A. Deprecated Security APIs

Index
About This Document

This document is organized as follows:

- **Chapter 1, “Introduction to Programming WebLogic Security,”** discusses the audiences of this document, the need for security, and the WebLogic Security application programming Interfaces (APIs).

- **Chapter 2, “Securing Web Applications,”** describes how to implement security in Web applications.

- **Chapter 3, “Using JAAS Authentication in Java Clients,”** describes how to implement JAAS authentication in Java clients.

- **Chapter 4, “Using SSL Authentication in Java Clients,”** describes how to implement SSL and digital certificate authentication in Java clients.

- **Chapter 5, “Securing Enterprise JavaBeans (EJBs),”** describes how to implement security in Enterprise JavaBeans.

- **Chapter 6, “Using Network Connection Filters,”** describes how to implement network connection filters.

- **Chapter 7, “Using Java Security to Protect WebLogic Resources,”** discusses using Java security to protect WebLogic resources.

- **Chapter 8, “SAML APIs,”** describes the WebLogic SAML APIs.

- **Chapter 9, “Using CertPath Building and Validation,”** describes how to build and validate certification paths.

- **Appendix A, “Deprecated Security APIs,”** provides a list of weblogic.security packages in which APIs have been deprecated.

**Note:** This document does not supply detailed information for developers who want to write custom security providers for use with WebLogic Server. For information on developing custom security providers, see *Developing Security Providers for WebLogic Server.*
About This Document

**Audience for This Guide**

This document is intended for the following audiences:

- **Application Developers**
  
  Java programmers who focus on developing client applications, adding security to Web applications and Enterprise JavaBeans (EJBs). They work with other engineering, Quality Assurance (QA), and database teams to implement security features. Application developers have in-depth/working knowledge of Java (including J2EE components such as servlets/JSPs and JSEE) and Java security.
  
  Application developers use the WebLogic security and Java 2 security application programming interfaces (APIs) to secure their applications. Therefore, this document provides instructions for using those APIs for securing Web applications, Java applications, and Enterprise JavaBeans (EJBs).

- **Security Developers**
  
  Developers who focus on defining the system architecture and infrastructure for security products that integrate into WebLogic Server and on developing custom security providers for use with WebLogic Server. They work with application architects to ensure that the security architecture is implemented according to design and that no security holes are introduced. They also work with WebLogic Server administrators to ensure that security is properly configured. Security developers have a solid understanding of security concepts, including authentication, authorization, auditing (AAA), in-depth knowledge of Java (including Java Management eXtensions (JMX), and working knowledge of WebLogic Server and security provider functionality.
  
  Security developers use the Security Service Provider Interfaces (SSPIs) to develop custom security providers for use with WebLogic Server. This document does not address this task; for information on how to use the SSPIs to develop custom security providers, see *Developing Security Providers for WebLogic Server*.

- **Server Administrators**
  
  Administrators who work closely with application architects to design a security scheme for the server and the applications running on the server, to identify potential security risks, and to propose configurations that prevent security problems. Related responsibilities may include maintaining critical production systems, configuring and managing security realms, implementing authentication and authorization schemes for server and application resources, upgrading security features, and maintaining security provider databases.
  
  WebLogic Server administrators have in-depth knowledge of the Java security architecture, including Web application and EJB security, Public Key security, and SSL.
Application Administrators

Administrators who work with WebLogic Server administrators to implement and maintain security configurations and authentication and authorization schemes, and to set up and maintain access to deployed application resources in defined security realms. Application administrators have general knowledge of security concepts and the Java Security architecture. They understand Java, XML, deployment descriptors, and can identify security events in server and audit logs.

While administrators typically use the Administration Console to deploy, configure, and manage applications when they put the applications into production, application developers may also use the Administration Console to test their applications before they are put into production. At a minimum, testing requires that applications be deployed and configured. This document does not cover some aspects of administration as it relates to security, rather, it references Securing WebLogic Server, Securing WebLogic Resources, and Administration Console Online Help for descriptions of how to use the Administration Console to perform security tasks.

Product Documentation on the dev2dev Web Site

BEA product documentation, along with other information about BEA software, is available from the BEA dev2dev Web site:

http://dev2dev.bea.com

To view the documentation for a particular product, select that product from the list on the dev2dev page. The home page for the selected product is displayed; the page provides links to product documentation.

Related Information

In addition to this document, Programming WebLogic Security, the following documents provide information on the WebLogic Security Service:

- Understanding WebLogic Security—This document summarizes the features of the WebLogic Security Service and presents an overview of the architecture and capabilities of the WebLogic Security Service. It is the starting point for understanding the WebLogic Security Service.

- Securing a Production Environment—This document highlights essential security measures for you to consider before you deploy WebLogic Server into a production environment.
About This Document

- **Developing Security Providers for WebLogic Server**—This document provides security vendors and application developers with the information needed to develop custom security providers that can be used with WebLogic Server.

- **Securing WebLogic Server**—This document explains how to configure security for WebLogic Server and how to use Compatibility security.

- **Securing WebLogic Resources**—This document introduces the various types of WebLogic resources, and provides information that allows you to secure these resources using WebLogic Server.

- **Administration Console Online Help**—This document describes how to use the Administration Console to perform security tasks.

- **Javadocs for WebLogic Classes**—This document includes reference documentation for the WebLogic security packages that are provided with and supported by the WebLogic Server software.

Contact Us!

Your feedback on BEA documentation is important to us. Send us e-mail at docsupport@bea.com if you have questions or comments. Your comments will be reviewed directly by the BEA professionals who create and update the documentation.

In your e-mail message, please indicate the software name and version you are using, as well as the title and document date of your documentation. If you have any questions about this version of BEA WebLogic Server, or if you have problems installing and running BEA WebLogic Server, contact BEA Customer Support through BEA WebSupport at http://www.bea.com. You can also contact Customer Support by using the contact information provided on the Customer Support Card, which is included in the product package.

When contacting Customer Support, be prepared to provide the following information:

- Your name, e-mail address, phone number, and fax number

- Your company name and company address

- Your machine type and authorization codes

- The name and version of the product you are using

- A description of the problem and the content of pertinent error messages
## Documentation Conventions

The following documentation conventions are used throughout this document.

<table>
<thead>

Introduction to Programming WebLogic Security

The following topics are covered in this section:

- “What Is Security?” on page 1-1
- “Types of Security Supported by WebLogic Server” on page 1-2
- “Security APIs” on page 1-4
- “Administration Console and Security” on page 1-7
- “Security Tasks and Code Examples” on page 1-7

What Is Security?

Security refers to techniques for ensuring that data stored in a computer or passed between computers is not compromised. Most security measures involve proof material and data encryption. Proof material is typically a secret word or phrase that gives a user access to a particular application or system. Data encryption is the translation of data into a form that cannot be interpreted without holding or supplying the same secret.

Distributed applications, such as those used for electronic commerce (e-commerce), offer many access points at which malicious people can intercept data, disrupt operations, or generate fraudulent input. As a business becomes more distributed the probability of security breaches increases. Accordingly, as a business distributes its applications, it becomes increasingly important for the distributed computing software upon which such applications are built to provide security.
An application server resides in the sensitive layer between end users and your valuable data and resources. WebLogic Server provides authentication, authorization, and encryption services with which you can guard these resources. These services cannot provide protection, however, from an intruder who gains access by discovering and exploiting a weakness in your deployment environment.

Therefore, whether you deploy WebLogic Server on the Internet or on an intranet, it is a good idea to hire an independent security expert to go over your security plan and procedures, audit your installed systems, and recommend improvements.

Another good strategy is to read as much as possible about security issues and appropriate security measures. The document *Securing a Production Environment* highlights essential security measures for you to consider before you deploy WebLogic Server into a production environment. The document *Securing WebLogic Resources* introduces the various types of WebLogic resources, and provides information that allows you to secure these resources using WebLogic Server. For the latest information about securing Web servers, BEA also recommends reading the Security Improvement Modules, Security Practices, and Technical Implementations information available from the CERT™ Coordination Center operated by Carnegie Mellon University.

BEA suggests that you apply the remedies recommended in our security advisories. In the event of a problem with a BEA product, BEA distributes an advisory and instructions with the appropriate course of action. If you are responsible for security related issues at your site, please register to receive future notifications. BEA has established an e-mail address (security-report@bea.com) to which you can send reports of any possible security issues in BEA products. In addition, you are advised to apply every Service Pack as they are released. Service Packs include a roll up of all bug fixes for each version of the product, as well as each of the previously released Service Packs.

Product provided by BEA partners can also help you in your effort to secure the WebLogic Server production environment. For more information, see the BEA Partner’s Page.

**Types of Security Supported by WebLogic Server**

WebLogic Server supports the following security mechanisms:

- “Authentication” on page 1-3
- “Authorization” on page 1-3
- “J2EE Security” on page 1-3
Authentication

Authentication is the mechanism by which callers and service providers prove that they are acting on behalf of specific users or systems. Authentication answers the question, "Who are you?" using credentials. When the proof is bidirectional, it is referred to as mutual authentication.

WebLogic Server supports username and password authentication and certificate authentication. For certificate authentication, WebLogic Server supports both one-way and two-way SSL (Secure Sockets Layer) authentication. Two-way SSL authentication is a form of mutual authentication.

In WebLogic Server, Authentication providers are used to prove the identity of users or system processes. Authentication providers also remember, transport, and make identity information available to various components of a system (via subjects) when needed. You can configure the Authentication providers using the Web application and EJB deployment descriptor files, or the Administration Console, or a combination of both.

Authorization

Authorization is the process whereby the interactions between users and WebLogic resources are controlled, based on user identity or other information. In other words, authorization answers the question, "What can you access?"

In WebLogic Server, a WebLogic Authorization provider is used to limit the interactions between users and WebLogic resources to ensure integrity, confidentiality, and availability. You can configure the Authorization provider using the Web application and EJB deployment descriptor files, or the Administration Console, or a combination of both.

WebLogic Server also supports the use of programmatic authorization (also referred to in this document as programmatic security) to limit the interactions between users and WebLogic resources.

J2EE Security

For implementation and use of user authentication and authorization, BEA WebLogic Server utilizes the security services of the security services of the J2SE Development Kit 5.0 (JDK 5.0). Like the other J2EE components, the security services are based on standardized, modular components. BEA WebLogic Server implements these Java security service methods according to the standard, and adds extensions that handle many details of application behavior automatically, without requiring additional programming.
Introduction to Programming WebLogic Security

Security APIs

This section lists the Security packages and classes that are implemented and supported by WebLogic Server. You use these packages to secure interactions between WebLogic Server and client applications, Enterprise JavaBeans (EJBs), and Web applications.

Note: Several of the WebLogic security packages, classes, and methods are deprecated in this release of WebLogic Server. For more detailed information on deprecated packages and classes, see Appendix A, “Deprecated Security APIs.”

The following topics are covered in this section:

- “JAAS Client Application APIs” on page 1-4
- “SSL Client Application APIs” on page 1-5
- “Other APIs” on page 1-6

JAAS Client Application APIs

You use Java APIs and WebLogic APIs to write client applications that use JAAS authentication.

The following topics are covered in this section:

- “Java JAAS Client Application APIs” on page 1-4
- “WebLogic JAAS Client Application APIs” on page 1-4

Java JAAS Client Application APIs

You use the following Java APIs to write JAAS client applications.

- `javax.naming`
- `javax.security.auth`
- `javax.security.auth.Callback`
- `javax.security.auth.login`
- `javax.security.auth.SPI`

For information on how to use these APIs, see “JAAS Authentication APIs” on page 3-4.

WebLogic JAAS Client Application APIs

You use the following WebLogic APIs to write JAAS client applications:
Security APIs

- weblogic.security
- weblogic.security.auth
- weblogic.security.auth.callback

For information on how to use these APIs, see “JAAS Authentication APIs” on page 3-4.

SSL Client Application APIs

You use Java and WebLogic APIs to write client applications that use SSL authentication:
The following topics are covered in this section:

- “Java SSL Client Application APIs” on page 1-5
- “WebLogic SSL Client Application APIs” on page 1-5

Java SSL Client Application APIs

You use the following Java APIs to write SSL client applications:

- java.security
- java.security.cert
- javax.crypto
- javax.naming
- javax.net
- javax.security
- javax.servlet
- javax.servlet.http

WebLogic Server also supports the javax.net.SSL API, but BEA recommends that you use the weblogic.security.SSL package when you use SSL with WebLogic Server.

For information on how to use these APIs, see “SSL Authentication APIs” on page 4-4.

WebLogic SSL Client Application APIs

You use the following WebLogic APIs to write SSL client applications.

- weblogic.net.http
For information on how to use these APIs, see “SSL Authentication APIs” on page 4-4.

Other APIs

Additionally, you use the following APIs to develop WebLogic Server applications:

- **weblogic.security.SSL**
  
  This API provides the `RoleMapper` interface. If you implement the Java Authorization Contract for Containers (JACC), you can use this package with the `javax.security.jacc` package. See “Using the Java Authorization Contract for Containers” on page 7-6 for information about the WebLogic JACC provider. See [http://java.sun.com/j2ee/javaacc/](http://java.sun.com/j2ee/javaacc/) for information on developing a JACC provider.

- **weblogic.security.jacc**
  
  This API provides the `RoleMapper` interface. If you implement the Java Authorization Contract for Containers (JACC), you can use this package with the `javax.security.jacc` package. See “Using the Java Authorization Contract for Containers” on page 7-6 for information about the WebLogic JACC provider. See [http://java.sun.com/j2ee/javaacc/](http://java.sun.com/j2ee/javaacc/) for information on developing a JACC provider.

- **weblogic.security.net**
  
  This API provides interfaces and classes that are used to implement network connection filters. Network connection filters allow or deny connections to WebLogic Server based on attributes such as the IP address, domain, or protocol of the initiator of the network connection. For more information about how to use this API, see “Using Network Connection Filters” on page 6-1.

- **weblogic.security.pk**
  
  This API provides interfaces and classes to build and validate certification paths. See Chapter 9, “Using CertPath Building and Validation,” for information on using this API to build and validate certificate chains.

  See the `java.security.cert` package for additional information on certificates and certificate paths.

- **weblogic.security.providers.saml**
  
  This API provides interfaces and classes that are used to perform mapping of user and group information to Security Assertion Markup Language (SAML) assertions, and to cache and retrieve SAML assertions.

  SAML is an XML-based framework for exchanging security information. WebLogic Server supports SAML V1.1, including the Browser/Post and Browser/Artifact profiles. SAML authorization is not supported in this release of WebLogic Server.

  For more information about SAML, see [http://www.oasis-open.org](http://www.oasis-open.org).

- **weblogic.security.service**
This API includes interfaces, classes, and exceptions that support security providers. The WebLogic Security Framework consists of interfaces, classes, and exceptions provided by this API. The interfaces, classes, and exceptions in this API should be used in conjunction with those in the `weblogic.security.spi` package. For more information about how to use this API, see *Developing Security Providers for WebLogic Server*.

- **weblogic.security.services**
  
  This API provides the server-side authentication class. This class is used to perform a local login to the server. It provides login methods that are used with CallbackHandlers to authenticate the user and return credentials using the default security realm.

- **weblogic.security.spi**
  
  This package provides the Security Service Provider Interfaces (SSPIs). It provides interfaces, classes, and exceptions that are used for developing custom security providers. In many cases, these interfaces, classes, and exceptions should be used in conjunction with those in the `weblogic.security.service` API. You implement interfaces, classes, and exceptions from this package to create runtime classes for security providers. For more information about how to use the SSPIs, see *Developing Security Providers for WebLogic Server*.

- **weblogic.servlet.security**
  
  This API provides a server-side API that supports programmatic authentication from within a servlet application. For more about how to use this API, see, “Using the Programmatic Authentication API” on page 2-40.

**Administration Console and Security**

With regard to security, you can use the Administration Console to define and edit deployment descriptors for Web Applications, EJBs, J2EE Connectors, and Enterprise Applications. This document, *Programming WebLogic Security*, does not describe how to use the Administration Console to configure security. For information on how to use the Administration Console to define and edit deployment descriptors, see *Securing WebLogic Resources* and *Securing WebLogic Server*.

**Security Tasks and Code Examples**

The security tasks and code examples provided in this document assume that you are using the WebLogic security providers that are included in the WebLogic Server distribution, not custom security providers. The usage of the WebLogic security APIs does not change if you elect to use
custom security providers, however, the management procedures of your custom security providers may be different.

**Note:** This document does not provide comprehensive instructions on how to configure WebLogic Security providers or custom security providers. For information on configuring WebLogic security providers and custom security providers, see *Securing WebLogic Server.*
Securing Web Applications

WebLogic Server supports the J2EE architecture security model for securing Web applications, which includes support for declarative authorization (also referred to in this document as declarative security) and programmatic authorization (also referred to in this document as programmatic security).

This section covers the following topics:

- “J2EE Architecture Security Model” on page 2-2
- “Authentication With Web Browsers” on page 2-4
- “Multiple Web Applications, Cookies, and Authentication” on page 2-8
- “Developing Secure Web Applications” on page 2-9
- “Using Declarative Security With Web Applications” on page 2-24
- “Web Application Security-Related Deployment Descriptors” on page 2-25
- “Using Programmatic Security With Web Applications” on page 2-37
- “Using the Programmatic Authentication API” on page 2-40

Note: You can use deployment descriptor files and the Administration Console to secure Web applications. This document describes how to use deployment descriptor files. For information on using the Administration Console to secure Web applications, see Securing WebLogic Resources.
J2EE Architecture Security Model

“In the J2EE architecture, a container serves as an authorization boundary between the components it hosts and their callers. The authorization boundary exists inside the container's authentication boundary so that authorization is considered in the context of successful authentication. For inbound calls, the container compares security attributes from the caller's credential with the access control rules for the target component. If the rules are satisfied, the call is allowed. Otherwise, the call is rejected.”

“There are two fundamental approaches to defining access control rules: capabilities and permissions. Capabilities focus on what a caller can do. Permissions focus on who can do something. The J2EE application programming model focuses on permissions. In the J2EE architecture, the job of the deployer is to map the permission model of the application to the capabilities of users in the operational environment.”

The same document then discusses two ways to control access to application resources using the J2EE architecture, declarative authorization and programmatic authorization.

**Note:** Declarative authorization and programmatic authorization are also referred to as, respectively, declarative security and programmatic security.

Declarative Authorization

The document *Designing Enterprise Applications with the J2EE Platform, Second Edition*, published by Sun Microsystems, Inc., states in Section 9.3.1 Authorization:

“The deployer establishes the container-enforced access control rules associated with a J2EE application. The deployer uses a deployment tool to map an application permission model, which is typically supplied by the application assembler, to policy and mechanisms specific to the operational environment. The application permission model is defined in a deployment descriptor.”

WebLogic Server supports the use of deployment descriptors to implement declarative authorization in Web applications.
Programmatic Authorization

The document *Designing Enterprise Applications with the J2EE Platform, Second Edition*, published by Sun Microsystems, Inc., states in Section 9.3.2 Programmatic Authorization:

“A J2EE container makes access control decisions before dispatching method calls to a component. The logic or state of the component doesn't factor in these access decisions. However, a component can use two methods, EJBContext.isCallerInRole (for use by enterprise bean code) and HttpServletRequest.isUserInRole (for use by Web components), to perform finer-grained access control. A component uses these methods to determine whether a caller has been granted a privilege selected by the component based on the parameters of the call, the internal state of the component, or other factors such as the time of the call.”

“The application component provider of a component that calls one of these functions must declare the complete set of distinct roleName values to be used in all calls. These declarations appear in the deployment descriptor as security-role-ref elements. Each security-role-ref element links a privilege name embedded in the application as a roleName to a security role. Ultimately, the deployer establishes the link between the privilege names embedded in the application and the security roles defined in the deployment descriptor. The link between privilege names and security roles may differ for components in the same application.”

“In addition to testing for specific privileges, an application component can compare the identity of its caller, acquired using EJBContext.getCallerPrincipal or HttpServletRequest.getUserPrincipal, to the distinguished caller identities embedded in the state of the component when it was created. If the identity of the caller is equivalent to a distinguished caller, the component can allow the caller to proceed. If not, the component can prevent the caller from further interaction. The caller principal returned by a container depends on the authentication mechanism used by the caller. Also, containers from different vendors may return different principals for the same user authenticating by the same mechanism. To account for variability in principal forms, an application developer who chooses to apply distinguished caller state in component access decisions should allow multiple distinguished caller identities, representing the same user, to be associated with components. This is recommended especially where application flexibility or portability is a priority.”

WebLogic Server supports the use of the HttpServletRequest.isUserInRole and HttpServletRequest.getUserPrincipal methods and the use of the security-role-ref element in deployment descriptors to implement programmatic authorization in Web applications.
Declarative Versus Programmatic Authorization

The document *Designing Enterprise Applications with the J2EE Platform, Second Edition*, published by Sun Microsystems, Inc., states in Section 9.3.3 Declarative Versus Programmatic Authorization:

“There is a trade-off between the external access control policy configured by the deployer and the internal policy embedded in the application by the component provider. The external policy is more flexible after the application has been written. The internal policy provides more flexible functionality while the application is being written. In addition, the external policy is transparent and completely comprehensible to the deployer, while internal policy is buried in the application and may only be completely understood by the application developer. These trade-offs should be considered in choosing the authorization model for particular components and methods.”

Authentication With Web Browsers

Web browsers can connect to WebLogic Server over either a HyperText Transfer Protocol (HTTP) port or an HTTP with SSL (HTTPS) port. The benefits of using an HTTPS port versus an HTTP port is two-fold. With HTTPS connections:

- All communication on the network between the Web browser and the server is encrypted. None of the communication, including the user name and password, is in clear text.
- As a minimum authentication requirement, the server is required to present a digital certificate to the Web browser client to prove its identity.

If the server is configured for two-way SSL authentication, both the server and client are required to present a digital certificate to each other to prove their identity.

User Name and Password Authentication

WebLogic Server performs user name and password authentication when users use a Web browser to connect to the server via the HTTP port. In this scenario, the browser and an instance of WebLogic Server interact in the following manner to authenticate a user (see Figure 2-1):

1. A user invokes a WebLogic resource in WebLogic Server by entering the URL for that resource in a Web browser. The http URL contains the HTTP listen port, for example, http://myserver:7001.
2. The Web server in WebLogic Server receives the request.
Note: WebLogic Server provides its own Web server but also supports the use of Apache Server, Microsoft Internet Information Server, and Netscape Enterprise Server as Web servers.

3. The Web server determines whether the WebLogic resource is protected by a security policy. If the WebLogic resource is protected, the Web server uses the established HTTP connection to request a user name and password from the user.

4. When the user’s Web browser receives the request from the Web server, it prompts the user for a user name and password.

5. The Web browser sends the request to the Web server again, along with the user name and password.

6. The Web server forwards the request to the Web server plug-in. WebLogic Server provides the following plug-ins for Web servers:
   - Apache-WebLogic Server plug-in
   - Netscape Server Application Programming Interface (NSAPI)
   - Internet Information Server Application Programming Interface (ISAPI)

   The Web server plug-in performs authentication by sending the request, via the HTTP protocol, to WebLogic Server, along with the authentication data (user name and password) received from the user.

7. Upon successful authentication, WebLogic Server proceeds to determine whether the user is authorized to access the WebLogic resource.

8. Before invoking a method on the WebLogic resource, the WebLogic Server instance performs a security authorization check. During this check, the server security extracts the user’s credentials from the security context, determines the user’s security role, compares the user’s security role to the security policy for the requested WebLogic resource, and verifies that the user is authorized to invoke the method on the WebLogic resource.

