A. Glossary of Terms
About This Document

This document explains how to use transactions in EJB and RMI applications that run in the BEA WebLogic Server™ environment.

This document is organized as follows:

- **Chapter 1, “Introducing Transactions,”** introduces transactions in EJB and RMI applications running in the WebLogic Server environment. This chapter also describes distributed transactions and the two-phase commit protocol for enterprise applications.

- **Chapter 2, “Configuring and Managing Transactions,”** describes how to administer transactions in the WebLogic Server environment.

- **Chapter 3, “Transaction Service,”** describes the WebLogic Server Transaction Service.

- **Chapter 4, “Java Transaction API and BEA WebLogic Extensions,”** provides a brief overview of the Java Transaction API (JTA).

- **Chapter 5, “Transactions in EJB Applications,”** describes how to implement transactions in EJB applications.

- **Chapter 6, “Transactions in RMI Applications,”** describes how to implement transactions in RMI applications.

- **Chapter 7, “Using Third-Party JDBC XA Drivers with WebLogic Server,”** describes how to configure and use third-party XA drivers in transactions.

- **Chapter 8, “Coordinating XAResources with the WebLogic Server Transaction Manager,”** describes the requirements for XA resources to participate in distributed transactions.
managed by WebLogic Server. This chapter is targeted at third-party application integrators.

- **Chapter 9, “Participating in Transactions Managed by a Third-Party Transaction Manager,”** describes the requirements for WebLogic Server to participate in distributed transactions managed by an external transaction manager. This chapter is targeted at third-party application integrators.

- **Chapter 10, “Troubleshooting Transactions,”** describes how to perform troubleshooting tasks for applications using JTA.

**Audience**

This document is written for application developers who are interested in building transactional Java applications that run in the WebLogic Server environment. It is assumed that readers are familiar with the WebLogic Server platform, Java™ 2, Enterprise Edition (J2EE) programming, and transaction processing concepts.

**e-docs Web Site**

BEA product documentation is available on the BEA corporate Web site. From the BEA Home page, click on Product Documentation or go directly to the WebLogic Server Product Documentation page at [http://e-docs.bea.com/wls/docs81](http://e-docs.bea.com/wls/docs81).

**How to Print the Document**

You can print a copy of this document from a Web browser, one main topic at a time, by using the File→Print option on your Web browser.

A PDF version of this document is available on the WebLogic Server documentation Home page on the e-docs Web site (and also on the documentation CD). You can open the PDF in Adobe Acrobat Reader and print the entire document (or a portion of it) in book format. To access the PDFs, open the WebLogic Server documentation Home page, click Download Documentation, and select the document you want to print.

Contact Us!

Your feedback on BEA documentation is important to us. Send us e-mail at docsupport@bea.com if you have questions or comments. Your comments will be reviewed directly by the BEA professionals who create and update the documentation.

In your e-mail message, please indicate the software name and version you are using, as well as the title and document date of your documentation. If you have any questions about this version of BEA WebLogic Server, or if you have problems installing and running BEA WebLogic Server, contact BEA Customer Support through BEA WebSupport at http://www.bea.com. You can also contact Customer Support by using the contact information provided on the Customer Support Card, which is included in the product package.

When contacting Customer Support, be prepared to provide the following information:

- Your name, e-mail address, phone number, and fax number
- Your company name and company address
- Your machine type and authorization codes
- The name and version of the product you are using
- A description of the problem and the content of pertinent error messages

Documentation Conventions

The following documentation conventions are used throughout this document.

Introducing Transactions

This section discusses the following topics:

- Overview of Transactions in WebLogic Server Applications
- When to Use Transactions
- What Happens During a Transaction
- Transactions Sample Code

Overview of Transactions in WebLogic Server Applications

This section includes the following sections:

- ACID Properties of Transactions
- Supported Programming Model
- Supported API Models
- Distributed Transactions and the Two-Phase Commit Protocol
- Support for Business Transactions
ACID Properties of Transactions

One of the most fundamental features of WebLogic Server is transaction management. Transactions are a means to guarantee that database changes are completed accurately and that they take on all the ACID properties of a high-performance transaction, including:

- Atomicity—all changes that a transaction makes to a database are made as one unit; otherwise, all changes are rolled back.
- Consistency—a successful transaction transforms a database from a previous valid state to a new valid state.
- Isolation—changes that a transaction makes to a database are not visible to other operations until the transaction completes its work.
- Durability—changes that a transaction makes to a database survive future system or media failures.

WebLogic Server protects the integrity of your transactions by providing a complete infrastructure for ensuring that database updates are done accurately, even across a variety of resource managers. If any one of the operations fails, the entire set of operations is rolled back.

Supported Programming Model

WebLogic Server supports transactions in the Sun Microsystems, Inc., Java™ 2, Enterprise Edition (J2EE) programming model. WebLogic Server provides full support for transactions in Java applications that use Enterprise JavaBeans, in compliance with the Enterprise JavaBeans Specification 2.0, published by Sun Microsystems, Inc. WebLogic Server also supports the Java Transaction API (JTA) Specification 1.0.1a, also published by Sun Microsystems, Inc.

Supported API Models

WebLogic Server supports the Sun Microsystems, Inc. Java Transaction API (JTA), which is used by:

- Enterprise JavaBean (EJB) applications within the WebLogic Server EJB container.
- Remote Method Invocation (RMI) applications within the WebLogic Server infrastructure.

For information about JTA, see the following sources:

- The `javax.transaction` and `javax.transaction.xa` package APIs.
- The Java Transaction API specification, published by Sun Microsystems, Inc.
Distributed Transactions and the Two-Phase Commit Protocol

WebLogic Server supports distributed transactions and the two-phase commit protocol for enterprise applications. A **distributed transaction** is a transaction that updates multiple resource managers (such as databases) in a coordinated manner. In contrast, a **local transaction** begins and commits the transaction to a single resource manager that internally coordinates API calls; there is no transaction manager. The **two-phase commit protocol** is a method of coordinating a single transaction across two or more resource managers. It guarantees data integrity by ensuring that transactional updates are committed in all of the participating databases, or are fully rolled back out of all the databases, reverting to the state prior to the start of the transaction. In other words, either all the participating databases are updated, or none of them are updated.

Distributed transactions involve the following participants:

- **Transaction originator**—initiates the transaction. The transaction originator can be a user application, an Enterprise JavaBean, or a JMS client.

- **Transaction manager**—manages transactions on behalf of application programs. A transaction manager coordinates commands from application programs to start and complete transactions by communicating with all resource managers that are participating in those transactions. When resource managers fail during transactions, transaction managers help resource managers decide whether to commit or roll back pending transactions.

- **Recoverable resource**—provides persistent storage for data. The resource is most often a database.

- **Resource manager**—provides access to a collection of information and processes. Transaction-aware JDBC drivers are common resource managers. Resource managers provide transaction capabilities and permanence of actions; they are entities accessed and controlled within a distributed transaction. The communication between a resource manager and a specific resource is called a **transaction branch**.

The first phase of the two-phase commit protocol is called the prepare phase. The required updates are recorded in a transaction log file, and the resource must indicate, through a resource manager, that it is ready to make the changes. Resources can either vote to commit the updates or to roll back to the previous state. What happens in the second phase depends on how the resources vote. If all resources vote to commit, all the resources participating in the transaction are updated. If one or more of the resources vote to roll back, then all the resources participating in the transaction are rolled back to their previous state.
Support for Business Transactions
WebLogic JTA provides the following support for your business transactions:

- Creates a unique transaction identifier when a client application initiates a transaction.
- Supports an optional transaction name describing the business process that the transaction represents. The transaction name makes statistics and error messages more meaningful.
- Works with the WebLogic Server infrastructure to track objects that are involved in a transaction and, therefore, need to be coordinated when the transaction is ready to commit.
- Notifies the resource managers—which are, most often, databases—when they are accessed on behalf of a transaction. Resource managers then lock the accessed records until the end of the transaction.
- Orchestrates the two-phase commit when the transaction completes, which ensures that all the participants in the transaction commit their updates simultaneously. It coordinates the commit with any databases that are being updated using Open Group’s XA protocol. Many popular relational databases support this standard.
- Executes the rollback procedure when the transaction must be stopped.
- Executes a recovery procedure when failures occur. It determines which transactions were active in the machine at the time of the crash, and then determines whether the transaction should be rolled back or committed.
- Manages transaction timeouts. If a business operation takes too much time or is only partially completed due to failures, the system takes action to automatically issue a timeout for the transaction and free resources, such as database locks.

When to Use Transactions
Transactions are appropriate in the situations described in the following list. Each situation describes a transaction model supported by the WebLogic Server system. Keep in mind that distributed transactions should not span more than a single user input screen; more complex, higher level transactions are best implemented with a series of distributed transactions.

- Within the scope of a single client invocation on an object, the object performs multiple edits to data in a database. If one of the edits fails, the object needs a mechanism to roll back all the edits. (In this situation, the individual database edits are not necessarily EJB or RMI invocations. A client, such as an applet, can obtain a reference to the Transaction and TransactionManager objects, using JNDI, and start a transaction.)
For example, consider a banking application. The client invokes the transfer operation on a
teller object. The transfer operation requires the teller object to make the following
invocations on the bank database:

- Invoking the debit method on one account.
- Invoking the credit method on another account.

If the credit invocation on the bank database fails, the banking application needs a way to
roll back the previous debit invocation.

- The client application needs a conversation with an object managed by the server
  application, and the client application needs to make multiple invocations on a specific
  object instance. The conversation may be characterized by one or more of the following:

  - Data is cached in memory or written to a database during or after each successive
    invocation.
  - Data is written to a database at the end of the conversation.
  - The client application needs the object to maintain an in-memory context between each
    invocation; that is, each successive invocation uses the data that is being maintained in
    memory across the conversation.
  - At the end of the conversation, the client application needs the ability to cancel all
    database write operations that may have occurred during or at the end of the
    conversation.

When Not to Use Transactions

Transactions are not always appropriate. For example, if a series of transactions take a long time,
implement them with a series of distributed transactions. Here is an example of an incorrect use
of transactions.

- The client application needs to make invocations on several objects, which may involve
  write operations to one or more databases. If any one invocation is unsuccessful, any state
  that is written (either in memory or, more typically, to a database) must be rolled back.

For example, consider a travel agent application. The client application needs to arrange
for a journey to a distant location; for example, from Strasbourg, France, to Alice Springs,
Australia. Such a journey would inevitably require multiple individual flight reservations.
The client application works by reserving each individual segment of the journey in
sequential order; for example, Strasbourg to Paris, Paris to New York, New York to Los
Angeles. However, if any individual flight reservation cannot be made, the client
application needs a way to cancel all the flight reservations made up to that point.
What Happens During a Transaction

This topic includes the following sections:

- Transactions in WebLogic Server EJB Applications
- Transactions in WebLogic Server RMI Applications

Transactions in WebLogic Server EJB Applications

Figure 1-1 illustrates how transactions work in a WebLogic Server EJB application.

WebLogic Server supports two types of transactions in WebLogic Server EJB applications:

- **In container-managed transactions**, the WebLogic Server EJB container manages the transaction demarcation. Transaction attributes in the EJB deployment descriptor determine how the WebLogic Server EJB container handles transactions with each method invocation. For more information about the deployment descriptor, see Programming WebLogic EJB.

- **In bean-managed transactions**, the EJB manages the transaction demarcation. The EJB makes explicit method invocations on the UserTransaction object to begin, commit, and roll back transactions. For more information about the UserTransaction object, see the WebLogic Server Javadoc at http://e-docs.bea.com/wls/docs81/javadocs/weblogic/transaction/UserTransaction.html.
The sequence of transaction events differs between container-managed and bean-managed transactions.

**Container-managed Transactions**

For EJB applications with container-managed transactions, a basic transaction works in the following way:

1. In the EJB’s deployment descriptor, the Bean Provider or Application Assembler specifies the transaction type (transaction-type element) for container-managed demarcation (Container).

2. In the EJB’s deployment descriptor, the Bean Provider or Application Assembler specifies the default transaction attribute (trans-attribute element) for the EJB, which is one of the following settings: NotSupported, Required, Supports, RequiresNew, Mandatory, or Never. For a detailed description of these settings, see Section 17.6.2 in the Enterprise JavaBeans Specification 2.0, published by Sun Microsystems, Inc.

3. Optionally, in the EJB’s deployment descriptor, the Bean Provider or Application Assembler specifies the trans-attribute for one or more methods.

4. When a client application invokes a method in the EJB, the EJB container checks the trans-attribute setting in the deployment descriptor for that method. If no setting is specified for the method, the EJB uses the default trans-attribute setting for that EJB.

5. The EJB container takes the appropriate action depending on the applicable trans-attribute setting.
   - For example, if the trans-attribute setting is Required, the EJB container invokes the method within the existing transaction context or, if the client called without a transaction context, the EJB container begins a new transaction before executing the method.
   - In another example, if the trans-attribute setting is Mandatory, the EJB container invokes the method within the existing transaction context. If the client called without a transaction context, the EJB container throws the javax.transaction.TransactionRequiredException exception.

