Introduction and Roadmap

This section describes the contents and organization of this guide—*Using Web Server Plug-Ins with WebLogic Server*.

- [“Document Scope and Audience”](#) on page 1-1
- [“Guide to this Document”](#) on page 1-1
- [“Related Documentation”](#) on page 1-2
- [“New and Changed Features in This Release”](#) on page 1-2

Document Scope and Audience

This document explains use of plug-ins provided for proxying requests to third party administration servers. This document is intended mainly for system administrators who manage the WebLogic Server® application platform and its various subsystems.

Guide to this Document

- This chapter, [“Introduction and Roadmap,”](#) introduces the organization of this guide.
- [Chapter 2, “Understanding Using Web Server Plug-Ins With WebLogic Server,”](#) describes the plug-ins available for use with WebLogic Server.
- [Chapter 3, “Installing and Configuring the Apache HTTP Server Plug-In,”](#) explains how to install and configure the WebLogic Server Apache plug-in.

- [Chapter 4, “Installing and Configuring the Microsoft IIS Plug-In,”](#) explains how to install and configure the WebLogic Server plug-in for the Microsoft Internet Information Server.
- [Chapter 5, “Proxying Requests to Another Web Server,”](#) describes the use of WebLogic Server as a proxy, forwarding HTTP requests to other Web servers.
- [Chapter 6, “Parameters for Web Server Plug-Ins,”](#) discusses the parameters for Web server plug-ins.

Related Documentation

This document contains information on using Web server plug-ins.

For information on using a proxy plug-in, see the following document:

- [Using Clusters](#) for information on load balancing servlets and JSPs using a proxy plug-in.

New and Changed Features in This Release

For a comprehensive listing of the new WebLogic Server features introduced in this release, see [“What’s New in WebLogic Server”](#) in *Release Notes*.

Understanding Using Web Server Plug-Ins With WebLogic Server

The following sections describe the plug-ins provided by Oracle for use with WebLogic Server:

- [“What Are Plug-Ins?” on page 2-1](#)
- [“Plug-Ins Included with WebLogic Server” on page 2-1](#)

What Are Plug-Ins?

Plug-ins are small software programs that developers use to extend a WebLogic Server implementation. Plug-ins enable WebLogic Server to communicate with applications deployed on Apache HTTP Server or Microsoft’s Internet Information Server. Typically, WebLogic Server handles the application requests that require dynamic functionality, the requests that can best be served with dynamic HTML pages or JSPs (Java Server Pages).

WebLogic Server Plug-Ins do not support two-way SSL. However, the Plug-Ins can be set up to require the client certificate and pass it on to WebLogic Server. For example:

```
apache ssl  
  
SSLVerifyClient require  
  
SSLVerifyDepth 10  
  
SSLOptions +FakeBasicAuth +ExportCertData +CompatEnvVars +StrictRequire
```

Plug-Ins Included with WebLogic Server

WebLogic Server includes plug-ins for the following Web servers:

- Apache HTTP Server
- Microsoft Internet Information Server

Installing and Configuring the Apache HTTP Server Plug-In

The following sections describe how to install and configure the Apache HTTP Server Plug-In:

- [“Overview of the Apache HTTP Server Plug-In” on page 3-1](#)
- [“Installing the Apache HTTP Server Plug-In” on page 3-3](#)
- [“Configuring the Apache HTTP Server Plug-In” on page 3-7](#)
- [“Setting Up Perimeter Authentication” on page 3-14](#)
- [“Using SSL with the Apache Plug-In” on page 3-16](#)
- [“Connection Errors and Clustering Failover” on page 3-17](#)

Overview of the Apache HTTP Server Plug-In

The Apache HTTP Server Plug-In allows requests to be proxied from an Apache HTTP Server to WebLogic Server. The plug-in enhances an Apache installation by allowing WebLogic Server to handle requests that require the dynamic functionality of WebLogic Server.

The plug-in is intended for use in an environment where an Apache Server serves static pages, and another part of the document tree (dynamic pages best generated by HTTP Servlets or JavaServer Pages) is delegated to WebLogic Server, which may be operating in a different process, possibly on a different host. To the end user—the browser—the HTTP requests delegated to WebLogic Server still appear to be coming from the same source.

HTTP-tunneling, a technique which allows HTTP requests and responses access through a company's firewall, can also operate through the plug-in, providing non-browser clients access to WebLogic Server services.

The Apache HTTP Server Plug-In operates as an Apache module within an Apache HTTP Server. An Apache module is loaded by Apache Server at startup, and then certain HTTP requests are delegated to it. Apache modules are similar to HTTP servlets, except that an Apache module is written in code native to the platform.

For information on configurations on which the Apache HTTP Server Plug-In is supported, see http://edocs.bea.com/platform/suppconfigs/configs103/103_over/add-ons.html.

Note: Apache 2.0 Plug-In was deprecated in the WebLogic Server 10.0 release.

Keep-Alive Connections in Apache Version 2.0

Version 2.0 of the Apache HTTP Server Plug-In improves performance by using a reusable pool of connections from the plug-in to WebLogic Server. The plug-in implements HTTP 1.1 keep-alive connections between the plug-in and WebLogic Server by reusing the same connection in the pool for subsequent requests from the same client. If the connection is inactive for more than 30 seconds, (or a user-defined amount of time) the connection is closed and returned to the pool. You can disable this feature if desired. For more information, see “KeepAliveEnabled”.

Proxying Requests

The plug-in proxies requests to WebLogic Server based on a configuration that you specify. You can proxy requests based on the URL of the request (or a portion of the URL). This is called proxying by *path*. You can also proxy requests based on the *MIME type* of the requested file. Or you can use a combination of the two methods. If a request matches both criteria, the request is proxied by path. You can also specify additional parameters for each type of request that define additional behavior of the plug-in. For more information, see “[Configuring the Apache HTTP Server Plug-In](#)” on page 3-7.

Apache 2.2

Although this document refers to Apache 2.0, you can apply the same instructions to use Apache 2.2 with the libraries shown in [Table 3-2](#).

Certifications

The Apache HTTP Server Plug-In is supported on AIX, Linux, Solaris, Windows, and HP-UX11 platforms. For information on support for specific versions of Apache, see http://edocs.bea.com/platform/suppconfigs/configs103/103_over/add-ons.html.

Installing the Apache HTTP Server Plug-In

You can install the Apache HTTP Server Plug-In as an Apache module in your Apache HTTP Server installation and link it as a Dynamic Shared Object (DSO).

A DSO is compiled as a library that is dynamically loaded by the server at run time, and can be installed without recompiling Apache.

Installing the Apache HTTP Server Plug-In as a Dynamic Shared Object

The Apache plug-in is distributed as a shared object (.so) for Solaris, Linux, AIX, Windows, and HP-UX11 platforms. The WLS 10.3 installation does not include the Apache HTTP server plug-ins. The Apache HTTP Server plug-ins are available in a separate zip file, available from the Oracle download and support sites. These plug-ins contain a fix for the security advisory described at:

http://www.oracle.com/technology/deploy/security/alerts/alert_cve2008-3257.html

After downloading the zip file, extract the zip to a directory of your choice on disk.

Table 3-1 shows the directories created after extracting the zip file to the directory you specified. These directories contain shared object files for various platforms.

Table 3-2 identifies the WebLogic Server Apache Plug-In modules for different versions of Apache HTTP Server and different encryption strengths.

Table 3-1 Locations of Plug-In Shared Object Files

Operating System	Shared Object Location
AIX	aix/ppc
Solaris	solaris/sparc solaris/sparc/largefile ¹ solaris/x86 solaris/x86/largefile ¹
Linux	linux/i686 linux/i686/largefile ¹ linux/ia64 linux/x86_64
Windows (Apache 2.0 and 2.2, 32-bit)	win\32
HPUX11	hpux11/IPF64 hpux11/PA_RISC
	<p>Note: If you are running Apache 2.0.x server on HP-UX11, set the environment variables specified immediately below before you build the Apache server. Because of a problem with the order in which linked libraries are loaded on HP-UX, a core dump can result if the load order is not preset as an environment variable before building. Set the following environment variables before proceeding with the Apache configure, make, and make install steps, (described in Apache HTTP Server documentation at http://httpd.apache.org/docs-2.1/install.html#configure):</p> <pre>export EXTRA_LDFLAGS="-lstd -lstream -lCsup -lm -lcl -ldld -lpthread"</pre>

1. See “Support for Large Files in Apache 2.0” on page 3-6.

Choose the appropriate version of the plug-in shared object from the following table:

Table 3-2 Apache Plug-In Shared Object File Versions

Apache Version	Regular Strength Encryption	128-bit Encryption
Standard Apache Version 2.0.x	mod_wl_20.so	mod_wl128_20.so
Standard Apache Version 2.2.x	mod_wl_22.so	mod_wl128_22.so

To install the Apache HTTP Server Plug-In as a dynamic shared object:

1. In the location where you unzipped the downloaded plug-in file, locate the shared object directory for your platform using [Table 3-1](#).

Note: Before making your selection, please review “[Support for Large Files in Apache 2.0](#)” on page 3-6.
2. Identify the plug-in shared object file for your version of Apache in [Table 3-2](#).
3. Verify that the WebLogic Server Apache HTTP Server Plug-In `mod_so.c` module is enabled.

The Apache HTTP Server Plug-In will be installed in your Apache HTTP Server installation as a Dynamic Shared Object (DSO). DSO support in Apache is based on module `mod_so.c`, which must be enabled before `mod_wl_20.so` is loaded. If you installed Apache HTTP Server using the script supplied by Apache, `mod_so.c` is already enabled. Verify that `mod_so.c` is enabled by executing the following command:

```
APACHE_HOME\bin\apachectl -l
```

(Where `APACHE_HOME` is the directory containing your Apache HTTP Server installation.)

This command lists all enabled modules. If `mod_so.c` is not listed, you must rebuild your Apache HTTP Server, making sure that the following options are configured:

```
...
--enable-module=so
--enable-rule=SHARED_CORE
...
```

See *Apache 2.0 Shared Object (DSO) Support* at <http://httpd.apache.org/docs/2.0/dso.html>.

4. Install the Apache HTTP Server Plug-In module for Apache 2.0.x by copying the `mod_wl_20.so` file to the `APACHE_HOME\modules` directory and adding the following line to your `APACHE_HOME/conf/httpd.conf` file manually:

```
LoadModule weblogic_module      modules/mod_wl_20.so
```

5. Define any additional parameters for the Apache HTTP Server Plug-In.

The Apache HTTP Server Plug-In recognizes the parameters listed in [“General Parameters for Web Server Plug-Ins” on page 6-2](#). To modify the behavior of your Apache HTTP Server Plug-In, define these parameters:

- In a `Location` block, for parameters that apply to proxying by *path*, or
- In an `IfModule` block, for parameters that apply to proxying by *MIME type*.

