class, which is the runtime class for the sample Identity Assertion provider. This runtime class includes implementations for:
Identity Assertion Providers

- The three methods inherited from the `SecurityProvider` interface: `initialize`, `getDescription`, and `shutdown` (as described in “Understand the Purpose of the “Provider” SSPIs” on page 3-3.)

- The four methods in the `AuthenticationProviderV2` SSPI: the `getLoginModuleConfiguration`, `getAssertionModuleConfiguration`, `getPrincipalValidator`, and `getIdentityAsserter` methods (as described in “Implement the AuthenticationProviderV2 SSPI” on page 5-11.

- The method in the `IdentityAsserterV2` SSPI: the `assertIdentity` method (described in “Implement the IdentityAsserterV2 SSPI” on page 5-12).

**Note:** The bold face code in Listing 5-4 highlights the class declaration and the method signatures.

**Listing 5-4 SampleIdentityAsserterProviderImpl.java**

```java
package examples.security.providers.identityassertion.simple;
import javax.security.auth.callback.CallbackHandler;
import javax.security.auth.login.AppConfigurationEntry;
import weblogic.management.security.ProviderMBean;
import weblogic.security.service.ContextHandler;
import weblogic.security.spi.AuthenticationProviderV2;
import weblogic.security.spi.IdentityAsserterV2;
import weblogic.security.spi.IdentityAssertionException;
import weblogic.security.spi.PrincipalValidator;
import weblogic.security.spi.SecurityServices;

public final class SimpleSampleIdentityAsserterProviderImpl implements
    AuthenticationProviderV2, IdentityAsserterV2 {
    final static private String TOKEN_TYPE = "SamplePerimeterAttnToken";
    final static private String TOKEN_PREFIX = "username=";

    private String description;

    public void initialize(ProviderMBean mbean, SecurityServices services)
    {
        System.out.println("SimpleSampleIdentityAsserterProviderImpl.initialize";
        SimpleSampleIdentityAsserterMBean myMBean = (SimpleSampleIdentityAsserterMBean)mbean;
        description = myMBean.getDescription() + "\n" + myMBean.getVersion();
    }
```
public String getDescription()
{
    return description;
}

public void shutdown()
{
    System.out.println("SimpleSampleIdentityAsserterProviderImpl.shutdown");
}

public IdentityAsserterV2 getIdentityAsserter()
{
    return this;
}

public CallbackHandler assertIdentity(String type, Object token,
ContextHandler context) throws IdentityAssertionException
{
    System.out.println("SimpleSampleIdentityAsserterProviderImpl.assertIdentity");
    System.out.println("\ttType\t= " + type);
    System.out.println("\ttToken\t= " + token);

    if (!TOKEN_TYPE.equals(type)) {
        String error = "SimpleSampleIdentityAsserter received unknown token type \\
        + type + "," + " Expected " + TOKEN_TYPE;
        System.out.println("\tError: " + error);
        throw new IdentityAssertionException(error);
    }

    if (!(token instanceof byte[])) {
        String error = "SimpleSampleIdentityAsserter received unknown token class \\
        + token.getClass() + "," + " Expected a byte[].";
        System.out.println("\tError: " + error);
        throw new IdentityAssertionException(error);
    }

    byte[] tokenBytes = (byte[])token;
    if (tokenBytes == null || tokenBytes.length < 1) {
        String error = "SimpleSampleIdentityAsserter received empty token byte array";
        System.out.println("\tError: " + error);
        throw new IdentityAssertionException(error);
    }

    String tokenStr = new String(tokenBytes);

    // Additional code here...
if (!(tokenStr.startsWith(TOKEN_PREFIX))) {
    String error = "SimpleSampleIdentityAsserter received unknown token string \n" + type + "." + " Expected "+ TOKEN_PREFIX + "username";
    System.out.println("\tError: " + error);
    throw new IdentityAssertionException(error);
}
String userName = tokenStr.substring(TOKEN_PREFIX.length());
System.out.println("\tuserName\t= " + userName);
return new SimpleSampleCallbackHandlerImpl(userName);

public AppConfigurationEntry getLoginModuleConfiguration()
{
    return null;
}

public AppConfigurationEntry getAssertionModuleConfiguration()
{
    return null;
}

public PrincipalValidator getPrincipalValidator()
{
    return null;
}

Listing 5-5 shows the sample CallbackHandler implementation that is used along with the SampleIdentityAssesterProviderImpl.java runtime class. This CallbackHandler implementation is used to send the username back to an Authentication provider’s LoginModule.

Listing 5-5  SampleCallbackHandlerImpl.java

package examples.security.providers.identityassertion.simple;
import javax.security.auth.callback.Callback;
import javax.security.auth.callback.NameCallback;
import javax.security.auth.callback.UnsupportedCallbackException;
How to Develop a Custom Identity Assertion Provider

/*package*/ class SimpleSimpleSampleCallbackHandler implements CallbackHandler
{
    private String userName;
    /*package*/ SimpleSampleCallbackHandlerImpl(String user)
    {
        userName = user;
    }
    public void handle(Callback[] callbacks) throws UnsupportedCallbackException
    {
        for (int i = 0; i < callbacks.length; i++) {
            Callback callback = callbacks[i];
            if (!(callback instanceof NameCallback)) {
                throw new UnsupportedCallbackException(callback, "Unrecognized Callback");
            }
            NameCallback nameCallback = (NameCallback)callback;
            nameCallback.setName(userName);
        }
    }
}

Generate an MBean Type Using the WebLogic MBeanMaker

Before you start generating an MBean type for your custom security provider, you should first:

- “Understand Why You Need an MBean Type” on page 3-11
- “Determine Which SSPI MBeans to Extend and Implement” on page 3-11
- “Understand the Basic Elements of an MBean Definition File (MDF)” on page 3-12
- “Understand the SSPI MBean Hierarchy and How It Affects the Administration Console” on page 3-15
- “Understand What the WebLogic MBeanMaker Provides” on page 3-17

When you understand this information and have made your design decisions, create the MBean type for your custom Identity Assertion provider by following these steps:

1. “Create an MBean Definition File (MDF)” on page 5-18
2. “Use the WebLogic MBeanMaker to Generate the MBean Type” on page 5-18
3. “Use the WebLogic MBeanMaker to Create the MBean JAR File (MJF)” on page 5-22

4. “Install the MBean Type Into the WebLogic Server Environment” on page 5-23

Notes: All instructions provided in this section assume that you are working in a Windows environment.

Create an MBean Definition File (MDF)

To create an MBean Definition File (MDF), follow these steps:

1. Copy the MDF for the sample Identity Assertion provider to a text file.
   Note: The MDF for the sample Identity Assertion provider is called SampleIdentityAsserter.xml.

2. Modify the content of the <MBeanType> and <MBeanAttribute> elements in your MDF so that they are appropriate for your custom Identity Assertion provider. For example, consider the following fragment to set the Base64DecodingRequired attribute to false:

   ```xml
   <MBeanAttribute
      Name = "Base64DecodingRequired"
      Type = "boolean"
      Writeable = "false"
      Default = "false"
      Description = "See MyIdentityAsserter-doc.xml."
   />
   ```

3. Add any custom attributes and operations (that is, additional <MBeanAttribute> and <MBeanOperation> elements) to your MDF.

4. Save the file.

Note: A complete reference of MDF element syntax is available in Appendix A, “MBean Definition File (MDF) Element Syntax.”

Use the WebLogic MBeanMaker to Generate the MBean Type

Once you create your MDF, you are ready to run it through the WebLogic MBeanMaker. The WebLogic MBeanMaker is currently a command-line utility that takes as its input an MDF, and outputs some intermediate Java files, including an MBean interface, an MBean implementation, and an associated MBean information file. Together, these intermediate files form the MBean type for your custom security provider.
The instructions for generating an MBean type differ based on the design of your custom Identity Assertion provider. Follow the instructions that are appropriate to your situation:

- “No Optional SSPI MBeans and No Custom Operations” on page 5-19
- “Optional SSPI MBeans or Custom Operations” on page 5-19

**No Optional SSPI MBeans and No Custom Operations**
If the MDF for your custom Identity Assertion provider does not implement any optional SSPI MBeans and does not include any custom operations, follow these steps:

1. Create a new DOS shell.
2. Type the following command:

   ```java
   java -DMDF=xmlfile -Dfiles=filesdir -DcreateStubs=true
   weblogic.management.commo.WebLogicMBeanMaker
   ```

   where the `-DMDF` flag indicates that the WebLogic MBeanMaker should translate the MDF into code, `xmlFile` is the MDF (the XML MBean Description File) and `filesdir` is the location where the WebLogic MBeanMaker will place the intermediate files for the MBean type.

   Whenever `xmlfile` is provided, a new set of output files is generated.

   Each time you use the `-DcreateStubs=true` flag, it overwrites any existing MBean implementation file.

   **Note:** As of version 9.0 of WebLogic Server, you can also provide a directory that contains multiple MDF's by using the `-DMDFDIR <MDF directory name>` option. In prior versions of WebLogic Server, the WebLogic MBeanMaker processed only one MDF at a time. Therefore, you had to repeat this process if you had multiple MDFs (in other words, multiple Identity Assertion providers).

3. Proceed to “Use the WebLogic MBeanMaker to Create the MBean JAR File (MJF)” on page 5-22.

**Optional SSPI MBeans or Custom Operations**
If the MDF for your custom Identity Assertion provider does implement some optional SSPI MBeans or does include custom operations, consider the following:

- Are you creating an MBean type for the first time? If so, follow these steps:
  1. Create a new DOS shell.
2. Type the following command:

```
java -DMDF=xmlfile -Dfiles=filesdir -DcreateStubs=true
weblogic.management.commo.WebLogicMBeanMaker
```

where the `-DMDF` flag indicates that the WebLogic MBeanMaker should translate the MDF into code, `xmlfile` is the MDF (the XML MBean Description File) and `filesdir` is the location where the WebLogic MBeanMaker will place the intermediate files for the MBean type.

Whenever `xmlfile` is provided, a new set of output files is generated.

Each time you use the `-DcreateStubs=true` flag, it overwrites any existing MBean implementation file.

**Note:** As of version 9.0 of WebLogic Server, you can also provide a directory that contains multiple MDF's by using the `-DMDFDIR <MDF directory name>` option. In prior versions of WebLogic Server, the WebLogic MBeanMaker processed only one MDF at a time. Therefore, you had to repeat this process if you had multiple MDFs (in other words, multiple Identity Assertion providers).

3. If you implemented optional SSPI MBeans in your MDF, follow these steps:

   a. Locate the MBean implementation file.

   The MBean implementation file generated by the WebLogic MBeanMaker is named `MBeanNameImpl.java`. For example, for the MDF named `SampleIdentityAsserter`, the MBean implementation file to be edited is named `SampleIdentityAsserterImpl.java`.

   b. For each optional SSPI MBean that you implemented in your MDF, implement each method. Be sure to also provide implementations for any methods that the optional SSPI MBean inherits.

4. If you included any custom operations in your MDF, implement the methods using the method stubs.

5. Save the file.

6. Proceed to “Use the WebLogic MBeanMaker to Create the MBean JAR File (MJF)” on page 5-22.

   • Are you updating an existing MBean type? If so, follow these steps:

   1. Copy your existing MBean implementation file to a temporary directory so that your current method implementations are not overwritten by the WebLogic MBeanMaker.
1. Create a new DOS shell.

2. Type the following command:

   ```java
   java -DMDF=xmlfile -Dfiles=filesdir -DcreateStubs=true
   weblogic.management.commo.WebLogicMBeanMaker
   ```

   where the `-DMDF` flag indicates that the WebLogic MBeanMaker should translate the MDF into code, `xmlfile` is the MDF (the XML MBean Description File) and `filesdir` is the location where the WebLogic MBeanMaker will place the intermediate files for the MBean type.

   Whenever `xmlfile` is provided, a new set of output files is generated.

   Each time you use the `-DcreateStubs=true` flag, it overwrites any existing MBean implementation file.

   **Note:** As of version 9.0 of WebLogic Server, you can also provide a directory that contains multiple MDF's by using the `-DMDFDIR <MDF directory name>` option. In prior versions of WebLogic Server, the WebLogic MBeanMaker processed only one MDF at a time. Therefore, you had to repeat this process if you had multiple MDFs (in other words, multiple Identity Assertion providers).

3. If you implemented optional SSPI MBeans in your MDF, follow these steps:

   a. Locate and open the MBean implementation file.

      The MBean implementation file generated by the WebLogic MBeanMaker is named `MBeanNameImpl.java`. For example, for the MDF named `SampleIdentityAsserter`, the MBean implementation file to be edited is named `SampleIdentityAsserterImpl.java`.

   b. Open your existing MBean implementation file (which you saved to a temporary directory in step 1).

   c. Synchronize the existing MBean implementation file with the MBean implementation file generated by the WebLogic MBeanMaker.

      Accomplishing this task may include, but is not limited to: copying the method implementations from your existing MBean implementation file into the newly-generated MBean implementation file (or, alternatively, adding the new methods from the newly-generated MBean implementation file to your existing MBean implementation file), and verifying that any changes to method signatures are reflected in the version of the MBean implementation file that you are going to use (for methods that exist in both MBean implementation files).
d. If you modified the MDF to implement optional SSPI MBeans that were not in the original MDF, implement each method. Be sure to also provide implementations for any methods that the optional SSPI MBean inherits.

4. If you modified the MDF to include any custom operations that were not in the original MDF, implement the methods using the method stubs.

5. Save the version of the MBean implementation file that is complete (that is, has all methods implemented).

6. Copy this MBean implementation file into the directory where the WebLogic MBeanMaker placed the intermediate files for the MBean type. You specified this as filesdir in step 3. (You will be overriding the MBean implementation file generated by the WebLogic MBeanMaker as a result of step 3.)

7. Proceed to “Use the WebLogic MBeanMaker to Create the MBean JAR File (MJF)” on page 5-22.

About the Generated MBean Interface File
The MBean interface file is the client-side API to the MBean that your runtime class or your MBean implementation will use to obtain configuration data. It is typically used in the initialize method as described in “Understand the Purpose of the “Provider” SSPIs” on page 3-3.

Because the WebLogic MBeanMaker generates MBean types from the MDF you created, the generated MBean interface file will have the name of the MDF, plus the text “MBean” appended to it. For example, the result of running the SampleIdentityAsserter MDF through the WebLogic MBeanMaker will yield an MBean interface file called SampleIdentityAsserterMBean.java.

Use the WebLogic MBeanMaker to Create the MBean JAR File (MJF)
Once your have run your MDF through the WebLogic MBeanMaker to generate your intermediate files, and you have edited the MBean implementation file to supply implementations for the appropriate methods within it, you need to package the MBean files and the runtime classes for the custom Identity Assertion provider into an MBean JAR File (MJF). The WebLogic MBeanMaker also automates this process.

To create an MJF for your custom Identity Assertion provider, follow these steps:

1. Create a new DOS shell.

2. Type the following command:
java -DMJF=jarfile -Dfiles=filesdir
weblogic.management.commo.WebLogicMBeanMaker

where the -DMJF flag indicates that the WebLogic MBeanMaker should build a JAR file containing the new MBean types, jarfile is the name for the MJF and filesdir is the location where the WebLogic MBeanMaker looks for the files to JAR into the MJF.

Compilation occurs at this point, so errors are possible. If jarfile is provided, and no errors occur, an MJF is created with the specified name.

Notes: When you create a JAR file for a custom security provider, a set of XML binding classes and a schema are also generated. You can choose a namespace to associate with that schema. Doing so avoids the possibility that your custom classes will conflict with those provided by Oracle. The default for the namespace is vendor. You can change this default by passing the -targetNameSpace argument to the WebLogicMBeanMaker or the associated WLMBeanMaker ant task.

If you want to update an existing MJF, simply delete the MJF and regenerate it. The WebLogic MBeanMaker also has a -DIncludeSource option, which controls whether source files are included into the resulting MJF. Source files include both the generated source and the MDF itself. The default is false. This option is ignored when -DMJF is not used.

The resulting MJF can be installed into your WebLogic Server environment, or distributed to your customers for installation into their WebLogic Server environments.

Install the MBean Type Into the WebLogic Server Environment

To install an MBean type into the WebLogic Server environment, copy the MJF into the WL_HOME\server\lib\mbeantypes directory, where WL_HOME is the top-level installation directory for WebLogic Server. This “deploys” your custom Identity Assertion provider—that is, it makes the custom Identity Assertion provider manageable from the WebLogic Server Administration Console.

Note: WL_HOME\server\lib\mbeantypes is the default directory for installing MBean types. (Beginning with 9.0, security providers can be loaded from ...\domaindir\lib\mbeantypes as well.) However, if you want WebLogic Server to look for MBean types in additional directories, use the -Dweblogic.alternateTypesDirectory=<dir> command-line flag when starting your server, where <dir> is a comma-separated list of directory names. When you use this flag, WebLogic Server will always load MBean types from WL_HOME\server\lib\mbeantypes first, then will look in the additional directories and load all valid archives present in those directories (regardless of their extension). For
example, if -Dweblogic.alternateTypesDirectory = dirX,dirY, WebLogic
Server will first load MBean types from \WL_HOME\server\lib\mbeantypes, then any
valid archives present in dirX and dirY. If you instruct WebLogic Server to look in
additional directories for MBean types and are using the Java Security Manager, you
must also update the weblogic.policy file to grant appropriate permissions for the
MBean type (and thus, the custom security provider). For more information, see "Using
the Java Security Manager to Protect WebLogic Resources" in Programming WebLogic
Security.

You can create instances of the MBean type by configuring your custom Identity Assertion
provider (see “Configure the Custom Identity Assertion Provider Using the Administration
Console” on page 5-24), and then use those MBean instances from a GUI, from other Java code,
or from APIs. For example, you can use the WebLogic Server Administration Console to get and
set attributes and invoke operations, or you can develop other Java objects that instantiate
MBeans and automatically respond to information that the MBeans supply. We recommend that
you back up these MBean instances.

Configure the Custom Identity Assertion Provider Using the
Administration Console

Configuring a custom Identity Assertion provider means that you are adding the custom Identity
Assertion provider to your security realm, where it can be accessed by applications requiring
identity assertion services.

Configuring custom security providers is an administrative task, but it is a task that may also be
performed by developers of custom security providers.

Note: The steps for configuring a custom Identity Assertion provider using the WebLogic
Server Administration Console are described under “Configuring WebLogic Security
Providers” in Securing WebLogic Server.

Challenge Identity Assertion

The Challenge Identity Asserter interface supports challenge response schemes in which multiple
challenges, responses messages, and state are required. The Challenge Identity Asserter
interface allows Identity Assertion providers to support authentication protocols such as
Microsoft's Windows NT Challenge/Response (NTLM), Simple and Protected GSS-API
Negotiation Mechanism (SPNEGO), and other challenge/response authentication mechanisms.
Challenge/Response Limitations in the Java Servlet API 2.3 Environment

The WebLogic Security Framework allows you to provide a custom Authentication and Identity Assertion provider. However, due to the nature of the Java Servlet API 2.3 specification, the interaction between the Authentication provider and the client or other servers is architecturally limited during the authentication process. This restricts authentication mechanisms to those that are compatible with the authentication mechanisms the Servlet container offers: basic, form, and certificate.

Servlet authentication filters, which are described in Chapter 13, “Servlet Authentication Filters,” have fewer architecturally-dependence limitations; that is, they are not dependent on the authentication mechanisms offered by the servlet container. By allowing filters to be invoked prior to the container beginning the authentication process, a security realm can implement a wider scope of authentication mechanisms. For example, a servlet authentication filter could redirect the user to a SAML provider site for authentication.

Servlet authentication filters provide a convenient way to implement a challenge/response protocol in your environment. Filters allow your Challenge Identity Assertion interface to loop through your challenge/response mechanism as often as needed to complete the challenge.

Filters and The Role of the weblogic.security.services.Authentication Class

Servlet authentication filters allow you to implement a challenge/response protocol without being limited to the authentication mechanisms compatible with the Servlet container. However, because servlet authentication filters operate outside of the authentication environment provided by the Security Framework, they cannot depend on the Security Framework to determine provider context, and require an API to drive the multiple-challenge Identity Assertion process.

The weblogic.security.services.Authentication class has been extended to allow multiple challenge/response identity assertion from a servlet authentication filter. The methods and interface provide a wrapper for the ChallengeIdentityAsserterV2 and ProviderChallengeContext interfaces so that you can invoke them from a servlet authentication filter.

There is no other documented way to perform a multiple challenge/response dialog from a servlet authentication filter within the context of the Security Framework. Your servlet authentication filter cannot directly invoke the ChallengeIdentityAsserterV2 and ProviderChallengeContext interfaces.

Therefore, you need to implement the ChallengeIdentityAsserterV2 and ProviderChallengeContext interfaces, and then use the weblogic.security.services.Authentication methods and AppChallengeContext interface to invoke them from a servlet authentication filter.
How to Develop a Challenge Identity Asserter

To develop a Challenge Identity Asserter:

- “Implement the AuthenticationProviderV2 SSPI” on page 5-11
- “Implement the IdentityAsserterV2 SSPI” on page 5-12
- “Implement the ChallengeIdentityAsserterV2 Interface” on page 5-26
- “Invoke the weblogic.security.services Challenge Identity Methods” on page 5-27
- “Invoke the weblogic.security.services AppChallengeContext Methods” on page 5-28

Implement the ChallengeIdentityAsserterV2 Interface

The ChallengeIdentityAsserterV2 interface extends the IdentityAsserterV2 SSPI. You must implement the ChallengeIdentityAsserterV2 interface in addition to the IdentityAsserterV2 SSPI.

Provide an implementation for all of the IdentityAsserterV2 methods, and the following methods:

assertChallengeIdentity

```
ProviderChallengeContext assertChallengeIdentity(String tokenType, Object token, ContextHandler handler)
```

Use the supplied client token to establish client identity, possibly with multiple challenges. This method returns your implementation of the ProviderChallengeContext interface. The ProviderChallengeContext interface provides a means to query the state of the challenges.

continueChallengeIdentity

```
void continueChallengeIdentity(ProviderChallengeContext context, String tokenType, Object token, ContextHandler handler)
```

Use the supplied provider context and client token to continue establishing client identity.

getChallengeToken

```
Object getChallengeToken(String type, ContextHandler handler)
```

This method returns the Identity Assertion provider's challenge token.

Implement the ProviderChallengeContext Interface

The ProviderChallengeContext interface provides a means to query the state of the challenges. It allows the assertChallengeIdentity and continueChallengeIdentity
How to Develop a Custom Identity Assertion Provider

methods of the ChallengeIdentityAssertionerV2 interface to return either the callback handler or a new challenge to which the client must respond.

To implement the ProviderChallengeContext interface, provide implementations for the following methods:

getCallbackHandler

CallbackHandler getCallbackHandler()

This method returns the callback handler for the challenge identity assertion. Call this method only when the hasChallengeIdentityCompleted method returns true.

getChallengeToken

Object getChallengeToken()

This method returns the challenge token for the challenge identity assertion. Call this method only when the hasChallengeIdentityCompleted method returns false.

hasChallengeIdentityCompleted

boolean hasChallengeIdentityCompleted

This method returns whether the challenge identity assertion has completed. It returns true if the challenge identity assertion has completed, false if not. If true, the caller should use the getCallbackHandler method. If false, then the caller should use the getChallengeToken method.

Invoke the weblogic.security.services Challenge Identity Methods

Have your servlet authentication filter invoke the following weblogic.security.services.Authentication methods instead of calling the ChallengeIdentityAssertionerV2 SSPI directly:

assertChallengeIdentity

AppChallengeContext assertChallengeIdentity(String tokenType, Object token, AppContext appContext)

Use the supplied client token to establish client identity, possibly with multiple challenges. This method returns the context of the challenge identity assertion. This result may contain either the authenticated subject or an additional challenge to which the client must respond. The AppChallengeContext interface provides a means to query the state of the challenges.

continueChallengeIdentity

void continueChallengeIdentity(AppChallengeContext context, String tokenType, Object token, AppContext appContext)
Identity Assertion Providers

Use the supplied provider context and client token to continue establishing client identity.

**getChallengeToken**

Object getChallengeToken

This method returns the initial challenge token for the challenge identity assertion.

**Invoke the weblogic.security.services AppChallengeContext Methods**

Have your servlet authentication filter invoke the following AppChallengeContext methods instead of invoking the ProviderChallengeContext interface directly:

**getAuthenticatedSubject**

Subject getAuthenticatedSubject()

Returns the authenticated subject for the challenge identity assertion. Call this method only when the `hasChallengeIdentityCompleted` method returns true.

**getChallengeToken**

Object getChallengeToken()

This method returns the challenge token for the challenge identity assertion. Call this method only when the `hasChallengeIdentityCompleted` method returns false.

**hasChallengeIdentityCompleted**

boolean hasChallengeIdentityCompleted()

This method returns whether the challenge identity assertion has completed. It returns true if the challenge identity assertion has completed, false if not. If true, the caller should use the `getCallbackHandler` method. If false, then the caller should use the `getChallengeToken` method.

**Implementing Challenge Identity Assertion from a Filter**

In the following code flow, assume that the servlet authentication filter, which is described in Chapter 13, “Servlet Authentication Filters,” handles the HTTP level interactions (Authorization and WWW-Authenticate) and is also responsible for calling the `weblogic.security.services.Authentication` methods and interfaces to drive the Challenge Identity Assertion process.

1. Browser sends a request
2. Filter sees requests and no Authorization header, so it calls the `weblogic.security.services.Authentication` `getChallengeToken` method to get an initial token and sends a 401 response with a WWW-Authenticate negotiate header back.

   
   a. Filter sees this and calls the `weblogic.security.services.Authentication` `assertChallengeIdentity` method. `assertChallengeIdentity` takes the token as input, processes it according to whatever rules it needs to follow for the assertion process it is following (for example, if NTLM, then do whatever NTLM requires to process the token), and determine if that succeeded or not. `assertChallengeIdentity` returns your implementation of the `AppChallengeContext` interface.
   
   b. Filter calls `AppChallengeContext` `hasChallengeCompleted` method. Use the `AppChallengeContext` `hasChallengeIdentityCompleted` method to see if the challenge has completed. For example, it can determine if the callback handler is not null, meaning that it contains a username, and return true. In this use it returns false, so it must issue another challenge to the client. The filter then calls `AppChallengeContext` `getChallengeToken` to get the token to challenge back with.
   
   c. Filter likely stores the `AppChallengeContext` somewhere such as a session attribute.
   
   d. Filter sends a 401 response with an WWW-Authenticate negotiate and the new token.

4. Browser sees the new challenge and responds again with an Authorization header.
   
   a. Filter sees this and calls the `weblogic.security.services.Authentication` `continueChallengeIdentity` method.
   
   b. Filter calls the `AppChallengeContext` `hasChallengeCompleted` method. If it returns false another challenge is in order, so call the `AppChallengeContext` `getChallengeToken` method to get the token to challenge back with, and so forth. If it returned true, then the challenge has completed and the filter would then call `AppChallengeContext` `getAuthenticatedSubject` method and perform a `runAs(subject, request)`.
Principal Validation Providers

Authentication providers rely on Principal Validation providers to sign and verify the authenticity of principals (users and groups) contained within a subject. Such verification provides an additional level of trust and may reduce the likelihood of malicious principal tampering. Verification of the subject’s principals takes place during the WebLogic Server’s demarshalling of RMI client requests for each invocation. The authenticity of the subject’s principals is also verified when making authorization decisions.

The following sections describe Principal Validation provider concepts and functionality, and provide step-by-step instructions for developing a custom Principal Validation provider:

- “Principal Validation Concepts” on page 6-1
- “The Principal Validation Process” on page 6-3
- “Do You Need to Develop a Custom Principal Validation Provider?” on page 6-4
- “How to Develop a Custom Principal Validation Provider” on page 6-5

Principal Validation Concepts

Before you develop a Principal Validation provider, you need to understand the following concepts:

- “Principal Validation and Principal Types” on page 6-2
- “How Principal Validation Providers Differ From Other Types of Security Providers” on page 6-2
Principal Validation Providers

- “Security Exceptions Resulting from Invalid Principals” on page 6-2

Principal Validation and Principal Types

Like Identity Assertion providers support specific types of tokens, Principal Validation providers support specific types of principals. For example, the WebLogic Principal Validation provider (described in “Do You Need to Develop a Custom Principal Validation Provider?” on page 6-4) signs and verifies the authenticity of WebLogic Server principals.

The Principal Validation provider that is associated with the configured Authentication provider (as described in “How Principal Validation Providers Differ From Other Types of Security Providers” on page 6-2) will sign and verify all the principals stored in the subject that are of the type the Principal Validation provider is designed to support.

How Principal Validation Providers Differ From Other Types of Security Providers

A Principal Validation provider is a special type of security provider that primarily acts as a “helper” to an Authentication provider. The main function of a Principal Validation provider is to prevent malicious individuals from tampering with the principals stored in a subject.

The AuthenticationProvider SSPI (as described in “Implement the AuthenticationProviderV2 SSPI” on page 4-13) includes a method called getPrincipalValidator. In this method, you specify the Principal Validation provider’s runtime class to be used with the Authentication provider. The Principal Validation provider’s runtime class can be the one Oracle provides (called the WebLogic Principal Validation provider) or one you develop (called a custom Principal Validation provider). An example of using the WebLogic Principal Validation provider in an Authentication provider’s getPrincipalValidator method is shown in Listing 4-1, “SimpleSampleAuthenticationProviderImpl.java,” on page 4-18.

Because you generate MBean types for Authentication providers and configure Authentication providers using the WebLogic Server Administration Console, you do not have to perform these steps for a Principal Validation provider.

Security Exceptions Resulting from Invalid Principals

When the WebLogic Security Framework attempts an authentication (or authorization) operation, it checks the subject’s principals to see if they are valid. If a principal is not valid, the
WebLogic Security Framework throws a security exception with text indicating that the subject is invalid. A subject may be invalid because:

- A principal in the subject does not have a corresponding Principal Validation provider configured (which means there is no way for the WebLogic Security Framework to validate the subject).

  **Note:** Because you can have multiple principals in a subject, each stored by the LoginModule of a different Authentication provider, the principals can have different Principal Validation providers.

- A principal was signed in another WebLogic Server security domain (with a different credential from this security domain) and the caller is trying to use it in the current domain.

- A principal with an invalid signature was created as part of an attempt to compromise security.

- A subject never had its principals signed.

### The Principal Validation Process

As shown in Figure 6-1, a user attempts to log into a system using a username/password combination. WebLogic Server establishes trust by calling the configured Authentication provider’s LoginModule, which validates the user’s username and password and returns a subject that is populated with principals per Java Authentication and Authorization Service (JAAS) requirements.
WebLogic Server passes the subject to the specified Principal Validation provider, which signs the principals and then returns them to the client application via WebLogic Server. Whenever the principals stored within the subject are required for other security operations, the same Principal Validation provider will verify that the principals stored within the subject have not been modified since they were signed.

**Do You Need to Develop a Custom Principal Validation Provider?**

The default (that is, active) security realm for WebLogic Server includes a WebLogic Principal Validation provider. Much like an Identity Assertion provider supports a specific type of token, a Principal Validation provider signs and verifies the authenticity of a specific type of principal. The WebLogic Principal Validation provider signs and verifies WebLogic Server principals. In other words, it signs and verifies principals that represent WebLogic Server users or WebLogic Server groups.

**Notes:** You can use the WLSPrincipals class (located in the weblogic.security package) to determine whether a principal (user or group) has special meaning to WebLogic Server. (That is, whether it is a predefined WebLogic Server user or WebLogic Server group.) Furthermore, any principal that is going to represent a WebLogic Server user or group needs to implement the WLSUser and WLSGroup interfaces (available in the weblogic.security.spi package).

WLSPrincipals is used only by PrincipalValidatorImpl, not by the Security Framework. An Authentication provider can implement its own principal validator, or it can use the PrincipalValidatorImpl. If you configure an Authentication provider with custom principal validators, then the WLSPrincipals interface is not used.

An Authentication provider needs to implement the WLSPrincipals interface if the provider is going to use PrincipalValidatorImpl.

The WebLogic Principal Validation provider includes implementations of the WLSUser and WLSGroup interfaces, named WLSUserImpl and WLSGroupImpl. These are located in the weblogic.security.principal package. It also includes an implementation of the PrincipalValidator SSPI called PrincipalValidatorImpl (located in the weblogic.security.provider package). The sign() method in the PrincipalValidatorImpl class generates a random seed and computes a digest based on that random seed. (For more information about the PrincipalValidator SSPI, see “Implement the PrincipalValidator SSPI” on page 6-6.)
How to Use the WebLogic Principal Validation Provider

If you have simple user and group principals (that is, they only have a name), and you want to use the WebLogic Principal Validation provider:

- Use the `weblogic.security.principal.WLSUserImpl` and `weblogic.security.principal.WLSGroupImpl` classes.

- Use the `weblogic.security.provider.PrincipalValidatorImpl` class.

If you have user or group principals with extra data members (that is, in addition to a name), and you want to use the WebLogic Principal Validation provider:

- Write your own `UserImpl` and `GroupImpl` classes.

- Extend the `weblogic.security.principal.WLSAbstractPrincipal` class.

- Implement the `weblogic.security.spi.WLSUser` and `weblogic.security.spi.WLSGroup` interfaces.

- Implement the `equals()` method to include your extra data members. Your implementation should call the `super.equals()` method when complete so the `WLSAbstractPrincipal` can validate the remaining data.

  **Note:** By default, only the user or group name will be validated. If you want to validate your extra data members as well, then implement the `getSignedData()` method.

- Use the `weblogic.security.provider.PrincipalValidatorImpl` class.

If you have your own validation scheme and do not want to use the WebLogic Principal Validation provider, or if you want to provide validation for principals other than WebLogic Server principals, then you need to develop a custom Principal Validation provider.

How to Develop a Custom Principal Validation Provider

To develop a custom Principal Validation provider:

- Write your own `UserImpl` and `GroupImpl` classes by:
  - Implementing the `weblogic.security.spi.WLSUser` and `weblogic.security.spi.WLSGroup` interfaces.
  - Implementing the `java.io.Serializable` interfaces.
Principal Validation Providers

- Write your own `PrincipalValidationImpl` class by implementing the `weblogic.security.spi.PrincipalValidator` SSPI. (See “Implement the PrincipalValidator SSPI” on page 6-6.)

**Implement the PrincipalValidator SSPI**

To implement the `PrincipalValidator` SSPI, provide implementations for the following methods:

validate

```java
public boolean validate(Principal principal) throws SecurityException;
```

The `validate` method takes a principal as an argument and attempts to validate it. In other words, this method verifies that the principal was not altered since it was signed.

sign

```java
public boolean sign(Principal principal);
```

The `sign` method takes a principal as an argument and signs it to assure trust. This allows the principal to later be verified using the `validate` method.

Your implementation of the `sign` method should be a secret algorithm that malicious individuals cannot easily recreate. You can include that algorithm within the `sign` method itself, have the `sign` method call out to a server for a token it should use to sign the principal, or implement some other way of signing the principal.

getPrincipalBaseClass

```java
public Class getPrincipalBaseClass();
```

The `getPrincipalBaseClass` method returns the base class of principals that this Principal Validation provider knows how to validate and sign.

For more information about the `PrincipalValidator` SSPI and the methods described above, see the `WebLogic Server API Reference Javadoc`. 
Authorization Providers

Authorization is the process whereby the interactions between users and WebLogic resources are controlled, based on user identity or other information. In other words, authorization answers the question, “What can you access?” In WebLogic Server, an Authorization provider is used to limit the interactions between users and WebLogic resources to ensure integrity, confidentiality, and availability.

The following sections describe Authorization provider concepts and functionality, and provide step-by-step instructions for developing a custom Authorization provider:

- “Authorization Concepts” on page 7-1
- “The Authorization Process” on page 7-2
- “Do You Need to Develop a Custom Authorization Provider?” on page 7-5
- “How to Develop a Custom Authorization Provider” on page 7-5

Authorization Concepts

Before you develop an Authorization provider, you need to understand the following concepts:

- “Access Decisions” on page 7-2
- “Using the Java Authorization Contract for Containers” on page 7-2
- “Security Providers and WebLogic Resources” on page 3-27
Authorization Providers

Access Decisions

Like LoginModules for Authentication providers, an **Access Decision** is the component of an Authorization provider that actually answers the “is access allowed?” question. Specifically, an Access Decision is asked whether a subject has permission to perform a given operation on a WebLogic resource, with specific parameters in an application. Given this information, the Access Decision responds with a result of **PERMIT**, **DENY**, or **ABSTAIN**.

**Note:** For more information about Access Decisions, see “Implement the AccessDecision SSPI” on page 7-9.

Using the Java Authorization Contract for Containers

The Java Authorization Contract for Containers (JACC) is part of Java EE. JACC extends the permission-based security model to EJBs and Servlets. JACC is defined by JSR-115.

JACC provides an alternate authorization mechanism for the EJB and Servlet containers in a WebLogic Server domain. When JACC is configured, the WebLogic Security framework access decisions, adjudication, and role mapping functions are not used for EJB and Servlet authorization decisions.

**Note:** You cannot use the JACC framework in conjunction with the WebLogic Security framework. The JACC classes used by WebLogic Server do not include an implementation of a Policy object for rendering decisions but instead rely on the `java.security.Policy` object.

WebLogic Server implements a JACC provider which, although fully compliant with JSR-115, is not as optimized as the WebLogic Authentication provider. The Java JACC classes are used for rendering access decisions. Because JSR-115 does not define how to address role mapping, WebLogic JACC classes are used for role-to-principal mapping. See [http://java.sun.com/javaee/5/docs/api/javax/security/jacc/package-frame.html](http://java.sun.com/javaee/5/docs/api/javax/security/jacc/package-frame.html) for information on developing a JACC provider.

The Authorization Process

[Figure 7-1](#) illustrates how Authorization providers (and the associated Adjudication and Role Mapping providers) interact with the WebLogic Security Framework during the authorization process, and an explanation follows.
Generally, authorization is performed in the following manner:

1. A user or system process requests a WebLogic resource on which it will attempt to perform a given operation.

2. The resource container that handles the type of WebLogic resource being requested receives the request (for example, the EJB container receives the request for an EJB resource).

   **Note:** The resource container could be the container that handles any one of the WebLogic Resources described in “Security Providers and WebLogic Resources” on page 3-27.

3. The resource container constructs a **ContextHandler** object that may be used by the configured Role Mapping providers and the configured Authorization providers’ Access Decisions to obtain information associated with the context of the request.

   **Note:** For more information about ContextHandlers, see “ContextHandlers and WebLogic Resources” on page 3-37. For more information about Access Decisions, see “Access
Authorization Providers

Decisions” on page 7-2. For more information about Role Mapping providers, see Chapter 9, “Role Mapping Providers.”

The resource container calls the WebLogic Security Framework, passing in the subject, the WebLogic resource, and optionally, the ContextHandler object (to provide additional input for the decision).

5. The Role Mapping providers use the ContextHandler to request various pieces of information about the request. They construct a set of Callback objects that represent the type of information being requested. This set of Callback objects is then passed as an array to the ContextHandler using the handle method.

The Role Mapping providers use the values contained in the Callback objects, the subject, and the resource to compute a list of security roles to which the subject making the request is entitled, and pass the list of applicable security roles back to the WebLogic Security Framework.

6. The WebLogic Security Framework delegates the actual decision about whether the subject is entitled to perform the requested action on the WebLogic resource to the configured Authorization providers.

   The Authorization providers’ Access Decisions also use the ContextHandler to request various pieces of information about the request. They too construct a set of Callback objects that represent the type of information being requested. This set of Callback objects is then passed as an array to the ContextHandler using the handle method. (The process is the same as described for Role Mapping providers in Step 5.)

7. The isAccessAllowed method of each configured Authorization provider’s Access Decision is called to determine if the subject is authorized to perform the requested access, based on the ContextHandler, subject, WebLogic resource, and security roles. Each isAccessAllowed method can return one of three values:
   - PERMIT—Indicates that the requested access is permitted.
   - DENY—Indicates that the requested access is explicitly denied.
   - ABSTAIN—Indicates that the Access Decision was unable to render an explicit decision.

   This process continues until all Access Decisions are used.