6. During invocation of the business method, if it is determined that a rollback is required, the business method calls the EJBContext.setRollbackOnly method, which notifies the EJB container that the transaction is to be rolled back at the end of the method invocation.

**Note:** Calling the EJBContext.setRollbackOnly method is allowed only for methods that have a meaningful transaction context.
Introducing Transactions

7. At the end of the method execution and before the result is sent to the client, the EJB container completes the transaction, either by committing the transaction or rolling it back (if the EJBContext.setRollbackOnly method was called).

You can control transaction timeouts by setting the Timeout Seconds attribute using the Administration Console. See the Administration Console Online Help at http://e-docs.bea.com/wls/docs81/ConsoleHelp/jta.html#jta_configure.

Bean-managed Transactions

For EJB applications with bean-managed transaction demarcations, a basic transaction works in the following way:

1. In the EJB’s deployment descriptor, the Bean Provider or Application Assembler specifies the transaction type (transaction-type element) for container-managed demarcation (Bean).

2. The client application uses JNDI to obtain an object reference to the UserTransaction object for the WebLogic Server domain.

3. The client application begins a transaction using the UserTransaction.begin method, and issues a request to the EJB through the EJB container. All operations on the EJB execute within the scope of a transaction.

   - If a call to any of these operations raises an exception (either explicitly or as a result of a communication failure), the exception can be caught and the transaction can be rolled back using the UserTransaction.rollback method.

   - If no exceptions occur, the client application commits the current transaction using the UserTransaction.commit method. This method ends the transaction and starts the processing of the operation. The transaction is committed only if all of the participants in the transaction agree to commit.

4. The UserTransaction.commit method causes the EJB container to call the transaction manager to complete the transaction.

5. The transaction manager is responsible for coordinating with the resource managers to update any databases.

Transactions in WebLogic Server RMI Applications

Figure 1-2 illustrates how transactions work in a WebLogic Server RMI application.
For RMI client and server applications, a basic transaction works in the following way:

1. The application uses JNDI to return an object reference to the UserTransaction object for the WebLogic Server domain. Obtaining the object reference begins a conversational state between the application and that object. The conversational state continues until the transaction is completed (committed or rolled back). Once instantiated, RMI objects remain active in memory until they are released (typically during server shutdown). For the duration of the transaction, the WebLogic Server infrastructure does not perform any deactivation or activation.

2. The client application begins a transaction using the UserTransaction.begin method, and issues a request to the server application. All operations on the server application execute within the scope of a transaction.
   - If a call to any of these operations raises an exception (either explicitly or as a result of a communication failure), the exception can be caught and the transaction can be rolled back using the UserTransaction.rollback method.
   - If no exceptions occur, the client application commits the current transaction using the UserTransaction.commit method. This method ends the transaction and starts the processing of the operation. The transaction is committed only if all of the participants in the transaction agree to commit.

3. The UserTransaction.commit method causes WebLogic Server to call the transaction manager to complete the transaction.
4. The transaction manager is responsible for coordinating with the resource managers to update any databases.

For more information, see Chapter 6, “Transactions in RMI Applications.”

Transactions Sample Code

This section includes the following sections:

- Transactions Sample EJB Code
- Transactions Sample RMI Code

Transactions Sample EJB Code

This section provides a walkthrough of sample code fragments from a class in an EJB application. This topic includes the following sections:

- Importing Packages
- Using JNDI to Return an Object Reference
- Starting a Transaction
- Completing a Transaction

The code fragments demonstrate using the UserTransaction object for bean-managed transaction demarcation. The deployment descriptor for this bean specifies the transaction type (transaction-type element) for transaction demarcation (Bean).

Notes: In a global transaction, use a database connection from a local TxDataSource—on the WebLogic Server instance on which the EJB is running. Do not use a connection from a TxDataSource on a remote WebLogic Server instance.

These code fragments do not derive from any of the sample applications that ship with WebLogic Server. They merely illustrate the use of the UserTransaction object within an EJB application.

Importing Packages

Listing 1-1 shows importing the necessary packages for transactions, including:

- javax.transaction.UserTransaction. For a list of methods associated with this object, see the online Javadoc.
• System exceptions. For a list of exceptions, see the online Javadoc.

Listing 1-1 Importing Packages

```java
import javax.naming.*;
import javax.transaction.UserTransaction;
import javax.transaction.SystemException;
import javax.transaction.HeuristicMixedException
import javax.transaction.HeuristicRollbackException
import javax.transaction.NotSupportedException
import javax.transaction.RollbackException
import javax.transaction.IllegalStateException
import javax.transaction.SecurityException
import java.sql.*;
import java.util.*;
```

Using JNDI to Return an Object Reference

Listing 1-2 shows how look up an object on the JNDI tree.

Listing 1-2 Performing a JNDI Lookup

```java
Context ctx = null;
Hashtable env = new Hashtable();

env.put(Context.INITIAL_CONTEXT_FACTORY,
        "weblogic.jndi.WLInitialContextFactory");

// Parameters for the WebLogic Server.
// Substitute the correct hostname, port number
// user name, and password for your environment:
env.put(Context.PROVIDER_URL, "t3://localhost:7001");
env.put(Context.SECURITY_PRINCIPAL, "Fred");
env.put(Context.SECURITY_CREDENTIALS, "secret");

ctx = new InitialContext(env);
```
Introducing Transactions

UserTransaction tx = (UserTransaction)
ctx.lookup("javax.transaction.UserTransaction");

Starting a Transaction
Listing 1-3 shows starting a transaction by getting a UserTransaction object and calling the javax.transaction.UserTransaction.begin() method. Database operations that occur after this method invocation and prior to completing the transaction exist within the scope of this transaction.

Listing 1-3  Starting a Transaction
UserTransaction tx = (UserTransaction)
ctx.lookup("javax.transaction.UserTransaction");
tx.begin();

Completing a Transaction
Listing 1-4 shows completing the transaction depending on whether an exception was thrown during any of the database operations that were attempted within the scope of this transaction:

- If an exception was thrown during any of the database operations, the application calls the javax.transaction.UserTransaction.rollback() method.
- If no exception was thrown, the application calls the javax.transaction.UserTransaction.commit() method to attempt to commit the transaction after all database operations completed successfully. Calling this method ends the transaction and starts the processing of the operation, causing the WebLogic Server EJB container to call the transaction manager to complete the transaction. The transaction is committed only if all of the participants in the transaction agree to commit.

Listing 1-4  Completing a Transaction

    tx.commit();
Transactions Sample Code

// or:

// tx.rollback();

Transactions Sample RMI Code

This topic provides a walkthrough of sample code fragments from a class in an RMI application. This topic includes the following sections:

- Importing Packages
- Using JNDI to Return an Object Reference to the UserTransaction Object
- Starting a Transaction
- Completing a Transaction

The code fragments demonstrate using the UserTransaction object for RMI transactions. For guidelines on using transactions in RMI applications, see Chapter 6, “Transactions in RMI Applications.”

Note: These code fragments do not derive from any of the sample applications that ship with WebLogic Server. They merely illustrate the use of the UserTransaction object within an RMI application.

Importing Packages

Listing 1-5 shows importing the necessary packages, including the following packages used to handle transactions:

- javax.transaction.UserTransaction. For a list of methods associated with this object, see the online Javadoc.
- System exceptions. For a list of exceptions, see the online Javadoc.

Listing 1-5   Importing Packages

```java
import javax.naming.*;
import java.rmi.*;
import javax.transaction.UserTransaction;
import javax.transaction.SystemException;
```
import javax.transaction.HeuristicMixedException
import javax.transaction.HeuristicRollbackException
import javax.transaction.NotSupportedException
import javax.transaction.RollbackException
import javax.transaction.IllegalStateException
import javax.transaction.SecurityException
import java.sql.*;
import java.util.*;

After importing these classes, initialize an instance of the UserTransaction object to null.

Using JNDI to Return an Object Reference to the UserTransaction Object

Listing 1-6 shows searching the JNDI tree to return an object reference to the UserTransaction object for the appropriate WebLogic Server domain.

Note: Obtaining the object reference begins a conversational state between the application and that object. The conversational state continues until the transaction is completed (committed or rolled back). Once instantiated, RMI objects remain active in memory until they are released (typically during server shutdown). For the duration of the transaction, the WebLogic Server infrastructure does not perform any deactivation or activation.

Listing 1-6 Performing a JNDI Lookup

Context ctx = null;
Hashtable env = new Hashtable();

env.put(Context.INITIAL_CONTEXT_FACTORY,
        "weblogic.jndi.WLInitialContextFactory");

// Parameters for the WebLogic Server.
// Substitute the correct hostname, port number
// user name, and password for your environment:
env.put(Context.PROVIDER_URL, "t3://localhost:7001");
env.put(Context.SECURITY_PRINCIPAL, "Fred");
env.put(Context.SECURITY_CREDENTIALS, "secret");
ctx = new InitialContext(env);

UserTransaction tx = (UserTransaction)
   ctx.lookup("javax.transaction.UserTransaction");

---

Starting a Transaction

Listing 1-7 shows starting a transaction by calling the
javax.transaction.UserTransaction.begin() method. Database operations that occur
after this method invocation and prior to completing the transaction exist within the scope of this
transaction.

Listing 1-7  Starting a Transaction

UserTransaction tx = (UserTransaction)
   ctx.lookup("javax.transaction.UserTransaction");
   tx.begin();

---

Completing a Transaction

Listing 1-8 shows completing the transaction depending on whether an exception was thrown
during any of the database operations that were attempted within the scope of this transaction:

- If an exception was thrown, the application calls the
  javax.transaction.UserTransaction.rollback() method if an exception was
  thrown during any of the database operations.

- If no exception was thrown, the application calls the
  javax.transaction.UserTransaction.commit() method to attempt to commit the
  transaction after all database operations completed successfully. Calling this method ends
  the transaction and starts the processing of the operation, causing WebLogic Server to call
  the transaction manager to complete the transaction. The transaction is committed only if
  all of the participants in the transaction agree to commit.
Introducing Transactions

Listing 1-8  Completing a Transaction

    tx.commit();

    // or:

    tx.rollback();
CHAPTER 2

Configuring and Managing Transactions

This section provides an overview of commonly performed administration tasks related to transactions. For general information on JTA configuration tasks, see JTA in the Administration Console Online Help.

This section discusses the following topics:

- Configuring Transactions
- Monitoring Transactions

Configuring Transactions

The Administration Console provides the interface used to configure features of WebLogic Server, including WebLogic JTA. To invoke the Administration Console, refer to the procedures described in Starting and Using the Administration Console in the Administration Guide at http://e-docs.bea.com/wls/docs81/adminguide/overview.html#start_admin_console. The configuration process involves specifying values for attributes. These attributes define the transaction environment, including the following:

- Transaction timeouts and limits
- Transaction manager behavior

You should also be familiar with the administration of J2EE components that can participate in transactions, such as EJBs, JDBC, and JMS.
Monitoring Transactions

You can monitor transactions on a server using the logging, statistics, and monitoring facilities. Use the Administration Console to configure these features and to display the resulting output.

Logging

The transaction log consists of multiple files. Each file is named using a prefix indicating the location in the file system, as defined by the TransactionLogFilePrefix attribute, the server name, a unique numeric suffix, and a file extension. The TransactionLogFilePrefix attribute is set for each server in a domain. The overall amount of space consumed by the transaction log is limited only by the file system’s available disk space. For more information on setting server logging attributes, see Server → Logging → JTA in the Administration Console Online Help at http://e-docs.bea.com/wls/docs81/ConsoleHelp/domain_server_logging_jta.htm1. Also see Monitoring Transactions in the Administration Console Online Help at http://e-docs.bea.com/wls/docs81/ConsoleHelp/jta.html#monitortx.

Note: The transaction log buffer is limited to 250 KB. If your application includes very large transactions that require transaction log writes that exceed this value, WebLogic Server will throw an exception. In that case, you must reconfigure your application to work around the buffer size.

WebLogic Server keeps statistics on transactions organized by server, resource, and transaction name. For more information on viewing statistics, see the JTA topic in the Administration Console Online Help. For information on using statistics in troubleshooting and debugging, see “Transaction Statistics” in Chapter 10, “Troubleshooting Transactions.”

Monitoring

You can monitor transactions in progress using the Administration Console. You can display information for transactions by name, transactions by resource, or all active transactions. For more information on monitoring transactions, see Server → Logging → JTA in the Administration Console Online Help at http://e-docs.bea.com/wls/docs81/ConsoleHelp/domain_serverLogging_logging_jta.html. For more information on using monitoring data in troubleshooting, see Monitoring Transactions in the Administration Console Online Help at http://e-docs.bea.com/wls/docs81/ConsoleHelp/jta.html#monitortx.
CHAPTER 3

Transaction Service

This section provides information that programmers need to write transactional applications for the WebLogic Server system.