6. Verify the syntax of the `APACHE_HOME\conf\httpd.conf` file with the following command:

```
APACHE_HOME\bin\apachectl -t
```

The output of this command reports any errors in your `httpd.conf` file or returns:

```
Syntax OK
```

7. Restart Weblogic Server.
8. Start (or restart if you have changed the configuration) Apache HTTP Server.
9. Test the plug-in by opening a browser and setting the URL to the Apache Server + `“/weblogic/”`, which should bring up the default WebLogic Server HTML page, welcome file, or default servlet, as defined for the default Web Application on WebLogic Server. For example:

```
http://myApacheserver.com/weblogic/
```

Support for Large Files in Apache 2.0

The version of Apache 2.0 that ships with some operating systems, including some versions of Solaris and Linux, is compiled with the following flags:

```
-D_LARGFILE_SOURCE  
-D_FILE_OFFSET_BITS=64
```

These compilation flags enable support for files larger than 2 GB. If you want to use a WebLogic Server Web server plug-in on such an Apache 2.0 Web server, you must use plug-ins compiled with the same compilation flags, which are available in the `largefile` subdirectory for your operating system. For example:

```
C:\bea\wlserver_10.3\server\plugin\solaris\sparc\largefile
```

Note: Apache 2.2 does not require special compilation flags to support files larger than 2 GB. Therefore, you do not need to use a specially compiled Web server plug-in if you are running Apache 2.2.

Configuring the Apache HTTP Server Plug-In

After installing the plug-in in the Apache HTTP Server, configure the WebLogic Server Apache Plug-In and configure the server to use the plug-in. This section explains how to edit the Apache `httpd.conf` file to instruct the Apache server to load the WebLogic Server library for the plug-in as an Apache module, and to specify the application requests that should be handled by the module.

Editing the `httpd.conf` File

Edit the `httpd.conf` file in your Apache HTTP server installation to configure the Apache HTTP Server Plug-In.

This section explains how to locate and edit the `httpd.conf` file, to configure the server to use the WebLogic Server Apache Plug-In, to proxy requests by path or by MIME type, to enable HTTP tunneling, and to use other WebLogic Server plug-in parameters.

1. Open the `httpd.conf` file.

The file is located at `APACHE_HOME\conf\httpd.conf` (where `APACHE_HOME` is the root directory of your Apache HTTP server installation). See a sample `httpd.conf` file at [“Setting Up Perimeter Authentication” on page 3-14](#).

2. Ensure that the WebLogic Server modules are included for Apache 2.0.x, manually add the following line to the `httpd.conf` file:

```
LoadModule weblogic_module    modules\mod_wl_20.so
```

3. Add an `IfModule` block that defines one of the following:

For a *non-clustered* WebLogic Server:

The `WebLogicHost` and `WebLogicPort` parameters.

For a *cluster* of WebLogic Servers:

The `WebLogicCluster` parameter.

For example:

```
<IfModule mod_weblogic.c>
    WebLogicHost myweblogic.server.com
```

Installing and Configuring the Apache HTTP Server Plug-In

```
WebLogicPort 7001
</IfModule>
```

4. To proxy requests by MIME type, add a `MatchExpression` line to the `IfModule` block. Note that if both MIME type and proxying by path are enabled, proxying by path takes precedence over proxying by MIME type.

For example, the following `IfModule` block for a non-clustered WebLogic Server specifies that all files with MIME type `.jsp` are proxied:

```
<IfModule mod_weblogic.c>
WebLogicHost myweblogic.server.com
WebLogicPort 7001
MatchExpression *.jsp
</IfModule>
```

You can also use multiple `MatchExpressions`, for example:

```
<IfModule mod_weblogic.c>
WebLogicHost myweblogic.server.com
WebLogicPort 7001
MatchExpression *.jsp
MatchExpression *.xyz
</IfModule>
```

If you are proxying requests by MIME type to a cluster of WebLogic Servers, use the [WebLogicCluster](#) parameter instead of the `WebLogicHost` and `WebLogicPort` parameters. For example:

```
<IfModule mod_weblogic.c>
WebLogicCluster wls1.com:7001,wls2.com:7001,wls3.com:7001
MatchExpression *.jsp
MatchExpression *.xyz
</IfModule>
```

5. To proxy requests by path, use the `Location` block and the `SetHandler` statement. `SetHandler` specifies the handler for the Apache HTTP Server Plug-In module. For example the following `Location` block proxies all requests containing `/weblogic` in the URL:

```
<Location /weblogic>
SetHandler weblogic-handler
PathTrim /weblogic
</Location>
```

The `PathTrim` parameter specifies a string trimmed from the beginning of the URL before the request is passed to the WebLogic Server instance (see [“General Parameters for Web Server Plug-Ins” on page 6-2](#)).

6. Optionally, enable HTTP tunneling for t3 or IIOP.

- a. To enable HTTP tunneling if you are using the t3 protocol and `weblogic.jar`, add the following Location block to the `httpd.conf` file:

```
<Location /HTTPClnt>
    SetHandler weblogic-handler
</Location>
```

- b. To enable HTTP tunneling if you are using the IIOP, the only protocol used by the WebLogic Server thin client, `wlclient.jar`, add the following Location block to the `httpd.conf` file:

```
<Location /iiop>
    SetHandler weblogic-handler
</Location>
```

7. Define any additional parameters for the Apache HTTP Server Plug-In.

The Apache HTTP Server Plug-In recognizes the parameters listed in [“General Parameters for Web Server Plug-Ins” on page 6-2](#). To modify the behavior of your Apache HTTP Server Plug-In, define these parameters either:

- In a `Location` block, for parameters that apply to proxying by *path*, or
- In an `IfModule` block, for parameters that apply to proxying by *MIME type*.

Including a `weblogic.conf` File in the `httpd.conf` File

If you want to keep several separate configuration files, you can define parameters in a separate configuration file called `weblogic.conf` file, by using the Apache Include directive in an `IfModule` block in the `httpd.conf` file:

```
<IfModule mod_weblogic.c>
    # Config file for WebLogic Server that defines the parameters
    Include conf/weblogic.conf
</IfModule>
```

The syntax of `weblogic.conf` files is the same as that for the `httpd.conf` file.

This section describes how to create `weblogic.conf` files, and includes sample `weblogic.conf` files.

Creating `weblogic.conf` Files

Be aware of the following when constructing a `weblogic.conf` file.

Installing and Configuring the Apache HTTP Server Plug-In

- If you are using SSL between the Apache HTTP Server Plug-In and WebLogic Server, you cannot define parameters in a file accessed, as the `weblogic.conf` file is, via the Apache `Include` directive.
- Enter each parameter on a new line. Do not put '=' between a parameter and its value. For example:

```
PARAM_1 value1
PARAM_2 value2
PARAM_3 value3
```

- If a request matches both a MIME type specified in a `MatchExpression` in an `IfModule` block and a path specified in a `Location` block, the behavior specified by the `Location` block takes precedence.
- If you define the `CookieName` parameter, you must define it in an `IfModule` block.
- If you use an Apache HTTP Server `<VirtualHost>` block, you must include all configuration parameters (`MatchExpression`, for example) for the virtual host within the `<VirtualHost>` block (see [Apache Virtual Host documentation](#)).
- If you want to have only one log file for all the virtual hosts configured in your environment, you can achieve it using global properties. Instead of specifying the same `Debug`, `WLLogFile` and `WLTempDir` properties in each virtual host you can specify them just once in the `<IfModule>` tag

■ Sample `httpd.conf` file:

```
<IfModule mod_weblogic.c>

    WebLogicCluster johndoe02:8005,johndoe:8006

    Debug                ON

    WLLogFile             c:/tmp/global_proxy.log

    WLTempDir             "c:/myTemp"

    DebugConfigInfo       On

    KeepAliveEnabled      ON

    KeepAliveSecs         15

</IfModule>

<Location /jurl>

    SetHandler weblogic-handler
```

```

    WebLogicCluster agarwalp01:7001
  </Location>

  <Location /web>

    SetHandler weblogic-handler

    PathTrim      /web

    Debug         OFF

    WLogFile      c:/tmp/web_log.log
  </Location>

  <Location /foo>

    SetHandler weblogic-handler

    PathTrim      /foo

    Debug         ERR

    WLogFile      c:/tmp/foo_proxy.log
  </Location>

```

- All the requests which match `/jurl/*` will have Debug Level set to ALL and log messages will be logged to `c:/tmp/global_proxy.log` file. All the requests which match `/web/*` will have Debug Level set to OFF and no log messages will be logged. All the requests which match `/foo/*` will have Debug Level set to ERR and log messages will be logged to `c:/tmp/foo_proxy.log` file
- Oracle recommends that you use the `MatchExpression` statement instead of the `<files>` block.

Sample weblogic.conf Configuration Files

The following examples of `weblogic.conf` files may be used as templates that you can modify to suit your environment and server. Lines beginning with `#` are comments.

Example Using WebLogic Clusters

```

# These parameters are common for all URLs which are
# directed to the current module. If you want to override
# these parameters for each URL, you can set them again in

```

Installing and Configuring the Apache HTTP Server Plug-In

```
# the <Location> or <Files> blocks. (Except WebLogicHost,
# WebLogicPort, WebLogicCluster, and CookieName.)

<IfModule mod_weblogic.c>
    WebLogicCluster wls1.com:7001,wls2.com:7001,wls3.com:7001
    ErrorPage http://myerrorpage.mydomain.com
    MatchExpression *.jsp
</IfModule>
#####
```

Example Using Multiple WebLogic Clusters

In this example, the `MatchExpression` parameter syntax for expressing the filename pattern, the WebLogic Server host to which HTTP requests should be forwarded, and various other parameters is as follows:

```
MatchExpression [filename pattern] [WebLogicHost=host] |
[paramName=value]
```

The first `MatchExpression` parameter below specifies the filename pattern `*.jsp`, and then names the single `WebLogicHost`. The `paramName=value` combinations following the pipe symbol specify the port at which WebLogic Server is listening for connection requests, and also activate the Debug option. The second `MatchExpression` specifies the filename pattern `*.html` and identifies the `WebLogicCluster` hosts and their ports. The `paramName=value` combination following the pipe symbol specifies the error page for the cluster.

```
# These parameters are common for all URLs which are
# directed to the current module. If you want to override
# these parameters for each URL, you can set them again in
# the <Location> or <Files> blocks (Except WebLogicHost,
# WebLogicPort, WebLogicCluster, and CookieName.)

<IfModule mod_weblogic.c>
    MatchExpression *.jsp WebLogicHost=myHost|WebLogicPort=7001|Debug=ON
    MatchExpression
*.html WebLogicCluster=myHost1:7282,myHost2:7283|ErrorPage=
    http://www.xyz.com/error.html
</IfModule>
```

Example Without WebLogic Clusters

```
# These parameters are common for all URLs which are
# directed to the current module. If you want to override
```

```
# these parameters for each URL, you can set them again in
# the <Location> or <Files> blocks (Except WebLogicHost,
# WebLogicPort, WebLogicCluster, and CookieName.)

<IfModule mod_weblogic.c>
    WebLogicHost myweblogic.server.com
    WebLogicPort 7001
    MatchExpression *.jsp
</IfModule>
```

Example Configuring Multiple Name-Based Virtual Hosts

```
# VirtualHost1 = localhost:80
<VirtualHost 127.0.0.1:80>
    DocumentRoot "C:/test/VirtualHost1"
    ServerName localhost:80<IfModule mod_weblogic.c>
        #... WLS parameter ...
        WebLogicCluster localhost:7101,localhost:7201
        # Example: MatchExpression *.jsp <some additional parameter>
        MatchExpression *.jsp PathPrepend=/test2
    </IfModule>
</VirtualHost>

# VirtualHost2 = 127.0.0.2:80
<VirtualHost 127.0.0.2:80>
    DocumentRoot "C:/test/VirtualHost1"
    ServerName 127.0.0.2:80
    <IfModule mod_weblogic.c>
        #... WLS parameter ...
        WebLogicCluster localhost:7101,localhost:7201
        # Example: MatchExpression *.jsp <some additional parameter>
        MatchExpression *.jsp PathPrepend=/test2
        #... WLS parameter ...
    </IfModule>
</VirtualHost><IfModule mod_weblogic.c>
```

You must define a unique value for 'ServerName' or some Plug-In parameters will not work as expected.