9. If authorization succeeds, the server fulfills the request.
Digital Certificate Authentication

WebLogic Server uses encryption and digital certificate authentication when Web browser users connect to the server via the HTTPS port. In this scenario, the browser and WebLogic Server instance interact in the following manner to authenticate and authorize a user (see Figure 2-1):

1. A user invokes a WebLogic resource in WebLogic Server by entering the URL for that resource in a Web browser. The HTTPS URL contains the SSL listen port, for example, `https://myserver:7002`.

2. The Web server in WebLogic Server receives the request.
   
   **Note:** WebLogic Server provides its own Web server but also supports the use of Apache Server, Microsoft Internet Information Server, and Netscape Enterprise Server as Web servers.

3. The Web server checks whether the WebLogic resource is protected by a security policy. If the WebLogic resource is protected, the Web server uses the established HTTPS connection to request a user name and password from the user.

4. When the user’s Web browser receives the request from WebLogic Server, it prompts the user for a user name and password. (This step is optional.)

5. The Web browser sends the request again, along with the user name and password. (Only supplied if requested by the server.)

---

**Figure 2-1  Secure Login for Web Browsers**

Note: Username/Password authentication can be required for HTTP and one-way SSL authentication. HTTPS connections can be configured for one-way or two-way SSL authentication.
6. WebLogic Server presents its digital certificate to the Web browser.

7. The Web browser checks that the server’s name used in the URL (for example, myserver) matches the name in the digital certificate and that the digital certificate was issued by a trusted third party, that is, a trusted CA.

8. If two-way SSL authentication is in force on the server, the server requests a digital certificate from the client.
   
   **Note:** Even though WebLogic Server cannot be configured to enforce the full two-way SSL handshake with Web Server proxy plug-ins, proxy plug-ins can be configured to provide the client certificate to the server if it is needed. To do this, configure the proxy plug-in to export the client certificate in the HTTP Header for WebLogic Server. For instructions on how to configure proxy plug-ins to export the client certificate to WebLogic Server, see the configuration information for the specific plug-in in *Using Web Server Plug-Ins With WebLogic Server*.

9. The Web server forwards the request to the Web server plug-in. If secure proxy is set (this is the case if the HTTPS protocol is being used), the Web server plug-in also performs authentication by sending the request, via the HTTPS protocol, to the WebLogic resource in WebLogic Server, along with the authentication data (user name and password) received from the user.
   
   **Note:** When using two-way SSL authentication, you can also configure the server to do identity assertion based on the client’s certificate, where, instead of supplying a user name and password, the server extracts the user name and password from the client’s certificate.

10. Upon successful authentication, WebLogic Server proceeds to determine whether the user is authorized to access the WebLogic resource.

11. Before invoking a method on the WebLogic resource, the server performs a security authorization check. During this check, the server extracts the user’s credentials from the security context, determines the user’s security role, compares the user’s security role to the security policy for the requested WebLogic resource, and verifies that the user is authorized to invoke the method on the WebLogic resource.

12. If authorization succeeds, the server fulfills the request.

For more information, see the following documents:

- **Securing WebLogic Server**
- **Installing and Configuring the Apache HTTP Server Plug-In**
Multiple Web Applications, Cookies, and Authentication

By default, WebLogic Server assigns the same cookie name (JSESSIONID) to all Web applications. When you use any type of authentication, all Web applications that use the same cookie name use a single sign-on for authentication. Once a user is authenticated, that authentication is valid for requests to any Web Application that uses the same cookie name. The user is not prompted again for authentication.

If you want to require separate authentication for a Web application, you can specify a unique cookie name or cookie path for the Web application. Specify the cookie name using the CookieName parameter and the cookie path with the CookiePath parameter, defined in the WebLogic-specific deployment descriptor weblogic.xml <session-descriptor> element. For more information, see session-descriptor in Developing Web Applications, Servlets, and JSPs for WebLogic Server.

If you want to retain the cookie name and still require independent authentication for each Web application, you can set the cookie path parameter (CookiePath) differently for each Web application.

WebLogic Server allows a user to securely access HTTPS resources in a session that was initiated using HTTP, without loss of session data. This feature enables Web site designers to prevent session stealing. For more information on this feature, see “Using Secure Cookies to Prevent Session Stealing” on page 2-8.

Using Secure Cookies to Prevent Session Stealing

A common Web security problem is session stealing. This happens when an attacker manages to get a copy of your session cookie, generally while the cookie is being transmitted over the network. This can only happen when the data is being sent in clear-text, that is, it is not encrypted.

BEA Systems added a capability to WebLogic Server that allows a user to securely access HTTPS resources in a session that was initiated using HTTP, without loss of session data. To enable this feature, add AuthCookieEnabled="true" to the WebServer element in config.xml:

```xml
<WebServer Name="myserver" AuthCookieEnabled="true"/>
```
Setting `AuthCookieEnabled` to `true`, which is the default setting, causes the WebLogic Server instance to send a new secure cookie, `_wl_authcookie_`, to the browser when authenticating via an HTTPS connection. Once the secure cookie is set, the session is allowed to access other security-constrained HTTPS resources only if the cookie is sent from the browser.

**Note:** This feature will work even when cookies are disabled because WebLogic Server will use URL rewriting over secure connections to rewrite secure URLs in order to encode the `authCookieID` in the URL along with the JSESSIONID.

Thus, WebLogic Server now uses two cookies: the `JSESSIONID` cookie and the `_wl_authcookie_` cookie. By default, the `JSESSIONID` cookie is never secure, but the `_wl_authcookie_` cookie is always secure. A secure cookie is only sent when an encrypted communication channel is in use. Assuming a standard HTTPS login (HTTPS is an encrypted HTTP connection), your browser gets both cookies. For subsequent HTTP access, you are considered authenticated if you have a valid `JSESSIONID` cookie, but for HTTPS access, you must have both cookies to be considered authenticated. If you only have the `JSESSIONID` cookie, you must re-authenticate.

With this feature enabled, once you have logged in over HTTPS, the secure cookie is only sent encrypted over the network and therefore can never be stolen in transit. The `JSESSIONID` cookie is still subject to in-transit hijacking. Therefore, a Web site designer can ensure that session stealing is not a problem by making all sensitive data require HTTPS. While the HTTP session cookie is still vulnerable to being stolen and used, all sensitive operations require the `_wl_authcookie_` cookie, which cannot be stolen, so those operations are protected.

### Developing Secure Web Applications

WebLogic Server supports three types of authentication for Web browsers:

- **BASIC**
- **FORM**
- **CLIENT-CERT**

The following sections cover the different ways to use these types of authentication:

- “Developing BASIC Authentication Web Applications” on page 2-10
- “Developing FORM Authentication Web Applications” on page 2-14
- “Using Identity Assertion for Web Application Authentication” on page 2-21
- “Using Two-Way SSL for Web Application Authentication” on page 2-22
Developing BASIC Authentication Web Applications

With basic authentication, the Web browser pops up a login screen in response to a WebLogic resource request. The login screen prompts the user for a user name and password. Figure 2-2 shows a typical login screen.

**Figure 2-2  Authentication Login Screen**

![Authentication Login Screen](image)

To develop a Web application that provides basic authentication, perform these steps:

1. Create the **web.xml** deployment descriptor. In this file you include the following information (see **Listing 2-1**):
   a. Define the welcome file. The welcome file name is `welcome.jsp`.
   b. Define a security constraint for each set of Web application resources, that is, URL resources, that you plan to protect. Each set of resources share a common URL. URL resources such as HTML pages, JSPs, and servlets are the most commonly protected, but other types of URL resources are supported. In **Listing 2-1**, the URL pattern points to the welcome.jsp file located in the Web application’s top-level directory; the HTTP methods that are allowed to access the URL resource, POST and GET; and the security role name, `webuser`.

**Note:** When specifying security role names, observe the following conventions and restrictions:
The proper syntax for a security role name is as defined for an Nmtoken in the Extensible Markup Language (XML) recommendation available on the Web at: http://www.w3.org/TR/REC-xml#NT-Nmtoken.

Do not use blank spaces, commas, hyphens, or any characters in this comma-separated list: \t, < >, #, |, &, ~, ?, ( ), { }.

Security role names are case sensitive.

The BEA suggested convention for security role names is that they be singular.

c. Use the <login-config> tag to define the type of authentication you want to use and the security realm to which the security constraints will be applied. In Listing 2-1, the BASIC type is specified and the realm is the default realm, which means that the security constraints will apply to the active security realm when the WebLogic Server instance boots.

d. Define one or more security roles and map them to your security constraints. In our sample, only one security role, webuser, is defined in the security constraint so only one security role name is defined here (see the <security-role> tag in Listing 2-1). However, any number of security roles can be defined.

Listing 2-1 Basic Authentication web.xml File

```xml
<?xml version='1.0' encoding='UTF-8'?>
<web-app xmlns="http://java.sun.com/xml/ns/j2ee"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <welcome-file-list>
    <welcome-file>welcome.jsp</welcome-file>
  </welcome-file-list>
  <security-constraint>
    <web-resource-collection>
      <web-resource-name>Success</web-resource-name>
      <url-pattern>/welcome.jsp</url-pattern>
      <http-method>GET</http-method>
      <http-method>POST</http-method>
    </web-resource-collection>
    <auth-constraint>
      <role-name>webuser</role-name>
    </auth-constraint>
  </security-constraint>
</web-app>
```
2. Create the `weblogic.xml` deployment descriptor. In this file you map security role names to users and groups. Listing 2-2 shows a sample `weblogic.xml` file that maps the `webuser` security role defined in the `<security-role>` tag in the `web.xml` file to a group named `myGroup`. Note that principals can be users or groups, so the `<principal-tag>` can be used for either. With this configuration, WebLogic Server will only allow users in `myGroup` to access the protected URL resource—`welcome.jsp`. However, you can use the Administration Console to modify the Web application’s security role so that other groups can be allowed to access the protected resource.

   **Note:** Creating the `weblogic.xml` deployment descriptor is optional. If you do not include this file, or include the file but do not include mappings for all security roles, all security roles without mappings will default to any user or group whose name matches the role name. For example, if you name a security role “SampleTester,” then any user or group with the name “SampleTester” will be included in that security role.

**Listing 2-2  BASIC Authentication weblogic.xml File**

```xml
<?xml version='1.0' encoding='UTF-8'?>
<weblogic-web-app xmlns="http://www.bea.com/ns/weblogic/90"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <weblogic-web-app>
    <security-role-assignment>
      <role-name>webuser</role-name>
    </security-role-assignment>
  </weblogic-web-app>
</weblogic-web-app>
```
3. Create a file that produces the Welcome screen that displays when the user enters a user name and password and is granted access. Listing 2-3 shows a sample welcome.jsp file. Figure 2-3 shows the Welcome screen.

**Listing 2-3  BASIC Authentication welcome.jsp File**

```html
<html>
<head>
  <title>Browser Based Authentication Example Welcome Page</title>
</head>
<h1> Browser Based Authentication Example Welcome Page </h1>
<p> Welcome <%= request.getRemoteUser() %>!</p>
</html>
```

**Note:** In Listing 2-3, notice that the JSP is calling an API (request.getRemoteUser()) to get the name of the user that logged in. A different API, weblogic.security.Security.getCurrentSubject(), could be used instead. To use this API to get the name of the user, use it with the SubjectUtils API as follows:

```java
String username = weblogic.security.SubjectUtils.getUsername(
  weblogic.security.Security.getCurrentSubject());
```
4. Start WebLogic Server and define the users and groups that will have access to the URL resource. In the `weblogic.xml` file (see Listing 2-2), the `<principal-name>` tag defines `myGroup` as the group that has access to the `welcome.jsp`. Therefore, use the Administration Console to define the `myGroup` group, define a user, and add that user to the `myGroup` group. For information on adding users and groups, see Users, Groups, and Security Roles in Securing WebLogic Resources.

5. Deploy the Web application and use the user defined in the previous step to access the protected URL resource.
   a. For deployment instructions, see “Deploying Web Applications” on page 2-23.
   b. Open a Web browser and enter this URL:
      
      | http://localhost:7001/basicauth/welcome.jsp |
      
   c. Enter the user name and password. The Welcome screen displays.

Developing FORM Authentication Web Applications

When using FORM authentication with Web applications, you provide a custom login screen that the Web browser displays in response to a Web application resource request and an error screen that displays if the login fails. The login screen can be generated using an HTML page, JSP, or servlet. The benefit of form-based login is that you have complete control over these screens so
that you can design them to meet the requirements of your application or enterprise policy/guideline.

The login screen prompts the user for a user name and password. Figure 2-4 shows a typical login screen generated using a JSP and Listing 2-4 shows the source code.

**Figure 2-4 Form-Based Login Screen (login.jsp)**

![Form-Based Login Screen](image)

**Listing 2-4 Form-Based Login Screen Source Code (login.jsp)**

```html
<html>
<head>)
    <title>Security WebApp login page</title>
</head>
<body bgcolor="#cccccc">
    <blockquote>
        <img src=BEA_Button_Final_web.gif align=right>
        <h2>Please enter your user name and password:</h2>
        <p>
            <form method="POST" action="j_security_check">
                <table border=1>
                    <tr>
                        <td>Username:</td>
                        <td><input type="text"></td>
                    </tr>
                    <tr>
                        <td>Password:</td>
                        <td><input type="password"></td>
                    </tr>
                </table>
                <input type="submit" value="Submit">
            </form>
        </p>
    </blockquote>
</body>
</html>
```
Securing Web Applications

Figure 2-5 shows a typical login error screen generated using HTML and Listing 2-5 shows the source code.

**Figure 2-5  Login Error Screen**

![Login Error Screen](image)

Sorry, your username and password were not recognized.

*Return to welcome page* or *logout*
To develop a Web application that provides FORM authentication, perform these steps:

1. Create the web.xml deployment descriptor. In this file you include the following information (see Listing 2-6):
   a. Define the welcome file. The welcome file name is welcome.jsp.
   b. Define a security constraint for each set of URL resources that you plan to protect. Each set of URL resources share a common URL. URL resources such as HTML pages, JSPs, and servlets are the most commonly protected, but other types of URL resources are supported. In Listing 2-6, the URL pattern points to /admin/edit.jsp, thus protecting the edit.jsp file located in the Web application’s admin sub-directory, defines the HTTP method that is allowed to access the URL resource, GET, and defines the security role name, admin.

   Note: Do not use hyphens in security role names. Security role names with hyphens cannot be modified in the Administration Console. Also, the BEA suggested convention for security role names is that they be singular.
   c. Define the type of authentication you want to use and the security realm to which the security constraints will be applied. In this case, the FORM type is specified and no realm
is specified, so the realm is the default realm, which means that the security constraints will apply to the security realm that is activated when a WebLogic Server instance boots.

d. Define one or more security roles and map them to your security constraints. In our sample, only one security role, admin, is defined in the security constraint so only one security role name is defined here. However, any number of security roles can be defined.

**Listing 2-6  FORM Authentication web.xml File**

```xml
<?xml version='1.0' encoding='UTF-8'?>
<web-app xmlns="http://java.sun.com/xml/ns/j2ee"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <web-app>
    <welcome-file-list>
      <welcome-file>welcome.jsp</welcome-file>
    </welcome-file-list>
    <security-constraint>
      <web-resource-collection>
        <web-resource-name>AdminPages</web-resource-name>
        <description>
          These pages are only accessible by authorized administrators.
        </description>
        <url-pattern>/admin/edit.jsp</url-pattern>
        <http-method>GET</http-method>
      </web-resource-collection>
      <auth-constraint>
        <description>
          These are the roles who have access.
        </description>
        <role-name>
          admin
        </role-name>
      </auth-constraint>
      <user-data-constraint>
        <description>
          This is how the user data must be transmitted.
        </description>
      </user-data-constraint>
    </security-constraint>
  </web-app>
</web-app>
```
Developing Secure Web Applications

2. Create the `weblogic.xml` deployment descriptor. In this file you map security role names to users and groups. Listing 2-7 shows a sample `weblogic.xml` file that maps the `admin` security role defined in the `<security-role>` tag in the `web.xml` file to the group `supportGroup`. With this configuration, WebLogic Server will only allow users in the `supportGroup` group to access the protected WebLogic resource. However, you can use the Administration Console to modify the Web application’s security role so that other groups can be allowed to access the protected WebLogic resource.

Listing 2-7  FORM Authentication weblogic.xml File

```xml
<?xml version='1.0' encoding='UTF-8'?>
<weblogic-web-app xmlns="http://www.bea.com/ns/weblogic/90"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <login-config>
    <auth-method>FORM</auth-method>
    <form-login-config>
      <form-login-page>/login.jsp</form-login-page>
      <form-error-page>/fail_login.html</form-error-page>
    </form-login-config>
  </login-config>
  <security-role>
    <description>
      An administrator
    </description>
    <role-name>
      admin
    </role-name>
  </security-role>
</weblogic-web-app>
```

Programming WebLogic Security 2-19
Securing Web Applications

<security-role-assignment>
  <role-name>admin</role-name>
  <principal-name>supportGroup</principal-name>
</security-role-assignment>
</weblogic-web-app>

3. Create a Web application file that produces the welcome screen when the user requests the protected Web application resource by entering the URL. Listing 2-8 shows a sample welcome.jsp file. Figure 2-3 shows the Welcome screen.

Listing 2-8  Form Authentication welcome.jsp File

<html>
<head>
  <title>Security login example</title>
</head>
<body bgcolor="#cccccc">
<blockquote>
  <img src=BEA_Button_Final_web.gif align=right>
  <h1>Security Login Example</h1>
  <p>Welcome <%= request.getRemoteUser() %>
  </p>
  <p>If you are an administrator, you can configure the background color of the Web Application.
  </p>
  <a href="admin/edit.jsp">Configure background</a>
</blockquote>
</body>
</html>
Note: In Listing 2-3, notice that the JSP is calling an API (request.getRemoteUser()) to get the name of the user that logged in. A different API, weblogic.security.Security.getCurrentSubject(), could be used instead. To use this API to get the name of the user, use it with the SubjectUtils API as follows:

```java
String username = weblogic.security.SubjectUtils.getUsername(
    weblogic.security.Security.getCurrentSubject());
```

4. Start WebLogic Server and define the users and groups that will have access to the URL resource. In the weblogic.xml file (see Listing 2-7), the <role-name> tag defines admin as the group that has access to the edit.jsp file and defines the user joe as a member of that group. Therefore, use the Administration Console to define the admin group, and define user joe and add joe to the admin group. You can also define other users and add them to the group and they will also have access to the protected WebLogic resource. For information on adding users and groups, see Users, Groups, and Security Roles in Securing WebLogic Resources.

5. Deploy the Web application and use the user(s) defined in the previous step to access the protected Web application resource.
   a. For deployment instructions, see “Deploying Web Applications” on page 2-23.
   b. Open a Web browser and enter this URL:

```
http://hostname:7001/security/welcome.jsp
```

   c. Enter the user name and password. The Welcome screen displays.

Using Identity Assertion for Web Application Authentication

You use identity assertion in Web applications to verify client identities for authentication purposes. When using identity assertion, the following requirements must be met:

1. The authentication type must be set to CLIENT-CERT.
2. An Identity Assertion provider must be configured in the server. If the Web browser or Java client requests a WebLogic Server resource protected by a security policy, WebLogic Server requires that the Web browser or Java client have an identity. The WebLogic Identity Assertion provider maps the token from a Web browser or Java client to a user in a WebLogic Server security realm. For information on how to configure an Identity Assertion provider, see Configuring Identity Assertion Providers in Securing WebLogic Server.

3. The user corresponding to the token’s value must be defined in the server’s security realm; otherwise the client will not be allowed to access a protected WebLogic resource. For information on configuring users on the server, see Users, Groups, and Security Roles in Securing WebLogic Resources.

Using Two-Way SSL for Web Application Authentication

You use two-way SSL in Web applications to verify that clients are whom they claim to be. When using two-way SSL, the following requirements must be met:

1. The authentication type must be set to CLIENT-CERT.

2. The server must be configured for two-way SSL. For information on using SSL and digital certificates, see Chapter 4, “Using SSL Authentication in Java Clients.”. For information on configuring SSL on the server, see Configuring SSL in Securing WebLogic Server.

3. The client must use HTTPS to access the Web application on the server.

4. An Identity Assertion provider must be configured in the server. If the Web browser or Java client requests a WebLogic Server resource protected by a security policy, WebLogic Server requires that the Web browser or Java client have an identity. The WebLogic Identity Assertion provider allows you to enable a user name mapper in the server that maps the digital certificate of a Web browser or Java client to a user in a WebLogic Server security realm. For information on how to configure security providers, see Configuring Security Providers in Managing WebLogic Security.

5. The user corresponding to the Subject's Distinguished Name (SubjectDN) attribute in the client’s digital certificate must be defined in the server’s security realm; otherwise the client will not be allowed to access a protected WebLogic resource. For information on configuring users on the server, see Users, Groups, and Security Roles in Securing WebLogic Resources.

Note: When you use SSL authentication, it is not necessary to use web.xml and weblogic.xml files to specify server configuration because you use the Administration Console to specify the server’s SSL configuration.
Developing Swing-Based Authentication Web Applications

Web browsers can also be used to run graphical user interfaces (GUIs) that were developed using Java Foundation Classes (JFC) Swing components; the Swing component kit is integrated into the Java 2 platform, Standard Edition (J2SE).

For information on how to create a graphical user interface (GUI) for applications and applets using the Swing components, see the Creating a GUI with JFC/Swing tutorial (also known as The Swing Tutorial) produced by Sun Microsystems, Inc. You can access this tutorial on the Web at http://java.sun.com/docs/books/tutorial/uiswing/.

After you have developed your Swing-based GUI, refer to “Developing FORM Authentication Web Applications” on page 2-14 and use the Swing-based screens to perform the steps required to develop a Web application that provides FORM authentication.

Note: When developing a Swing-based GUI, do not rely on the Java Virtual Machine-wide user for child threads of the swing event thread. This is not J2EE compliant and does not work in thin clients, or in IIOP in general. Instead, take either of the following approaches:

- Make sure an InitialContext is created before any Swing artifacts.
- Or, use the Java Authentication and Authorization Service (JAAS) to log in and then use the Security.runAs() method inside the Swing event thread and its children.

Deploying Web Applications

To deploy a Web application on a server running in development mode, perform the following steps:

Note: For more information about deploying Web applications in either development of production mode, see Deploying Applications and Modules in Deploying Applications to WebLogic Server.

1. Set up a directory structure for the Web application’s files. Figure 2-6 shows the directory structure for the Web application named basicauth. The top-level directory must be assigned the name of the Web application and the sub-directory must be named WEB-INF.
2. To deploy the Web application in exploded directory format, that is, not in the Java archive (jar) format, simply move your directory to the applications directory on your server. For example, you would deploy the basicauth Web application in the following location:

\`\`WL_HOME\user_projects\domains\mydomain\applications\basicauth\`

If the WebLogic Server instance is running, the application should auto-deploy. Use the Administration Console to verify that the application deployed.

If the WebLogic Server instance is not running, the Web application should auto-deploy when you start the server.

3. If you have not done so already, use the Administration Console to configure the users and groups that will have access to the Web application. To determine the users and groups that are allowed access to the protected WebLogic resource, examine the weblogic.xml file. For example, the weblogic.xml file for the basicauth sample (see Listing 2-2) defines myGroup as the only group to have access to the welcome.jsp file.

For more information on deploying secure Web applications, see Deploying Applications and Modules in Deploying Applications to WebLogic Server.

### Using Declarative Security With Web Applications

There are three ways to implement declarative security:

1. Security providers via the Administration Console, as described in Securing WebLogic Resources.

2. Java Authorization Contract for Containers (JACC), as described in “Using the Java Authorization Contract for Containers” on page 7-6.