This section discusses the following topics:

- About the Transaction Service
- Capabilities and Limitations
- Transaction Scope
- Transaction Service in EJB Applications
- Transaction Service in RMI Applications

About the Transaction Service

WebLogic Server provides a Transaction Service that supports transactions in EJB and RMI applications. In the WebLogic Server EJB container, the Transaction Service provides an implementation of the transaction services described in the Enterprise JavaBeans Specification 2.0, published by Sun Microsystems, Inc.

For EJB and RMI applications, WebLogic Server also provides the `javax.transaction` and `javax.transaction.xa` packages, from Sun Microsystems, Inc., which implements the Java Transaction API (JTA) for Java applications. For more information about JTA, see the Java Transaction API (JTA) Specification 1.0.1a, published by Sun Microsystems, Inc. For more information about the `UserTransaction` object that applications use to demarcate transaction boundaries, see the WebLogic Server Javadoc.
Capabilities and Limitations

This section includes the following sections:

- Lightweight Clients with Delegated Commit
- Client-initiated Transactions
- Transaction Integrity
- Transaction Termination
- Flat Transactions
- Relationship of the Transaction Service to Transaction Processing
- Multithreaded Transaction Client Support
- General Constraints

These sections describe the capabilities and limitations of the Transaction Service that supports EJB and RMI applications:

Lightweight Clients with Delegated Commit

A lightweight client runs on a single-user, unmanaged desktop system that has irregular availability. Owners may turn their desktop systems off when they are not in use. These single-user, unmanaged desktop systems should not be required to perform network functions such as transaction coordination. In particular, unmanaged systems should not be responsible for ensuring atomicity, consistency, isolation, and durability (ACID) properties across failures for transactions involving server resources. WebLogic Server remote clients are lightweight clients.

The Transaction Service allows lightweight clients to do a delegated commit, which means that the Transaction Service allows lightweight clients to begin and terminate transactions while the responsibility for transaction coordination is delegated to a transaction manager running on a server machine. Client applications do not require a local transaction server. The remote implementation of UserTransaction that EJB or RMI clients use delegates the actual responsibility of transaction coordination to the transaction manager on the server.

Client-initiated Transactions

A client, such as an applet, can obtain a reference to the UserTransaction and TransactionManager objects using JNDI. A client can begin a transaction using either object
Capabilities and Limitations

reference. To get the Transaction object for the current thread, the client program must invoke the 
((TransactionManager)tm).getTransaction() method.

Transaction Integrity

Checked transaction behavior provides transaction integrity by guaranteeing that a commit will 
not succeed unless all transactional objects involved in the transaction have completed the 
processing of their transactional requests. The Transaction Service provides checked transaction 
behavior that is equivalent to that provided by the request/response interprocess communication 
models defined by The Open Group.

Transaction Termination

WebLogic Server allows transactions to be terminated only by the client that created the 
transaction.

Note: The client may be a server object that requests the services of another object.

Flat Transactions

WebLogic Server implements the flat transaction model. Nested transactions are not supported.

Relationship of the Transaction Service to Transaction 
Processing

The Transaction Service relates to various transaction processing servers, interfaces, protocols, 
and standards in the following ways:

- **Support for The Open Group XA interface.** The Open Group Resource Managers are 
resource managers that can be involved in a distributed transaction by allowing their 
two-phase commit protocol to be controlled via The Open Group XA interface. WebLogic 
Server supports interaction with The Open Group Resource Managers.

- **Support for the OSI TP protocol.** Open Systems Interconnect Transaction Processing 
(OSI TP) is the transactional protocol defined by the International Organization for 
Standardization (ISO). WebLogic Server does not support interactions with OSI TP 
transactions.

- **Support for the LU 6.2 protocol.** Systems Network Architecture (SNA) LU 6.2 is a 
transactional protocol defined by IBM. WebLogic Server does not support interactions with 
LU 6.2 transactions.
Support for the ODMG standard. ODMG-93 is a standard defined by the Object Database Management Group (ODMG) that describes a portable interface to access Object Database Management Systems. WebLogic Server does not support interactions with ODMG transactions.

Multithreaded Transaction Client Support

WebLogic Server supports multithreaded transactional clients. Clients can make transaction requests concurrently in multiple threads.

General Constraints

The following constraints apply to the Transaction Service:

- In WebLogic Server, a client or a server object cannot invoke methods on an object that is infected with (or participating in) another transaction. The method invocation issued by the client or the server will return an exception.
- In WebLogic Server, clients using third-party implementations of the Java Transaction API (for Java applications) are not supported.
- The transaction log buffer is limited to 250 KB. If your application includes very large transactions that require transaction log writes that exceed this value, WebLogic Server will throw an exception. In that case, you must reconfigure your application to work around the buffer size.

Transaction Scope

The scope of a transaction refers to the environment in which the transaction is performed. WebLogic Server supports transactions on standalone servers, between non-clustered servers, between clustered servers within a domain, and between domains. To enable inter-domain transaction support, you must configure a common credential for all participating domains. See Configuring Domains for Inter-Domain Transactions in the Administration Console Online Help at http://e-docs.bea.com/wls/docs81/ConsoleHelp/jta.html#interop.

Transaction Service in EJB Applications

The WebLogic Server EJB container provides a Transaction Service that supports the two types of transactions in WebLogic Server EJB applications:
• **Container-managed transactions.** In container-managed transactions, the WebLogic Server EJB container manages the transaction demarcation. Transaction attributes in the EJB deployment descriptor determine how the WebLogic Server EJB container handles transactions with each method invocation.

• **Bean-managed transactions.** In bean-managed transactions, the EJB manages the transaction demarcation. The EJB makes explicit method invocations on the `UserTransaction` object to begin, commit, and roll back transactions. For more information about `UserTransaction` methods, see the online Javadoc.

For an introduction to transaction management in EJB applications, see “Transactions in WebLogic Server EJB Applications,” and “Transactions Sample EJB Code” in the “Introducing Transactions” section.

**Transaction Service in RMI Applications**

WebLogic Server provides a Transaction Service that supports transactions in WebLogic Server RMI applications. In RMI applications, the client or server application makes explicit method invocations on the `UserTransaction` object to begin, commit, and roll back transactions.

For more information about `UserTransaction` methods, see the online javadoc. For an introduction to transaction management in RMI applications, see “Transactions in WebLogic Server RMI Applications,” and “Transactions Sample RMI Code” in the “Introducing Transactions” section.

**Transaction Service Interoperating with OTS**

WebLogic Server provides a Transaction Service that supports interoperation with the Object Transaction Service (OTS). See the Java Transaction Service (JTS) Specification at http://java.sun.com/j2ee/transactions/downloads/. For this release, WebLogic Server interoperates with OTS in the following scenarios:

- “Server-Server 2PC” on page 3-5
- “Client demarcated transactions” on page 3-6

**Server-Server 2PC**

In this situation, a server-to-server 2PC transaction is completed using interposition. The originating server creates an xid and propagates the transaction to the target server. The target server registers itself as a resource with the originating server. The originating server drives the completion of the transaction. (no last resource optimization).
Client demarcated transactions

The client starts a transaction on the server via the OTS client APIs. The client then retrieves the
xid from this transaction and then propagates this per-request until the transaction is committed.
Although the client initiates the transaction, all the commit processing is done on the server.
CHAPTER 4

Java Transaction API and BEA WebLogic Extensions

This section provides a brief overview of the Java Transaction API (JTA) and extensions to the API provided by BEA Systems.

This section discusses the following topics:

- JTA API Overview
- BEA WebLogic Extensions to JTA

JTA API Overview

WebLogic Server supports the javax.transaction package and the javax.transaction.xa package, from Sun Microsystems, Inc., which implement the Java Transaction API (JTA) for Java applications. For more information about JTA, see the Java Transaction API (JTA) Specification (version 1.0.1a) published by Sun Microsystems, Inc. For a detailed description of the javax.transaction and javax.transaction.xa interfaces, see the JTA Javadoc.

JTA includes the following components:

- An interface for demarcating and controlling transactions from an application, javax.transaction.UserTransaction. You use this interface as part of a Java client program or within an EJB as part of a bean-managed transaction.

- An interface for allowing a transaction manager to demarcate and control transactions for an application, javax.transaction.TransactionManager. This interface is used by an EJB container as part of a container-managed transaction and uses the javax.transaction.Transaction interface to perform operations on a specific transaction.
• Interfaces that allow the transaction manager to provide status and synchronization information to an applications server, `javax.transaction.Status` and `javax.transaction.Synchronization`. These interfaces are accessed only by the transaction manager and cannot be used as part of an applications program.

• Interfaces for allowing a transaction manager to work with resource managers for XA-compliant resources (`javax.transaction.xa.XAResource`) and to retrieve transaction identifiers (`javax.transaction.xa.Xid`). These interfaces are accessed only by the transaction manager and cannot be used as part of an applications program.

### BEA WebLogic Extensions to JTA

Extensions to the Java Transactions API are provided where the JTA specification does not cover implementation details and where additional capabilities are required.

BEA WebLogic provides the following capabilities based on interpretations of the JTA specification:

• Client-initiated transactions—the JTA transaction manager interface (`javax.transaction.TransactionManager`) is made available to clients and bean providers through JNDI. This allows clients and EJBs using bean-managed transactions to suspend and resume transactions.

  **Note:** A suspended transaction must be resumed in the same server process in which it was suspended.

• Scope of transactions—transactions can operate within and between clusters and domains.

BEA WebLogic provides the following classes and interfaces as extensions to JTA:

• `weblogic.transaction.RollbackException` (extends `javax.transaction.RollbackException`)

  This class preserves the original reason for a rollback for use in more comprehensive exception information.

• `weblogic.transaction.TransactionManager` (extends `javax.transaction.TransactionManager`)

  The WebLogic JTA transaction manager object supports this interface, which allows XA resources to register and unregister themselves with the transaction manager on startup. It also allows a transaction to be resumed after suspension.

  This interface includes the following methods:

– registerResource— (new in WebLogic Server 8.1) This method includes support for properties that determine how the resource is controlled by the transaction manager.

– getTransaction
– forceResume and forceSuspend
– begin

**weblogic.transaction.Transaction** *(extends javax.transaction.Transaction)*

The WebLogic JTA transaction object supports this interface, which allows users to get and set transaction properties.

This interface includes the following methods:

– setName and getName
– addProperties, setProperty, getProperty, and getProperties
– setRollbackReason and getRollbackReason
– getHeuristicErrorMessage
– getXID and getXid
– getStatusAsString
– getMillisSinceBegin
– getTimeToLiveMillis
– isTimedOut

**weblogic.transaction.TransactionHelper**

This class allows you to obtain the current transaction manager and transaction. It replaces TxHelper.

This interface includes the following static methods:

– getTransaction
– getUserTransaction
– getTransactionManager

**weblogic.transaction.TxHelper** *(Deprecated, use TransactionHelper instead)*

This class allows you to obtain the current transaction manager and transaction.

This interface includes the following static methods:
Java Transaction API and BEA WebLogic Extensions

- `getTransaction`, `getUserTransaction`, `getTransactionManager`
- `status2String`

- `weblogic.transaction.XAResource` (extends `javax.transaction.xa.XAResource`)
  This class provides delistment capabilities for XA resources.
  This interface includes the following method:
  - `getDelistFlag`

- `weblogic.transaction.nonxa.NonXAResource`
  This interface enables resources that do not support the
  `javax.transaction.xa.XAResource` interface to easily integrate with the WebLogic
  Server transaction manager. The transaction manager supports a variation of the Last
  Agent two-phase commit optimization that allows a non-XA resource to participate in a
  distributed transaction. The protocol issues a one-phase commit to the non-XA resource
  and uses the result of the operation to base the commit decision for the transaction.
  For a detailed description of the WebLogic extensions to the `javax.transaction` and
  `javax.transaction.xa` interfaces, see the `weblogic.transaction` package description.
Transactions in EJB Applications

This section includes the following topics:

- Before You Begin
- General Guidelines
- Transaction Attributes
- Participating in a Transaction
- Transaction Semantics
- Session Synchronization
- Synchronization During Transactions
- Setting Transaction Timeouts
- Handling Exceptions in EJB Transactions

This section describes how to integrate transactions in Enterprise JavaBeans (EJBs) applications that run under BEA WebLogic Server.
Before You Begin

Before you begin, you should read Chapter 1, “Introducing Transactions,” particularly the following topics:

- Transactions in WebLogic Server EJB Applications
- Transactions Sample EJB Code

This document describes the BEA WebLogic Server implementation of transactions in Enterprise JavaBeans. The information in this document supplements the Enterprise JavaBeans Specification 2.0, published by Sun Microsystems, Inc.

Note: Before proceeding with the rest of this chapter, you should be familiar with the contents of the EJB Specification 2.0 document, particularly the concepts and material presented in Chapter 16, “Support for Transactions.”

General Guidelines

The following general guidelines apply when implementing transactions in EJB applications for WebLogic Server:

- The EJB specification allows for flat transactions only. Transactions cannot be nested.

- The EJB specification allows for distributed transactions that span multiple resources (such as databases) and supports the two-phase commit protocol for both EJB CMP 2.0 and EJB CMP 1.1.