Template for the Apache HTTP Server `httpd.conf` File

This section contains a sample `httpd.conf` file for Apache 2.0. You can use this sample as a template and modify it to suit your environment and server. Lines beginning with `#` are comments.

Note that Apache HTTP Server is not case sensitive.

```
#####
APACHE-HOME/conf/httpd.conf file
#####

LoadModule weblogic_module    libexec/mod_wl_20.so

<Location /weblogic>
    SetHandler weblogic-handler
    PathTrim /weblogic
    ErrorPage http://myerrorpagel.mydomain.com
</Location>

<Location /servletimages>
    SetHandler weblogic-handler
    PathTrim /something
    ErrorPage http://myerrorpagel.mydomain.com
</Location>

<IfModule mod_weblogic.c>
    MatchExpression *.jsp
    WebLogicCluster wls1.com:7001,wls2.com:7001,wls3.com:7001
    ErrorPage http://myerrorpage.mydomain.com
</IfModule>
```

Setting Up Perimeter Authentication

Use perimeter authentication to secure WebLogic Server applications that are accessed via the Apache Plug-In.

A WebLogic Identity Assertion Provider authenticates tokens from outside systems that access your WebLogic Server application, including users who access your WebLogic Server application through the Apache HTTP Server Plug-In. Create an Identity Assertion Provider that will safely secure your Plug-In as follows:

1. Create a custom Identity Assertion Provider on your WebLogic Server application. See [How to Develop a Custom Identity Assertion Provider](#) in *Developing Security Providers for WebLogic Server*.
2. Configure the custom Identity Assertion Provider to support the Cert token type and make Cert the active token type. See [How to Create New Token Types](#) in *Developing Security Providers for WebLogic Server*.
3. Set `clientCertProxy` to True in the `web.xml` deployment descriptor file for the Web application (or, if using a cluster, optionally set the `Client Cert Proxy Enabled` attribute to true for the whole cluster on the Administration Console Cluster-->Configuration-->General tab). The `clientCertProxy` attribute can be used with a third party proxy server, such as a load balancer or an SSL accelerator, to enable 2-way SSL authentication. For more information about the `clientCertProxy` attribute, see [context-param](#) in *Developing Web Applications, Servlets and JSPs for WebLogic Server*.
4. Once you have set `clientCertProxy`, be sure to use a connection filter to ensure that WebLogic Server accepts connections only from the machine on which the Apache Plug-In is running. See [Using Network Connection Filters](#) in *Programming WebLogic Security*.
5. Web server plug-ins require a trusted Certificate Authority file in order to use SSL between the plug-in and WebLogic Server. Use Sun Microsystems' keytool utility to export a trusted Certificate Authority file from the `DemoTrust.jks` keystore file that resides in `BEA_HOME/wlserver_10.3/server/lib`.
 - a. To extract the `wlsdemoca` file, for example, use the command:

```
keytool -export -file trustedcafile.der -keystore DemoTrust.jks -alias wlsdemoca
```

Change the alias name to obtain a different trusted CA file from the keystore.

To look at all of the keystore's trusted CA files, use:

```
keytool -list -keystore DemoTrust.jks
```

Press enter if prompted for password.
 - b. To convert the Certificate Authority file to pem format: `java utils.der2pem trustedcafile.der`

See [Identity Assertion Providers](#) in *Developing Security Providers for WebLogic Server*.

Using SSL with the Apache Plug-In

You can use the Secure Sockets Layer (SSL) protocol to protect the connection between the Apache HTTP Server Plug-In and WebLogic Server. The SSL protocol provides confidentiality and integrity to the data passed between the Apache HTTP Server Plug-In and WebLogic Server.

The Apache HTTP Server Plug-In does *not* use the transport protocol (`http` or `https`) specified in the HTTP request (usually by the browser) to determine whether or not the SSL protocol is used to protect the connection between the Apache HTTP Server Plug-In and WebLogic Server.

Although two-way SSL can be used between the HTTP client and Apache HTTP server, note that one-way SSL is used between Apache HTTP Server and WebLogic Server.

Configuring SSL Between the Apache HTTP Server Plug-In and WebLogic Server

To use the SSL protocol between Apache HTTP Server Plug-In and WebLogic Server:

1. Configure WebLogic Server for SSL. For more information, see [Configuring SSL](#).
2. Configure the WebLogic Server SSL listen port. For more information, see [Configuring SSL](#).
3. In the Apache Server, set the `WebLogicPort` parameter in the `httpd.conf` file to the WebLogic Server SSL listen port configured in Step 2.
4. In the Apache Server, set the `SecureProxy` parameter in the `httpd.conf` file to `ON`.
5. Set any additional parameters in the `httpd.conf` file that define information about the SSL connection. For a complete list of the SSL parameters that you can configure for the plug-in, see [“SSL Parameters for Web Server Plug-Ins” on page 6-14](#).

Issues with SSL-Apache Configuration

These known issues arise when you configure the Apache plug-in to use SSL:

- To prepare the plugin configuration, double click the lock and go to the certificates path:
 - Select the root CA (at the top).
 - Display it.
 - Detail and then copy this certificate to a file using the Coded "Base 64 X509" option.
 - Save the file, for example, to `"MyWeblogicCAToTrust.cer"` (which is also a PEM file).

- The PathTrim parameter (see [“General Parameters for Web Server Plug-Ins” on page 6-2](#)) must be configured inside the <Location> tag.

The following configuration is **incorrect**:

```
<Location /weblogic>
    SetHandler weblogic-handler
</Location>

<IfModule mod_weblogic.c>
    WebLogicHost localhost
    WebLogicPort 7001
    PathTrim /weblogic
</IfModule>
```

The following configuration is the **correct** setup:

```
<Location /weblogic>
    SetHandler weblogic-handler
    PathTrim /weblogic
</Location>
```

- The Include directive does not work with Apache SSL. You must configure all parameters directly in the httpd.conf file. Do not use the following configuration when using SSL:

```
<IfModule mod_weblogic.c>
    MatchExpression *.jsp
    Include weblogic.conf
</IfModule>
```

- The current implementation of the WebLogic Server Apache Plug-In does not support the use of multiple certificate files with Apache SSL.

Connection Errors and Clustering Failover

When the Apache HTTP Server Plug-In attempts to connect to WebLogic Server, the plug-in uses several configuration parameters to determine how long to wait for connections to the WebLogic Server host and, after a connection is established, how long the plug-in waits for a response. If the plug-in cannot connect or does not receive a response, the plug-in attempts to connect and send the request to other WebLogic Server instances in the cluster. If the connection fails or there is no response from any WebLogic Server in the cluster, an error message is sent.

[Figure 3-1 “Connection Failover” on page 3-21](#) demonstrates how the plug-in handles failover.

Possible Causes of Connection Failures

Failure of the WebLogic Server host to respond to a connection request could indicate the following problems:

- Physical problems with the host machine
- Network problems
- Other server failures

Failure of all WebLogic Server instances to respond could indicate the following problems:

- WebLogic Server is not running or is unavailable
- A hung server
- A database problem
- An application-specific failure

Tuning to Reduce Connection_Refused Errors

Under load, an Apache plug-in may receive CONNECTION_REFUSED errors from a back-end WebLogic Server instance. Follow these tuning tips to reduce CONNECTION_REFUSED errors:

- Increase the `AcceptBackLog` setting in the configuration of your WebLogic Server domain.
- On Apache 2.0.x, set the `KeepAlive` directive in the `httpd.conf` file to `On`. For example:

```
# KeepAlive: Whether or not to allow persistent connections (more than
# one request per connection). Set to "Off" to deactivate.
#
KeepAlive On
```

See Apache HTTP Server 2.0 documentation at <http://httpd.apache.org/docs-project/>.

- Decrease the time wait interval. This setting varies according to the operating system you are using. For example:
 - On Windows NT, set the `TcpTimedWaitDelay` on the proxy and WebLogic Server servers to a lower value. Set the `TIME_WAIT` interval in Windows NT by editing the registry key under `HKEY_LOCAL_MACHINE`:

```
SYSTEM\CurrentControlSet\Services\Tcpip\Parameters\TcpTimedWaitDelay
```

If this key does not exist you can create it as a **DWORD** value. The numeric value is the number of seconds to wait and may be set to any value between 30 and 240. If not set, Windows NT defaults to 240 seconds for `TIME_WAIT`.

- On Windows 2000, lower the value of the `TcpTimedWaitDelay` by editing the registry key under `HKEY_LOCAL_MACHINE`:

```
SYSTEM\CurrentControlSet\Services\Tcpip\Parameters
```

- On Solaris, reduce the setting `tcp_time_wait_interval` to one second (for both the WebLogic Server machine and the Apache machine, if possible):

```
$nodd /dev/tcp
```

```
param name to set - tcp_time_wait_interval
value=1000
```

- Increase the open file descriptor limit on your machine. This limit varies by operating system. Using the `limit (.csh)` or `ulimit (.sh)` directives, you can make a script to increase the limit. For example:

```
#!/bin/sh
ulimit -S -n 100
exec httpd
```

- On Solaris, increase the values of the following tunables on the WebLogic Server machine:
 - `tcp_conn_req_max_q`
 - `tcp_conn_req_max_q0`

Failover with a Single, Non-Clustered WebLogic Server

If you are running only a single WebLogic Server instance the plug-in only attempts to connect to the server defined with the `WebLogicHost` parameter. If the attempt fails, an `HTTP 503` error message is returned. The plug-in continues trying to connect to that same WebLogic Server instance until `ConnectTimeoutSecs` is exceeded.

The Dynamic Server List

When you use the `WebLogicCluster` parameter in your `httpd.conf` or `weblogic.conf` file to specify a list of WebLogic Servers, the plug-in uses that list as a starting point for load balancing among the members of the cluster. After the first request is routed to one of these servers, a

dynamic server list is returned containing an updated list of servers in the cluster. The updated list adds any new servers in the cluster and deletes any that are no longer part of the cluster or that have failed to respond to requests. This list is updated automatically with the HTTP response when a change in the cluster occurs.

Failover, Cookies, and HTTP Sessions

When a request contains session information stored in a cookie or in the POST data, or encoded in a URL, the session ID contains a reference to the specific server instance in which the session was originally established (called the *primary* server) and a reference to an additional server where the original session is replicated (called the *secondary* server). A request containing a cookie attempts to connect to the primary server. If that attempt fails, the request is routed to the secondary server. If both the primary and secondary servers fail, the session is lost and the plug-in attempts to make a fresh connection to another server in the dynamic cluster list. See [Figure 3-1 “Connection Failover” on page 3-21](#).