3. Deployment descriptors, which are discussed in this section.
Which of these three methods is used is defined by the JACC flags and the security model. (Security models are described in Options for Securing EJB and Web Application Resources in Securing WebLogic Resources.)

To implement declarative security in Web applications, you can use deployment descriptors (web.xml and weblogic.xml) to define security requirements. The deployment descriptors map the application’s logical security requirements to its runtime definitions. And at runtime, the servlet container uses the security definitions to enforce the requirements. For a discussion of using deployment descriptors, see “Developing Secure Web Applications” on page 2-9.

For information about how to use deployment descriptors and the externally-defined element to configure security in Web applications declaratively, see “externally-defined” on page 2-31.

For information about how to use the Administration Console to configure security in Web applications, see Securing WebLogic Resources.

Web Application Security-Related Deployment Descriptors

The following topics describe the deployment descriptor elements that are used in the web.xml and weblogic.xml files to define security requirements in Web applications:

- “web.xml Deployment Descriptors” on page 2-25
- “weblogic.xml Deployment Descriptors” on page 2-31

web.xml Deployment Descriptors

The following web.xml security-related deployment descriptor elements are supported by WebLogic Server:

- “auth-constraint” on page 2-26
- “security-constraint” on page 2-26
- “security-role” on page 2-28
- “security-role-ref” on page 2-28
- “user-data-constraint” on page 2-29
- “web-resource-collection” on page 2-30
auth-constraint

The optional auth-constraint element defines which groups or principals have access to the collection of Web resources defined in this security constraint.

The following table describes the elements you can define within an auth-constraint element.

<table>
<thead>
<tr>
<th>Element</th>
<th>Required/Optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;description&gt;</td>
<td>Optional</td>
<td>A text description of this security constraint.</td>
</tr>
<tr>
<td>&lt;role-name&gt;</td>
<td>Optional</td>
<td>Defines which security roles can access resources defined in this</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&lt;security-constraint&gt;. Security role names are mapped to principals using</td>
</tr>
<tr>
<td></td>
<td></td>
<td>the &lt;security-role-ref&gt; element. See “security-role-ref” on page 2-28.</td>
</tr>
</tbody>
</table>

Used Within

The auth-constraint element is used within the security-constraint element.

Example

See Listing 2-9 for an example of how to use the auth-constraint element in a web.xml file.

security-constraint

The security-constraint element is used in the web.xml file to define the access privileges to a collection of resources defined by the web-resource-collection element.

The following table describes the elements you can define within a security-constraint element.

<table>
<thead>
<tr>
<th>Element</th>
<th>Required/Optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;web-resource-collection&gt;</td>
<td>Required</td>
<td>Defines the components of the Web Application to which this security</td>
</tr>
<tr>
<td></td>
<td></td>
<td>constraint is applied. For more information, see “web-resource-collection”</td>
</tr>
<tr>
<td></td>
<td></td>
<td>on page 2-30.</td>
</tr>
<tr>
<td>&lt;auth-constraint&gt;</td>
<td>Optional</td>
<td>Defines which groups or principals have access to the collection of web</td>
</tr>
<tr>
<td></td>
<td></td>
<td>resources defined in this security constraint. For more information, see</td>
</tr>
<tr>
<td></td>
<td></td>
<td>“auth-constraint” on page 2-26.</td>
</tr>
</tbody>
</table>
Example

Listing 2-9 shows how to use the security-constraint element to define security for the SecureOrdersEast resource in a web.xml file.

Listing 2-9 Security Constraint Example

web.xml entries:
<security-constraint>
    <web-resource-collection>
        <web-resource-name>SecureOrdersEast</web-resource-name>
        <description>
            Security constraint for resources in the orders/east directory
        </description>
        <url-pattern>/orders/east/*</url-pattern>
        <http-method>POST</http-method>
        <http-method>GET</http-method>
    </web-resource-collection>
    <auth-constraint>
        <description>
            constraint for east coast sales
        </description>
        <role-name>east</role-name>
        <role-name>manager</role-name>
    </auth-constraint>
    <user-data-constraint>
        <description>SSL not required</description>
        <transport-guarantee>NONE</transport-guarantee>
    </user-data-constraint>
</security-constraint>
security-role

The security-role element contains the definition of a security role. The definition consists of an optional description of the security role, and the security role name.

The following table describes the elements you can define within a security-role element.

<table>
<thead>
<tr>
<th>Element</th>
<th>Required/Optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;description&gt;</td>
<td>Optional</td>
<td>A text description of this security role.</td>
</tr>
<tr>
<td>&lt;role-name&gt;</td>
<td>Required</td>
<td>The role name. The name you use here must have a corresponding entry in the WebLogic-specific deployment descriptor, weblogic.xml, which maps roles to principals in the security realm. For more information, see “security-role-assignment” on page 2-36.</td>
</tr>
</tbody>
</table>

Example

See Listing 2-12 for an example of how to use the security-role element in a web.xml file.

security-role-ref

The security-role-ref element links a security role name defined by <security-role> to an alternative role name that is hard-coded in the servlet logic. This extra layer of abstraction allows the servlet to be configured at deployment without changing servlet code.

The following table describes the elements you can define within a security-role-ref element.

<table>
<thead>
<tr>
<th>Element</th>
<th>Required/Optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;description&gt;</td>
<td>Optional</td>
<td>Text description of the role.</td>
</tr>
<tr>
<td>&lt;role-name&gt;</td>
<td>Required</td>
<td>Defines the name of the security role or principal that is used in the servlet code.</td>
</tr>
</tbody>
</table>
Example

See Listing 2-15 for an example of how to use the security-role-ref element in a web.xml file.

user-data-constraint

The user-data-constraint element defines how data communicated between the client and the server should be protected.

The following table describes the elements you can define within a user-data-constraint element.

<table>
<thead>
<tr>
<th>Element</th>
<th>Required/Optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;description&gt;</td>
<td>Optional</td>
<td>A text description.</td>
</tr>
<tr>
<td>&lt;transport-guarantee&gt;</td>
<td>Required</td>
<td>Specifies data security requirements for communications between the client and the server.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Range of values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>NONE—The application does not require any transport guarantees.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>INTEGRAL—The application requires that the data be sent between the client and server in such a way that it cannot be changed in transit.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>CONFIDENTIAL—The application requires that data be transmitted so as to prevent other entities from observing the contents of the transmission.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>WebLogic Server establishes a Secure Sockets Layer (SSL) connection when the user is authenticated using the INTEGRAL or CONFIDENTIAL transport guarantee.</td>
</tr>
</tbody>
</table>

Used Within

The user-data-constraint element is used within the security-constraint element.
Example
See Listing 2-9 for an example of how to use the user-data-constraint element in a web.xml file.

**web-resource-collection**

The web-resource-collection element identifies a subset of the resources and HTTP methods on those resources within a Web application to which a security constraint applies. If no HTTP methods are specified, the security constraint applies to all HTTP methods.

The following table describes the elements you can define within a web-resource-collection element.

<table>
<thead>
<tr>
<th>Element</th>
<th>Required/Optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;web-resource-name&gt;</td>
<td>Required</td>
<td>The name of this web resource collection.</td>
</tr>
<tr>
<td>&lt;description&gt;</td>
<td>Optional</td>
<td>Text description of the Web resource.</td>
</tr>
<tr>
<td>&lt;url-pattern&gt;</td>
<td>Required</td>
<td>The mapping, or location, of the Web resource collection. URL patterns must use the syntax defined in section 11.2 of JSR-000154, Java Servlet Specification Version 2.4. The pattern &lt;url-pattern&gt;/&lt;/url-pattern&gt; applies the security constraint to the entire Web application.</td>
</tr>
<tr>
<td>&lt;http-method&gt;</td>
<td>Optional</td>
<td>The HTTP methods to which the security constraint applies when clients attempt to access the Web resource collection. If no HTTP methods are specified, then the security constraint applies to all HTTP methods.</td>
</tr>
</tbody>
</table>

**Used Within**

The web-resource-collection element is used within the security-constraint element.

Example
See Listing 2-9 for an example of how to use the web-resource-collection element in a web.xml file.
weblogic.xml Deployment Descriptors

The following weblogic.xml security-related deployment descriptor elements are supported by WebLogic Server:

- “externally-defined” on page 2-31
- “run-as-principal-name” on page 2-34
- “run-as-role-assignment” on page 2-34
- “security-permission” on page 2-35
- “security-permission-spec” on page 2-35
- “security-role-assignment” on page 2-36

For additional information on weblogic.xml deployment descriptors, see the section XML Deployment Descriptors in Developing Applications with WebLogic Server.

For additional information on the weblogic.xml elements, see weblogic.xml Deployment Descriptor Elements in Developing Web Applications, Servlets, and JSPs for WebLogic Server.

externally-defined

In WebLogic Server 8.1 and later, the externally-defined element is supported for use in the weblogic.xml deployment descriptors. You use this element, instead of the `<principal-name>` tag, to explicitly indicate that you want the security roles defined by the `<role-name>` element in the web.xml deployment descriptors to use the mappings that you specify in the Administration Console.

Note: The externally-defined element replaces the global-role element that was used in WebLogic Server 7.0 SP1. The externally-defined element has the same functionality as the global-role element. The global-role element was deprecated in WebLogic Server 8.1.

The externally-defined element gives you the flexibility of not having to specify a specific security role mapping for each security role defined in the deployment descriptors for a particular Web application. Rather, you can use the Administration Console to specify and modify a specific role mapping for each defined role at any time. Additionally, because you may elect to use this element on some applications and not others, it is not necessary to select the ignore roles and policies from DD option for the security realm. You select this option in the On Future Redeploys: field on the General tab of the Security->Realms->myrealm control panel on the Administration Console. Therefore, within the same security realm, deployment descriptors can
be used to specify and modify security for some applications while the Administration Console can be used to specify and modify security for others.

**Note:** When specifying security role names, observe the following conventions and restrictions:

- The proper syntax for a security role name is as defined for an `Nmtoken` in the Extensible Markup Language (XML) recommendation available on the Web at: [http://www.w3.org/TR/REC-xml#NT-Nmtoken](http://www.w3.org/TR/REC-xml#NT-Nmtoken).
- Do not use blank spaces, commas, hyphens, or any characters in this comma-separated list: `\t, <, >, #, &, ~, ?, (, )`.
- Security role names are case sensitive.
- The BEA suggested convention for security role names is that they be singular.

**Used Within**

The externally-defined element is used within the `security-role-assignment` element.

**Example**

Listing 2-10 and Listing 2-11 show by comparison how to use the externally-defined element in the `weblogic.xml` file. In Listing 2-11, the specification of the "webuser" externally-defined element in the `weblogic.xml` means that for security to be correctly configured on the `getReceipts` method, the principals for `webuser` will have to be created in the Administration Console.

**Note:** If you need to list a significant number of principals, consider specifying groups instead of users. There are performance issues if you specify too many users.

**Listing 2-10** Using the `web.xml` and `weblogic.xml` Files to Map Security Roles and Principals to a Security Realm

```xml
web.xml entries:
<web-app>
  ...
  <security-role>
    <role-name>webuser</role-name>
  </security-role>
  ...
```
Web Application Security-Related Deployment Descriptors

Listing 2-11 Using the externally-defined tag in Web Application Deployment Descriptors

web.xml entries:
<web-app>
  ...
  <security-role>
    <role-name>webuser</role-name>
  </security-role>
  ...
</web-app>

<weblogic.xml entries:
<weblogic-web-app>
  <security-role-assignment>
    <role-name>webuser</role-name>
    <externally-defined/>
  </security-role-assignment>
</weblogic-web-app>

For information about how to use the Administration Console to configure security for Web applications, see Securing WebLogic Resources.
run-as-principal-name

The run-as-principal-name element specifies the name of a principal to use for a security role defined by a run-as element in the companion web.xml file.

Used Within

The run-as-principal-name element is used within a run-as-role-assignment element.

Example

For an example of how to use the run-as-principal-name element, see Listing 2-12.

run-as-role-assignment

The run-as-role-assignment element maps a given role name, defined by a role-name element in the companion web.xml file, to a valid user name in the system. The value can be overridden for a given servlet by the run-as-principal-name element in the servlet-descriptor. If the run-as-role-assignment element is absent for a given role name, the Web application container chooses the first principal-name defined in the security-role-assignment element.

The following table describes the elements you can define within a run-as-role-assignment element.

<table>
<thead>
<tr>
<th>Element</th>
<th>Required</th>
<th>Optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;role-name&gt;</td>
<td>Required</td>
<td>Optional</td>
<td>Specifies the name of a security role name specified in a run-as element in the companion web.xml file.</td>
</tr>
<tr>
<td>&lt;run-as-principal-name&gt;</td>
<td>Required</td>
<td></td>
<td>Specifies a principal for the security role name defined in a run-as element in the companion web.xml file.</td>
</tr>
</tbody>
</table>

Example:

Listing 2-12 shows how to use the run-as-role-assignment element to have the SnoopServlet always execute as a user joe.

---

Listing 2-12  run-as-role-assignment Element Example

web.xml:
<servlet>
  <servlet-name>SnoopServlet</servlet-name>
  <servlet-class>extra.SnoopServlet</servlet-class>
  <run-as>
    <role-name>runasrole</role-name>
  </run-as>
</servlet>

<security-role>
  <role-name>runasrole</role-name>
</security-role>

weblogic.xml:
<weblogic-web-app>
  <run-as-role-assignment>
    <role-name>runasrole</role-name>
    <run-as-principal-name>joe</run-as-principal-name>
  </run-as-role-assignment>
</weblogic-web-app>

security-permission
The security-permission element specifies a security permission that is associated with a J2EE Sandbox.

Example
For an example of how to use the security-permission element, see Listing 2-13.

security-permission-spec
The security-permission-spec element specifies a single security permission based on the Security policy file syntax. Refer to the following URL for Sun's implementation of the security permission specification:
http://java.sun.com/j2se/1.5.0/docs/guide/security/PolicyFiles.html#FileSyntax

Note: Disregard the optional codebase and signedBy clauses.
Securing Web Applications

Used Within
The security-permission-spec element is used within the security-permission element.

Example
Listing 2-13 shows how to use the security-permission-spec element to grant permission to the java.net.SocketPermission class.

Listing 2-13   security-permission-spec Element Example

<weblogic-web-app>
  <security-permission>
    <description>Optional explanation goes here</description>
    <security-permission-spec>
      <!--
      A single grant statement following the syntax of http://java.sun.com/j2se/1.5.0/docs/guide/security/PolicyFiles.html#FileSyntax, without the "codebase" and "signedBy" clauses, goes here. For example: -->
      grant {
        permission java.net.SocketPermission ",", "resolve";
      };
    </security-permission-spec>
  </security-permission>
</weblogic-web-app>

In Listing 2-13, permission java.net.SocketPermission is the permission class name, "***" represents the target name, and resolve indicates the action (resolve host/IP name service lookups).

security-role-assignment
The security-role-assignment element declares a mapping between a security role and one or more principals in the WebLogic Server security realm,
Example

Listing 2-14 shows how to use the `security-role-assignment` element to assign principals to the PayrollAdmin role.

**Note:** If you need to list a significant number of principals, consider specifying groups instead of users. There are performance issues if you specify too many users.

**Listing 2-14  security-role-assignment Element Example**

```xml
<weblogic-web-app>
  <security-role-assignment>
    <role-name>PayrollAdmin</role-name>
    <principal-name>Tanya</principal-name>
    <principal-name>Fred</principal-name>
    <principal-name>system</principal-name>
  </security-role-assignment>
</weblogic-web-app>
```

Using Programmatic Security With Web Applications

You can write your servlets to access users and security roles programmatically in your servlet code. To do this, use the following methods in your servlet code:

- `javax.servlet.http.HttpServletRequest.getUserPrincipal`
- `javax.servlet.http.HttpServletRequest.isUserInRole(String role)`

**getUserPrincipal**

You use the `getUserPrincipal()` method to determine the current user of the Web application. This method returns a WLSUser Principal if one exists in the current user. In the case of multiple WLSUser Principals, the method returns the first in the ordering defined by the `Subject.getPrincipals().iterator()` method. If there are no WLSUser Principals, then the `getUserPrincipal()` method returns the first non-WLSGroup Principal. If there are no Principals or all Principals are of type WLSGroup, this method returns null. This behavior is identical to the semantics of the `weblogic.security.SubjectUtils.getUserPrincipal()` method.
For more information about how to use the `getUserPrincipal()` method, see http://java.sun.com/j2ee/1.4/docs/tutorial/doc/Security4.html.

**isUserInRole**

The `javax.servlet.http.HttpServletRequest.isUserInRole(String role)` method returns a boolean indicating whether the authenticated user is granted the specified logical security “role.” If the user has not been authenticated, this method returns false.

The `isUserInRole()` method maps security roles to the group names in the security realm. **Listing 2-15** shows the elements that are used with the `<servlet>` element to define the security role in the `web.xml` file.

**Listing 2-15  IsUserInRole web.xml and weblogic.xml Elements**

```xml
Begin web.xml entries:
...
<servlet>
    <security-role-ref>
        <role-name>user-rolename</role-name>
        <role-link>rolename-link</role-link>
    </security-role-ref>
</servlet>

<security-role>
    <role-name>rolename-link</role-name>
</security-role>
...
Begin weblogic.xml entries:
...
<security-role-assignment>
    <role-name>rolename-link</role-name>
    <principal-name>groupname</principal>
    <principal-name>username</principal>
</security-role-assignment>
...```
The string role is mapped to the name supplied in the <role-name> element, which is nested inside the <security-role-ref> element of a <servlet> declaration in the web.xml deployment descriptor. The <role-name> element defines the name of the security role or principal (the user or group) that is used in the servlet code. The <role-link> element maps to a <role-name> defined in the <security-role-assignment> element in the weblogic.xml deployment descriptor.

**Note:** When specifying security role names, observe the following conventions and restrictions:

- The proper syntax for a security role name is as defined for an Nmtoken in the Extensible Markup Language (XML) recommendation available on the Web at: [http://www.w3.org/TR/REC-xml#NT-Nmtoken](http://www.w3.org/TR/REC-xml#NT-Nmtoken).
- Do not use blank spaces, commas, hyphens, or any characters in this comma-separated list: \t, < >, #, |, &, ~, ?, ( ), { }.
- Security role names are case sensitive.
- The BEA suggested convention for security role names is that they be singular.

For example, if the client has successfully logged in as user Bill with the security role of manager, the following method would return true:

request.isUserInRole(“manager”)  

**Listing 2-16** provides an example.

**Listing 2-16  Example of Security Role Mapping**

Servlet code:

```java
out.println("Is the user a Manager? " +
        request.isUserInRole("manager"));
```

web.xml entries:

```xml
<servlet>
    ...
    <role-name>manager</role-name>
    <role-link>mgr</role-link>
    ...
</servlet>
```
<security-role>
    <role-name>mgr</role-name>
</security-role>

weblogic.xml entries:

<security-role-assignment>
    <role-name>mgr</role-name>
    <principal-name>bostonManagers</principal-name>
    <principal-name>Bill</principal-name>
    <principal-name>Ralph</principal-name>
</security-role-ref>

### Using the Programmatic Authentication API

There are some applications where programmatic authentication is appropriate.

WebLogic Server provides a server-side API that supports programmatic authentication from within a servlet application:

```java
weblogic.servlet.security.ServletAuthentication
```

Using this API, you can write servlet code that authenticates the user, logs in the user, and associates the user with the current session so that the user is registered in the default (active) security realm. Once the login is completed, it appears as if the user logged in using the standard mechanism.

You have the option of using either of two WebLogic-supplied classes with the ServletAuthentication API, the `weblogic.security.SimpleCallbackHandler` class or the `weblogic.security.URLCallbackHandler` class. For more information on these classes, see Javadocs for WebLogic Classes.

Listing 2-17 shows an example that uses `SimpleCallbackHandler`. Listing 2-18 shows an example that uses `URLCallbackHandler`.

### Listing 2-17  Programmatic Authentication Code Fragment Using the SimpleCallbackHandler Class

```java
CallbackHandler handler = new SimpleCallbackHandler(username, password);