- Use standard programming techniques to optimize transaction processing. For example, properly demarcate transaction boundaries and complete transactions quickly.

- Use a database connection from a local TxDataSource—on the WebLogic Server instance on which the EJB is running. Do not use a connection from a TxDataSource on a remote WebLogic Server instance.
Be sure to tune the EJB cache to ensure maximum performance in transactional EJB applications. For more information, see Programming WebLogic Server Enterprise Java Beans at http://e-docs.bea.com/wls/docs81/ejb/index.html.

For general guidelines about the WebLogic Server Transaction Service, see “Capabilities and Limitations.”

Transaction Attributes

This section includes the following sections:

- About Transaction Attributes for EJBs
- Transaction Attributes for Container-Managed Transactions
- Transaction Attributes for Bean-Managed Transactions

About Transaction Attributes for EJBs

Transaction attributes determine how transactions are managed in EJB applications. For each EJB, the transaction attribute specifies whether transactions are demarcated by the WebLogic Server EJB container (container-managed transactions) or by the EJB itself (bean-managed transactions). The setting of the transaction-type element in the deployment descriptor determines whether an EJB is container-managed or bean-managed. See Chapter 16, “Support for Transactions,” and Chapter 21, “Deployment Descriptor,” in the EJB Specification 2.0, for more information about the transaction-type element.

In general, the use of container-managed transactions is preferred over bean-managed transactions because application coding is simpler. For example, in container-managed transactions, transactions do not need to be started explicitly.

WebLogic Server fully supports method-level transaction attributes as defined in Section 16.4 in the EJB Specification 2.0.

Transaction Attributes for Container-Managed Transactions

For container-managed transactions, the transaction attribute is specified in the container-transaction element in the deployment descriptor. Container-managed transactions include all entity beans and any stateful or stateless session beans with a transaction-type set to Container. For more information about these elements, see Programming WebLogic Server Enterprise JavaBeans at http://e-docs.bea.com/wls/docs81/ejb/index.html.
The Application Assembler can specify the following transaction attributes for EJBs and their business methods:

- NotSupported
- Supports
- Required
- RequiresNew
- Mandatory
- Never

For a detailed explanation about how the WebLogic Server EJB container responds to the trans-attribute setting, see section 17.6.2 in the EJB Specification 2.0.

The WebLogic Server EJB container automatically sets the transaction timeout if a timeout value is not defined in the deployment descriptor. The container uses the value of the Timeout Seconds configuration parameter. The default timeout value is 30 seconds.

For more information on transaction configuration parameters, see Chapter 2, “Configuring and Managing Transactions,” in this guide and in the Administration Console Online Help.

For EJBs with container-managed transactions, the EJBs have no access to the javax.transaction.UserTransaction interface, and the entering and exiting transaction contexts must match. In addition, EJBs with container-managed transactions have limited support for the setRollbackOnly and getRollbackOnly methods of the javax.ejb.EJBContext interface, where invocations are restricted by rules specified in Sections 16.4.4.2 and 16.4.4.3 of the EJB Specification 2.0.

Transaction Attributes for Bean-Managed Transactions

For bean-managed transactions, the bean specifies transaction demarcations using methods in the javax.transaction.UserTransaction interface. Bean-managed transactions include any stateful or stateless session beans with a transaction-type set to Bean. Entity beans cannot use bean-managed transactions.

For stateless session beans, the entering and exiting transaction contexts must match. For stateful session beans, the entering and exiting transaction contexts may or may not match. If they do not match, the WebLogic Server EJB container maintains associations between the bean and the nonterminated transaction.

Session beans with bean-managed transactions cannot use the setRollbackOnly and getRollbackOnly methods of the javax.ejb.EJBContext interface.
Participating in a Transaction

When the EJB Specification 2.0 uses the phrase “participating in a transaction,” BEA interprets this to mean that the bean meets either of the following conditions:

- The bean is invoked in a transactional context (container-managed transaction).
- The bean begins a transaction using the UserTransaction API in a bean method invoked by the client (bean-managed transaction), and it does not suspend or terminate that transaction upon completion of the corresponding bean method invoked by the client.

Transaction Semantics

This topic contains the following sections:

- Transaction Semantics for Container-Managed Transactions
- Transaction Semantics for Bean-Managed Transactions

The EJB Specification 2.0 describes semantics that govern transaction processing behavior based on the EJB type (entity bean, stateless session bean, or stateful session bean) and the transaction type (container-managed or bean-managed). These semantics describe the transaction context at the time a method is invoked and define whether the EJB can access methods in the javax.transaction.UserTransaction interface. EJB applications must be designed with these semantics in mind.

Transaction Semantics for Container-Managed Transactions

For container-managed transactions, transaction semantics vary for each bean type.
Table 5-1 describes the transaction semantics for stateful session beans in container-managed transactions.

Table 5-1  Transaction Semantics for Stateful Session Beans in Container-Managed Transactions

</tr>
</tbody>
</table>
Transaction Semantics for Bean-Managed Transactions

For bean-managed transactions, the transaction semantics differ between stateful and stateless session beans. For entity beans, transactions are never bean-managed.

Transaction Semantics for Stateful Session Beans

Table 5-4 describes the transaction semantics for stateful session beans in bean-managed transactions.

Session Synchronization

A stateful session bean using container-managed transactions can implement the javax.ejb.SessionSynchronization interface to provide transaction synchronization notifications. In addition, all methods on the stateful session bean must support one of the following transaction attributes: REQUIRES_NEW, MANDATORY or REQUIRED. For more
information about the javax.ejb.SessionSynchronization interface, see Section 6.5.3 in
the EJB Specification 2.0.

Synchronization During Transactions

If a bean implements SessionSynchronization, the WebLogic Server EJB container will
typically make the following callbacks to the bean during transaction commit time:

- afterBegin()
- beforeCompletion()
- afterCompletion()

The EJB container can call other beans or involve additional XA resources in the
beforeCompletion method. The number of calls is limited by the
beforeCompletionIterationLimit attribute. This attribute specifies how many cycles of
callbacks are processed before the transaction is rolled back. A synchronization cycle can occur
when a registered object receives a beforeCompletion callback and then enlists additional
resources or causes a previously synchronized object to be reregistered. The iteration limit
ensures that synchronization cycles do not run indefinitely.

Setting Transaction Timeouts

Bean providers can specify the timeout period for transactions in EJB applications. If the duration
of a transaction exceeds the specified timeout setting, then the Transaction Service rolls back the
transaction automatically.

Note: You must set the timeout before you begin() the transaction. Setting a timeout does not
affect transaction transactions that have already begun.

Timeouts are specified according to the transaction type:

- Container-managed transactions. The Bean Provider configures the
  trans-timeout-seconds attribute in the weblogic-ejb-jar.xml deployment
descriptor. For more information, see the Administration Guide.

  The Bean Provider should configure the trans-timeout-seconds attribute in the
  weblogic-ejb-jar.xml deployment descriptor.

- Bean-managed transactions. An application calls the
  UserTransaction.setTransactionTimeout method.
Handling Exceptions in EJB Transactions

WebLogic Server EJB applications need to catch and handle specific exceptions thrown during transactions. For detailed information about handling exceptions, see Chapter 17, “Exception Handling,” in the EJB Specification 2.0 published by Sun Microsystems, Inc.

For more information about how exceptions are thrown by business methods in EJB transactions, see the following tables in Section 17.3: Table 12 (for container-managed transactions) and Table 13 (for bean-managed transactions).

For a client’s view of exceptions, see Section 17.4, particularly Section 12.4.1 (application exceptions), Section 17.4.2 (java.rmi.RemoteException), Section 17.4.2.1 (javax.transaction.TransactionRolledBackException), and Section 17.4.2.2 (javax.transaction.TransactionRequiredException).
Transactions in RMI Applications

The following sections provide guidelines and additional references for using transactions in RMI applications that run under BEA WebLogic Server:

- Before You Begin
- General Guidelines

Before You Begin

Before you begin, read Chapter 1, “Introducing Transactions,” particularly the following topics:

- “Transactions in WebLogic Server RMI Applications” on page 1-8
- “Transactions Sample RMI Code” on page 1-13

For more information about RMI applications, see Programming WebLogic RMI at http://e-docs.bea.com/wls/docs81/rmi/index.html.

General Guidelines

The following general guidelines apply when implementing transactions in RMI applications for WebLogic Server:

- WebLogic Server allows for flat transactions only. Transactions cannot be nested.
- Use standard programming techniques to optimize transaction processing. For example, properly demarcate transaction boundaries and complete transactions quickly.
For RMI applications, callback objects are not recommended for use in transactions because they are not subject to WebLogic Server administration.

By default, all method invocations on the remote objects are transactional. If a callback object is required, you must compile these classes using the WebLogic RMI compiler (weblogic.rmic) using the -nontransactional flag.

In RMI applications, an RMI client can initiate a transaction, but all transaction processing must occur on server objects or remote objects hosted by WebLogic Server. Remote objects hosted on a client JVM cannot participate in the transaction processing.

As a work-around, you can suspend the transaction before making a call to a remote object on a client JVM, and then resume the transaction after the remote operation returns.

For general guidelines about the WebLogic Server Transaction Service, see “Capabilities and Limitations.”
Using Third-Party JDBC XA Drivers with WebLogic Server

This section discusses the following topics:

- “Overview of Third-Party XA Drivers” on page 7-1
- “Third-Party Driver Configuration and Performance Requirements” on page 7-2

Overview of Third-Party XA Drivers

This section provides an overview of using third-party JDBC two-tier drivers with WebLogic Server in distributed transactions. These drivers provide connectivity between WebLogic Server connection pools and the DBMS. Drivers used in distributed transactions are designated by the driver name followed by /XA; for example, Oracle Thin/XA Driver.

Table of Third-Party XA Drivers

The following table summarizes known functionality of these third-party JDBC/XA drivers when used with WebLogic Server:

| Table 7-1  Two-Tier JDBC/XA Drivers |
|-----------------|-----------------------------------|
| **Driver/Database Version** | **Comments**                     |
| Oracle Thin Driver XA       | See “Using Oracle Thin/XA Driver” on page 7-2. |
Third-Party Driver Configuration and Performance Requirements

Here are requirements and guidelines for using specific third-party XA drivers with WebLogic Server.

Using Oracle Thin/XA Driver

WebLogic Server ships with the Oracle Thin Driver version 10g (10.1.0.2.0) preconfigured and ready to use. If you want to update the driver or use a different version, see Using the Oracle Thin Driver in Programming WebLogic JDBC at http://e-docs.bea.com/wls/docs81/jdbc/thirdparty.html#update_thin.

The following sections provide information for using the Oracle Thin/XA Driver with WebLogic Server.

Software Requirements for the Oracle Thin/XA Driver

The Oracle Thin/XA Driver requires the following:

- Java 2 SDK 1.4.x or later. WebLogic Server requires a Java 2 SDK 1.4.X (and ships with SDK 1.4.1.XX).
  
  **Note:** The Oracle 10g and 9.2 Thin driver (ojdbc14.jar) is the only versions of the driver supported for use with a Java 2 SDK 1.4.X.

- Oracle server configured for XA functionality (limitation does not apply for non-XA usage).

Table 7-1  Two-Tier JDBC/XA Drivers

<table>
<thead>
<tr>
<th>Driver/Database Version</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>IBM DB2 Type 2</td>
<td>See “Using the IBM DB2 Type 2 XA JDBC Driver” on page 7-7.</td>
</tr>
<tr>
<td>Sybase jConnect/XA</td>
<td>See “Using Sybase jConnect 5.5/XA Driver” on page 7-8.</td>
</tr>
<tr>

<td></td>
</tr>
<tr>
<td>• Adaptive Server Enterprise 12.0</td>
<td></td>
</tr>
</tbody>
</table>

IBM DB2 Type 2

(x)

SDK 1.4.1_x

Note:

The Oracle 10g and 9.2 Thin driver (ojdbc14.jar) is the only versions of the driver supported for use with a Java 2 SDK 1.4.X.

• Oracle server configured for XA functionality (limitation does not apply for non-XA usage).
Known Oracle Thin Driver Issues

Table 7-2 lists known issues and workarounds for the Oracle Thin driver. See the Oracle Web site for the most up-to-date information about these issues.