8. The WebLogic Security Framework delegates the job of reconciling any discrepancies among the results rendered by the configured Authorization providers’ Access Decisions to the Adjudication provider. The Adjudication provider determines the ultimate outcome of the authorization decision.
Do You Need to Develop a Custom Authorization Provider?

Note: For more information about the Adjudication provider, see Chapter 8, “Adjudication Providers.”

9. The Adjudication provider returns either a **TRUE** or **FALSE** verdict, which is forwarded to the resource container through the WebLogic Security Framework.
   - If the decision is **TRUE**, the resource container dispatches the request to the protected WebLogic resource.
   - If the decision is **FALSE**, the resource container throws a security exception that indicates that the requestor was not authorized to perform the requested access on the protected WebLogic resource.

Do You Need to Develop a Custom Authorization Provider?

The default (that is, active) security realm for WebLogic Server includes a WebLogic Authorization provider. The WebLogic Authorization provider supplies the default enforcement of authorization for this version of WebLogic Server. The WebLogic Authorization provider returns an access decision using a policy-based authorization engine to determine if a particular user is allowed access to a protected WebLogic resource. The WebLogic Authorization provider also supports the deployment and undeployment of security policies within the system. If you want to use an authorization mechanism that already exists within your organization, you could create a custom Authorization provider to tie into that system.

Does Your Custom Authorization Provider Need to Support Application Versioning?

All Authorization, Role Mapping, and Credential Mapping providers for the security realm must support application versioning in order for an application to be deployed using versions. If you develop a custom security provider for Authorization, Role Mapping, or Credential Mapping and need to support versioned applications, you must implement the Versionable Application SSPI, as described in Chapter 14, “Versionable Application Providers.”

How to Develop a Custom Authorization Provider

If the WebLogic Authorization provider does not meet your needs, you can develop a custom Authorization provider by following these steps:
1. “Create Runtime Classes Using the Appropriate SSPIs” on page 7-6, or, optionally, implement the “Bulk Authorization Providers” on page 7-26

2. Optionally, implement the “Policy Consumer SSPI” on page 7-17

3. Optionally, implement the “PolicyStoreMBean” on page 7-21

4. “Generate an MBean Type Using the WebLogic MBeanMaker” on page 7-27

5. “Configure the Custom Authorization Provider Using the Administration Console” on page 7-33

6. “Provide a Mechanism for Security Policy Management” on page 7-36

Create Runtime Classes Using the Appropriate SSPIs

Before you start creating runtime classes, you should first:

- “Understand the Purpose of the “Provider” SSPIs” on page 3-3
- “Determine Which “Provider” Interface You Will Implement” on page 3-5
- “Understand the SSPI Hierarchy and Determine Whether You Will Create One or Two Runtime Classes” on page 3-7

When you understand this information and have made your design decisions, create the runtime classes for your custom Authorization provider by following these steps:

- “Implement the AuthorizationProvider SSPI” on page 7-6 or “Implement the DeployableAuthorizationProviderV2 SSPI” on page 7-7
- “Implement the AccessDecision SSPI” on page 7-9

Note: At least one Authorization provider in a security realm must implement the DeployableAuthorizationProvider SSPI, or else it will be impossible to deploy Web applications and EJBs.

For an example of how to create a runtime class for a custom Authorization provider, see “Example: Creating the Runtime Class for the Sample Authorization Provider” on page 7-11.

Implement the AuthorizationProvider SSPI

To implement the AuthorizationProvider SSPI, provide implementations for the methods described in “Understand the Purpose of the “Provider” SSPIs” on page 3-3 and the following method:
getAccessDecision

public AccessDecision getAccessDecision();

The getAccessDecision method obtains the implementation of the AccessDecision SSPI. For a single runtime class called MyAuthorizationProviderImpl.java, the implementation of the getAccessDecision method would be:

return this;

If there are two runtime classes, then the implementation of the getAccessDecision method could be:

return new MyAccessDecisionImpl;

This is because the runtime class that implements the AuthorizationProvider SSPI is used as a factory to obtain classes that implement the AccessDecision SSPI.

For more information about the AuthorizationProvider SSPI and the getAccessDecision method, see the WebLogic Server API Reference Javadoc.

Implement the DeployableAuthorizationProviderV2 SSPI

To implement the DeployableAuthorizationProviderV2 SSPI, provide implementations for the methods described in “Understand the Purpose of the “Provider” SSPIs” on page 3-3, “Implement the AuthorizationProvider SSPI” on page 7-6, and the following methods:

deleteApplicationPolicies

public void deleteApplicationPolicies(ApplicationInfo application) throws ResourceRemovalException

The deleteApplicationPolicies method deletes all policies for an application. The deleteApplicationPolicies method is called only on the Administration Server.

deployExcludedPolicy

public void deployExcludedPolicy(DeployPolicyHandle handle, Resource resource) throws ResourceCreationException

The deployExcludedPolicy method deploys a policy that always denies access. If a policy already exists, it is removed and replaced by this policy.

deployPolicy

public void deployPolicy(DeployPolicyHandle handle, Resource resource, String[] roleNames) throws ResourceCreationException
The deployPolicy method creates a security policy on behalf of a deployed Web application or EJB, based on the WebLogic resource to which the security policy should apply and the security role names that are in the security policy.

deployUncheckedPolicy

public void deployUncheckedPolicy(DeployPolicyHandle handle, Resource resource) throws ResourceCreationException

The deployUncheckedPolicy method deploys a policy that always grants access. If a policy already exists, it is removed and replaced by this policy.

deployExcludedPolicy

public void deployExcludedPolicy(DeployPolicyHandle handle) throws ResourceCreationException

The deployExcludedPolicy method deploys a policy that always denies access. If a policy already exists, it is removed and replaced by this policy.

startDeployPolicies

public deployPolicyHandle startDeployPolicies(ApplicationInfo application) throws DeployHandleCreationException

The startDeployPolicies method marks the beginning of an application policy deployment and is called on all servers within a WebLogic Server domain where an application is targeted.

undeployAllPolicies

public void undeployAllPolicies(DeployPolicyHandle handle) throws ResourceRemovalException

The undeployAllPolicies method deletes a set of policy definitions on behalf of an undeployed Web application or EJB.

For more information about the DeployableAuthorizationProviderV2 SSPI and the deployPolicy and undeployPolicy methods, see the WebLogic Server API Reference Javadoc.

The ApplicationInfo Interface

The ApplicationInfo interface passes data about an application deployment to a security provider. You can use this data to uniquely identity the application.

The Security Framework implements the ApplicationInfo interface for your convenience. You do not need to implement any methods for this interface.
The DeployableAuthorizationProviderV2 and DeployableRoleProviderV2 interfaces use ApplicationInfo. For example, consider an implementation of the DeployableAuthorizationProviderV2 methods. The Security Framework calls the DeployableAuthorizationProviderV2 startDeployPolicies method and passes in the ApplicationInfo interface for this application. The ApplicationInfo data is determined based on the information supplied in the Administration Console when an application is deployed.

The startDeployPolicies method returns DeployPolicyHandle, which you can then use in the other DeployableAuthorizationProviderV2 methods.

You use the ApplicationInfo interface to get the application identifier, the component name, and the component type for this application. Component type can be APPLICATION, CONTROL_RESOURCE, EJB, or WEBAPP, as defined in the ApplicationInfo.ComponentType class.

The following example shows one way to accomplish this task:

```java
public DeployPolicyHandle startDeployPolicies(ApplicationInfo appInfo) throws DeployHandleCreationException {
    // Obtain the application information...
    String appId = appInfo.getApplicationIdentifier();
    ComponentType compType = appInfo.getComponentType();
    String compName = appInfo.getComponentName();
    ...
}
```

The Security Framework calls the DeployableAuthorizationProviderV2 deleteApplicationPolicies method and passes in the ApplicationInfo interface for this application. The deleteApplicationPolicies method deletes all policies for an application and is called (only on the Administration Server within a WebLogic Server domain) at the time an application is deleted.

**Implement the AccessDecision SSPI**

When you implement the AccessDecision SSPI, you must provide implementations for the following methods:

**isAccessAllowed**

```java
public Result isAccessAllowed(Subject subject, Map roles, Resource resource, ContextHandler handler, Direction direction) throws InvalidPrincipalException {
    ...
}
```
Authorization Providers

The \texttt{isAccessAllowed} method utilizes information contained within the subject to determine if the requestor should be allowed to access a protected method. The \texttt{isAccessAllowed} method may be called prior to or after a request, and returns values of \texttt{PERMIT}, \texttt{DENY}, or \texttt{ABSTAIN}. If multiple Access Decisions are configured and return conflicting values, an Adjudication provider will be needed to determine a final result. For more information, see Chapter 8, “Adjudication Providers.”

\textbf{isProtectedResource}

\begin{verbatim}
public boolean isProtectedResource(Subject subject, Resource resource) throws InvalidPrincipalException
\end{verbatim}

The \texttt{isProtectedResource} method is used to determine whether the specified WebLogic resource is protected, without incurring the cost of an actual access check. It is only a lightweight mechanism because it does not compute a set of security roles that may be granted to the caller’s subject.

For more information about the \texttt{AccessDecision SSPI} and the \texttt{isAccessAllowed} and \texttt{isProtectedResource} methods, see the \textit{WebLogic Server API Reference Javadoc}.

Developing Custom Authorization Providers That Are Compatible With the Realm Adapter Authentication Provider

An Authentication provider is the security provider responsible for populating a subject with users and groups, which are then extracted from the subject by other types of security providers, including Authorization providers. If the Authentication provider configured in your security realm is a Realm Adapter Authentication provider, the user and group information will be stored in the subject in a way that is slightly different from other Authentication providers. Therefore, this user and group information must also be extracted in a slightly different way.

\textbf{Listing 7-1} provides code that can be used by custom Authorization providers to check whether a subject matches a user or group name when a Realm Adapter Authentication provider was used to populate the subject. This code belongs in both the \texttt{isAccessAllowed} and \texttt{isProtectedResource} methods.

\textbf{Listing 7-1   Sample Code to Check if a Subject Matches a User or Group Name}

\begin{verbatim}
/**
 * Determines if the Subject matches a user/group name.
 *
 * @param principalWant A String containing the name of a principal in this role (that is, the role definition).
 */
\end{verbatim}
@param subject A Subject that contains the Principals that identify the user who is trying to access the resource as well as the user's groups.
* @return A boolean. true if the current subject matches the name of the principal in the role, false otherwise.
*
private boolean subjectMatches(String principalWant, Subject subject)
{
    // first, see if it's a group name match
    if (SubjectUtils.isUserInGroup(subject, principalWant)) {
        return true;
    }
    // second, see if it's a user name match
    if (principalWant.equals(SubjectUtils.getUsername(subject))) {
        return true;
    }
    // didn't match
    return false;
}

Example: Creating the Runtime Class for the Sample Authorization Provider

Listing 7-2 shows the SampleAuthorizationProviderImpl.java class, which is the runtime class for the sample Authorization provider. This runtime class includes implementations for:

- The three methods inherited from the SecurityProvider interface: initialize, getDescription and shutdown (as described in “Understand the Purpose of the “Provider” SSPIs” on page 3-3).
- The method inherited from the AuthorizationProvider SSPI: the getAccessDecision method (as described in “Implement the AuthorizationProvider SSPI” on page 7-6).
- The seven methods in the DeployableAuthorizationProviderV2 SSPI: the deleteApplicationPolicies, deployExcludedPolicy, deployPolicy, deployUncheckedPolicy, endDeployPolicies, startDeployPolicies, and undeployAllPolicies methods (as described in “Implement the DeployableAuthorizationProviderV2 SSPI” on page 7-7).
- The two methods in the AccessDecision SSPI: the isAccessAllowed and isProtectedResource methods (as described in “Implement the AccessDecision SSPI” on page 7-9).

Note: The bold face code in Listing 7-2 highlights the class declaration and the method signatures.
Listing 7-2 SimpleSampleAuthorizationProviderImpl.java

```java
package examples.security.providers.authorization.simple;

import java.security.Principal;
import java.util.Date;
import java.util.Enumeration;
import java.util.Iterator;
import java.util.Map;
import java.util.Set;
import javax.security.auth.Subject;
import weblogic.management.security.ProviderMBean;
import weblogic.security.SubjectUtils;
import weblogic.security.WLSPrincipals;
import weblogic.security.service.ContextHandler;
import weblogic.security.spi.AccessDecision;

    System.out.println("SimpleSampleAuthorizationProviderImpl.createApplication
    Version");
    System.out.println("\tapplication identifier\t= " + appId);
    System.out.println("\tsource app identifier\t= " + ((sourceAppId != null) ?
                        sourceAppId : "None");
    // create new policies when existing application is specified
    if (sourceAppId != null) {
        database.clonePoliciesForApplication(sourceAppId, appId);
    }
}

public void deleteApplicationVersion(String appId)
{
    System.out.println("SimpleSampleAuthorizationProviderImpl.deleteApplication
    Version");
    System.out.println("\tapplication identifier\t= " + appId);
    // clear out policies for the application
    database.removePoliciesForApplication(appId);
}

public void deleteApplication(String appName)
{
    System.out.println("SimpleSampleAuthorizationProviderImpl.deleteApplication

    ");
    System.out.println("\tapplication name\t= " + appName);
    // clear out policies for the application
}
How to Develop a Custom Authorization Provider

```java
database.removePoliciesForApplication(appName);

class SampleDeployPolicyHandle implements DeployPolicyHandle {
    Date date;
    String application;
    String component;
    ComponentType componentType;

    SampleDeployPolicyHandle(String app, String comp, ComponentType type) {
        this.application = app;
        this.component = comp;
        this.componentType = type;
        this.date = new Date();
    }

    public String getApplication() { return application; }
    public String getComponent() { return component; }
    public ComponentType getComponentType() { return componentType; }

    public String toString() {
        String name = component;
        if (componentType == ComponentType.APPLICATION)
            name = application;
        return componentType + " " + name + " [" + date.toString() + "]";
    }
}
```

---

Policy Consumer SSPI

WebLogic Server implements a policy consumer for JMX (MBean) default policies and Web Service annotations. This release of WebLogic Server includes an SSPI that Authorization providers can use to obtain the policy collections.

The PolicyConsumer SSPI is optional; only those Authorization providers that implement the SSPI are called to consume a policy collection.

The SSPI supports both the delivery of initial policy collections and the delivery of updated policy collections.
All Authorization providers that support the PolicyConsumer SSPI are called to consume a policy collection. Each Authorization provider can choose to skip or obtain the policy collection for a given policy set. In the case where a provider persists policy, the provider need only collect the policy once. However, providers keeping policy in memory can obtain the policy collection again.

The out-of-the-box WebLogic Server Authorization providers persist the policy into LDAP.

**Required SSPI Interfaces**

If you want your custom Authorization provider to support the delivery of policy collections, you must implement three interfaces:

- `weblogic.security.spi.PolicyConsumerFactory`
- `weblogic.security.spi.PolicyConsumer`
- `weblogic.security.spi.PolicyCollectionHandler`

These interfaces are described in the sections that follow.

**Implement the PolicyConsumerFactory SSPI Interface**

An Authorization provider implements the `PolicyConsumerFactory` interface so that an instance of a `PolicyConsumer` is available to the WebLogic Security Framework. The WebLogic Security Framework calls your `PolicyConsumerFactory` implementation to obtain the provider's implementation of the policy consumer.

The `PolicyConsumerFactory` SSPI has one method, which returns your implementation of the `PolicyConsumer` SSPI interface.

```java
public interface PolicyConsumerFactory {
    /**
     * Obtain the implementation of the PolicyConsumer security service provider interface (SSPI).
     * @return a PolicyConsumer SSPI implementation.
     */
    public PolicyConsumer getPolicyConsumer();
}
```

**Implement the PolicyConsumer SSPI Interface**

The `PolicyConsumer` SSPI returns a policy collection handler for consumption of a policy collection. It has one method, `getPolicyCollectionHandler()`, which takes a
PolicyCollectionInfo implementation as an argument and returns your implementation of
the PolicyCollectionHandler interface.

public interface PolicyConsumer
{
/**
 * Obtain a policy handler for consumption of a policy set.
 * @param info the PolicyCollectionInfo for the policy set.
 * @return a PolicyCollectionHandler or NULL which indicates
 * that the policy set is not needed.
 * @exception ConsumptionException if an error occurs
 * obtaining the handler and the policy set cannot be consumed.
 */
public PolicyCollectionHandler getPolicyCollectionHandler(
        PolicyCollectionInfo info)
        throws ConsumptionException;
}

The WebLogic Security Framework calls the getPolicyCollectionHandler() method and
passes data about a policy collection to a security provider as an implementation of the
PolicyCollectionInfo interface. (This interface implementation is provided for you, you do
not have to implement it.)

You use the PolicyCollectionInfo getName(), getVersion(), getTimestamp(), and
getResourceTypes() methods to discover information about this policy set. You then return a
PolicyCollectionHandler, or NULL to indicate that the policy collection is not needed.

public interface PolicyCollectionInfo
{
/**
 * Get the name of the collection.
 */
public String getName();

/**
 * Get the runtime version of the policy.
 */
public String getVersion();
Authorization Providers

```java
/**
 * Get the timestamp of the policy.
 */
public String getTimestamp();

/**
 * Get the resource types used in the policy collection.
 */
public Resource[] getResourceTypes();
}
```

**Implement the PolicyCollectionHandler SSPI Interface**

The `PolicyCollectionHandler` interface has three methods: `setPolicy`, `setUncheckedPolicy`, and `done()`. The `setPolicy()` method takes a resource and role names and sets a policy based on the role. The `setUncheckedPolicy()` method opens access to everyone.

The `done()` method signals the completion of the policy collection. We recommend that the `done()` method remove all old policies for the policy set.

```java
public interface PolicyCollectionHandler {
    /**
     * Set a policy for the specified resource.
     */
    public void setPolicy(Resource resource, String[] roleNames)
            throws ConsumptionException;

    /**
     * Sets a policy which always grants access.
     */
    public void setUncheckedPolicy(Resource resource)
            throws ConsumptionException;

    /**
     * Signals the completion of the policy collection.
     */
    public void done()
            throws ConsumptionException;
}
```
Supporting an Updated Policy Collection

To support the delivery of an updated policy collection, all Authorization providers that support the PolicyConsumer SSPI need to examine the contents of the PolicyCollectionInfo passed in the PolicyConsumer.getPolicyCollectionHandler() method to determine if a policy set has changed. Each provider must decide (possibly by configuration) how to perform conflict resolution with the initial policy collection and any customized policy received outside of the SSPI.

For the WebLogic Server supplied Authorization providers, customized policy will not be replaced by the updated policy collection: all policy from the initial policy collection will be removed and only the customized policies, plus the updated policy collection, will be in effect. If the policy collection info has a different timestamp or version, it's treated as an updated policy collection. The collection name is used as a persistence key.

The PolicyConsumerMBean

Authorization providers that implement the Policy Consumer SSPI must also implement the weblogic.management.security.authorization.PolicyConsumerMBean to indicate that the provider supports policy consumption.

PolicyStoreMBean

This release of WebLogic Server includes support for a new MBean (weblogic.management.security.authorization.PolicyStoreMBean) that allows for standard management (add, delete, get, list, modify, read) of administrator-generated XACML policies and policy sets. An Authorization or Role Mapping provider MBean can optionally implement this MBean interface.

The PolicyStoreMBean methods allow security administrators to manage policy in the server as XACML documents. This includes creating and managing a domain that uses the default XACML provider, as well as managing XACML documents that the administrator has created. The administrator can then use WLST to manage these XACML policies in WebLogic Server.

WebLogic Server includes an implementation of this MBean for use with the out-of-the-box XACML providers, and you can write your own implementation of this MBean for use with your own custom Authorization or Role Mapping providers. The WebLogic Server out-of-the-box XACML providers support the mandatory features of XACML, as described in the XACML 2.0
Core Specification, with the Oracle-specific usage described in Securing WebLogic Resources Using Roles and Policies.

Policies are expressed as XACML 2.0 Policy or PolicySet documents. Custom Authorization providers should expect standard Policy or PolicySet documents as described in the XACML 2.0 Core Specification. Custom Role Mapping providers should expect Policy or PolicySet documents consistent with role assignment policies described by the Core and hierarchical role based access control (RBAC) profile of XACML v2.0.

Specifically, the Target must contain:

- An ActionAttributeDesignator with the id, urn:oasis:names:tc:xacml:1.0:action:action-id, and the value, urn:oasis:names:tc:xacml:2.0:actions:enableRole, according to anyURI-equal. For example:

```
<Action>
<ActionMatch MatchId="urn:oasis:names:tc:xacml:1.0:function:anyURI-equal">
  <AttributeValue
    DataType="http://www.w3.org/2001/XMLSchema#anyURI">
    urn:oasis:names:tc:xacml:2.0:actions:enableRole
  </AttributeValue>
  <ActionAttributeDesignator
    AttributeId="urn:oasis:names:tc:xacml:1.0:action:action-id"
    DataType="http://www.w3.org/2001/XMLSchema#anyURI" MustBePresent="true"/>
</ActionMatch>
</Action>
```

- A ResourceAttributeDesignator with the id, urn:oasis:names:tc:xacml:2.0:subject:role, and a value naming the role being assigned, according to string-equal. For example:

```
<ResourceAttributeDesignator
  AttributeId="urn:oasis:names:tc:xacml:2.0:resource:resource-ancestor-or-self" DataType="http://www.w3.org/2001/XMLSchema#string" MustBePresent="true"/>
```
Examining the Format of a XACML Policy File

The XACML 2.0 Core Specification and the Oracle extensions described in Securing WebLogic Resources Using Roles and Policies are the definitive sources of information for the XACML policy files used by the supplied XACML Authorization and Role Mapping Providers.

However, if as part of your development process you want to take a look at the format of a supported XACML file, perhaps the most convenient way is to use the Administration Console to export the data from the XACML Authorization or Role Mapping provider’s database as a XACML file. Copy this exported XACML file to a file with some other name and use the tool of your choice to review the copy.

**Note:** Treat the exported file as read-only. If you do make changes, do not import the file back into WebLogic Server. Editing exported files might result in an unusable WebLogic Server configuration and is not supported.

Using WLST to Add a Policy to the PolicyStoreMBean

Listing 7-3 shows an example of using WLST to add a single policy to an instance of the PolicyStoreMBean from a XACML file.

The example assumes that you have defined the properties used in this script elsewhere, in a manner similar to the following lines from an ant script:

```
<property name="xacml-docs-dir" value="${xacmldir}/xacml-docs"/>
<sysproperty key="file" value="${xacml-docs-dir}/policy-getSubject.xacml"/>
```

Listing 7-3  Using WLST to Add a Policy to the PolicyStoreMBean

```java
try:
    protocol = System.getProperty("protocol")
    host = System.getProperty("host")
    user = System.getProperty("authuser")
    passwd = System.getProperty("authpwd")
    port = System.getProperty("port")
    dom = System.getProperty("domain")
    rlm = System.getProperty("realm")
    fil = System.getProperty("file")
    prov = System.getProperty("provider")
    stat = System.getProperty("status")
```
As described in the Navigating and Interrogating MBeans section of WebLogic Scripting Tool, when WLST first connects to an instance of WebLogic Server, the variable, cmo (Current Management Object), is initialized to the root of all configuration management objects, DomainMBean. When you navigate to an MBean type, in this case SecurityConfigurationMBean, the value of cmo reflects SecurityConfigurationMBean. When you navigate to an MBean instance, in this case to an Authorizer MBean that implements the PolicyStoreMBean, identified in the example by the variable prov, WLST changes the value of cmo to be the current MBean instance.

The example uses the addPolicy() method of the PolicyStoreMBean to add a policy read from a XACML file to the policy store. Two variants of the addPolicy() method (without and with status) are shown.

If you use an addPolicy() method that does not specify status, it defaults to ACTIVE, which indicates that the policy is evaluated for any decision to which its target applies. You can explicitly set status to be ACTIVE, INACTIVE, or BYREFERENCE. The INACTIVE status indicates that the policy will never be evaluated and is only being stored. The BYREFERENCE status indicates that the policy will only be evaluated when referenced by a policy set that is being evaluated.
You can invoke this type of WLST script from the command line, in a manner similar to the following:

```java
java -Dhost="localhost " -Dprotocol="t3" -Dauthuser="weblogic" -Dauthpwd="weblogic" -Dport="7001" -Ddomain="mydomain" -Drealm="myrealm" -Dprovider="Authorizers/XACMLAuthorizer" -Dfile="C:/XACML/xacml-docs/policy12.xml" -Dstatus="none" weblogic.WLST XACML/scripts/XACMLaddPolicy.py
```

**Using WLST to Read a PolicySet as a String**

Listing 7-4 shows an example of using WLST to read a PolicySet as a string.

The example assumes that you have defined the properties used in this script elsewhere, in a manner similar to the following lines from an `ant` script:

```xml
<sysproperty key="identifier" value="urn:sample:xacml:2.0:wlssecqa:resource:type@E@Fejb@G@M@Oapplication@ENo
D@DRolesOrPoliciesEar@M@Omodule@Eejb11inEarMiniAppBean.jar@M@Oejb@EMiniAppBean@ M@Omethod@EgetSubject@M@OmethodInterface@ERemote"/>
<sysproperty key="version" value="1.0"/>
```

**Listing 7-4  Using WLST to Read a PolicySet as a String**

```python
: :
try:

    print("start XACMLreadPolicySet.py")
    protocol = System.getProperty("protocol")
    host = System.getProperty("host")
    user = System.getProperty("authuser")
    passwd = System.getProperty("authpwd")
    port = System.getProperty("port")
    dom = System.getProperty("domain")
    rlm = System.getProperty("realm")
    prov = System.getProperty("provider")
    id = System.getProperty("identifier")
    vers = System.getProperty("version")

: :
def configure():

    try:
```
url = protocol + "://" + host + ":" + port
connect(user, passwd, url)
path = "/SecurityConfiguration/" + dom + "/Realms/" + rlm + "/" + prov
print("cd'ing to " + path)
cd(path)
polset = cmo.readPolicySetAsString(id, vers)
print("readPolicySetAsString() returned the following policy set: " + polset)
print("Add error handling.")

As described in the XACML 2.0 Core Specification, the <PolicySet> element contains a set of <Policy> or other <PolicySet> elements and a specified procedure for combining the results of their evaluation. See the XACML 2.0 Core Specification for complete information.

**Bulk Authorization Providers**

This release of WebLogic Server includes bulk access versions of the following Authorization provider SSPI interfaces:

- BulkAuthorizationProvider
- BulkAccessDecision

The bulk access SSPI interfaces allow Authorization providers to receive multiple decision requests in one call rather than through multiple calls, typically in a 'for' loop. The intent of the bulk SSPI variants is to allow provider implementations to take advantage of internal performance optimizations, such as detecting that many of the passed-in Resource objects are protected by the same policy and will generate the same decision result.

There are subtle differences in how the non-bulk and bulk versions of the SSPI interfaces are used.

**Note** that the BulkAccessDecision.isAccessAllowed() method takes a Map of roles, indexed first by Resource object and then by role name (Map<Resource, Map<String, SecurityRole>> roles), that are associated with the subject and should be taken into consideration when making the authorization decision.

**The** BulkAccessDecision.isAccessAllowed() **method returns** a Map (indexed by Resource, result) that indicates whether the authorization policies defined for the resources allow the requested methods to be performed.
Generate an MBean Type Using the WebLogic MBeanMaker

Before you start generating an MBean type for your custom security provider, you should first:

- “Understand Why You Need an MBean Type” on page 3-11
- “Determine Which SSPI MBeans to Extend and Implement” on page 3-11
- “Understand the Basic Elements of an MBean Definition File (MDF)” on page 3-12
- “Understand the SSPI MBean Hierarchy and How It Affects the Administration Console” on page 3-15
- “Understand What the WebLogic MBeanMaker Provides” on page 3-17

When you understand this information and have made your design decisions, create the MBean type for your custom Authorization provider by following these steps:

1. “Create an MBean Definition File (MDF)” on page 7-27
2. “Use the WebLogic MBeanMaker to Generate the MBean Type” on page 7-28
3. “Use the WebLogic MBeanMaker to Create the MBean JAR File (MJF)” on page 7-31
4. “Install the MBean Type Into the WebLogic Server Environment” on page 7-32

Notes: All instructions provided in this section assume that you are working in a Windows environment.

Create an MBean Definition File (MDF)

To create an MBean Definition File (MDF), follow these steps:

1. Copy the MDF for the sample Authorization provider to a text file.
   
   Note: The MDF for the sample Authorization provider is called SimpleSampleAuthorizer.xml.

2. Modify the content of the <MBeanType> and <MBeanAttribute> elements in your MDF so that they are appropriate for your custom Authorization provider.

3. Add any custom attributes and operations (that is, additional <MBeanAttribute> and <MBeanOperation> elements) to your MDF.

4. Save the file.
Use the WebLogic MBeanMaker to Generate the MBean Type

Once you create your MDF, you are ready to run it through the WebLogic MBeanMaker. The WebLogic MBeanMaker is currently a command-line utility that takes as its input an MDF, and outputs some intermediate Java files, including an MBean interface, an MBean implementation, and an associated MBean information file. Together, these intermediate files form the MBean type for your custom security provider.

The instructions for generating an MBean type differ based on the design of your custom Authorization provider. Follow the instructions that are appropriate to your situation:

- “No Optional SSPI MBeans and No Custom Operations” on page 7-28
- “Optional SSPI MBeans or Custom Operations” on page 7-29

No Optional SSPI MBeans and No Custom Operations

If the MDF for your custom Authorization provider does not implement any optional SSPI MBeans and does not include any custom operations, follow these steps:

1. Create a new DOS shell.
2. Type the following command:

   java -DMDF=xmlFile -Dfiles=filesdir -DcreateStubs=true
   weblogic.management.commo.WebLogicMBeanMaker

   where the -DMDF flag indicates that the WebLogic MBeanMaker should translate the MDF into code, xmlFile is the MDF (the XML MBean Description File) and filesdir is the location where the WebLogic MBeanMaker will place the intermediate files for the MBean type.

   Whenever xmlFile is provided, a new set of output files is generated.

   Each time you use the -DcreateStubs=true flag, it overwrites any existing MBean implementation file.

   Note: As of version 9.0 of WebLogic Server, you can also provide a directory that contains multiple MDF's by using the -DMDFDIR <MDF directory name> option. In prior versions of WebLogic Server, the WebLogic MBeanMaker processed only one MDF at a time. Therefore, you had to repeat this process if you had multiple MDFs (in other words, multiple Authorization providers).
3. Proceed to “Use the WebLogic MBeanMaker to Create the MBean JAR File (MJF)” on page 7-31.

Optional SSPI MBeans or Custom Operations

If the MDF for your custom Authorization provider does implement some optional SSPI MBeans or does include custom operations, consider the following:

- Are you creating an MBean type for the first time? If so, follow these steps:
  1. Create a new DOS shell.
  2. Type the following command:

    ```
    java -DMDF=xmlfile -Dfiles=filesdir -DcreateStubs=true
    weblogic.management.commo.WebLogicMBeanMaker
    ```

    where the `-DMDF` flag indicates that the WebLogic MBeanMaker should translate the MDF into code, `xmlFile` is the MDF (the XML MBean Description File) and `filesdir` is the location where the WebLogic MBeanMaker will place the intermediate files for the MBean type.

    Whenever `xmlfile` is provided, a new set of output files is generated.

    Each time you use the `-DcreateStubs=true` flag, it overwrites any existing MBean implementation file.

    **Note:** As of version 9.0 of WebLogic Server, you can also provide a directory that contains multiple MDF's by using the `-DMDFDIR <MDF directory name>` option. In prior versions of WebLogic Server, the WebLogic MBeanMaker processed only one MDF at a time. Therefore, you had to repeat this process if you had multiple MDFs (in other words, multiple Authorization providers).

3. If you implemented optional SSPI MBeans in your MDF, follow these steps:
   a. Locate the MBean implementation file.

      The MBean implementation file generated by the WebLogic MBeanMaker is named `MBeanNameImpl.java`. For example, for the MDF named `SampleAuthorizer`, the MBean implementation file to be edited is named `SampleAuthorizerImpl.java`.

   b. For each optional SSPI MBean that you implemented in your MDF, implement each method. Be sure to also provide implementations for any methods that the optional SSPI MBean inherits.

4. If you included any custom operations in your MDF, implement the methods using the method stubs.
5. Save the file.

6. Proceed to “Use the WebLogic MBeanMaker to Create the MBean JAR File (MJF)” on page 7-31.

- Are you updating an existing MBean type? If so, follow these steps:

1. Copy your existing MBean implementation file to a temporary directory so that your current method implementations are not overwritten by the WebLogic MBeanMaker.

2. Create a new DOS shell.

3. Type the following command:

   ```java
   java -DMDF=xmlFile -Dfiles=filesdir -DcreateStubs=true
default.weblogic.management.commo.WebLogicMBeanMaker
   
   ```

   where the `-DMDF` flag indicates that the WebLogic MBeanMaker should translate the MDF into code, `xmlFile` is the MDF (the XML MBean Description File) and `filesdir` is the location where the WebLogic MBeanMaker will place the intermediate files for the MBean type.

   Whenever `xmlfile` is provided, a new set of output files is generated.

   Each time you use the `-DcreateStubs=true` flag, it overwrites any existing MBean implementation file.

   **Note:** As of version 9.0 of WebLogic Server, you can also provide a directory that contains multiple MDF's by using the `-DMDFDIR <MDF directory name>` option. In prior versions of WebLogic Server, the WebLogic MBeanMaker processed only one MDF at a time. Therefore, you had to repeat this process if you had multiple MDFs (in other words, multiple Authorization providers).

4. If you implemented optional SSPI MBeans in your MDF, follow these steps:

   a. Locate the MBean implementation file.

      The MBean implementation file generated by the WebLogic MBeanMaker is named `MBeanNameImpl.java`. For example, for the MDF named `SampleAuthorizer`, the MBean implementation file to be edited is named `SampleAuthorizerImpl.java`.

   b. Open your existing MBean implementation file (which you saved to a temporary directory in step 1).

   c. Synchronize the existing MBean implementation file with the MBean implementation file generated by the WebLogic MBeanMaker.
Accomplishing this task may include, but is not limited to: copying the method implementations from your existing MBean implementation file into the newly-generated MBean implementation file (or, alternatively, adding the new methods from the newly-generated MBean implementation file to your existing MBean implementation file), and verifying that any changes to method signatures are reflected in the version of the MBean implementation file that you are going to use (for methods that exist in both MBean implementation files).

d. If you modified the MDF to implement optional SSPI MBeans that were not in the original MDF, implement each method. Be sure to also provide implementations for any methods that the optional SSPI MBean inherits.

5. If you modified the MDF to include any custom operations that were not in the original MDF, implement the methods using the method stubs.

6. Save the version of the MBean implementation file that is complete (that is, has all methods implemented).

7. Copy this MBean implementation file into the directory where the WebLogic MBeanMaker placed the intermediate files for the MBean type. You specified this as filesdir in step 3. (You will be overriding the MBean implementation file generated by the WebLogic MBeanMaker as a result of step 3.)

8. Proceed to “Use the WebLogic MBeanMaker to Create the MBean JAR File (MJF)” on page 7-31.

About the Generated MBean Interface File

The MBean interface file is the client-side API to the MBean that your runtime class or your MBean implementation will use to obtain configuration data. It is typically used in the initialize method as described in “Understand the Purpose of the “Provider” SSPIs” on page 3-3.

Because the WebLogic MBeanMaker generates MBean types from the MDF you created, the generated MBean interface file will have the name of the MDF, plus the text “MBean” appended to it. For example, the result of running the SampleAuthorizer MDF through the WebLogic MBeanMaker will yield an MBean interface file called SampleAuthorizerMBean.java.

Use the WebLogic MBeanMaker to Create the MBean JAR File (MJF)

Once your have run your MDF through the WebLogic MBeanMaker to generate your intermediate files, and you have edited the MBean implementation file to supply implementations for the appropriate methods within it, you need to package the MBean files and the runtime
classes for the custom Authorization provider into an MBean JAR File (MJF). The WebLogic MBeanMaker also automates this process.

To create an MJF for your custom Authorization provider, follow these steps:

1. Create a new DOS shell.
2. Type the following command:
   
   ```
   java -DMJF=jarfile -Dfiles=filesdir
   weblogic.management.commo.WebLogicMBeanMaker
   
   where the -DMJF flag indicates that the WebLogic MBeanMaker should build a JAR file containing the new MBean types, `jarfile` is the name for the MJF and `filesdir` is the location where the WebLogic MBeanMaker looks for the files to JAR into the MJF.
   
   Compilation occurs at this point, so errors are possible. If `jarfile` is provided, and no errors occur, an MJF is created with the specified name.
   
   Notes: When you create a JAR file for a custom security provider, a set of XML binding classes and a schema are also generated. You can choose a namespace to associate with that schema. Doing so avoids the possibility that your custom classes will conflict with those provided by Oracle. The default for the namespace is `vendor`. You can change this default by passing the `-targetNamespace` argument to the WebLogicMBeanMaker or the associated WLMBeanMaker ant task.
   
   If you want to update an existing MJF, simply delete the MJF and regenerate it. The WebLogic MBeanMaker also has a `-DIncludeSource` option, which controls whether source files are included into the resulting MJF. Source files include both the generated source and the MDF itself. The default is `false`. This option is ignored when `-DMJF` is not used.

   The resulting MJF can be installed into your WebLogic Server environment, or distributed to your customers for installation into their WebLogic Server environments.

   **Install the MBean Type Into the WebLogic Server Environment**

   To install an MBean type into the WebLogic Server environment, copy the MJF into the `WL_HOME\server\lib\mbeantypes` directory, where `WL_HOME` is the top-level installation directory for WebLogic Server. This “deploys” your custom Authorization provider—that is, it makes the custom Authorization provider manageable from the WebLogic Server Administration Console.
How to Develop a Custom Authorization Provider

Note:  `WL_HOME\server\lib\mbeantypes` is the default directory for installing MBean types. (Beginning with 9.0, security providers can be loaded from `...\domaindir\lib\mbeantypes` as well.) However, if you want WebLogic Server to look for MBean types in additional directories, use the `-Dweblogic.alternateTypesDirectory=<dir>` command-line flag when starting your server, where `<dir>` is a comma-separated list of directory names. When you use this flag, WebLogic Server will always load MBean types from `WL_HOME\server\lib\mbeantypes` first, then will look in the additional directories and load all valid archives present in those directories (regardless of their extension). For example, if `-Dweblogic.alternateTypesDirectory = dirX,dirY`, WebLogic Server will first load MBean types from `WL_HOME\server\lib\mbeantypes`, then any valid archives present in `dirX` and `dirY`. If you instruct WebLogic Server to look in additional directories for MBean types and are using the Java Security Manager, you must also update the `weblogic.policy` file to grant appropriate permissions for the MBean type (and thus, the custom security provider). For more information, see "Using the Java Security Manager to Protect WebLogic Resources" in Programming WebLogic Security.

You can create instances of the MBean type by configuring your custom Authorization provider (see “Configure the Custom Authorization Provider Using the Administration Console” on page 7-33), and then use those MBean instances from a GUI, from other Java code, or from APIs. For example, you can use the WebLogic Server Administration Console to get and set attributes and invoke operations, or you can develop other Java objects that instantiate MBeans and automatically respond to information that the MBeans supply. We recommend that you back up these MBean instances.

Configure the Custom Authorization Provider Using the Administration Console

Configuring a custom Authorization provider means that you are adding the custom Authorization provider to your security realm, where it can be accessed by applications requiring authorization services.

Configuring custom security providers is an administrative task, but it is a task that may also be performed by developers of custom security providers. This section contains information that is important for the person configuring your custom Authorization providers:

- “Managing Authorization Providers and Deployment Descriptors” on page 7-34
- “Enabling Security Policy Deployment” on page 7-35

Developing Security Providers for WebLogic Server 7-33
Authorization Providers

Note: The steps for configuring a custom Authorization provider using the WebLogic Server Administration Console are described under “Configuring WebLogic Security Providers” in Securing WebLogic Server.

Managing Authorization Providers and Deployment Descriptors

Some application components, such as Enterprise JavaBeans (EJBs) and Web applications, store relevant deployment information in Java EE and WebLogic Server deployment descriptors. For Web applications, the deployment descriptor files (called web.xml and weblogic.xml) contain information for implementing the Java EE security model, including declarations of security policies. Typically, you will want to include this information when first configuring your Authorization providers in the WebLogic Server Administration Console.