Note: If the POST data is larger than 64K, the plug-in will not parse the POST data to obtain the session ID. Therefore, if you store the session ID in the POST data, the plug-in cannot route the request to the correct primary or secondary server, resulting in possible loss of session data.

Figure 3-1 Connection Failover

In the preceding figure, the Maximum number of retries allowed in the red loop is equal to $\text{ConnectTimeoutSecs} \div \text{ConnectRetrySecs}$.

Installing and Configuring the Apache HTTP Server Plug-In

Installing and Configuring the Microsoft IIS Plug-In

The following sections describe how to install and configure the Microsoft Internet Information Server Plug-In.

- [“Overview of the Microsoft Internet Information Server Plug-In” on page 4-1](#)
- [“Certifications” on page 4-3](#)
- [“Installing and Configuring the Microsoft Internet Information Server Plug-In” on page 4-3](#)
- [“Proxying Requests from Multiple Virtual Websites to WebLogic Server” on page 4-9](#)
- [“Creating ACLs Through IIS” on page 4-11](#)
- [“Setting Up Perimeter Authentication” on page 4-11](#)
- [“Using SSL with the Microsoft Internet Information Server Plug-In” on page 4-13](#)
- [“Proxying Servlets from IIS to WebLogic Server” on page 4-13](#)
- [“Testing the Installation” on page 4-14](#)
- [“Connection Errors and Clustering Failover” on page 4-15](#)

Overview of the Microsoft Internet Information Server Plug-In

The Microsoft Internet Information Server Plug-In allows requests to be proxied from a Microsoft Internet Information Server (IIS) to WebLogic Server. The plug-in enhances an IIS

installation by allowing WebLogic Server to handle those requests that require the dynamic functionality of WebLogic Server.

You use the Microsoft Internet Information Server Plug-In in an environment where the Internet Information Server (IIS) serves static pages such as HTML pages, while dynamic pages such as HTTP Servlets or JavaServer Pages are served by WebLogic Server. WebLogic Server may be operating in a different process, possibly on a different host. To the end user—the browser—the HTTP requests delegated to WebLogic Server still appear to be coming from IIS. The HTTP-tunneling facility of the WebLogic client-server protocol also operates through the plug-in, providing access to all WebLogic Server services.

Connection Pooling and Keep-Alive

The Microsoft Internet Information Server Plug-In improves performance using a pool of connections from the plug-in to WebLogic Server. The plug-in implements HTTP 1.1 keep-alive connections between the plug-in and WebLogic Server by re-using the same connection for subsequent requests from the same client. If the connection is inactive for more than 30 seconds, (or a user-defined amount of time) the connection is closed. The connection with the client can be reused to connect to the same client at a later time if it has not timed out. You can disable this feature if desired. For more information, see [“KeepAliveEnabled” on page 6-12](#).

Proxying Requests

The plug-in proxies requests to WebLogic Server based on a configuration that you specify. You can proxy requests based on either the URL of the request or a portion of the URL. This is called proxying by *path*.

You can also proxy a request based on the *MIME type* of the requested file, which called proxying by file extension.

You can also enable both methods. If you do enable both methods and a request matches both criteria, the request is proxied by path.

You can also specify additional parameters for each of these types of requests that define additional behavior of the plug-in. For more information, see [“Installing and Configuring the Microsoft Internet Information Server Plug-In” on page 4-3](#).

Certifications

For the latest information on operating system and IIS version compatibility with the Microsoft Internet Information Server Plug-In, see the [platform support page in Supported Configurations for WebLogic Platform 10.3](#).

Installing and Configuring the Microsoft Internet Information Server Plug-In

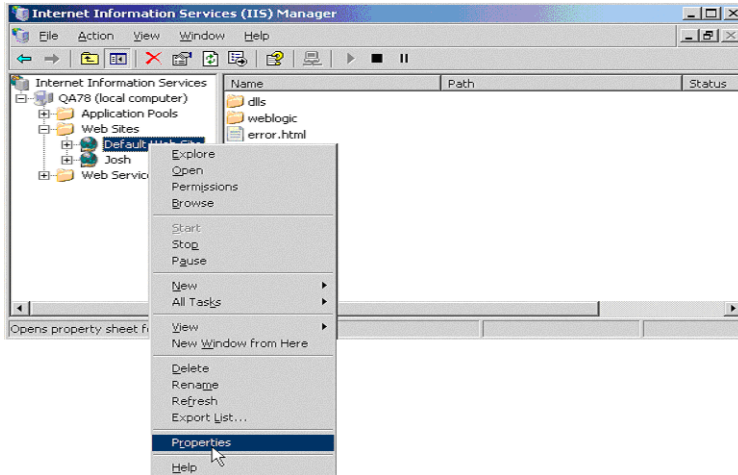

To install the Microsoft Internet Information Server Plug-In:

1. Copy the `iisproxy.dll` file from the `WL_HOME/server/plugin/win/32` or `WL_HOME/server/plugin/win/64` directory of your WebLogic Server installation (where `WL_HOME` is the top-level directory for the WebLogic Platform and Server and contains the WebLogic Server installation files into a convenient directory that is accessible to IIS). This directory must also contain the `iisproxy.ini` file that you will create in step 4. Set the user permissions for the `iisproxy.dll` file to include the name of the user who will be running IIS. One way to do this is by right clicking on the `iisproxy.dll` file and selecting Permissions, then adding the username of the person who will be running IIS.
2. If you want to configure proxying by file extension (MIME type) complete this step. (You can configure proxying by path in addition to or instead of configuring by MIME type. See [step 3](#))
 - a. Start the Internet Information Service Manager by selecting it from the Start menu.
 - b. In the left panel of the Service Manager, select your website (the default is “Default Web Site”).

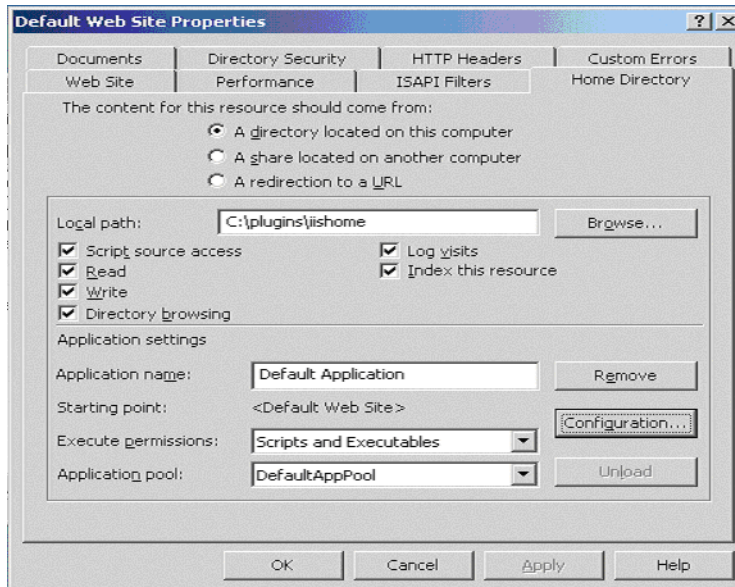

Installing and Configuring the Microsoft IIS Plug-In

- c. Click the “Play” arrow in the toolbar to start.
- d. Open the properties for the selected website by right-clicking the website selection in the left panel and selecting Properties.

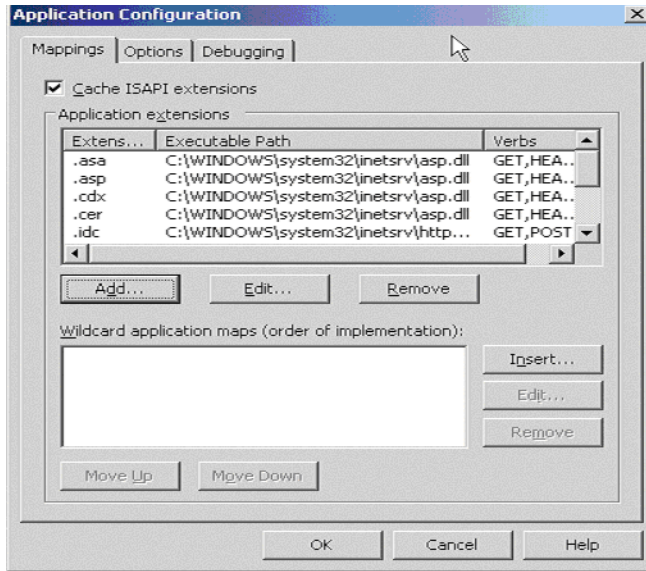

- e. In the Properties panel, select the Home Directory tab, and click the Configuration button in the Applications Settings section.

- f. On the Mappings tab, click the Add button to add file types and configure them to be proxied to WebLogic Server.

Installing and Configuring the Microsoft IIS Plug-In

- g. In the Add dialog box, browse to find the “iisproxy.dll” file.
- h. Set the Extension to the type of file that you want to proxy to WebLogic Server.
- i. If you are configuring for IIS 6.0 or later, be sure to deselect the “Check that file exists” check box. The behavior of this check has changed from earlier versions of IIS: it used to check that the iisproxy.dll file exists; now it checks that files requested from the proxy exist in the root directory of the Web server. If the check does not find the files there, the iisproxy.dll file will not be allowed to proxy requests to the WebLogic Server.
- j. In the Directory Security tab, set the Method exclusions as needed to create a secure installation.
- k. When you finish, click the OK button to save the configuration. Repeat this process for each file type you want to proxy to WebLogic.
- l. When you finish configuring file types, click the OK button to close the Properties panel.

Note: In the URL, any path information you add after the server and port is passed directly to WebLogic Server. For example, if you request a file from IIS with the URL:

http://myiis.com/jspfiles/myfile.jsp

it is proxied to WebLogic Server with a URL such as

`http://mywebLogic:7001/jspfiles/myfile.jsp`

Note: To avoid out-of-process errors, do not deselect the "Cache ISAPI Applications" check box.

3. If you want to configure proxying by path complete this step. (In addition to proxying by file type, you can configure the Microsoft Internet Information Server Plug-In to serve files based on their *path* by specifying some additional parameters in the `iisproxy.ini` file.) Proxying by path takes precedence over proxying by MIME type.

You can also proxy multiple websites defined in IIS by path. For more information, see [“Proxying Requests from Multiple Virtual Websites to WebLogic Server” on page 4-9.](#)

To configure proxying by path:

- a. Start the Internet Information Service Manager by selecting it from the Start menu.
- b. Place the `iisforward.dll` file in the same directory as the `iisproxy.dll` file and add the `iisforward.dll` file as a filter service in IIS (WebSite *Properties* → ISAPI Filters tab → Add the `iisforward.dll`). Set the user permissions for the `iisforward.dll` file to include the name of the user who will be running IIS. One way to do this is by right clicking on the `iisproxy.dll` file and selecting Permissions, then adding the username of the person who will be running IIS.
- c. Register `.wlforward` as a special file type to be handled by `iisproxy.dll` in IIS.
- d. Define the property `WlForwardPath` in `iisproxy.ini`. `WlForwardPath` defines the path that is proxied to WebLogic Server, for example: `WlForwardPath=/weblogic`.
- e. Set the `PathTrim` parameter to trim off the `WlForwardPath` when necessary. For example, using

```
WlForwardPath=/weblogic
PathTrim=/weblogic
```

trims a request from IIS to WebLogic Server. Therefore, `/weblogic/session` is changed to `/session`.