Table 7-2  Oracle Thin Driver Known Issues and Workarounds

<table>
<thead>
<tr>
<th>Description</th>
<th>Oracle Bug</th>
<th>Comments/Workarounds for WebLogic Server</th>
</tr>
</thead>
<tbody>
<tr>
<td>When using the 9.2.0.3 or earlier version of the Oracle Thin driver, after restarting WebLogic Server, you may see an XAER_PROTO error or an intermittent hang.</td>
<td>2717235</td>
<td>This situation occurs because on server restart, WebLogic Server calls XA.recover() to recover any pending transactions. With the 9.2.0.3 or earlier version of the Oracle Thin driver, the Oracle DBMS opens a local transaction to complete the transaction recovery work, but the local transaction is never closed. When the connection used to recover transactions is returned to the connection pool and is then reused by an application, the local transaction is still present. With the first operation on the connection, an XAER_PROTO error is thrown. (If TestConnsOnReserve is set to true, the connection test is the first operation on the connection.) WebLogic Server then attempts to unregister the connection with the resource and waits a fixed amount of time for all transaction work on the resource to complete. This may appear as a hang. Oracle has provided a patch for this bug. You can download the patch from the Oracle Metalink Web site at <a href="http://metalink.oracle.com">http://metalink.oracle.com</a>. Refer to the Oracle bug number 2717235. This issue is fixed in version 9.2.0.4 and 10G.</td>
</tr>
</tbody>
</table>
Using Third-Party JDBC XA Drivers with WebLogic Server

The 9.2.0.1 and 9.2.0.2 versions of the Oracle Thin driver do not allow you to work with a BLOB in tables that also contain a long raw. When you retrieve a BLOB from the table and call blob.length(), you will get a SQL protocol violation.

This issue is fixed in version 9.2.0.3 and 10G.

When using the Oracle 9.2.0.1 or 9.2.0.2 Thin driver, you will get a null pointer exception when you run `addBatch` with `setNull` with a data conversion. For example, the following will fail with the Oracle 9.2.0 Thin driver:

1. `pstmt.setNull(1, java.sql.Types.REAL)`
2. `pstmt.addBatch()`
3. `pstmt.setNull(1, java.sql.Types.VARCHAR)`

This issue is fixed in version 9.2.0.3 and 10G.

The 9.2.0.1 and 9.2.0.2 versions of the Oracle Thin driver do not allow you to work with a CLOB in tables that also contain a long. When you retrieve a CLOB from the table and call clob.length(), you will get a SQL protocol violation.

Workaround: In this scenario, you can read the LONG column before calling clob.length().

This issue is fixed in version 9.2.0.3 and 10G.

The 9.2.0.1 and 9.2.0.2.0 versions of the Oracle Thin driver do not allow you to use "alter session set NLS_DATE_FORMAT='YYYY-MM-DD HH24:MI:SS'" to change the default Oracle timestamp format. Previous versions did allow this.

TAR number 2677656.995.

Fixed in 9.2.0.2.1.

Oracle has provided a patch for this bug. You can download the patch from the Oracle Metalink Web site at http://metalink.oracle.com. Refer to the Oracle bug number 2632931.

ORA-01453 - SET TRANSACTION must be first statement of transaction

When using the Oracle Thin/XA driver, you cannot change the transaction isolation level for a transaction. Transactions use the default transaction isolation as set for the database.

Table 7-2  Oracle Thin Driver Known Issues and Workarounds

<table>
<thead>
<tr>
<th>Description</th>
<th>Oracle Bug</th>

</tbody>
</table>
Set the Environment for the Oracle Thin/XA Driver

Configure WebLogic Server

Enable XA on the Database Server

To prepare the database for XA, perform these steps:

1. Log on to sqlplus as system user, e.g. sqlplus sys/CHANGE_ON_INSTALL@<DATABASE_ALIAS_NAME>
2. Execute the following command: @xaview.sql
3. Grant the following permissions:

- grant select on v$xatrans$ to public (or <user>);
- grant select on pending_trans$ to public;
- grant select on dba_2pc_pending to public;
- grant select on dba_pending_transactions to public;
- (when using the Oracle Thin driver 10.1.0.3 or later)
  grant execute on dbms_system to <user>;

If the above steps are not performed on the database server, normal XA database queries and updates may work fine. However, when the Weblogic Server Transaction Manager performs recovery on a re-boot after a crash, recover for the Oracle resource will fail with \texttt{XAER_RMERR}. Crash recovery is a standard operation for an XA resource.

**Oracle Thin/XA Driver Configuration Properties**

The following table contains sample code for configuring a Connection Pool:

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Property Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>jtaXAPool</td>
</tr>
<tr>

</tr>
</tbody>
</table>

The following table contains sample attributes for configuring a TxDataSource. To create a TxDataSource from the Administration Console, select Honor Global Transactions when creating a data source.
Third-Party Driver Configuration and Performance Requirements

The following sections describe how to set your environment to use the Type2 DB2 7.2/XA Driver with WebLogic Server.

For installation instructions and connection pool configuration instructions, see "Installing and Using the IBM DB2 Type 2 JDBC Driver" in Programming WebLogic JDBC at http://e-docs.bea.com/wls/docs81/jdbc/thirdparty.html#db2.

**Table 7-3 Oracle Thin/XA Driver: TxDataSource Configuration**

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Property Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>jtaXADS</td>
</tr>
<tr>
<td>Targets</td>
<td>myserver,server1</td>
</tr>
<tr>
<td>JNDIName</td>
<td>jtaXADS</td>
</tr>
<tr>
<td>PoolName</td>
<td>jtaXAPool</td>
</tr>
</tbody>
</table>

**Using the IBM DB2 Type 2 XA JDBC Driver**

The following sections describe how to set your environment to use the Type2 DB2 7.2/XA Driver with WebLogic Server.

For installation instructions and connection pool configuration instructions, see "Installing and Using the IBM DB2 Type 2 JDBC Driver" in Programming WebLogic JDBC at http://e-docs.bea.com/wls/docs81/jdbc/thirdparty.html#db2.

**Set the Environment for the DB2 7.2/XA Driver**

Set your environment as follows:

- Execute the batch file usejdbc2.bat located in the <db2>/java12 directory to extract the correct version of the db2java.zip file and move it to the proper location. This enables the JDBC2.0 features of the driver. Make sure that no DB2 processes are running before executing this batch file.
- Include <db2>/java/db2java.zip in the CLASSPATH environment variable.
- Include <db2>/bin in PATH environment variable.

Where <db2> represents the directory in which the DB2 server is installed.

**Limitation and Restrictions using DB2 as an XAResource**

1. In case of multiple connection-pooled configurations, each connection pool should have separate database instance.
2. A transaction cannot be initiated with a resource that is already associated with a suspended transaction. In this case, a `javax.transaction.InvalidTransactionException` (attempt to resume an inactive transaction) is thrown. If in between `suspend` and `resume`, an intermediate transaction enlists the same resource as used in the suspended transaction, a `javax.transaction.InvalidTransaction` exception is thrown. If a different resource is used inside the intermediate transaction, it works fine.

**Using Sybase jConnect 5.5/XA Driver**

The following sections provide important configuration information and performance issues when using the Sybase jConnect Driver 5.5/XA Driver.

**Known Sybase jConnect 5.5/XA Issues**

These are the known issues and BEA workarounds:

<table>
<thead>
<tr>
<th>Description</th>
<th>Sybase Bug</th>
<th>Comments/Workarounds for WebLogic Server</th>
</tr>
</thead>
<tbody>
<tr>
<td>When calling <code>setAutoCommit(true)</code> the following exception is thrown: <code>java.sql.SQLException: JZ0S3: The inherited method </code>setAutoCommit(true)` cannot be used in this subclass.</td>
<td>10726192</td>
<td>No workaround. Vendor fix required.</td>
</tr>
<tr>
<td>When driver used in distributed transactions, calling <code>XAResource.end(TMSUSPEND)</code> followed by <code>XAResource.end(TMSUCCESS)</code> results in <code>XAER_RMERR</code>.</td>
<td>10727617</td>
<td>WebLogic Server has provided an internal workaround for this bug: Set the connection pool property <code>XAEndOnlyOnce=&quot;true&quot;</code>. Vendor fix has been requested.</td>
</tr>
<tr>
<td>An <code>OutOfMemoryError</code> is encountered as a result of a detached Sybase transaction.</td>
<td></td>
<td>Upgrade to the latest Sybase jConnect Driver</td>
</tr>
</tbody>
</table>

**Set Up the Sybase Server for XA Support**

Follow these instructions to set up the environment on your database server:
- Install license for Distributed Transaction Management.
- Run `sp_configure "enable DTM",1` to enable transactions.
- Run `sp_configure "enable xact coordination",1`.
- Run `grant role dtm_tm_role` to `<USER_NAME>`.
- Copy the sample `xa_config` file from the `SYBASE_INSTALL\OCS-12.0\sample\xa-dtm` subdirectory up three levels to `SYBASE_INSTALL`, where `SYBASE_INSTALL` is the directory of your Sybase server installation. For example:

  ```
  $ SYBASE_INSTALL\xa_config
  ```

  - Edit the `xa_config` file. In the first `[xa]` section, modify the sample server name to reflect the correct server name.

  To prevent deadlocks when running transactions, enable row level lock by default:

  - Run `sp_configure "lock scheme",0,` `datarows`

  **Note:** Both the `jConnect.jar` and `jconn2.jar` files are included in the `WL_HOME\server\lib` folder and are referenced in the `weblogic.jar` manifest file. When you start WebLogic Server, the drivers are loaded automatically and are ready to use with WebLogic Server. To use these drivers with the WebLogic utilities or with other applications, you must include the path to these files in your `CLASSPATH`.

**Notes About XA and Sybase Adaptive Server**

Correct support for XA connections is available in the Sybase Adaptive Server Enterprise 12.0 and later versions only. XA connections with WebLogic Server are not supported on Sybase Adaptive Server 11.5 and 11.9.

**Execution Threads and Transactions in Sybase Adaptive Server**

Prior to Adaptive Server version 12.0, all resources of a transaction were privately owned by a single task on the server. The server could not share a transaction with any task other than the one that initiated the transaction. Adaptive Server version 12.x includes support for the suspend and join semantics used by XA-compliant transaction managers (such as WebLogic Server). Transactions can be shared among different execution threads, or may not be associated with an execution thread (detached).
Setting the Timeout for Detached Transactions

On the Sybase server, you can set the dtm detach timeout period, which sets the amount of time (in minutes) that a distributed transaction branch can remain in the detached state (without an associated execution thread). After this period, the DBMS automatically rolls back the transaction. The dtm detach timeout period applies to all transactions on the database server. It cannot be set for each transaction.

For example, to automatically rollback transactions after being detached for 10 minutes, use the following command:

```
sp_configure 'dtm detach timeout period', 10
```

You should set the dtm detach timeout period higher than the transaction timeout to prevent the database server from rolling back the transaction before the transaction times out in WebLogic Server. For information about setting the transaction timeout, see "JTA" in the Administration Console Online Help.

For more information about the dtm detach timeout period, see the Sybase documentation.

Transaction Behavior on Sybase Adaptive Server

If a global transaction is started on the Sybase server, but is not completed, the outcome of the transaction varies depending on the transaction state before the transaction is abandoned:

- If the client is terminated before the xa.end call, the transaction is rolled back.
- If the client is terminated after the xa.end call, the transaction remains on the database server (and holds all relevant locks).
- If an application calls xa.start but has not called xa.end and the application terminates unexpectedly, the database server immediately rolls back the transaction and frees locks held by the transaction.
- If an application calls xa.start and xa.end and the application terminates unexpectedly, the database server rolls back the transaction and frees locks held by the transaction after the dtm detach timeout period has elapsed. See “Setting the Timeout for Detached Transactions” on page 7-10.
- If an application calls xa.start and xa.end, and then the transaction is prepared, if the application terminates unexpectedly, the transaction will persist so that it can be properly recovered. The Transaction Manager must call rollback or commit to complete the transaction.
Connection Pools for the Sybase jConnect 5.5/XA Driver

The following table contains sample code for configuring a Connection Pool:

Table 7-5  Sybase jConnect 5.5/XA Driver: Sample Connection Pool Configuration

</tbody>
</table>

Other Third-Party XA Drivers

To use other third-party XA-compliant JDBC drivers, you must include the path to the driver class libraries in your `CLASSPATH` and follow the configuration instructions provided by the vendor.
External, third-party systems can participate in distributed transactions coordinated by the WebLogic Server transaction manager by registering a `javax.transaction.xa.XAResource` implementation with the WebLogic Server transaction manager. The WebLogic Server transaction manager then drives the XAResource as part of its Two-Phase Commit (2PC) protocol. This is referred to as “exporting transactions.”

By exporting transactions, you can integrate third-party transaction managers with the WebLogic Server transaction manager if the third-party transaction manager implements the `XAResource` interface. With an exported transaction, the third-party transaction manager would act as a subordinate transaction manager to the WebLogic Server transaction manager.

WebLogic Server can also participate in distributed transactions coordinated by third-party systems (sometimes referred to as foreign transaction managers). The WebLogic Server processing is done as part of the work of the external transaction. The third-party transaction manager then drives the WebLogic Server transaction manager as part of its commit processing. This is referred to as “importing transactions.”