Because the Java EE platform standardizes Web application and EJB security in deployment descriptors, WebLogic Server integrates this standard mechanism with its Security Service to give you a choice of techniques for securing Web application and EJB resources. You can use deployment descriptors exclusively, the Administration Console exclusively, or you can combine the techniques for certain situations.

Depending on the technique you choose, you also need to apply a Security Model. WebLogic supports different security models for individual deployments, and a security model for realm-wide configurations that incorporate the technique you want to use.

When configured to use deployment descriptors, WebLogic Server reads security policy information from the web.xml and weblogic.xml deployment descriptor files (examples of web.xml and weblogic.xml files are shown in Listing 7-5 and Listing 7-6). This information is then copied into the security provider database for the Authorization provider.

Listing 7-5  Sample web.xml File

```xml
<web-app>

  <welcome-file-list>
    <welcome-file>welcome.jsp</welcome-file>
  </welcome-file-list>

  <security-constraint>
    <web-resource-collection>
      <web-resource-name>Success</web-resource-name>
      <url-pattern>/welcome.jsp</url-pattern>
      <http-method>GET</http-method>
    </web-resource-collection>

<web-app>
```
How to Develop a Custom Authorization Provider

Developing Security Providers for WebLogic Server

  </security-role-assignment>
</weblogic-web-app>

Enabling Security Policy Deployment

If you implemented the DeployableAuthorizationProviderV2 SSPI as part of developing your custom Authorization provider and want to support deployable security policies, the person configuring the custom Authorization provider (that is, you or an administrator) must be sure that the Policy Deployment Enabled check box in the WebLogic Server Administration Console is checked. Otherwise, deployment for the Authorization provider is considered “turned off.” Therefore, if multiple Authorization providers are configured, the Policy Deployment Enabled check box can be used to control which Authorization provider is used for security policy deployment.
Provide a Mechanism for Security Policy Management

While configuring a custom Authorization provider via the WebLogic Server Administration Console makes it accessible by applications requiring authorization services, you also need to supply administrators with a way to manage this security provider’s associated security policies. The WebLogic Authorization provider, for example, supplies administrators with a Policy Editor page that allows them to add, modify, or remove security policies for various WebLogic resources.

Neither the Policy Editor page nor access to it is available to administrators when you develop a custom Authorization provider. Therefore, you must provide your own mechanism for security policy management. This mechanism must read and write security policy data (that is, expressions) to and from the custom Authorization provider’s database.

You can accomplish this task in one of three ways:

- “Option 1: Develop a Stand-Alone Tool for Security Policy Management” on page 7-36
- “Option 2: Integrate an Existing Security Policy Management Tool into the Administration Console” on page 7-36

**Option 1: Develop a Stand-Alone Tool for Security Policy Management**

You would typically select this option if you want to develop a tool that is entirely separate from the WebLogic Server Administration Console.

For this option, you do not need to write any console extensions for your custom Authorization provider, nor do you need to develop any management MBeans. However, your tool needs to:

1. Determine the WebLogic resource’s ID, since it is not automatically provided to you by the console extension. For more information, see “WebLogic Resource Identifiers” on page 3-30.

2. Determine how to represent the expressions that make up a security policy. (This representation is entirely up to you and need not be a string.)

3. Read and write the expressions from and to the custom Authorization provider’s database.

**Option 2: Integrate an Existing Security Policy Management Tool into the Administration Console**

You would typically select this option if you have a tool that is separate from the WebLogic Server Administration Console, but you want to launch that tool from the Administration Console.
For this option, your tool needs to:

1. Determine the WebLogic resource’s ID, since it is not automatically provided to you by the console extension. For more information, see “WebLogic Resource Identifiers” on page 3-30.

2. Determine how to represent the expressions that make up a security policy. (This representation is entirely up to you and need not be a string.)

3. Read and write the expressions from and to the custom Authorization provider’s database.

4. Link into the Administration Console using basic console extension techniques, as described in Extending the Administration Console.
Adjudication Providers

Adjudication involves resolving any authorization conflicts that may occur when more than one Authorization provider is configured, by weighing the result of each Authorization provider’s Access Decision. In WebLogic Server, an Adjudication provider is used to tally the results that multiple Access Decisions return, and determines the final PERMIT or DENY decision. An Adjudication provider may also specify what should be done when an answer of ABSTAIN is returned from a single Authorization provider’s Access Decision.

The following sections describe Adjudication provider concepts and functionality, and provide step-by-step instructions for developing a custom Adjudication provider:

- “The Adjudication Process” on page 8-1
- “Do You Need to Develop a Custom Adjudication Provider?” on page 8-1
- “How to Develop a Custom Adjudication Provider” on page 8-3

The Adjudication Process

The use of Adjudication providers is part of the authorization process, and is described in “The Authorization Process” on page 7-2.

Do You Need to Develop a Custom Adjudication Provider?

The default (that is, active) security realm for WebLogic Server includes a WebLogic Adjudication provider. The WebLogic Adjudication provider is responsible for adjudicating between potentially differing results rendered by multiple Authorization providers’ Access
Developing Security Providers for WebLogic Server

Adjudication Providers

Decisions, and rendering a final verdict on whether or not access will be granted to a WebLogic resource.

The WebLogic Adjudication provider has an attribute called Require Unanimous Permit that governs its behavior. By default, the Require Unanimous Permit attribute is set to TRUE, which causes the WebLogic Adjudication provider to act as follows:

- If all the Authorization providers’ Access Decisions return PERMIT, then return a final verdict of TRUE (that is, permit access to the WebLogic resource).
- If some Authorization providers’ Access Decisions return PERMIT and others return ABSTAIN, then return a final verdict of FALSE (that is, deny access to the WebLogic resource).
- If any of the Authorization providers’ Access Decisions return ABSTAIN or DENY, then return a final verdict of FALSE (that is, deny access to the WebLogic resource).

If you change the Require Unanimous Permit attribute to FALSE, the WebLogic Adjudication provider acts as follows:

- If all the Authorization providers’ Access Decisions return PERMIT, then return a final verdict of TRUE (that is, permit access to the WebLogic resource).
- If some Authorization providers’ Access Decisions return PERMIT and others return ABSTAIN, then return a final verdict of TRUE (that is, permit access to the WebLogic resource).
- If any of the Authorization providers’ Access Decisions return DENY, then return a final verdict of FALSE (that is, deny access to the WebLogic resource).

**Note:** You set the Require Unanimous Permit attributes when you configure the WebLogic Adjudication provider. For more information about configuring the WebLogic Adjudication provider, see “Configuring the WebLogic Adjudication Provider” in Securing WebLogic Server.

If you want an Adjudication provider that behaves in a way that is different from what is described above, then you need to develop a custom Adjudication provider. (Keep in mind that an Adjudication provider may also specify what should be done when an answer of ABSTAIN is returned from a single Authorization provider’s Access Decision, based on your specific security requirements.)
How to Develop a Custom Adjudication Provider

If the WebLogic Adjudication provider does not meet your needs, you can develop a custom Adjudication provider by following these steps:

1. “Create Runtime Classes Using the Appropriate SSPIs” on page 8-3, or, optionally, use the “Bulk Adjudication Providers” on page 8-4
2. “Generate an MBean Type Using the WebLogic MBeanMaker” on page 8-5
3. “Configure the Custom Adjudication Provider Using the Administration Console” on page 8-11

Create Runtime Classes Using the Appropriate SSPIs

Before you start creating runtime classes, you should first:

- “Understand the Purpose of the “Provider” SSPIs” on page 3-3
- “Understand the SSPI Hierarchy and Determine Whether You Will Create One or Two Runtime Classes” on page 3-7

When you understand this information and have made your design decisions, create the runtime classes for your custom Adjudication provider by following these steps:

- “Implement the AdjudicationProviderV2 SSPI” on page 8-3
- “Implement the AdjudicatorV2 SSPI” on page 8-4

Implement the AdjudicationProviderV2 SSPI

To implement the AdjudicationProviderV2 SSPI, provide implementations for the methods described in “Understand the Purpose of the “Provider” SSPIs” on page 3-3 and the following method:

getAdjudicator

```java
public AdjudicatorV2 getAdjudicator()
```

The getAdjudicator method obtains the implementation of the AdjudicatorV2 SSPI. For a single runtime class called MyAdjudicationProviderImpl.java, the implementation of the getAdjudicator method would be:

```java
return this;
```
If there are two runtime classes, then the implementation of the `getAdjudicator` method could be:

```java
return new MyAdjudicatorImpl;
```

This is because the runtime class that implements the `AdjudicationProviderV2` SSPI is used as a factory to obtain classes that implement the `AdjudicatorV2` SSPI.

For more information about the `AdjudicationProviderV2` SSPI and the `getAdjudicator` method, see the *WebLogic Server API Reference Javadoc*.

### Implement the AdjudicatorV2 SSPI

To implement the `AdjudicatorV2` SSPI, provide implementations for the following methods:

**initialize**

```java
public void initialize(AuthorizerMBean[] accessDecisionClassNames)
```

The `initialize` method initializes the names of all the configured Authorization providers’ Access Decisions that will be called to supply a result for the “is access allowed?” question. The `accessDecisionClassNames` parameter may also be used by an Adjudication provider in its `adjudicate` method to favor a result from a particular Access Decision. For more information about Authorization providers and Access Decisions, see Chapter 7, “Authorization Providers.”

**adjudicate**

```java
public boolean adjudicate(Result[] results, Resource resource, ContextHandler handler)
```

The `adjudicate` method determines the answer to the “is access allowed?” question, given all the results from the configured Authorization providers’ Access Decisions. For more information about the `Adjudicator` SSPI and the `initialize` and `adjudicate` methods, see the *WebLogic Server API Reference Javadoc*.

### Bulk Adjudication Providers

This release of WebLogic Server includes bulk access versions of the following Adjudication provider SSPI interfaces:

- `BulkAdjudicationProvider`
- `BulkAdjudicator`

The bulk access SSPI interfaces allow Adjudication providers to receive multiple decision requests in one call rather than through multiple calls, typically in a 'for' loop. The intent of the
bulk SSPI variants is to allow provider implementations to take advantage of internal performance optimizations, such as detecting that many of the passed-in Resource objects are protected by the same policy and will generate the same decision result.

There are subtle differences in how the non-bulk and bulk versions of the SSPI interfaces are used.

The `BulkAdjudicator.adjudicate()` method takes a List of Map (Resource, Result) instances, as passed in by the WebLogic Server Authorization Manager, which contain the results of each bulk access decision. The order of results is the same as the order of the Access Decision class names that were passed in the `BulkAdjudicator.initialize()` method.

Note too that the `BulkAdjudicator.adjudicate()` method returns a Set of Resource objects. If a Resource object is present in the set, access has been granted for that object; otherwise, access has been denied.

**Generate an MBean Type Using the WebLogic MBeanMaker**

Before you start generating an MBean type for your custom security provider, you should first:

- “Understand Why You Need an MBean Type” on page 3-11
- “Determine Which SSPI MBeans to Extend and Implement” on page 3-11
- “Understand the Basic Elements of an MBean Definition File (MDF)” on page 3-12
- “Understand the SSPI MBean Hierarchy and How It Affects the Administration Console” on page 3-15
- “Understand What the WebLogic MBeanMaker Provides” on page 3-17

When you understand this information and have made your design decisions, create the MBean type for your custom Adjudication provider by following these steps:

1. “Create an MBean Definition File (MDF)” on page 8-6
2. “Use the WebLogic MBeanMaker to Generate the MBean Type” on page 8-6
3. “Use the WebLogic MBeanMaker to Create the MBean JAR File (MJF)” on page 8-9
4. Install the MBean Type Into the WebLogic Server Environment
Notes: All instructions provided in this section assume that you are working in a Windows environment.

Create an MBean Definition File (MDF)

To create an MBean Definition File (MDF), follow these steps:

1. Copy the MDF for the sample Authentication provider to a text file.
   
   Note: The MDF for the sample Authentication provider is called SampleAuthenticator.xml. (There is currently no sample Adjudication provider.)

2. Modify the content of the <MBeanType> and <MBeanAttribute> elements in your MDF so that they are appropriate for your custom Adjudication provider.

3. Add any custom attributes and operations (that is, additional <MBeanAttribute> and <MBeanOperation> elements) to your MDF.

4. Save the file.

   Note: A complete reference of MDF element syntax is available in Appendix A, “MBean Definition File (MDF) Element Syntax.”

Use the WebLogic MBeanMaker to Generate the MBean Type

Once you create your MDF, you are ready to run it through the WebLogic MBeanMaker. The WebLogic MBeanMaker is currently a command-line utility that takes as its input an MDF, and outputs some intermediate Java files, including an MBean interface, an MBean implementation, and an associated MBean information file. Together, these intermediate files form the MBean type for your custom security provider.

The instructions for generating an MBean type differ based on the design of your custom Adjudication provider. Follow the instructions that are appropriate to your situation:

- “No Custom Operations” on page 8-6
- “Custom Operations” on page 8-7

No Custom Operations

If the MDF for your custom Adjudication provider does not include any custom operations, follow these steps:

1. Create a new DOS shell.
2. Type the following command:

   java -DMDF=xmlfile -Dfiles=filesdir -DcreateStubs=true
   weblogic.management.commo.WebLogicMBeanMaker

   where the -DMDF flag indicates that the WebLogic MBeanMaker should translate the MDF
   into code, xmlFile is the MDF (the XML MBean Description File) and filesdir is the
   location where the WebLogic MBeanMaker will place the intermediate files for the MBean
   type.

   Whenever xmlfile is provided, a new set of output files is generated.

   Each time you use the -DcreateStubs=true flag, it overwrites any existing MBean
   implementation file.

   **Note:** The WebLogic MBeanMaker processes one MDF at a time. Therefore, you may have
   to repeat this process if you have multiple MDFs (in other words, multiple
   Adjudication providers).

3. Proceed to “Use the WebLogic MBeanMaker to Create the MBean JAR File (MJF)” on
   page 8-9.

**Custom Operations**

If the MDF for your custom Adjudication provider does include custom operations, consider the
following:

- Are you creating an MBean type for the first time? If so, follow these steps:

  1. Create a new DOS shell.

   2. Type the following command:

      java -DMDF=xmlfile -Dfiles=filesdir -DcreateStubs=true
      weblogic.management.commo.WebLogicMBeanMaker

      where the -DMDF flag indicates that the WebLogic MBeanMaker should translate the MDF
      into code, xmlFile is the MDF (the XML MBean Description File) and filesdir is the
      location where the WebLogic MBeanMaker will place the intermediate files for the MBean
      type.

      Whenever xmlfile is provided, a new set of output files is generated.

      Each time you use the -DcreateStubs=true flag, it overwrites any existing MBean
      implementation file.

      **Note:** As of version 9.0 of WebLogic Server, you can also provide a directory that contains
      multiple MDF's by using the -DMDFDIR <MDF directory name> option. In prior
Adjudication Providers

versions of WebLogic Server, the WebLogic MBeanMaker processed only one MDF at a time. Therefore, you had to repeat this process if you had multiple MDFs (in other words, multiple Adjudication providers).

3. For any custom operations in your MDF, implement the methods using the method stubs.

4. Save the file.

5. Proceed to “Use the WebLogic MBeanMaker to Create the MBean JAR File (MJF)” on page 8-9.

- Are you updating an existing MBean type? If so, follow these steps:

1. Copy your existing MBean implementation file to a temporary directory so that your current method implementations are not overwritten by the WebLogic MBeanMaker.

2. Create a new DOS shell.

3. Type the following command:

```
java -DMDF=xmlfile -Dfiles=filesdir -DcreateStubs=true
weblogic.management.commo.WebLogicMBeanMaker
```

where the -DMDF flag indicates that the WebLogic MBeanMaker should translate the MDF into code, xmlFile is the MDF (the XML MBean Description File) and filesdir is the location where the WebLogic MBeanMaker will place the intermediate files for the MBean type.

Whenever xmlfile is provided, a new set of output files is generated.

Each time you use the -DcreateStubs=true flag, it overwrites any existing MBean implementation file.

Note: As of version 9.0 of WebLogic Server, you can also provide a directory that contains multiple MDF's by using the -DMDFDIR <MDF directory name> option. In prior versions of WebLogic Server, the WebLogic MBeanMaker processed only one MDF at a time. Therefore, you had to repeat this process if you had multiple MDFs (in other words, multiple Adjudication providers).

4. If you modified the MDF to include any custom operations that were not in the original MDF, implement the methods using the method stubs.

5. Save the version of the MBean implementation file that is complete (that is, has all methods implemented).

6. Copy this MBean implementation file into the directory where the WebLogic MBeanMaker placed the intermediate files for the MBean type. You specified this as filesdir in step 3.
How to Develop a Custom Adjudication Provider

(You will be overriding the MBean implementation file generated by the WebLogic MBeanMaker as a result of step 3.)

7. Proceed to “Use the WebLogic MBeanMaker to Create the MBean JAR File (MJF)” on page 8-9.

About the Generated MBean Interface File

The MBean interface file is the client-side API to the MBean that your runtime class or your MBean implementation will use to obtain configuration data. It is typically used in the initialize method as described in “Understand the Purpose of the “Provider” SSPIs” on page 3-3.

Because the WebLogic MBeanMaker generates MBean types from the MDF you created, the generated MBean interface file will have the name of the MDF, plus the text “MBean” appended to it. For example, the result of running the MyAdjudicator MDF through the WebLogic MBeanMaker will yield an MBean interface file called MyAdjudicatorMBean.java.

Use the WebLogic MBeanMaker to Create the MBean JAR File (MJF)

Once your have run your MDF through the WebLogic MBeanMaker to generate your intermediate files, and you have edited the MBean implementation file to supply implementations for the appropriate methods within it, you need to package the MBean files and the runtime classes for the custom Adjudication provider into an MBean JAR File (MJF). The WebLogic MBeanMaker also automates this process.

To create an MJF for your custom Adjudication provider, follow these steps:

1. Create a new DOS shell.
2. Type the following command:
   ```
   java -DMJF=jarfile -Dfiles=filesdir
   weblogic.management.commo.WebLogicMBeanMaker
   ```
   where the -DMJF flag indicates that the WebLogic MBeanMaker should build a JAR file containing the new MBean types, jarfile is the name for the MJF and filesdir is the location where the WebLogic MBeanMaker looks for the files to JAR into the MJF.

   Compilation occurs at this point, so errors are possible. If jarfile is provided, and no errors occur, an MJF is created with the specified name.

   Notes: When you create a JAR file for a custom security provider, a set of XML binding classes and a schema are also generated. You can choose a namespace to associate with that schema. Doing so avoids the possibility that your custom classes will conflict with those provided by Oracle. The default for the namespace is vendor. You can change this
default by passing the `-targetNameSpace` argument to the WebLogicMBeanMaker or the associated WLMBeanMaker ant task.

If you want to update an existing MJF, simply delete the MJF and regenerate it. The WebLogic MBeanMaker also has a `-DIncludeSource` option, which controls whether source files are included into the resulting MJF. Source files include both the generated source and the MDF itself. The default is `false`. This option is ignored when `-DMJF` is not used.

The resulting MJF can be installed into your WebLogic Server environment, or distributed to your customers for installation into their WebLogic Server environments.

**Install the MBean Type Into the WebLogic Server Environment**

To install an MBean type into the WebLogic Server environment, copy the MJF into the `WL_HOME\server\lib\mbeantypes` directory, where `WL_HOME` is the top-level installation directory for WebLogic Server. This “deploys” your custom Adjudication provider—that is, it makes the custom Adjudication provider manageable from the WebLogic Server Administration Console.

**Note:** `WL_HOME\server\lib\mbeantypes` is the default directory for installing MBean types. (Beginning with 9.0, security providers can be loaded from `...\domaindir\lib\mbeantypes` as well.) However, if you want WebLogic Server to look for MBean types in additional directories, use the `-Dweblogic.alternateTypesDirectory=<dir>` command-line flag when starting your server, where `<dir>` is a comma-separated list of directory names. When you use this flag, WebLogic Server will always load MBean types from `WL_HOME\server\lib\mbeantypes` first, then will look in the additional directories and load all valid archives present in those directories (regardless of their extension). For example, if `-Dweblogic.alternateTypesDirectory = dirX,dirY`, WebLogic Server will first load MBean types from `WL_HOME\server\lib\mbeantypes`, then any valid archives present in `dirX` and `dirY`. If you instruct WebLogic Server to look in additional directories for MBean types and are using the Java Security Manager, you must also update the `weblogic.policy` file to grant appropriate permissions for the MBean type (and thus, the custom security provider). For more information, see “Using the Java Security Manager to Protect WebLogic Resources” in *Programming WebLogic Security*.

You can create instances of the MBean type by configuring your custom Adjudication provider (see “Configure the Custom Adjudication Provider Using the Administration Console” on page 8-11), and then use those MBean instances from a GUI, from other Java code, or from APIs. For example, you can use the WebLogic Server Administration Console to get and set attributes.
and invoke operations, or you can develop other Java objects that instantiate MBeans and automatically respond to information that the MBeans supply. We recommend that you back up these MBean instances.

**Configure the Custom Adjudication Provider Using the Administration Console**

Configuring a custom Adjudication provider means that you are adding the custom Adjudication provider to your security realm, where it can be accessed by applications requiring adjudication services.

Configuring custom security providers is an administrative task, but it is a task that may also be performed by developers of custom security providers. The steps for configuring a custom Adjudication provider using the WebLogic Server Administration Console are described under “Configuring WebLogic Security Providers” in *Securing WebLogic Server*. 
Role Mapping Providers

**Role mapping** is the process whereby principals (users or groups) are dynamically mapped to security roles at runtime. In WebLogic Server, a Role Mapping provider determines what security roles apply to the principals stored a subject when the subject is attempting to perform an operation on a WebLogic resource. Because this operation usually involves gaining access to the WebLogic resource, Role Mapping providers are typically used with Authorization providers.

The following sections describe Role Mapping provider concepts and functionality, and provide step-by-step instructions for developing a custom Role Mapping provider:

- “Role Mapping Concepts” on page 9-1
- “The Role Mapping Process” on page 9-3
- “Do You Need to Develop a Custom Role Mapping Provider?” on page 9-6
- “How to Develop a Custom Role Mapping Provider” on page 9-6

### Role Mapping Concepts

Before you develop a Role Mapping provider, you need to understand the following concepts:

- “Security Roles” on page 9-2
- “Dynamic Security Role Computation” on page 9-2
- “Security Providers and WebLogic Resources” on page 3-27
Security Roles

A security role is a named collection of users or groups that have similar permissions to access WebLogic resources. Like groups, security roles allow you to control access to WebLogic resources for several users at once. However, security roles are scoped to specific resources in a WebLogic Server domain (unlike groups, which are scoped to an entire WebLogic Server domain), and can be defined dynamically (as described in “Dynamic Security Role Computation” on page 9-2).

The SecurityRole interface in the weblogic.security.service package is used to represent the abstract notion of a security role. (For more information, see the WebLogic Server API Reference Javadoc for the SecurityRole interface.)

Mapping a principal to a security role grants the defined access permissions to that principal, as long as the principal is “in” the security role. For example, an application may define a security role called AppAdmin, which provides write access to a small subset of that application's resources. Any principal in the AppAdmin security role would then have write access to those resources. For more information, see “Dynamic Security Role Computation” on page 9-2 and “Users, Groups, and Security Roles” in Securing WebLogic Resources Using Roles and Policies.

Many principals can be mapped to a single security role. For more information about principals, see “Users and Groups, Principals and Subjects” on page 4-2.

Security roles are specified in Java EE deployment descriptor files and/or in the WebLogic Server Administration Console. For more information, see “Managing Role Mapping Providers and Deployment Descriptors” on page 9-36.

Dynamic Security Role Computation

Security roles can be declarative (that is, Java 2 Enterprise Edition roles) or dynamically computed based on the context of the request.

Dynamic security role computation is the term for this late binding of principals (that is, users or groups) to security roles at runtime. The late binding occurs just prior to an authorization decision for a protected WebLogic resource, regardless of whether the principal-to-security role association is statically defined or dynamically computed. Because of its placement in the
invocation sequence, the result of any principal-to-security role computations can be taken as an authentication identity, as part of the authorization decision made for the request.

This dynamic computation of security roles provides a very important benefit: users or groups can be granted a security role based on business rules. For example, a user may be allowed to be in a Manager security role only while the actual manager is away on an extended business trip. Dynamically computing this security role means that you do not need to change or redeploy your application to allow for such a temporarily arrangement. Further, you would not need to remember to revoke the special privileges when the actual manager returns, as you would if you temporarily added the user to a Managers group.

**Note:** You typically grant users or groups security roles using the role conditions available in the WebLogic Server Administration Console. (In this release of WebLogic Server, you cannot write custom role conditions.) For more information, see “Users, Groups, and Security Roles” in *Securing WebLogic Resources Using Roles and Policies*.

The computed security role is able to access a number of pieces of information that make up the context of the request, including the identity of the target (if available) and the parameter values of the request. The context information is typically used as values of parameters in an expression that is evaluated by the WebLogic Security Framework. This functionality is also responsible for computing security roles that were statically defined through a deployment descriptor or through the WebLogic Server Administration Console.

**Notes:** The computation of security roles for an authenticated user enhances the Role-Based Access Control (RBAC) security defined by the Java EE specification.

You create dynamic security role computations by defining role statements in the WebLogic Server Administration Console. For more information, see “Users, Groups, and Security Roles” in *Securing WebLogic Resources Using Roles and Policies*.

### The Role Mapping Process

The WebLogic Security Framework calls each Role Mapping provider that is configured for a security realm as part of an authorization decision. For related information, see “The Authorization Process” on page 7-2.

The result of the dynamic security role computation (performed by the Role Mapping providers) is a set of security roles that apply to the principals stored in a subject at a given moment. These security roles can then be used to make authorization decisions for protected WebLogic resources, as well as for resource container and application code. For example, an Enterprise JavaBean (EJB) could use the Java EE isCallerInRole method to retrieve fields from a record.
Role Mapping Providers

in a database, without having knowledge of the business policies that determine whether access
is allowed.

Figure 9-1 shows how the Role Mapping providers interact with the WebLogic Security
Framework to create dynamic security role computations, and an explanation follows.

Figure 9-1  Role Mapping Providers and the Role Mapping Process

Generally, role mapping is performed in the following manner:

1. A user or system process requests a WebLogic resource on which it will attempt to perform a
given operation.

2. The resource container that handles the type of WebLogic resource being requested receives
the request (for example, the EJB container receives the request for an EJB resource).

   Note: The resource container could be the container that handles any one of the WebLogic
   Resources described in “Security Providers and WebLogic Resources” on page 3-27.

3. The resource container constructs a ContextHandler object that may be used by Role
   Mapping providers to obtain information associated with the context of the request.

   Note: For more information about ContextHandlers, see “ContextHandlers and WebLogic
   Resources” on page 3-37.
The resource container calls the WebLogic Security Framework, passing in the subject (which already contains user and group principals), an identifier for the WebLogic resource, and optionally, the ContextHandler object (to provide additional input).

**Note:** For more information about subjects, see “Users and Groups, Principals and Subjects” on page 4-2. For more information about resource identifiers, see “WebLogic Resource Identifiers” on page 3-30.

4. The WebLogic Security Framework calls each configured Role Mapping provider to obtain a list of the security roles that apply. This works as follows:

a. The Role Mapping providers use the ContextHandler to request various pieces of information about the request. They construct a set of Callback objects that represent the type of information being requested. This set of Callback objects is then passed as an array to the ContextHandler using the handle method.

   The Role Mapping providers may call the ContextHandler more than once in order to obtain the necessary context information. (The number of times a Role Mapping provider calls the ContextHandler is dependent upon its implementation.)

b. Using the context information and their associated security provider databases containing security policies, the subject, and the WebLogic resource, the Role Mapping providers determine whether the requestor (represented by the user and group principals in the subject) is entitled to a certain security role.

   The security policies are represented as a set of expressions or rules that are evaluated to determine if a given security role is to be granted. These rules may require the Role Mapping provider to substitute the value of context information obtained as parameters into the expression. In addition, the rules may also require the identity of a user or group principal as the value of an expression parameter.

   **Note:** The rules for security policies are set up in the WebLogic Server Administration Console and in Java EE deployment descriptors. For more information, see “Security Policies” in Securing WebLogic Resources Using Roles and Policies.

c. If a security policy specifies that the requestor is entitled to a particular security role, the security role is added to the list of security roles that are applicable to the subject.

d. This process continues until all security policies that apply to the WebLogic resource or the resource container have been evaluated.

5. The list of security roles is returned to the WebLogic Security Framework, where it can be used as part of other operations, such as access decisions.
Do You Need to Develop a Custom Role Mapping Provider?

The default (that is, active) security realm for WebLogic Server includes a WebLogic Role Mapping provider. The WebLogic Role Mapping provider computes dynamic security roles for a specific user (subject) with respect to a specific protected WebLogic resource for each of the default users and WebLogic resources. The WebLogic Role Mapping provider supports the deployment and undeployment of security roles within the system. The WebLogic Role Mapping provider uses the same security policy engine as the WebLogic Authorization provider. If you want to use a role mapping mechanism that already exists within your organization, you could create a custom Role Mapping provider to tie into that system.

Does Your Custom Role Mapping Provider Need to Support Application Versioning?

All Authorization, Role Mapping, and Credential Mapping providers for the security realm must support application versioning in order for an application to be deployed using versions. If you develop a custom security provider for Authorization, Role Mapping, or Credential Mapping and need to support versioned applications, you must implement the Versionable Application SSPI, as described in Chapter 14, “Versionable Application Providers.”

How to Develop a Custom Role Mapping Provider

If the WebLogic Role Mapping provider does not meet your needs, you can develop a custom Role Mapping provider by following these steps:

1. “Create Runtime Classes Using the Appropriate SSPIs” on page 9-6, or, optionally, implement the “Bulk Role Mapping Providers” on page 9-29
2. Optionally, implement the “Role Consumer SSPI” on page 9-20
3. “Generate an MBean Type Using the WebLogic MBeanMaker” on page 9-30
4. “Configure the Custom Role Mapping Provider Using the Administration Console”
5. “Provide a Mechanism for Security Role Management” on page 9-38

Create Runtime Classes Using the Appropriate SSPIs

Before you start creating runtime classes, you should first:
When you understand this information and have made your design decisions, create the runtime classes for your custom Role Mapping provider by following these steps:

- “Implement the RoleProvider SSPI” on page 9-7 or “Implement the DeployableRoleProviderV2 SSPI” on page 9-8
- “Implement the RoleMapper SSPI” on page 9-9
- “Implement the SecurityRole Interface” on page 9-11

Note: At least one Role Mapping provider in a security realm must implement the DeployableRoleProviderV2 SSPI, or else it will be impossible to deploy Web applications and EJBs.

For an example of how to create a runtime class for a custom Role Mapping provider, see “Example: Creating the Runtime Class for the Sample Role Mapping Provider” on page 9-12.

**Implement the RoleProvider SSPI**

To implement the RoleProvider SSPI, provide implementations for the methods described in “Understand the Purpose of the “Provider” SSPIs” on page 3-3 and the following method:

**getRoleMapper**

```java
public RoleMapper getRoleMapper()
```

The `getRoleMapper` method obtains the implementation of the RoleMapper SSPI. For a single runtime class called `MyRoleProviderImpl.java`, the implementation of the `getRoleMapper` method would be:

```java
return this;
```

If there are two runtime classes, then the implementation of the `getRoleMapper` method could be:

```java
return new MyRoleMapperImpl;
```

This is because the runtime class that implements the RoleProvider SSPI is used as a factory to obtain classes that implement the RoleMapper SSPI.
For more information about the RoleProvider SSPI and the getRoleMapper method, see the WebLogic Server API Reference Javadoc.

**Implement the DeployableRoleProviderV2 SSPI**

**Note:** The DeployableRoleProvider SSPI is deprecated in this release of WebLogic Server. Use the DeployableRoleProviderV2 SSPI instead.

To implement the DeployableRoleProviderV2 SSPI, provide implementations for the methods described in “Understand the Purpose of the “Provider” SSPIs” on page 3-3, “Implement the RoleProvider SSPI” on page 9-7, and the following methods:

**deleteApplicationRoles**

```java
void deleteApplicationRoles(ApplicationInfo application)
```

Deletes all roles for an application and is called only on the Administration Server within a WLS domain at the time an application is deleted.

**deployRole**

```java
void deployRole(DeployRoleHandle handle, Resource resource, String roleName, String[] userAndGroupNames)
```

Creates a role on behalf of a deployed Web application or EJB. If the role already exists, it is removed and replaced by this role.

**endDeployRoles**

```java
void endDeployRoles(DeployRoleHandle handle)
```

Marks the end of an application role deployment.

**startDeployRoles**

```java
DeployRoleHandle startDeployRoles(ApplicationInfo application)
```

Marks the beginning of an application role deployment and is called on all servers within a WebLogic Server domain where an application is targeted.

**undeployAllRoles**

```java
void undeployAllRoles(DeployRoleHandle handle)
```

Deletes a set of roles on behalf of an undeployed Web application or EJB.

For more information about the DeployableRoleProvider SSPI and the deployRole and undeployRole methods, see the WebLogic Server API Reference Javadoc.
The ApplicationInfo Interface

The ApplicationInfo interface passes data about an application deployment to a security provider. You can use this data to uniquely identify the application.

The Security Framework implements the ApplicationInfo interface for your convenience. You do not need to implement any methods for this interface.

The DeployableAuthorizationProviderV2 and DeployableRoleProviderV2 interfaces use ApplicationInfo. For example, consider an implementation of the DeployableRoleProviderV2 methods. The Security Framework calls the DeployableRoleProviderV2 startDeployRoles method and passes in the ApplicationInfo interface for this application. The ApplicationInfo data is determined based on the information supplied in the Administration Console when an application is deployed.

The startDeployRoles method returns DeployRoleHandle, which you can then use in the other DeployableRoleProviderV2 methods.

You use the ApplicationInfo interface to get the application identifier, the component name, and the component type for this application. Component type can be APPLICATION, CONTROL_RESOURCE, EJB, or WEBAPP, as defined in the ApplicationInfo.ComponentType class.

The following example shows one way to accomplish this task:

```java
public DeployRoleHandle startDeployRoles(ApplicationInfo appInfo)
    throws DeployHandleCreationException
{
    // Obtain the application information...
    String appId = appInfo.getApplicationIdentifier();
    ComponentType compType = appInfo.getComponentType();
    String compName = appInfo.getComponentName();
}
```

The Security Framework calls the DeployableRoleProviderV2 deleteApplicationRoles method and passes in the ApplicationInfo interface for this application. The deleteApplicationRoles method deletes all roles for an application and is called (only on the Administration Server within a WebLogic Server domain) at the time an application is deleted.

Implement the RoleMapper SSPI

To implement the RoleMapper SSPI, provide implementations for the following methods:
Role Mapping Providers

getRoles

```java
public Map getRoles(Subject subject, Resource resource, ContextHandler handler)
```

The `getRoles` method returns the security roles associated with a given subject for a specified WebLogic resource, possibly using the optional information specified in the `ContextHandler`. For more information about `ContextHandlers`, see “ContextHandlers and WebLogic Resources” on page 3-37.

For more information about the `RoleMapper` SSPI and the `getRoles` methods, see the WebLogic Server API Reference Javadoc.

Developing Custom Role Mapping Providers That Are Compatible With the Realm Adapter Authentication Provider

An Authentication provider is the security provider responsible for populating a subject with users and groups, which are then extracted from the subject by other types of security providers, including Role Mapping providers. If the Authentication provider configured in your security realm is a Realm Adapter Authentication provider, the user and group information will be stored in the subject in a way that is slightly different from other Authentication providers. Therefore, this user and group information must also be extracted in a slightly different way.

Listing 9-1 provides code that can be used by custom Role Mapping providers to check whether a subject matches a user or group name when a Realm Adapter Authentication provider was used to populate the subject. This code belongs in the `getRoles` method.

Listing 9-1 Sample Code to Check if a Subject Matches a User or Group Name

```java
/**
 * Determines if the Subject matches a user/group name.
 * @param principalWant A String containing the name of a principal in this role
 * (that is, the role definition).
 * @param subject A Subject that contains the Principals that identify the user
 * who is trying to access the resource as well as the user’s groups.
 * @return A boolean. true if the current subject matches the name of the
 * principal in the role, false otherwise.
 */
private boolean subjectMatches(String principalWant, Subject subject) {
    // first, see if it's a group name match
    if (SubjectUtils.isUserInGroup(subject, principalWant)) {
```
return true;
} // second, see if it's a user name match
if (principalWant.equals(SubjectUtils.getUsername(subject))) {
    return true;
} // didn't match
return false;

Implement the SecurityRole Interface

The methods on the SecurityRole interface allow you to obtain basic information about a
security role, or to compare it to another security role. These methods are designed for the
convenience of security providers.

Note: SecurityRole implementations are returned as a Map by the getRoles() method (see
“Implement the RoleMapper SSPI” on page 9-9).

To implement the SecurityRole interface, provide implementations for the following methods:

equals
    public boolean equals(Object another)

    The equals method returns TRUE if the security role passed in matches the security role
    represented by the implementation of this interface, and FALSE otherwise.

toString
    public String toString()

    The toString method returns this security role, represented as a String.

hashCode
    public int hashCode()

    The hashCode method returns a hashcode for this security role, represented as an integer.

getName
    public String getName()

    The getName method returns the name of this security role, represented as a String.

description
    public String getDescription()
Role Mapping Providers

The `getDescription` method returns a description of this security role, represented as a String. The description should describe the purpose of this security role.

**Example: Creating the Runtime Class for the Sample Role Mapping Provider**

Listing 9-2 shows the `SimpleSampleRoleMapperProviderImpl.java` class, which is the runtime class for the sample Role Mapping provider. This runtime class includes implementations for:

- The three methods inherited from the `SecurityProvider` interface: `initialize`, `getDescription` and `shutdown` (as described in “Understand the Purpose of the Provider SSPIs” on page 3-3.)

- The method inherited from the `RoleProvider` SSPI: the `getRoleMapper` method (as described in “Implement the RoleProvider SSPI” on page 9-7).

- The five methods in the `DeployableRoleProviderV2` SSPI: the `deleteApplicationRoles`, `deployRole`, `endDeployRoles`, `startDeployRoles`, and `undeployAllRoles` methods (as described in “Implement the DeployableRoleProviderV2 SSPI” on page 9-8).

- The method in the `RoleMapper` SSPI: the `getRoles` method (as described in “Implement the RoleMapper SSPI” on page 9-9).

**Note:** The bold face code in Listing 9-2 highlights the class declaration and the method signatures.

```
package examples.security.providers.roles.simple;

import java.security.Principal;

    public String getComponent() { return component; } 
    public ComponentType getComponentType() { return componentType; }

    public String toString()
    {
        String name = component;
        if (componentType == ComponentType.APPLICATION)
            name = application;
        return componentType +" "+ name +" "+ date.toString() +"]";
    }
}

Listing 9-3 shows the sample SecurityRole implementation that is used along with the SimpleSampleRoleMapperProviderImpl.java runtime class.
package examples.security.providers.roles.simple;

import weblogic.security.service.SecurityRole;

/*package*/ class SimpleSampleSecurityRoleImpl implements SecurityRole {
    private String roleName; // the role's name
    private int    hashCode; // the role's hash code

    /*package*/ SimpleSampleSecurityRoleImpl(String roleName) {
        this.roleName = roleName;
        this.hashCode = roleName.hashCode() + 17;
    }

    public boolean equals(Object genericRole) {
        // if the other role is null, we're not the same
        if (genericRole == null) {
            return false;
        }

        // if we're the same java object, we're the same
        if (this == genericRole) {
            return true;
        }

        // if the other role is not a simple sample role mapper role,
        // we're not the same
        if (!(genericRole instanceof SimpleSampleSecurityRoleImpl)) {
            return false;
        }

        // Cast the other role to a simple sample role mapper role.
        SimpleSampleSecurityRoleImpl sampleRole =
            (SimpleSampleSecurityRoleImpl)genericRole;

        // if our names don't match, we're not the same
        if (!roleName.equals(sampleRole.getName())) {
            return false;
        }

        // we're the same
        return true;
    }
}
Role Mapping Providers

```java
}
public String toString()
{
    return roleName;
}

public int hashCode()
{
    return hashCode;
}

public String getName()
{
    return roleName;
}

public String getExpression()
{
    return "";
}
```

Role Consumer SSPI

WebLogic Server implements a role consumer for Web Service annotations. This release of WebLogic Server includes an SSPI that Role Mapping providers can use to obtain the role collections.

The RoleConsumer SSPI is optional; only those Role Mapping providers that implement the SSPI are called to consume a role collection.

The SSPI supports both the delivery of initial role collections and the delivery of updated role collections.

All Role Mapping providers that support the RoleConsumer SSPI are called to consume a role collection. Each Role Mapping provider can choose to skip or obtain the role collection for a given role set. In the case where a provider persists roles, the provider need only collect the role once. However, providers keeping roles in memory can obtain the role collection again.

The out-of-the-box WebLogic Server Role Mapping providers persist the role into LDAP.
Required SSPI Interfaces
If you want your custom Role Mapping provider to support the delivery of role collections, you must implement three interfaces:

- `weblogic.security.spi.RoleConsumerFactory`
- `weblogic.security.spi.RoleConsumer`
- `weblogic.security.spi.RoleCollectionHandler`

These interfaces are described in the sections that follow.

Implement the RoleConsumerFactory SSPI Interface
A Role Mapping provider implements the `RoleConsumerFactory` interface so that an instance of a `RoleConsumer` is available to the WebLogic Security Framework. The WebLogic Security Framework calls your `RoleConsumerFactory` implementation to obtain the provider's implementation of the role consumer.

The `RoleConsumerFactory` SSPI has one method, which returns your implementation of the `RoleConsumer` SSPI interface.