Subject mySubject =
```

weblogic.security.services.Authentication.login(handler);
weblogic.servlet.security.ServletAuthentication.runAs(mySubject, request);
// Where request is the HttpServletRequest object.

Listing 2-18  Programmatic Authentication Code Fragment Using the URLCallbackHandler Class

CallbackHandler handler = new URLCallbackHandler(username, password);
Subject mySubject =
    weblogic.security.services.Authentication.login(handler);
weblogic.servlet.security.ServletAuthentication.runAs(mySubject, request);
// Where request is the HttpServletRequest object.
Using JAAS Authentication in Java Clients

The following topics are covered in this section:

- “JAAS and WebLogic Server” on page 3-2
- “JAAS Authentication Development Environment” on page 3-3
- “Writing a Client Application Using JAAS Authentication” on page 3-12
- “Using JNDI Authentication” on page 3-17
- “Java Client JAAS Authentication Code Examples” on page 3-19

The sections refer to sample code which is available online at BEA’s dev2dev web site, and is also included in the WebLogic Server distribution at:

SAMPLES_HOME\server\examples\src\examples\security\jaas

The jaas directory contains an instructions.html file, ant build files, a sample_jaas.config file, and the following Java files:

- BaseClient.java
- BaseClientConstants.java
- SampleAction.java
- SampleCallbackHandler.java
- SampleClient.java
- TradeResult.java
Using JAAS Authentication in Java Clients

- TraderBean.java

You will need to look at the examples when reading the information in the following sections.

**JAAS and WebLogic Server**

The Java Authentication and Authorization Service (JAAS) is a standard extension to the security in the J2SE Development Kit 5.0. JAAS provides the ability to enforce access controls based on user identity. JAAS is provided in WebLogic Server as an alternative to the JNDI authentication mechanism.

WebLogic Server clients use the authentication portion of the standard JAAS only. The JAAS LoginContext provides support for the ordered execution of all configured authentication provider LoginModule instances and is responsible for the management of the completion status of each configured provider.

Note the following considerations when using JAAS authentication for Java clients:

- WebLogic Server clients can either use the JNDI login or JAAS login for authentication, however JAAS login is the preferred method.

- While JAAS is the preferred method of authentication, the WebLogic-supplied LoginModule (weblogic.security.auth.login.UsernamePasswordLoginModule) only supports username and password authentication. Thus, for client certificate authentication (also referred to as two-way SSL authentication), you should use JNDI. To use JAAS for client certificate authentication, you must write a custom LoginModule that does certificate authentication.

  **Note:** If you write your own LoginModule for use with WebLogic Server clients, have it call weblogic.security.auth.Authenticate.authenticate() to perform the login.

- To perform a JAAS login from a remote Java client (that is, the Java client is not a WebLogic Server client), you may use the WebLogic-supplied LoginModule to perform the login. However, if you elect not to use the WebLogic-supplied LoginModule but decide to write your own instead, you must have it call the weblogic.security.auth.Authenticate.authenticate() method to perform the login.

- If you are using a remote, or perimeter, login system such as Security Assertion Markup Language (SAML), you do not need to call weblogic.security.auth.Authenticate.authenticate(). You only need to call the authenticate() method if you are using WebLogic Server to perform the logon.
Note: WebLogic Server provides full container support for JAAS authentication and supports full use of JAAS authentication and authorization in application code.

- Within WebLogic Server, JAAS is called to perform the login. Each Authentication provider includes a LoginModule. This is true for servlet logins as well as Java client logins via JNDI or JAAS. The method WebLogic Server calls internally to perform the JAAS logon is `weblogic.security.services.Authentication.authenticate()`. When using the `Authenticate` class, `weblogic.security.SimpleCallbackHandler` may be a useful helper class.

- While WebLogic Server does not protect any resources using JAAS authorization (it uses WebLogic security), you can use JAAS authorization in application code to protect the application’s own resources.

For more information about JAAS, see the JAAS documentation at http://java.sun.com/products/jaas/reference/docs/index.html.

### JAAS Authentication Development Environment

Whether the client is an application, applet, Enterprise JavaBean (EJB), or servlet that requires authentication, WebLogic Server uses the JAAS classes to reliably and securely authenticate to the server. JAAS implements a Java version of the Pluggable Authentication Module (PAM) framework, which permits applications to remain independent from underlying authentication technologies. Therefore, the PAM framework allows the use of new or updated authentication technologies without requiring modifications to a Java application.

WebLogic Server uses JAAS for remote Java client authentication, and internally for authentication. Therefore, only developers of custom Authentication providers and developers of remote Java client applications need to be involved with JAAS directly. Users of Web browser clients or developers of within-container Java client applications (for example, those calling an EJB from a servlet) do not require direct use or knowledge of JAAS.

Note: In order to implement security in a WebLogic client you must install the WebLogic Server software distribution kit on the Java client.

The following topics are covered in this section:

- “JAAS Authentication APIs” on page 3-4
- “JAAS Client Application Components” on page 3-9
- “WebLogic LoginModule Implementation” on page 3-11
JAAS Authentication APIs

To implement Java clients that use JAAS authentication on WebLogic Server, you use a combination of Java J2SE 5.0 application programming interfaces (APIs) and WebLogic APIs. Table 3-1 lists and describes the Java API packages used to implement JAAS authentication. The information in Table 3-1 is taken from the Java API documentation and annotated to add WebLogic Server specific information. For more information on the Java APIs, see the Javadocs at http://java.sun.com/j2se/1.5.0/docs/api/index.html and http://java.sun.com/j2ee/1.4/docs/api/index.html.

Table 3-2 lists and describes the WebLogic APIs used to implement JAAS authentication. For more information, see Javadocs for WebLogic Classes.
<table>
<thead>
<tr>
<th>Java JAAS API</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>javax.security.auth.Subject</code></td>
<td>The Subject class represents the source of the request, and can be an individual user or a group. The Subject object is created only after the subject is successfully logged in.</td>
</tr>
<tr>
<td><code>javax.security.auth.login.LoginContext</code></td>
<td>The LoginContext class describes the basic methods used to authenticate Subjects and provides a way to develop an application independent of the underlying authentication technology. A Configuration specifies the authentication technology, or LoginModule, to be used with a particular application. Therefore, different LoginModules can be plugged in under an application without requiring any modifications to the application itself. After the caller instantiates a LoginContext, it invokes the login method to authenticate a Subject. This login method invokes the login method from each of the LoginModules configured for the name specified by the caller. If the login method returns without throwing an exception, then the overall authentication succeeded. The caller can then retrieve the newly authenticated Subject by invoking the getSubject method. Principals and credentials associated with the Subject may be retrieved by invoking the Subject's respective getPrincipals, getPublicCredentials, and getPrivateCredentials methods. To log the Subject out, the caller invokes the logout method. As with the login method, this logout method invokes the logout method for each LoginModule configured for this LoginContext. For a sample implementation of this class, see Listing 3-3.</td>
</tr>
<tr>
<td><code>javax.security.auth.login.Configuration</code></td>
<td>This is an abstract class for representing the configuration of LoginModules under an application. The Configuration specifies which LoginModules should be used for a particular application, and in what order the LoginModules should be invoked. This abstract class needs to be subclassed to provide an implementation which reads and loads the actual configuration. In WebLogic Server, use a login configuration file instead of this class. For a sample configuration file, see Listing 3-2. By default, WebLogic Server uses the Sun Microsystems, Inc. configuration class, which reads from a configuration file.</td>
</tr>
</tbody>
</table>

Table 3-1 Java JAAS APIs
Using JAAS Authentication in Java Clients

Table 3-1 Java JAAS APIs

<table>
<thead>
<tr>
<th>Java JAAS API</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>javax.security.auth.spi.</td>
<td></td>
</tr>
<tr>
<td>LoginModule</td>
<td>LoginModule describes the interface implemented by authentication technology providers. LoginModules are plugged in under applications to provide a particular type of authentication. While application developers write to the LoginContext API, authentication technology providers implement the LoginModule interface. A configuration specifies the LoginModule(s) to be used with a particular login application. Therefore, different LoginModules can be plugged in under the application without requiring any modifications to the application itself.</td>
</tr>
</tbody>
</table>

Note: WebLogic Server provides an implementation of the LoginModule (weblogic.security.auth.login.UsernamePasswordLoginModule). BEA recommends that you use this implementation for JAAS authentication in WebLogic Server Java clients; however, you can develop your own LoginModule.
Implementations of this interface are passed to a `CallbackHandler`, allowing underlying security services to interact with a calling application to retrieve specific authentication data, such as usernames and passwords, or to display information such as error and warning messages.

Callback implementations do not retrieve or display the information requested by underlying security services. Callback implementations simply provide the means to pass such requests to applications, and for applications to return requested information to the underlying security services.

An application implements a `CallbackHandler` and passes it to underlying security services so that they can interact with the application to retrieve specific authentication data, such as usernames and passwords, or to display information such as error and warning messages.

CallbackHandlers are implemented in an application-dependent fashion.

Underlying security services make requests for different types of information by passing individual `Callbacks` to the `CallbackHandler`. The `CallbackHandler` implementation decides how to retrieve and display information depending on the `Callbacks` passed to it. For example, if the underlying service needs a username and password to authenticate a user, it uses a `NameCallback` and `PasswordCallback`. The `CallbackHandler` can then choose to prompt for a username and password serially, or to prompt for both in a single window.

<table>
<thead>
<tr>
<th>Java JAAS API</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>javax.security.auth.callback.Callback</code></td>
<td>Implementations of this interface are passed to a <code>CallbackHandler</code>, allowing underlying security services to interact with a calling application to retrieve specific authentication data, such as usernames and passwords, or to display information such as error and warning messages. Callback implementations do not retrieve or display the information requested by underlying security services. Callback implementations simply provide the means to pass such requests to applications, and for applications to return requested information to the underlying security services.</td>
</tr>
<tr>
<td><code>javax.security.auth.callback.CallbackHandler</code></td>
<td>An application implements a <code>CallbackHandler</code> and passes it to underlying security services so that they can interact with the application to retrieve specific authentication data, such as usernames and passwords, or to display information such as error and warning messages. CallbackHandlers are implemented in an application-dependent fashion. Underlying security services make requests for different types of information by passing individual <code>Callbacks</code> to the <code>CallbackHandler</code>. The <code>CallbackHandler</code> implementation decides how to retrieve and display information depending on the <code>Callbacks</code> passed to it. For example, if the underlying service needs a username and password to authenticate a user, it uses a <code>NameCallback</code> and <code>PasswordCallback</code>. The <code>CallbackHandler</code> can then choose to prompt for a username and password serially, or to prompt for both in a single window.</td>
</tr>
</tbody>
</table>
### Table 3-2 WebLogic JAAS APIs

<table>
<thead>
<tr>
<th>WebLogic JAAS API</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>weblogic.security.auth.Authenticate</code></td>
<td>An authentication class used to authenticate user credentials. The WebLogic implementation of the LoginModule, (weblogic.security.auth.login.UsernamePasswordLoginModule, uses this class to authenticate a user and add Principals to the Subject. Developers who write LoginModules must also use this class for the same purpose.</td>
</tr>
<tr>
<td><code>weblogic.security.auth.Callback.ContextHandlerCallback</code></td>
<td>Underlying security services use this class to instantiate and pass a ContextHandlerCallback to the invokeCallback method of a CallbackHandler to retrieve the ContextHandler related to this security operation. If no ContextHandler is associated with this operation, the javax.security.auth.callback.UnsupportedCallback exception is thrown. This callback passes the ContextHandler to LoginModule.login() methods.</td>
</tr>
<tr>
<td><code>weblogic.security.auth.Callback.GroupCallback</code></td>
<td>Underlying security services use this class to instantiate and pass a GroupCallback to the invokeCallback method of a CallbackHandler to retrieve group information.</td>
</tr>
<tr>
<td><code>weblogic.security.auth.Callback.URLCallback</code></td>
<td>Underlying security services use this class to instantiate and pass a URLCallback to the invokeCallback method of a CallbackHandler to retrieve URL information. The WebLogic implementation of the LoginModule, (weblogic.security.auth.login.UsernamePasswordLoginModule, uses this class. Note: Application developers should not use this class to retrieve URL information. Instead, they should use the weblogic.security.URLCallbackHandler.</td>
</tr>
</tbody>
</table>
JAAS Client Application Components

At a minimum, a JAAS authentication client application includes the following components:

- **Java client**
  
The Java client instantiates a `LoginContext` object and invokes the login by calling the object’s `login()` method. The `login()` method calls methods in each LoginModule to perform the login and authentication.

  The `LoginContext` also instantiates a new empty `javax.security.auth.Subject` object (which represents the user or service being authenticated), constructs the configured `LoginModule`, and initializes it with this new `Subject` and `CallbackHandler`.

  The `LoginContext` subsequently retrieves the authenticated `Subject` by calling the `LoginContext`'s `getSubject` method. The `LoginContext` uses the `weblogic.security.Security.runAs()` method to associate the `Subject` identity with the `PrivilegedAction` or `PrivilegedExceptionAction` to be executed on behalf of the user identity.

- **LoginModule**
  
The `LoginModule` uses the `CallbackHandler` to obtain the user name and password and determines whether that name and password are the ones required.

  If authentication is successful, the `LoginModule` populates the `Subject` with a `Principal` representing the user. The `Principal` the `LoginModule` places in the `Subject` is an instance of `Principal`, which is a class implementing the `java.security.Principal` interface.

---

### Table 3-2  WebLogic JAAS APIs

<table>
<thead>
<tr>
<th>WebLogic JAAS API</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>weblogic.security.Security</code></td>
<td>This class implements the WebLogic Server client <code>runAs</code> methods. Client applications use the <code>runAs</code> methods to associate their Subject identity with the <code>PrivilegedAction</code> or <code>PrivilegedExceptionAction</code> that they execute. For a sample implementation, see Listing 3-5.</td>
</tr>
<tr>
<td><code>weblogic.security.URLCallbackHandler</code></td>
<td>The class used by application developers for returning a username, password and URL. Application developers should use this class to handle the URLCallback to retrieve URL information.</td>
</tr>
</tbody>
</table>
You can write LoginModule files that perform different types of authentication, including username/password authentication and certificate authentication. A client application can include one LoginModule (the minimum requirement) or several LoginModules.

**Note:** Use of the JAAS `javax.security.auth.Subject.doAs` methods in WebLogic Server applications do not associate the Subject with the client actions. You can use the `doAs` methods to implement J2SE security in WebLogic Server applications, but such usage is independent of the need to use the `Security.runAs()` method.

- **Callbackhandler**
  The CallbackHandler implements the `javax.security.auth.callback.CallbackHandler` interface. The LoginModule uses the CallbackHandler to communicate with the user and obtain the requested information, such as the username and password.

- **Configuration file**
  This file configures the LoginModule(s) used in the application. It specifies the location of the LoginModule(s) and, if there are multiple LoginModules, the order in which they are executed. This file enables Java applications to remain independent from the authentication technologies, which are defined and implemented using the LoginModule.

- **Action file**
  This file defines the operations that the client application will perform.

- **ant build script** (build.xml)
  This script compiles all the files required for the application and deploys them to the WebLogic Server applications directories.

For a complete working JAAS authentication client that implements the components described here, see the JAAS sample application in the `SAMPLES_HOME\server\examples\src\examples\security\jaas` directory provided with WebLogic Server. This example is also available online at BEA’s dev2dev site.

For more information on the basics of JAAS authentication, see Sun’s JAAS Authentication Tutorial available at [http://java.sun.com/j2se/1.5.0/docs/guide/security/jaas/tutorials/GeneralAcnOnly.html](http://java.sun.com/j2se/1.5.0/docs/guide/security/jaas/tutorials/GeneralAcnOnly.html).
WebLogic LoginModule Implementation

The WebLogic implementation of the LoginModule class is provided in the WebLogic Server distribution in the weblogic.jar file, located in the WL_HOME\server\lib directory.

**Note:** WebLogic Server supports all callback types defined by JAAS as well as all callback types that extend the JAAS specification.

The WebLogic Server UsernamePasswordLoginModule checks for existing system user authentication definitions prior to execution, and does nothing if they are already defined.

For more information about implementing JAAS LoginModules, see the LoginModule Developer’s Guide at http://java.sun.com/j2se/1.5.0/docs/guide/security/jaas/JAASLMDevGuide.html

JVM-Wide Default User and the runAs() Method

The first time you use the WebLogic Server implementation of the LoginModule (weblogic.security.auth.login.UsernamePasswordLoginModule) to log on, the specified user becomes the machine-wide default user for the JVM (Java virtual machine). When you execute the weblogic.security.Security.runAs() method, it associates the specified Subject with the current thread’s access permissions and then executes the action. If a specified Subject represents a non-privileged user (users who are not assigned to any groups are considered non-privileged), the JVM-wide default user is used. Therefore, it is important make sure that the runAs() method specifies the desired Subject. You can do this using one of the following options:

- **Option 1:** If the client has control of main(), implement the wrapper code shown in Listing 3-1 in the client code.

- **Option 2:** If the client does not have control of main(), implement the wrapper code shown in Listing 3-1 on each thread’s run() method.

### Listing 3-1  runAs() Method Wrapper Code

```java
import java.security.PrivilegedAction;
import javax.security.auth.Subject;
import weblogic.security.Security;

public class client
{
```

...
public static void main(String[] args) {
    Security.runAs(new Subject(),
        new PrivilegedAction() {
            public Object run() {
                //
                // If implementing in client code, main() goes here.
                //
                return null;
            }
        });
}

Writing a Client Application Using JAAS Authentication

To use JAAS in a WebLogic Server Java client to authenticate a subject, perform the following procedure:

1. Implement LoginModule classes for the authentication mechanisms you want to use with WebLogic Server. You will need a LoginModule class for each type of authentication mechanism. You can have multiple LoginModule classes for a single WebLogic Server deployment.

   **Note:** BEA recommends that you use the implementation of the LoginModule provided by WebLogic Server (weblogic.security.auth.login.UsernamePasswordLoginModule) for username/password authentication. You can write your own LoginModule for username/password authentication, however, do not attempt to modify the WebLogic Server LoginModule and reuse it. If you write your own LoginModule, you must have it call the weblogic.security.auth.Authenticate.authenticate() method to perform the login. If you use a remote login mechanism such as SAML, you do not need to call the authenticate() method. You only need to call authenticate() if you are using WebLogic Server to perform the logon.

   The weblogic.security.auth.Authenticate class uses a JNDI Environment object for initial context as described in Table 3-3.
2. Implement the `CallbackHandler` class that the LoginModule will use to communicate with the user and obtain the requested information, such as the username, password, and URL. The URL can be the URL of a WebLogic cluster, providing the client with the benefits of server failover. The WebLogic Server distribution provides a `SampleCallbackHandler` which is used in the JAAS client sample. The `SampleCallbackHandler.java` code is available online and as part of the distribution:

WebLogic Server Distribution: In the directory `SAMPLES_HOME\server\examples\src\examples\security\jaas`

**Note:** Instead of implementing your own `CallbackHandler` class, you can use either of two WebLogic-supplied `CallbackHandler` classes, `weblogic.security.SimpleCallbackHandler` or `weblogic.security.URLCallbackHandler`. For more information on these classes, see Javadocs for WebLogic Classes.

3. Write a configuration file that specifies which LoginModule classes to use for your WebLogic Server and in which order the LoginModule classes should be invoked. See Listing 3-2 for the sample configuration file used in the JAAS client sample provided in the WebLogic Server distribution.

Listing 3-2  sample_jaas.config Code Example

```java
/** Login Configuration for the JAAS Sample Application **/
Sample {
    weblogic.security.auth.login.UsernamePasswordLoginModule
        required debug=false;
};
```

4. In the Java client, write code to instantiate a `LoginContext`. The `LoginContext` consults the configuration file, `sample_jaas.config`, to load the default LoginModule configured for WebLogic Server. See Listing 3-3 for an example `LoginContext` instantiation.

**Note:** If you use another means to authenticate the user, such as an Identity Assertion provider or a remote instance of WebLogic Server, the default LoginModule is determined by the remote source.
Using JAAS Authentication in Java Clients

Listing 3-3  LoginContext Code Fragment

...  
import javax.security.auth.login.LoginContext;  
...  
LoginContext loginContext = null;  
try  
{
  // Create LoginContext; specify username/password login module
  loginContext = new LoginContext("Sample",
     new SampleCallbackHandler(username, password, url));
}

5. Invoke the login() method of the LoginContext instance. The login() method invokes all the loaded LoginModules. Each LoginModule attempts to authenticate the subject. If the configured login conditions are not met, the LoginContext throws a LoginException. See Listing 3-4 for an example of the login() method.

Listing 3-4  Login() Method Code Fragment

...  
import javax.security.auth.login.LoginContext;  
import javax.security.auth.login.LoginException;  
import javax.security.auth.login.FailedLoginException;  
import javax.security.auth.login.AccountExpiredException;  
import javax.security.auth.login.CredentialExpiredException;  
...  
/**
   * Attempt authentication
   */
  try  
  {  
    // If we return without an exception, authentication succeeded
    loginContext.login();
  }

3-14  Programming WebLogic Security
Writing a Client Application Using JAAS Authentication

```java
try {
    Subject subject = loginContext.login(new Principal[] {principal}, credentials);
    System.out.println("User: "+subject.getPrincipal().toString());
}

catch(FailedLoginException fle)
{
    System.out.println("Authentication Failed, " +
                      fle.getMessage());
    System.exit(-1);
}

catch(AccountExpiredException aee)
{
    System.out.println("Authentication Failed: Account Expired");
    System.exit(-1);
}

catch(CredentialExpiredException cee)
{
    System.out.println("Authentication Failed: Credentials Expired");
    System.exit(-1);
}

catch(Exception e)
{
    System.out.println("Authentication Failed: Unexpected Exception, " + e.getMessage());
    e.printStackTrace();
    System.exit(-1);
}
```

6. Write code in the Java client to retrieve the authenticated Subject from the LoginContext instance using the javax.security.auth.Subject.getSubject() method and call the action as the Subject. Upon successful authentication of a Subject, access controls can be placed upon that Subject by invoking the weblogic.security.Security.runAs() method. The runAs() method associates the specified Subject with the current thread’s access permissions and then executes the action. See Listing 3-5 for an example implementation of the getSubject() and runAs() methods.

**Note:** Use of the JAAS javax.security.auth.Subject.doAs methods in WebLogic Server applications do not associate the Subject with the client actions. You can use the doAs methods to implement J2SE security in WebLogic Server applications, but such usage is independent of the need to use the Security.runAs() method.
Listing 3-5  getSubject() and runAs() Methods Code Fragment

```java
...  
/**
 * Retrieve authenticated subject, perform SampleAction as Subject
 */
    Subject subject = loginContext.getSubject();
    SampleAction sampleAction = new SampleAction(url);
    Security.runAs(subject, sampleAction);
    System.exit(0);
...
```

7. Write code to execute an action if the Subject has the required privileges. BEA provides a sample implementation, SampleAction, of the javax.security.PrivilegedAction class that executes an EJB to trade stocks. The SampleAction.java code is available online and as part of the distribution:
   – WebLogic Server Distribution: In the directory `SAMPLES_HOME\server\examples\src\examples\security\jaas`

8. Invoke the logout() method of the LoginContext instance. The logout() method closes the user’s session and clears the Subject. See Listing 3-6 for an example of the login() method.

Listing 3-6  logout() Method Code Example