Details about coordinating third-party systems within a transaction (exporting transactions) are described in this section. Details about participating in transactions coordinated by third-party systems (importing transactions) are described in Chapter 9, “Participating in Transactions Managed by a Third-Party Transaction Manager.” Note that WebLogic Server IIOP, WebLogic Tuxedo Connector (WTC) gateway, and BEA Java Adapter for Mainframe (JAM) gateway internally use the same mechanism described in these chapters to import and export transactions in WebLogic Server.
The following sections describe how to configure third-party systems to participate in transactions coordinated by the WebLogic Server transaction manager:

- “Overview of Coordinating Distributed Transactions with Foreign XAResources” on page 8-2
- “Registering an XAResource to Participate in Transactions” on page 8-3
- “Enlisting and Delisting an XAResource in a Transaction” on page 8-6
- “Commit processing” on page 8-9
- “Recovery” on page 8-10
- “Resource Health Monitoring” on page 8-11
- “J2EE Connector Architecture Resource Adapter” on page 8-12
- “Implementation Tips” on page 8-12
- “FAQs” on page 8-14
- “Additional Documentation about JTA” on page 8-14

**Overview of Coordinating Distributed Transactions with Foreign XAResources**

In order to participate in distributed transactions coordinated by the WebLogic Server transaction manager, third-party systems must implement the `javax.transaction.xa.XAResource` interface and then register its `XAResource` object with the WebLogic Server transaction manager. For details about implementing the `javax.transaction.xa.XAResource` interface, refer to the J2EE Javadocs at http://java.sun.com/j2ee/sdk_1.3/techdocs/api/index.html.

During transaction processing, you must enlist the `XAResource` object of the third-party system with each applicable transaction object.

Figure 8-1 shows the process for third-party systems to participate in transactions coordinated by the WebLogic Server transaction manager.
Figure 8-1   Distributed Transactions with Third-Party Participants

Depending on the enlistment mode that you use when you enlist an XAResource object with a transaction, WebLogic Server may automatically delist the XAResource object at the appropriate time. For more information about enlistment and delistment, see “Enlisting and Delisting an XAResource in a Transaction” on page 8-6. For more information about registering XAResource objects with the WebLogic Server transaction manager, see “Registering an XAResource to Participate in Transactions” on page 8-3.

Registering an XAResource to Participate in Transactions

In order to participate in distributed transactions coordinated by the WebLogic Server transaction manager, third-party systems must implement the javax.transaction.xa.XAResource interface and then register its XAResource object with the WebLogic Server transaction manager. Registration is required to:

- Specify the transaction branch qualifier for the XAResource. The branch qualifier identifies the transaction branch of the resource manager instance and is used for all distributed transactions that the resource manager (RM) instance participates in. Each transaction branch represents a unit of work in the distributed transaction and is isolated from other branches. Each transaction branch receives exactly one set of prepare-commit
calls during Two-Phase Commit (2PC) processing. The WebLogic Server transaction manager uses the resource name as the transaction branch qualifier.

A resource manager instance is defined by the `XAResource.isSameRM` method. XAResource instances that belong to the same resource manager instance should return true for `isSameRM`. Note that you should avoid registering the same resource manager instance under different resource names (i.e., different resource branches) to avoid confusion of transaction branches.

- Specify the enlistment mode. For a resource manager instance to participate in a specific distributed transaction, it needs to enlist an XAResource instance with the JTA `javax.transaction.Transaction` object. The WebLogic Server transaction manager provides three enlistment modes: static, dynamic, and object-oriented. Enlistment modes are discussed in greater detail in “Enlisting and Delisting an XAResource in a Transaction” on page 8-6.

- Bootstrap the XAResource in the event that the WebLogic Server transaction manager must perform crash recovery. (The JTA Specification does not define a standard API to do so; refer to JTA 1.0.1 Specification Section 3.4.8 for details).

The JTA 1.0.1 specification section 3.4.9 suggests that the transaction manager is responsible for assigning the branch qualifiers. However, for recovery to work properly, the same transaction branch qualifier needs to be supplied both at normal processing and upon crash recovery. As the transaction branch qualifier is specified during registration, registration with the WebLogic Server transaction manager is required to support crash recovery and normal transaction processing.

During recovery, the WebLogic Server transaction manager performs the following tasks:

- It reads its transaction log and for those XA resources that participated in the distributed transactions that were logged, it continues the second phase of the 2PC protocol to commit the XA resources with the specified branch qualifier.

- It resolves any other in-doubt transactions of the XA resources by calling `XAResource.recover`. It then commits or rolls back the returned transactions (Xids) that belonged to it. (Note that the returned Xids would already have the specified branch qualifier.)

**Note:** Registration is a per-process action (compared with enlistment and delistment which is per-transaction).

Failure to register the XAResource implementation with the WebLogic Server transaction manager may result in unexpected transaction branching behavior. If registration is not performed before the XA resource is enlisted with a WebLogic Server distributed transaction, the WebLogic Server transaction manager will use the class name of the XAResource instance as the
Registering an XAResource to Participate in Transactions

resource name (and thus the branch qualifier), which may cause undesirable resource name and transaction branch conflicts.

Each resource manager instance should register itself only once with the WebLogic Server transaction manager. Each resource manager instance, as identified by the resource name during registration, adds significant overhead to the system during recovery and commit processing and health monitoring, increases memory used by associated internal data structures, reduces efficiency in searching through internal maps, and so forth. Therefore, for scalability and performance reasons, you should not indiscriminately register XAResource instances under different transaction branches.

Note that the JTA XAResource adopts an explicit transaction model, where the Xid is always explicitly passed in the XAResource methods and a single resource manager instance handles all of the transactions. This is in contrast to the CORBA OTS Resource, which adopts an implicit transaction model, where there is a different OTS Resource instance for each transaction that it participates in. You should use the JTA model when designing an XAResource.

Each foreign resource manager instance should register an XAResource instance with the WebLogic Server transaction manager upon server startup. In WebLogic Server, you can use startup classes to register foreign transaction managers. For information about configuring startup classes, see the Administration Console Online Help.

Follow these steps to register the resource manager with the WebLogic Server transaction manager:

1. Obtain the WebLogic Server transaction manager using JNDI or the TxHelper interface:

   ```java
   import javax.transaction.xa.XAResource;
   import weblogic.transaction.TransactionManager;
   import weblogic.transaction.TxHelper;

   InitialContext initCtx = ...; // initialized to the initial context
   TransactionManager tm = TxHelper.getTransactionManager();
   
   or
   
   TransactionManager tm = (TransactionManager)initCtx.lookup("weblogic.transaction.TransactionManager");
   
   or
   
   TransactionManager tm = (TransactionManager)initCtx.lookup("javax.transaction.TransactionManager");
   ```

Programming WebLogic JTA 8-5
2. Register the XA resource instance with the WebLogic Server transaction manager:

   String name = ... ; // name of the RM instance
   XAResource res = ... ; // an XAResource instance of the RM instance
   tm.registerResource(name, res); // register a resource with the standard enlistment mode
   
or
   tm.registerDynamicResource(name, res); // register a resource with the dynamic enlistment mode
   
or
   tm.registerStaticResource(name, res); // register a resource with the static enlistment mode

Refer to “Enlisting and Delisting an XAResource in a Transaction” on page 8-6 for a detailed discussion of the different enlistment modes. Note that when you register the XAResource, you specify the enlistment mode that will be used subsequently, but you are not actually enlisting the resource during the registration process. Actual enlistment should be done with the transaction (not at server startup) using a different API, which is also discussed in detail in “Enlisting and Delisting an XAResource in a Transaction.”

Each XAResource instance that you register is used for recovery and commit processing of multiple transactions in parallel. Make sure that the XAResource instance supports resource sharing as defined in JTA Specification Version 1.0.1B Section 3.4.6.

**Note:** Duplicate registration of the same XAResource is ignored.

You should unregister the XAResource from the WebLogic Server transaction manager when the resource no longer accept new requests. Use the following method to unregister the XAResource:

   tm.unregisterResource(name, res);

---

**Enlisting and Delisting an XAResource in a Transaction**

For an XAResource to participate in a distributed transaction, the XAResource instance must be enlisted with the Transaction object. Depending on the enlistment mode, you may need to perform different actions. The WebLogic Server transaction manager supports the following enlistment modes:

- **Standard Enlistment**
- **Dynamic Enlistment**
Enlisting and Delisting an XAResource in a Transaction

- **Static Enlistment**

  Even though you enlist the XAResource with the Transaction object, the enlistment mode is determined when you register the XAResource with the WebLogic Server transaction manager, not when you enlist the resource in the Transaction. See “Registering an XAResource to Participate in Transactions” on page 8-3.

  XAResource.start and end calls can be expensive. The WebLogic Server transaction manager provides the following optimizations to minimize the number of these calls:

  - **Delayed delistment:**

    Whether or not your XAResource implementation performs any explicit delistment or not, the WebLogic Server transaction manager always delays delisting of any XAResource instances that are enlisted in the current transaction until immediately before the following events, at which time the XAResource is delisted:
    - Returning the call to the caller, whether it is returned normally or with an exception
    - Making a call to another server

  - **Ignored duplicate enlistment:**

    The WebLogic Server transaction manager ignores any explicit enlistment of an XAResource that is already enlisted. This may happen if the XAResource is explicitly delisted (which is delayed or ignored by the WebLogic Server transaction manager as mentioned above) and is subsequently re-enlisted within the duration of the same call.

  By default, the WebLogic Server transaction manager delists the XAResource by calling XAResource.end with the TMSUSPEND flag. Some database management systems may keep cursors open if XAResource.end is called with TMSUSPEND, so you may prefer to delist an XAResource by calling XAResource.end with TMSUCCESS wherever possible. To do so, you can implement the weblogic.transaction.XAResource interface (instead of the javax.transaction.xa.XAResource), which includes the getDelistFlag method. See the WebLogic Server Javadocs for more details.

- **Standard Enlistment**

  With standard enlistment mode, you need to enlist the XAResource instance only once with the Transaction object. Also, it is possible to enlist more than one XAResource instance of the same branch with the same transaction. The WebLogic Server transaction manager ensures that XAResource.end is called on all XAResource instances when appropriate (as discussed below). The WebLogic Server transaction manager ensures that each branch receives only one set of
prepare-commit calls during transaction commit time. However, attempting to enlist a particular XAResource instance when it is already enlisted will be ignored.

Standard enlistment simplifies enlistment, but it may also cause unnecessary enlistment and delistment of an XAResource if the resource is not accessed at all within the duration of a particular method call.

To enlist an XAResource with the Transaction object, follow these steps:

1. Obtain the current Transaction object using the TransactionHelper interface:

   ```java
   import weblogic.transaction.Transaction; // extends javax.transaction.Transaction
   import weblogic.transaction.TransactionHelper;
   Transaction tx = TransactionHelper.getTransaction();
   ```

2. Enlist the XAResource instance with the Transaction object:

   ```java
   tx.enlistResource(res);
   ```

After the XAResource is enlisted with the Transaction, the WebLogic Server transaction manager manages any subsequent delistment (as described in “Enlisting and Delisting an XAResource in a Transaction”) and re-enlistment. For standard enlistment mode, the WebLogic Server transaction manager re-enlists the XAResource in the same Transaction upon the following occasions:

- Before a request is executed
- After a reply is received from another server. (The WebLogic Server transaction manager delists the XAResource before sending the request to another server.)

**Dynamic Enlistment**

With the dynamic enlistment mode, you must enlist the XAResource instance with the Transaction object before every access of the resource. With this enlistment mode, only one XAResource instance from each transaction branch is allowed to be enlisted for each transaction at a time. The WebLogic Server transaction manager ignores attempts to enlist additional XAResource instances (of the same transaction branch) after the first instance is enlisted, but before it is delisted.

With dynamic enlistment, enlistments and delistments of XAResource instances are minimized. The steps for enlisting the XAResource is the same as described in “Standard Enlistment.”
Commit processing

Static Enlistment

With static enlistment mode, you do not need to enlist the XAResource instance with any Transaction object. The WebLogic Server transaction manager implicitly enlists the XAResource for all transactions with the following events:

- Before a request is executed
- After a reply is received from another server

**Note:** Consider the following before using the static enlistment mode:

- Static enlistment mode eliminates the need to enlist XAResources. However, unnecessary enlistment and delistment may result, if the resource is not used in a particular transaction.
- A faulty XAResource may adversely affect all transactions even if the resource is not used in the transaction.
- A single XAResource instance is used to associate different transactions with different threads at the same time. That is, XAResource.start and XAResource.end can be called on the same XAResource instance in an interleaved manner for different Xids in different threads. You must ensure that the XAResource supports such an association pattern, which is not required by the JTA specification.

Due to the performance overhead, poor fault isolation, and demanding transaction association requirement, static enlistment should only be used with discretion and after careful consideration.

Commit processing

During commit processing, the WebLogic Server transaction manager will either use the XAResource instances currently enlisted with the transaction, or the XAResource instances that are registered with the transaction manager to perform the two-phase commit. The WebLogic Server transaction manager ensures that each transaction branch will receive only one set of prepare-commit calls. You must ensure that any XAResource instance can be used for commit processing for multiple transactions simultaneously from different threads, as defined in JTA Specification Version 1.0.1B Section 3.4.6.
Coordinating XAResources with the WebLogic Server Transaction Manager

Recovery

When a WebLogic Server server is restarted, the WebLogic Server transaction manager reads its own transaction logs (with log records of transactions that are successfully prepared, but may not have completed the second commit phase of 2PC processing). The WebLogic Server transaction manager then continues to retry commit of the XAResources for these transactions. As discussed in “Registering an XAResource to Participate in Transactions,” one purpose of the WebLogic Server transaction manager resource registration API is for bootstrapping XAResource instances for recovery. You must make sure that an XAResource instance is registered with the WebLogic Server transaction manager upon server restart. The WebLogic Server transaction manager retries the commit call every minute, until a valid XAResource instance is registered with the WebLogic Server transaction manager.