```java
public interface RoleConsumerFactory {
    /**
     * Obtain the implementation of the RoleConsumer security service provider interface (SSPI).
     * @return a RoleConsumer SSPI implementation.
     */
    public RoleConsumer getRoleConsumer();
}
```

Implement the RoleConsumer SSPI Interface
The `RoleConsumer` SSPI returns a role collection handler for consumption of a role collection. It has one method, `getRoleCollectionHandler()`, which takes a `RoleCollectionInfo` implementation as an argument and returns your implementation of the `RoleCollectionHandler` interface.

```java
public interface RoleConsumer {
    // ...
}
```
The WebLogic Security Framework calls the `getRoleCollectionHandler()` method and passes data about a role collection to a security provider as an implementation of the `RoleCollectionInfo` interface. (This interface implementation is provided for you, you do not have to implement it.)

You use the `RoleCollectionInfo.getName()`, `getVersion()`, `getTimestamp()`, and `getResourceTypes()` methods to discover information about this role collection. You then return a `RoleCollectionHandler`, or `NULL` to indicate that the role collection is not needed.

```java
public interface RoleCollectionInfo {
    /**
     * Get the name of the collection.
     */
    public String getName();

    /**
     * Obtain a role handler for consumption of a role collection.
     *
     * @param info the RoleCollectionInfo for the role collection.
     * @return a RoleCollectionHandler or NULL which indicates
     *         that the role collection is not needed.
     * @exception ConsumptionException if an error occurs
     *         obtaining the handler and the role collection cannot be consumed.
     */
    public RoleCollectionHandler getRoleCollectionHandler(
        RoleCollectionInfo info)
    throws ConsumptionException;
}
```
* Get the runtime version of the role.
  */
public String getVersion();

/**
 * Get the timestamp of the role.
 * */
public String getTimestamp();

/**
 * Get the resource types used in the role collection.
 * */
public Resource[] getResouceTypes();
}

**Implement the RoleCollectionHandler SSPI Interface**

The `RoleConsumer.getRoleCollectionHandler()` method returns your implementation of the `RoleCollectionHandler` interface. `RoleCollectionHandler` has two methods: `setRole()` and `done()`. The `setRole()` method takes a resource, a role name, and an array of user and group names that defines what user names and group names are to be assigned to that role for the given resource.

The `done()` method signals the completion of the role collection.

```java
public interface RoleCollectionHandler
{
  /**
   * Set a role for the specified resource.
   * */
  public void setRole(Resource resource, String roleName, String[] userAndGroupNames)
    throws ConsumptionException;
}
```
 Supporting an Updated Role Collection

To support the delivery of an updated role collection, all Role Mapping providers that support the RoleConsumer SSPI need to examine the contents of the RoleCollectionInfo passed in the RoleConsumer.getRoleCollectionHandler() method to determine if a role collection has changed. Each provider must decide (possibly by configuration) how to perform conflict resolution with the initial role collection and any customized role received outside of the SSPI.

For the WebLogic Server supplied Role Mapping providers, customized roles will not be replaced by the updated role collection: all roles from the initial role collection will be removed and only the customized roles, plus the updated role collection, will be in effect. If the role collection info has a different timestamp or version, it's treated as an updated role collection. The collection name is used as a persistence key.

The RoleConsumerMBean

Role Mapping providers that implement the Role Consumer SSPI must also implement the weblogic.management.security.authorization.RoleConsumerMBean to indicate that the provider supports policy consumption.

PolicyStoreMBean

This release of WebLogic Server includes support for a new MBean (weblogic.management.security.authorization.PolicyStoreMBean) that allows for standard management (add, delete, get, list, modify, read) of administrator-generated XACML policies and policy sets. An Authorization or Role Mapping provider MBean can optionally implement this MBean interface.
The PolicyStoreMBean methods allow security administrators to manage policy in the server as XACML documents. This includes creating and managing a domain that uses the default XACML provider, as well as managing XACML documents that the administrator has created. The administrator can then use WLST to manage these XACML policies in WebLogic Server.

WebLogic Server includes an implementation of this MBean for use with the out-of-the-box XACML providers, and you can write your own implementation of this MBean for use with your own custom Authorization or Role Mapping providers. The WebLogic Server out-of-the-box XACML providers support the mandatory features of XACML, as described in the XACML 2.0 Core Specification, with the Oracle-specific usage described in Securing WebLogic Resources Using Roles and Policies.

Policies are expressed as XACML 2.0 Policy or PolicySet documents. Custom Authorization providers should expect standard Policy or PolicySet documents as described in the XACML 2.0 Core Specification. Custom Role Mapping providers should expect Policy or PolicySet documents consistent with role assignment policies described by the Core and hierarchical role based access control (RBAC) profile of XACML v2.0.

Specifically, the Target must contain:

- An ActionAttributeDesignator with the id, urn:oasis:names:tc:xacml:1.0:action:action-id, and the value, urn:oasis:names:tc:xacml:2.0:actions:enableRole, according to anyURI-equal. For example:

  ```
  <Action>
  <ActionMatch MatchId="urn:oasis:names:tc:xacml:1.0:function:anyURI-equal">
    <AttributeValue
      DataType="http://www.w3.org/2001/XMLSchema#anyURI">urn:oasis:names:tc:xacml:2.0:actions:enableRole</AttributeValue>
    <ActionAttributeDesignator
      AttributeId="urn:oasis:names:tc:xacml:1.0:action:action-id"
      Datatype="http://www.w3.org/2001/XMLSchema#anyURI" MustBePresent="true"/>
  </ActionMatch>
  </Action>
  ```
A ResourceAttributeDesignator with the id, urn:oasis:names:tc:xacml:2.0:subject:role, and a value naming the role being assigned, according to string-equal. For example:

```xml
<ResourceAttributeDesignator
    AttributeId="urn:oasis:names:tc:xacml:2.0:resource:resource-ancestor-or-self"
    DataType="http://www.w3.org/2001/XMLSchema#string" MustBePresent="true"/>
```

### Examining the Format of a XACML Policy File

The XACML 2.0 Core Specification and the Oracle extensions described in Securing WebLogic Resources Using Roles and Policies are the definitive sources of information for the XACML policy files used by the supplied XACML Authorization and Role Mapping Providers.

However, if as part of your development process you want to take a look at the format of a supported XACML file, perhaps the most convenient way is to use the Administration Console to export the data from the XACML Authorization or Role Mapping provider's database as a XACML file. Copy this exported XACML file to a file with some other name and use the tool of your choice to review the copy.

**Note:** Treat the exported file as read-only. If you do make changes, do not import the file back into WebLogic Server. Editing exported files might result in an unusable WebLogic Server configuration and is not supported.

### Using WLST to Add a Policy to the PolicyStoreMBean

Listing 9-4 shows an example of using WLST to add a single policy to an instance of the PolicyStoreMBean from a XACML file.

The example assumes that you have defined the properties used in this script elsewhere, in a manner similar to the following lines from an ant script:

```xml
<property name="xacml-docs-dir" value="${xacmldir}/xacml-docs"/>
<sysproperty key="file" value="${xacml-docs-dir}/policy-getSubject.xacml"/>
```

Listing 9-4 Using WLST to Add a Policy to the PolicyStoreMBean

```
try:
```
def configure():
    try:
        url = protocol + '://' + host + ':' + port
        connect(user, passwd, url)
        path = '/SecurityConfiguration/' + dom + '/Realms/' + rlm + '/'+ prov
        print("cd'ing to " + path)
        cd(path)
        print("calling open()")
        xacmlFile = open(fil,"r")
        print("calling read()")
        xacmlDoc = xacmlFile.read()
        print("calling cmo.addPolicy")
        if stat == "none":
            cmo.addPolicy(xacmlDoc)
        else:
            cmo.addPolicy(xacmlDoc, stat)
        print("Add error handling")

As described in the Navigating and Interrogating MBeans section of WebLogic Scripting Tool, when WLST first connects to an instance of WebLogic Server, the variable, \texttt{cmo} (Current Management Object), is initialized to the root of all configuration management objects, \texttt{DomainMBean}. When you navigate to an MBean type, in this case \texttt{SecurityConfigurationMBean}, the value of \texttt{cmo} reflects \texttt{SecurityConfigurationMBean}. When you navigate to an MBean instance, in this case to an Authorizer MBean that implements the PolicyStoreMBean, identified in the example by the variable \texttt{prov}, WLST changes the value of \texttt{cmo} to be the current MBean instance.
The example uses the `addPolicy()` method of the PolicyStoreMBean to add a policy read from a XACML file to the policy store. Two variants of the `addPolicy()` method (without and with status) are shown.

If you use an `addPolicy()` method that does not specify status, it defaults to ACTIVE, which indicates that the policy is evaluated for any decision to which its target applies. You can explicitly set status to be ACTIVE, INACTIVE, or BYREFERENCE. The INACTIVE status indicates that the policy will never be evaluated and is only being stored. The BYREFERENCE status indicates that the policy will only be evaluated when referenced by a policy set that is being evaluated.

You can invoke this type of WLST script from the command line, in a manner similar to the following:

```
java -Dhost="localhost" -Dprotocol="t3" -Dauthuser="weblogic"
-Dauthpwd="weblogic" -Dport="7001" -Ddomain="mydomain" -Drealm="myrealm"
-Dprovider="Authorizers/XACMLAuthorizer"
-Dfile="C:/XACML/xacml-docs/policy12.xml" -Dstatus="none" weblogic.WLST
XACML/scripts/XACMLaddPolicy.py
```

### Using WLST to Read a PolicySet as a String

Listing 9-5 shows an example of using WLST to read a PolicySet as a string.

The example assumes that you have defined the properties used in this script elsewhere, in a manner similar to the following lines from an ant script:

```xml
<sysproperty key="identifier" value="urn:sample:xacml:2.0:wlssecqa:resource:type@E@Fejb@G@M@Oapplication@ENoD
DRolesOrPoliciesEar@M@Omodule@Eejb11inEarMiniAppBean.jar@M@Oejb@EMiniAppBean@
M@Omethod@EgetSubject@M@OmethodInterface@ERemote"/>
```

### Listing 9-5 Using WLST to Read a PolicySet as a String

```python
try:

    print("start XACMLreadPolicySet.py")
    protocol = System.getProperty("protocol")
    host = System.getProperty("host")
    user = System.getProperty("authuser")
    passwd = System.getProperty("authpwd")
```
How to Develop a Custom Role Mapping Provider

```
port = System.getProperty("port")
dom = System.getProperty("domain")
rlm = System.getProperty("realm")
prov = System.getProperty("provider")
id = System.getProperty("identifier")
vers = System.getProperty("version")
```

```
def configure():
    try:
        url = protocol + "://" + host + ":" + port
        connect(user, passwd, url)
        path = "/SecurityConfiguration/" + dom + "/Realms/" + rlm + "/" + prov
        print("cd'ing to " + path)
        cd(path)
        polset = cmo.readPolicySetAsString(id, vers)
        print("readPolicySetAsString() returned the following policy set: " +
        polset)
        print"Add error handling."
    :
```

As described in the XACML 2.0 Core Specification, the <PolicySet> element contains a set of <Policy> or other <PolicySet> elements and a specified procedure for combining the results of their evaluation. See the XACML 2.0 Core Specification for complete information.

**Bulk Role Mapping Providers**

This release of WebLogic Server includes bulk access versions of the following Role Mapping provider SSPI interfaces:

- BulkRoleProvider
- BulkRoleMapper

The bulk access SSPI interfaces allow Role Mapping providers to receive multiple decision requests in one call rather than through multiple calls, typically in a 'for' loop. The intent of the bulk SSPI variants is to allow provider implementations to take advantage of internal performance optimizations, such as detecting that many of the passed-in Resource objects are protected by the same policy and will generate the same decision result.
There are subtle differences in how the non-bulk and bulk versions of the SSPI interfaces are used. For example, the `BulkRoleMapper.getRoles()` method returns a `Map` of roles indexed first by resource and then by their names (`Map<Resource, Map<String, SecurityRole>>`), representing the security roles associated with the specified resources that have been granted to the subject.

**Generate an MBean Type Using the WebLogic MBeanMaker**

Before you start generating an MBean type for your custom security provider, you should first:

- “Understand Why You Need an MBean Type” on page 3-11
- “Determine Which SSPI MBeans to Extend and Implement” on page 3-11
- “Understand the Basic Elements of an MBean Definition File (MDF)” on page 3-12
- “Understand the SSPI MBean Hierarchy and How It Affects the Administration Console” on page 3-15
- “Understand What the WebLogic MBeanMaker Provides” on page 3-17

When you understand this information and have made your design decisions, create the MBean type for your custom Role Mapping provider by following these steps:

1. “Create an MBean Definition File (MDF)” on page 9-30
2. “Use the WebLogic MBeanMaker to Generate the MBean Type” on page 9-31
3. “Use the WebLogic MBeanMaker to Create the MBean JAR File (MJF)” on page 9-34
4. “Install the MBean Type Into the WebLogic Server Environment” on page 9-35

**Notes:** All instructions provided in this section assume that you are working in a Windows environment.

### Create an MBean Definition File (MDF)

To create an MBean Definition File (MDF), follow these steps:

1. Copy the MDF for the sample Role Mapping provider to a text file.
   
   **Note:** The MDF for the sample Role Mapping provider is called `SimpleSampleRoleMapper.xml`. 

2. "Create an MBean Definition File (MDF)" on page 9-30
3. "Use the WebLogic MBeanMaker to Generate the MBean Type" on page 9-31
4. "Use the WebLogic MBeanMaker to Create the MBean JAR File (MJF)" on page 9-34
5. "Install the MBean Type Into the WebLogic Server Environment" on page 9-35

**Notes:** All instructions provided in this section assume that you are working in a Windows environment.

### Create an MBean Definition File (MDF)

To create an MBean Definition File (MDF), follow these steps:

1. Copy the MDF for the sample Role Mapping provider to a text file.
   
   **Note:** The MDF for the sample Role Mapping provider is called `SimpleSampleRoleMapper.xml`. 

2. "Create an MBean Definition File (MDF)" on page 9-30
3. "Use the WebLogic MBeanMaker to Generate the MBean Type" on page 9-31
4. "Use the WebLogic MBeanMaker to Create the MBean JAR File (MJF)" on page 9-34
5. "Install the MBean Type Into the WebLogic Server Environment" on page 9-35

**Notes:** All instructions provided in this section assume that you are working in a Windows environment.

### Create an MBean Definition File (MDF)

To create an MBean Definition File (MDF), follow these steps:

1. Copy the MDF for the sample Role Mapping provider to a text file.
   
   **Note:** The MDF for the sample Role Mapping provider is called `SimpleSampleRoleMapper.xml`. 

2. "Create an MBean Definition File (MDF)" on page 9-30
3. "Use the WebLogic MBeanMaker to Generate the MBean Type" on page 9-31
4. "Use the WebLogic MBeanMaker to Create the MBean JAR File (MJF)" on page 9-34
5. "Install the MBean Type Into the WebLogic Server Environment" on page 9-35

**Notes:** All instructions provided in this section assume that you are working in a Windows environment.
2. Modify the content of the `<MBeanType>` and `<MBeanAttribute>` elements in your MDF so that they are appropriate for your custom Role Mapping provider.

3. Add any custom attributes and operations (that is, additional `<MBeanAttribute>` and `<MBeanOperation>` elements) to your MDF.

4. Save the file.

   **Note:** A complete reference of MDF element syntax is available in Appendix A, “MBean Definition File (MDF) Element Syntax.”

### Use the WebLogic MBeanMaker to Generate the MBean Type

Once you create your MDF, you are ready to run it through the WebLogic MBeanMaker. The WebLogic MBeanMaker is currently a command-line utility that takes as its input an MDF, and outputs some intermediate Java files, including an MBean interface, an MBean implementation, and an associated MBean information file. Together, these intermediate files form the **MBean type** for your custom security provider.

The instructions for generating an MBean type differ based on the design of your custom Role Mapping provider. Follow the instructions that are appropriate to your situation:

- “No Custom Operations” on page 9-31
- “Custom Operations” on page 9-32

### No Custom Operations

If the MDF for your custom Role Mapping provider does not include any custom operations, follow these steps:

1. Create a new DOS shell.

2. Type the following command:

   ```
   java -DMDF=xmlfile -Dfiles=filesdir -DcreateStubs=true weblogic.management.commo.WebLogicMBeanMaker
   ```

   where the `-DMDF` flag indicates that the WebLogic MBeanMaker should translate the MDF into code, `xmlFile` is the MDF (the XML MBean Description File) and `filesdir` is the location where the WebLogic MBeanMaker will place the intermediate files for the MBean type.

   Whenever `xmlfile` is provided, a new set of output files is generated.
Each time you use the `-DcreateStubs=true` flag, it overwrites any existing MBean implementation file.

**Note:** As of version 9.0 of WebLogic Server, you can also provide a directory that contains multiple MDF's by using the `-DMDFDIR <MDF directory name>` option. In prior versions of WebLogic Server, the WebLogic MBeanMaker processed only one MDF at a time. Therefore, you had to repeat this process if you had multiple MDFs (in other words, multiple Role Mapping providers).

3. Proceed to “Use the WebLogic MBeanMaker to Create the MBean JAR File (MJF)” on page 9-34.

**Custom Operations**

If the MDF for your custom Role Mapping provider does include custom operations, consider the following:

- Are you creating an MBean type for the first time? If so, follow these steps:

1. Create a new DOS shell.

2. Type the following command:

   ```java
   java -DMDF=xmlfile -Dfiles=filesdir -DcreateStubs=true
   weblogic.management.commo.WebLogicMBeanMaker
   ```

   where the `-DMDF` flag indicates that the WebLogic MBeanMaker should translate the MDF into code, `xmlFile` is the MDF (the XML MBean Description File) and `filesdir` is the location where the WebLogic MBeanMaker will place the intermediate files for the MBean type.

   Whenever `xmlfile` is provided, a new set of output files is generated.

   Each time you use the `-DcreateStubs=true` flag, it overwrites any existing MBean implementation file.

   **Note:** As of version 9.0 of WebLogic Server, you can also provide a directory that contains multiple MDF's by using the `-DMDFDIR <MDF directory name>` option. In prior versions of WebLogic Server, the WebLogic MBeanMaker processed only one MDF at a time. Therefore, you had to repeat this process if you had multiple MDFs (in other words, multiple Role Mapping providers).

3. For any custom operations in your MDF, implement the methods using the method stubs.

4. Save the file.
5. Proceed to “Use the WebLogic MBeanMaker to Create the MBean JAR File (MJF)” on page 9-34.

- Are you updating an existing MBean type? If so, follow these steps:

1. Copy your existing MBean implementation file to a temporary directory so that your current method implementations are not overwritten by the WebLogic MBeanMaker.

2. Create a new DOS shell.

3. Type the following command:

   ```java
   java -DMDF=xmlfile -Dfiles=filesdir -DcreateStubs=true
   weblogic.management.commo.WebLogicMBeanMaker
   ```

   where the -DMDF flag indicates that the WebLogic MBeanMaker should translate the MDF into code, xmlFile is the MDF (the XML MBean Description File) and filesdir is the location where the WebLogic MBeanMaker will place the intermediate files for the MBean type.

   Whenever xmlfile is provided, a new set of output files is generated.

   Each time you use the -DcreateStubs=true flag, it overwrites any existing MBean implementation file.

   **Note:** As of version 9.0 of WebLogic Server, you can also provide a directory that contains multiple MDF's by using the -DMDFDIR <MDF directory name> option. In prior versions of WebLogic Server, the WebLogic MBeanMaker processed only one MDF at a time. Therefore, you had to repeat this process if you had multiple MDFs (in other words, multiple Role Mapping providers).

4. If you modified the MDF to include any custom operations that were not in the original MDF, implement the methods using the method stubs.

5. Save the version of the MBean implementation file that is complete (that is, has all methods implemented).

6. Copy this MBean implementation file into the directory where the WebLogic MBeanMaker placed the intermediate files for the MBean type. You specified this as filesdir in step 3. (You will be overriding the MBean implementation file generated by the WebLogic MBeanMaker as a result of step 3.)

7. Proceed to “Use the WebLogic MBeanMaker to Create the MBean JAR File (MJF)” on page 9-34.
About the Generated MBean Interface File

The MBean interface file is the client-side API to the MBean that your runtime class or your MBean implementation will use to obtain configuration data. It is typically used in the initialize method as described in “Understand the Purpose of the “Provider” SSPIs” on page 3-3.

Because the WebLogic MBeanMaker generates MBean types from the MDF you created, the generated MBean interface file will have the name of the MDF, plus the text “MBean” appended to it. For example, the result of running the SampleRoleMapper MDF through the WebLogic MBeanMaker will yield an MBean interface file called SampleRoleMapperMBean.java.

Use the WebLogic MBeanMaker to Create the MBean JAR File (MJF)

Once you have run your MDF through the WebLogic MBeanMaker to generate your intermediate files, and you have edited the MBean implementation file to supply implementations for the appropriate methods within it, you need to package the MBean files and the runtime classes for the custom Role Mapping provider into an MBean JAR File (MJF). The WebLogic MBeanMaker also automates this process.

To create an MJF for your custom Role Mapping provider, follow these steps:

1. Create a new DOS shell.
2. Type the following command:

   ```
   java -DMJF=jarfile -Dfiles=filesdir
   weblogic.management.commo.WebLogicMBeanMaker
   ```

   where the -DMJF flag indicates that the WebLogic MBeanMaker should build a JAR file containing the new MBean types, jarfile is the name for the MJF and filesdir is the location where the WebLogic MBeanMaker looks for the files to JAR into the MJF.

   Compilation occurs at this point, so errors are possible. If jarfile is provided, and no errors occur, an MJF is created with the specified name.

Notes: When you create a JAR file for a custom security provider, a set of XML binding classes and a schema are also generated. You can choose a namespace to associate with that schema. Doing so avoids the possibility that your custom classes will conflict with those provided by Oracle. The default for the namespace is vendor. You can change this default by passing the -targetNamespace argument to the WebLogicMBeanMaker or the associated WLMBeanMaker ant task.

If you want to update an existing MJF, simply delete the MJF and regenerate it. The WebLogic MBeanMaker also has a -DIncludeSource option, which controls whether
source files are included into the resulting MJF. Source files include both the generated source and the MDF itself. The default is false. This option is ignored when `-DMJF` is not used.

The resulting MJF can be installed into your WebLogic Server environment, or distributed to your customers for installation into their WebLogic Server environments.

**Install the MBean Type Into the WebLogic Server Environment**

To install an MBean type into the WebLogic Server environment, copy the MJF into the \$WL_HOME\server\lib\mbeantypes directory, where \$WL_HOME\ is the top-level installation directory for WebLogic Server. This “deploys” your custom Role Mapping provider—that is, it makes the custom Role Mapping provider manageable from the WebLogic Server Administration Console.

**Note:** \$WL_HOME\server\lib\mbeantypes is the default directory for installing MBean types. (Beginning with 9.0, security providers can be loaded from \...\domaindir\lib\mbeantypes as well.) However, if you want WebLogic Server to look for MBean types in additional directories, use the `-Dweblogic.alternateTypesDirectory=<dir>` command-line flag when starting your server, where `<dir>` is a comma-separated list of directory names. When you use this flag, WebLogic Server will always load MBean types from \$WL_HOME\server\lib\mbeantypes first, then will look in the additional directories and load all valid archives present in those directories (regardless of their extension). For example, if `-Dweblogic.alternateTypesDirectory = dirX,dirY`, WebLogic Server will first load MBean types from \$WL_HOME\server\lib\mbeantypes, then any valid archives present in dirX and dirY. If you instruct WebLogic Server to look in additional directories for MBean types and are using the Java Security Manager, you must also update the `weblogic.policy` file to grant appropriate permissions for the MBean type (and thus, the custom security provider). For more information, see “Using the Java Security Manager to Protect WebLogic Resources” in *Programming WebLogic Security*.

You can create instances of the MBean type by configuring your custom Role Mapping provider (see “Configure the Custom Role Mapping Provider Using the Administration Console” on page 9-36), and then use those MBean instances from a GUI, from other Java code, or from APIs. For example, you can use the WebLogic Server Administration Console to get and set attributes and invoke operations, or you can develop other Java objects that instantiate MBeans and automatically respond to information that the MBeans supply. We recommend that you back up these MBean instances.
Configure the Custom Role Mapping Provider Using the Administration Console

Configuring a custom Role Mapping provider means that you are adding the custom Role Mapping provider to your security realm, where it can be accessed by applications requiring role mapping services.

Configuring custom security providers is an administrative task, but it is a task that may also be performed by developers of custom security providers. This section contains information that is important for the person configuring your custom Role Mapping providers:

- “Managing Role Mapping Providers and Deployment Descriptors” on page 9-36
- “Enabling Security Role Deployment” on page 9-38

Note: The steps for configuring a custom Role Mapping provider using the WebLogic Server Administration Console are described under “Configuring WebLogic Security Providers” in Securing WebLogic Server.

Managing Role Mapping Providers and Deployment Descriptors

Some application components, such as Enterprise JavaBeans (EJBs) and Web applications, store relevant deployment information in Java EE and WebLogic Server deployment descriptors. For Web applications, the deployment descriptor files (called web.xml and weblogic.xml) contain information for implementing the Java EE security model, including security roles. Typically, you will want to include this information when first configuring your Role Mapping providers in the WebLogic Server Administration Console.

Because the Java EE platform standardizes Web application and EJB security in deployment descriptors, WebLogic Server integrates this standard mechanism with its Security Service to give you a choice of techniques for securing Web application and EJB resources. You can use deployment descriptors exclusively, the Administration Console exclusively, or you can combine the techniques for certain situations.

Depending on the technique you choose, you also need to apply a Security Model. WebLogic supports different security models for individual deployments, and a security model for realm-wide configurations that incorporate the technique you want to use.

For more information, see “Options for Securing EJB and Web Application Resources” in Securing WebLogic Resources Using Roles and Policies.

When configured to use deployment descriptors, WebLogic Server reads security role information from the web.xml and weblogic.xml deployment descriptor files (examples of
web.xml and weblogic.xml files are shown in Listing 9-6 and Listing 9-7. This information is then copied into the security provider database for the Role Mapping provider.

**Listing 9-6  Sample web.xml File**

```xml
<web-app>
  <welcome-file-list>
    <welcome-file>welcome.jsp</welcome-file>
  </welcome-file-list>
  <security-constraint>
    <web-resource-collection>
      <web-resource-name>Success</web-resource-name>
      <url-pattern>/welcome.jsp</url-pattern>
      <http-method>GET</http-method>
      <http-method>POST</http-method>
    </web-resource-collection>
    <auth-constraint>
      <role-name>developers</role-name>
    </auth-constraint>
  </security-constraint>
  <login-config>
    <auth-method>BASIC</auth-method>
  </login-config>
  <security-role>
    <role-name>developers</role-name>
  </security-role>
</web-app>
```

**Listing 9-7  Sample weblogic.xml File**

```xml
<weblogic-web-app>
  <security-role-assignment>
    <role-name>developers</role-name>
  </security-role-assignment>
</weblogic-web-app>
```
Enabling Security Role Deployment

If you implemented the `DeployableRoleProviderV2` SSPI as part of developing your custom Role Mapping provider and want to support deployable security roles, the person configuring the custom Role Mapping provider (that is, you or an administrator) must be sure that the Role Deployment Enabled box in the WebLogic Server Administration Console is checked. Otherwise, deployment for the Role Mapping provider is considered “turned off.” Therefore, if multiple Role Mapping providers are configured, the Role Deployment Enabled box can be used to control which Role Mapping provider is used for security role deployment.

Provide a Mechanism for Security Role Management

While configuring a custom Role Mapping provider via the WebLogic Server Administration Console makes it accessible by applications requiring role mapping services, you also need to supply administrators with a way to manage this security provider’s associated security roles. The WebLogic Role Mapping provider, for example, supplies administrators with a Role Editor page that allows them to add, modify, or remove security roles for various WebLogic resources.

Neither the Role Editor page nor access to it is available to administrators when you develop a custom Role Mapping provider. Therefore, you must provide your own mechanism for security role management. This mechanism must read and write security role data (that is, expressions) to and from the custom Role Mapping provider’s database.

You can accomplish this task in one of two ways:

- “Option 1: Develop a Stand-Alone Tool for Security Role Management” on page 9-38
- “Option 2: Integrate an Existing Security Role Management Tool into the Administration Console” on page 9-39

Option 1: Develop a Stand-Alone Tool for Security Role Management

You would typically select this option if you want to develop a tool that is entirely separate from the WebLogic Server Administration Console.
How to Develop a Custom Role Mapping Provider

For this option, you do not need to write any console extensions for your custom Role Mapping provider, nor do you need to develop any management MBeans. However, your tool needs to:

1. Determine the WebLogic resource’s ID, since it is not automatically provided to you by the console extension. For more information, see “WebLogic Resource Identifiers” on page 3-30.

2. Determine how to represent the expressions that make up a security role. (This representation is entirely up to you and need not be a string.)

3. Read and write the expressions from and to the custom Role Mapping provider’s database.

**Option 2: Integrate an Existing Security Role Management Tool into the Administration Console**

You would typically select this option if you have a tool that is separate from the WebLogic Server Administration Console, but you want to launch that tool from the Administration Console.

For this option, your tool needs to:

1. Determine the WebLogic resource’s ID, since it is not automatically provided to you by the console extension. For more information, see “WebLogic Resource Identifiers” on page 3-30.

2. Determine how to represent the expressions that make up a security role. (This representation is entirely up to you and need not be a string.)

3. Read and write the expressions from and to the custom Role Mapping provider’s database.

4. Link into the Administration Console using basic console extension techniques, as described in *Extending the Administration Console*. 
Role Mapping Providers
Auditing Providers

Auditing is the process whereby information about operating requests and the outcome of those requests are collected, stored, and distributed for the purposes of non-repudiation. In WebLogic Server, an Auditing provider provides this electronic trail of computer activity.

The following sections describe Auditing provider concepts and functionality, and provide step-by-step instructions for developing a custom Auditing provider:

- “Auditing Concepts” on page 10-1
- “The Auditing Process” on page 10-2
- “Extend weblogic.management.security.audit.ContextHandlerImpl” on page 10-7
- “How to Develop a Custom Auditing Provider” on page 10-10
- “Security Framework Audit Events” on page 10-21

Auditing Concepts

Before you develop an Auditing provider, you need to understand the following concepts:

- “Audit Channels” on page 10-2
- “Auditing Events From Custom Security Providers” on page 10-2
Audit Channels

An Audit Channel is the component of an Auditing provider that determines whether a security event should be audited, and performs the actual recording of audit information based on Quality of Service (QoS) policies.

Note: For more information about Audit Channels, see “Implement the AuditChannel SSPI” on page 10-12.

Auditing Events From Custom Security Providers

Each type of security provider can call the configured Auditing providers with a request to write out information about security-related events, before or after these events take place. For example, if a user attempts to access a withdraw method in a bank account application (to which they should not have access), the Authorization provider can request that this operation be recorded. Security-related events are only recorded when they meet or exceed the severity level specified in the configuration of the Auditing providers.

For information about how to post audit events from a custom security provider, see Chapter 12, “Auditing Events From Custom Security Providers.”

The Auditing Process

Figure 10-1 shows how Auditing providers interact with the WebLogic Security Framework and other types of security providers (using Authentication providers as an example) to audit selected events. An explanation follows.
Auditing providers interact with the WebLogic Security Framework and other types of security providers in the following manner:

**Note:** In Figure 10-1 and the explanation below, the “other types of security providers” are a WebLogic Authentication provider and a custom Authentication provider. However, these can be any type of security provider that is developed as described in Chapter 12, “Auditing Events From Custom Security Providers.”

1. A resource container passes a user’s authentication information (for example, a username/password combination) to the WebLogic Security Framework as part of a login request.

2. The WebLogic Security Framework passes the information associated with the login request to the configured Authentication providers.
3. If, in addition to providing authentication services, the Authentication providers are designed to post audit events, the Authentication providers will each:

   a. Instantiate an AuditEvent object. At minimum, the AuditEvent object includes information about the event type to be audited and an audit severity level.

      Note: An AuditEvent class is created by implementing either the AuditEvent SSPI or an AuditEvent convenience interface in the Authentication provider’s runtime class, in addition to the other security service provider interfaces (SSPIs) the custom Authentication provider must already implement. For more information about Audit Events and the AuditEvent SSPI/convenience interfaces, see “Create an Audit Event” on page 12-3.

   b. Make a trusted call to the Auditor Service, passing in the AuditEvent object.

      Note: This is a trusted call because the Auditor Service is already passed to the security provider’s initialize method as part of its “Provider” SSPI implementation. For more information, see “Understand the Purpose of the “Provider” SSPIs” on page 3-3.

4. The Auditor Service passes the AuditEvent object to the configured Auditing providers’ runtime classes (that is, the AuditChannel SSPI implementations), enabling audit event recording.

   Note: Depending on the Authentication providers’ implementations of the AuditEvent convenience interface, audit requests may occur both pre and post event, as well as just once for an event.

5. The Auditing providers’ runtime classes use the event type, audit severity and other information (such as the Audit Context) obtained from the AuditEvent object to control audit record content. Typically, only one of the configured Auditing providers will meet all the criteria for auditing.

   Note: For more information about audit severity levels and the Audit Context, see “Audit Severity” on page 12-7 and “Audit Context” on page 12-8, respectively.

6. When the criteria for auditing specified by the Authentication providers in their AuditEvent objects is met, the appropriate Auditing provider’s runtime class (that is, the AuditChannel SSPI implementation) writes out audit records in the manner their implementation specifies.

   Note: Depending on the AuditChannel SSPI implementation, audit records may be written to a file, a database, or some other persistent storage medium when the criteria for auditing is met.
Implementing the ContextHandler MBean

The ContextHandlerMBean, `weblogic.management.security.audit.ContextHandler`, provides a set of attributes for ContextHandler support. You use this interface to manage audit providers that support context handler entries in a standard way.

An Auditor provider MBean can optionally implement the ContextHandlerMBean MBean. The Auditor provider can then use the MBean to determine the supported and active ContextHandler entries.

The WebLogic Server Administration Console detects when an Auditor provider implements this MBean and automatically provides a tab for using these attributes.

**Note:** The ContextHandler entries associated with the ContextHandlerMBean are not related to, nor do they affect, the contents of an AuditEvent that is passed to the Audit providers. An AuditEvent received by a provider may or may not include a ContextHandler with ContextElements. If a ContextHandler is included, an Audit provider can get the ContextHandler from the AuditEvent, regardless of whether you implemented the ContextHandlerMBean management interface. In particular, the AuditContext `getContext` method returns a `weblogic.security.service.ContextHandler` interface that is independent of the context handler implemented by the ContextHandlerMBean.

You can choose to implement the ContextHandlerMBean context handler in a manner that compliments the AuditContext `getContext` method. (The `SimpleSampleAuditProviderImpl.java` sample takes this approach.) However, there is no requirement that you do so.

**ContextHandlerMBean Methods**

The ContextHandlerMBean interface implements the following methods:

- **getActiveContextHandlerEntries**
  ```java
  public String[] getActiveContextHandlerEntries()
  ```
  Returns the ContextHandler entries that the Audit provider is currently configured to process.

- **getSupportedContextHandlerEntries**
  ```java
  public String[] getSupportedContextHandlerEntries()
  ```
  Returns the list of all ContextHandler entries supported by the auditor.
setActiveContextHandlerEntries
   public void setActiveContextHandlerEntries(String[] types) throws
   InvalidAttributeValueException

   Sets the ContextHandler entries that the Audit provider will process. The entries you
   specify must be listed in the Audit provider's SupportedContextHandlerEntries attribute.

Example: Implementing the ContextHandlerMBean

Listing 10-5 shows the SimpleSampleAuditProviderImpl.java class, which is the runtime
class for the sample Auditing provider. This sample Auditing provider has been enhanced to
implement the ContextHandlerMBean.

An MBean Definition File (MDF) is an XML file used by the WebLogic MBeanMaker utility to
generate the Java files that comprise an MBean type. All MDFs must extend a required SSPI
MBean that is specific to the type of the security provider you have created, and can implement
optional SSPI MBeans.

Listing 10-1 shows the key sections of the MDF for the sample Auditing provider, which
implements the optional ContextHandlerMBean.

Listing 10-1   Example: SimpleSampleAuditor.xml

   <MBeanType
      Name          = "SimpleSampleAuditor"
      DisplayName   = "SimpleSampleAuditor"
      Package       = "examples.security.providers.audit.simple"
      Extends       = "weblogic.management.security.audit.Auditor"
      Implements    = "weblogic.management.security.audit.ContextHandler"
      PersistPolicy = "OnUpdate"
   >
   ...

   <MBeanAttribute
      Name          = "SupportedContextHandlerEntries"
      Type          = "java.lang.String[]"
      Writeable     = "false"
      Default       = "new String[] { "com.bea.contextelement.servlet.HttpServletRequest" }"
      Description   = "List of all ContextHandler entries"
Extend `weblogic.management.security.audit.ContextHandlerImpl`

The ContextHandlerMBean has an `setActiveContextHandlerEntries` attribute that sets the ContextHandler entries that the Audit provider is currently configured to process. The entries you specify must be listed in the Audit provider’s `SupportedContextHandlerEntries` attribute. However, this requirement is not actually enforced by the MBean. Additional work is required to validate that this attribute can set only values from the `SupportedContextHandlerEntries` attribute.

You must also create an MBean customizer (for example, you might call it `MyAuditorImpl.java`) file that extends `weblogic.management.security.audit.ContextHandlerImpl`. Extending `weblogic.management.security.audit.ContextHandlerImpl` gives the provider access to the `ActiveContextHandlerEntries` attribute validator, which ensures that the entries include only `SupportedContextHandlerEntries`.

An example of extending `ContextHandlerImpl` is available in `SimpleSampleAuditorImpl`, which is shown in Listing 10-2.

Listing 10-2 SimpleSampleAuditorImpl

```java
package examples.security.providers.audit.simple;
import javax.management.MBeanException;
import javax.management.modelmbean.RequiredModelMBean;
import weblogic.management.security.audit.ContextHandlerImpl;