- f. If you want requests that do not contain extra path information (in other words, requests containing only a host name), set the `DefaultFileName` parameter to the name of the welcome page of the Web Application to which the request is being proxied. The value of this parameter is appended to the URL.
- g. If you need to debug your application, set the `Debug=ON` parameter in `iisproxy.ini`. A `c:\tmp\iisforward.log` is generated containing a log of the plug-in's activity that you can use for debugging purposes.

4. In WebLogic Server, create the `iisproxy.ini` file.

The `iisproxy.ini` file contains name=value pairs that define configuration parameters for the plug-in. The parameters are listed in [“General Parameters for Web Server Plug-Ins” on page 6-2](#).

Use the example `iisproxy.ini` file in this section ([“Sample iisproxy.ini File” on page 4-10](#)) as a template for your `iisproxy.ini` file.

Note: Changes in the parameters will not go into effect until you restart the “IIS Admin Service” (under *services*, in the control panel).

Oracle recommends that you locate the `iisproxy.ini` file in the same directory that contains the `iisproxy.dll` file. You can also use other locations. If you place the file elsewhere, note that WebLogic Server searches for `iisproxy.ini` in the following directories, in the following order:

- a. in the same directory where `iisproxy.dll` is located
 - b. in the home directory of the most recent version of WebLogic Server that is referenced in the Windows Registry. (If WebLogic Server does not find the `iisproxy.ini` file in the home directory, it continues looking in the Windows Registry for older versions of WebLogic Server and looks for the `iisproxy.ini` file in the home directories of those installations.)
 - c. in the directory `c:\weblogic`, if it exists
5. Define the WebLogic Server host and port number to which the Microsoft Internet Information Server Plug-In proxies requests. Depending on your configuration, there are two ways to define the host and port:

- If you are proxying requests to a single WebLogic Server, define the [WebLogicHost](#) and [WebLogicPort](#) parameters in the `iisproxy.ini` file. For example:

```
WebLogicHost=localhost
WebLogicPort=7001
```

- If you are proxying requests to a cluster of WebLogic Servers, define the [WebLogicCluster](#) parameter in the `iisproxy.ini` file. For example:

```
WebLogicCluster=myweblogic.com:7001,yourweblogic.com:7001
```

Where *myweblogic.com* and *yourweblogic.com* are instances of Weblogic Server running in a cluster.

6. Optionally, enable HTTP tunneling by following the instructions for proxying by path (see step 8 above), substituting the WebLogic Server host name and the WebLogic Server port number, or the name of a WebLogic Cluster that you wish to handle HTTP tunneling requests.

- a. If you are using `weblogic.jar` and the T3 protocol, set `WlForwardPath` to this URL pattern:

```
WlForwardPath=*/HTTPCInt*
```

- b. If you are using IIOP, which is the only protocol used by the WebLogic Server thin client, `wlclient.jar`, set the value of `WlForwardPath` to `*/iiop*`:

```
WlForwardPath=*/iiop*
```

You do not need to use the `PathTrim` parameter.

7. Set any additional parameters in the `iisproxy.ini` file. A complete list of parameters is available in the appendix [“General Parameters for Web Server Plug-Ins”](#) on page 6-2.
8. If you are proxying servlets from IIS to WebLogic Server and you are not proxying by path, read the section [“Proxying Servlets from IIS to WebLogic Server”](#) on page 4-13.
9. The installed version of IIS with its initial settings does not allow the `iisproxy.dll`. Use the IIS Manager console to enable the Plug-In:
 - a. Open the IIS Manager console.
 - b. Select Web Service Extensions.
 - c. Set “All Unknown ISAPI Extensions” to Allowed.

Proxying Requests from Multiple Virtual Websites to WebLogic Server

To proxy requests from multiple websites (defined as virtual directories in IIS) to WebLogic Server:

1. Create a new directory for the virtual directories. This directory will contain `dll` and `ini` files used to define the proxy.
2. Copy `iisforward.dll` to the directory you created in step 1.
3. Register the `iisforward.dll` for each website with IIS.

4. Create a file called `iisforward.ini`. Place this file in the same directory that contains `iisforward.dll`. This file should contain the following entry for each virtual website defined in IIS:

```
vhostN=websiteName:port
websiteName:port=dll_directory/iisproxy.ini
```

Where:

- *N* is an integer representing the virtual website. The first virtual website you define should use the integer 1 and each subsequent website should increment this number by 1.
- *websiteName* is the name of the virtual website as registered with IIS.
- *port* is the port number where IIS listens for HTTP requests.
- *dll_directory* is the path to the directory you created in step 1.

For example:

```
vhost1=strawberry.com:7001
strawberry.com:7001=c:\strawberry\iisproxy.ini
vhost2=blueberry.com:7001
blueberry.com:7001=c:\blueberry\iisproxy.ini
...
```

5. Create an `iisproxy.ini` file for the virtual websites, as described in [step 4](#) in “Proxying Requests”. Copy this `iisproxy.ini` file to the directory you created in step 1.
6. Copy `iisproxy.dll` to the directory you created in step 1.
7. In IIS, set the value for the Application Protection option to high (isolated). If the Application Protection option is set to Medium(pooled), the `iisproxy.dll` that registered as the first website will always be invoked. In this event, all the requests will be proxied to the same WebLogic Server instances defined in the `iisproxy.ini` of the first website.

Sample iisproxy.ini File

Here is a sample `iisproxy.ini` file for use with a single, non-clustered WebLogic Server. Comment lines are denoted with the “#” character.

```
# This file contains initialization name/value pairs
# for the IIS/WebLogic plug-in.

WebLogicHost=localhost
WebLogicPort=7001
```

```
ConnectTimeoutSecs=20
```

```
ConnectRetrySecs=2
```

Here is a sample `iisproxy.ini` file with clustered WebLogic Servers. Comment lines are denoted with the “#” character.

```
# This file contains initialization name/value pairs
# for the IIS/WebLogic plug-in.
```

```
WebLogicCluster=myweblogic.com:7001,yourweblogic.com:7001
```

```
ConnectTimeoutSecs=20
```

```
ConnectRetrySecs=2
```

Note: If you are using SSL between the plug-in and WebLogic Server, the port number should be defined as the SSL listen port.

Creating ACLs Through IIS

ACLs will not work through the Microsoft Internet Information Server Plug-In if the Authorization header is not passed by IIS. Use the following information to ensure that the Authorization header is passed by IIS.

When using Basic Authentication, the user is logged on with local log-on rights. To enable the use of Basic Authentication, grant each user account the *Log On Locally* user right on the IIS server. Two problems may result from Basic Authentication's use of local logon:

- If the user does not have local logon rights, Basic Authentication does not work even if the FrontPage, IIS, and Windows NT configurations appear to be correct.
- A user who has local log-on rights and who can obtain physical access to the host computer running IIS will be permitted to start an interactive session at the console.

To enable Basic Authentication, in the Directory Security tab of the console, ensure that the Allow Anonymous option is “on” and all other options are “off”.

Setting Up Perimeter Authentication

Use perimeter authentication to secure your WebLogic Server applications that are accessed via the Microsoft Internet Information Server Plug-In.

A WebLogic Identity Assertion Provider authenticates tokens from outside systems that access your WebLogic Server application, including users who access your WebLogic Server

application through the Microsoft Internet Information Server Plug-In. Create an Identity Assertion Provider that will safely secure your Plug-In as follows:

1. Create a custom Identity Assertion Provider on your WebLogic Server application. See [How to Develop a Custom Identity Assertion Provider](#) in *Developing Security Providers for WebLogic Server*.
2. Configure the custom Identity Assertion Provider to support the "Cert" token type and make it the active token type. See [How to Create New Token Types](#) in *Developing Security Providers for WebLogic Server*.
3. Set the `clientCertProxy` attribute to `True` in the `web.xml` deployment descriptor file for the Web application (or, if using a cluster, optionally set the `Client Cert Proxy Enabled` attribute to `true` for the whole cluster on the Administration Console Cluster-->Configuration-->General tab). See [context-param](#) in *Developing Web Applications for WebLogic Server*.
4. Once you have set `clientCertProxy`, be sure to use a connection filter to ensure that WebLogic Server accepts connections only from the machine on which the Microsoft Internet Information Server Plug-In is running. See [Using Network Connection Filters](#) in *Programming WebLogic Security*.
5. Web server plug-ins require a trusted Certificate Authority file in order to use SSL between the plug-in and WebLogic Server. Use Sun Microsystems' `keytool` utility to export a trusted Certificate Authority file from the `DemoTrust.jks` keystore file that resides in `BEA_HOME/wlserver_10.3/server/lib`.
 - a. To extract the `wlsdemoca` file, for example, use the command:

```
keytool -export -file trustedcafile.der -keystore DemoTrust.jks -alias wlsdemoca
```

Change the alias name to obtain a different trusted CA file from the keystore.
To look at all of the keystore's trusted CA files, use:

```
keytool -list -keystore DemoTrust.jks
```

Press enter if prompted for password.
 - b. To convert the Certificate Authority file to pem format: `java utils.der2pem trustedcafile.der`

See [Identity Assertion Providers](#) in *Developing Security Providers for WebLogic Server* for more information about Identity Assertion Providers.

Using SSL with the Microsoft Internet Information Server Plug-In

You can use the Secure Sockets Layer (SSL) protocol to protect the connection between WebLogic Server and the Microsoft Internet Information Server Plug-In. The SSL protocol provides confidentiality and integrity to the data passed between the Microsoft Internet Information Server Plug-In and WebLogic Server.

The Microsoft Internet Information Server Plug-In does not use the transport protocol (`http` or `https`) to determine whether the SSL protocol will be used to protect the connection between the proxy plug-in and the Microsoft Internet Information Server. In order to use the SSL protocol with the Microsoft Internet Information Server Plug-In, configure the WebLogic Server instance receiving the proxied requests to use the SSL protocol. The port on the WebLogic Server that is configured for secure SSL communication is used by the Microsoft Internet Information Server Plug-In to communicate with the Microsoft Internet Information Server.

To use the SSL protocol between Microsoft Internet Information Server Plug-In and WebLogic Server:

1. Configure WebLogic Server for SSL. For more information, see [Configuring SSL](#).
2. Configure the WebLogic Server SSL listen port. For more information, see [Configuring SSL](#).
3. Set the `WebLogicPort` parameter in the `iisproxy.ini` file to the listen port configured in step 2
4. Set the `SecureProxy` parameter in the `iisproxy.ini` file to ON.
5. Set additional parameters in the `iisproxy.ini` file that define the SSL connection. For a complete list of parameters, see [“SSL Parameters for Web Server Plug-Ins”](#) on page 6-14.