When a transaction manager that is acting as a transaction coordinator crashes, it is possible that the coordinator may not have logged some in-doubt transactions in the coordinator’s transaction log. Thus, upon server restart, the coordinator needs to call XAResource.recover on the resource managers, and roll back the in-doubt transactions that were not logged. As with commit retries, the WebLogic Server transaction manager retries XAResource.recover every 5 minutes, until a valid XAResource instance is registered with the WebLogic Server transaction manager.

The WebLogic Server transaction manager checkpoints a new XAResource in its transaction log when it is first enlisted with the WebLogic Server transaction manager. Upon server restart, the WebLogic Server transaction manager then calls XAResource.recover on all the resources previously checkpointed (removed from the transaction log after the transaction completed). A resource is only removed from a checkpoint record if it has not been accessed for the last PurgeResourceFromCheckpointIntervalSeconds interval (default is 24 hours). Therefore, to reduce the resource recovery overhead, you should make sure that only a small number of resource manager instances are registered with the WebLogic Server transaction manager.

When implementing XAResource.recover, you should use the flags as described in the X/Open XA specification as follows:

- When the WebLogic Server transaction manager calls XAResource.recover with TMSTARTRSCAN, the resource returns the first batch of in-doubt Xids.

  The WebLogic Server transaction manager then calls XAResource.recover with TMNOFLAGS repeatedly, until the resource returns either null or a zero-length array to signal that there are no more Xids to recover. If the resource has already returned all the Xids in the previous XAResource.recover (TMSTARTRSCAN) call, then it can either return null or a zero-length array here, or it may also throw XAERPROTO, to indicate that it has already
finished and forgotten the previous recovery scan. A common XAResource.recover implementation problem is ignoring the flags or always returning the same set of Xids on XAResource.recover(TMNOFLAGS). This will cause the WebLogic Server transaction manager recovery to loop infinitely, and subsequently fail.

- The WebLogic Server transaction manager XAResource.recover with TMENDRSCAN flag to end the recovery scan. The resource may return additional Xids.

**Note:** It is possible that transactions that have already been completed successfully are re-committed upon server restart. This happens because of a WebLogic Server transaction log optimization: the WebLogic Server transaction manager never deletes individual log records from the transaction log file, but waits until all the transactions of a particular log file are completed successfully and deletes the whole file. As a result, upon server restart, some of the transactions read from a particular log file may have already completed successfully.

### Resource Health Monitoring

To prevent losing server threads to faulty XAResources, WebLogic Server JTA has an internal resource health monitoring mechanism. A resource is considered active if either there are no pending requests or the result from any of the XAResource pending requests is not XAER_RMFAIL. If an XAResource is not active within two minutes, the WebLogic Server transaction manager will declare it dead. Any further requests to the XAResource are shunned, and an XAER_RMFAIL XAException is thrown.

The two minute interval can be configured via the `maxXACallMillis` JTAMBean attribute. It is not exposed through the Administration Console. You can configure `maxXACallMillis` in the `config.xml` file. For example:

```xml
<Domin>
    ....
    <JTA>
        MaxXACallMillis="240000"
    </JTA>
    ....
</Domain>
```

To receive notification from the WebLogic Server transaction manager and to inform the WebLogic Server transaction manager whether it is indeed dead when the resource is about to be declared dead, you can implement `weblogic.transaction.XAResource` (which extends
Coordinating XAResources with the WebLogic Server Transaction Manager

javax.transaction.xa.XAResource) and register it with the transaction manager. The transaction manager will call the detectUnavailable method of the XAResource when it is about to declare it unavailable. If the XAResource returns true, then it will not be declared unavailable. If the XAResource is indeed unavailable, it can use this opportunity to perform cleanup and re-registration with the transaction manager. See the WebLogic Server Javadocs for weblogic.transaction.XAResource for more information.

J2EE Connector Architecture Resource Adapter

Besides registering with the WebLogic Server transaction manager directly, you can also implement the J2EE Connector Architecture resource adapter interfaces. When you deploy the resource adapter, the WebLogic Server J2EE container will register the resource manager's XAResource with the WebLogic Server transaction manager automatically.

For more information, see Programming WebLogic J2EE Connectors.

Implementation Tips

The following sections provide tips for exporting and importing transactions with the WebLogic Server transaction manager:

- “Sharing the WebLogic Server Transaction Log” on page 8-12
- “Transaction global properties” on page 8-13
- “TxHelper.createXid” on page 8-14

Sharing the WebLogic Server Transaction Log

The WebLogic Server transaction manager exposes the transaction log to be shared with system applications such as gateways. This provides a way for system applications to take advantage of the box-carrying (batching) transaction log optimization of the WebLogic Server transaction manager for fast logging. Note that it is important to release the transaction log records in a timely fashion. (The WebLogic Server transaction manager will only remove a transaction log file if all the records in it are released). Failure to do so may result in a large number of transaction log files, and could lead to re-commit of a large number of already committed transactions, or in an extreme case, circular collision and overwriting of transaction log files.

The WebLogic Server transaction manager exposes a transaction logger interface: weblogic.transaction.TransactionLogger. It is only available on the server, and it can be obtained with the following steps:
Implementation Tips

1. Get the server transaction manager:

```java
import weblogic.transaction.ServerTransactionManager;
import weblogic.transaction.TxHelper;
ServerTransactionManager stm =
  (ServerTransactionManager)TxHelper.getTransactionManager();
```

2. Get the `TransactionLogger`:

```java
TransactionLogger tlog = stm.getTransactionLogger();
```

The XAResource’s log records must implement the `weblogic.transaction.TransactionLoggable` interface in order to be written to the transaction log. See the [WebLogic Server Javadocs](https://docs.oracle.com/cd/E191470_01/appdev.102/e43948/tjta_javadoc.html) for the `TransactionLogger` interface for more details and the usage of the `TransactionLogger` interface.

Transaction global properties

A WebLogic Server JTA transaction object is associated with both local and global properties. Global properties are propagated with the transaction propagation context among servers, and are also saved as part of the log record in the transaction log. You can access the transaction global properties as follows:

1. Obtain the transaction object:

```java
import weblogic.transaction.Transaction;
import weblogic.transaction.TransactionHelper;
Transaction tx = TransactionHelper.getTransaction();  // Get the transaction associated with the thread
or
Transaction tx = TxHelper.getTransaction(xid); // Get the transaction with the given Xid
```

2. Get or set the properties on the transaction object:

```java
tx.setProperty("foo", "fooValue");
```

See the [WebLogic Server Javadocs](https://docs.oracle.com/cd/E191470_01/appdev.102/e43948/tjta_javadoc.html) for the `weblogic.transaction.TxHelper` class for more information.
Coordinating XAResources with the WebLogic Server Transaction Manager

**TxHelper.createXid**

You can use the `TxHelper.createXid(int formatId, byte[] gtrid, byte[] bqual)` method to create Xids, for example, to return to the WebLogic Server transaction manager on recovery.

See the [WebLogic Server Javadocs](http://java.sun.com/products/jta/) for the `weblogic.transaction.TxHelper` class for more information.

**FAQs**

- XAResource's Xid has a branch qualifier, but not the transaction manager's transaction.

  WebLogic Server JTA transaction objects do not have branch qualifiers (i.e., `TxHelper.getTransaction().getXid().getBranchQualifier()` would be null). Since the branch qualifiers are specific to individual resource managers, the WebLogic Server transaction manager only sets the branch qualifiers in the Xids that are passed into XAResource methods.

- What is the `TxHelper.getTransaction()` method used for?

  The WebLogic Server JTA provides the `TxHelper.getTransaction()` API to return the transaction associated with the current thread. However, note that WebLogic Server JTA suspends the transaction context before calling the XAResource methods, so you should only rely on the Xid input parameter to identify the transaction, but not the transaction associated with the current thread.

**Additional Documentation about JTA**

Refer to the JTA specification 1.0.1B Section 4.1 for a connection-based Resource Usage scenario, which illustrates the JTA interaction between the transaction manager and resource manager. The JTA specification is available at [http://java.sun.com/products/jta/](http://java.sun.com/products/jta/).
WebLogic Server can participate in distributed transactions coordinated by third-party systems (referred to as foreign transaction managers). The WebLogic Server processing is done as part of the work of the external transaction. The foreign transaction manager then drives the WebLogic Server transaction manager as part of its commit processing. This is referred to as “importing” transactions into WebLogic Server.

The following sections describe the process for configuring and participating in foreign-managed transactions:

- “Overview of Participating in Foreign-Managed Transactions” on page 9-1
- “Importing Transactions with the Client Interposed Transaction Manager” on page 9-2
- “Importing Transactions with the Server Interposed Transaction Manager” on page 9-5
- “Transaction Processing for Imported Transactions” on page 9-7
- “Commit Processing for Imported Transactions” on page 9-8
- “Recovery for Imported Transactions” on page 9-9
- “JCA Resource Adapter” on page 9-9

Overview of Participating in Foreign-Managed Transactions

The WebLogic Server transaction manager exposes a javax.transaction.xa.XAResource implementation via the weblogic.transaction.InterposedTransactionManager interface. A foreign transaction manager can access the InterposedTransactionManager...
interface to coordinate the WebLogic Server transaction manager XAResource during its commit processing.

When importing a transaction from a foreign transaction manager into the WebLogic Server transaction manager, you must register the WebLogic Server interposed transaction manager as a subordinate with the foreign transaction manager. The WebLogic Server transaction manager then acts as the coordinator for the imported transaction within WebLogic Server.

WebLogic Server supports two configuration schemes for importing transactions:

- Using a client-side gateway (implemented externally to WebLogic Server) that uses the client interposed transaction manager
- Using a server-side gateway implemented on a WebLogic Server instance that uses the server interposed transaction manager

Although there are some differences in limitations and in implementation details, the basic behavior is the same for importing transactions in both configurations:

1. Lookup the WebLogic Server transaction manager and register it as an XAResource as necessary in the third-party system.
2. Enlist and delist applicable transaction participants during transaction processing.
3. Send the prepare message to the WebLogic Server transaction manager, which then acts as a subordinate transaction manager and coordinates the prepare phase for transaction participants within WebLogic Server.
4. Send the commit or roll back message to the WebLogic Server transaction manager, which then acts as a subordinate transaction manager and coordinates the second phase of the two-phase commit process for transaction participants within WebLogic Server.
5. Unregister, as necessary.

Importing Transactions with the Client Interposed Transaction Manager

You can use the client interposed transaction manager in WebLogic Server to drive the two-phase commit process for transactions that are coordinated by a third-party transaction manager and include transaction participants within WebLogic Server, such as JMS resources and JDBC resources. The client interposed transaction manager is an implementation of the javax.transaction.xa.XAResource interface. You access the client interposed transaction manager directly from the third-party application, typically from a gateway in the third-party
application. The transaction manager in the third-party system then sends the prepare and commit messages to the gateway, which propagates the message to the WebLogic Server transaction manager. The WebLogic Server transaction manager then acts as a subordinate transaction manager and coordinates the transaction participants within WebLogic Server. Figure 9-1 shows the interaction between the two transaction managers and the client-side gateway.

**Figure 9-1** Importing Transactions into WebLogic Server Using a Client-Side Gateway

Figure 9-2 shows the flow of interactions between a foreign transaction manager, WebLogic Server client-side JTA objects, and the WebLogic Server transaction manager.
To access the interposed transaction manager in WebLogic Server using a client-side gateway, you must perform the following steps:

- **Get the Client Interposed Transaction Manager**
- **Get the XAResource from the Interposed Transaction Manager**

### Get the Client Interposed Transaction Manager

In a client-side gateway, the you can get the WebLogic server interposed transaction manager's XAResource with the `getClientInterposedTransactionManager` method. For example:

```java
import javax.naming.Context;
import weblogic.transaction.InterposedTransactionManager;
import weblogic.transaction.TxHelper;

Context initialCtx;
String serverName;
```
InterposedTransactionManager itm =
TxHelper.getClientInterposedTransactionManager(initialCtx, serverName);

The server name parameter is the name of the server that acts as the interposed transaction
manager for the foreign transaction. When the foreign transaction manager performs crash
recovery, it needs to contact the same WebLogic Server server to obtain the list of in-doubt
transactions that were previously imported into WebLogic Server.

See the WebLogic Server Javadocs for the weblogic.transaction.TxHelper class for more
information.

Get the XAResource from the Interposed Transaction Manager

After you get the interposed transaction manager, you must get the XAResource object associated
with the interposed transaction manager:

import javax.transaction.xa.XAResource;
XAResource xar = itm.getXAResource();

Limitations of the Client Interposed Transaction Manager

Note the following limitations when importing transactions using a client-side gateway:

• You cannot use the TxHelper.getServerInterposedTransactionManager() method
  in client-side gateways.