/**
 * The simple sample auditor's mbean implementation.
 * It is needed to inherit the ContextHandlerMBean's ActiveContextHandlerEntries attribute validator that ensures that the ActiveContextHandlerEntries attribute only contains values from the SupportedContextHandlerEntries attribute.
 */
```
Auditing Providers

public class SimpleSampleAuditorImpl extends ContextHandlerImpl
// Note: extend ContextHandlerImpl instead of AuditorImpl to inherit
// the ActiveContextHandlerEntries attribute validator.
{
/**
 * Standard mbean impl constructor.
 *
 * @throws MBeanException
 */
public SimpleSampleAuditorImpl(RequiredModelMBean base) throws MBeanException
{
    super(base);
}
}

After you implement code similar to that in SimpleSampleAuditorImpl, add code to your Audit runtime provider to get the ActiveContextHandlerEntries. One possible way to do this is shown in Listing 10-3.

Listing 10-3 Getting Active Context Handler Entries

String [] activeHandlerEntries = myMBean.getActiveContextHandlerEntries();
if (activeHandlerEntries != null) {
    for (int i=0; i<activeHandlerEntries.length; i++) {
        if ((activeHandlerEntries[i] != null) &&
            (activeHandlerEntries[i].equalsIgnoreCase(HTTP_REQUEST_ELEMENT))) {
            handlerEnabled = true;
            break;
        }
    }
}
Do You Need to Develop a Custom Auditing Provider?

The default (that is, active) security realm for WebLogic Server includes a WebLogic Auditing provider. The WebLogic Auditing provider records information from a number of security requests, which are determined internally by the WebLogic Security Framework. The WebLogic Auditing provider also records the event data associated with these security requests, and the outcome of the requests.

The WebLogic Auditing provider makes an audit decision in its `writeEvent` method, based on the audit severity level it has been configured with and the audit severity contained within the `AuditEvent` object that is passed into the method. (For more information about `AuditEvent` objects, see “Create an Audit Event” on page 12-3.

**Note:** You can change the audit severity level that the WebLogic Auditing provider is configured with using the WebLogic Server Administration Console. For more information, see “Configuring a WebLogic Auditing Provider” in *Securing WebLogic Server*.

If there is a match, the WebLogic Auditing provider writes audit information to the `DefaultAuditRecorder.log` file, which is located in the `WL_HOME\yourdomain\yourserver\logs` directory. **Listing 10-4** is an excerpt from the `DefaultAuditRecorder.log` file.

**Listing 10-4 DefaultAuditRecorder.log File: Sample Output**

```plaintext
When Authentication succeeds. [SUCCESS]
### Audit Record Begin <Feb 23, 2005 11:42:17 AM>  <Severity=SUCCESS>
<<<Event Type = Authentication Audit Event><TestUser><AUTHENTICATE>>> Audit Record End ###

When Authentication fails. [FAILURE]
### Audit Record Begin <Feb 23, 2005 11:42:01 AM>  <Severity=FAILURE>
<<<Event Type = Authentication Audit Event><TestUser><AUTHENTICATE>>> Audit Record End ###

When Operations are invoked. [SUCCESS]

When a user account is unlocked. [SUCCESS]
```
Auditing Providers

Specifically, Listing 10-4 shows the Role Manager (a component in the WebLogic Security Framework that deals specifically with security roles) recording an audit event to indicate that an authorized administrator has accessed a protected method in a certificate servlet.

Each time the WebLogic Server instance is booted, a new DefaultAuditRecorder.log file is created (the old DefaultAuditRecorder.log file is renamed to DefaultAuditRecorder.log.old).

You can specify a new directory location for the DefaultAuditRecorder.log file on the command line with the following Java startup option:

-Dweblogic.security.audit.auditLogDir=c:\foo

The new file location will be c:\foo\yourservice\DefaultAuditRecorder.log.

If you want to write audit information in addition to that which is specified by the WebLogic Security Framework, or to an output repository that is not the DefaultAuditRecorder.log (that is, to a simple file with a different name/location or to an existing database), then you need to develop a custom Auditing provider.

How to Develop a Custom Auditing Provider

If the WebLogic Auditing provider does not meet your needs, you can develop a custom Auditing provider by following these steps:

1. “Create Runtime Classes Using the Appropriate SSPIs” on page 10-11
2. “Generate an MBean Type Using the WebLogic MBeanMaker” on page 10-15
3. “Configure the Custom Auditing Provider Using the Administration Console” on page 10-20
Create Runtime Classes Using the Appropriate SSPIs

Before you start creating runtime classes, you should first:

- “Understand the Purpose of the “Provider” SSPIs” on page 3-3
- “Understand the SSPI Hierarchy and Determine Whether You Will Create One or Two Runtime Classes” on page 3-7

When you understand this information and have made your design decisions, create the runtime classes for your custom Auditing provider by following these steps:

- “Implement the AuditProvider SSPI” on page 10-11
- “Implement the AuditChannel SSPI” on page 10-12

For an example of how to create a runtime class for a custom Auditing provider, see “Example: Creating the Runtime Class for the Sample Auditing Provider” on page 10-12.

Implement the AuditProvider SSPI

To implement the AuditProvider SSPI, provide implementations for the methods described in “Understand the Purpose of the “Provider” SSPIs” on page 3-3 and the following method:

getAuditChannel

```java
public AuditChannel getAuditChannel();
```

The getAuditChannel method obtains the implementation of the AuditChannel SSPI. For a single runtime class called MyAuditProviderImpl.java, the implementation of the getAuditChannel method would be:

```java
return this;
```

If there are two runtime classes, then the implementation of the getAuditChannel method could be:

```java
return new MyAuditChannelImpl;
```

This is because the runtime class that implements the AuditProvider SSPI is used as a factory to obtain classes that implement the AuditChannel SSPI.

For more information about the AuditProvider SSPI and the getAuditChannel method, see the WebLogic Server API Reference Javadoc.
Implement the AuditChannel SSPI

To implement the AuditChannel SSPI, provide an implementation for the following method:

```java
public void writeEvent(AuditEvent event)
```

The `writeEvent` method writes an audit record based on the information specified in the `AuditEvent` object that is passed in. For more information about `AuditEvent` objects, see “Create an Audit Event” on page 12-3.

For more information about the AuditChannel SSPI and the `writeEvent` method, see the WebLogic Server API Reference Javadoc.

Example: Creating the Runtime Class for the Sample Auditing Provider

Listing 10-5 shows the `SimpleSampleAuditProviderImpl.java` class, which is the runtime class for the sample Auditing provider. This runtime class includes implementations for:

- The three methods inherited from the `SecurityProvider` interface: `initialize`, `getDescription` and `shutdown` (as described in “Understand the Purpose of the "Provider" SSPIs” on page 3-3.)

- The method inherited from the `AuditProvider` SSPI: the `getAuditChannel` method (as described in “Implement the AuditProvider SSPI” on page 10-11).

- The method in the `AuditChannel` SSPI: the `writeEvent` method (as described in “Implement the AuditChannel SSPI” on page 10-12).

Note: The bold face code in Listing 10-5 highlights the class declaration and the method signatures.

```
package examples.security.providers.audit.simple;
import java.io.File;
import java.io.FileOutputStream;
import java.io.IOException;
import java.io.PrintStream;
import javax.servlet.http.HttpServletRequest;
import weblogic.management.security.ProviderMBean;
import weblogic.security.service.ContextHandler;
```
import weblogic.security.spi.AuditChannel;
import weblogic.security.spi.AuditContext;
import weblogic.security.spi.AuditEvent;
import weblogic.security.spi.AuditProvider;
import weblogic.security.spi.SecurityServices;

public final class SimpleSampleAuditProviderImpl implements AuditProvider,
AuditChannel
{
    private String      description; // a description of this provider
    private PrintStream log;         // the log file that events are written to
    private boolean     handlerEnabled = false;
    private final static String HTTP_REQUEST_ELEMENT =
"com.bea.contextelement.servlet.HttpServletRequest";

    public void initialize(ProviderMBean mbean, SecurityServices services)
    {
        System.out.println("SimpleSampleAuditProviderImpl.initialize");
        SimpleSampleAuditorMBean myMBean = (SimpleSampleAuditorMBean)mbean;
        description = myMBean.getDescription() + "\n" + myMBean.getVersion();
        String [] activeHandlerEntries = myMBean.getActiveContextHandlerEntries();
        if (activeHandlerEntries != null) {
            for (int i=0; i<activeHandlerEntries.length; i++) {
                if ((activeHandlerEntries[i] != null) &&
                    activeHandlerEntries[i].equalsIgnoreCase(HTTP_REQUEST_ELEMENT))
                {
                    handlerEnabled = true;
                    break;
                }
            }
        }
        File file = new File(myMBean.getLogFileName());
        System.out.println("\tlogging to " + file.getAbsolutePath());
        try {
            log = new PrintStream(new FileOutputStream(file), true);
        } catch (IOException e) {
            throw new RuntimeException(e.toString());
        }
    }

    public String getDescription()
    {
    }
Auditing Providers

public void shutdown()
{
    System.out.println("SimpleSampleAuditProviderImpl.shutdown");
    log.close();
}

public AuditChannel getAuditChannel()
{
    return this;
}

public void writeEvent(AuditEvent event)
{
    log.println(event);
    if (!handlerEnabled || !(event instanceof AuditContext))
        return;
    AuditContext auditContext = (AuditContext)event;
    ContextHandler handler = auditContext.getContext();
    if ((handler == null) || (handler.size() == 0))
        return;

    Object requestValue = handler.getValue("com.bea.contextelement.servlet.HttpServletRequest");
    if ((requestValue == null) || (!(requestValue instanceof HttpServletRequest)))
        return;
    HttpServletRequest request = (HttpServletRequest) requestValue;
    log.println("    " + HTTP_REQUEST_ELEMENT + " method: " + request.getMethod());
    log.println("    " + HTTP_REQUEST_ELEMENT + " URL: " + request.getRequestURL());
    log.println("    " + HTTP_REQUEST_ELEMENT + " URI: " + request.getRequestURI());
    return;
}
How to Develop a Custom Auditing Provider

Generate an MBean Type Using the WebLogic MBeanMaker

Before you start generating an MBean type for your custom security provider, you should first:

- “Understand Why You Need an MBean Type” on page 3-11
- “Determine Which SSPI MBeans to Extend and Implement” on page 3-11
- “Understand the Basic Elements of an MBean Definition File (MDF)” on page 3-12
- “Understand the SSPI MBean Hierarchy and How It Affects the Administration Console” on page 3-15
- “Understand What the WebLogic MBeanMaker Provides” on page 3-17

When you understand this information and have made your design decisions, create the MBean type for your custom Auditing provider by following these steps:

1. “Create an MBean Definition File (MDF)” on page 10-15
2. “Use the WebLogic MBeanMaker to Generate the MBean Type” on page 10-16
3. “Use the WebLogic MBeanMaker to Create the MBean JAR File (MJF)” on page 10-18
4. “Install the MBean Type Into the WebLogic Server Environment” on page 10-19

Notes: All instructions provided in this section assume that you are working in a Windows environment.

Create an MBean Definition File (MDF)

To create an MBean Definition File (MDF), follow these steps:

1. Copy the MDF for the sample Auditing provider to a text file.
   
   Note: The MDF for the sample Auditing provider is called SampleAuditor.xml.

2. Modify the content of the <MBeanType> and <MBeanAttribute> elements in your MDF so that they are appropriate for your custom Auditing provider.

3. Add any custom attributes and operations (that is, additional <MBeanAttribute> and <MBeanOperation> elements) to your MDF.

4. Save the file.

Note: A complete reference of MDF element syntax is available in Appendix A, “MBean Definition File (MDF) Element Syntax.”
Use the WebLogic MBeanMaker to Generate the MBean Type

Once you create your MDF, you are ready to run it through the WebLogic MBeanMaker. The WebLogic MBeanMaker is currently a command-line utility that takes as its input an MDF, and outputs some intermediate Java files, including an MBean interface, an MBean implementation, and an associated MBean information file. Together, these intermediate files form the **MBean type** for your custom security provider.

The instructions for generating an MBean type differ based on the design of your custom Auditing provider. Follow the instructions that are appropriate to your situation:

- “No Custom Operations” on page 10-16
- “Custom Operations” on page 10-17

No Custom Operations

If the MDF for your custom Auditing provider does not include any custom operations, follow these steps:

1. Create a new DOS shell.
2. Type the following command:
   ```
   java -DMDF=xmlfile -Dfiles=filesdir -DcreateStubs=true
   weblogic.management.commo.WebLogicMBeanMaker
   ```
   where the `-DMDF` flag indicates that the WebLogic MBeanMaker should translate the MDF into code, `xmlFile` is the MDF (the XML MBean Description File) and `filesdir` is the location where the WebLogic MBeanMaker will place the intermediate files for the MBean type.

   Whenever `xmlfile` is provided, a new set of output files is generated.

   Each time you use the `-DcreateStubs=true` flag, it overwrites any existing MBean implementation file.

   **Note:** As of version 9.0 of WebLogic Server, you can also provide a directory that contains multiple MDF's by using the `-DMDFDIR <MDF directory name>` option. In prior versions of WebLogic Server, the WebLogic MBeanMaker processed only one MDF at a time. Therefore, you had to repeat this process if you had multiple MDFs (in other words, multiple Auditing providers).

3. Proceed to “Use the WebLogic MBeanMaker to Create the MBean JAR File (MJF)” on page 10-18.
Custom Operations

If the MDF for your custom Auditing provider does include custom operations, consider the following:

- Are you creating an MBean type for the first time? If so, follow these steps:
  1. Create a new DOS shell.
  2. Type the following command:
     
     ```
     java -DMDF=xmlfile -Dfiles=filesdir -DcreateStubs=true
     weblogic.management.commo.WebLogicMBeanMaker
     ```
     
     where the `-DMDF` flag indicates that the WebLogic MBeanMaker should translate the MDF into code, `xmlFile` is the MDF (the XML MBean Description File) and `filesdir` is the location where the WebLogic MBeanMaker will place the intermediate files for the MBean type.

     Whenever `xmlfile` is provided, a new set of output files is generated.

     Each time you use the `DcreateStubs=true` flag, it overwrites any existing MBean implementation file.

     **Note:** As of version 9.0 of WebLogic Server, you can also provide a directory that contains multiple MDF's by using the `-DMDFDIR <MDF directory name>` option. In prior versions of WebLogic Server, the WebLogic MBeanMaker processed only one MDF at a time. Therefore, you had to repeat this process if you had multiple MDFs (in other words, multiple Auditing providers).

     3. For any custom operations in your MDF, implement the methods using the method stubs.

     4. Save the file.

     5. Proceed to “Use the WebLogic MBeanMaker to Create the MBean JAR File (MJF)” on page 10-18.

- Are you updating an existing MBean type? If so, follow these steps:
  1. Copy your existing MBean implementation file to a temporary directory so that your current method implementations are not overwritten by the WebLogic MBeanMaker.

  2. Create a new DOS shell.

  3. Type the following command:
     
     ```
     java -DMDF=xmlfile -Dfiles=filesdir -DcreateStubs=true
     weblogic.management.commo.WebLogicMBeanMaker
     ```
where the -DMDF flag indicates that the WebLogic MBeanMaker should translate the MDF into code, xmlFile is the MDF (the XML MBean Description File) and filesdir is the location where the WebLogic MBeanMaker will place the intermediate files for the MBean type.

Whenever xmlfile is provided, a new set of output files is generated.

Each time you use the -DcreateStubs=true flag, it overwrites any existing MBean implementation file.

**Note:** The WebLogic MBeanMaker processes one MDF at a time. Therefore, you may have to repeat this process if you have multiple MDFs (in other words, multiple Auditing providers).

4. If you modified the MDF to include any custom operations that were not in the original MDF, implement the methods using the method stubs.

5. Save the version of the MBean implementation file that is complete (that is, has all methods implemented).

6. Copy this MBean implementation file into the directory where the WebLogic MBeanMaker placed the intermediate files for the MBean type. You specified this as filesdir in step 3. (You will be overriding the MBean implementation file generated by the WebLogic MBeanMaker as a result of step 3.)

7. Proceed to “Use the WebLogic MBeanMaker to Create the MBean JAR File (MJF)” on page 10-18.

**About the Generated MBean Interface File**

The MBean interface file is the client-side API to the MBean that your runtime class or your MBean implementation will use to obtain configuration data. It is typically used in the initialize method as described in “Understand the Purpose of the “Provider” SSPIs” on page 3-3.

Because the WebLogic MBeanMaker generates MBean types from the MDF you created, the generated MBean interface file will have the name of the MDF, plus the text “MBean” appended to it. For example, the result of running the SampleAuditor MDF through the WebLogic MBeanMaker will yield an MBean interface file called SampleAuditorMBean.java.

**Use the WebLogic MBeanMaker to Create the MBean JAR File (MJF)**

Once your have run your MDF through the WebLogic MBeanMaker to generate your intermediate files, and you have edited the MBean implementation file to supply implementations for the appropriate methods within it, you need to package the MBean files and the runtime...
classes for the custom Auditing provider into an MBean JAR File (MJF). The WebLogic MBeanMaker also automates this process.

To create an MJF for your custom Auditing provider, follow these steps:

1. Create a new DOS shell.
2. Type the following command:
   ```
   java -DMJF=jarfile -Dfiles=filesdir
   weblogic.management.commo.WebLogicMBeanMaker
   ```
   where the -DMJF flag indicates that the WebLogic MBeanMaker should build a JAR file containing the new MBean types, `jarfile` is the name for the MJF and `<filesdir>` is the location where the WebLogic MBeanMaker looks for the files to JAR into the MJF.

   Compilation occurs at this point, so errors are possible. If `jarfile` is provided, and no errors occur, an MJF is created with the specified name.

   **Notes:** When you create a JAR file for a custom security provider, a set of XML binding classes and a schema are also generated. You can choose a namespace to associate with that schema. Doing so avoids the possibility that your custom classes will conflict with those provided by Oracle. The default for the namespace is vendor. You can change this default by passing the -targetNameSpace argument to the WebLogicMBeanMaker or the associated WLMBeanMaker ant task.

   If you want to update an existing MJF, simply delete the MJF and regenerate it. The WebLogic MBeanMaker also has a -DIncludeSource option, which controls whether source files are included into the resulting MJF. Source files include both the generated source and the MDF itself. The default is false. This option is ignored when -DMJF is not used.

   The resulting MJF can be installed into your WebLogic Server environment, or distributed to your customers for installation into their WebLogic Server environments.

**Install the MBean Type Into the WebLogic Server Environment**

To install an MBean type into the WebLogic Server environment, copy the MJF into the `WL_HOME\server\lib\mbeantypes` directory, where `WL_HOME` is the top-level installation directory for WebLogic Server. This “deploys” your custom Auditing provider—that is, it makes the custom Auditing provider manageable from the WebLogic Server Administration Console.

**Note:** `WL_HOME\server\lib\mbeantypes` is the default directory for installing MBean types. (Beginning with 9.0, security providers can be loaded from...
Auditing Providers

However, if you want WebLogic Server to look for MBean types in additional directories, use the
-Dweblogic.alternateTypesDirectory=<dir> command-line flag when starting your server, where <dir> is a comma-separated list of directory names. When you use this flag, WebLogic Server will always load MBean types from
WL_HOME\server\lib\mbeantypes first, then will look in the additional directories and load all valid archives present in those directories (regardless of their extension). For example, if -Dweblogic.alternateTypesDirectory = dirX,dirY, WebLogic Server will first load MBean types from WL_HOME\server\lib\mbeantypes, then any valid archives present in dirX and dirY. If you instruct WebLogic Server to look in additional directories for MBean types and are using the Java Security Manager, you must also update the weblogic.policy file to grant appropriate permissions for the MBean type (and thus, the custom security provider). For more information, see "Using the Java Security Manager to Protect WebLogic Resources" in Programming WebLogic Security.

You can create instances of the MBean type by configuring your custom Auditing provider (see “Configure the Custom Auditing Provider Using the Administration Console” on page 10-20), and then use those MBean instances from a GUI, from other Java code, or from APIs. For example, you can use the WebLogic Server Administration Console to get and set attributes and invoke operations, or you can develop other Java objects that instantiate MBeans and automatically respond to information that the MBeans supply. We recommend that you back up these MBean instances.

Configure the Custom Auditing Provider Using the Administration Console

Configuring a custom Auditing provider means that you are adding the custom Auditing provider to your security realm, where it can be accessed by security providers requiring audit services.

Configuring custom security providers is an administrative task, but it is a task that may also be performed by developers of custom security providers. This section contains information that is important for the person configuring your custom Auditing providers:

- Configuring Audit Severity

Note:  The steps for configuring a custom Auditing provider using the WebLogic Server Administration Console are described under “Configuring WebLogic Security Providers” in Securing WebLogic Server.
Configuring Audit Severity

During the configuration process, an Auditing provider’s audit severity must be set to one of the following severity levels:

- INFORMATION
- WARNING
- ERROR
- SUCCESS
- FAILURE

This severity represents the level at which the custom Auditing provider will initiate auditing.

Security Framework Audit Events

This section describes the audit events that are posted by the WebLogic Server Security Framework. If you write a custom audit provider, it should be prepared to handle these events. The following topics are covered in this section:

- “Passing Additional Audit Information” on page 10-21
- “Audit Event Interfaces and Audit Events” on page 10-23

Passing Additional Audit Information

The WebLogic Security providers implement the appropriate AuditEvent interfaces and post those events to the Audit provider. The audit events that also implement the AuditContext interface can provide more information via a ContextHandler.

Table 10-1 lists the weblogic.security.spi subinterfaces that extend the AuditEvent SSPI, and indicates which subinterfaces implement the AuditContext interface.
## Table 10-1 Audit Events

<table>
<thead>
<tr>
<th>Audit Event Name</th>

Audit Event Interfaces and Audit Events

In the weblogic.security.spi package, WebLogic Security defines one top-level base interface (AuditEvent) with derived interfaces that represent the different types of audit events. Subsequent sections describe when the security framework and security providers post the following audit events:

- AuditApplicationVersionEvent
- AuditAtnEventV2
- AuditAtzEvent
- AuditCertPathBuilderEvent, AuditCertPathValidatorEvent
- AuditConfigurationEvent (AuditCreateConfigurationEvent, AuditDeleteConfigurationEvent, AuditInvokeConfigurationEvent, AuditSetAttributeConfigurationEvent)
- AuditCredentialMappingEvent
Auditing Providers

- AuditLifecycleEvent
- AuditMgmtEvent
- AuditRoleDeploymentEvent (AuditStartRoleDeployEvent, AuditEndRoleDeployEvent, AuditRoleUndeployEvent, AuditRoleDeleteAppEvent)
- AuditRoleEvent (RoleConsumerAuditEvent)

**AuditApplicationVersionEvent**

Application version audit events are posted by the security framework. You can use the `getEventType` method to get the type of the audit event. The actual audit string returned by `getEventType` is `String = "Application Version Audit Event"`. Table 10-2 describes the conditions under which the event is posted and severity level of the event.
## Table 10-2 Application Version Events

<table>
<thead>
<tr>
<th>Component</th>
<th>Description</th>

<td></td>
</tr>
</tbody>
</table>
AuditAtnEventV2

Authentication audit events are posted by the security framework. You can use the `getEventType` method to get the type of the audit event. The actual audit string returned by `getEventType` is 

```
String eventType = "Event Type = Authentication Audit Event"
```

Table 10-3 describes the conditions under which the event is posted and severity level of the event.

<table>
<thead>
<tr>
<th>Component</th>
<th>Description</th>
<th>Severity</th>
</tr>
</thead>
<tbody>
<tr>
<td>Security Framework</td>
<td>Posted after successful authentication of a user.</td>
<td>Success</td>
</tr>
<tr>

<td>Failure</td>
</tr>
<tr>
<td>Security Framework</td>
<td>Posted after an unsuccessful identity assertion (when username returned from identity assertion callback handler is null or zero length).</td>
<td>Failure</td>
</tr>
</tbody>
</table>
AuditAtzEvent

Authorization audit events are posted by the security framework. You can use the `getEventType` method to get the type of the audit event. The actual audit string returned by `getEventType` is `String eventType = "Event Type = Authorization Audit Event V2 ".

Table 10-4 describes the conditions under which the events are posted and severity level of the event.

AuditCerPathBuilderEvent, AuditCertPathValidatorEvent

CertPath Builder and Validation audit events are posted by the security framework. You can use the `getEventType` method to get the type of the audit event. The actual audit strings returned by `getEventType` are as follows:
• String eventType = "Event Type = CertPathBuilder Audit Event"

• String eventType = "Event Type = CertPathValidator Audit Event"

Table 10-5 describes the conditions under which the events are posted and severity level of the event.

Table 10-5 CertPath Builder and Validation Events

<table>
<thead>
<tr>
<th>Component</th>
<th>Description</th>
<th>Severity</th>
</tr>
</thead>
<tbody>
<tr>
<td>Security Framework</td>

<td>Failure</td>
</tr>
<tr>
<td>Security Framework</td>
<td>Posted if the Certificate Path is successfully validated.</td>
<td>Success</td>
</tr>
<tr>
<td>Security Framework</td>
<td>Posted if the Certificate Path is not successfully validated.</td>
<td>Failure</td>
</tr>
</tbody>
</table>

**AuditConfigurationEvent**

Configuration audit events are posted by the security framework. The following events are posted:

• AuditConfigurationEvent

• AuditCreateConfigurationEvent (The actual audit string returned by `getEventType` is `String CREATE_EVENT = "Create Configuration Audit Event"`)

• AuditDeleteConfigurationEvent (The actual audit string returned by `getEventType` is `String DELETE_EVENT = "Delete Configuration Audit Event"`)

• AuditInvokeConfigurationEvent (The actual audit string returned by `getEventType` is `String INVOKE_EVENT = "Invoke Configuration Audit Event"`)

• AuditSetAttributeConfigurationEvent (The actual audit string returned by `getEventType` is `String SETATTRIBUTE_EVENT = "SetAttribute Configuration Audit Event"`)
Table 10-6 describes the conditions under which the events are posted and severity level of the events.

<table>
<thead>
<tr>
<th>Component</th>
<th>Description</th>
<th>Severity</th>
</tr>
</thead>
<tbody>
<tr>
<td>WebLogic Management Infrastructure</td>
<td>The WebLogic Management infrastructure implements this interface and may post configuration audit events for the following configuration change events:</td>
<td>Success or Failure</td>
</tr>
</tbody>
</table>

- A request to create a new configuration artifact has been allowed or disallowed.
- A request to delete an existing configuration artifact has been allowed or disallowed.
- A request to modify an existing configuration artifact has been allowed or disallowed.
- A invoke an operation on an existing configuration artifact has been allowed or disallowed.

AuditCredentialMappingEvent

Credential Mapping audit events are posted by the security framework. You can use the `getEventType` method to get the type of the audit event. The actual audit string returned by `getEventType` is `String EVENT_TYPE = "Event Type = Credential Mapping Audit Event"`. Table 10-7 describes the condition under which the events are posted and severity level of the event.
The AuditLifecycleEvent interface is used to post audit lifecycle events. The WebLogic Security Framework implements this interface and may post audit events for the following security events:

- After the auditing service in the framework is started.
- Before the auditing service in the framework is stopped.

The actual audit string returned by getEventType is `String eventType = "Event Type = AuditLifecycle Audit Event"`.

The AuditLifecycleEventType class describes the audit service lifecycle event types that are supported. Possible values are `START_AUDIT` and `STOP_AUDIT`.

An Auditing provider can use this interface to get additional information about the audit lifecycle event. The `AuditSeverity` and `AuditLifecycleEventType` attributes can be used to determine which of the above audit events has been posted.

### AuditMgmtEvent

Management audit events are not currently posted by either the Security Framework or by the supplied providers. However, a custom security provider may implement this interface and post different audit events for the various management operations performed by the custom security provider.

An Auditing provider can use this interface to get additional information about the management audit event. The `AuditSeverity` attribute can be used to determine whether the management operation succeeded or failed.

---

**Table 10-7  Credential Mapping Audit Events**

<table>
<thead>
<tr>
<th>Component</th>
<th>Description</th>
<th>Severity</th>
</tr>
</thead>
<tbody>
<tr>
<td>Security Framework</td>
<td>The WebLogic Security Framework implements this interface and may post audit events for the following security events:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Credentials for a WLS User are requested</td>
<td>Success</td>

<tr>
<td></td>
<td>Credentials for a Subject are requested</td>
<td></td>
</tr>
</tbody>
</table>
AuditPolicyEvent

AuditPolicyEvent is posted by the security framework and the WebLogic Authorization provider. The security framework posts audit policy events when policies are deployed to or undeployed from an authorization provider. The WebLogic Server authorization provider posts audit policy events when creating, deleting, or updating policies. You can use the `getEventType` method to get the type of the audit event. The audit events and the actual audit strings returned by `getEventType` are as follows:

- **AuditStartPolicyDeployEvent** (The actual audit string returned by `getEventType` is `String eventType = "Event Type = Authorization Start Policy Deploy Audit Event ".`)
- **AuditPolicyUndeployEvent** (The actual audit string returned by `getEventType` is `String eventType = "Event Type = Authorization Policy Undeploy Audit Event ".`)
- **AuditPolicyDeployEvent** (The actual audit string returned by `getEventType` is `String eventType = "Event Type = Authorization Policy Deploy Audit Event ".`)
- **AuditPolicyDeleteAppEvent** (The actual audit string returned by `getEventType` is `String eventType = "Event Type = Authorization Delete Application Policies Audit Event ".`)
- **AuditEndPolicyDeployEvent** (The actual audit string returned by `getEventType` is `String eventType = "Event Type = Authorization End Policy Deploy Audit Event ".`)

For **PolicyConsumerAuditEvent**, which implements **AuditPolicyEvent**, the actual audit strings returned by `getEventType` are:

- `String eventType = "Event Type = Policy Consumer Get Handler"
- `String eventType = "Event Type = Policy Consumer Set Policy"
- `String eventType = "Event Type = Policy Consumer Set Unchecked Policy"
- `String eventType = "Event Type = Policy Consumer Done"

Table 10-8 describes the conditions under which the events are posted and lists the event severity level.
AuditRoleDeploymentEvent

The security framework posts audit role deployment events when roles are deployed to or undeployed from a role mapping provider. You can use the `getEventType` method to get the type of the audit event. The following events are posted:

- `AuditRoleDeployEvent` *(The actual audit string returned by `getEventType` is `String eventType = "Event Type = RoleManager Deploy Audit Event ".`)*
- `AuditStartRoleDeployEvent` *(The actual audit string returned by `getEventType` is `String eventType = "Event Type = RoleManager Start Deploy Role Audit Event ".`)*
- `AuditEndRoleDeployEvent` *(The actual audit string returned by `getEventType` is `String eventType = "Event Type = RoleManager End Deploy Role Audit Event ".`)*

AuditRoleEvent
The WebLogic Authorization provider posts audit role events when roles are created, deleted, or updated. You can use the getEventType method to get the type of the audit event. The actual audit strings returned by getEventType are as follows:

- String eventType = "Event Type = RoleManager Audit Event 
- String eventType = "Event Type = RoleManager Delete Application Roles Audit Event 

Table 10-9  Audit Role Deployment Events
For RoleConsumerAuditEvent, which implements AuditRoleEvent, the actual audit strings returned by getEventType are:

- String eventType = "Event Type = Role Consumer Get Handler"
- String eventType = "Event Type = Role Consumer Set Role"
- String eventType = "Event Type = Role Consumer Done"

Table 10-10 describes the conditions under which the events are posted and lists the event severity level.

</table>
Credential mapping is the process whereby a legacy system's database is used to obtain an appropriate set of credentials to authenticate users to a target resource. In WebLogic Server, a Credential Mapping provider is used to provide credential mapping services and bring new types of credentials into the WebLogic Server environment.

The following sections describe Credential Mapping provider concepts and functionality, and provide step-by-step instructions for developing a custom Credential Mapping provider:

- “Credential Mapping Concepts” on page 11-1
- “Do You Need to Develop a Custom Credential Mapping Provider?” on page 11-3
- “How to Develop a Custom Credential Mapping Provider” on page 11-4

**Credential Mapping Concepts**

A subject, or source of a WebLogic resource request, has security-related attributes called credentials. A credential may contain information used to authenticate the subject to new services. Such credentials include username/password combinations, Kerberos tickets, and public key certificates. Credentials might also contain data that allows a subject to perform certain activities. Cryptographic keys, for example, represent credentials that enable the subject to sign or encrypt data.

A credential map is a mapping of credentials used by WebLogic Server to credentials used in a legacy (or any remote) system, which tell WebLogic Server how to connect to a given resource.
in that system. In other words, credential maps allow WebLogic Server to log in to a remote system on behalf of a subject that has already been authenticated. You can map credentials in this way by developing a Credential Mapping provider.

The Credential Mapping Process

Figure 11-1 illustrates how Credential Mapping providers interact with the WebLogic Security Framework during the credential mapping process, and an explanation follows.

Figure 11-1  Credential Mapping Providers and the Credential Mapping Process

Generally, credential mapping is performed in the following manner:

1. Application components, such as JavaServer Pages (JSPs), servlets, Enterprise JavaBeans (EJBs), or Resource Adapters call into the WebLogic Security Framework through the appropriate resource container. As part of the call, the application component passes in the subject (that is, the “who” making the request), the WebLogic resource (that is, the “what” that is being requested) and information about the type of credentials needed to access the WebLogic resource.
Do You Need to Develop a Custom Credential Mapping Provider?

2. The WebLogic Security Framework sends the application component’s request for credentials to a configured Credential Mapping provider. It is up to the credential mapper to decide whether it supports the token or not. If it supports the token, it performs its processing.

3. The Credential Mapping provider consults the legacy system's database to obtain a set of credentials that match those requested by the application component.

5. The WebLogic Security Framework passes the credentials back to the requesting application component through the resource container.

   The application component uses the credentials to access the external system. The external system might be a database resource, such as an Oracle or SQL Server.

Do You Need to Develop a Custom Credential Mapping Provider?

The default (that is, active) security realm for WebLogic Server includes a WebLogic Credential Mapping provider. The WebLogic Credential Mapping provider maps WebLogic Server users and groups to the appropriate username/password credentials that may be required by other, external systems. If the type of credential mapping you want is between WebLogic Server users and groups and username/password credentials in another system, then the WebLogic Credential Mapping provider is sufficient.

WebLogic Server includes a PKI Credential Mapping provider. The PKI (Public Key Infrastructure) Credential Mapping provider included in WebLogic Server maps a WebLogic Server subject (the initiator) and target resource (and an optional credential action) to a key pair or public certificate that should be used by the application when using the targeted resource. The PKI Credential Mapping provider uses the subject and resource name to retrieve the corresponding credential from the keystore. The PKI Credential Mapping provider supports the CredentialMapperV2.PKI_KEY_PAIR_TYPE and CredentialMapperV2.PKI_TRUSTED_CERTIFICATE_TYPE token types.

WebLogic Server also includes the SAML Credential Mapping provider. The SAML Credential Mapping provider generates SAML 1.1 assertions for authenticated subjects based on a target site or resource. If the requested target has not been configured and no defaults are set, an assertion will not be generated. User information and group membership (if configured as such) are put in the AttributeStatement. The SAML Credential Mapping provider supports the CredentialMapperV2.SAML_ASSERTION_B64_TYPE,
CredentialMapperV2.SAML_ASSERTION_DOM_TYPE, and
CredentialMapperV2.SAML_ASSERTION_TYPE token types.

If the out-of-the-box Credential Mapping providers do not meet your needs, then you need to
develop a custom Credential Mapping provider. Note, however, that only the following token
types are ever requested by the WLS resource containers:

- CredentialMapperV2.PASSWORD_TYPE
- CredentialMapperV2.PKI_KEY_PAIR_TYPE
- CredentialMapperV2.PKI_TRUSTED_CERTIFICATE_TYPE
- CredentialMapperV2.SAML_ASSERTION_B64_TYPE
- CredentialMapperV2.SAML_ASSERTION_DOM_TYPE
- CredentialMapperV2.SAML_ASSERTION_TYPE
- CredentialMapperV2.USER_PASSWORD_TYPE

**Does Your Custom Credential Mapping Provider Need to Support Application Versioning?**

All Authorization, Role Mapping, and Credential Mapping providers for the security realm must
support application versioning in order for an application to be deployed using versions. If you
develop a custom security provider for Authorization, Role Mapping, or Credential Mapping and
need to support versioned applications, you must implement the Versionable Application SSPI,
as described in Chapter 14, “Versionable Application Providers.”

**How to Develop a Custom Credential Mapping Provider**

If the WebLogic Credential Mapping provider does not meet your needs, you can develop a
custom Credential Mapping provider by following these steps:

1. “Create Runtime Classes Using the Appropriate SSPIs” on page 11-5
2. “Generate an MBean Type Using the WebLogic MBeanMaker” on page 11-8
3. “Provide a Mechanism for Credential Map Management” on page 11-15
4. “Provide a Mechanism for Credential Map Management” on page 11-15
Create Runtime Classes Using the Appropriate SSPIs

Before you start creating runtime classes, you should first:

- “Understand the Purpose of the “Provider” SSPIs” on page 3-3
- “Determine Which “Provider” Interface You Will Implement” on page 3-5
- “Understand the SSPI Hierarchy and Determine Whether You Will Create One or Two Runtime Classes” on page 3-7

When you understand this information and have made your design decisions, create the runtime classes for your custom Credential Mapping provider by following these steps:

- “Implement the CredentialProviderV2 SSPI” on page 11-5 or “Implement the DeployableCredentialProvider SSPI” on page 11-6
- “Implement the CredentialMapperV2 SSPI” on page 11-6

Implement the CredentialProviderV2 SSPI

To implement the CredentialProviderV2 SSPI, provide implementations for the methods described in “Understand the Purpose of the “Provider” SSPIs” on page 3-3 and the following method:

```
public CredentialMapperV2 getCredentialProvider();
```

The `getCredentialProviderV2` method obtains the implementation of the `CredentialMapperV2` SSPI. For a single runtime class called `MyCredentialMapperProviderImpl.java` (as in Figure 3-3), the implementation of the `getCredentialProvider` method would be:

```
return this;
```

If there are two runtime classes, then the implementation of the `getCredentialProvider` method could be:

```
return new MyCredentialMapperImpl;
```

This is because the runtime class that implements the `CredentialProviderV2` SSPI is used as a factory to obtain classes that implement the `CredentialMapperV2` SSPI.

For more information about the `CredentialProviderV2` SSPI and the `getCredentialProvider` method, see the WebLogic Server API Reference Javadoc.
Implement the DeployableCredentialProvider SSPI

**Note:** The DeployableCredentialProvider SSPI is deprecated in this release of WebLogic Server.

To implement the DeployableCredentialProvider SSPI, provide implementations for the methods described in “Understand the Purpose of the “Provider” SSPIs” on page 3-3, “Implement the CredentialProviderV2 SSPI” on page 11-5, and the following methods:

**deployCredentialMapping**

```java
public void deployCredentialMapping(Resource resource, String initiatingPrincipal, String eisUsername, String eisPassword) throws ResourceCreationException;
```

The `deployCredentialMapping` method deploys credential maps. If the mapping already exists, it is removed and replaced by this mapping. The `resource` parameter represents the WebLogic resource to which the initiating principal (represented as a `String`) is requesting access. The Enterprise Information System (EIS) username and password are the credentials in the legacy (remote) system to which the credential maps are being made.

**undeployCredentialMappings**

```java
public void undeployCredentialMappings(Resource resource) throws ResourceRemovalException;
```

The `undeployCredentialMappings` method undeploys credential maps (that is, deletes a credential mapping on behalf of an undeployed Resource Adapter from a database). The `resource` parameter represents the WebLogic resource for which the mapping should be removed.

**Note:** The `deployCredentialMapping/undeployCredentialMappings` methods operate on username/password credentials only.

For more information about the DeployableCredentialProvider SSPI and the `deployCredentialMapping/undeployCredentialMappings` methods, see the *WebLogic Server API Reference Javadoc*.

Implement the CredentialMapperV2 SSPI

The CredentialMapperV2 interface defines the security service provider interface (SSPI) for objects capable of obtaining the appropriate set of credentials for a particular resource that is scoped within an application.

Only the following credential types are supported and passed to the `CredentialMapperV2` interface:
How to Develop a Custom Credential Mapping Provider

- PASSWORD_TYPE
- PKI_KEY_PAIR_TYPE
- PKI_TRUSTED_CERTIFICATE_TYPE
- SAML_ASSERTION_B64_TYPE
- SAML_ASSERTION_DOM_TYPE
- SAML_ASSERTION_TYPE
- USER_PASSWORD_TYPE

To implement the CredentialMapperV2 SSPI, you must provide implementations for the following methods:

getCredential

```java
public Object getCredential(Subject requestor, String initiator, Resource resource, ContextHandler handler, String credType);
```

The `getCredential` method returns the credential of the specified type from the target resource associated with the specified initiator.

getCredentials