```java
...  
import javax.security.auth.login.LoginContext;
...
try
{
    System.out.println("logging out...");
    loginContext.logout();
}
```
Using JNDI Authentication

Note: The LoginModule.logout() method is never called for a WebLogic Authentication provider or a custom Authentication provider, because once the Principals are created and placed into a Subject, the WebLogic Security Framework no longer controls the lifecycle of the Subject. Therefore, code that creates the JAAS LoginContext to log in and obtain the Subject should also call the LoginContext to log out. Calling LoginContext.logout() results in the clearing of the Principals from the Subject.

Using JNDI Authentication

Java clients use the Java Naming and Directory Interface (JNDI) to pass credentials to WebLogic Server. A Java client establishes a connection with WebLogic Server by getting a JNDI InitialContext. The Java client then uses the InitialContext to look up the resources it needs in the WebLogic Server JNDI tree.

Note: JAAS is the preferred method of authentication, however, the WebLogic Authentication provider’s LoginModule supports only user name and password authentication. Thus, for client certificate authentication (also referred to as two-way SSL authentication), you should use JNDI. To use JAAS for client certificate authentication, you must write a custom Authentication provider whose LoginModule does certificate authentication. For information on how to write LoginModules, see http://java.sun.com/j2se/1.5.0/docs/guide/security/jaas/JAASLMDevGuide.html.

To specify a user and the user’s credentials, set the JNDI properties listed in Table 3-3.

Table 3-3  JNDI Properties Used for Authentication

<table>
<thead>
<tr>
<th>Property</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>INITIAL_CONTEXT_FACTORY</td>
<td>Provides an entry point into the WebLogic Server environment. The class weblogic.jndi.WLInitialContextFactory is the JNDI SPI for WebLogic Server.</td>
</tr>
<tr>
<td>PROVIDER_URL</td>
<td>Specifies the host and port of the WebLogic Server that provides the name service. For example: t3://weblogic:7001.</td>
</tr>
</tbody>
</table>
These properties are stored in a hash table that is passed to the InitialContext constructor. Listing 3-7 illustrates how to use JNDI authentication in a Java client running on WebLogic Server.

Listing 3-7   Example of Authentication

...  
Hashtable env = new Hashtable();  
env.put(Context.INITIAL_CONTEXT_FACTORY,  
   "weblogic.jndi.WLInitialContextFactory");  
env.put(Context.PROVIDER_URL, "t3://weblogic:7001");  
env.put(Context.SECURITY_PRINCIPAL, "javaclient");  
env.put(Context.SECURITY_CREDENTIALS, "javaclientpassword");  
ctx = new InitialContext(env);

Note:  For information on JNDI contexts and threads and how to avoid potential JNDI context problems, see “JNDI Contexts and Threads” and “How to Avoid Potential JNDI Context Problems” in Programming WebLogic JNDI.

Note:  In versions of WebLogic Server prior to 9.0, when using protocols other than IIOP with JNDI, the first user is "sticky" in the sense that it becomes the default user when no other user is present. This is not a good practice, as any subsequent logins that do not have a username and credential are granted the identify of the default user.

In version 9.0, this is no longer true and there is no default user.

To return to the previous behavior, the weblogic.jndi.WLContext.ENABLE_DEFAULT_USER field must be set, either via the command line or through the InitialContext interface.
Java Client JAAS Authentication Code Examples

A complete working JAAS authentication sample is provided with the WebLogic Server product. The sample is located in the 
SAMPLES_HOME\server\examples\src\examples\security\jaas directory. For a description of the sample and instructions on how to build, configure, and run this sample, see the package.html file in the sample directory. You can modify this code example and reuse it.
Using JAAS Authentication in Java Clients
Using SSL Authentication in Java Clients

The following topics are covered in this section:

- “JSSE and WebLogic Server” on page 4-2
- “Using JNDI Authentication” on page 4-2
- “SSL Certificate Authentication Development Environment” on page 4-4
- “Writing Applications that Use SSL” on page 4-10
- “SSL Client Code Examples” on page 4-31

The sections refer to sample code which is available online at BEA’s dev2dev web site, and is also included in the WebLogic Server distribution at:

SAMPLES_HOME/server/examples/src/examples/security/sslclient

The sslclient directory contains an instructions.html file, ant build files, and the following Java and JavaServer Pages (.jsp) files:

- MyListener.java
- NulledHostnameVerifier.java
- NulledTrustManager.java
- SSLClient.java
- SSLClientServlet.java
- SSLSocketClient.java
- SnoopServlet.jsp
You will need to look at the examples when reading the information in the following sections.

**JSSE and WebLogic Server**

The Java Secure Socket Extension (JSSE) is a set of packages that support and implement the SSL and TLS v1 protocols, making those capabilities programmatically available. BEA WebLogic Server provides Secure Sockets Layer (SSL) support for encrypting data transmitted between WebLogic Server clients and servers, Java clients, Web browsers, and other servers.

WebLogic Server’s JSSE implementation can be used by WebLogic clients, but is not required. Other JSSE implementations can be used for their client-side code outside the server as well.

The following restrictions apply when using SSL in WebLogic server-side applications:

- The use of other (third-party) JSSE implementations to develop WebLogic Server applications is not supported. The SSL implementation that WebLogic Server uses is static to the server configuration and is not replaceable by customer applications.

- The WebLogic implementation of JSSE does support JCE Cryptographic Service Providers (CSPs); however, due to the inconsistent provider support for JCE, BEA cannot guarantee that untested providers will work out of the box. BEA has tested WebLogic Server with the following providers:
  - The default JCE provider (SunJCE provider) included with JDK 5.0. See http://java.sun.com/j2se/1.5.0/docs/guide/security/jce/HowToImplAJCEProvider.html for information about the SunJCE provider.
  - The nCipher JCE provider.

Other providers may work with WebLogic Server, but an untested provider is not likely to work out of the box. For more information on using the JCE providers supported by WebLogic Server, see Configuring SSL in Securing WebLogic Server.

WebLogic Server uses the HTTPS port for Secure Sockets Layer (SSL) encrypted communication; only SSL can be used on that port.

**Note:** In order to implement security in a WebLogic client, you must install the WebLogic Server software distribution kit on the Java client.

**Using JNDI Authentication**

Java clients use the Java Naming and Directory Interface (JNDI) to pass credentials to WebLogic Server. A Java client establishes a connection with WebLogic Server by getting a JNDI
Using JNDI Authentication

InitialContext. The Java client then uses the InitialContext to look up the resources it needs in the WebLogic Server JNDI tree.

**Note:** JAAS is the preferred method of authentication; however, the Authentication provider’s LoginModule supports only username and password authentication. Thus, for client certificate authentication (also referred to as two-way SSL authentication), you should use JNDI. To use JAAS for client certificate authentication, you must write a custom Authentication provider whose LoginModule does certificate authentication.

To specify a user and the user’s credentials, set the JNDI properties listed in the Table 4-1.

### Table 4-1 JNDI Properties Used for Authentication

<table>
<thead>
<tr>
<th>Property</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>INITIAL_CONTEXT_FACTORY</td>
<td>Provides an entry point into the WebLogic Server environment. The class <code>weblogic.jndi.WLInitialContextFactory</code> is the JNDI SPI for WebLogic Server.</td>

<tr>
<td>PROVIDER_URL</td>
<td>Specifies the host and port of the WebLogic Server that provides the name service. For example: <code>t3s://weblogic:7002</code>. (t3s is a WebLogic Server proprietary version of SSL.)</td>
</tr>
<tr>
<td>SECURITY_PRINCIPAL</td>
<td>Specifies the identity of the user when that user authenticates to the default (active) security realm.</td>
</tr>
<tr>
<td>SECURITY_CREDENTIALS</td>
<td>Specifies the credentials of the user when that user authenticates to the default (active) security realm.</td>
</tr>
</tbody>
</table>

These properties are stored in a hash table which is passed to the InitialContext constructor. **Listing 4-1** demonstrates how to use one-way SSL certificate authentication in a Java client. For a two-SSL authentication code example, see Listing 4-4, “Example of a Two-Way SSL Authentication Client That Uses JNDI,” on page 4-16.

### Listing 4-1 Example of One-Way SSL Authentication Using JNDI

```java
... 
Hashtable env = new Hashtable();
    env.put(Context.INITIAL_CONTEXT_FACTORY,
```
Using SSL Authentication in Java Clients

```java
"weblogic.jndi.WLInitialContextFactory");
env.put(Context.PROVIDER_URL, "t3s://weblogic:7002");
env.put(Context.SECURITY_PRINCIPAL, "javaclient");
env.put(Context.SECURITY_CREDENTIALS, "javaclientpassword");
ctx = new InitialContext(env);
```

**Note:** For information on JNDI contexts and threads and how to avoid potential JNDI context problems, see “JNDI Contexts and Threads” and “How to Avoid Potential JNDI Context Problems” in Programming WebLogic JNDI.

### SSL Certificate Authentication Development Environment

The following topics are covered in this section:

- “SSL Authentication APIs” on page 4-4
- “SSL Client Application Components” on page 4-8

### SSL Authentication APIs

To implement Java clients that use SSL authentication on WebLogic Server, use a combination of Java JDK 5.0 application programming interfaces (APIs) and WebLogic APIs.

Table 4-2 lists and describes the Java APIs packages used to implement certificate authentication. The information in Table 4-2 is taken from the Java API documentation and annotated to add WebLogic Server specific information. For more information on the Java APIs, see the Javadocs at [http://java.sun.com/j2se/1.5.0/docs/api/index.html](http://java.sun.com/j2se/1.5.0/docs/api/index.html) and [http://java.sun.com/j2ee/1.4/docs/api/index.html](http://java.sun.com/j2ee/1.4/docs/api/index.html).

Table 4-3 lists and describes the WebLogic APIs used to implement certificate authentication. For more information, see Javadocs for WebLogic Classes.
### Table 4-2 Java Certificate APIs

<table>
<thead>
<tr>
<th>Java Certificate APIs</th>
<th>Description</th>

<table>
<thead>
<tr>
<th>Java Certificate APIs</th>
<th>Description</th>
</tr>
</thead>
</table>
| java.security.KeyStore      | This class represents an in-memory collection of keys and certificates. It is used to manage two types of keystore entries:  
  • Key Entry  
    This type of keystore entry holds cryptographic key information, which is stored in a protected format to prevent unauthorized access.  
    Typically, a key stored in this type of entry is a secret key, or a private key accompanied by the certificate chain for the corresponding public key.  
    Private keys and certificate chains are used by a given entity for self-authentication. Applications for this authentication include software distribution organizations that sign JAR files as part of releasing and/or licensing software.  
  • Trusted Certificate Entry  
    This type of entry contains a single public key certificate belonging to another party. It is called a trusted certificate because the keystore owner trusts that the public key in the certificate indeed belongs to the identity identified by the subject (owner) of the certificate.  
    This type of entry can be used to authenticate other parties.                                                                                     |
| java.security.PrivateKey    | A private key. This interface contains no methods or constants. It merely serves to group (and provide type safety for) all private key interfaces.  
  Note: The specialized private key interfaces extend this interface.  
  For example, see the DSAPrivateKey interface in java.security.interfaces.                                                                         |
This class represents a “Cryptographic Service Provider” for the Java Security API, where a provider implements some or all parts of Java Security, including:

- Algorithms (such as DSA, RSA, MD5 or SHA-1).
- Key generation, conversion, and management facilities (such as for algorithm-specific keys).

Each provider has a name and a version number, and is configured in each runtime it is installed in.

To supply implementations of cryptographic services, a team of developers or a third-party vendor writes the implementation code and creates a subclass of the Provider class.

This interface extends the ServletRequest interface to provide request information for HTTP servlets.

The servlet container creates an HttpServletRequest object and passes it as an argument to the servlet's service methods (doGet, doPost, and so on.).

This interface extends the ServletRequest interface to provide HTTP-specific functionality in sending a response. For example, it has methods to access HTTP headers and cookies.

The servlet container creates an HttpServletRequest object and passes it as an argument to the servlet's service methods (doGet, doPost, and so on.).

This class provides an output stream for sending binary data to the client. A ServletOutputStream object is normally retrieved via the ServletResponse.getOutputStream() method.

This is an abstract class that the servlet container implements. Subclasses of this class must implement the java.io.OutputStream.write(int) method.

This class defines an object to assist a servlet in sending a response to the client. The servlet container creates a ServletResponse object and passes it as an argument to the servlet's service methods (doGet, doPost, and so on.).
Using SSL Authentication in Java Clients

</tr>
</tbody>
</table>

**SSL Client Application Components**

At a minimum, an SSL client application includes the following components:
SSL Certificate Authentication Development Environment

• Java client

Typically, a Java client performs these functions:

– Initializes an SSLContext with client identity, a HostnameVerifier, a TrustManager, and a HandshakeCompletedListener.

– Creates a keystore and retrieves the private key and certificate chain

– Uses an SSLSocketFactory

– Uses HTTPS to connect to a JSP served by an instance of WebLogic Server

• HostnameVerifier

The HostnameVerifier implements the weblogic.security.SSL.HostnameVerifier interface. It provides a callback mechanism so that implementers of this interface can supply a policy on whether the connection to the URL’s hostname should be allowed. The policy can be certificate-based or may depend on other authentication schemes.

• HandshakeCompletedListener

The HandshakeCompletedListener implements the javax.net.ssl.HandshakeCompletedListener interface. It defines how the SSL client receives notifications about the completion of an SSL handshake on a given SSL connection. It also defines the number of times an SSL handshake takes place on a given SSL connection.

• TrustManager

The TrustManager implements the weblogic.security.SSL.TrustManager interface. It builds a certificate path to a trusted root and returns true if it can be validated and is trusted for client SSL authentication.

• ant build script (build.xml)

This script compiles all the files required for the application and deploys them to the WebLogic Server applications directories.

For a complete working SSL authentication client that implements the components described here, see the SSLClient sample application in the SAMPLES_HOME\server\examples\src\examples\security\sslclient directory provided with WebLogic Server. This example is also available online at BEA’s dev2dev site

For more information on JSSE authentication, see Sun’s Java Secure Socket Extension (JSSE) Reference Guide available at http://java.sun.com/j2se/1.5.0/docs/guide/security/jsse/JSSERefGuide.html.
Writing Applications that Use SSL

This section covers the following topics:

- “Communicating Securely From WebLogic Server to Other WebLogic Servers” on page 4-10
- “Writing SSL Clients” on page 4-10
- “Using Two-Way SSL Authentication” on page 4-14
- “Two-Way SSL Authentication with JNDI” on page 4-15
- “Using a Custom Hostname Verifier” on page 4-22
- “Using a Trust Manager” on page 4-23
- “Using an SSLContext” on page 4-27
- “Using an SSL Server Socket Factory” on page 4-28
- “Using URLs to Make Outbound SSL Connections” on page 4-28

Communicating Securely From WebLogic Server to Other WebLogic Servers

You can use a URL object to make an outbound SSL connection from a WebLogic Server instance acting as a client to another WebLogic Server instance. The `weblogic.net.http.HttpsURLConnection` class provides a way to specify the security context information for a client, including the digital certificate and private key of the client.

The `weblogic.net.http.HttpsURLConnection` class provides methods for determining the negotiated cipher suite, getting/setting a hostname verifier, getting the server’s certificate chain, and getting/setting an `SSLSocketFactory` in order to create new SSL sockets.

The SSLClient code example uses the `weblogic.net.http.HttpsURLConnection` class to make an outbound SSL connection. The SSLClient code example is available in the `examples.security.sslclient` package in the `SAMPLES_HOME\server\examples\src\examples\security\sslclient` directory.

Writing SSL Clients

This section uses examples to show how to write various types of SSL clients. Examples of the following types of SSL clients are provided:
SSL Client License Requirement: Any stand-alone Java client that uses WebLogic SSL classes (weblogic.security.SSL) to invoke an Enterprise JavaBean (EJB) must use the BEA license file. When you run your client application, set the following system properties on the command line:

- `bea.home=license_file_directory`
- `java.protocol.handler.pkgs=com.certicom.net.ssl`

Where `license_file_directory` refers to the directory that contains the BEA license file (license.bea). Here is an example of a run command that uses the default location of the license file (c:\bea):

```
java -Dbea.home=c:\bea \n   -Djava.protocol.handler.pkgs=com.certicom.net.ssl  my_app
```

SSLClient Sample

The SSLClient sample demonstrates how to use the WebLogic SSL library to make outgoing SSL connections using URL and URLConnection objects. It shows both how to do this from a stand-alone application as well as from a servlet in WebLogic Server.

Note: When making an outgoing SSL connection, a WebLogic Server instance uses the server's certificate. When communicating to either the same or another WebLogic Server instance with two-way SSL, the originating server's certificate will be verified against the client root CA list in the receiving WebLogic Server instance.

Listing 4-2 shows code fragments from the SSLClient example; the complete example is located at `SAMPLES_HOME\server\examples\src\examples\security\sslclient` directory in the SSLClient.java file.

Listing 4-2 SSLClient Sample Code Fragments

```java
package examples.security.sslclient;

import java.io.*;
import java.net.URL;
```
import java.security.Provider;
import javax.servlet.ServletOutputStream;
...

/*
 * This method contains an example of how to use the URL and
 * URLConnection objects to create a new SSL connection, using
 * WebLogic SSL client classes.
 */

public void wlsURLConnect(String host, String port,
    String sport, String query,
    OutputStream out)
    throws Exception {
    ...

    URL wlsUrl = null;
    try {
        wlsUrl = new URL("http", host, Integer.valueOf(port).intValue(),
            query);
        weblogic.net.http.HttpURLConnection connection =
            new weblogic.net.http.HttpURLConnection(wlsUrl);
        tryConnection(connection, out);
    }
    ...

    wlsUrl = new URL("https", host, Integer.valueOf(sport).intValue(),
        query);
    weblogic.net.http.HttpsURLConnection sconnection =
        new weblogic.net.http.HttpsURLConnection(wlsUrl);
    ...

SSLSocketClient Sample

The SSLSocketClient sample demonstrates how to use SSL sockets to go directly to the secure
port to connect to a JSP served by an instance of WebLogic Server and display the results of that
connection. It shows how to implement the following functions:
• Initializing an SSLContext with client identity, a HostnameVerifier, and a TrustManager

• Creating a keystore and retrieving the private key and certificate chain

• Using an SSLSocketFactory

• Using HTTPS to connect to a JSP served by WebLogic Server

• Implementing the javax.net.ssl.HandshakeCompletedListener interface

• Creating a dummy implementation of the weblogic.security.SSL.HostnameVerifier class to verify that the server the example connects to is running on the desired host

Listing 4-3 shows code fragments from the SSLSocketClient example; the complete example is located at SAMPLES_HOME\server\examples\src\examples\security\sslclient directory in the SSLSocketClient.java file. (The SSLClientServlet example in the sslclient directory is a simple servlet wrapper of the SSLSocketClient example.)

Listing 4-3  SSLSocketClient Sample Code Fragments

```java
package examples.security.sslclient;

import java.io.*;
import java.security.KeyStore;
import java.security.PrivateKey;
import java.security.cert.Certificate;
import javax.net.ssl.HandshakeCompletedListener;
import javax.net.ssl.SSLSocket;
import weblogic.security.SSL.HostnameVerifier;
import weblogic.security.SSL.SSLContext;
import weblogic.security.SSL.SSLSocketFactory;
import weblogic.security.SSL.TrustManager;
...

SSLContext ss1Ctx = SSLContext.getInstance("https");
File KeyStoreFile  = new File ("mykeystore");
...

// Open the keystore, retrieve the private key, and certificate chain
KeyStore ks = KeyStore.getInstance("jks");
```
Using SSL Authentication in Java Clients

```
ks.load(new FileInputStream("mykeystore"), null);
PrivateKey key = (PrivateKey)ks.getKey("mykey",
    "testkey".toCharArray());
Certificate [] certChain = ks.getCertificateChain("mykey");
sslCtx.loadLocalIdentity(certChain, key);
HostnameVerifier hVerifier = null;
if (argv.length < 3)
    hVerifier = new NulledHostnameVerifier();
else
    hVerifier = (HostnameVerifier)
        Class.forName(argv[2]).newInstance();

sslCtx.setHostnameVerifier(hVerifier);
TrustManager tManager = new NulledTrustManager();
sslCtx.setTrustManager(tManager);
System.out.println(" Creating new SSLSocketFactory with SSLContext");
SSLContext sslsf = sslCtx.getSocketFactory();
System.out.println(" Creating and opening new SSLSocket with 
                SSLSocketFactory");
// using createSocket(String hostname, int port)
SSLSocket ss1Sock = (SSLSocket) sslsf.createSocket(argv[0],
        new Integer(argv[1]).intValue());
System.out.println(" SSLSocket created");
HandshakeCompletedListener mListener = null;
mListener = new MyListener();
ss1Sock.addHandshakeCompletedListener(new MyListener());
...
```

Using Two-Way SSL Authentication

When using certificate authentication, WebLogic Server sends a digital certificate to the requesting client. The client examines the digital certificate to ensure that it is authentic, has not expired, and matches the WebLogic Server instance that presented it.
With two-way SSL authentication (a form of mutual authentication), the requesting client also presents a digital certificate to WebLogic Server. When the instance of WebLogic Server is configured for two-way SSL authentication, requesting clients are required to present digital certificates from a specified set of certificate authorities. WebLogic Server accepts only digital certificates that are signed by root certificates from the specified trusted certificate authorities. For information on how to configure WebLogic Server for two-way SSL authentication, see the Configuring SSL in Securing WebLogic Server.

The following sections describe the different ways two-way SSL authentication can be implemented in WebLogic Server.

- “Two-Way SSL Authentication with JNDI” on page 4-15
- “Using Two-Way SSL Authentication Between WebLogic Server Instances” on page 4-19
- “Using Two-Way SSL Authentication with Servlets” on page 4-21

Two-Way SSL Authentication with JNDI

When using JNDI for two-way SSL authentication in a Java client, use the setSSLClientCertificate() method of the WebLogic JNDI Environment class. This method sets a private key and chain of X.509 digital certificates for client authentication.

To pass digital certificates to JNDI, create an array of InputStreams opened on files containing DER-encoded digital certificates and set the array in the JNDI hash table. The first element in the array must contain an InputStream opened on the Java client’s private key file. The second element must contain an InputStream opened on the Java client’s digital certificate file. (This file contains the public key for the Java client.) Additional elements may contain the digital certificates of the root certificate authority and the signer of any digital certificates in a certificate chain. A certificate chain allows WebLogic Server to authenticate the digital certificate of the Java client if that digital certificate was not directly issued by a certificate authority registered for the Java client in the WebLogic Server keystore file.

You can use the weblogic.security.PEMInputStream class to read digital certificates stored in Privacy Enhanced Mail (PEM) files. This class provides a filter that decodes the base 64-encoded DER certificate into a PEM file.

Listing 4-4 demonstrates how to use two-way SSL authentication in a Java client.
Using SSL Authentication in Java Clients

Listing 4-4  Example of a Two-Way SSL Authentication Client That Uses JNDI

```java
import javax.naming.Context;
import javax.naming.InitialContext;
import javax.naming.NamingException;
import weblogic.jndi.Environment;
import weblogic.security.PEMInputStream;
import java.io.InputStream;
import java.io.FileInputStream;

public class SSLJNDIClient {
    public static void main(String[] args) throws Exception {
        Context context = null;
        try {
            Environment env = new Environment();
            // set connection parameters
            env.setProviderUrl("t3s://localhost:7002");
            // The next two set methods are optional if you are using
            // a UserNameMapper interface.
            env.setSecurityPrincipal("system");
            env.setSecurityCredentials("weblogic");
            InputStream key = new FileInputStream("certs/demokey.pem");
            InputStream cert = new FileInputStream("certs/democert.pem");
            // wrap input streams if key/cert are in pem files
            key = new PEMInputStream(key);
            cert = new PEMInputStream(cert);
            env.setSSLClientCertificate(new InputStream[] { key, cert });
            env.setInitialContextFactory(Environment.DEFAULT_INITIAL_CONTEXT_FACTORY);
            context = env.getInitialContext();
            Object myEJB = (Object) context.lookup("myEJB");
        }
        finally {
```

Programming WebLogic Security
if (context != null) context.close();

When the JNDI getInitialContext() method is called, the Java client and WebLogic Server execute mutual authentication in the same way that a Web browser performs mutual authentication to get a secure Web server connection. An exception is thrown if the digital certificates cannot be validated or if the Java client’s digital certificate cannot be authenticated in the default (active) security realm. The authenticated user object is stored on the Java client’s server thread and is used for checking the permissions governing the Java client’s access to any protected WebLogic resources.

When you use the WebLogic JNDI Environment class, you must create a new Environment object for each call to the getInitialContext() method. Once you specify a User object and security credentials, both the user and their associated credentials remain set in the Environment object. If you try to reset them and then call the JNDI getInitialContext() method, the original user and credentials are used.

When you use two-way SSL authentication from a Java client, WebLogic Server gets a unique Java Virtual Machine (JVM) ID for each client JVM so that the connection between the Java client and WebLogic Server is constant. Unless the connection times out from lack of activity, it persists as long as the JVM for the Java client continues to execute. The only way a Java client can negotiate a new SSL connection reliably is by stopping its JVM and running another instance of the JVM.

The code in Listing 4-4, “Example of a Two-Way SSL Authentication Client That Uses JNDI,” on page 4-16 generates a call to the WebLogic Identity Assertion provider that implements the weblogic.security.providers.authentication.UserNameMapper interface. The class that implements the UserNameMapper interface returns a user object if the digital certificate is valid. WebLogic Server stores this authenticated user object on the Java client’s thread in WebLogic Server and uses it for subsequent authorization requests when the thread attempts to use WebLogic resources protected by the default (active) security realm.

Note: Your CLASSPATH must specify the implementation of the weblogic.security.providers.authentication.UserNameMapper interface.

If you have not configured an Identity Assertion provider that performs certificate-based authentication, a Java client running in a JVM with an SSL connection can change the WebLogic
Using SSL Authentication in Java Clients

Server user identity by creating a new JNDI InitialContext and supplying a new user name and password in the JNDI SECURITY_PRINCIPAL and SECURITY_CREDENTIALS properties. Any digital certificates passed by the Java client after the SSL connection is made are not used. The new WebLogic Server user continues to use the SSL connection negotiated with the initial user’s digital certificate.

If you have configured an Identity Assertion provider that performs certificate-based authentication, WebLogic Server passes the digital certificate from the Java client to the class that implements the UserNameMapper interface and the UserNameMapper class maps the digital certificate to a WebLogic Server user name. Therefore, if you want to set a new user identity when you use the certificate-based identity assertion, you cannot change the identity. This is because the digital certificate is processed only at the time of the first connection request from the JVM for each Environment.

Caution: Restriction: Multiple, concurrent, user logins to WebLogic Server from a single client JVM when using two-way SSL and JNDI is not supported. If multiple logins are executed on different threads, the results are undeterminable and might result in one user’s requests being executed on another user’s login, thereby allowing one user to access another user’s data. WebLogic Server does not support multiple, concurrent, certificate-based logins from a single client JVM. For information on JNDI contexts and threads and how to avoid potential JNDI context problems, see “JNDI Contexts and Threads” and “How to Avoid JNDI Context Problems” in Programming WebLogic JNDI.

Writing a User Name Mapper

When using two-way SSL, WebLogic Server verifies the digital certificate of the Web browser or Java client when establishing an SSL connection. However, the digital certificate does not identify the Web browser or Java client as a user in the WebLogic Server security realm. If the Web browser or Java client requests a WebLogic Server resource protected by a security policy, WebLogic Server requires the Web browser or Java client to have an identity. To handle this requirement, the WebLogic Identity Assertion provider allows you to enable a user name mapper that maps the digital certificate of a Web browser or Java client to a user in a WebLogic Server security realm. The user name mapper must be an implementation the weblogic.security.providers.authentication.UserNameMapper interface.

In this release of WebLogic Server, you have the option of using the default implementation of the weblogic.security.providers.authentication.UserNameMapper interface, DefaultUserNameMapperImpl, or developing your own implementation.
The WebLogic Identity Assertion provider can call the implementation of the `UserNameMapper` interface for the following types of identity assertion token types:

- X.509 digital certificates passed via the SSL handshake
- X.509 digital certificates passed via CSIv2
- X.501 distinguished names passed via CSIv2

If you need to map different types of certificates, write your own implementation of the `UserNameMapper` interface.

To implement a `UserNameMapper` interface that maps a digital certificate to a user name, write a `UserNameMapper` class that performs the following operations:

1. Instantiates the `UserNameMapper` implementation class.
2. Creates the `UserNameMapper` interface implementation.
3. Uses the `mapCertificateToUserName()` method to map a certificate to a user name based on a certificate chain presented by the client.
4. Maps a string attribute type to the corresponding `Attribute Value Assertion` field type.

### Using Two-Way SSL Authentication Between WebLogic Server Instances

You can use two-way SSL authentication in server-to-server communication in which one WebLogic Server instance is acting as the client of another WebLogic Server instance. Using two-way SSL authentication in server-to-server communication enables you to have dependable, highly-secure connections, even without the more common client/server environment.

Listing 4-5 shows an example of how to establish a secure connection from a servlet running in one instance of WebLogic Server to a second WebLogic Server instance called server2.weblogic.com.

### Listing 4-5 Establishing a Secure Connection to Another WebLogic Server Instance