For example:

```
WebLogicHost=myweblogic.com
WebLogicPort=7002
SecureProxy=ON
```

Proxying Servlets from IIS to WebLogic Server

You can proxy servlets by path if the `iisforward.dll` is registered as a filter. You would then invoke your servlet with a URL similar to the following:

```
http://IISserver/weblogic/myServlet
```

To proxy servlets if `iisforward.dll` is not registered as a filter, you must configure servlet proxying by file type. To proxy servlets by file type:

1. Register an arbitrary file type (extension) with IIS to proxy the request to the WebLogic Server, as described in [step 2](#) under “Installing and Configuring the Microsoft Internet Information Server Plug-In” on page 4-3.
2. Register your servlet in the appropriate Web Application. For more information on registering servlets, see [Creating and Configuring Servlets](#).
3. Invoke your servlet with a URL formed according to this pattern:

```
http://www.myserver.com/virtualName/anyfile.ext
```

where *virtualName* is the URL pattern defined in the `<servlet-mapping>` element of the Web Application deployment descriptor (`web.xml`) for this servlet and *ext* is a file type (extension) registered with IIS for proxying to WebLogic Server. The *anyfile* part of the URL is ignored in this context.

Note:

- If the image links called from the servlet are part of the Web Application, you must also proxy the requests for the images to WebLogic Server by registering the appropriate file types (probably `.gif` and `.jpg`) with IIS. You can, however, choose to serve these images directly from IIS if desired.
- If the servlet being proxied has links that call other servlets, then these links must also be proxied to WebLogic Server, conforming to the pattern described in step 3.

Testing the Installation

After you install and configure the Microsoft Internet Information Server Plug-In, follow these steps for deployment and testing:

1. Make sure WebLogic Server and IIS are running.
2. Save a JSP file into the document root of the default Web Application.
3. Open a browser and set the URL to the IIS + `filename.jsp` as shown in this example:

```
http://myii.server.com/filename.jsp
```

If `filename.jsp` is displayed in your browser, the plug-in is functioning.

Connection Errors and Clustering Failover

When the Microsoft Internet Information Server Plug-In attempts to connect to WebLogic Server, the plug-in uses several configuration parameters to determine how long to wait for connections to the WebLogic Server host, and, after a connection is established, how long the plug-in waits for a response. If the plug-in cannot connect or does not receive a response, the plug-in attempts to connect and sends the request to other WebLogic Servers in the cluster. If the connection fails or there is no response from any WebLogic Server instance in the cluster, an error message is sent.

[Figure 4-1 “Connection Failover” on page 4-17](#) demonstrates how the plug-in handles failover.

Possible Causes of Connection Failures

Failure of the WebLogic Server host to respond to a connection request could indicate problems with the host machine, networking problems, or other server failures.

Failure of any WebLogic Server instance in the cluster to respond, could indicate that WebLogic Server is not running or is unavailable, a hung server, a database problem, or other application failure.

Failover with a Single, Non-Clustered WebLogic Server

If you are running only a single WebLogic Server, the plug-in only attempts to connect to the server defined with the [WebLogicHost](#) parameter. If the attempt fails, an HTTP 503 error message is returned. The plug-in continues trying to connect to WebLogic Server until [ConnectTimeoutSecs](#) is exceeded.

The Dynamic Server List

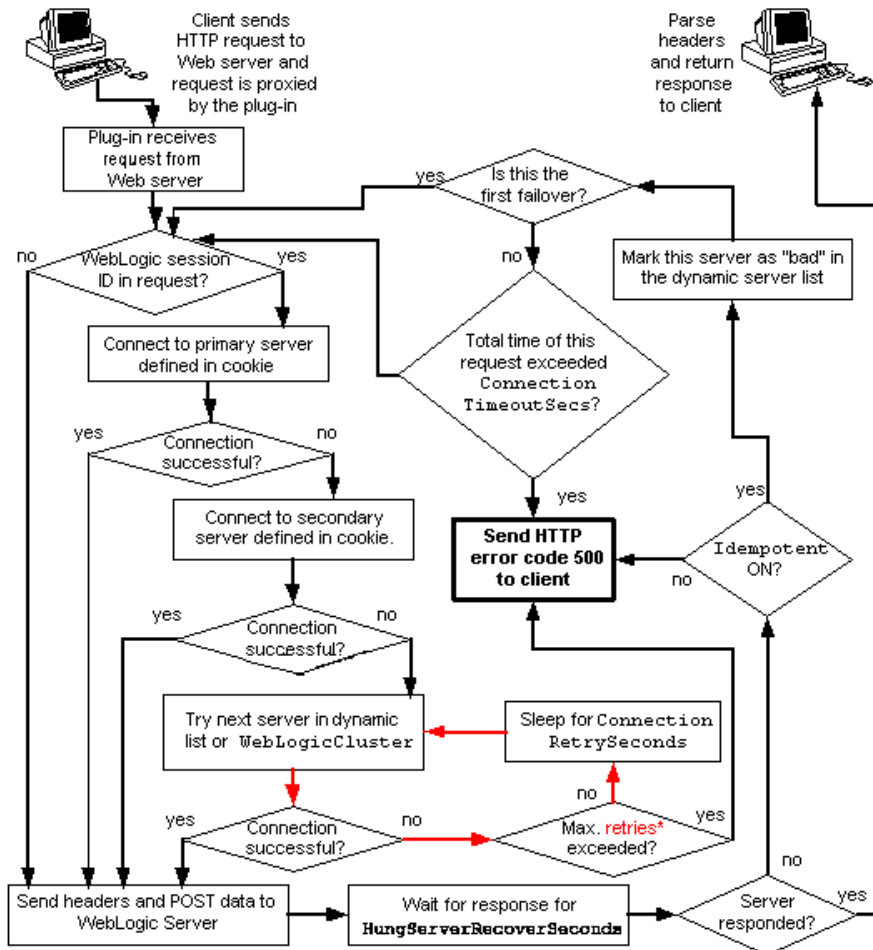

When you specify a list of WebLogic Servers in the `webLogicCluster` parameter, the plug-in uses that list as a starting point for load balancing among the members of the cluster. After the first request is routed to one of these servers, a dynamic server list is returned containing an updated list of servers in the cluster. The updated list adds any new servers in the cluster and deletes any that are no longer part of the cluster or that have failed to respond to requests. This list is updated automatically with the HTTP response when a change in the cluster occurs.

Failover, Cookies, and HTTP Sessions

When a request contains a session information stored in a cookie, in the POST data, or by URL encoding, the session ID contains a reference to the specific server in which the session was originally established (called the *primary* server) and a reference to an additional server where the original session is replicated (called the *secondary* server). A request containing a cookie attempts to connect to the primary server. If that attempt fails, the request is routed to the secondary server. If both the primary and secondary servers fail, the session is lost and the plug-in attempts to make a fresh connection to another server in the dynamic cluster list. For more information see [Figure 4-1 “Connection Failover” on page 4-17](#).

Note: If the POST data is larger than 64K, the plug-in will not parse the POST data to obtain the session ID. Therefore, if you store the session ID in the POST data, the plug-in cannot route the request to the correct primary or secondary server, resulting in possible loss of session data.

Figure 4-1 Connection Failover

In the preceding graphic, the Maximum number of retries allowed in the red loop is equal to $\text{ConnectTimeoutSecs} \div \text{ConnectRetrySecs}$.

Installing and Configuring the Microsoft IIS Plug-In

Proxying Requests to Another Web Server

The following sections discuss how to proxy HTTP requests to another Web server:

- [“Overview of Proxying Requests to Another Web Server” on page 5-1](#)
- [“Setting Up a Proxy to a Secondary Web Server” on page 5-1](#)
- [“Sample Deployment Descriptor for the Proxy Servlet” on page 5-3](#)

Overview of Proxying Requests to Another Web Server

When you use WebLogic Server as your primary Web server, you may also want to configure WebLogic Server to pass on, or proxy, certain requests to a secondary Web server, such as Apache or Microsoft Internet Information Server. Any request that gets proxied is redirected to a specific URL. You can even proxy to another Web server on a different machine. You proxy requests based on the URL of the incoming request.

The `HttpProxyServlet` (provided as part of the distribution) takes an HTTP request, redirects it to the proxy URL, and sends the response to the client's browser back through WebLogic Server. To use the `HttpProxyServlet`, you must configure it in a Web Application and deploy that Web Application on the WebLogic Server that is redirecting requests.

Setting Up a Proxy to a Secondary Web Server

To set up a proxy to a secondary HTTP server:

1. Register the proxy servlet in your Web Application deployment descriptor (see “[Sample web.xml for Use with ProxyServlet](#)” on page 5-3). The Web Application must be the default Web Application of the server instance that is responding to requests. The class name for the proxy servlet is `weblogic.servlet.proxy.HttpProxyServlet`. For more information, see [Developing Web Applications, Servlets, and JSPs for WebLogic Server](#).
2. Define an initialization parameter for the `ProxyServlet` with a `<param-name>` of `redirectURL` and a `<param-value>` containing the URL of the server to which proxied requests should be directed.
3. Optionally, define the following `<KeyStore>` initialization parameters to use two-way SSL with your own identity certificate and key. If no `<KeyStore>` is specified in the deployment descriptor, the proxy will assume one-way SSL.

- `<KeyStore>` – The key store location in your Web application.
- `<KeyStoreType>` – The key store type. If it is not defined, the default type will be used instead.
- `<PrivateKeyAlias>` – The private key alias.
- `<KeyStorePasswordProperties>` – A property file in your Web application that defines encrypted passwords to access the key store and private key alias. The file contents looks like this:

```
KeyStorePassword={3DES}i4+50LCKenQ08BBvlsXTrg\=\=  
PrivateKeyPassword={3DES}a4TcG4mtVVBKRtZwH3p7yA\=\=
```

You must use the `weblogic.security.Encrypt` command-line utility to encrypt the password. For more information on the `Encrypt` utility, as well as the `CertGen`, and `der2pem` utilities, see [Using the WebLogic Server Java Utilities](#) in the *WebLogic Server Command Reference*.

4. Map the `ProxyServlet` to a `<url-pattern>`. Specifically, map the file extensions you wish to proxy, for example `*.jsp`, or `*.html`. Use the `<servlet-mapping>` element in the `web.xml` Web Application deployment descriptor.

If you set the `<url-pattern>` to `“/”`, then any request that cannot be resolved by WebLogic Server is proxied to the remote server. However, you must also specifically map the following extensions: `*.jsp`, `*.html`, and `*.html` if you want to proxy files ending with those extensions.

5. Deploy the Web Application on the WebLogic Server instance that redirects incoming requests.

Sample Deployment Descriptor for the Proxy Servlet

The following is an sample of a Web Applications deployment descriptor for using the Proxy Servlet.