```java
public Object[] getCredentials(Subject requestor, Subject initiator, Resource resource, ContextHandler handler, String credType);
```

The `getCredentials` method returns the credentials of the specified type from the target resource associated with the specified initiator.

For more information about the `CredentialMapperV2 SSPI` and the `getCredential` and `getCredentials` methods, see the `WebLogic Server API Reference Javadoc`.

Developing Custom Credential Mapping Providers That Are Compatible With the Realm Adapter Authentication Provider

An Authentication provider is the security provider responsible for populating a subject with users and groups, which are then extracted from the subject by other types of security providers, including Credential Mapping providers. If the Authentication provider configured in your security realm is a Realm Adapter Authentication provider, the user and group information will be stored in the subject in a way that is slightly different from other Authentication providers. Therefore, this user and group information must also be extracted in a slightly different way.

Listing 11-1 provides code that can be used by custom Credential Mapping providers to check whether a subject matches a user or group name when a Realm Adapter Authentication provider
was used to populate the subject. This code belongs in whatever form of the `getCredentials`
method you choose to implement. The code makes use of the methods available in the
`weblogic.security.SubjectUtils` class.

**Listing 11-1  Sample Code to Check if a Subject Matches a User or Group Name**

```java
/**
 * Determines if the Subject matches a user/group name.
 *
 * @param principalWant A String containing the name of a principal in this role
 * (that is, the role definition).
 *
 * @param subject A Subject that contains the Principals that identify the user
 * who is trying to access the resource as well as the user's groups.
 *
 * @return A boolean. true if the current subject matches the name of the
 * principal in the role, false otherwise.
 */
private boolean subjectMatches(String principalWant, Subject subject) {
    // first, see if it's a group name match
    if (SubjectUtils.isUserInGroup(subject, principalWant)) {
        return true;
    }
    // second, see if it's a user name match
    if (principalWant.equals(SubjectUtils.getUsername(subject))) {
        return true;
    }
    // didn't match
    return false;
}
```

**Generate an MBean Type Using the WebLogic MBeanMaker**

Before you start generating an MBean type for your custom security provider, you should first:

- “Understand Why You Need an MBean Type” on page 3-11
- “Determine Which SSPI MBeans to Extend and Implement” on page 3-11
- “Understand the Basic Elements of an MBean Definition File (MDF)” on page 3-12
How to Develop a Custom Credential Mapping Provider

- “Understand the SSPI MBean Hierarchy and How It Affects the Administration Console” on page 3-15
- “Understand What the WebLogic MBeanMaker Provides” on page 3-17

When you understand this information and have made your design decisions, create the MBean type for your custom Credential Mapping provider by following these steps:

1. “Create an MBean Definition File (MDF)” on page 11-9
2. “Use the WebLogic MBeanMaker to Generate the MBean Type” on page 11-9
3. “Use the WebLogic MBeanMaker to Create the MBean JAR File (MJF)” on page 11-13
4. “Install the MBean Type Into the WebLogic Server Environment” on page 11-14

Notes: All instructions provided in this section assume that you are working in a Windows environment.

Create an MBean Definition File (MDF)

To create an MBean Definition File (MDF), follow these steps:

1. Copy the MDF for the sample Authentication provider to a text file.
   Note: The MDF for the sample Authentication provider is called SimpleSampleAuthenticator.xml. (There is currently no sample Credential Mapping provider.)
2. Modify the content of the <MBeanType> and <MBeanAttribute> elements in your MDF so that they are appropriate for your custom Credential Mapping provider.
3. Add any custom attributes and operations (that is, additional <MBeanAttribute> and <MBeanOperation> elements) to your MDF.
4. Save the file.
   Note: A complete reference of MDF element syntax is available in Appendix A, “MBean Definition File (MDF) Element Syntax.”

Use the WebLogic MBeanMaker to Generate the MBean Type

Once you create your MDF, you are ready to run it through the WebLogic MBeanMaker. The WebLogic MBeanMaker is currently a command-line utility that takes as its input an MDF, and outputs some intermediate Java files, including an MBean interface, an MBean implementation,
and an associated MBean information file. Together, these intermediate files form the **MBean type** for your custom security provider.

The instructions for generating an MBean type differ based on the design of your custom Credential Mapping provider. Follow the instructions that are appropriate to your situation:

- “No Optional SSPI MBeans and No Custom Operations” on page 11-10
- “Optional SSPI MBeans or Custom Operations” on page 11-10

**No Optional SSPI MBeans and No Custom Operations**

If the MDF for your custom Credential Mapping provider does not implement any optional SSPI MBeans and does not include any custom operations, follow these steps:

1. Create a new DOS shell.
2. Type the following command:
   ```
   java -DMDF=xmlfile -Dfiles=filesdir -DcreateStubs=true
   weblogic.management.commo.WebLogicMBeanMaker
   ```
   where the `-DMDF` flag indicates that the WebLogic MBeanMaker should translate the MDF into code, `xmlFile` is the MDF (the XML MBean Description File) and `filesdir` is the location where the WebLogic MBeanMaker will place the intermediate files for the MBean type.
   
   Whenever `xmlfile` is provided, a new set of output files is generated.
   
   Each time you use the `-DcreateStubs=true` flag, it overwrites any existing MBean implementation file.

   **Note:** As of version 9.0 of WebLogic Server, you can also provide a directory that contains multiple MDFs by using the `-DMDFDIR <MDF directory name>` option. In prior versions of WebLogic Server, the WebLogic MBeanMaker processed only one MDF at a time. Therefore, you had to repeat this process if you had multiple MDFs (in other words, multiple Credential Mapping providers).

**Optional SSPI MBeans or Custom Operations**

If the MDF for your custom Credential Mapping provider does implement some optional SSPI MBeans or does include custom operations, consider the following:
How to Develop a Custom Credential Mapping Provider

- Are you creating an MBean type for the first time? If so, follow these steps:
  1. Create a new DOS shell.
  2. Type the following command:

     java -DMDF=xmlfile -Dfiles=filesdir -DcreateStubs=true
     weblogic.management.commo.WebLogicMBeanMaker

     where the -DMDF flag indicates that the WebLogic MBeanMaker should translate the MDF into code, xmlFile is the MDF (the XML MBean Description File) and filesdir is the location where the WebLogic MBeanMaker will place the intermediate files for the MBean type.

     Whenever xmlfile is provided, a new set of output files is generated.

     Each time you use the -DcreateStubs=true flag, it overwrites any existing MBean implementation file.

     Note: As of version 9.0 of WebLogic Server, you can also provide a directory that contains multiple MDF's by using the -DMDFDIR <MDF directory name> option. In prior versions of WebLogic Server, the WebLogic MBeanMaker processed only one MDF at a time. Therefore, you had to repeat this process if you had multiple MDFs (in other words, multiple Credential Mapping providers).

  3. If you implemented optional SSPI MBeans in your MDF, follow these steps:

     a. Locate the MBean implementation file.

        The MBean implementation file generated by the WebLogic MBeanMaker is named MBeanNameImpl.java. For example, for the MDF named MyCredentialMapper, the MBean implementation file to be edited is named MyCredentialMapperImpl.java.

     b. For each optional SSPI MBean that you implemented in your MDF, implement each method. Be sure to also provide implementations for any methods that the optional SSPI MBean inherits.

  4. If you included any custom operations in your MDF, implement the methods using the method stubs.

  5. Save the file.

- Are you updating an existing MBean type? If so, follow these steps:
1. Copy your existing MBean implementation file to a temporary directory so that your current method implementations are not overwritten by the WebLogic MBeanMaker.

2. Create a new DOS shell.

3. Type the following command:
   ```
   java -DMDF=xmlfile -Dfiles=filesdir -DcreateStubs=true
   weblogic.management.commo.WebLogicMBeanMaker
   ```
   where the -DMDF flag indicates that the WebLogic MBeanMaker should translate the MDF into code, xmlFile is the MDF (the XML MBean Description File) and filesdir is the location where the WebLogic MBeanMaker will place the intermediate files for the MBean type.
   
   Whenever xmlfile is provided, a new set of output files is generated.
   
   Each time you use the -DcreateStubs=true flag, it overwrites any existing MBean implementation file.

   **Note:** As of version 9.0 of WebLogic Server, you can also provide a directory that contains multiple MDFs by using the -DMDFDIR <MDF directory name> option. In prior versions of WebLogic Server, the WebLogic MBeanMaker processed only one MDF at a time. Therefore, you had to repeat this process if you had multiple MDFs (in other words, multiple Credential Mapping providers).

4. If you implemented optional SSPI MBeans in your MDF, follow these steps:
   a. Locate the MBean implementation file.

      The MBean implementation file generated by the WebLogic MBeanMaker is named MBeanNameImpl.java. For example, for the MDF named SampleCredentialMapper, the MBean implementation file to be edited is named SampleCredentialMapperImpl.java.

   b. Open your existing MBean implementation file (which you saved to a temporary directory in step 1).

   c. Synchronize the existing MBean implementation file with the MBean implementation file generated by the WebLogic MBeanMaker.

      Accomplishing this task may include, but is not limited to: copying the method implementations from your existing MBean implementation file into the newly-generated MBean implementation file (or, alternatively, adding the new methods from the newly-generated MBean implementation file to your existing MBean implementation file), and verifying that any changes to method signatures are reflected.
in the version of the MBean implementation file that you are going to use (for methods that exist in both MBean implementation files).

d. If you modified the MDF to implement optional SSPI MBeans that were not in the original MDF, implement each method. Be sure to also provide implementations for any methods that the optional SSPI MBean inherits.

5. If you modified the MDF to include any custom operations that were not in the original MDF, implement the methods using the method stubs.

6. Save the version of the MBean implementation file that is complete (that is, has all methods implemented).

7. Copy this MBean implementation file into the directory where the WebLogic MBeanMaker placed the intermediate files for the MBean type. You specified this as filesdir in step 3. (You will be overriding the MBean implementation file generated by the WebLogic MBeanMaker as a result of step 3.)

About the Generated MBean Interface File

The MBean interface file is the client-side API to the MBean that your runtime class or your MBean implementation will use to obtain configuration data. It is typically used in the initialize method as described in “Understand the Purpose of the “Provider” SSPIs” on page 3-3.

Because the WebLogic MBeanMaker generates MBean types from the MDF you created, the generated MBean interface file will have the name of the MDF, plus the text “MBean” appended to it. For example, the result of running the MyCredentialMapper MDF through the WebLogic MBeanMaker will yield an MBean interface file called MyCredentialMapperMBean.java.

Use the WebLogic MBeanMaker to Create the MBean JAR File (MJF)

Once you have run your MDF through the WebLogic MBeanMaker to generate your intermediate files, and you have edited the MBean implementation file to supply implementations for the appropriate methods within it, you need to package the MBean files and the runtime classes for the custom Credential Mapping provider into an MBean JAR File (MJF). The WebLogic MBeanMaker also automates this process.

To create an MJF for your custom Credential Mapping provider, follow these steps:

1. Create a new DOS shell.
2. Type the following command:

```
java -DMJF=jarfile -Dfiles=filesdir
weblogic.management.commo.WebLogicMBeanMaker
```

where the `-DMJF` flag indicates that the WebLogic MBeanMaker should build a JAR file containing the new MBean types, `jarfile` is the name for the MJF and `filesdir` is the location where the WebLogic MBeanMaker looks for the files to JAR into the MJF.

Compilation occurs at this point, so errors are possible. If `jarfile` is provided, and no errors occur, an MJF is created with the specified name.

**Notes:** When you create a JAR file for a custom security provider, a set of XML binding classes and a schema are also generated. You can choose a namespace to associate with that schema. Doing so avoids the possibility that your custom classes will conflict with those provided by Oracle. The default for the namespace is vendor. You can change this default by passing the `--targetNameSpace` argument to the WebLogicMBeanMaker or the associated WLMBeanMaker ant task.

If you want to update an existing MJF, simply delete the MJF and regenerate it. The WebLogic MBeanMaker also has a `-DIncludeSource` option, which controls whether source files are included into the resulting MJF. Source files include both the generated source and the MDF itself. The default is `false`. This option is ignored when `-DMJF` is not used.

The resulting MJF can be installed into your WebLogic Server environment, or distributed to your customers for installation into their WebLogic Server environments.

### Install the MBean Type Into the WebLogic Server Environment

To install an MBean type into the WebLogic Server environment, copy the MJF into the `WL_HOME`\server\lib\mbeantypes directory, where `WL_HOME` is the top-level installation directory for WebLogic Server. This “deploys” your custom Credential Mapping provider—that is, it makes the custom Credential Mapping provider manageable from the WebLogic Server Administration Console.

**Note:** `WL_HOME`\server\lib\mbeantypes is the default directory for installing MBean types. (Beginning with 9.0, security providers can be loaded from ...\domain\domain\lib\mbeantypes as well.) However, if you want WebLogic Server to look for MBean types in additional directories, use the `-Dweblogic.alternateTypesDirectory=<dir>` command-line flag when starting your server, where `<dir>` is a comma-separated list of directory names. When you use this flag, WebLogic Server will always load MBean types from...
How to Develop a Custom Credential Mapping Provider

WL_HOME\server\lib\mbeantypes first, then will look in the additional directories and load all valid archives present in those directories (regardless of their extension). For example, if -Dweblogic.alternateTypesDirectory = dirX,dirY, WebLogic Server will first load MBean types from WL_HOME\server\lib\mbeantypes, then any valid archives present in dirX and dirY. If you instruct WebLogic Server to look in additional directories for MBean types and are using the Java Security Manager, you must also update the weblogic.policy file to grant appropriate permissions for the MBean type (and thus, the custom security provider). For more information, see "Using the Java Security Manager to Protect WebLogic Resources" in Programming WebLogic Security.

You can create instances of the MBean type by configuring your custom Credential Mapping provider (see “Provide a Mechanism for Credential Map Management” on page 11-15), and then use those MBean instances from a GUI, from other Java code, or from APIs. For example, you can use the WebLogic Server Administration Console to get and set attributes and invoke operations, or you can develop other Java objects that instantiate MBeans and automatically respond to information that the MBeans supply. We recommend that you back up these MBean instances.

Provide a Mechanism for Credential Map Management

While configuring a custom Credential Mapping provider via the WebLogic Server Administration Console makes it accessible by applications requiring credential mapping services, you also need to supply administrators with a way to manage this security provider’s associated credential maps. The WebLogic Credential Mapping provider, for example, supplies administrators with a Credential Mappings page that allows them to add, modify, or remove credential mappings for various Connector modules.

Neither the Credential Mapping page nor access to it is available to administrators when you develop a custom Credential Mapping provider. Therefore, you must provide your own mechanism for credential map management. This mechanism must read and write credential maps to and from the custom Credential Mapping provider’s database.

You can accomplish this task in one of two ways:

- “Option 1: Develop a Stand-Alone Tool for Credential Map Management” on page 11-16
- “Option 2: Integrate an Existing Credential Map Management Tool into the Administration Console” on page 11-16
Option 1: Develop a Stand-Alone Tool for Credential Map Management

You would typically select this option if you want to develop a tool that is entirely separate from the WebLogic Server Administration Console.

For this option, you do not need to write any console extensions for your custom Credential Mapping provider, nor do you need to develop any management MBeans. However, your tool needs to:

1. Determine the WebLogic resource’s ID, since it is not automatically provided to you by the console extension. For more information, see “WebLogic Resource Identifiers” on page 3-30.
2. Determine how to represent the local-to-remote user relationship. (This representation is entirely up to you and need not be a string.)
3. Read and write the expressions from and to the custom Credential Mapping provider’s database.

Option 2: Integrate an Existing Credential Map Management Tool into the Administration Console

You would typically select this option if you have a tool that is separate from the WebLogic Server Administration Console, but you want to launch that tool from the Administration Console.

For this option, your tool needs to:

1. Determine the WebLogic resource’s ID. For more information, see “WebLogic Resource Identifiers” on page 3-30.
2. Determine how to represent the local-to-remote user relationship. (This representation is entirely up to you and need not be a string.)
3. Read and write the expressions from and to the custom Credential Mapping provider’s database.
4. Link into the Administration Console using basic console extension techniques, as described in Extending the Administration Console.
Auditing Events From Custom Security Providers

As described in Chapter 10, “Auditing Providers,” auditing is the process whereby information about operating requests and the outcome of those requests are collected, stored, and distributed for the purposes of non-repudiation. Auditing providers provide this electronic trail of computer activity.

Each type of security provider can call the configured Auditing providers with a request to write out information about security-related events, before or after these events take place. For example, if a user attempts to access a withdraw method in a bank account application (to which they should not have access), the Authorization provider can request that this operation be recorded. Security-related events are only recorded when they meet or exceed the severity level specified in the configuration of the Auditing providers.

The following sections provide the background information you need to understand before adding auditing capability to your custom security providers, and provide step-by-step instructions for adding auditing capability to a custom security provider:

- “Security Services and the Auditor Service” on page 12-1
- “How to Audit From a Custom Security Provider” on page 12-3

Security Services and the Auditor Service

The SecurityServices interface, located in the weblogic.security.spi package, is a repository for security services (currently just the Auditor Service). As such, the SecurityServices interface is responsible for supplying callers with a reference to the Auditor Service via the following method:
The `getAuditorService` method returns the `AuditService` if an Auditing provider is configured.

The `AuditService` interface, also located in the `weblogic.security.spi` package, provides other types of security providers (for example, Authentication providers) with limited (write-only) auditing capabilities. In other words, the Auditor Service fans out invocations of each configured Auditing provider’s `writeEvent` method, which simply writes an audit record based on the information specified in the `AuditEvent` object that is passed in.

For more information about the `writeEvent` method, see “Implement the AuditChannel SSPI” on page 10-12. For more information about `AuditEvent` objects, see “Create an Audit Event” on page 12-3. The `AuditService` interface includes the following method:

```
public void providerAuditWriteEvent (AuditEvent event)
```

The `providerAuditWriteEvent` method gives security providers write access to the object in the WebLogic Security Framework that calls the configured Auditing providers. The `event` parameter is an `AuditEvent` object that contains the audit criteria, including the type of event to audit and the audit severity level. For more information about Audit Events and audit severity levels, see “Create an Audit Event” on page 12-3 and “Audit Severity” on page 12-7, respectively.

The Auditor Service can be called to write audit events before or after those events have taken place, but does not maintain context in between pre and post operations. Security providers designed with auditing capabilities will need to obtain the Auditor Service as described in “Obtain and Use the Auditor Service to Write Audit Events” on page 12-10.

Notes: Implementations for both the `SecurityServices` and `AuditorService` interfaces are created by the WebLogic Security Framework at boot time if an Auditing provider is configured. (For more information about configuring Auditing providers, see “Configure the Custom Auditing Provider Using the Administration Console” on page 10-20.) Therefore, you do not need to provide your own implementations of these interfaces.

Additionally, `SecurityServices` objects are specific to the security realm in which your security providers are configured. Your custom security provider’s runtime class automatically obtains a reference to the realm-specific `SecurityServices` object as part of its `initialize` method. (For more information, see “Understand the Purpose of the “Provider” SSPIs” on page 3-3.)
How to Audit From a Custom Security Provider

Add auditing capability to your custom security provider by following these steps:

- “Create an Audit Event” on page 12-3
- “Obtain and Use the Auditor Service to Write Audit Events” on page 12-10

Examples for each of these steps are provided in “Example: Implementation of the AuditRoleEvent Interface” on page 12-8 and “Example: Obtaining and Using the Auditor Service to Write Role Audit Events” on page 12-11, respectively.

Note: If your custom security provider is to record audit events, be sure to include any classes created as a result of these steps into the MBean JAR File (MJF) for the custom security provider (that is, in addition to the other files that are required).

Create an Audit Event

Security providers must provide information about the events they want audited, such as the type of event (for example, an authentication event) and the audit severity (for example, “error”). Audit Events contain this information, and can also contain any other contextual data that is understandable to a configured Auditing provider. To create an Audit Event, either:

- “Implement the AuditEvent SSPI” on page 12-3 or
- “Implement an Audit Event Convenience Interface” on page 12-4

Implement the AuditEvent SSPI

To implement the AuditEvent SSPI, provide implementations for the following methods:

getEventType

public java.lang.String getEventType() 

The getEventType method returns a string representation of the event type that is to be audited, which is used by the Audit Channel (that is, the runtime class that implements the AuditChannel SSPI). For example, the event type for the Oracle-provided implementation is “Authentication Audit Event”. For more information, see “Audit Channels” on page 10-2 and “Implement the AuditChannel SSPI” on page 10-12.

For more information about these interfaces and their methods, see the WebLogic Server API Reference Javadoc for the SecurityServices interface and the AuditorService interface.
getFailureException
public java.lang.Exception getFailureException()

The getFailureException method returns an Exception object, which is used by the Audit Channel to obtain audit information, in addition to the information provided by the toString method.

getAddress
public AuditSeverity getSeverity()

The getSeverity method returns the severity level value associated with the event type that is to be audited, which is used by the Audit Channel. This allows the Audit Channel to make the decision about whether or not to audit. For more information, see “Audit Severity” on page 12-7.

toString
public java.lang.String toString()

The toString method returns preformatted audit information to the Audit Channel.

Note: The toString method can produce any character and no escaping is used. If your Audit provider is writing the toString value into a format that uses characters for syntax, escape the toString value before writing it.

For more information about the AuditEvent SSPI and these methods, see the WebLogic Server API Reference Javadoc.

Implement an Audit Event Convenience Interface

There are several subinterfaces of the AuditEvent SSPI that are provided for your convenience, and that can assist you in structuring and creating Audit Events.

Each of these Audit Event convenience interfaces can be used by an Audit Channel (that is, a runtime class that implements the AuditChannel SSPI) to more effectively determine the instance types of extended event type objects, for a certain type of security provider. For example, the AuditAtnEventV2 convenience interface can be used by an Audit Channel that wants to determine the instance types of extended authentication event type objects. (For more information, see “Audit Channels” on page 10-2 and “Implement the AuditChannel SSPI” on page 10-12.)

The Audit Event convenience interfaces are:

- “The AuditAtnEventV2 Interface” on page 12-5
- “The AuditAtzEvent and AuditPolicyEvent Interfaces” on page 12-6
How to Audit From a Custom Security Provider

- “The AuditMgmtEvent Interface” on page 12-7
- “The AuditRoleEvent and AuditRoleDeploymentEvent Interfaces” on page 12-7

Note: It is recommended, but not required, that you implement one of the Audit Event convenience interfaces.

The AuditAtnEventV2 Interface

Note: The AuditAtnEvent interface is deprecated in this release of WebLogic Server.

The AuditAtnEventV2 convenience interface helps Audit Channels to determine instance types of extended authentication event type objects.

To implement the AuditAtnEventV2 interface, provide implementations for the methods described in “Implement the AuditEvent SSPI” on page 12-3 and the following methods:

getUsername

```java
public String getUsername()
```

The getUsername method returns the username associated with the authentication event.

getAtnEventType

```java
public AuditAtnEventV2.AtnEventTypeV2 getAtnEventType()
```

The getAtnEventType method returns an event type that more specifically represents the authentication event. The specific authentication event types are:

- AUTHENTICATE—simple authentication using a username and password occurred.
- ASSERTIDENTITY—perimeter authentication based on tokens occurred.
- CREATEDERIVEDKEY—represents the creation of the Derived key.
- CREATEPASSWORDDIGEST—represents the creation of the Password Digest.
- IMPERSONATEIDENTITY—client identity has been established using the supplied client username (requires kernel identity).
- USERLOCKED—a user account has been locked because of invalid login attempts.
- USERUNLOCKED—a lock on a user account has been cleared.
- USERLOCKOUTEXPIRED—a lock on a user account has expired.
- VALIDATEIDENTITY—authenticity (trust) of the principals within the supplied subject has been validated.
**toString**

```java
public String toString()
```

The `toString` method returns the specific authentication information to audit, represented as a string.

**Notes:** The `toString` method can produce any character and no escaping is used. If your Audit provider is writing the `toString` value into a format that uses characters for syntax, escape the `toString` value before writing it.

The `AuditAtnEventV2` convenience interface extends both the `AuditEvent` and `AuditContext` interfaces. For more information about the `AuditContext` interface, see “Audit Context” on page 12-8.

For more information about the `AuditAtnEventV2` convenience interface and these methods, see the *WebLogic Server API Reference Javadoc*.

**The AuditAtzEvent and AuditPolicyEvent Interfaces**

The `AuditAtzEvent` and `AuditPolicyEvent` convenience interfaces help Audit Channels to determine instance types of extended authorization event type objects.

**Note:** The difference between the `AuditAtzEvent` convenience interface and the `AuditPolicyEvent` convenience interface is that the latter only extends the `AuditEvent` interface. (It does not also extend the `AuditContext` interface.) For more information about the `AuditContext` interface, see “Audit Context” on page 12-8.

To implement the `AuditAtzEvent` or `AuditPolicyEvent` interface, provide implementations for the methods described in “Implement the AuditEvent SSPI” on page 12-3 and the following methods:

**getSubject**

```java
public Subject getSubject()
```

The `getSubject` method returns the subject associated with the authorization event (that is, the subject attempting to access the WebLogic resource).

**getResource**

```java
public Resource getResource()
```

The `getResource` method returns the WebLogic resource associated with the authorization event that the subject is attempting to access.

For more information about these convenience interfaces and methods, see the *WebLogic Server API Reference Javadoc* for the `AuditAtzEvent` interface or the `AuditPolicyEvent` interface.
How to Audit From a Custom Security Provider

The AuditMgmtEvent Interface
The AuditMgmtEvent convenience interface helps Audit Channels to determine instance types of extended security management event type objects, such as a security provider’s MBean. It contains no methods that you must implement, but maintains the best practice structure for an Audit Event implementation.

Note: For more information about MBeans, see “Security Service Provider Interface (SSPI) MBeans” on page 3-10.

For more information about the AuditMgmtEvent convenience interface, see the WebLogic Server API Reference Javadoc.

The AuditRoleEvent and AuditRoleDeploymentEvent Interfaces
The AuditRoleDeploymentEvent and AuditRoleEvent convenience interfaces help Audit Channels to determine instance types of extended role mapping event type objects. They contain no methods that you must implement, but maintain the best practice structure for an Audit Event implementation.

Note: The difference between the AuditRoleEvent convenience interface and the AuditRoleDeploymentEvent convenience interface is that the latter only extends the AuditEvent interface. (It does not also extend the AuditContext interface.) For more information about the AuditContext interface, see “Audit Context” on page 12-8.

For more information about these convenience interfaces, see the WebLogic Server API Reference Javadoc for the AuditRoleEvent interface or the AuditRoleDeploymentEvent interface.

Audit Severity
The audit severity is the level at which a security provider wants audit events to be recorded. When the configured Auditing providers receive a request to audit, each will examine the severity level of events taking place. If the severity level of an event is greater than or equal to the level an Auditing provider was configured with, that Auditing provider will record the audit data.

Note: Auditing providers are configured using the WebLogic Server Administration Console. For more information, see “Configure the Custom Auditing Provider Using the Administration Console” on page 10-20.

The AuditSeverity class, which is part of the weblogic.security.spi package, provides audit severity levels as both numeric and text values to the Audit Channel (that is, the AuditChannel SSPI implementation) through the AuditEvent object. The numeric severity value is to be used in logic, and the text severity value is to be used in the composition of the audit.
record output. For more information about the AuditChannel SSPI and the AuditEvent object, see “Implement the AuditChannel SSPI” on page 10-12 and “Create an Audit Event” on page 12-3, respectively.

Audit Context

Some of the Audit Event convenience interfaces extend the AuditContext interface to indicate that an implementation will also contain contextual information. This contextual information can then be used by Audit Channels. For more information, see “Audit Channels” on page 10-2 and “Implement the AuditChannel SSPI” on page 10-12.

The AuditContext interface includes the following method:

getContext

    public ContextHandler getContext()

The getContext method returns a ContextHandler object, which is used by the runtime class (that is, the AuditChannel SSPI implementation) to obtain additional audit information. For more information about ContextHandlers, see “ContextHandlers and WebLogic Resources” on page 3-37.

Example: Implementation of the AuditRoleEvent Interface

Listing 12-1 shows the MyAuditRoleEventImpl.java class, which is a sample implementation of an Audit Event convenience interface (in this case, the AuditRoleEvent convenience interface). This class includes implementations for:

- The four methods inherited from the AuditEvent SSPI: getEventType, getFailureException, getSeverity and toString (as described in “Implement the AuditEvent SSPI” on page 12-3).

- One additional method: getContext, which returns additional contextual information via the ContextHandler. (For more information about ContextHandlers, see “ContextHandlers and WebLogic Resources” on page 3-37.)

Note: The bold face code in Listing 12-1 highlights the class declaration and the method signatures.

Listing 12-1  MyAuditRoleEventImpl.java

package mypackage;
import javax.security.auth.Subject;
import weblogic.security.SubjectUtils;
import weblogic.security.service.ContextHandler;
import weblogic.security.spi.AuditRoleEvent;
import weblogic.security.spi.AuditSeverity;
import weblogic.security.spi.Resource;

/*package*/ class MyAuditRoleEventImpl implements AuditRoleEvent
{
    private Subject subject;
    private Resource resource;
    private ContextHandler context;
    private String details;
    private Exception failureException;

    /*package*/ MyAuditRoleEventImpl(Subject subject, Resource resource,
                                        ContextHandler context, String details, Exception
                                            failureException) {
        this.subject = subject;
        this.resource = resource;
        this.context = context;
        this.details = details;
        this.failureException = failureException;
    }

    public Exception getFailureException()
    {
        return failureException;
    }

    public AuditSeverity getSeverity()
    {
        return (failureException == null) ? AuditSeverity.SUCCESS :
                     AuditSeverity.FAILURE;
    }

    public String getEventType()
    {
        return "MyAuditRoleEventType";
    }
}
Obtain and Use the Auditor Service to Write Audit Events

To obtain and use the Auditor Service to write audit events from a custom security provider, follow these steps:

1. Use the `getAuditorService` method to return the Audit Service.

   **Note:** Recall that a `SecurityServices` object is passed into a security provider’s implementation of a “Provider” SSPI as part of the `initialize` method. (For more information, see “Understand the Purpose of the “Provider” SSPIs” on page 3-3.) An `AuditorService` object will only be returned if an Auditing provider has been configured.
2. Instantiate the Audit Event you created in “Implement the AuditEvent SSPI” on page 12-3 and send it to the Auditor Service through the \texttt{AuditService.providerAuditWriteEvent} method.

**Example: Obtaining and Using the Auditor Service to Write Role Audit Events**

Listing 12-2 illustrates how a custom Role Mapping provider’s runtime class (called \texttt{MyRoleMapperProviderImpl.java}) would obtain the Auditor Service and use it to write out audit events.

**Note:** The \texttt{MyRoleMapperProviderImpl.java} class relies on the \texttt{MyAuditRoleEventImpl.java} class from Listing 12-1.

**Listing 12-2 \ MyRoleMapperProviderImpl.java**

```java
package mypackage;

import javax.security.auth.Subject;
import weblogic.management.security.ProviderMBean;
import weblogic.security.SubjectUtils;
import weblogic.security.service.ContextHandler;
import weblogic.security.spi.AuditorService;
import weblogic.security.spi.RoleMapper;
import weblogic.security.spi.RoleProvider;
import weblogic.security.spi.Resource;
import weblogic.security.spi.SecurityServices;

public final class MyRoleMapperProviderImpl implements RoleProvider, RoleMapper {

    private AuditorService auditor;

    public void initialize(ProviderMBean mbean, SecurityServices services) {
        auditor = services.getAuditorService();
        ...
    }

    public Map getRoles(Subject subject, Resource resource, ContextHandler handler) {
        // Implementation...
    }
}
```

[321x98]How to Audit From a Custom Security Provider

[138x605]Example: Obtaining and Using the Auditor Service to Write Role Audit Events

Listing 12-2 illustrates how a custom Role Mapping provider’s runtime class (called MyRoleMapperProviderImpl.java) would obtain the Auditor Service and use it to write out audit events.

**Note:** The MyRoleMapperProviderImpl.java class relies on the MyAuditRoleEventImpl.java class from Listing 12-1.

**Listing 12-2   MyRoleMapperProviderImpl.java**

```java
package mypackage;

import javax.security.auth.Subject;
import weblogic.management.security.ProviderMBean;
import weblogic.security.SubjectUtils;
import weblogic.security.service.ContextHandler;
import weblogic.security.spi.AuditorService;
import weblogic.security.spi.RoleMapper;
import weblogic.security.spi.RoleProvider;
import weblogic.security.spi.Resource;
import weblogic.security.spi.SecurityServices;

public final class MyRoleMapperProviderImpl implements RoleProvider, RoleMapper {

    private AuditorService auditor;

    public void initialize(ProviderMBean mbean, SecurityServices services) {
        auditor = services.getAuditorService();
        ...
    }

    public Map getRoles(Subject subject, Resource resource, ContextHandler handler) {
        // Implementation...
    }
}
```
if (auditor != null)
{
    auditor.providerAuditWriteEvent(
        new MyRoleEventImpl(subject, resource, context,
                            "why logging this event",
                            null); // no exception occurred
}
...

Auditing Management Operations from a Provider’s MBean

A SecurityServices object is passed into a security provider’s implementation of a “Provider” SSPI as part of the initialize method. (For more information, see “Understand the Purpose of the “Provider” SSPIs” on page 3-3.) The provider can use this object's auditor to audit provider-specific security events, such as when a user is successfully logged in.

A security provider's MBean implementation is not passed a SecurityServices object. However, the provider may need to audit its MBean operations, such as a user being created.

To work around this, the provider's runtime implementation can cache the SecurityServices object and use a provider-specific mechanism to pass it to the provider's MBean implementation. This allows the provider to audit its MBean operations.

The Manageable Sample Authentication Provider shows one way to accomplish this task. The sample provider contains three major implementation classes:

- ManageableSampleAuthenticationProviderImpl contains its security runtime implementation.
- ManageableSampleAuthenticatorImpl contains its MBean implementation.
- UserGroupDatabase is a helper class used by ManageableSampleAuthenticationProviderImpl and ManageableSampleAuthenticatorImpl.

The code flow to cache and obtain the SecurityServices object is as follows:
1. The ManageableSampleAuthenticationProviderImpl's `initialize` method is passed a SecurityServices object.

2. The `initialize` method creates a UserGroupDataBase object and passes it the SecurityServices object.

3. The UserGroupDataBaseObject caches the SecurityServices object. The `initialize` method also puts the UserGroupDatabase object into a hash table using the realm's name as the lookup key.

4. The ManageableSampleAuhtenticatorImpl's `init` method finds its realm name from its MBean.

5. The `init` method uses the realm name to find the corresponding UserGroupDataBase object from the hash table.

6. The `init` method then retrieves the SecurityServices object from the UserGroupDatabase object, and uses its auditor to audit management operations such as "createUser."

**Note:** A provider's runtime implementation is initialized only if the provider is part of the default realm when the server is booted. Therefore, if the provider is not in the default realm when the server is booted, its runtime implementation is never initialized, and the provider's MBean implementation cannot gain access to the SecurityServices object. That is, if the provider is not in the default realm when the server is booted, the provider cannot audit its MBean operations.

**Example: Auditing Management Operations from a Provider’s MBean**

Listing 12-3 illustrates how the ManageableSampleAuhtenticatorImpl's `init` method finds its realm name from its MBean, how it uses the realm name to find the corresponding UserGroupDataBase object from the hash table (via the UserGroupDatabase helper class), and how it then retrieves the SecurityServices object from the UserGroupDatabase object.

Listing 12-3 also shows how ManageableSampleAuhtenticatorImpl uses its auditor to audit management operations such as "createUser."

**Listing 12-3  ManageableSampleAuthenticatorImpl.java**