• You can only use one WebLogic Server client interposed transaction manager at a time. Do
  not use more than one client interposed transaction manager (connecting to different
  WebLogic Server servers) to import transactions at the same time. (See “Transaction
  Processing for Imported Transactions” on page 9-7 for more information about this
  limitation and how transactions are processed with the WebLogic Server interposed
  transaction manager.)

Importing Transactions with the Server Interposed Transaction Manager

You can use the server interposed transaction manager in WebLogic Server to drive the
two-phase commit process for transactions that are coordinated by a third-party transaction
manager and include transaction participants within WebLogic Server, such as JMS resources
and JDBC resources. The server interposed transaction manager is an implementation of the
javax.transaction.xa.XAResource interface. You access the server interposed transaction
manager by creating a server-side gateway on WebLogic Server and then accessing the gateway from a third-party system. The transaction manager in the third-party system then sends the prepare and commit messages to the server-side gateway, which propagates the message to the WebLogic Server transaction manager. The WebLogic Server transaction manager then acts as a subordinate transaction manager and coordinates the transaction participants within WebLogic Server. Figure 9-3 shows the interaction between the two transaction managers and the server-side gateway.

**Figure 9-3** Importing Transactions into WebLogic Server Using a Server-Side Gateway

To access the interposed transaction manager in WebLogic Server using a server-side gateway, you must perform the following steps:

- **Get the Server Interposed Transaction Manager**
- **Get the XAResource from the Interposed Transaction Manager**

### Get the Server Interposed Transaction Manager

In a server-side gateway, you can get the interposed transaction manager's XAResource as follows:

```java
import javax.naming.Context;
import weblogic.transaction.InterposedTransactionManager;
import weblogic.transaction.TxHelper;
```
InterposedTransactionManager itm =
TxHelper.getServerInterposedTransactionManager();

See the WebLogic Server Javadocs for the weblogic.transaction.TxHelper class for more information.

After you get the interposed transaction manager, you must get the XAResource. See “Get the XAResource from the Interposed Transaction Manager” on page 9-5.

Limitations of the Server Interposed Transaction Manager

Note the following limitations when importing transactions using a server-side gateway:

- Do not use the TxHelper.getClientInterposedTransactionManager() method in a server-side gateway on a WebLogic Server server. Doing so will cause performance issues.

- You can only use one WebLogic Server server interposed transaction manager at a time. Do not use more than one server interposed transaction manager (on the same thread) to import transactions at the same time. (See “Transaction Processing for Imported Transactions” for more information about this limitation and how transactions are processed with the WebLogic Server interposed transaction manager.)

Transaction Processing for Imported Transactions

To import a foreign transaction into WebLogic Server, the foreign transaction manager or gateway can do the following:

xar.start(foreignXid, TMNOFLAGS);

This operation associates the current thread with the imported transaction. All subsequent calls made to other servers will propagate the imported WebLogic Server transaction, until the transaction is disassociated from the thread.

Note: The flag is ignored by the WebLogic Server transaction manager. If the foreign Xid has already been imported previously on the same WebLogic Server server, WebLogic Server will associate the current thread with the previously imported WebLogic Server transaction.

To disassociate the imported transaction from the current thread, the foreign transaction manager or gateway should do the following:

xar.end(foreignXid, TMSUCCESS);

Note that the WebLogic Server transaction manager ignores the flag.
Transaction Processing Limitations for Imported Transactions

Note the following processing limitations and behavior for imported transactions:

- After a WebLogic Server transaction is started, the gateway cannot call start again on the same thread. With a client-side gateway, you can only call `xar.start` on one client interposed transaction manager at a time. Attempting to call `xar.start` on another client interposed transaction manager (before `xar.end` was called on the first one) will throw an `XAException` with `XAER_RMERR`. With a server-side gateway, attempting to call `xar.start` on a client or server interposed transaction manager will also throw a `XAException` with `XAER_RMERR` if there is already an active transaction associated with the current thread.

- The WebLogic Server interposed transaction manager's XAResource exhibits loosely-coupled transaction branching behavior on different WebLogic Server servers. That is, if the same foreign Xid is imported on different WebLogic Server servers, they will be imported to different WebLogic Server transactions.

- The WebLogic Server transaction manager does not flatten the transaction tree, for example, the imported transaction of a previously exported WebLogic Server transaction will be in a separate branch from the original WebLogic Server transaction.

- A foreign transaction manager should make sure that all foreign Xids that are imported into WebLogic Server are unique and are not reused within the sum of the transaction abandon timeout period (see “Abandon Timeout Seconds” in the Administration Console Help) and the transaction timeout period (see “Timeout Seconds” in the Administration Console Help). Failure to do so may result in log records that are never released in the WebLogic Server transaction manager. This could lead to inefficient crash recovery and overwriting of TLOG files.

Commit Processing for Imported Transactions

The foreign transaction manager should drive the interposed transaction manager in the 2PC protocol as it does the other XAResources. Note that the `beforeCompletion` callbacks registered with the WebLogic Server JTA (e.g., the EJB container) are called when the foreign transaction manager prepares the interposed transaction manager's XAResource. The `afterCompletion` callbacks are called during `XAResource.commit` or `XAResource.rollback`.

The WebLogic Server interposed transaction manager honors the XAResource contract as described in section 3.4 of the JTA 1.0.1b specification:
Recovery for Imported Transactions

- Once prepared by a foreign transaction manager, the WebLogic Server interposed transaction manager waits persistently for a commit or rollback outcome from the foreign transaction manager until the transaction abandon timeout expires.

- The WebLogic Server interposed transaction manager remembers heuristic outcomes persistently until being told to forget about the transaction by the foreign transaction manager or until transaction abandon timeout.

The WebLogic Server transaction manager logs a prepare record for the imported transaction after all the WebLogic Server participants are successfully prepared. If there are more than one WebLogic Server participants for the imported transaction, the transaction manager logs a prepare record even if the XAResource.commit is a one-phase commit.

The WebLogic Server transaction manager logs a heuristic record for the imported transaction if there is heuristic outcome for XAResource.commit or rollback. The heuristic log records are stored in heuristic log files (separate from the transaction log files). The heuristic log files have extensions heur.tlog. For complete details about heuristic log files, see Heuristic Log Files in the Administration Console Help.

Recovery for Imported Transactions

During the crash recovery of the foreign transaction manager, the foreign transaction manager must get the XAResource of the WebLogic Server interposed transaction manager again, and call recover on it. The WebLogic Server interposed transaction manager then returns the list of prepared or heuristically completed transactions. The foreign transaction manager should then resolve those in-doubt transactions: either commit or rollback the prepared transactions, and call forget on the heuristically completed transactions.

JCA Resource Adapter

The current JCA specification version does not have provisions for importing transactions. The JCA 1.5 specification will have APIs for importing transactions into the J2EE container. When the WebLogic Server JCA container supports the JCA 1.5 specification, resource providers can then also import transactions via JCA APIs.
Troubleshooting Transactions

This section describes troubleshooting tools and tasks for use in determining why transactions fail and deciding what actions to take to correct the problem.

This section discusses the following topics:

- **Overview**
- **Troubleshooting Tools**

**Overview**

WebLogic Server includes the ability to monitor currently running transactions and ensure that adequate information is captured in the case of heuristic completion. It also provides the ability to monitor performance of database queries, transactional requests, and bean methods.

**Troubleshooting Tools**

WebLogic Server provides the following aids to transaction troubleshooting:

- “Exceptions” on page 10-2
- “Transaction Identifier” on page 10-2
- “Transaction Name and Properties” on page 10-2

Exceptions

WebLogic JTA supports all standard JTA exceptions. For more information about standard JTA exceptions, see the [Javadoc for the `javax.transaction` and `javax.transaction.xa` package APIs](https://docs.oracle.com/javase/7/docs/api/javax/transaction/package-summary.html).

In addition to the standard JTA exceptions, WebLogic Server provides the class `weblogic.transaction.RollbackException`. This class extends `javax.transaction.RollbackException` and preserves the original reason for a rollback. Before rolling a transaction back, or before setting it to `rollbackonly`, an application can supply a reason for the rollback. All rollbacks triggered inside the transaction service set the reason (for example, timeouts, XA errors, unchecked exceptions in `beforeCompletion`, or inability to contact the transaction manager). Once set, the reason cannot be overwritten.

Transaction Identifier

The Transaction Service assigns a transaction identifier (`Xid`) to each transaction. This ID can be used to isolate information about a specific transaction in a log file. You can retrieve the transaction identifier using the `getXID` method in the `weblogic.transaction.Transaction` interface. For detailed information on methods for getting the transaction identifier, see the `weblogic.transaction.Transaction` Javadoc.

Transaction Name and Properties

WebLogic JTA provides extensions to `javax.transaction.Transaction` that support transaction naming and user-defined properties. These extensions are included in the `weblogic.transaction.Transaction` interface.

The transaction name indicates a type of transaction (for example, funds transfer or ticket purchase) and should not be confused with the transaction ID, which identifies a unique transaction on a server. The transaction name makes it easier to identify a transaction type in the context of an exception or a log file.

User-defined properties are key/value pairs, where the key is a string identifying the property and the value is the current value assigned to the property. Transaction property values must be objects that implement the `Serializable` interface. You manage properties in your application using the set and get methods defined in the `weblogic.transaction.Transaction` interface. Once set, properties stay with a transaction during its entire lifetime and are passed between...
machines as the transaction travels through the system. Properties are saved in the transaction log, and are restored during crash recovery processing. If a transaction property is set more than once, the latest value is retained.

For detailed information on methods for setting and getting the transaction name and transaction properties, see the `weblogic.transaction.Transaction` Javadoc.

### Transaction Status

The Java Transaction API provides transaction status codes using the `javax.transaction.Status` class. Use the `getStatusAsString` method in `weblogic.transaction.Transaction` to return the status of the transaction as a string. The string contains the major state as specified in `javax.transaction.Status` with an additional minor state (such as logging or pre-preparing).

### Transaction Statistics

Transaction statistics are provided for all transactions handled by the transaction manager on a server. These statistics include the number of total transactions, transactions with a specific outcome (such as committed, rolled back, or heuristic completion), rolled back transactions by reason, and the total time that transactions were active. For detailed information on transaction statistics, see the Administration Console Online Help.

### Transaction Monitoring and Logging

The Administration Console allows you to monitor transactions and to specify the transaction log file prefix. Monitoring and logging tasks are performed at the server level. Transaction statistics are displayed for a specific server and each server has a transaction log file.

For details, see Monitoring Transactions in the Administration Console Online Help at http://e-docs.bea.com/wls/docs81/ConsoleHelp/jta.html#monitortx.
Troubleshooting Transactions
Glossary of Terms

local transaction
Transactions that are local to a single resource manager only; for example a transaction that relates to only one database.

distributed transaction
Global transaction involving multiple servers and one or more resources. In a distributed transaction environment, a client application may send requests to several servers resulting in resource updates at multiple resource managers. To complete a transaction, the transaction manager for each participant (client, servers, and resource managers) must be polled to coordinate the commit process for each participant within its domain.

global transactions
Transaction managed by an external transaction manager (such as WebLogic Server) that can include multiple servers or multiple resources as participants. The transaction is coordinated as an atomic unit of work: All participants either commit or rollback the entire transaction.

transaction branches
Each resource manager’s internal unit of work in support of a global transaction is part of exactly one transaction branch. Each Global Transaction Identifier (GTRID or XID) that the transaction manager gives to the resource manager identifies both a distributed transaction and a specific branch.
heuristic decision
An heuristic decision (or heuristic completion) occurs when a resource makes a unilateral
decision during the completion stage of a distributed transaction to commit or rollback updates.
This can leave distributed data in an indeterminate state. Network failures or transaction timeouts
are possible causes for a heuristic decision.

HeuristicRollback
One resource participating in a transaction decided to autonomously rollback its work, even
though it agreed to prepare itself and wait for a commit decision. If the Transaction Manager
decided to commit the transaction, the resource's heuristic rollback decision was incorrect, and
might lead to an inconsistent outcome since other branches of the transaction were committed.

HeuristicCommit
One resource participating in a transaction decided to autonomously commit its work, even
though it agreed to prepare itself and wait for a commit decision. If the Transaction Manager
decided to rollback the transaction, the resource's heuristic commit decision was incorrect, and
might lead to an inconsistent outcome since other branches of the transaction were rolled back.

HeuristicMixed
The Transaction Manager is aware that a transaction resulted in a mixed outcome, where some
participating resources committed and some rolled back. The underlying cause was most likely
heuristic rollback or heuristic commit decisions made by one or more of the participating
resources.

HeuristicHazard
The Transaction Manager is aware that a transaction might have resulted in a mixed outcome,
where some participating resources committed and some rolled back. But system or resource
failures make it impossible to know for sure whether a Heuristic Mixed outcome definitely
occurred. The underlying cause was most likely heuristic rollback or heuristic commit decisions
made by one or more of the participating resources.