Listing 5-1 Sample web.xml for Use with ProxyServlet

```
<!DOCTYPE web-app PUBLIC "-//Sun Microsystems, Inc.
//DTD Web Application 2.3//EN"
"http://java.sun.com/j2ee/dtds/web-app_2_3.dtd">

<web-app>

Parameters for Web Server Plug-Ins

The following sections describe the parameters that you use to configure the Apache and Microsoft IIS Web server plug-ins:

- [“Entering Parameters in Web Server Plug-In Configuration Files” on page 6-1](#)
- [“General Parameters for Web Server Plug-Ins” on page 6-2](#)
- [“SSL Parameters for Web Server Plug-Ins” on page 6-14](#)

Entering Parameters in Web Server Plug-In Configuration Files

You enter the parameters for each Web server plug-in in special configuration files. Each Web server has a different name for this configuration file and different rules for formatting the file. For details, see the following sections on each plug-in:

- [“Installing and Configuring the Apache HTTP Server Plug-In” on page 3-1](#)
- [“Installing and Configuring the Microsoft IIS Plug-In” on page 4-1](#)

General Parameters for Web Server Plug-Ins

Parameters are case sensitive.

Table 6-1 General Parameters for Web Service Plug-Ins

Parameter	Default	Description
WebLogicHost (Required when proxying to a single WebLogic Server.)	none	WebLogic Server host (or virtual host name as defined in WebLogic Server) to which HTTP requests should be forwarded. If you are using a WebLogic cluster, use the WebLogicCluster parameter instead of WebLogicHost.
WebLogicPort (Required when proxying to a single WebLogic Server.)	none	Port at which the WebLogic Server host is listening for connection requests from the plug-in (or from other servers). (If you are using SSL between the plug-in and WebLogic Server, set this parameter to the SSL listen port (see Configuring the SSL Protocol) and set the SecureProxy parameter to ON). If you are using a WebLogic Cluster, use the WebLogicCluster parameter instead of WebLogicPort.

Table 6-1 General Parameters for Web Service Plug-Ins

Parameter	Default	Description
WebLogicCluster (Required when proxying to a cluster of WebLogic Servers.)	none	<p>List of WebLogic Servers that can be used for load balancing. The server or cluster list is a list of host:port entries. If a mixed set of clusters and single servers is specified, the dynamic list returned for this parameter will return only the clustered servers. The method of specifying the parameter, and the required format vary by plug-in. See the examples in:</p> <ul style="list-style-type: none"> • Installing and Configuring the Microsoft Internet Information Server (ISAPI) Plug-In • Installing and Configuring the Apache HTTP Server Plug-In <p>If you are using SSL between the plug-in and WebLogic Server, set the port number to the SSL listen port (see Configuring the SSL Protocol) and set the SecureProxy parameter to ON.</p> <p>The plug-in does a simple round-robin between all available servers. The server list specified in this property is a starting point for the dynamic server list that the server and plug-in maintain. WebLogic Server and the plug-in work together to update the server list automatically with new, failed, and recovered cluster members.</p> <p>You can disable the use of the dynamic cluster list by setting the DynamicServerList parameter to OFF</p> <p>The plug-in directs HTTP requests containing a cookie, URL-encoded session, or a session stored in the POST data to the server in the cluster that originally created the cookie.</p>

Table 6-1 General Parameters for Web Service Plug-Ins

Parameter	Default	Description
PathTrim	null	<p>As per the RFC specification, generic syntax for URL is: <code>[PROTOCOL]://[HOSTNAME]:{PORT}/{PATH}/{FILENAME};{PATH_PARAMS}/{QUERY_STRING}...</code></p> <p>PathTrim specifies the string trimmed by the plug-in from the <code>{PATH}/{FILENAME}</code> portion of the original URL, before the request is forwarded to WebLogic Server. For example, if the URL</p> <pre>http://myWeb.server.com/weblogic/foo</pre> <p>is passed to the plug-in for parsing and if PathTrim has been set to strip off <code>/weblogic</code> before handing the URL to WebLogic Server, the URL forwarded to WebLogic Server is:</p> <pre>http://myWeb.server.com:7001/foo</pre> <p>Note that if you are newly converting an existing third-party server to proxy requests to WebLogic Server using the plug-in, you will need to change application paths to <code>/foo</code> to include <code>weblogic/foo</code>. You can use PathTrim and PathPrepend in combination to change this path.</p>
PathPrepend	null	<p>As per the RFC specification, generic syntax for URL is: <code>[PROTOCOL]://[HOSTNAME]:{PORT}/{PATH}/{FILENAME};{PATH_PARAMS}/{QUERY_STRING}...</code></p> <p>PathPrepend specifies the path that the plug-in prepends to the <code>{PATH}</code> portion of the original URL, after PathTrim is trimmed and before the request is forwarded to WebLogic Server.</p> <p>Note that if you need to append File Name, use DefaultFileName plug-in parameter instead of PathPrepend.</p>
ConnectTimeoutSecs	10	<p>Maximum time in seconds that the plug-in should attempt to connect to the WebLogic Server host. Make the value greater than ConnectRetrySecs. If ConnectTimeoutSecs expires without a successful connection, even after the appropriate retries (see ConnectRetrySecs), an HTTP 503/Service Unavailable response is sent to the client.</p> <p>You can customize the error response by using the ErrorPage parameter.</p>

Table 6-1 General Parameters for Web Service Plug-Ins

Parameter	Default	Description
ConnectRetrySecs	2	<p>Interval in seconds that the plug-in should sleep between attempts to connect to the WebLogic Server host (or all of the servers in a cluster). Make this number less than the ConnectTimeoutSecs. The number of times the plug-in tries to connect before returning an HTTP 503/Service Unavailable response to the client is calculated by dividing ConnectTimeoutSecs by ConnectRetrySecs.</p> <p>To specify no retries, set ConnectRetrySecs equal to ConnectTimeoutSecs. However, the plug-in attempts to connect at least twice.</p> <p>You can customize the error response by using the ErrorPage parameter.</p>

Table 6-1 General Parameters for Web Service Plug-Ins

Parameter	Default	Description
Debug	OFF	Sets the type of logging performed for debugging operations. The debugging information is written to the /tmp/wlproxy.log file on UNIX systems and c:\TEMP\wlproxy.log on Windows NT/2000 systems. Override this location and filename by setting the WLLogFile parameter to a different directory and file. Ensure that the tmp or TEMP directory has write permission assigned to the user who is logged in to the server. Set any of the following logging options (HFC , HTW , HFW, and HTC options may be set in combination by entering them separated by commas, for example “HFC , HTW”):
	ON	The plug-in logs informational and error messages.
	OFF	No debugging information is logged.
	HFC	The plug-in logs headers from the client, informational, and error messages.
	HTW	The plug-in logs headers sent to WebLogic Server, and informational and error messages.
	HFW	The plug-in logs headers sent from WebLogic Server, and informational and error messages.
	HTC	The plug-in logs headers sent to the client, informational messages, and error messages.
	ERR	Prints only the Error messages in the plug-in.
	ALL	The plug-in logs headers sent to and from the client, headers sent to and from WebLogic Server, information messages, and error messages.

Table 6-1 General Parameters for Web Service Plug-Ins

Parameter	Default	Description
WLLogFile	See the Debug parameter	Specifies path and file name for the log file that is generated when the Debug parameter is set to ON. You must create this directory before setting this parameter.
WLDNSRefreshInterval	0 (Lookup once, during startup)	Only applies to NSAPI and Apache. If defined in the proxy configuration, specifies number of seconds interval at which WebLogic Server refreshes DNS name to IP mapping for a server. This can be used in the event that a WebLogic Server instance is migrated to a different IP address, but the DNS name for that server's IP remains the same. In this case, at the specified refresh interval the DNS<->IP mapping will be updated.
WLTempDir	See the Debug parameter	Specifies the directory where a <code>wlproxy.log</code> will be created. If the location fails, the Plug-In resorts to creating the log file under <code>C:/temp</code> in Windows and <code>/tmp</code> in all Unix platforms. Also specifies the location of the <code>_wl_proxy</code> directory for post data files. When both <code>WLTempDir</code> and <code>WLLogFile</code> are set, <code>WLLogFile</code> will override as to the location of <code>wlproxy.log</code> . <code>WLTempDir</code> will still determine the location of <code>_wl_proxy</code> directory.
DebugConfigInfo	OFF	Enables the special query parameter “ <code>__WebLogicBridgeConfig</code> ”. Use it to get details about configuration parameters from the plug-in. For example, if you enable “ <code>__WebLogicBridgeConfig</code> ” by setting <code>DebugConfigInfo</code> and then send a request that includes the query string <code>?__WebLogicBridgeConfig</code> , then the plug-in gathers the configuration information and run-time statistics and returns the information to the browser. The plug-in does not connect to WebLogic Server in this case. This parameter is strictly for debugging and the format of the output message can change with releases. For security purposes, keep this parameter turned OFF in production systems.

Table 6-1 General Parameters for Web Service Plug-Ins

Parameter	Default	Description
StatPath (Not available for the Microsoft Internet Information Server Plug-In)	false	<p>If set to <code>true</code>, the plug-in checks the existence and permissions of the translated path (“Proxy-Path-Translated”) of the request before forwarding the request to WebLogic Server.</p> <p>If the file does not exist, an HTTP 404 File Not Found response is returned to the client. If the file exists but is not world-readable, an HTTP 403/Forbidden response is returned to the client. In either case, the default mechanism for the Web server to handle these responses fulfills the body of the response. This option is useful if both the WebLogic Server Web Application and the Web Server have the same document root.</p> <p>You can customize the error response by using the ErrorPage parameter.</p>
ErrorPage	none	You can create your own error page that is displayed when your Web server is unable to forward requests to WebLogic Server.
WLSocketTimeoutSecs	2 (must be greater than 0)	Set the timeout for the socket while connecting, in seconds.
WLIOTimeoutSecs (new name for HungServerRecoverSecs)	300	<p>Defines the amount of time the plug-in waits for a response to a request from WebLogic Server. The plug-in waits for HungServerRecoverSecs for the server to respond and then declares that server dead, and fails over to the next server. The value should be set to a very large value. If the value is less than the time the servlets take to process, then you may see unexpected results.</p> <p>Minimum value: 10 Maximum value: Unlimited</p>
Idempotent	ON	<p>When set to ON and if the servers do not respond within WLIOTimeoutSecs (new name for HungServerRecoverSecs), the plug-ins fail over.</p> <p>If set to “OFF” the plug-ins do not fail over. If you are using the Apache HTTP Server you can set this parameter differently for different URLs or MIME types.</p>

Table 6-1 General Parameters for Web Service Plug-Ins

Parameter	Default	Description
CookieName	JSESSIONID	If you change the name of the WebLogic Server session cookie in the WebLogic Server Web application, you need to change the CookieName parameter in the plug-in to the same value. The name of the WebLogic session cookie is set in the WebLogic-specific deployment descriptor, in the <code><session-descriptor></code> element.
DefaultFileName	none	<p>If the URI is “/” then the plug-in performs the following steps:</p> <ol style="list-style-type: none"> 1. Trims the path specified with the <code>PathTrim</code> parameter. 2. Appends the value of <code>DefaultFileName</code>. 3. Prepends the value specified with <code>PathPrepend</code>. <p>This procedure prevents redirects from WebLogic Server.</p> <p>Set the <code>DefaultFileName</code> to the default welcome page of the Web Application in WebLogic Server to which requests are being proxied. For example, If the <code>DefaultFileName</code> is set to <code>welcome.html</code>, an HTTP request like “<code>http://somehost/weblogic</code>” becomes “<code>http://somehost/weblogic/welcome.html</code>”. For this parameter to function, the same file must be specified as a welcome file in all the Web Applications to which requests are directed. For more information, see “Configuring Welcome Pages”.</p> <p>Note for Apache users: If you are using Stronghold or Raven versions, define this parameter inside of a <code>Location</code> block, and not in an <code>IfModule</code> block.</p>