```java
package examples.security.providers.authentication.manageable;
import java.util.Enumeration;
import javax.management.MBeanException;
import javax.management.modelmbean.ModelMBean;
import weblogic.management.security.authentication.AuthenticatorImpl;
```
import weblogic.management.utils.AlreadyExistsException;
import weblogic.management.utils.InvalidCursorException;
import weblogic.management.utils.NotFoundException;
import weblogic.security.spi.AuditorService;
import weblogic.security.spi.SecurityServices;

public class ManageableSampleAuthenticatorImpl extends AuthenticatorImpl {
    // Manages the user and group definitions for this provider:
    private UserGroupDatabase database;

    // Manages active queries (see listUsers, listGroups, listMemberGroups):
    private ListManager listManager = new ListManager();

    // The name of the realm containing this provider:
    private String realm;

    // The name of this provider:
    private String provider;

    // The auditor for auditing user/group management operations.
    // This is only available if this provider was configured in
    // the default realm when the server was booted.
    private AuditorService auditor;

    public ManageableSampleAuthenticatorImpl(ModelMBean base) throws MBeanException {
        super(base);
    }

    private synchronized void init() throws MBeanException {
        if (database == null) {
            try {
                ManageableSampleAuthenticatorMBean myMBean =
                        (ManageableSampleAuthenticatorMBean)getProxy();
                database = UserGroupDatabase.getDatabase(myMBean);
                realm    = myMBean.getRealm().getName();
                provider = myMBean.getName();
                SecurityServices services = database.getSecurityServices();
                auditor = (services != null) ? services.getAuditorService() : null;
            }
            catch(Exception e) {
                throw new MBeanException(e, "SampleAuthenticatorImpl.init failed");
            }
        }
    }

    public void createUser(String user, String password, String description)
How to Audit From a Custom Security Provider

throws MBeanException, AlreadyExistsException
{
  init();
  String details = (auditor != null) ?
  "createUser(user = " + user + ", password = " + password + ", description = " +
  description + ")" : null;
  try {
    // we don't support descriptions so just ignore it
    database.checkDoesntExist(user);
    database.getUser(user).create(password);
    database.updatePersistentState();
    auditOperationSucceeded(details);
  }
  catch (AlreadyExistsException e) {
    auditOperationFailed(details, e);
  }
  catch (IllegalArgumentException e) {
    auditOperationFailed(details, e);
  }
}

private void auditOperationSucceeded(String details)
{
  if (auditor != null) {
    auditor.providerAuditWriteEvent(
      new ManageableSampleAuthenticatorManagementEvent(realm, provider, details,
      null)
    );
  }
}

private void auditOperationFailed(String details, Exception failureException)
{
  if (auditor != null) {
    auditor.providerAuditWriteEvent(
      new ManageableSampleAuthenticatorManagementEvent(realm, provider, details,
      failureException)
    );
  }
}
Best Practice: Posting Audit Events from a Provider's MBean

Provider’s management operations that do writes (for example, create user, delete user, remove data) should post audit events, regardless of whether or not the operation succeeds.

If your provider audits MBean operations, you should keep the following Best Practice guidelines in mind.

- If the write operation succeeds, post an INFORMATION audit event.
- If the write operation fails because of a bad parameter (for example, because the user already exists, or due to a bad import format name, a non-existent file name, or the wrong file format), do not post an audit event.
- If the write operation fails because of an error (for example, LDAPException, RuntimeException), post a FAILURE audit event.
- Import operations can partially succeed. For example, some of the users are imported, but others are skipped because there are already users with that name in the provider.
- If you can easily detect that the data you are skipping is identical to the data already in the provider (for example, the username, description, and password are the same) then consider posting a WARNING event.
- If you are skipping data because there is a partial collision (for example, the username is the same but the password is different), you should post a FAILURE event.
- If it is too difficult to distinguish the import data from the data already stored in the provider, post a FAILURE event.
A Servlet Authentication Filter is a provider type that performs pre- and post-processing for authentication functions, including identity assertion. A Servlet Authentication Filter is a special type of security provider that primarily acts as a “helper” to an Authentication provider.

The ServletAuthenticationFilter interface defines the security service provider interface (SSPI) for authentication filters that can be plugged into WebLogic Server. You implement the ServletAuthenticationFilter interface as part of an Authentication provider, and typically as part of the Identity Assertion form of Authentication provider, to signal that the Authentication provider has authentication filters that it wants the servlet container to invoke during the authentication process.

The following sections describe Servlet Authentication Filter interface concepts and functionality, and provide step-by-step instructions for developing a Servlet Authentication Filter:

- “Authentication Filter Concepts” on page 13-1
- “How Filters Are Invoked” on page 13-3
- “Example of a Provider that Implements a Filter” on page 13-5
- “How to Develop a Custom Servlet Authentication Filter” on page 13-6

**Authentication Filter Concepts**

Filters, as defined by the Java Servlet API 2.3 specification, are preprocessors of the request before it reaches the servlet, and/or postprocessors of the response leaving the servlet. Filters
provide the ability to encapsulate recurring tasks in reusable units and can be used to transform
the response from a servlet or JSP page.

Servlet Authentication filters are an extension to of the filter object that allows filters to replace
or extend container-based authentication.

**Why Filters are Needed**

The WebLogic Security Framework allows you to provide a custom Authentication provider.
However, due to the nature of the Java Servlet API 2.3 specification, the interaction between the
Authentication provider and the client or other servers is architecturally limited during the
authentication process. This restricts authentication mechanisms to those that are compatible with
the authentication mechanisms the Servlet container offers: basic, form, and certificate.

Filters have fewer architecturally-dependence limitations; that is, they are not dependent on the
authentication mechanisms offered by the Servlet container. By allowing filters to be invoked
prior to the container beginning the authentication process, a security realm can implement a
wider scope of authentication mechanisms. For example, a Servlet Authentication Filter could
redirect the user to a SAML provider site for authentication.

JAAS LoginModules (within a WebLogic Authentication provider) can be used for
customization of the login process. Customizing the location of the user database, the types of
proof material required to execute a login, or the population of the Subject with groups is
implemented via a LoginModule.

Conversely, redirecting to a remote site to execute the login, extracting login information out of
the query string, and negotiating a login mechanism with a browser are implemented via a Servlet
Authentication Filter.

**Servlet Authentication Filter Design Considerations**

You should consider the following design considerations when writing Servlet Authentication
Filters:

- Do you need to allow multiple filters to be specified? You might want to allow this so that
  administrative decisions can be made at configuration time.

- Do you depend on a particular order of-execution? Servlet Authentication Filters must not
  be dependent on the order in which filters are executed.
• Have you considered allowing each filter to process the request both before and after authentication? If so, the filter should not make any assumptions about when it is being invoked.

• Consider allowing each filter to have the option of stopping the execution of the remaining filters and the Servlet’s authentication process by not calling the Filter doFilter method.

• Do you need to allow a filter to cause the browser to redirect?

• Consider allowing a filter to work for 1-way SSL, 2-way SSL, identity assertion, form authentication, and basic authentication. For example, Form authentication is a two-request process and the filter is called twice for form authentication.

How Filters Are Invoked

The Servlet Authentication Filter interface allows an Authentication provider to implement zero or more Servlet Authentication Filter classes. The filters are invoked as follows:

1. The servlet container calls the Servlet Authentication Filters prior to authentication occurring. The servlet container gets the configured chain of Servlet Authentication Filters from the WebLogic Security Framework.

   The Security Framework returns the Servlet Authentication Filters in the order of the authentication providers. If one provider has multiple Servlet Authentication Filters, the Security Framework uses the ordered list of javax.servlet.Filters returned by the ServletAuthenticationFilter getAuthenticationFilters method.

   Duplicate filters are allowed because they might need to execute multiple times to correctly manipulate the request.

2. For each filter, the servlet container calls the Filter init method to indicate to a filter that it is being placed into service.

3. The servlet container calls the Filter doFilter method on the first filter each time a request/response pair is passed through the chain due to a client request for a resource at the end of the chain.

   The FilterChain object passed in to this method allows the Filter to pass on the request and response to the next entity in the chain. Filters use the FilterChain object to invoke the next filter in the chain, or if the calling filter is the last filter in the chain, to invoke the resource at the end of the chain.
4. If all Servlet Authentication Filters call the Filter `doFilter` method then, when the final one calls the `doFilter` method, the servlet container then performs authentication as it would if the filters were not present.

However, if any of the Servlet Authentication Filters do not call the `doFilter` method, the remaining filters, the servlet, and the servlet container’s authentication procedure are not called. This allows a filter to replace the servlet’s authentication process. This typically involves authentication failure or redirecting to another URL for authentication.

**Do Not Call Servlet Authentication Filters From Authentication Providers**

Although you implement the Servlet Authentication Filter interface as part of an Authentication provider, Authentication providers do not actually call Servlet Authentication Filters directly. The implementation of Servlet Authentication Filters depends upon particular features of the WebLogic Security Framework that know how to locate and invoke the filters.

If you develop a custom Servlet Authentication Filter, make sure that your custom Authentication providers do not call the WLS-specific classes (for example, `weblogic.servlet.*`) and the Java EE-specific classes (for example, `javax.servlet.*`). Following this rule ensures maximum portability with WebLogic Enterprise Security.

*Figure 13-1* illustrates this requirement.
Example of a Provider that Implements a Filter

WebLogic Server includes a Servlet Authentication Filter that handles the header manipulation required by the Simple and Protected Negotiate (SPNEGO). This Servlet Authentication Filter, called the “Negotiate Servlet Authentication Filter,” is configured to support the WWW-Authenticate and Authorization HTTP headers.

The Negotiate Servlet Authentication Filter generates the appropriate WWW-Authenticate header on unauthorized responses for the negotiate protocol and handles the Authorization headers on subsequent requests. The filter is available through the Negotiate Identity Assertion Provider.
By default, the Negotiate Identity Assertion provider is available, but not configured, in the WebLogic default security realm. The Negotiate Identity Assertion provider can be used instead of, or in addition to, the WebLogic Identity Assertion provider.

How to Develop a Custom Servlet Authentication Filter

You can develop a custom Servlet Authentication Filter by following these steps:

1. “Create Runtime Classes Using the Appropriate SSPIs” on page 13-6
2. “Generate an MBean Type Using the WebLogic MBeanMaker” on page 13-9
3. “Configure the Authentication Provider Using Administration Console” on page 13-10

Create Runtime Classes Using the Appropriate SSPIs

Before you start creating runtime classes, you should first:

- “Understand the Purpose of the “Provider” SSPIs” on page 3-3
- “Understand the SSPI Hierarchy and Determine Whether You Will Create One or Two Runtime Classes” on page 3-7

When you understand this information and have made your design decisions, create the runtime classes for your Servlet Authentication Filter by following these steps:

- “Implement the AuthenticationProviderV2 SSPI” on page 5-11 or “Implement the IdentityAsserterV2 SSPI” on page 5-12
- “Implement the Servlet Authentication Filter SSPI” on page 13-6
- “Implement the Filter Interface Methods” on page 13-7

For an example of how to create a runtime class for a custom Servlet Authentication Filter provider, see “Generate an MBean Type Using the WebLogic MBeanMaker” on page 13-9

Implement the Servlet Authentication Filter SSPI

You implement the ServletAuthenticationFilter interface as part of an Authentication provider to signal that the Authentication provider has authentication filters that it wants the servlet container to invoke during the authentication process.

To implement the Servlet Authentication Filter SSPI, provide an implementation for the following method:
How to Develop a Custom Servlet Authentication Filter

get Servlet Authentication Filters

```java
public Filter[] getServletAuthenticationFilters
```

The `getServletAuthenticationFilters` method returns an ordered list of the `javax.servlet.Filter` instances that are executed during the authentication process of the Servlet container. The container may call this method multiple times to get multiple instances of the Servlet Authentication Filter. On each call, this method should return a list of new instances of the filters.

Implement the Filter Interface Methods

To implement the Filter interface methods, provide implementations for the following methods. In typical use, you would call `init()` once, `doFilter()` possibly many times, and `destroy()` once.

**destroy**

```java
public void destroy()
```

The `destroy` method is called by the web container to indicate to a filter that it is being taken out of service. This method is only called once all threads within the filter's `doFilter` method have exited, or after a timeout period has passed. After the web container calls this method, it does not call the `doFilter` method again on this instance of the filter.

This method gives the filter an opportunity to clean up any resources that are being held (for example, memory, file handles, threads) and make sure that any persistent state is synchronized with the filter's current state in memory.

**doFilter**

```java
public void doFilter(ServletRequest request, ServletResponse response, FilterChain chain)
```

The `doFilter` method of the Filter is called by the container each time a request/response pair is passed through the chain due to a client request for a resource at the end of the chain. The `FilterChain` passed in to this method allows the Filter to pass on the request and response to the next entity in the chain.

A typical implementation of this method would follow the following pattern:

1. Examine the request.
2. Optionally, wrap the request object with a custom implementation to filter content or headers for input filtering.
3. Optionally, wrap the response object with a custom implementation to filter content or headers for output filtering.
4. Either invoke the next entity in the chain using the FilterChain object (chain.doFilter()), or do not pass on the request/response pair to the next entity in the filter chain to block the request processing.

5. Directly set headers on the response after invocation of the next entity in the filter chain.

```java
public void init(FilterConfig filterConfig)
```

The init method is called by the web container to indicate to a filter that it is being placed into service. The servlet container calls the init method exactly once after instantiating the filter. The init method must complete successfully before the filter is asked to do any filtering work.

**Implementing Challenge Identity Assertion from a Filter**

As described in Chapter 5, “Identity Assertion Providers,” the Challenge Identity Assertion interface supports challenge response schemes in which multiple challenges, responses messages, and state are required. The Challenge Identity Asserter interface allows Identity Assertion providers to support authentication protocols such as Microsoft's Windows NT Challenge/Response (NTLM), Simple and Protected GSS-API Negotiation Mechanism (SPNEGO), and other challenge/response authentication mechanisms.

Servlet Authentication Filters allow you to implement a challenge/response protocol without being limited to the authentication mechanisms compatible with the Servlet container. However, because Servlet Authentication Filters operate outside of the authentication environment provided by the Security Framework, they cannot depend on the Security Framework to determine provider context, and require an API to drive the multiple-challenge Identity Assertion process.

The `weblogic.security.services.Authentication` class has been extended to allow multiple challenge/response identity assertion from a Servlet Authentication Filter. The methods and interface provide a wrapper for the `ChallengeIdentityAsserterV2` and `ProviderChallengeContext` SSPI interfaces so that you can invoke them from a Servlet Authentication Filter.

There is no other documented way to perform a multiple challenge/response dialog from a Servlet Authentication Filter within the context of the Security Framework. Your Servlet Authentication Filter cannot directly invoke the `ChallengeIdentityAsserterV2` and `ProviderChallengeContext` interfaces.
Therefore, if you plan to implement multiple challenge/response identity assertion from a filter, you need to implement the ChallengeIdentityAsserterV2 and ProviderChallengeContext interfaces, and then use the weblogic.security.services.Authentication methods and AppChallengeContext interface to invoke them from a Servlet Authentication Filter.

The steps to accomplish this process are described in Chapter 5, “Identity Assertion Providers,” and are summarized here:

- “Implement the AuthenticationProviderV2 SSPI” on page 5-11 or “Implement the IdentityAsserterV2 SSPI” on page 5-12
- “Implement the ChallengeIdentityAsserterV2 Interface” on page 5-26
- “Implement the ProviderChallengeContext Interface” on page 5-26
- “Invoke the weblogic.security.services Challenge Identity Methods” on page 5-27
- “Invoke the weblogic.security.services AppChallengeContext Methods” on page 5-28

### Generate an MBean Type Using the WebLogic MBeanMaker

When you generate the MBean type for your custom Authentication provider as described in Chapter 4, “Authentication Providers,” you must also implement the MBean for your Servlet Authentication Filter.

The ServletAuthenticationFilter MBean extends the AuthenticationProvider MBean. The ServletAuthenticationFilter MBean is a marker interface and has no methods.

```xml
<?xml version="1.0" ?>
<!DOCTYPE MBeanType SYSTEM "commo.dtd">
<MBeanType

Name = "ServletAuthenticationFilter"
Package = "weblogic.management.security.authentication"
Extends = "weblogic.management.security.authentication.AuthenticationProvider"
PersistPolicy = "OnUpdate"
Abstract = "true"
Description = "The SSPI MBean that all Servlet Authentication Filter providers must extend."
```
Use the WebLogic MBeanMaker to Create the MBean JAR File (MJF)

Once your have run your MDF through the WebLogic MBeanMaker to generate your intermediate files, and you have edited the MBean implementation file to supply implementations for the appropriate methods within it, you need to package the MBean files and the runtime classes for the custom Authentication provider, including the Servlet Authentication Filter, into an MBean JAR File (MJF).

These steps are described for the custom Authentication provider in “Use the WebLogic MBeanMaker to Create the MBean JAR File (MJF)” on page 4-30.

Configure the Authentication Provider Using Administration Console

Configuring a custom Authentication provider that implements a Servlet Authentication Filter means that you are adding the custom Authorization provider to your security realm, where it can be accessed by applications requiring authorization services.

Configuring custom security providers is an administrative task, but it is a task that may also be performed by developers of custom security providers.

The steps for configuring a custom Authorization provider using the WebLogic Server Administration Console are described under “Configuring WebLogic Security Providers” in Securing WebLogic Server.
A versionable application is an application that has an application archive version specified in the manifest of the application archive (EAR file). Versionable applications can be deployed side-by-side and active simultaneously. Versionable applications allow multiple versions of an application, where security constraints can vary between the application versions.

The Versionable Application provider SSPI enables all security providers that support application versioning to be notified when versions are created and deleted. It also enables all security providers that support application versioning to be notified when non-versioned applications are removed.

The following sections provide the background information you need to understand before adding application versioning capability to your custom security providers, and provide step-by-step instructions for adding application versioning capability to a custom security provider:

- “Versionable Application Concepts” on page 14-2
- “The Versionable Application Process” on page 14-2
- “Do You Need to Develop a Custom Versionable Application Provider?” on page 14-2
- “How to Develop a Custom Versionable Application Provider” on page 14-3
Versionable Application Concepts

Redeployment of versionable applications is always done via side-by-side versions, unless the same archive version is specified in the subsequent redeployments. However, a versionable application has to be written in such a way that multiple versions of it can be run side-by-side without conflicts; that is, it does not make any assumption of the uniqueness of the application name, and so forth. For example, in the case where an applications may use the application name as a unique key for global data structures, such as database tables or LDAP stores, the applications would need to change to use the application identifier instead.

Production Redeployment is allowed only if the configured security providers support the application versioning security SSPI. All Authorization, Role Mapping, and Credential Mapping providers for the security realm must support application versioning for an application to be deployed using versions.

See Developing Applications for Production Redeployment in Developing Applications with WebLogic Server for detailed information on how an application assigns an application version.

The Versionable Application Process

For a security provider to support application versioning, it must implement the Versionable Application SSPI. The WebLogic Security Framework calls the Versionable Application provider SSPI when an application version is created and deleted so that the provider can take any required actions to create, copy or removed data associated with the application version. It is up to the provider to determine the appropriate action to take, if any.

In addition, the Versionable Application provider SSPI is also called when a non-versioned application is deleted so that the provider can perform cleanup actions.

The WebLogic Security Framework passes the Versionable Application provider the application identifier for the new version and the application identifier of the version used as the source of application data. When the source identifier is not supplied, the initial version of the application is being created.

Do You Need to Develop a Custom Versionable Application Provider?

The WebLogic Server out-of-the-box security providers for Authorization, Role Mapping and Credential Mapping support the application versioning SSPI. When a new version is created, all the customized roles, policies and credential maps are cloned with new resource identifiers.
representing the new application version. In addition, when an application version is deleted, resources associated with the deleted version are removed.

If you develop a custom security provider for Authorization, Role Mapping, or Credential Mapping and need to support versioned applications, you must implement the Versionable Application SSPI.

How to Develop a Custom VersionableApplication Provider

If you need to support the Versionable Application SSPI, you can develop a custom Versionable Application provider by following these steps:

- Implement your custom Authorization, Role Mapping, or Credential Mapping providers. All Authorization, Role Mapping, or Credential Mapping providers for the security realm must support application versioning for an application to be deployed using versions.

- “Create Runtime Classes Using the Appropriate SSPIs” on page 14-3

- “Generate an MBean Type Using the WebLogic MBeanMaker” on page 14-5

Create Runtime Classes Using the Appropriate SSPIs

Before you start creating runtime classes, you should first:

- “Understand the Purpose of the “Provider” SSPIs” on page 3-3

- “Understand the SSPI Hierarchy and Determine Whether You Will Create One or Two Runtime Classes” on page 3-7

When you understand this information and have made your design decisions, create the runtime classes for your custom Versionable Application provider by following these steps:

- Implement your custom Authorization, Role Mapping, or Credential Mapping providers.

- “Implement the VersionableApplication SSPI” on page 14-3

Implement the VersionableApplication SSPI

To implement the VersionableApplication SSPI, provide implementations for the methods described in “Understand the Purpose of the “Provider” SSPIs” on page 3-3 and the following methods:
createApplicationVersion

void createApplicationVersion(String appIdentifier, String sourceAppIdentifier)

 Marks the creation of a new application version and is called (only on the Administration Server within a WebLogic Server domain) on one server within a WebLogic Server domain at the time the version is created. The WebLogic Security Framework passes the createApplicationVersion method the application identifier for the new version (appIdentifier) and the application identifier of the version used as the source of application data (sourceAppIdentifier). When the source identifier is not supplied, the initial version of the application is being created.

deleteApplication

void deleteApplication(String appName)

 Marks the deletion of a non-versioned application and is called (only on the Administration Server within a WebLogic Server domain) at the time the application is deleted.

deleteApplicationVersion

void deleteApplicationVersion(String appIdentifier)

 Marks the deletion of an application version and is only called (only on the Administration Server within a WebLogic Server domain) at the time the version is deleted.

Example: Creating the Runtime Class for the Sample VersionableApplication Provider

Listing 14-1 shows how the Versionable Application SSPI is implemented in the sample Authorization provider.

Listing 14-1 SimpleSampleAuthorizationProviderImpl

public final class SimpleSampleAuthorizationProviderImpl
    implements DeployableAuthorizationProviderV2, AccessDecision, VersionableApplicationProvider
    :
    :
    public void createApplicationVersion(String appId, String sourceAppId)
{ System.out.println("SimpleSampleAuthorizationProviderImpl.createApplicationVersion"); System.out.println("\tapplication identifier\t= " + appId); System.out.println("\tsource app identifier\t= " + ((sourceAppId != null) ? sourceAppId : "None")); // create new policies when existing application is specified if (sourceAppId != null) { database.clonePoliciesForApplication(sourceAppId,appId); } }

public void deleteApplicationVersion(String appId) {
{ System.out.println("SimpleSampleAuthorizationProviderImpl.deleteApplicationVersion"); System.out.println("\tapplication identifier\t= " + appId);

// clear out policies for the application
database.removePoliciesForApplication(appId); }

public void deleteApplication(String appName) {
{ System.out.println("SimpleSampleAuthorizationProviderImpl.deleteApplication"); System.out.println("\tapplication name\t= " + appName);

// clear out policies for the application
database.removePoliciesForApplication(appName); }

---

Generate an MBean Type Using the WebLogic MBeanMaker

When you generate the MBean type for your custom Authorization, Role Mapping, and Credential Mapping providers, you must also implement the MBean for your Versionable
Application provider. The ApplicationVersionerMBean is a marker interface and has no methods.

Listing 14-2 shows how the SimpleSampleAuthorizer MBean Definition File (MDF) implements the ApplicationVersionerMBean MBean.

Listing 14-2  Implementing the ApplicationVersionerMBean

```xml
<MBeanType
    Name = "SimpleSampleAuthorizer"
    DisplayName = "SimpleSampleAuthorizer"
    Package = "examples.security.providers.authorization.simple"
    Extends = "weblogic.management.security.authorization.DeployableAuthorizer"
    Implements = "weblogic.management.security.ApplicationVersioner"
    PersistPolicy = "OnUpdate"
>
```

Use the WebLogic MBeanMaker to Create the MBean JAR File (MJF)

Once you have run your MDF through the WebLogic MBeanMaker to generate your intermediate files, and you have edited the MBean implementation file to supply implementations for the appropriate methods within it, you need to package the MBean files and the runtime classes for the custom Authorization, Role Mapping, or Credential Mapping provider, including the Versionable Application provider, into an MBean JAR File (MJF).

For a custom Authorization provider, these steps are described in “Use the WebLogic MBeanMaker to Create the MBean JAR File (MJF)” on page 7-31.

For a custom Role Mapping provider, these steps are described in “Use the WebLogic MBeanMaker to Create the MBean JAR File (MJF)” on page 9-34.

For a custom Credential Mapping provider, these steps are described in “Use the WebLogic MBeanMaker to Create the MBean JAR File (MJF)” on page 11-13.
Configure the Custom Versionable Application Provider Using the Administration Console

Configuring a custom Versionable Application provider means that you are adding the custom Versionable Application provider to your security realm, where it can be accessed by applications requiring application version services.

Configuring custom security providers is an administrative task, but it is a task that may also be performed by developers of custom security providers.

The steps for configuring a custom Versionable Application provider using the WebLogic Server Administration Console are described under “Configuring WebLogic Security Providers” in Securing WebLogic Server.
CertPath Providers

The WebLogic Security service provides a framework that finds and validates X509 certificate chains for inbound 2-way SSL, outbound SSL, application code, and WebLogic Web services. The Certificate Lookup and Validation (CLV) framework is a new security plug-in framework that finds and validates certificate chains. The framework extends and completes the JDK CertPath functionality, and allows you to create a custom CertPath provider.

The following sections provide the background information you need to understand before adding certificate lookup and validation capability to your custom security providers, and provide step-by-step instructions for adding certificate lookup and validation capability to a custom security provider:

- “Certificate Lookup and Validation Concepts” on page 15-1
- “Do You Need to Develop a Custom CertPath Provider?” on page 15-8
- “How to Develop a Custom CertPath Provider” on page 15-9

Certificate Lookup and Validation Concepts

A CertPath is a JDK class that stores a certificate chain in memory. The term CertPath is also used to refer to the JDK architecture and framework that is used to locate and validate certificate chains.

There are two distinct types of providers, CertPath Validators and CertPath Builders:
The purpose of a certificate validator is to determine if the presented certificate chain is valid and trusted. As the CertPath Validator provider writer, you decide how to validate the certificate chain and determine whether you need to use the trusted CA’s.

The purpose of a certificate builder is to use a selector (which holds the selection criteria for finding the CertPath) to find a certificate chain. Certificate builders often validate the certificate chain as well. As the CertPath Builder provider writer, you decide which of the four selector types you support and whether you also validate the certificate chain. You also decide how much of the certificate chain you fill in and whether you need to use the trusted CA’s.

The WebLogic CertPath providers are built using both the JDK and WebLogic CertPath SPI’s.

**The Certificate Lookup and Validation Process**

The certificate lookup and validation process is shown in Figure 15-1.
Do You Need to Implement Separate CertPath Validators and Builders?

You can implement the CertPath provider in several ways:

- You can implement a CertPath Builder that performs both building and validation. In this case, you are responsible for:
  
  a. Implementing the Validator SPI.
b. Implementing the Builder SPI.

c. You must validate the certificate chain you build as part of the Builder SPI. Your provider will be called only once; you will not be called a second time specifically for validation.

d. You decide the validation algorithm, which selectors to support, and whether to use trusted CA's.

- You can implement a CertPath Validator that performs only validation. In this case, you are responsible for:
  a. Implementing the Validator SPI.
  b. You decide the validation algorithm and whether to use trusted CA’s.

- You can implement a CertPath Builder that performs only building. In this case, you are responsible for:
  a. Implementing the Builder SPI.
  b. You decide whether to validate the chain you build.
  c. You decide which selectors to support and whether to use trusted CA’s.

**CertPath Provider SPI MBeans**

WebLogic Server includes two CertPath provider SPI MBeans, both of which extend CertPathProviderMBean:

- CertPathBuilderMBean indicates that the provider can look up certificate chains. It adds no attributes or methods. CertPathBuilder providers must implement a custom MBean that extends this MBean.

- CertPathValidatorMBean indicates that the provider can validate a certificate chain. It adds no attributes or methods. CertPathValidator providers must implement a custom MBean that extends this MBean.

Your CertPath provider, depending on its type, must extend one or both of the MBeans. A security provider that supports both building and validating should write an MBean that extends both of these MBeans, as shown in Listing 15-1.
Listing 15-1  Sample CertPath MBean MDF

```xml
<?xml version="1.0" ?>
<!DOCTYPE MBeanType SYSTEM "commo.dtd">

<MBeanType
    Name          = "MyCertPathProvider"
    DisplayName   = "MyCertPathProvider"
    Package       = "com.acme"
    Extends       = "weblogic.management.security.pk.CertPathBuilder"
    Implements    = "weblogic.management.security.pk.CertPathValidator"
    PersistPolicy = "OnUpdate"
>
    <MBeanAttribute
        Name          = "ProviderClassName"
        Type          = "java.lang.String"
        Writeable     = "false"
        Default       = ""com.acme.MyCertPathProviderRuntimeImpl""
    />

    <MBeanAttribute
        Name          = "Description"
        Type          = "java.lang.String"
        Writeable     = "false"
        Default       = ""My CertPath Provider"
    />

    <MBeanAttribute
        Name          = "Version"
        Type          = "java.lang.String"
        Writeable     = "false"
        Default       = "1.0"
    />

<!-- add custom attributes for the configuration data needed by this provider -->
```
WebLogic CertPath Validator SSPI

The WebLogic CertPath Validator SSPI has four parts:

- An MBean SSPI, described in “CertPath Provider SPI MBeans” on page 15-4.
- The JDK CertPathValidatorSpi interface, as described in “Implement the JDK CertPathBuilderSpi and/or CertPathValidatorSpi Interfaces” on page 15-10.
- The WebLogic Server CertPathProvider SSPI interface, as described in “Implement the CertPath Provider SSPI” on page 15-10.
- The JDK security provider that registers your CertPathValidatorSpi implementation with the JDK, as described in “Implement the JDK Security Provider SPI” on page 15-13.

WebLogic CertPath Builder SSPI

The WebLogic CertPath Builder SSPI has four parts:

- An MBean SSPI, described in “CertPath Provider SPI MBeans” on page 15-4.
- The JDK CertPathBuilderSpi interface, as described in “Implement the JDK CertPathBuilderSpi and/or CertPathValidatorSpi Interfaces” on page 15-10.
- The WebLogic Server CertPathProvider SSPI interface, as described in “Implement the CertPath Provider SSPI” on page 15-10.
- The JDK security provider that registers your CertPathBuilderSpi with the JDK, as described in “Implement the JDK Security Provider SPI” on page 15-13.
Relationship Between the WebLogic Server CertPath SSPI and the JDK SPI

Unlike other WebLogic Security Framework providers, your implementation of the CertPath provider relies on a tightly-coupled integration of WebLogic and JDK interfaces. This integration might best be shown in the tasks you perform to create a CertPath provider.

If you are writing a CertPath Validator, you must perform the following tasks:

1. Create a CertPathValidatorMBean that extends CertPathProviderMBean, as described in “Generate an MBean Type Using the WebLogic MBeanMaker” on page 15-24.

2. Implement the JDK java.security.cert.CertPathValidatorSpi, as described in “Implement the JDK CertPathBuilderSpi and/or CertPathValidatorSpi Interfaces” on page 15-10.

Your JDK implementation will be passed a JDK CertPathParameters object that you can cast to a WebLogic CertPathValidatorParametersSpi. You can then access its WebLogic methods to get the trusted CA's and ContextHandler. You can also use it to access your WebLogic CertPath provider object.

Use the CertPathValidatorParametersSpi to provide the data you need to validate the certificate chain, such as Trusted CA’s, the ContextHandler, and your CertPath provider SSPI implementation, which gives access to any custom configuration data provided by your MBean, as described in “Use the CertPathValidatorParametersSpi SSPI in Your CertPathValidatorSpi Implementation” on page 15-16.

Your WebLogic CertPath provider is important because your CertPathValidatorSpi implementation has no direct way to get the custom configuration data in your MBean. Your WebLogic CertPath provider can provide a proprietary mechanism to make your custom MBean data available to your JDK implementation.

3. Implement the WebLogic CertPath provider SSPI, as described in “Implement the CertPath Provider SSPI” on page 15-10. In particular, you use the initialize method of the CertPath provider SSPI to hook into the MBean and make its custom configuration data available to your CertPathValidatorSpi implementation, as shown in Listing 15-2.

4. Implement a JDK security provider that registers your CertPathValidatorSpi implementation, as described in “Implement the JDK Security Provider SPI” on page 15-13. This coding might not be intuitive, and is called out in Listing 15-5.
If you are writing a CertPath Builder, you must perform the following tasks:

1. Create a CertPathBuilderMBean that extends CertPathProviderMBean, as described in “Generate an MBean Type Using the WebLogic MBeanMaker” on page 15-24.

2. Implement the JDK java.security.cert.CertPathBuilderSpi, as described in “Implement the JDK CertPathBuilderSpi and/or CertPathValidatorSpi Interfaces” on page 15-10.

Your JDK implementation will be passed a JDK CertPathParameters object that you can cast to a WebLogic CertPathBuilderParametersSpi. You can then access its WebLogic methods to get the trusted CA’s, selector, and ContextHandler. You can also use it to access your WebLogic CertPath provider object.

Use the CertPathBuilderParametersSpi to provide the data you need to build the CertPath, such as Trusted CA’s, ContextHandler, the CertPathSelector, and your CertPath provider SSPI implementation, which gives access to any custom configuration data provided by your MBean, as described in “Use the CertPathBuilderParametersSpi SSPI in Your CertPathBuilderSpi Implementation” on page 15-14.

Your WebLogic CertPath provider is important because your CertPathBuilderSpi implementation has no direct way to get the custom configuration data in your MBean. Your WebLogic CertPath provider can provide a proprietary mechanism to make your custom MBean data available to your JDK implementation.

3. Implement a WebLogic CertPath provider SSPI, as described in “Implement the CertPath Provider SSPI” on page 15-10. In particular, you use the initialize method of the CertPath provider SSPI to hook into the MBean and make its custom configuration data available to your CertPathBuilderSpi implementation, as shown in Listing 15-2.

4. Implement the JDK security provider that registers your CertPathBuilderSpi implementation, as described in “Implement the JDK Security Provider SPI” on page 15-13. This coding might not be intuitive, and is called out in Listing 15-5.

**Do You Need to Develop a Custom CertPath Provider?**

WebLogic Server includes a CertPath provider and the Certificate Registry.

The WebLogic Server CertPath provider is both a CertPath Builder and a CertPath Validator. The provider completes certificate paths and validates the certificates using the trusted CA configured for a particular WebLogic Server instance. It can build only chains that are self-signed or are
issued by a self-signed certificate authority, which must be listed in the server’s trusted CA’s. If a certificate chain cannot be completed, it is invalid. The provider uses only the EndCertificateSelector selector.

The WebLogic Server CertPath provider also checks the signatures in the chain, ensures that the chain has not expired, and checks that one of the certificates in the chain is issued by one of the trusted CAs configured for the server. If any of these checks fail, the chain is not valid. Finally, the provider checks each certificate’s basic constraints (that is, the ability of the certificate to issue other certificates) to ensure the certificate is in the proper place in the chain.

The WebLogic Server CertPath provider can be used as a CertPath Builder and a CertPath Validator in a security realm.

The WebLogic Server Certificate Registry is an out-of-the-box CertPath provider that allows the administrator to configure a list of trusted end certificates via the Administration Console. The Certificate Registry is a builder/validator. The selection criteria can be EndCertificateSelector, SubjectDNSelector, IssuerDNSerialNumberSelector, or SubjectKeyIdentifier. The certificate chain that is returned has only the end certificate. When it validates a chain, it makes sure only that the end certificate is registered; no further checking is done.

You can configure both the CertPath provider and the Certificate Registry. You might do this to make sure that a certificate chain is valid only if signed by a trusted CA, and that the end certificate is in the registry.

If the supplied WebLogic Server CertPath providers do not meet your needs, you can develop a custom CertPath provider.

How to Develop a Custom CertPath Provider

If the WebLogic CertPath provider or Certificate Registry does not meet your needs, you can develop a custom CertPath provider by following these steps:

Create Runtime Classes Using the Appropriate SSPIs

Before you start creating runtime classes, you should first:

- “Understand the Purpose of the “Provider” SSPIs” on page 3-3
- “Understand the SSPI Hierarchy and Determine Whether You Will Create One or Two Runtime Classes” on page 3-7
When you understand this information and have made your design decisions, create the runtime classes for your custom CertPath provider by following these steps:

- “Generate an MBean Type Using the WebLogic MBeanMaker” on page 15-24.
- “Implement the JDK CertPathBuilderSpi and/or CertPathValidatorSpi Interfaces” on page 15-10
- “Implement the CertPath Provider SSPI” on page 15-10
- “Implement the JDK Security Provider SPI” on page 15-13
- “Use the CertPathBuilderParametersSpi SSPI in Your CertPathBuilderSpi Implementation” on page 15-14 and/or “Use the CertPathValidatorParametersSpi SSPI in Your CertPathValidatorSpi Implementation” on page 15-16.

**Implement the JDK CertPathBuilderSpi and/or CertPathValidatorSpi Interfaces**

The java.security.cert.CertPathBuilderSpi interface is the Service Provider Interface (SPI) for the CertPathBuilder class. All CertPathBuilder implementations must include a class that implements this interface (CertPathBuilderSpi).

The java.security.cert.CertPathValidatorSpi interface is the Service Provider Interface (SPI) for the CertPathValidator class. All CertPathValidator implementations must include a class that implements this interface (CertPathValidatorSpi).

Listing 15-6 shows an example of implementing the CertPathBuilderSpi and CertPathValidatorSpi interfaces.

**Implement the CertPath Provider SSPI**

The CertPathProvider SSPI interface exposes the services provided by both the JDK CertPathValidator and CertPathBuilder SPIs and allows the provider to be manipulated (initialized, started, stopped, and so on).

In particular, you use the initialize method of the CertPath provider SSPI to hook into the MBean and make its custom configuration data available to your CertPathBuilderSpi or CertPathValidatorSpi implementation, as shown in Listing 15-2.

A more complete example is available in Listing 15-6.
How to Develop a Custom CertPath Provider

Listing 15-2  Code Fragment: Obtaining Custom Configuration Data From MBean

```java
public class MyCertPathProviderRuntimeImpl implements CertPathProvider {

    public void initialize(ProviderMBean mBean, SecurityServices securityServices) {
        MyCertPathProviderMBean myMBean = (MyCertPathProviderMBean)mBean;
        description = myMBean.getDescription();
        customConfigData = myMBean.getCustomConfigData();
    }

    // make my config data available to my JDK CertPathBuilderSpi and CertPathValidatorSpi impls
    private String getCustomConfigData() { return customConfigData; }
}

static public class MyJDKCertPathBuilder extends CertPathBuilderSpi {

    MyCertPathProviderRuntimeImpl runtime =
        (MyCertPathProviderRuntimeImpl)params.getCertPathProvider();
    String myCustomConfigData = runtime.getCustomConfigData();
}
```

Listing 15-5 shows how to register your JDK implementation with the JDK.

To implement the CertPathProvider SSPI, provide implementations for the methods described in “Understand the Purpose of the “Provider” SSPIs” on page 3-3 and the following methods:
getCertPathBuilder

    public CertPathBuilder getCertPathBuilder()

    Gets a CertPath Provider's JDK CertPathBuilder that invokes your JDK
    CertPathBuilderSpi implementation, as shown in Listing 15-3. A CertPathBuilder finds,
    and optionally validates, a certificate chain.

Listing 15-3  Code Fragment: getCertPathBuilder

    public void initialize(ProviderMBean mBean, SecurityServices
    securityServices)
    {
        // get my JDK cert path impls
        try {
            certPathBuilder = CertPathBuilder.getInstance(BUILDER_ALGORITHM);
        } catch (NoSuchAlgorithmException e) { throw new
        AssertionError("..."); }

getCertPathValidator

    public CertPathValidator getCertPathValidator()

    Gets a CertPath Provider's JDK CertPathValidator that invokes your JDK
    CertPathValidatorSpi implementation, as shown in Listing 15-4. A CertPathValidator
    validates a certificate chain.

Listing 15-4  Code Fragment: getCertPathValidator

    public void initialize(ProviderMBean mBean, SecurityServices
    securityServices)
    {
        // get my JDK cert path impls
        try {
            certPathValidator =
How to Develop a Custom CertPath Provider

Developing Security Providers for WebLogic Server

CertPathValidator.getInstance(VALIDATOR_ALGORITHM);

Listing 15-6 shows an example of creating the runtime class for a sample CertPath provider. Listing 15-5 shows the fragment from that larger example that implements the JDK security provider.

Listing 15-5 Implementing the JDK Security Provider

public class MyCertPathProviderRuntimeImpl implements CertPathProvider

    private static final String MY_JDK_SECURITY_PROVIDER_NAME = 
        "MyCertPathProvider";
    private static final String BUILDER_ALGORITHM = MY_JDK_SECURITY_PROVIDER_NAME + 
        "CertPathBuilder";
    private static final String VALIDATOR_ALGORITHM = MY_JDK_SECURITY_PROVIDER_NAME + 
        "CertPathValidator";

    public void initialize(ProviderMBean mBean, SecurityServices securityServices)
    {
        MyCertPathProviderMBean myMBean = (MyCertPathProviderMBean)mBean;
        description = myMBean.getDescription();
        customConfigData = myMBean.getCustomConfigData();

        // register my cert path imple with the JDK
        // so that the CLV framework may invoke them via
        // the JDK cert path api.

Implement the JDK Security Provider SPI

Implement the JDK security provider SPI and use it to register your CertPathBuilderSpi or CertPathValidatorSpi implementations with the JDK. Use it to register your JDK implementation in your provider’s initialize method.

Listing 15-6 shows an example of creating the runtime class for a sample CertPath provider. Listing 15-5 shows the fragment from that larger example that implements the JDK security provider.
if (Security.getProvider(MY_JDK_SECURITY_PROVIDER_NAME) == null) {
    AccessController.doPrivileged(
        new PrivilegedAction() {
            public Object run() {
                Security.addProvider(new MyJDKSecurityProvider());
                return null;
            }
        }
    );
}

// This class implements the JDK security provider that registers
// this provider's cert path builder and cert path validator implementations
// with the JDK.

private class MyJDKSecurityProvider extends Provider {
    private MyJDKSecurityProvider() {
        super(MY_JDK_SECURITY_PROVIDER_NAME, 1.0, "MyCertPathProvider JDK
        CertPath provider");
        put("CertPathBuilder." + BUILDER_ALGORITHM,
            "com.acme.MyPathProviderRuntimeImpl$MyJDKCertPathBuilder");
        put("CertPathValidator." + VALIDATOR_ALGORITHM,
            "com.acme.MyCertPathProviderRuntimeImpl$MyJDKCertPathValidator");
    }
}

---

**Use the CertPathBuilderParametersSpi SSPI in Your CertPathBuilderSpi Implementation**

Your JDK implementation will be passed a JDK `CertPathParameters` object that you can cast to a WebLogic `CertPathBuilderParametersSpi`. You can then access its WebLogic methods to get the trusted CA's, selector, and ContextHandler. You can also use it to access your WebLogic `CertPath` provider object. The following methods are provided:

**getCertPathProvider**

```java
CertPathProvider getCertPathProvider()
```

Gets the CertPath Provider SSPI interface that exposes the services provided by a CertPath provider to the WebLogic Security Framework. In particular, you use the `initialize` method of the CertPath provider SSPI to hook into the MBean and make its...
custom configuration data available to your CertPathBuilderSpi implementation, as shown in Listing 15-2.

getCertPathSelector

```java
CertPathSelector getCertPathSelector()
```

Gets the CertPathSelector interface that holds the selection criteria for finding the CertPath.

WebLogic Server provides a set of classes in `weblogic.security.pk` that implement the `CertPathSelector` interface, one for each supported type of certificate chain lookup. Therefore, the `getCertPathSelector` method returns one of the following derived classes:

- `EndCertificateSelector` – used to find and validate a certificate chain given its end certificate.
- `IssuerDNSerialNumberSelector` – used to find and validate a certificate chain from its end certificate’s issuer DN and serial number.
- `SubjectDNSelector` – used to find and validate a certificate chain from its end certificate’s subject DN.
- `SubjectKeyIdentifierSelector` – used to find and validate a certificate chain from its end certificate’s subject key identifier (an optional field in X509 certificates).

Each selector class has one or more methods to retrieve the selection data and a constructor.

Your `CertPathBuilderSpi` implementation decides which selectors it supports. The `CertPathBuilderSpi` implementation must use the `getCertPathSelector` method of the `CertPathBuilderParametersSpi` SSPI to get the `CertPathSelector` that holds the selection criteria for finding the CertPath. If your `CertPathBuilderSpi` implementation supports that type of selector, it then uses the selector to build and validate the chain. Otherwise, it must throw an `InvalidAlgorithmParameterException`, which is propagated back to the caller.

getContext()

```java
ContextHandler getContext()
```

Gets a ContextHandler that may pass in extra parameters that can be used for building and validating the CertPath.

getTrustedCAs()

```java
X509Certificate[] getTrustedCAs()
```
CertPath Providers

Gets a list of trusted certificate authorities that may be used for building the certificate chain. If your CertPathBuilderSpi implementation needs Trusted CA’s to build the chain, it should use these Trusted CA’s.

**clone**

Object clone()

This interface is not cloneable.

**Use the CertPathValidatorParametersSpi SSPI in Your CertPathValidatorSpi Implementation**

Your JDK implementation will be passed a JDK CertPathParameters object that you can cast to a WebLogic CertPathValidatorParametersSpi. You can then access its WebLogic methods to get the trusted CA’s and ContextHandler. You can also use it to access your WebLogic CertPath provider object. The CLV framework ensures that the certificate chain passed to the validator SPI is in order (starting at the end certificate), and that each cert has signed the next. The following methods are provided:

**getCertPathProvider**

CertPathProvider getCertPathProvider()

Gets the CertPath Provider SSPI interface that exposes the services provided by a CertPath provider to the WebLogic Security Framework. In particular, you use the initialize method of the CertPath provider SSPI to hook into the MBean and make its custom configuration data available to your CertPathValidatorSpi implementation, as shown in Listing 15-2.

**getContext()**

ContextHandler getContext()

Gets a ContextHandler that may pass in extra parameters that can be used for building and validating the CertPath.

SSL performs some built-in validation before it calls one or more CertPathValidator objects to perform additional validation. A validator can reduce the amount of validation it must do by discovering what validation has already been done.

For example, the WebLogic CertPath Provider performs the same Certicom validation that SSL does, and there is no need to duplicate that validation when invoked by SSL. Therefore, SSL puts some information into the context it hands to the validators to indicate what validation has already occurred. The weblogic.security.SSL.SSLValidationConstants
CHAIN_PREVALIDATED_BY_SSL field is a Boolean that indicates whether SSL has pre-validated the certificate chain. Your application code can test this field, which is set to true if SSL has pre-validated the certificate chain, and is false otherwise.

getTrustedCAs()

X509Certificate[] getTrustedCAs()

Gets a list of trusted certificate authorities that may be used for validating the certificate chain. If your CertPathBuilderSpi implementation needs Trusted CA’s to validate the chain, it should use these Trusted CA’s.

clone

Object clone()

This interface is not cloneable.

Returning the Builder or Validator Results

Your JDK CertPathBuilder or CertPathValidator implementation must return an object that implements the java.security.cert.CertPathValidatorResult or java.security.cert.CertPathValidatorResult interface.

You can write your own results implementation or you can use the WebLogic Server convenience routines.

WebLogic Server provides two convenience results-implementation classes, WLSCertPathBuilderResult and WLSCertPathValidatorResult, both of which are located in weblogic.security.pk, that you can use to return instances of java.security.cert.CertPathValidatorResult or java.security.cert.CertPathValidatorResult.

Note: The results you return are not passed through the WebLogic Security framework.

Example: Creating the Sample Cert Path Provider

Listing 15-6 shows an example CertPath builder/validator provider. The example includes extensive comments that explain the code flow.

Listing 15-1 shows the CertPath MBean that Listing 15-6 uses.

CertPath Providers

// make my config data available to my JDK CertPathBuilderSpi and
// CertPathValidatorSpi implems
private String getCustomConfigData() { return customConfigData; }

/**
 * This class contains JDK cert path builder implementation for this provider.
 */
static public class MyJDKCertPathBuilder extends CertPathBuilderSpi
{
    public CertPathBuilderResult
        engineBuild(CertPathParameters genericParams)
        throws CertPathBuilderException, InvalidAlgorithmParameterException
    {

        // narrow the CertPathParameters to the WLS ones so we can get the
        // data needed to build and validate the cert path
        if (!(genericParams instanceof CertPathBuilderParametersSpi)) {
            throw new InvalidAlgorithmParameterException("The CertPathParameters must
            be a weblogic.security.pk.CertPathBuilderParametersSpi instance.");
        }

        CertPathBuilderParametersSpi params =
            (CertPathBuilderParametersSpi)genericParams;

        // get my runtime implementation instance which holds the configuration
        // data needed to build and validate the cert path
        MyCertPathProviderRuntimeImpl runtime =
            (MyCertPathProviderRuntimeImpl)params.getCertPathProvider();
        String myCustomConfigData = runtime.getCustomConfigData();

        // get the selector which indicates which cert path the caller wants built.
        // it can be an EndCertificateSelector, SubjectDNSelector,
        // IssuerDNSerialNumberSelector
        // or a SubjectKeyIdentifier.
        CertPathSelector genericSelector = params.getCertPathSelector();

        // decide which kinds of selectors this builder wants to support.
        if (genericSelector instanceof SubjectDNSelector) {

            // get the subject dn of the end certificate of the cert path the caller
            // wants built
            SubjectDNSelector selector = (SubjectDNSelector)genericSelector;
String subjectDN = selector.getSubjectDN();

// if your implementation requires trusted CAs, get them.
// otherwise, ignore them. that is, it's a quality of service
// issue whether or not you require trusted CAs.
X509Certificate[] trustedCAs = params.getTrustedCAs();

// if your implementation requires looks for extra data in
// the context handler, get it. otherwise ignore it.
ContextHandler context = params.getContext();
if (context != null) {
    // ...
}

// use my custom configuration data (ie. myCustomConfigData),
// the trusted CAs (if applicable to my implementation),
// the context (if applicable to my implementation),
// and the subject DN to build and validate the cert path
CertPath certpath = ...
// or X509Certificate[] chain = ...

// if not found, throw an exception:
if (...) {
    throw new CertPathBuilderException("Could not build a cert path for " +
        subjectDN);
}

// if not valid, throw an exception:
if (...) {
    throw new CertPathBuilderException("Could not validate the cert path for " +
        subjectDN);
}

// if found and valid, return the cert path.
// for convenience, use the WLSCertPathBuilderResult class
return new WLSCertPathBuilderResult(certpath);
// or return new WLSCertPathBuilderResult(chain);
}

// the caller passed in a selector that my implementation does not support
throw new InvalidAlgorithmParameterException("MyCertPathProvider only supports weblogic.security.pk.SubjectDNSector");
CertPath Providers

```java
/**
 * This class contains JDK cert path validator implementation for this provider.
 */
static public class MyJDKCertPathValidator extends CertPathValidatorSpi
{
    public CertPathValidatorResult
        engineValidate(CertPath certPath, CertPathParameters genericParams)
            throws CertPathValidatorException, InvalidAlgorithmParameterException
    {
        // narrow the CertPathParameters to the WLS ones so we can get the
        // data needed to build and validate the cert path
        if (!(genericParams instanceof CertPathValidatorParametersSpi)) {
            throw new InvalidAlgorithmParameterException("The CertPathParameters must
            be a weblogic.security.pk.CertPathValidatorParametersSpi instance.");
        }

        CertPathValidatorParametersSpi params =
            (CertPathValidatorParametersSpi)genericParams;

        // get my runtime implementation instance which holds the configuration
        // data needed to build and validate the cert path
        MyCertPathProviderRuntimeImpl runtime =
            (MyCertPathProviderRuntimeImpl)params.getCertPathProvider();
        String myCustomConfigData = runtime.getCustomConfigData();

        // if your implementation requires trusted CAs, get them.
        // otherwise, ignore them. that is, it's a quality of service
        // issue whether or not you require trusted CAs.
        X509Certificate[] trustedCAs = params.getTrustedCAs();

        // if your implementation requires looks for extra data in
        // the context handler, get it. otherwise ignore it.
        ContextHandler context = params.getContext();
        if (context != null) {
            // ...
```
How to Develop a Custom CertPath Provider

// The CLV framework has already done some minimal validation
// on the cert path before sending it to your provider:
// 1) the cert path is not empty
// 2) the cert path starts with the end cert
// 3) each certificate in the cert path was issued and
//    signed by the next certificate in the chain
// So, your validator can rely on these checks having
// already been performed (vs your validator needing to
// do these checks too).

// Use my custom configuration data (ie. myCustomConfigData),
// the trusted CAs (if applicable to my implementation),
// and the context (if applicable to my implementation)
// to validate the cert path

// if not valid, throw an exception:
if (...) {
    throw new CertPathValidatorException("Could not validate the cerpath " +
            certPath);
}
// if valid, return success

// For convenience, use the WLSCertPathValidatorResult class
return new WLSCertPathValidatorResult();

// This class implements the JDK security provider that registers this
// provider's
cert path builder and cert path validator implementations with the JDK.
private class MyJDKSecurityProvider extends Provider
{
    private MyJDKSecurityProvider()
    {
        super(MY_JDK_SECURITY_PROVIDER_NAME, 1.0, "MyCertPathProvider JDK CertPath provider");
        put("CertPathBuilder." + BUILDER_ALGORITHM,
"com.acme.MyPathProviderRuntimeImpl$MyJDKCertPathBuilder");
        put("CertPathValidator." + VALIDATOR_ALGORITHM,
"com.acme.MyCertPathProviderRuntimeImpl$MyJDKCertPathValidator");
    }
}
Before you start generating an MBean type for your custom security provider, you should first:

- “Understand Why You Need an MBean Type” on page 3-11
- “Determine Which SSPI MBeans to Extend and Implement” on page 3-11
- “Understand the Basic Elements of an MBean Definition File (MDF)” on page 3-12
- “Understand the SSPI MBean Hierarchy and How It Affects the Administration Console” on page 3-15
- “Understand What the WebLogic MBeanMaker Provides” on page 3-17

When you understand this information and have made your design decisions, create the MBean type for your custom CertPath provider by following these steps:

- “Create an MBean Definition File (MDF)” on page 15-24
- “Use the WebLogic MBeanMaker to Generate the MBean Type” on page 15-25
- “Use the WebLogic MBeanMaker to Create the MBean JAR File (MJF)” on page 15-29
- “Install the MBean Type Into the WebLogic Server Environment” on page 15-30

**Notes:** All instructions provided in this section assume that you are working in a Windows environment.

## Create an MBean Definition File (MDF)

To create an MBean Definition File (MDF), follow these steps:

1. Copy the MDF for the sample Authentication provider to a text file.
   
   **Note:** The MDF for the sample Authentication provider is called SimpleSampleAuthenticator.xml. There is no sample CertPath provider.

2. Modify the content of the `<MBeanType>` and `<MBeanAttribute>` elements in your MDF so that they are appropriate for your custom CertPath provider. You need to extend or implement CertPathBuilderMBean or CertPathValidatorMBean.
3. Add any custom attributes and operations (that is, additional `<MBeanAttribute>` and `<MBeanOperation>` elements) to your MDF.

4. Save the file.

   **Note:** A complete reference of MDF element syntax is available in Appendix A, “MBean Definition File (MDF) Element Syntax.”

### Use the WebLogic MBeanMaker to Generate the MBean Type

Once you create your MDF, you are ready to run it through the WebLogic MBeanMaker. The WebLogic MBeanMaker is currently a command-line utility that takes as its input an MDF, and outputs some intermediate Java files, including an MBean interface, an MBean implementation, and an associated MBean information file. Together, these intermediate files form the MBean type for your custom security provider.

The instructions for generating an MBean type differ based on the design of your custom CertPath provider. Follow the instructions that are appropriate to your situation:

- “No Optional SSPI MBeans and No Custom Operations” on page 15-25
- “Optional SSPI MBeans or Custom Operations” on page 15-26

### No Optional SSPI MBeans and No Custom Operations

If the MDF for your custom CertPath provider does not implement any optional SSPI MBeans and does not include any custom operations, follow these steps:

1. Create a new DOS shell.

2. Type the following command:

   ```
   java -DMDF=xmlfile -Dfiles=filesdir -DcreateStubs=true weblogic.management.commo.WebLogicMBeanMaker
   ```

   where the `-DMDF` flag indicates that the WebLogic MBeanMaker should translate the MDF into code, `xmlfile` is the MDF (the XML MBean Description File) and `filesdir` is the location where the WebLogic MBeanMaker will place the intermediate files for the MBean type.

   Whenever `xmlfile` is provided, a new set of output files is generated.

   Each time you use the `-DcreateStubs=true` flag, it overwrites any existing MBean implementation file.
CertPath Providers

**Note:** As of version 9.0 of WebLogic Server, you can also provide a directory that contains multiple MDF's by using the `-DMDFDIR <MDF directory name>` option. In prior versions of WebLogic Server, the WebLogic MBeanMaker processed only one MDF at a time. Therefore, you had to repeat this process if you had multiple MDFs (in other words, multiple CertPath providers).

3. Proceed to “Use the WebLogic MBeanMaker to Create the MBean JAR File (MJF)” on page 15-29.

**Optional SSPI MBeans or Custom Operations**

If the MDF for your custom CertPath provider does implement some optional SSPI MBeans or does include custom operations, consider the following:

- Are you creating an MBean type for the first time? If so, follow these steps:
  1. Create a new DOS shell.
  2. Type the following command:

     ```
     java -DMDF=xmlfile -Dfiles=filesdir -DcreateStubs=true
     weblogic.management.commo.WebLogicMBeanMaker
     ```

     where the `-DMDF` flag indicates that the WebLogic MBeanMaker should translate the MDF into code, `xmlFile` is the MDF (the XML MBean Description File) and `filesdir` is the location where the WebLogic MBeanMaker will place the intermediate files for the MBean type.

     Whenever `xmlfile` is provided, a new set of output files is generated.

     Each time you use the `-DcreateStubs=true` flag, it overwrites any existing MBean implementation file.

     **Note:** As of version 9.0 of WebLogic Server, you can also provide a directory that contains multiple MDF's by using the `-DMDFDIR <MDF directory name>` option. In prior versions of WebLogic Server, the WebLogic MBeanMaker processed only one MDF at a time. Therefore, you had to repeat this process if you had multiple MDFs (in other words, multiple CertPath providers).

3. If you implemented optional SSPI MBeans in your MDF, follow these steps:
   a. Locate the MBean implementation file.

     The MBean implementation file generated by the WebLogic MBeanMaker is named `MBeanNameImpl.java`. For example, for the MDF named `SampleIdentityAssertion`,
the MBean implementation file to be edited is named SampleIdentityAssertionImpl.java.

b. For each optional SSPI MBean that you implemented in your MDF, implement each method. Be sure to also provide implementations for any methods that the optional SSPI MBean inherits.

4. If you included any custom operations in your MDF, implement the methods using the method stubs.

5. Save the file.

6. Proceed to “Use the WebLogic MBeanMaker to Create the MBean JAR File (MJF)” on page 15-29.

• Are you updating an existing MBean type? If so, follow these steps:

1. Copy your existing MBean implementation file to a temporary directory so that your current method implementations are not overwritten by the WebLogic MBeanMaker.

2. Create a new DOS shell.

3. Type the following command:

```java -DMDF=xmlFile -Dfiles=filesdir -DcreateStubs=true weblogic.management.commo.WebLogicMBeanMaker```

where the -DMDF flag indicates that the WebLogic MBeanMaker should translate the MDF into code, xmlFile is the MDF (the XML MBean Description File) and filesdir is the location where the WebLogic MBeanMaker will place the intermediate files for the MBean type.

Whenever xmlFile is provided, a new set of output files is generated.

Each time you use the -DcreateStubs=true flag, it overwrites any existing MBean implementation file.

Note: As of version 9.0 of WebLogic Server, you can also provide a directory that contains multiple MDF's by using the -DMDFDIR <MDF directory name> option. In prior versions of WebLogic Server, the WebLogic MBeanMaker processed only one MDF at a time. Therefore, you had to repeat this process if you had multiple MDFs (in other words, multiple Cert Path providers).

4. If you implemented optional SSPI MBeans in your MDF, follow these steps:

   a. Locate and open the MBean implementation file.
The MBean implementation file generated by the WebLogic MBeanMaker is named MBeanNameImpl.java. For example, for the MDF named SampleIdentityAsserter, the MBean implementation file to be edited is named SampleIdentityAsserterImpl.java.

b. Open your existing MBean implementation file (which you saved to a temporary directory in step 1).

c. Synchronize the existing MBean implementation file with the MBean implementation file generated by the WebLogic MBeanMaker.

Accomplishing this task may include, but is not limited to: copying the method implementations from your existing MBean implementation file into the newly-generated MBean implementation file (or, alternatively, adding the new methods from the newly-generated MBean implementation file to your existing MBean implementation file), and verifying that any changes to method signatures are reflected in the version of the MBean implementation file that you are going to use (for methods that exist in both MBean implementation files).

d. If you modified the MDF to implement optional SSPI MBeans that were not in the original MDF, implement each method. Be sure to also provide implementations for any methods that the optional SSPI MBean inherits.

5. If you modified the MDF to include any custom operations that were not in the original MDF, implement the methods using the method stubs.

6. Save the version of the MBean implementation file that is complete (that is, has all methods implemented).

7. Copy this MBean implementation file into the directory where the WebLogic MBeanMaker placed the intermediate files for the MBean type. You specified this as filesdir in step 3. (You will be overriding the MBean implementation file generated by the WebLogic MBeanMaker as a result of step 3.)

8. Proceed to “Use the WebLogic MBeanMaker to Create the MBean JAR File (MJF)” on page 15-29.

About the Generated MBean Interface File

The MBean interface file is the client-side API to the MBean that your runtime class or your MBean implementation will use to obtain configuration data. It is typically used in the initialize method as described in “Understand the Purpose of the “Provider” SSPIs” on page 3-3.
Because the WebLogic MBeanMaker generates MBean types from the MDF you created, the generated MBean interface file will have the name of the MDF, plus the text “MBean” appended to it. For example, the result of running the SampleIdentityAsserter MDF through the WebLogic MBeanMaker will yield an MBean interface file called SampleIdentityAsserterMBean.java.

Use the WebLogic MBeanMaker to Create the MBean JAR File (MJF)

Once your have run your MDF through the WebLogic MBeanMaker to generate your intermediate files, and you have edited the MBean implementation file to supply implementations for the appropriate methods within it, you need to package the MBean files and the runtime classes for the custom CertPath provider into an MBean JAR File (MJF). The WebLogic MBeanMaker also automates this process.

To create an MJF for your custom CertPath provider, follow these steps:

1. Create a new DOS shell.
2. Type the following command:

   ```
   java -DMJF=jarfile -Dfiles=filesdir
   weblogic.management.commo.WebLogicMBeanMaker
   ```

   where the `-DMJF` flag indicates that the WebLogic MBeanMaker should build a JAR file containing the new MBean types, `jarfile` is the name for the MJF and `filesdir` is the location where the WebLogic MBeanMaker looks for the files to JAR into the MJF.

   Compilation occurs at this point, so errors are possible. If `jarfile` is provided, and no errors occur, an MJF is created with the specified name.

   Notes: When you create a JAR file for a custom security provider, a set of XML binding classes and a schema are also generated. You can choose a namespace to associate with that schema. Doing so avoids the possibility that your custom classes will conflict with those provided by Oracle. The default for the namespace is vendor. You can change this default by passing the `-targetNameSpace` argument to the WebLogicMBeanMaker or the associated WLMBeanMaker ant task.

   If you want to update an existing MJF, simply delete the MJF and regenerate it. The WebLogic MBeanMaker also has a `-DIncludeSource` option, which controls whether source files are included into the resulting MJF. Source files include both the generated
source and the MDF itself. The default is false. This option is ignored when -DMJF is not used.

The resulting MJF can be installed into your WebLogic Server environment, or distributed to your customers for installation into their WebLogic Server environments.

Install the MBean Type Into the WebLogic Server Environment

To install an MBean type into the WebLogic Server environment, copy the MJF into the \WL_HOME\server\lib\mbeantypes directory, where WL_HOME is the top-level installation directory for WebLogic Server. This “deploys” your custom CertPath provider—that is, it makes the custom CertPath provider manageable from the WebLogic Server Administration Console.

Note: WL_HOME\server\lib\mbeantypes is the default directory for installing MBean types. (Beginning with 9.0, security providers can be loaded from \...\domaindir\lib\mbeantypes as well.) However, if you want WebLogic Server to look for MBean types in additional directories, use the -Dweblogic.alternateTypesDirectory=<dir> command-line flag when starting your server, where <dir> is a comma-separated list of directory names. When you use this flag, WebLogic Server will always load MBean types from \WL_HOME\server\lib\mbeantypes first, then will look in the additional directories and load all valid archives present in those directories (regardless of their extension). For example, if -Dweblogic.alternateTypesDirectory = dirX,dirY, WebLogic Server will first load MBean types from \WL_HOME\server\lib\mbeantypes, then any valid archives present in dirX and dirY. If you instruct WebLogic Server to look in additional directories for MBean types and are using the Java Security Manager, you must also update the weblogic.policy file to grant appropriate permissions for the MBean type (and thus, the custom security provider). For more information, see “Using the Java Security Manager to Protect WebLogic Resources” in Programming WebLogic Security.

You can create instances of the MBean type by configuring your custom CertPath provider (see “Configure the Custom CertPath Provider Using the Administration Console” on page 15-31), and then use those MBean instances from a GUI, from other Java code, or from APIs. For example, you can use the WebLogic Server Administration Console to get and set attributes and invoke operations, or you can develop other Java objects that instantiate MBeans and automatically respond to information that the MBeans supply. We recommend that you back up these MBean instances.
Configure the Custom CertPath Provider Using the Administration Console

Configuring a custom CertPath provider means that you are adding the custom CertPath provider to your security realm, where it can be accessed by applications requiring CertPath services.

Configuring custom security providers is an administrative task, but it is a task that may also be performed by developers of custom security providers.

**Note:** The steps for configuring a custom CertPath provider using the WebLogic Server Administration Console are described under “Configuring WebLogic Security Providers” in Securing WebLogic Server.
CertPath Providers
An **MBean Definition File (MDF)** is an input file to the WebLogic MBeanMaker utility, which uses the file to create an MBean type for managing a custom security provider. An MDF must be formatted as a well-formed and valid XML file that describes a single MBean type. The following sections describe all the elements and attributes that are available for use in a valid MDF:

- “The MBeanType (Root) Element” on page A-1
- “The MBeanAttribute Subelement” on page A-4
- “The MBeanConstructor Subelement” on page A-10
- “The MBeanOperation Subelement” on page A-10
- “Examples: Well-Formed and Valid MBean Definition Files (MDFs)” on page A-15

### The MBeanType (Root) Element

All MDFs must contain exactly one root element called **MBeanType**, which has the following syntax:

```xml
<MBeanType Name= "string optional_attributes"> subelements </MBeanType>
```

The **MBeanType** element must include a **Name** attribute, which specifies the internal, programmatic name of the MBean type. (To specify a name that is visible in a user interface, use the **DisplayName** attribute.) Other attributes are optional.
The following is a simplified example of an MBeanType (root) element:

```xml
<MBeanType Name="MyMBean" Package="com.mycompany">
  <MBeanAttribute Name="MyAttr" Type="java.lang.String" Default="Hello World"/>
</MBeanType>
```

Attributes specified in the MBeanType (root) element apply to the entire set of MBeans instantiated from that MBean type. To override attributes for specific MBean instances, you need to specify attributes in the MBeanAttribute subelement. For more information, see “The MBeanAttribute Subelement” on page A-4.

Table A-1 describes the attributes available to the MBeanType (root) element. The JMX Specification/Oracle Extension column indicates whether the attribute is an Oracle extension to the JMX specification or a standard JMX attribute. Note that Oracle extensions might not function on other Java EE Web servers.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>JMX Specification/Oracle Extension</th>
<th>Allowed Values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Abstract</td>
<td>Oracle Extension</td>
<td>true/false</td>
<td>A true value specifies that the MBean type cannot be instantiated (like any abstract Java class), though other MBean types can inherit its attributes and operations. If you specify true, you must create other non-abstract MBean types for carrying out management tasks. If you do not specify a value for this attribute, the assumed value is false.</td>
</tr>
<tr>
<td>Deprecated</td>
<td>Oracle Extension</td>
<td>true/false</td>
<td>Indicates that the MBean type is deprecated. This information appears in the generated Java source, and is also placed in the ModelMBeanInfo object for possible use by a management application. If you do not specify this attribute, the assumed value is false.</td>
</tr>
</tbody>
</table>
The `MBeanType (Root)` Element

<table>
<thead>
<tr>
<th>Attribute</th>
<th>JMX Specification /Oracle Extension</th>
<th>Allowed Values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Description</td>
<td>JMX Specification</td>
<td><code>String</code></td>
<td>An arbitrary string associated with the MBean type that appears in various locations, such as the Javadoc for generated classes. There is no default or assumed value.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td><strong>Note:</strong> To specify a description that is visible in a user interface, use the <code>DisplayName</code> attribute.</td>
</tr>
<tr>
<td>DisplayName</td>
<td>JMX Specification</td>
<td><code>String</code></td>
<td>The name that a user interface displays to identify instances of MBean types. For an instance of type X, the default <code>DisplayName</code> is &quot;instance of type X.&quot; This value is typically overridden when instances are created.</td>
</tr>
<tr>
<td>Extends</td>
<td>Oracle Extension</td>
<td><code>Pathname</code></td>
<td>A fully qualified MBean type name that this MBean type extends.</td>
</tr>
<tr>
<td>Implements</td>
<td>Oracle Extension</td>
<td><code>Comma-separated list</code></td>
<td>A comma-separated list of fully qualified MBean type names that this MBean type implements. See also <code>Extends</code>.</td>
</tr>
<tr>
<td>Name</td>
<td>JMX Specification</td>
<td><code>String</code></td>
<td>Mandatory attribute that specifies the internal, programmatic name of the MBean type.</td>
</tr>
</tbody>
</table>
The MBeanAttribute Subelement

You must supply one instance of an MBeanAttribute subelement for each attribute in your MBean type. The MBeanAttribute subelement must be formatted as follows:

```xml
<MBeanAttribute Name="string optional_attributes" />
```

The MBeanAttribute subelement must include a Name attribute, which specifies the internal, programmatic name of the Java attribute in the MBean type. (To specify a name that is visible in a user interface, use the DisplayName attribute.) Other attributes are optional.

The following is a simplified example of an MBeanAttribute subelement within an MBeanType element:

```xml
<MBeanType Name="MyMBean" Package="com.mycompany">
  <MBeanAttribute Name="WhenToCache"
      Type="java.lang.String"
      LegalValues="'cache-on-reference', 'cache-at-initialization', 'cache-never'"
      Default= "cache-on-reference"
  />
</MBeanType>
```

Table A-1  MBeanType (Root) Element Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>JMX Specification / Oracle Extension</th>
<th>Allowed Values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Package</td>
<td>Oracle Extension</td>
<td>String</td>
<td>Specifies the package name of the MBean type and determines the location of the class files that the WebLogic MBeanMaker creates. If you do not specify this attribute, the MBean type is placed in the Java default package. Note: MBean type names can be the same as long as the package name varies.</td>
</tr>
<tr>
<td>PersistPolicy</td>
<td>JMX Specification / OnUpdate</td>
<td></td>
<td>Specifies how persistence will occur: OnUpdate. The attribute is stored every time the attribute is updated. Note: When specified in the MBeanType element, this value overrides any setting within an individual MBeanAttribute subelement.</td>
</tr>
</tbody>
</table>
Attributes specified in an MBeanAttribute subelement apply to a specific MBean instance. To set attributes for the entire set of MBeans instantiated from an MBean type, you need to specify attributes in the MBeanType (root) element. For more information, see “The MBeanType (Root) Element” on page A-1.

Table A-2 describes the attributes available to the MBeanAttribute subelement. The JMX Specification/Oracle Extension column indicates whether the attribute is an Oracle extension to the JMX specification. Note that Oracle extensions might not function on other Java EE Web servers.

Table A-2  MBeanAttribute Subelement Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>JMX Specification /Oracle Extension</th>
<th>Allowed Values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>JMX Specification</td>
<td>String</td>
<td>The value to be returned if the MBeanAttribute subelement does not provide a getter method or a cached value. The string represents a Java expression that must evaluate to an object of a type that is compatible with the provided data type for this attribute. If you do not specify this attribute, the assumed value is null. If you use this assumed value, and if you set the LegalNull attribute to false, then an exception is thrown by WebLogic MBeanMaker and WebLogic Server.</td>
</tr>
<tr>
<td>Deprecated</td>
<td>Oracle Extension</td>
<td>true/false</td>
<td>Indicates that the MBean attribute is deprecated. This information appears in the generated Java source, and is also placed in the ModelMBeanInfo object for possible use by a management application. If you do not specify this attribute, the assumed value is false.</td>
</tr>
</tbody>
</table>

A-6  Developing Security Providers for WebLogic Server
The MBeanAttribute Subelement

### Table A-2  MBeanAttribute Subelement Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>JMX Specification /Oracle Extension</th>
<th>Allowed Values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IsIs</td>
<td>JMX Specification</td>
<td>true/false</td>
<td>Specifies whether a generated Java interface uses the JMX <code>is&lt;AttributeName&gt;</code> method to access the boolean value of the MBean attribute (as opposed to the <code>get&lt;AttributeName&gt;</code> method). If you do not specify this attribute, the assumed value is <code>false</code>.</td>
</tr>
<tr>
<td>LegalNull</td>
<td>Oracle Extension</td>
<td>true/false</td>
<td>Specifies whether <code>null</code> is an allowable value for the current MBeanAttribute subelement. If you do not specify this attribute, the assumed value is <code>true</code>.</td>
</tr>
</tbody>
</table>
| LegalValues | Oracle Extension          | Comma-separated list | Specifies a fixed set of allowable values for the current MBeanAttribute subelement. If you do not specify this attribute, the MBean attribute allows any value of the type that is specified by the `Type` attribute.  
**Note:** The items in the list must be convertible to the data type that is specified by the subelement’s `Type` attribute. |
| Max       | Oracle Extension                   | Integer        | For numeric MBean attribute types only, provides a numeric value that represents the inclusive maximum value for the attribute. If you do not specify this attribute, the value can be as large as the data type allows. |
| Min       | Oracle Extension                   | Integer        | For numeric MBean attribute types only, provides a numeric value which represents the inclusive minimum value for the attribute. If you do not specify this attribute, the value can be as small as the data type allows. |
### Table A-2  MBeanAttribute Subelement Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>JMX Specification /Oracle Extension</th>
<th>Allowed Values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>JMX Specification</td>
<td>String</td>
<td>Mandatory attribute that specifies the internal, programmatic name of the MBean attribute.</td>
</tr>
</tbody>
</table>
The MBeanAttribute Subelement

<table>
<thead>
<tr>
<th>Attribute</th>
<th>JMX Specification /Oracle Extension</th>
<th>Allowed Values</th>
<th>Description</th>
</tr>
</thead>
</table>
| Type      | JMX Specification                   | Java class name | The fully qualified classname of the data type of this attribute. This corresponding class must be available on the classpath. If you do not specify this attribute, the assumed value is `java.lang.String`. Type can be:  
  - `java.lang.Integer`  
  - `java.lang.Integer[]`  
  - `java.lang.Long`  
  - `java.lang.Long[]`  
  - `java.lang.Float`  
  - `java.lang.Float[]`  
  - `java.lang.Double`  
  - `java.lang.Double[]`  
  - `java.lang.Char`  
  - `java.lang.Char[]`  
  - `java.lang.Byte`  
  - `java.lang.Byte[]`  
  - `java.lang.String`  
  - `java.lang.String[]`  
  - `java.util.Properties` |
| Writeable | JMX Specification                   | true/false      | A true value allows the MBean API to set an MBeanAttribute's value. If you do not specify this attribute in MBeanType or MBeanAttribute, the assumed value is true. When specified in the MBeanType element, this value is considered the default for individual MBeanAttribute subelements. |
The MBeanConstructor Subelement

MBeanConstructor subelements are not currently used by the WebLogic MBeanMaker, but are supported for compliance with the *Java Management eXtensions 1.0 specification* and upward compatibility. Therefore, attribute details for the MBeanConstructor subelement (and its associated MBeanConstructorArg subelement) are omitted from this documentation.

The MBeanOperation Subelement

You must supply one instance of an MBeanOperation subelement for each operation (method) that your MBean type supports. The MBeanOperation must be formatted as follows:

```xml
<MBeanOperation Name="string optional_attributes" />
</MBeanOperation>
```

The MBeanOperation subelement must include a Name attribute, which specifies the internal, programmatic name of the operation. (To specify a name that is visible in a user interface, use the DisplayName attribute.) Other attributes are optional.

Within the MBeanOperation element, you must supply one instance of an MBeanOperationArg subelement for each argument that your operation (method) uses. The MBeanOperationArg must be formatted as follows:

```xml
<MBeanOperationArg Name="string optional_attributes" />
```

The Name attribute must specify the name of the operation. The only optional attribute for MBeanOperationArg is Type, which provides the Java class name that specifies behavior for a specific type of Java attribute. If you do not specify this attribute, the assumed value is java.lang.String.

The following is a simplified example of an MBeanOperation and MBeanOperationArg subelement within an MBeanType element:

```xml
<MBeanType Name="MyMBean" Package="com.mycompany">  
  <MBeanOperation Name= "findParserSelectMBeanByKey" 
                  ReturnType="XMLParserSelectRegistryEntryMBean" 
                  Description="Given a public ID, system ID, or root element tag, returns the 
                  object name of the corresponding XMLParserSelectRegistryEntryMBean." 
  >  
    <MBeanOperationArg Name="publicID" Type="java.lang.String"/>  
    <MBeanOperationArg Name="systemID" Type="java.lang.String"/>
  </MBeanOperation>
</MBeanType>
```
Table A-3 describes the attributes available to the MBeanOperation subelement. The JMX Specification/Oracle Extension column indicates whether the attribute is an Oracle extension to the JMX specification. Note that Oracle extensions might not function on other Java EE Web servers.

### Table A-3  MBeanOperation Subelement Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>JMX Specification/Oracle Extension</th>
<th>Allowed Values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deprecated</td>
<td>Oracle Extension</td>
<td>true/false</td>
<td>Indicates that the MBean operation is deprecated. This information appears in the generated Java source, and is also placed in the ModelMBeanInfo object for possible use by a management application. If you do not specify this attribute, the assumed value is false.</td>
</tr>
<tr>
<td>Description</td>
<td>JMX Specification</td>
<td>String</td>
<td>An arbitrary string associated with the MBean operation that appears in various locations, such as the Javadoc for generated classes. There is no default or assumed value.</td>
</tr>
</tbody>
</table>

Note: To specify a description that is visible in a user interface, use the DisplayName attribute.
Table A-4 describes the attributes available to the MBeanOperationArg subelement. The JMX Specification/Oracle Extension column indicates whether the attribute is an Oracle extension to

<table>
<thead>
<tr>
<th>Attribute</th>
<th>JMX Specification /Oracle Extension</th>
<th>Allowed Values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>JMX Specification</td>
<td>String</td>
<td>Mandatory attribute that specifies the internal, programmatic name of the MBean operation.</td>
</tr>
<tr>
<td>ReturnType</td>
<td>JMX Specification</td>
<td>String</td>
<td>A string containing the fully qualified classname of the Java object returned by the operation being described. ReturnType can be void or the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• int</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• int[]</td>
</tr>
<tr>
<td></td>
<td></td>

<td>• java.util.Properties</td>
</tr>
</tbody>
</table>
the JMX specification. Note that Oracle extensions might not function on other Java EE Web servers.

<table>
<thead>
<tr>
<th>Description</th>
<th>JMX Specification /Oracle Extension</th>
<th>Allowed Values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Description</td>
<td>JMX Specification</td>
<td>String</td>
<td>An arbitrary string associated with the MBean operation argument that appears in various locations, such as the Javadoc for generated classes. There is no default or assumed value.</td>
</tr>
</tbody>
</table>
Your MBean Definition Files (MDFs) must use only JDK exception types or `weblogic.management.utils` exception types. The following is a code fragment from Listing A-1 that shows the use of an `MBeanException` within an `MBeanOperation` subelement:

```java
MBeanOperation Exception
```

Table A-4  MBeanOperationArg Subelement Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>JMX Specification</th>
<th>Allowed Values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>JMX Specification</td>
<td>String</td>
<td>Mandatory attribute that specifies the name of the argument.</td>
</tr>
<tr>
<td>Type</td>
<td>JMX Specification</td>
<td>String</td>
<td>The type of the MBean operation argument. If you do not specify this attribute, the assumed value is <code>java.lang.String</code>. Type can be:</td>
</tr>
<tr>

<td>- java.util.Properties</td>
</tr>
</tbody>
</table>

**MBean Operation Exceptions**

Your MBean Definition Files (MDFs) must use only JDK exception types or `weblogic.management.utils` exception types. The following is a code fragment from Listing A-1 that shows the use of an `MBeanException` within an `MBeanOperation` subelement:
Examples: Well-Formed and Valid MBean Definition Files (MDFs)

Listing A-1 and Listing A-2 provide examples of MBean Definition Files (MDFs) that use many of the attributes described in this Appendix. Listing A-1 shows the MDF used to generate an MBean type that manages predicates and reads data about predicates and their arguments. Listing A-2 shows the MDF used to generate the MBean type for the WebLogic (default) Authorization provider.

Listing A-1  PredicateEditor.xml

<?xml version="1.0" ?>
<!DOCTYPE MBeanType SYSTEM "commo.dtd">

<MBeanType
Name = "PredicateEditor"
Package = "weblogic.security.providers.authorization"
Implements = "weblogic.security.providers.authorization.PredicateReader"
PersistPolicy = "OnUpdate"
Abstract = "false"

Examples: Well-Formed and Valid MBean Definition Files (MDFs)
Description = "This MBean manages predicates and reads data about predicates and their arguments.&lt;p&gt;"
>
&lt;MBeanOperation
Name = "registerPredicate"
ReturnType = "void"
Description = "Registers a new predicate with the specified class name." 
&gt;

&lt;MBeanOperationArg
Name = "predicateClassName"
Type = "java.lang.String"
Description = "The name of the Java class that implements the predicate." 
/>

&lt;MBeanException>weblogic.management.utils.InvalidPredicateException</MBeanException>

&lt;MBeanException>weblogic.management.utils.AlreadyExistsException</MBeanException>

&lt;/MBeanOperation&gt;

&lt;MBeanOperation
Name = "unregisterPredicate"
ReturnType = "void"
Description = "Unregisters the currently registered predicate." 
&gt;

&lt;MBeanOperationArg
Name = "predicateClassName"
Type = "java.lang.String"
Description = "The name of the Java class that implements predicate to be unregistered." 
/>

&lt;MBeanException>weblogic.management.utils.NotFoundException</MBeanException>
Examples: Well-Formed and Valid MBean Definition Files (MDFs)

Listing A-2  DefaultAuthorizer.xml

```xml
<?xml version="1.0" ?>
<!DOCTYPE MBeanType SYSTEM "commo.dtd">
<MBeanType
  Name = "DefaultAuthorizer"
  DisplayName = "DefaultAuthorizer"
  Package = "weblogic.security.providers.authorization"
  Extends = "weblogic.management.security.authorizationDeployableAuthorizer"
  Implements = "weblogic.management.security.authorization.PolicyEditor, weblogic.security.providers.authorization.PredicateEditor"
  PersistPolicy = "OnUpdate"
  Description = "This MBean represents configuration attributes for the WebLogic Authorization provider. &lt;p&gt;"
>
  <MBeanAttribute
    Name = "ProviderClassName"
    Type = "java.lang.String"
    Writeable = "false"
    Default = "weblogic.security.providers.authorization.DefaultAuthorizati onProviderImpl"
    Description = "The name of the Java class used to load the WebLogic Authorization provider." 
  />

  <MBeanAttribute
    Name = "Description"
    Type = "java.lang.String"
    Writeable = "false"
    Default = "Weblogic Default Authorization Provider"
    Description = "A short description of the WebLogic Authorization provider." 
  />
```

Developing Security Providers for WebLogic Server
<MBeanAttribute
Name = "Version"
Type = "java.lang.String"
Writeable = "false"
Default = ""1.0"
Description = "The version of the WebLogic Authorization provider."
/>

</MBeanType>