MaxPostSize	-1	Maximum allowable size of POST data, in bytes. If the content-length exceeds <code>MaxPostSize</code> , the plug-in returns an error message. If set to -1, the size of POST data is not checked. This is useful for preventing denial-of-service attacks that attempt to overload the server with POST data.

Table 6-1 General Parameters for Web Service Plug-Ins

Parameter	Default	Description
MatchExpression (Apache HTTP Server only)	none	<p>When proxying by MIME type, set the filename pattern inside of an IfModule block using the MatchExpression parameter.</p> <p>Example when proxying by MIME type:</p> <pre><IfModule mod_weblogic.c> MatchExpression *.jsp WebLogicHost=myHost paramName=value </IfModule></pre> <p>Example when proxying by path:</p> <pre><IfModule mod_weblogic.c> MatchExpression /weblogic WebLogicHost=myHost paramName=value </IfModule></pre> <p>It is possible to define a new parameter for MatchExpression using the following syntax:</p> <pre>MatchExpression *.jsp PathPrepend=/test PathTrim=/foo</pre>

Table 6-1 General Parameters for Web Service Plug-Ins

Parameter	Default	Description
FileCaching	ON	<p>When set to ON, and the size of the POST data in a request is greater than 2048 bytes, the POST data is first read into a temporary file on disk and then forwarded to the WebLogic Server in chunks of 8192 bytes. This preserves the POST data during failover, allowing all necessary data to be repeated to the secondary if the primary goes down.</p> <p>Note that when FileCaching is ON, any client that tracks the progress of the POST will see that the transfer has completed even though the data is still being transferred between the WebServer and WebLogic. So, if you want the progress bar displayed by a browser during the upload to reflect when the data is actually available on the WebLogic Server, you might not want to have FileCaching ON.</p> <p>When set to OFF and the size of the POST data in a request is greater than 2048 bytes, the reading of the POST data is postponed until a WebLogic Server cluster member is identified to serve the request. Then the Plugin reads and immediately sends the POST data to the WebLogic Server in chunks of 8192 bytes.</p> <p>Note that turning FileCaching OFF limits failover. If the WebLogic Server primary server goes down while processing the request, the POST data already sent to the primary cannot be repeated to the secondary.</p> <p>Finally, regardless of how FileCaching is set, if the size of the POST data is 2048 bytes or less the plugin will read the data into memory and use it if needed during failover to repeat to the secondary.</p>
FilterPriorityLevel (Microsoft Internet Information Server only)	2	<p>The values for this parameter are 0 (low), 1 (medium), and 2 (high). The default value is 2. This priority should be put in iisforward.ini file. This property is used to set the priority level for the iisforward.dll filter in IIS. Priority level is used by IIS to decide which filter will be invoked first, in case multiple filters match the incoming request.</p>

Table 6-1 General Parameters for Web Service Plug-Ins

Parameter	Default	Description
WLExcludePathOrMimeType	none	<p>This parameter allows you make exclude certain requests from proxying.</p> <p>This parameter can be defined locally at the Location tag level as well as globally. When the property is defined locally, it does not override the global property but defines a union of the two parameters.</p>
WlForwardPath (Microsoft Internet Information Server only)	null	<p>If WlForwardPath is set to "/" all requests are proxied. To forward any requests starting with a particular string, set WlForwardPath to the string. For example, setting WlForwardPath to /weblogic forwards all requests starting with /weblogic to Weblogic Server.</p> <p>This parameter is required if you are proxying by path. You can set multiple strings by separating the strings with commas. For example: WlForwardPath=/weblogic,/bea.</p>
KeepAliveSecs	20	<p>The length of time after which an inactive connection between the plug-in and WebLogic Server is closed. You must set KeepAliveEnabled to true (ON when using the Apache plug-in) for this parameter to be effective.</p> <p>The value of this parameter must be less than or equal to the value of the Duration field set in the Administration Console on the Server/HTTP tab, or the value set on the server Mbean with the KeepAliveSecs attribute.</p>
KeepAliveEnabled	true (Microsoft IIS plug-in) ON (Apache plug-in)	<p>Enables pooling of connections between the plug-in and WebLogic Server.</p> <p>Valid values for the Microsoft IIS plug-ins are true and false.</p> <p>Valid values for the Apache plug-in are ON and OFF.</p>

Table 6-1 General Parameters for Web Service Plug-Ins

Parameter	Default	Description
QueryFromRequest (Apache HTTP Server only)	OFF	<p>When set to ON, specifies that the Apache plug-in use (request_rec *)r->the request to pass the query string to WebLogic Server. (For more information, see your Apache documentation.) This behavior is desirable in the following situations:</p> <ul style="list-style-type: none"> • When a Netscape version 4.x browser makes requests that contain spaces in the query string • If you are using Raven Apache 1.5.2 on HP <p>When set to OFF, the Apache plug-in uses (request_rec *)r->args to pass the query string to WebLogic Server.</p>
MaxSkipTime	10	<p>If a WebLogic Server listed in either the WebLogicCluster parameter or a dynamic cluster list returned from WebLogic Server fails, the failed server is marked as “bad” and the plug-in attempts to connect to the next server in the list.</p> <p>MaxSkips sets the amount of time after which the plug-in will retry the server marked as “bad.” The plug-in attempts to connect to a new server in the list each time a unique request is received (that is, a request without a cookie).</p>
DynamicServerList	ON	<p>When set to OFF, the plug-in ignores the dynamic cluster list used for load balancing requests proxied from the plug-in and only uses the static list specified with the WebLogicCluster parameter. Normally this parameter should remain set to ON.</p> <p>There are some implications for setting this parameter to OFF:</p> <ul style="list-style-type: none"> • If one or more servers in the static list fails, the plug-in could waste time trying to connect to a dead server, resulting in decreased performance. • If you add a new server to the cluster, the plug-in cannot proxy requests to the new server unless you redefine this parameter. WebLogic Server automatically adds new servers to the dynamic server list when they become part of the cluster.

Table 6-1 General Parameters for Web Service Plug-Ins

Parameter	Default	Description
WLProxySSL	OFF	<p>Set this parameter to ON to maintain SSL communication between the plug-in and WebLogic Server when the following conditions exist:</p> <ul style="list-style-type: none">• An HTTP client request specifies the HTTPS protocol• The request is passed through one or more proxy servers (including the WebLogic Server proxy plug-ins)• The connection between the plug-in and WebLogic Server uses the HTTP protocol <p>When WLProxySSL is set to ON, the location header returned to the client from WebLogic Server specifies the HTTPS protocol.</p>
WLLocalIP	none	<p>Defines the IP address to bind to when the plug-in connects to a WebLogic Server instance running on a multihomed machine.</p> <p>If WLLocalIP is not set, a random IP address on the multi-homed machine is used.</p>

SSL Parameters for Web Server Plug-Ins

Notes: SCG Certificates are not supported for use with WebLogic Server Proxy Plug-Ins. Non-SCG certificates work appropriately and allow SSL communication between WebLogic Server and the plug-in.

KeyStore-related initialization parameters are not supported for use with WebLogic Server Proxy Plug-Ins.

Parameters are case sensitive.

Table 6-2 SSL Parameters for Web Server Plug-Ins

Parameter	Default	Description
EnforceBasicConstraints	Strong	<p>This parameter closes a security hole which existed with SSL certificate validation where certificate chains with invalid V3 CA certificates would not be properly rejected. This allowed certificate chains with invalid intermediate CA certificates, rooted with a valid CA certificate to be trusted. X509 V3 CA certificates are required to contain the BasicConstraints extension, marked as being a CA, and marked as a critical extension. This checking protects against non-CA certificates masquerading as intermediate CA certificates.</p> <p>The levels of enforcement are as follows:</p> <p>OFF</p> <p>This level entirely disables enforcement and is not recommended. Most current commercial CA certificates should work under the default STRONG setting.</p> <pre>EnforceBasicConstraints=off EnforceBasicConstraints=false</pre> <p>STRONG</p> <p>Default. The BasicConstraints for V3 CA certificates are checked and the certificates are verified to be CA certificates.</p> <pre>EnforceBasicConstraints=strong EnforceBasicConstraints=true</pre> <p>STRICT</p> <p>This level does the same checking as the STRONG level, but in addition it also strictly enforces IETF RFC 2459 which specifies the BasicConstraints for CA certificates also must be marked as "critical". This is not the default setting because a number of current commercially available CA certificates don't conform to RFC 2459 and don't mark the BasicConstraints as critical. Set this if you want to strict conformance to RFC 2459.</p> <pre>EnforceBasicConstraints=strict</pre>

Table 6-2 SSL Parameters for Web Server Plug-Ins

Parameter	Default	Description
SecureProxy	OFF	<p>Set this parameter to ON to enable the use of the SSL protocol for all communication between the plug-in and WebLogic Server. Remember to configure a port on the corresponding WebLogic Server for the SSL protocol before defining this parameter.</p> <p>This parameter may be set at two levels: in the configuration for the main server and—if you have defined any virtual hosts—in the configuration for the virtual host. The configuration for the virtual host inherits the SSL configuration from the configuration of the main server if the setting is not overridden in the configuration for the virtual host.</p>
TrustedCAFile	none	<p>Name of the file that contains the digital certificates for the trusted certificate authorities for the plug-in. This parameter is required if the SecureProxy parameter is set to ON.</p> <p>The filename must include the full directory path of the file.</p>
RequireSSLHostMatch	true	<p>Determines whether the host name to which the plug-in is connecting must match the Subject Distinguished Name field in the digital certificate of the WebLogic Server to which the proxy plug-in is connecting.</p> <p>When specifying SecureProxy=ON and RequireSSLHostMatch=true in the plug-in, then the value specified in the ListenAddress property should exactly match the hostname value specified in the certificate.</p> <p>When using the ExternalDNSName property for WebLogic Server and setting SecureProxy=ON and RequireSSLHostMatch=true in the plug-in, then the value specified in the ExternalDNSName property should exactly match the hostname value specified in the certificate.</p>

Table 6-2 SSL Parameters for Web Server Plug-Ins

Parameter	Default	Description
SSLHostMatchOID	22	<p>The ASN.1 Object ID (OID) that identifies which field in the Subject Distinguished Name of the peer digital certificate is to be used to perform the host match comparison. The default for this parameter corresponds to the <code>CommonName</code> field of the Subject Distinguished Name. Common OID values are:</p> <ul style="list-style-type: none"> • Sur Name—23 • Common Name—22 • Email—13 • Organizational Unit—30 • Organization—29 • Locality—26
KeyStore	none	For generic proxy servlets, the key store location in a Web application when using two-way SSL to create a user-defined identity certificate and key.
KeyStoreType	none	The key store type when using two-way SSL with a generic proxy servlet. If it is not defined, the default type will be used instead.
PrivateKeyAlias	none	The private key alias when using two-way SSL with a generic proxy servlet.
KeyStorePasswordProperties	none	<p>A property file in a Web application that defines encrypted passwords to access the key store and private key alias when using two-way SSL with a generic proxy servlet. The file contents looks like this:</p> <pre>KeyStorePassword={3DES}i4+50LCKenQ08BBvlsXTrg\=\= PrivateKeyPassword={3DES}a4TcG4mtVVBKRtZwH3p7yA\=\=</pre> <p>You must use the <code>weblogic.security.Encrypt</code> command-line utility to encrypt the password. For more information on the <code>Encrypt</code> utility, as well as the <code>CertGen</code>, and <code>der2pem</code> utilities, see Using the WebLogic Server Java Utilities in the <i>WebLogic Server Command Reference</i>.</p>

Parameters for Web Server Plug-Ins