```java
FileInputStream[] f = new FileInputStream[3];
    f[0]= new FileInputStream("demokey.pem");
    f[1]= new FileInputStream("democert.pem");
    f[2]= new FileInputStream("ca.pem");
```
Using SSL Authentication in Java Clients

Environment e = new Environment();
e.setProviderURL("t3s://server2.weblogic.com:443");
e.setSSLClientCertificate(f);
e.setSSLServerName("server2.weblogic.com");
e.setSSLRootCAFingerprints("ac45e2d1ce492252acc27ee5c345ef26");

e.setInitialContextFactory(
    "weblogic.jndi.WLInitialContextFactory");
Context ctx = new InitialContext(e.getProperties());

In Listing 4-5, the WebLogic JNDI Environment class creates a hash table to store the following parameters:

- `setProviderURL`—specifies the URL of the WebLogic Server instance acting as the SSL server. The WebLogic Server instance acting as SSL client calls this method. The URL specifies the t3s protocol which is a WebLogic Server proprietary protocol built on the SSL protocol. The SSL protocol protects the connection and communication between the two WebLogic Servers instances.

- `setSSLClientCertificate`—specifies a certificate chain to use for the SSL connection. You use this method to specify an input stream array that consists of a private key (which is the first input stream in the array) and a chain of X.509 certificates (which make up the remaining input streams in the array). Each certificate in the chain of certificates is the issuer of the certificate preceding it in the chain.

- `setSSLServerName`—specifies the name of the WebLogic Server instance acting as the SSL server. When the SSL server presents its digital certificate to the server acting as the SSL client, the name specified using the `setSSLServerName` method is compared to the common name field in the digital certificate. In order for hostname verification to succeed, the names must match. This parameter is used to prevent man-in-the-middle attacks.

- `setSSLRootCAFingerprints`—specifies digital codes that represent a set of trusted certificate authorities. The root certificate in the certificate chain received from the WebLogic Server instance acting as the SSL server has to match one of the fingerprints specified with this method to be trusted. This parameter is used to prevent man-in-the-middle attacks.
Note: For information on JNDI contexts and threads and how to avoid potential JNDI context problems, see “JNDI Contexts and Threads” and “How to Avoid JNDI Context Problems” in Programming WebLogic JNDI.

Using Two-Way SSL Authentication with Servlets

To authenticate Java clients in a servlet (or any other server-side Java class), you must check whether the client presented a digital certificate and if so, whether the certificate was issued by a trusted certificate authority. The servlet developer is responsible for asking whether the Java client has a valid digital certificate. When developing servlets with the WebLogic Servlet API, you must access information about the SSL connection through the `getAttribute()` method of the `HttpServletRequest` object.

The following attributes are supported in WebLogic Server servlets:

- `javax.servlet.request.cipher_suite` — returns a string representing the cipher suite used by HTTPS.
- `javax.servlet.request.key_size` — returns an integer (0, 40, 56, 128, 168) representing the bit size of the symmetric (bulk encryption) key algorithm.
- `weblogic.servlet.request.SSLSession` — returns the SSL session object that contains the cipher suite and the dates on which the object was created and last used.

You have access to the user information defined in the digital certificates. When you get the `javax.servlet.request.X509Certificate` attribute, it is an array of the `java.security.cert.X509Certificate` objects. You simply cast the array to that and examine the certificates.

A digital certificate includes information, such as the following:

- The name of the subject (holder, owner) and other identification information required to verify the unique identity of the subject, such as the uniform resource locator (URL) of the Web server using the digital certificate, or an individual user’s e-mail address
- The subject’s public key
- The name of the certificate authority that issued the digital certificate
- A serial number
The validity period (or lifetime) of the digital certificate (as defined by a start date and an end date)

Using a Custom Hostname Verifier

A hostname verifier validates that the host to which an SSL connection is made is the intended or authorized party. A hostname verifier is useful when a WebLogic client or a WebLogic Server instance is acting as an SSL client to another application server. It helps prevent man-in-the-middle attacks.

Note: In this release of WebLogic Server, the demonstration digital certificates are generated during installation so they do contain the hostname of the system on which the WebLogic Server software installed. Therefore, you should leave hostname verification on when using the demonstration certificates for development or testing purposes.

By default, WebLogic Server, as a function of the SSL handshake, compares the common name in the Subject’s Distinguished Name (SubjectDN) of the SSL server’s digital certificate with the hostname of the SSL server used to initiate the SSL connection. If these names do not match, the SSL connection is dropped.

The dropping of the SSL connection is caused by the SSL client, which validates the hostname of the server against the digital certificate of the server. If anything but the default behavior is desired, you can either turn off hostname verification or register a custom hostname verifier.

Turning off hostname verification leaves the SSL connections vulnerable to man-in-the-middle attacks.

You can turn off hostname verification in the following ways:

- In the Administration Console, specify None in the Hostname Verification field that is located on the Advanced Options pane under the Keystore & SSL tab for the server (for example, myserver).
- On the command line of the SSL client, enter the following argument:

  -Dweblogic.security.SSL.ignoreHostnameVerification=true

You can write a custom hostname verifier. The weblogic.security.SSL.HostnameVerifier interface provides a callback mechanism so that implementers of this interface can supply a policy on whether the connection to the URL’s hostname should be allowed. The policy can be certificate-based or can depend on other authentication schemes.

To use a custom hostname verifier, create a class that implements the weblogic.security.SSL.HostnameVerifier interface and define the methods that capture information about the server’s security identity.
Note: This interface takes new style certificates and replaces the `weblogic.security.SSL.HostnameVerifierJSSE` interface, which is deprecated in this release of WebLogic Server.

Before you can use a custom hostname verifier, you need to specify the class for your implementation in the following ways:

- In the Administration Console, set the SSL.HostName Verifier field on the SSL tab under Server Configuration to the name of a class that implements this interface. The specified class must have a public no-arg constructor.
- On the command line, enter the following argument:

  ```
  -Dweblogic.security.SSL.HostnameVerifier=hostnameverifier
  ```

  The value for `hostnameverifier` is the name of the class that implements the custom hostname verifier.

Listing 4-6 shows code fragments from the NulledHostnameVerifier example; the complete example is located at `SAMPLES_HOME\server\examples\src\examples\security\sslclient` directory in the `NulledHostnameVerifier.java` file. This code example contains a `NulledHostnameVerifier` class which always returns true for the comparison. The sample allows the WebLogic SSL client to connect to any SSL server regardless of the server’s hostname and digital certificate SubjectDN comparison.

Listing 4-6  Hostname Verifier Sample Code Fragment

```java
public class NulledHostnameVerifier implements weblogic.security.SSL.HostnameVerifier {
    public boolean verify(String urlHostname, javax.net.ssl.SSLSession session) {
        return true;
    }
}
```

Using a Trust Manager

The `weblogic.security.SSL.TrustManager` interface allows you to override validation errors in a peer’s digital certificate and continue the SSL handshake. You can also use the
interface to discontinue an SSL handshake by performing additional validation on a server’s
digital certificate chain.

**Note:** This interface takes new style certificates and replaces the
weblogic.security.SSL.TrustManagerJSSE interface, which is deprecated in this
release of WebLogic Server.

When an SSL client connects to an instance of WebLogic Server, the server presents its digital
certificate chain to the client for authentication. That chain could contain an invalid digital
certificate. The SSL specification says that the client should drop the SSL connection upon
discovery of an invalid certificate. Web browsers, however, ask the user whether to ignore the
invalid certificate and continue up the chain to determine if it is possible to authenticate the SSL
server with any of the remaining certificates in the certificate chain. You can use the
TrustManager interface to eliminate this inconsistent practice by controlling when to continue
or discontinue an SSL connection. Using a trust manager, you can perform custom checks before
continuing an SSL connection. For example, you can use a trust manager to specify that only
users from specific localities, such as towns, states, or countries, or users with other special
attributes, are allowed to gain access via the SSL connection.

Use the weblogic.security.SSL.TrustManager interface to create a trust manager. The
interface contains a set of error codes for certificate verification. You can also perform additional
validation on the peer certificate and interrupt the SSL handshake if need be. After a digital
certificate has been verified, the weblogic.security.SSL.TrustManager interface uses a
callback function to override the result of verifying the digital certificate. You can associate an
instance of a trust manager with an SSL context through the setTrustManager() method.

The weblogic.security.SSL.TrustManager interface conforms to the JSSE specification.
You can only set up a trust manger programmatically; its use cannot be defined through the
Administration Console or on the command-line.

**Note:** Depending on the checks performed, use of a trust manager may potentially impact
performance.

Listing 4-7 shows code fragments from the NulledTrustManager example; the complete example
is located at SAMPLES_HOME\server\examples\src\examples\security\sslclient
directory in the NulledTrustManager.java file. The SSLSocketClient example uses the
custom trust manager. The SSLSocketClient shows how to set up a new SSL connection by using
an SSL context with the trust manager.
Listing 4-7 NulledTrustManager Sample Code Fragments

```java
package examples.security.sslclient;

import weblogic.security.SSL.TrustManager;
import javax.security.cert.X509Certificate;
...
public class NulledTrustManager implements TrustManager {
    public boolean certificateCallback(X509Certificate[] o, int validateErr) {
        System.out.println(" --- Do Not Use In Production ---\n" +
                " By using this NulledTrustManager, the trust in" +
                " the server's identity is completely lost.\n" +
                " --------------------------------");
        for (int i=0; i<o.length; i++)
            System.out.println(" certificate " + i + " -- " + o[i].toString());
        return true;
    }
}
```

Using the CertPath Trust Manager

The CertPathTrustManager, `weblogic.security.SSL.CertPathTrustManager`, makes use of the default security realm's configured CertPath validation providers to perform extra validation such as revocation checking.

By default, application code using outbound SSL in the server has access only to the built-in SSL certificate validation. However, application code can specify the CertPathTrustManager in order to access any additional certificate validation that the administrator has configured for the server. If you want your application code to also run the CertPath validators, the application code should use the CertPathTrustManager.

There are three ways to use this class:

- The Trust Manager calls the configured CertPathValidators only if the administrator has set a switch on the SSLMBean stating that outbound SSL should use the validators. That is, the application completely delegates validation to whatever the administrator configures.
You use the `setUseConfiguredSSLValidation()` method for this purpose. This is the default.

- The Trust Manager always calls any configured CertPathValidators. You use the `setBuiltinSSLValidationAndCertPathValidators()` method for this purpose.

- The Trust Manager never calls any configured CertPathValidators. You use the `setBuiltinSSLValidationOnly()` method for this purpose.

### Using a Handshake Completed Listener

The `javax.net.ssl.HandshakeCompletedListener` interface defines how an SSL client receives notifications about the completion of an SSL protocol handshake on a given SSL connection. It also defines the number of times an SSL handshake takes place on a given SSL connection. Listing 4-8 shows code fragments from the MyListener example; the complete example is located at `SAMPLES_HOME\server\examples\src\examples\security\sslclient` directory in the MyListener.java file.

#### Listing 4-8   MyListener (HandshakeCompletedListener) Sample Code Fragments

```java
package examples.security.sslclient;

import java.io.File;
import java.io.IOException;
import java.io.InputStream;
import java.io.OutputStream;
import java.io.FileInputStream;
import javax.net.ssl.HandshakeCompletedListener;
import java.util.Hashtable;
import javax.net.ssl.SSLSession;
...

public class MyListener implements HandshakeCompletedListener
{
    public void handshakeCompleted(javax.net.ssl.HandshakeCompletedEvent event)
    {
        SSLSession session = event.getSession();
    }
```
System.out.println("Handshake Completed with peer " + 
    session.getPeerHost());
System.out.println(" cipher: " + session.getCipherSuite());
Certificate[] certs = null;
try 
{
    certs = session.getPeerCertificates();
}
catch (SSLPeerUnverifiedException puv)
{
    certs = null;
}
if  (certs != null)
{
    System.out.println(" peer certificates:");
    for (int z=0; z<certs.length; z++)
        System.out.println(" certs["+z+"]: " + certs[z]);
}else
{
    System.out.println("No peer certificates presented");
}
}

Using an SSLContext

The SSLContext class is used to programmatically configure SSL and retain SSL session information. For example, all sockets that are created by socket factories provided by the SSLContext class can agree on session state by using the handshake protocol associated with the SSL context. Each instance can be configured with the keys, certificate chains, and trusted root certificate authorities that it needs to perform authentication. These sessions are cached so that other sockets created under the same SSL context can potentially reuse them later. For more information on session caching see SSL Session Behavior in Securing WebLogic Server. To associate an instance of a trust manager class with its SSL context, use the weblogic.security.SSL.SSLContext.setTrustManager() method.
Using SSL Authentication in Java Clients

You can only set up an SSL context programmatically; not by using the Administration Console or the command line. A Java new expression or the getInstance() method of the SSLContext class can create an SSLContext object. The getInstance() method is static and it generates a new SSLContext object that implements the specified secure socket protocol. An example of using the SSLContext class is provided in the SSLSocketClient.java sample in the SAMPLES_HOME\server\examples\src\examples\security\sslclient directory. The SSLSocketClient example shows how to create a new SSL socket using SSLContext.

Listing 4-9 shows a sample instantiation using the getInstance() method.

Listing 4-9   SSL Context Code Example

import weblogic.security.SSL.SSLContext;

SSLcontext sslctx = SSLContext.getInstance ("https")

Using an SSL Server Socket Factory

Instances of the SSLSocketFactory class create and return SSL sockets. This class extends javax.net.SocketFactory. Listing 4-10 shows a sample instantiation of this class.

Listing 4-10   SSLSocketFactory Code Example

import weblogic.security.SSL.SSLSocketFactory;

SSLSocketFactory sslSF = sslCtx.getSocketFactory();

Using URLs to Make Outbound SSL Connections

You can use a URL object to make an outbound SSL connection from a WebLogic Server instance acting as a client to another WebLogic Server instance. WebLogic Server supports both one-way and two-way SSL authentication for outbound SSL connections.

For one-way SSL authentication, you use the java.net.URL, java.net.URLConnection, and java.net.HTTPURLConnection classes to make outbound SSL connections using URL objects.
Listing 4-11 shows a `simpleURL` class that supports both HTTP and HTTPS URLs and that only uses these Java classes (that is, no WebLogic classes are required). To use the `simpleURL` class for one-way SSL authentication (HTTPS) on WebLogic Server, all that is required is that "weblogic.net" be defined in the system property for `java.protocols.handler.pkgs`.

Note: Because the `simpleURL` sample shown in Listing 4-11 defaults trust and hostname checking, this sample requires that you connect to a real Web server that is trusted and that passes hostname checking by default. Otherwise, you must override trust and hostname checking on the command line.

Listing 4-11  One-Way SSL Authentication URL Outbound SSL Connection Class That Uses Java Classes Only

```java
import java.net.URL;
import java.net.URLConnection;
import java.net.HttpURLConnection;
import java.io.IOException;

public class simpleURL
{
    public static void main (String [] argv)
    {
        if (argv.length != 1)
        {
            System.out.println("Please provide a URL to connect to");
            System.exit(-1);
        }
        setupHandler();
        connectToURL(argv[0]);
    }

    private static void setupHandler()
    {
        java.util.Properties p = System.getProperties();
        String s = p.getProperty("java.protocol.handler.pkgs");
        if (s == null)
            s = "weblogic.net";
        else if (s.indexOf("weblogic.net") == -1)
            s += ":weblogic.net";
        p.put("java.protocol.handler.pkgs", s);
    }
```
System.setProperties(p);

private static void connectToURL(String theURLSpec)
{
    try
    {
        URL theURL = new URL(theURLSpec);
        URLConnection urlConnection = theURL.openConnection();
        HttpURLConnection connection = null;
        if (!(urlConnection instanceof HttpURLConnection))
        {
            System.out.println("The URL is not using HTTP/HTTPS: " +
                    theURLSpec);
            return;
        }
        connection = (HttpURLConnection) urlConnection;
        connection.connect();
        String responseStr = "\t\t" +
                connection.getResponseCode() + " -- " +
                connection.getResponseMessage() + "\t\t" +
                connection.getContent().getClass().getName() + "\n";
        connection.disconnect();
        System.out.println(responseStr);
    }
    catch (IOException ioe)
    {
        System.out.println("Failure processing URL: " + theURLSpec);
        ioe.printStackTrace();
    }
}

For two-way SSL authentication, the `weblogic.net.http.HttpsURLConnection` class provides a way to specify the security context information for a client, including the digital certificate and private key of the client. Instances of this class represent an HTTPS connection to a remote object.
The SSLClient sample code demonstrates using the WebLogic URL object to make an outbound SSL connection (see Listing 4-12). The code example shown in Listing 4-12 is excerpted from the SSLClient.java file in the

SAMPLES_HOME\server\examples\src\examples\security\sslclient directory.

Listing 4-12  WebLogic Two-Way SSL Authentication URL Outbound SSL Connection Code Example

    wlsUrl = new URL("https", host, Integer.valueOf(sport).intValue(), query);
    weblogic.net.http.HttpsURLConnection sconnection =
        new weblogic.net.http.HttpsURLConnection(wlsUrl);
    ...
    InputStream [] ins = new InputStream[2];
    ins[0] = new FileInputStream("client2certs.pem");
    ins[1] = new FileInputStream("clientkey.pem");
    String pwd = "clientkey";
    sconnection.loadLocalIdentity(ins[0], ins[1], pwd.toCharArray());

SSL Client Code Examples

A complete working SSL authentication sample is provided with the WebLogic Server product. The sample is located in the

SAMPLES_HOME\server\examples\src\examples\security\sslclient directory. For a description of the sample and instructions on how to build, configure, and run this sample, see the package.html file in the sample directory. You can modify this code example and reuse it.
Using SSL Authentication in Java Clients
WebLogic Server supports the J2EE architecture security model for securing Enterprise JavaBeans (EJBs), which includes support for declarative authorization (also referred to in this document as declarative security) and programmatic authorization (also referred to in this document as programmatic security).

The following topics are covered in this section:

- “J2EE Architecture Security Model” on page 5-1
- “Using Declarative Security With EJBs” on page 5-4
- “EJB Security-Related Deployment Descriptors” on page 5-6
- “Using Programmatic Security With EJBs” on page 5-29

Note: You can use deployment descriptor files, the Administration Console, and JACC to secure EJBs. For information on using the Administration Console to secure EJBs, see Securing WebLogic Resources. For information on JACC, see “Using the Java Authorization Contract for Containers” on page 7-6.

**J2EE Architecture Security Model**

“In the J2EE architecture, a container serves as an authorization boundary between the components it hosts and their callers. The authorization boundary exists inside the container’s authentication boundary so that authorization is considered in the context of
successful authentication. For inbound calls, the container compares security attributes from the caller's credential with the access control rules for the target component. If the rules are satisfied, the call is allowed. Otherwise, the call is rejected.”

“There are two fundamental approaches to defining access control rules: capabilities and permissions. Capabilities focus on what a caller can do. Permissions focus on who can do something. The J2EE application programming model focuses on permissions. In the J2EE architecture, the job of the deployer is to map the permission model of the application to the capabilities of users in the operational environment.”

The same document then discusses two ways to control access to application resources using the J2EE architecture, declarative authorization and programmatic authorization.

The document Designing Enterprise Applications with the J2EE Platform, Second Edition, published by Sun Microsystems, Inc., states in Section 9.3.1 Authorization:

“The deployer establishes the container-enforced access control rules associated with a J2EE application. The deployer uses a deployment tool to map an application permission model, which is typically supplied by the application assembler, to policy and mechanisms specific to the operational environment. The application permission model is defined in a deployment descriptor.”

WebLogic Server supports the use of deployment descriptors to implement declarative authorization in EJBs.

**Note:** Declarative authorization is also referred in this document as declarative security.

**Declarative Authorization**

**Programmatic Authorization**

“A J2EE container makes access control decisions before dispatching method calls to a component. The logic or state of the component doesn't factor in these access decisions. However, a component can use two methods, EJBContext.isCallerInRole (for use by enterprise bean code) and HttpServletRequest.isUserInRole (for use by Web components), to perform finer-grained access control. A component uses these methods to determine whether a caller has been granted a privilege selected by the component based on the parameters of the call, the internal state of the component, or other factors such as the time of the call.”

“The application component provider of a component that calls one of these functions must declare the complete set of distinct roleName values to be used in all calls. These declarations appear in the deployment descriptor as security-role-ref elements. Each security-role-ref element links a privilege name embedded in the application as a roleName to a security role. Ultimately, the deployer establishes the link between the privilege names embedded in the application and the security roles defined in the deployment descriptor. The link between privilege names and security roles may differ for components in the same application.”

“In addition to testing for specific privileges, an application component can compare the identity of its caller, acquired using EJBContext.getCallerPrincipal or HttpServletRequest.getUserPrincipal, to the distinguished caller identities embedded in the state of the component when it was created. If the identity of the caller is equivalent to a distinguished caller, the component can allow the caller to proceed. If not, the component can prevent the caller from further interaction. The caller principal returned by a container depends on the authentication mechanism used by the caller. Also, containers from different vendors may return different principals for the same user authenticating by the same mechanism. To account for variability in principal forms, an application developer who chooses to apply distinguished caller state in component access decisions should allow multiple distinguished caller identities, representing the same user, to be associated with components. This is recommended especially where application flexibility or portability is a priority.”

WebLogic Server supports the use of the EJBContext.isCallerInRole and EJBContext.getCallerPrincipal methods and the use of the security-role-ref element in deployment descriptors to implement programmatic authorization in EJBs.

**Note:** Programmatic authorization is also referred in this document as programmatic security.

Declarative Versus Programmatic Authorization

The document *Designing Enterprise Applications with the J2EE Platform, Second Edition*, published by Sun Microsystems, Inc., states in Section 9.3.3 Declarative Versus Programmatic Authorization:

“There is a trade-off between the external access control policy configured by the deployer and the internal policy embedded in the application by the component provider. The external policy is more flexible after the application has been written. The internal policy provides more flexible functionality while the application is being written. In addition, the external policy is transparent and completely comprehensible to the deployer, while internal policy is buried in the application and may only be completely understood by the application developer. These trade-offs should be considered in choosing the authorization model for particular components and methods.”

Using Declarative Security With EJBs

There are three ways to implement declarative security:

1. Security providers via the Administration Console, as described in *Securing WebLogic Resources*.

2. Java Authorization Contract for Containers (JACC), as described in “Using the Java Authorization Contract for Containers” on page 7-6.

3. Deployment descriptors, which are discussed in this section.

Which of these three methods is used is defined by the JACC flags and the security model. (Security models are described in Options for Securing EJB and Web Application Resources in *Securing WebLogic Resources*.)

To implement declarative security in EJBs you can use deployment descriptors (ejb-jar.xml and weblogic-ejb-jar.xml) to define the security requirements. Listing 5-1 shows examples of how to use the ejb-jar.xml and weblogic-ejb-jar.xml deployment descriptors to map security role names to a security realm. The deployment descriptors map the application’s logical security requirements to its runtime definitions. And at runtime, the EJB container uses the security definitions to enforce the requirements.
To configure security in the EJB deployment descriptors, perform the following steps (see Listing 5-1):

1. Use a text editor to create ejb-jar.xml and weblogic-ejb-jar.xml deployment descriptor files.

2. In the ejb-jar.xml file, define the security role name, the EJB name, and the method name (see bold text).

   **Note:** When specifying security role names, observe the following conventions and restrictions:

   **Note:** The proper syntax for a security role name is as defined for an Nmtoken in the Extensible Markup Language (XML) recommendation available on the Web at:
   http://www.w3.org/TR/REC-xml#NT-Nmtoken.
   - Do not use blank spaces, commas, hyphens, or any characters in this comma-separated list: \t, < >, #, & , ~, ?, ( ), { }.
   - Security role names are case sensitive.
   - The BEA suggested convention for security role names is that they be singular.

   For more information on configuring security in the ejb-jar.xml file, see the Sun Microsystems Enterprise JavaBeans Specification, Version 2.0 which is at this location on the Internet: http://java.sun.com/products/ejb/docs.html.

3. In the WebLogic-specific EJB deployment descriptor file, weblogic-ejb-jar.xml, define the security role name and link it to one or more principals (users or groups) in a security realm.

   For more information on configuring security in the weblogic-ejb-jar.xml file, see weblogic-ejb-jar.xml Deployment Descriptor Reference in Programming WebLogic Enterprise JavaBeans.

**Listing 5-1** Using the ejb-jar.xml and weblogic-ejb-jar.xml Files to Map Security Role Names to a Security Realm

ejb-jar.xml entries:

```xml
...<assembly-descriptor>
<security-role>
  <role-name>manger</role-name>
</security-role>
</assembly-descriptor>
```
EJB Security-Related Deployment Descriptors

The following topics describe the deployment descriptor elements that are used in the
\texttt{ejb-jar.xml} and \texttt{weblogic-ejb-jar.xml} files to define security requirements in EJBs:

- “\texttt{ejb-jar.xml} Deployment Descriptors” on page 5-6
- “\texttt{weblogic-ejb-jar.xml} Deployment Descriptors” on page 5-13

\textbf{ejb-jar.xml} Deployment Descriptors

The following \texttt{ejb-jar.xml} deployment descriptor elements are used to define security
requirements in WebLogic Server:
method

The method element is used to denote a method of an enterprise bean’s home or component interface, or, in the case of a message-driven bean, the bean’s onMessage method, or a set of methods.

The following table describes the elements you can define within a method element.

<table>
<thead>
<tr>
<th>Element</th>
<th>Required/Optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;description&gt;</td>
<td>Optional</td>
<td>A text description of the method.</td>
</tr>
<tr>
<td>&lt;ejb-name&gt;</td>
<td>Required</td>
<td>Specifies the name of one of the enterprise beans declared in the ejb-jar.xml file.</td>
</tr>
<tr>
<td>&lt;method-intf&gt;</td>
<td>Optional</td>
<td>Allows you to distinguish between a method with the same signature that is multiply defined across both the home and component interfaces of the enterprise bean.</td>
</tr>
<tr>
<td>&lt;method-name&gt;</td>
<td>Required</td>
<td>Specifies a name of an enterprise bean method or the asterisk (*) character. The asterisk is used when the element denotes all the methods of an enterprise bean’s component and home interfaces.</td>
</tr>
<tr>
<td>&lt;method-params&gt;</td>
<td>Optional</td>
<td>Contains a list of the fully-qualified Java type names of the method parameters.</td>
</tr>
</tbody>
</table>
**Used Within**

The `method` element is used within the `method-permission` element.

**Example**

For an example of how to use the `method` element, see Listing 5-1, “Using the ejb-jar.xml and weblogic-ejb-jar.xml Files to Map Security Role Names to a Security Realm,” on page 5-5.

**method-permission**

The `method-permission` element specifies that one or more security roles are allowed to invoke one or more enterprise bean methods. The `method-permission` element consists of an optional description, a list of security role names or an indicator to state that the method is unchecked for authorization, and a list of method elements.

The security roles used in the `method-permission` element must be defined in the `security-role` elements of the deployment descriptor, and the methods must be methods defined in the enterprise bean's component and/or home interfaces.

The following table describes the elements you can define within a `method-permission` element.

<table>
<thead>
<tr>
<th>Element</th>
<th>Required/Optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;description&gt;</code></td>
<td>Optional</td>
<td>A text description of this security constraint.</td>
</tr>
<tr>
<td><code>&lt;role-name&gt;</code> or <code>&lt;unchecked&gt;</code></td>
<td>Required</td>
<td>The <code>role-name</code> element or the <code>unchecked</code> element must be specified. The <code>role-name</code> element contains the name of a security role. The name must conform to the lexical rules for an <code>NMTOKEN</code>. The <code>unchecked</code> element specifies that a method is not checked for authorization by the container prior to invocation of the method.</td>
</tr>
<tr>
<td><code>&lt;method&gt;</code></td>
<td>Required</td>
<td>Specifies a method of an enterprise bean's home or component interface, or, in the case of a message-driven bean, the bean's <code>onMessage</code> method, or a set of methods.</td>
</tr>
</tbody>
</table>

**Used Within**

The `method-permission` element is used within the `assembly-descriptor` element.
Example
For an example of how to use the method-permission element, see Listing 5-1, “Using the ejb-jar.xml and weblogic-ejb-jar.xml Files to Map Security Role Names to a Security Realm,” on page 5-5.

role-name
The role-name element contains the name of a security role. The name must conform to the lexical rules for an NMTOKEN.

Used Within
The role-name element is used within the method-permission, run-as, security-role, and security-role-ref elements.

Example
For an example of how to use the role-name element, see Listing 5-1, “Using the ejb-jar.xml and weblogic-ejb-jar.xml Files to Map Security Role Names to a Security Realm,” on page 5-5.

run-as
The run-as element specifies the run-as identity to be used for the execution of the enterprise bean. It contains an optional description, and the name of a security role.

Used Within
The run-as element is used within the security-identity element.

Example
For an example of how to use the run-as element, see Listing 5-8, “run-as-role-assignment Element Example,” on page 5-24.

security-identity
The security-identity element specifies whether the caller’s security identity is to be used for the execution of the methods of the enterprise bean or whether a specific run-as identity is to be used. It contains an optional description and a specification of the security identity to be used.
Securing Enterprise JavaBeans (EJBs)

The following table describes the elements you can define within a security-identity element.

<table>
<thead>
<tr>
<th>Element</th>
<th>Required/Optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;description&gt;</td>
<td>Optional</td>
<td>A text description of the security identity.</td>
</tr>
<tr>
<td>&lt;use-caller-identity&gt; or &lt;run-as&gt;</td>
<td>Required</td>
<td>The use-caller-identity element or the run-as element must be specified.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The use-caller-identity element specifies that the caller's security identity be used as the security identity for the execution of the enterprise bean's methods.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The run-as element specifies the run-as identity to be used for the execution of the enterprise bean. It contains an optional description, and the name of a security role.</td>
</tr>
</tbody>
</table>

**Used Within**

The security-identity element is used within the entity, message-driven, and session elements.

**Example**

**security-role**

The security-role element contains the definition of a security role. The definition consists of an optional description of the security role, and the security role name.

**Used Within**

The security-role element is used within the assembly-descriptor element.

**Example**

For an example of how to use the assembly-descriptor element, see Listing 5-1, “Using the ejb-jar.xml and weblogic-ejb-jar.xml Files to Map Security Role Names to a Security Realm,” on page 5-5.
security-role-ref

The `security-role-ref` element contains the declaration of a security role reference in the enterprise bean's code. The declaration consists of an optional description, the security role name used in the code, and an optional link to a security role. If the security role is not specified, the Deployer must choose an appropriate security role.

The value of the `role-name` element must be the String used as the parameter to the EJBContext.isCallerInRole(String roleName) method or the HttpServletRequest.isUserInRole(String role) method.

Used Within

The `security-role-ref` element is used within the entity and session elements.

Example

For an example of how to use the `security-role-ref` element, see Listing 5-2.

Listing 5-2  Security-role-ref Element Example

```xml
<!DOCTYPE weblogic-ejb-jar
 xmlns="http://www.bea.com/ns/weblogic/90"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:schemaLocation="http://www.bea.com/ns/weblogic/90
 http://www.bea.com/ns/weblogic/90/weblogic-ejb-jar.xsd">
<ejb-jar>
<enterprise-beans>
...
<session>
  <ejb-name>SecuritySLEJB</ejb-name>
  <home>weblogic.ejb20.security.SecuritySLHome</home>
  <remote>weblogic.ejb20.security.SecuritySL</remote>
  <ejb-class>weblogic.ejb20.security.SecuritySLBean</ejb-class>
  <session-type>Stateless</session-type>
  <transaction-type>Container</transaction-type>
  <security-role-ref>
    <role-name>rolenamedifffromlink</role-name>
    <role-link>role121SL</role-link>
  </security-role-ref>
</session>
```
Securing Enterprise JavaBeans (EJBs)

```xml
<security-role-ref>
   <role-name>roleForRemotes</role-name>
   <role-link>roleForRemotes</role-link>
</security-role-ref>

<security-role-ref>
   <role-name>roleForLocalAndRemote</role-name>
   <role-link>roleForLocalAndRemote</role-link>
</security-role-ref>
</session>
...
</enterprise-beans>
</ejb-jar>
```

**unchecked**

The `unchecked` element specifies that a method is not checked for authorization by the container prior to invocation of the method.

**Used Within**

The `unchecked` element is used within the `method-permission` element.

**Example**

For an example of how to use the `unchecked` element, see Listing 5-1, “Using the ejb-jar.xml and weblogic-ejb-jar.xml Files to Map Security Role Names to a Security Realm,” on page 5-5.

**use-caller-identity**

The `use-caller-identity` element specifies that the caller's security identity be used as the security identity for the execution of the enterprise bean's methods.

**Used Within**

The `use-caller-identity` element is used within the `security-identity` element.

**Example**

For an example of how to use the `use-caller-identity` element, see Listing 5-3.
Listing 5-3  use-caller-identity Element Example

```xml
<ejb-jar>
  <enterprise-beans>
    <session>
      <ejb-name>SecurityEJB</ejb-name>
      <home>weblogic.ejb20.SecuritySLHome</home>
      <remote>weblogic.ejb20.SecuritySL</remote>
      <local-home>
        weblogic.ejb20.SecurityLocalSLHome
      </local-home>
      <local>weblogic.ejb20.SecurityLocalSL</local>
      <ejb-class>weblogic.ejb20.SecuritySLBean</ejb-class>
      <session-type>Stateless</session-type>
      <transaction-type>Container</transaction-type>
    </session>
    <message-driven>
      <ejb-name>SecurityEJB</ejb-name>
      <ejb-class>weblogic.ejb20.SecuritySLBean</ejb-class>
      <transaction-type>Container</transaction-type>
      <security-identity>
        <use-caller-identity/>
      </security-identity>
    </message-driven>
  </enterprise-beans>
</ejb-jar>
```

**weblogic-ejb-jar.xml Deployment Descriptors**

The following `weblogic-ejb-jar.xml` deployment descriptor elements are used to define security requirements in WebLogic Server:

- “client-authentication” on page 5-14
- “client-cert-authentication” on page 5-15
client-authentication

The client-authentication element specifies whether the EJB supports or requires client authentication.

The following table defines the possible settings.

<table>
<thead>
<tr>
<th>Setting</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>Client authentication is not supported.</td>
</tr>
<tr>
<td>supported</td>
<td>Client authentication is supported, but not required.</td>
</tr>
<tr>
<td>required</td>
<td>Client authentication is required.</td>
</tr>
</tbody>
</table>
Example
For an example of how to use the `client-authentication` element, see Listing 5-6, “iiop-security-descriptor Element Example,” on page 5-19.

**client-cert-authentication**
The `client-cert-authentication` element specifies whether the EJB supports or requires client certificate authentication at the transport level.

The following table defines the possible settings.

<table>
<thead>
<tr>
<th>Setting</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>Client certificate authentication is not supported.</td>
</tr>
<tr>
<td>supported</td>
<td>Client certificate authentication is supported, but not required.</td>
</tr>
<tr>
<td>required</td>
<td>Client certificate authentication is required.</td>
</tr>
</tbody>
</table>

Example
For an example of how to use the `client-cert-authentication` element, see Listing 5-10, “transport-requirements Element Example,” on page 5-28.

**confidentiality**
The `confidentiality` element specifies the transport confidentiality requirements for the EJB. Using the `confidentiality` element ensures that the data is sent between the client and server in such a way as to prevent other entities from observing the contents.

The following table defines the possible settings.

<table>
<thead>
<tr>
<th>Setting</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>Confidentiality is not supported.</td>
</tr>
<tr>
<td>supported</td>
<td>Confidentiality is supported, but not required.</td>
</tr>
<tr>
<td>required</td>
<td>Confidentiality is required.</td>
</tr>
</tbody>
</table>
Example

For an example of how to use the confidentiality element, see Listing 5-10, “transport-requirements Element Example,” on page 5-28.

externally-defined

In WebLogic Server 8.1 and later, the externally-defined tag is supported for use in the weblogic-ejb-jar.xml deployment descriptors. You can use this tag, instead of the <principal-name> tag, to explicitly indicate that you want the security roles defined in the deployment descriptors by the <role-name> tag in the weblogic-ejb-jar.xml file to use the mappings that you specify in the Administration Console.

Note: The externally-defined element replaces the global-role element that was used in WebLogic Server 7.0 SP1. The externally-defined tag has the same functionality as the global-role element. The global-role element was deprecated in WebLogic Server 8.1.

The externally-defined element gives you the flexibility of not having to specify a specific role mapping for each security role defined in the deployment descriptors for a particular EJB. Rather, you can use the Administration Console to specify and modify a specific role mapping for each defined role at anytime. Additionally, because you may elect to use this tag on some EJBs and not others, it is not necessary to select the ignore roles and polices from DD option for the security realm. You select this option in the On Future Redeploys: field on the General tab of the Security->Realms->myrealm control panel on the Administration Console. Thus, within the same security realm, deployment descriptors can be used to specify and modify security for some EJBs, while the Administration Console can be used to specify and modify security for others.

Note: When specifying security role names, observe the following conventions and restrictions:

- The proper syntax for a security role name is as defined for an Nmtoken in the Extensible Markup Language (XML) recommendation available on the Web at: http://www.w3.org/TR/REC-xml#NT-Nmtoken.

- Do not use blank spaces, commas, hyphens, or any characters in this comma-separated list: \t, < >, #, &, ~, ?, ( ), { }.

- Security role names are case sensitive.

- The BEA suggested convention for security role names is that they be singular.
Listing 5-4 and Listing 5-5 show by comparison how to use the externally-defined element in the weblogic-ejb-jar.xml file. In Listing 5-5, the specification of the “manager” externally-defined element in the weblogic-ejb-jar.xml means that for security to be correctly configured on the getReceipts method, the principals for manager will have to be created in the Administration Console.

Listing 5-4 Using the ejb-jar.xml and weblogic-ejb-jar.xml Deployment Descriptors to Map Security Roles in EJBs

ejb-jar.xml entries:

...  
<assembly-descriptor>
    <security-role>
        <role-name>manager</role-name>
    </security-role>
    <security-role>
        <role-name>east</role-name>
    </security-role>
    <method-permission>
        <role-name>manager</role-name>
        <role-name>east</role-name>
        <method>
            <ejb-name>accountsPayable</ejb-name>
            <method-name>getReceipts</method-name>
        </method>
    </method-permission>
    ...
</assembly-descriptor>
...

weblogic-ejb-jar.xml entries:

<security-role-assignment>
    <role-name>manager</role-name>
    <principal-name>joe</principal-name>
    <principal-name>Bill</principal-name>
    <principal-name>Mary</principal-name>
...

Listing 5-5  Using the externally-defined Element in EJB Deployment Descriptors for Role Mapping

ejb-jar.xml entries:
...
<assembly-descriptor>
 <security-role>
  <role-name>manager</role-name>
 </security-role>
 <security-role>
  <role-name>east</role-name>
 </security-role>
 <method-permission>
  <role-name>manager</role-name>
  <role-name>east</role-name>
  <method>
   <ejb-name>accountsPayable</ejb-name>
   <method-name>getReceipts</method-name>
  </method>
 </method-permission>
...
</assembly-descriptor>
...

weblogic-ejb-jar.xml entries:
<security-role-assignment>
 <role-name>manager</role-name>
 <externally-defined/>
...
</security-role-assignment>
...
For more information on using the Administration Console to configure security for EJBs, see *Securing WebLogic Resources*.

**identity-assertion**

The `identity-assertion` element specifies whether the EJB supports identity assertion.

The following table defines the possible settings.

<table>
<thead>
<tr>
<th>Setting</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>Identity assertion is not supported</td>
</tr>
<tr>
<td>supported</td>
<td>Identity assertion is supported, but not required.</td>
</tr>
<tr>
<td>required</td>
<td>Identity assertion is required.</td>
</tr>
</tbody>
</table>

**Used Within**

The `identity-assertion` element is used with the `iiop-security-descriptor` element.

**Example**

For an example of how to use the `identity-assertion` element, see Listing 5-6, “iiop-security-descriptor Element Example,” on page 5-19.

**iiop-security-descriptor**

The `iiop-security-descriptor` element specifies security configuration parameters at the bean-level. These parameters determine the IIOP security information contained in the interoperable object reference (IOR).

**Example**

For an example of how to use the `iiop-security-descriptor` element, see Listing 5-6.

**Listing 5-6  iiop-security-descriptor Element Example**

```xml
<weblogic-enterprise-bean>
  <iiop-security-descriptor>
    <transport-requirements>
      <confidentiality>supported</confidentiality>
    </transport-requirements>
  </iiop-security-descriptor>
</weblogic-enterprise-bean>
```
Securing Enterprise JavaBeans (EJBs)

<integrity>supported</integrity>
<client-cert-authorization>
  supported
</client-cert-authorization>
</transport-requirements>
<client-authentication>supported</client-authentication>
<identity-assertion>supported</identity-assertion>
</iiop-security-descriptor>
</weblogic-enterprise-bean>

**integrity**

The *integrity* element specifies the transport integrity requirements for the EJB. Using the *integrity* element ensures that the data is sent between the client and server in such a way that it cannot be changed in transit.

The following table defines the possible settings.

<table>
<thead>
<tr>
<th>Setting</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>Integrity is not supported.</td>
</tr>
<tr>
<td>supported</td>
<td>Integrity is supported, but not required.</td>
</tr>
<tr>
<td>required</td>
<td>Integrity is required.</td>
</tr>
</tbody>
</table>

**Used Within**

The *integrity* element is used within the *transport-requirements* element.

**Example**

For an example of how to use the *integrity* element, see Listing 5-10, “transport-requirements Element Example,” on page 5-28.

**principal-name**

The *principal-name* element specifies the name of the principal in the ProductName security realm that applies to role name specified in the security-role-assignment element. At least one
principal is required in the security-role-assignment element. You may define more than one principal-name for each role name.

**Note:** If you need to list a significant number of principals, consider specifying groups instead of users. There are performance issues if you specify too many users.

**Used Within**

The principal-name element is used within the security-role-assignment element.

**Example**

For an example of how to use the principal-name element, see Listing 5-1, “Using the ejb-jar.xml and weblogic-ejb-jar.xml Files to Map Security Role Names to a Security Realm,” on page 5-5.

**role-name**

The role-name element identifies an application role name that the EJB provider placed in the companion ejb-jar.xml file. Subsequent principal-name elements in the stanza map ProductName principals to the specified role-name.

**Used Within**

The role-name element is used within the security-role-assignment element.

**Example**

For an example of how to use the role-name element, see Listing 5-1, “Using the ejb-jar.xml and weblogic-ejb-jar.xml Files to Map Security Role Names to a Security Realm,” on page 5-5.

**run-as-identity-principal**

The run-as-identity-principal element specifies which security principal name is to be used as the run-as principal for a bean that has specified a security-identity run-as role-name in its ejb-jar deployment descriptor. For an explanation of how of run-as role-names to are mapped to run-as-identity-principals (or run-as-principal-names, see “run-as-role-assignment” on page 5-24.

**Note:** **Deprecated:** The run-as-identity-principal element is deprecated in the WebLogic Server 8.1. Use the run-as-principal-name element instead.
Securing Enterprise JavaBeans (EJBs)

Used Within
The run-as-identity-principal element is used within the run-as-role-assignment element.

Example
For an example of how to use the run-as-identity-principal element, see Listing 5-7.

Listing 5-7  run-as-identity-principal Element Example

ejb-jar.xml:

  <ejb-jar>
  <enterprise-beans>
  <session>
    <ejb-name>Caller2EJB</ejb-name>
    <home>weblogic.ejb11.security.CallerBeanHome</home>
    <remote>weblogic.ejb11.security.CallerBeanRemote</remote>
    <ejb-class>weblogic.ejb11.security.CallerBean</ejb-class>
    <session-type>Stateful</session-type>
    <transaction-type>Container</transaction-type>
    <ejb-ref>
      <ejb-ref-name>Callee2Bean</ejb-ref-name>
      <ejb-ref-type>Session</ejb-ref-type>
      <home>weblogic.ejb11.security.CalleeBeanHome</home>
      <remote>weblogic.ejb11.security.CalleeBeanRemote</remote>
    </ejb-ref>
  </session>
  <security-role-ref>
    <role-name>users1</role-name>
    <role-link>users1</role-link>
  </security-role-ref>
  <security-identity>
    <run-as>
      <role-name>users2</role-name>
    </run-as>
  </security-identity>
  </enterprise-beans>
</ejb-jar>
woblogic-ejb-jar.xml:

```xml
<weblogic-ejb-jar>
  <weblogic-enterprise-bean>
    <ejb-name>Caller2EJB</ejb-name>
    <reference-descriptor>
      <ejb-ref-name>Callee2Bean</ejb-ref-name>
      <jndi-name>security.Callee2Bean</jndi-name>
    </reference-descriptor>
    <run-as-identity-principal>wsUser3</run-as-identity-principal>
  </weblogic-enterprise-bean>
  <security-role-assignment>
    <role-name>user</role-name>
    <principal-name>wsUser2</principal-name>
    <principal-name>wsUser3</principal-name>
    <principal-name>wsUser4</principal-name>
  </security-role-assignment>
</weblogic-ejb-jar>
```

**run-as-principal-name**

The `run-as-principal-name` element specifies which security principal name is to be used as the run-as principal for a bean that has specified a security-identity run-as role-name in its ejb-jar deployment descriptor. For an explanation of how the run-as role-names map to run-as-principal-names, see “run-as-role-assignment” on page 5-24.

**Used Within**

The `run-as-principal-name` element is used within the `run-as-role-assignment` element.

**Example**

For an example of how to use the `run-as-principal-name` element, see Listing 5-8, “run-as-role-assignment Element Example,” on page 5-24.
run-as-role-assignment

The run-as-role-assignment element is used to map a given security-identity run-as role-name that is specified in the ejb-jar.xml file to a run-as-principal-name specified in the weblogic-ejb-jar.xml file. The value of the run-as-principal-name element for a given role-name is scoped to all beans in the ejb-jar.xml file that use the specified role-name as their security-identity. The value of the run-as-principal-name element specified in weblogic-ejb-jar.xml file can be overridden at the individual bean level by specifying a run-as-principal-name element under that bean's weblogic-enterprise-bean element.

Note: For a given bean, if there is no run-as-principal-name element specified in either a run-as-role-assignment element or in a bean specific run-as-principal-name element, then the EJB container will choose the first principal-name of a security user in the weblogic-enterprise-bean security-role-assignment element for the role-name and use that principal-name as the run-as-principal-name.

Example

For an example of how to use the run-as-role-assignment element, see Listing 5-8.

Listing 5-8  run-as-role-assignment Element Example

In the ejb-jar.xml file:

// Beans "A_EJB_with_runAs_role_X" and "B_EJB_with_runAs_role_X"
// specify a security-identity run-as role-name "runAs_role_X".
// Bean "C_EJB_with_runAs_role_Y" specifies a security-identity
// run-as role-name "runAs_role_Y".
<ejb-jar>
  <enterprise-beans>
    <session>
      <ejb-name>SecurityEJB</ejb-name>
      <home>weblogic.ejb20.SecuritySLHome</home>
      <remote>weblogic.ejb20.SecuritySL</remote>
      <local-home>
        weblogic.ejb20.SecurityLocalSLHome
      </local-home>
      <ejb-class>weblogic.ejb20.SecuritySLBean</ejb-class>
    </session>
  </enterprise-beans>
</ejb-jar>
<session-type>Stateless</session-type>
<transaction-type>Container</transaction-type>
</session>

<message-driven>
<ejb-name>SecurityEJB</ejb-name>
<ejb-class>weblogic.ejb20.SecuritySLBean</ejb-class>
<transaction-type>Container</transaction-type>
<security-identity>
<run-as>
  <role-name>runAs_role_X</role-name>
</run-as>
</security-identity>
<security-identity>
<run-as>
  <role-name>runAs_role_Y</role-name>
</run-as>
</security-identity>
</message-driven>
</enterprise-beans>
</ejb-jar>

weblogic-ejb-jar file:

<weblogic-ejb-jar>
<weblogic-enterprise-bean>
  <ejb-name>A_EJB_with_runAs_role_X</ejb-name>
</weblogic-enterprise-bean>
<weblogic-enterprise-bean>
  <ejb-name>B_EJB_with_runAs_role_X</ejb-name>
  <run-as-principal-name>Joe</run-as-principal-name>
</weblogic-enterprise-bean>
<weblogic-enterprise-bean>
  <ejb-name>C_EJB_with_runAs_role_Y</ejb-name>
</weblogic-enterprise-bean>
<security-role-assignment>
  <role-name>runAs_role_Y</role-name>
  <principal-name>Harry</principal-name>
</security-role-assignment>
Each of the three beans shown in Listing 5-8 will choose a different principal name to run as.

- **A_EJB_with_runAs_role_X**
  This bean’s run-as role-name is runAs_role_X. The jar-scoped
  <run-as-role-assignment> mapping will be used to look up the name of the principal
to use. The <run-as-role-assignment> mapping specifies that for <role-name>
runAs_role_X we are to use <run-as-principal-name> Fred. Therefore, Fred is the
principal name that will be used.

- **B_EJB_with_runAs_role_X**
  This bean’s run-as role-name is also runAs_role_X. This bean will not use the jar scoped
  <run-as-role-assignment> to look up the name of the principal to use because that
  value is overridden by this bean’s <weblogic-enterprise-bean>
  <run-as-principal-name> value Joe. Therefore Joe is the principal name that will be
  used.

- **C_EJB_with_runAs_role_Y**
  This bean’s run-as role-name is runAs_role_Y. There is no explicit mapping of
  runAs_role_Y to a run-as principal name, that is, there is no jar scoped
  <run-as-role-assignment> for runAs_role_Y nor is there a bean scoped
  <run-as-principal-name> specified in this bean’s <weblogic-enterprise-bean>. To
determine the principal name to use, the <security-role-assignment> for
  <role-name> runAs_role_Y is examined. The first <principal-name> corresponding to
  a user that is not a Group is chosen. Therefore, Harry is the principal name that will be
  used.

**security-permission**

The security-permission element specifies a security permission that is associated with a
J2EE Sandbox.
Example
For an example of how to use the `security-permission` element, see Listing 5-9, “security-permission-spec Element Example,” on page 5-27.

**security-permission-spec**

The `security-permission-spec` element specifies a single security permission based on the Security policy file syntax.

For more information, see Sun’s implementation of the security permission specification:
http://java.sun.com/j2se/1.5.0/docs/guide/security/PolicyFiles.html#FileSyntax

**Note:** Disregard the optional `codebase` and `signedBy` clauses.

**Used Within**
The `security-permission-spec` element is used within the `security-permission` element.

Example
For an example of how to use the `security-permission-spec` element, see Listing 5-9.

**Listing 5-9 security-permission-spec Element Example**

```xml
<weblogic-ejb-jar>
  <security-permission>
    <description>Optional explanation goes here</description>
    <security-permission-spec>
      <![CDATA[
        A single grant statement following the syntax of
        http://java.sun.com/j2se/1.5.0/docs/guide/security/PolicyFiles.html#FileSyntax,
        without the codebase and signedBy clauses, goes here. For example:
        -->
        grant {
          permission java.net.SocketPermission *, resolve;
        };
      ]]>
      </security-permission-spec>
    </security-permission>
  </security-permission>
</weblogic-ejb-jar>
```
In Listing 5-9, permission java.net.SocketPermission is the permission class name, *** represents the target name, and resolve (resolve host/IP name service lookups) indicates the action.

**security-role-assignment**

The security-role-assignment element maps application roles in the ejb-jar.xml file to the names of security principals available in ProductName.

**Example**

For an example of how to use the security-role-assignment element, see Listing 5-1, “Using the ejb-jar.xml and weblogic-ejb-jar.xml Files to Map Security Role Names to a Security Realm,” on page 5-5.

**transport-requirements**

The transport-requirements element defines the transport requirements for the EJB.

**Used Within**

The transport-requirements element is used within the iiop-security-descriptor element.

**Example**

For an example of how to use the transport-requirements element, see Listing 5-10.

**Listing 5-10  transport-requirements Element Example**

```xml
<weblogic-enterprise-bean>
  <iiop-security-descriptor>
    <transport-requirements>
      <confidentiality>supported</confidentiality>
      <integrity>supported</integrity>
      <client-cert-authorization>
        supported
      </client-cert-authorization>
    </transport-requirements>
  </iiop-security-descriptor>
</weblogic-enterprise-bean>
```
Using Programmatic Security With EJBs

To implement programmatic security in EJBs, use the javax.ejb.EJBContext.getCallerPrincipal() and the javax.ejb.EJBContext.isCallerInRole() methods.

getCallerPrincipal

Use the getCallerPrincipal() method to determine the caller of the EJB. The javax.ejb.EJBContext.getCallerPrincipal() method returns a WLSUser Principal if one exists in the Subject of the calling user. In the case of multiple WLSUser Principals, the method returns the first in the ordering defined by the Subject.getPrincipals().iterator() method. If there are no WLSUser Principals, then the getCallerPrincipal() method returns the first non-WLSGroup Principal. If there are no Principals or all Principals are of type WLSGroup, this method returns weblogic.security.WLSPrincipals.getAnonymousUserPrincipal(). This behavior is similar to the semantics of weblogic.security.SubjectUtils.getUserPrincipal() except that SubjectUtils.getUserPrincipal() returns a null whereas EJBContext.getCallerPrincipal() returns WLSPrincipals.getAnonymousUserPrincipal().

For more information about how to use the getCallerPrincipal() method, see http://java.sun.com/j2ee/1.4/docs/tutorial/doc/Security8.html.

isCallerInRole

The isCallerInRole() method is used to determine if the caller (the current user) has been assigned a security role that is authorized to perform actions on the WebLogic resources in that thread of execution. For example, the method javax.ejb.EJBContext.isCallerInRole("admin") will return true if the current user has admin privileges.

For more information about how to use the isCallerInRole() method, see http://java.sun.com/j2ee/1.4/docs/tutorial/doc/Security8.html.
For Javadoc for the isCallerInRole() method, see
http://java.sun.com/j2ee/1.4/docs/api/javax/ejb/EJBContext.html#isCallerInRole(java.lang.String).
CHAPTER 6

Using Network Connection Filters

This section covers the following topics:

- “The Benefits of Using Network Connection Filters” on page 6-1
- “Network Connection Filter API” on page 6-2
- “Guidelines for Writing Connection Filter Rules” on page 6-4
- “Configuring the WebLogic Connection Filter” on page 6-7
- “Developing Custom Connection Filters” on page 6-7
- “Connection Filter Examples” on page 6-8

The Benefits of Using Network Connection Filters

Security roles and security policies let you secure WebLogic resources at the domain level, the application level, and the application-component level. Connection filters let you deny access at the network level. Thus, network connection filters provide an additional layer of security. Connection filters can be used to protect server resources on individual servers, server clusters, or an entire internal network.

Connection filters are particularly useful for controlling access through the Administration port. Depending on your network firewall configuration, you might be able to use a connection filter to further restrict administration access. A typical use is to restrict access to the Administration port to only the servers and machines in the domain. Even if an attacker gets access to a machine
Using Network Connection Filters

inside the firewall, they will not be able to perform administration operations unless they are on
one of the permitted machines.

Network connection filters are a type of firewall in that they can be configured to filter on
protocols, IP addresses, and DNS node names. For example, you can deny any non-SSL
connections originating outside of your corporate network. This would ensure that all access from
systems on the Internet would be secure.

Network Connection Filter API

This section describes the weblogic.security.net package. This API provides interfaces and
classes for developing network connection filters. It also includes a class,
ConnectionFilterImpl, which is a ready-to-use implementation of a network connection
filter. For more information, see Javadocs for WebLogic Classes for this release of WebLogic
Server.

This section covers the following topics:

- “Connection Filter Interfaces” on page 6-2
- “Connection Filter Classes” on page 6-3

Connection Filter Interfaces

To implement connection filtering, write a class that implements the connection filter interfaces.
The following weblogic.security.net interfaces are provided for implementing connection
filters:

- “ConnectionFilter Interface” on page 6-2
- “ConnectionFilterRulesListener Interface” on page 6-3

ConnectionFilter Interface

This interface defines the accept() method, which is used to implement connection filtering. To
program the server to perform connection filtering, instantiate a class that implements this
interface and then configure that class in the Administration Console. This interface is the
minimum implementation requirement for connection filtering.

Note: Implementing this interface alone does not permit the use of the Administration Console
to enter and modify filtering rules to restrict client connections; you must use some other
form (such as a flat file, which is defined in the Administration Console) for that purpose.
To use the Administration Console to enter and modify filtering rules, you must also
implement the `ConnectionFilterRulesListener` interface. For a description of the `ConnectionFilterRulesListener` interface, see “ConnectionFilterRulesListener Interface” on page 6-3.

For code examples that demonstrate how to use this interface, see “Connection Filter Examples” on page 6-8.

**ConnectionFilterRulesListener Interface**

The server uses this interface to determine whether the rules specified in the Administration Console in the `ConnectionFilterRules` field are valid during startup and at runtime.

**Note:** You can implement this interface or just use the WebLogic connection filter implementation, `weblogic.security.net.ConnectionFilterImpl`, which is provided as part of the WebLogic Server product.

This interface defines two methods that are used to implement connection filtering: `setRules()` and `checkRules()`. Implementing this interface in addition to the `ConnectionFilter` interface allows the use of the Administration Console to enter filtering rules to restrict client connections.

**Note:** In order to enter and edit connection filtering rules on the Administration Console, you must implement the `ConnectionFilterRulesListener` interface; otherwise some other means must be used. For example, you could use a flat file.

For a code example of how to use this interface, see “Connection Filter Examples” on page 6-8.

**Connection Filter Classes**

Two `weblogic.security.net` classes are provided for implementing connection filters:

- “`ConnectionFilterImpl Class`” on page 6-3
- “`ConnectionEvent Class`” on page 6-4

**ConnectionFilterImpl Class**

This class is the WebLogic connection filter implementation of the `ConnectionFilter` and `ConnectionFilterRulesListener` interfaces. Once configured using the Administration Console, this connection filter accepts all incoming connections by default, and also provides static factory methods that allow the server to obtain the current connection filter. To use this connection to deny access, simply enter connection filter rules using the Administration Console.

This class is provided as part of the WebLogic Server product. To configure this class for use, see “Configuring the WebLogic Connection Filter” on page 6-7.
Using Network Connection Filters

ConnectionEvent Class
This is the class from which all event state objects are derived. All events are constructed with a reference to the object, that is, the source that is logically deemed to be the object upon which a specific event initially occurred. To create a new ConnectionEvent instance, applications use the methods provided by this class: getLocalAddress(), getLocalPort(), getRemoteAddress(), getRemotePort(), and hashCode().

For a code example of how to use this class, see Listing 6-1, “Example of Filtering Network Connections,” on page 6-9.

Guidelines for Writing Connection Filter Rules
This section describes how connection filter rules are written and evaluated. If no connection rules are specified, all connections are accepted.

Depending on how you implement connection filtering, connection filter rules can be written in a flat file or input directly on the Administration Console. The “Connection Filter Examples” on page 6-8 demonstrate both methods.

The following sections provide information and guidelines for writing connection filter rules:

- “Connection Filter Rules Syntax” on page 6-4
- “Types of Connection Filter Rules” on page 6-5
- “How Connection Filter Rules are Evaluated” on page 6-6

Connection Filter Rules Syntax
The syntax of connection filter rules is as follows:

- Each rule must be written on a single line.
- Tokens in a rule are separated by white space.
- A pound sign (#) is the comment character. Everything after a pound sign on a line is ignored.
- Whitespace before or after a rule is ignored.
- Lines consisting only of whitespace or comments are skipped.

The format of filter rules differ depending on whether you are using a filter file to enter the filter rules or you enter the filter rules on the Administration Console.
When entering the filter rules on the Administration Console, enter them in the following format:

targetAddress localAddress localPort action protocols

When specifying rules in the filter file, enter them in the following format:

targetAddress action protocols

- `targetAddress` specifies one or more systems to filter.
- `localAddress` defines the host address of the WebLogic Server instance. (If you specify an asterisk (*), the match returns all local IP addresses.)
- `localPort` defines the port on which the WebLogic Server instance is listening. (If you specify an asterisk (*), the match returns all available ports on the server).
- `action` specifies the action to perform. This value must be `allow` or `deny`.
- `protocols` is the list of protocol names to match. The following protocols may be specified: `http`, `https`, `t3`, `t3s`, `ldap`, `ldaps`, `iiop`, `iiops`, and `com`. (Although the `giop`, `giops`, and `dcom` protocol names are still supported, their use is deprecated as of release 9.0; you should use the equivalent `iiop`, `iiops`, and `com` protocol names.)

Note: The `SecurityConfigurationMBean` provides a `CompatibilityConnectionFiltersEnabled` attribute for enabling compatibility with previous connection filters.

- If no protocol is defined, all protocols will match a rule.

**Types of Connection Filter Rules**

Two types of filter rules are recognized:

- Fast rules

  A fast rule applies to a hostname or IP address with an optional netmask. If a hostname corresponds to multiple IP addresses, multiple rules are generated (in no particular order). Netmasks can be specified either in numeric or dotted-quad form. For example:

  dialup-555-1212.pa.example.net 127.0.0.1 7001 deny t3 t3s #http(s) OK
  192.168.81.0/255.255.254.0 127.0.0.1 8001 allow #23-bit netmask
  192.168.0.0/16 127.0.0.1 8002 deny #like /255.255.0.0

  Hostnames for fast rules are looked up once at startup of the WebLogic Server instance. While this design greatly reduces overhead at connect time, it can result in the filter obtaining out of date information about what addresses correspond to a hostname. BEA recommends using numeric IP addresses instead.
Using Network Connection Filters

- Slow rules

  A slow rule applies to part of a domain name. Because a slow rule requires a connect-time DNS lookup on the client-side in order to perform a match, it may take much longer to run than a fast rule. Slow rules are also subject to DNS spoofing. Slow rules are specified as follows:

  
  *.script-kiddiez.org 127.0.0.1 7001 deny

  An asterisk only matches at the head of a pattern. If you specify an asterisk anywhere else in a rule, it is treated as part of the pattern. Note that the pattern will never match a domain name since an asterisk is not a legal part of a domain name.

How Connection Filter Rules are Evaluated

When a client connects to WebLogic Server, the rules are evaluated in the order in which they were written. The first rule to match determines how the connection is treated. If no rules match, the connection is permitted.

To further protect your server and only allow connections from certain addresses, specify the last rule as:

  0.0.0.0/0  *  *  deny

With this as the last rule, only connections that are allowed by preceding rules are allowed, all others are denied. For example, if you specify the following rules:

  <Remote IP Address>  *  *  allow https
  0.0.0.0/0  *  *  deny

Only machines with the Remote IP Address are allowed to access the instance of WebLogic Server running connection filter. All other systems are denied access.

Note: The default connection filter implementation interprets a target address of 0 (0.0.0.0/0) as meaning “the rule should apply to all IP addresses.” By design, the default filter does not evaluate the port, just the action. To clearly specify restrictions when using the default filter, modify the rules.

Another option is to implement a custom connection filter. A sample filter is available at http://dev.bea.com/code/security.jsp; the FastFilterEntry.java example contains match() methods, which determine how to process the rules.
Configuring the WebLogic Connection Filter

WebLogic Server provides an out-of-the-box network connection filter. To use the filter, simply configure it using the Administration Console. For information on how to configure connection filters, see Securing WebLogic Server.

Developing Custom Connection Filters

If you decide not to use the WebLogic connection filter and want to develop your own, you can use the application programming interface (API) provided in the weblogic.security.net package to do so. For a description of this API, see “Network Connection Filter API” on page 6-2.

To develop custom connection filters with WebLogic Server, perform the following steps:

1. Write a class that implements the ConnectionFilter interface (minimum requirement).
   Or, optionally, if you want to use the Administration Console to enter and modify the connection filtering rules directly, write a class that implements both the ConnectionFilter interface and the ConnectionFilterRulesListener interface.

2. If you choose the minimum requirement in step 1 (only implementing the ConnectionFilter interface), enter the connection filtering rules in a flat file and define the location of the flat file in the class that implements the ConnectionFilter interface. Then use the Administration Console to configure the class in WebLogic Server. For instructions for configuring the class in the Administration Console, see the “Configuring Connection Filtering” section in Securing WebLogic Server. For an example of how to use a flat file to implement connection filtering, see the referenced SimpleConnectionFilter.java file in “Connection Filter Examples” on page 6-8.

3. If you choose to implement both interfaces in step 1, use the Administration Console to configure the class and to enter the connection filtering rules. For instructions on configuring the class in the Administration Console, see “Configuring Connection Filtering” in Securing WebLogic Server. For an example of how to use the ConnectionFilterRulesListener interface to implement connection filtering, see the referenced SimpleConnectionFilter2.java file in “Connection Filter Examples” on page 6-8.

Note that if connection filtering is implemented when a Java or Web browser client tries to connect to a WebLogic Server instance, The WebLogic Server instance constructs a ConnectionEvent object and passes it to the accept() method of your connection filter class. The connection filter class examines the ConnectionEvent object and accepts the connection by returning, or denies the connection by throwing a FilterException.
Both implemented classes (the class that implements only the ConnectionFilter interface and the class that implements both the ConnectionFilter interface and the ConnectionFilterRulesListener interface) must call the accept() method after gathering information about the client connection. However, if you only implement the ConnectionFilter interface, the information gathered includes the remote IP address and the connection protocol: http, https, t3, t3s, ldap, ldaps, iiop, iiops, or com. If you implement both interfaces, the information gathered includes the remote IP address, remote port number, local IP address, local port number and the connection protocol.

Connection Filter Examples

This section refers to sample code which is available online at BEA’s dev2dev web site. The net directory contains ant build files, a package.html file which contains instructions, a connection filter file, and the following Java files which include examples of two connection filters:

- FastFilterEntry.java
- FilterEntry.java
- SimpleConnectionFilter.java
- SimpleConnectionFilter2.java
- SlowFilterEntry.java

Each connection filter example provides an efficient, generalized connection filter which parses the rules and sets up a rule-matching algorithm so that connection filtering adds minimal overhead to a WebLogic Server connection. If necessary, you can modify this sample code and reuse it. You might, for example, want to accommodate the local or remote port number in your filter or a more site-specific algorithm that will reduce filtering overhead. For instructions on how to build, configure, and run these samples, see the package-summary.html file included with the examples.

The SimpleConnectionFilter example implements the ConnectionFilter interface and filters connections using rules that you define in the filter file.

```java
public class SimpleConnectionFilter implements ConnectionFilter {
    public static final String FILTER_FILE = "filter";
    private FilterEntry[] rules;
    ...
}
```

The SimpleConnectionFilter2 example implements the ConnectionFilter and ConnectionFilterRulesListener interfaces and filters connections using the rules that you define using the Administration Console.
public class SimpleConnectionFilter2
    implements ConnectionFilter, ConnectionFilterRulesListener {

    private FilterEntry[] rules;
    private Vector entries;
    ...

    In Listing 6-1, WebLogic Server calls the SimpleConnectionFilter.accept() method with a ConnectionEvent. The SimpleConnectionFilter.accept() method gets the remote address and protocol and converts the protocol to a bitmask to avoid string comparisons in rule-matching. Then the SimpleConnectionFilter.accept() method compares the remote address and protocol against each rule until it finds a match.

    This code fragment is taken from the SimpleConnectionFilter.java file in the Network Connection Filter code example.

Listing 6-1  Example of Filtering Network Connections

    public void accept(ConnectionEvent evt)
    throws FilterException
    {
        InetAddress remoteAddress = evt.getRemoteAddress();
        String protocol = evt.getProtocol().toLowerCase();
        int bit = protocolToMaskBit(protocol);
        if (bit == 0xdeadbeef)
        {
            bit = 0;
        } // Check rules in the order in which they were written.
        for (int i = 0; i < rules.length; i++)
        {
            switch (rules[i].check(remoteAddress, bit))
            {
                case FilterEntry.ALLOW:
                    return;
                case FilterEntry.DENY:
                    throw new FilterException("rule "+(i+1));
                case FilterEntry.IGNORE:
                    break;
            }
Using Network Connection Filters

```java
    default:
        throw new RuntimeException("connection filter internal error!");
    }
}

// If no rule matched, we allow the connection to succeed.
return;
}
```
Using Java Security to Protect WebLogic Resources

This section discusses the following topics:

- “Using J2EE Security to Protect WebLogic Resources” on page 7-1
- “Using the Java Security Manager to Protect WebLogic Resources” on page 7-2

Using J2EE Security to Protect WebLogic Resources

WebLogic Server supports the use of J2EE security to protect URL (Web), Enterprise JavaBeans (EJBs), and Connector components. In addition, WebLogic Server extends the connector model of specifying additional security policies in the deployment descriptor to the URL and EJB components.

Note: J2EE has requirements for Java 2 security default permissions for different application types (see the J2EE 1.4 specification) as does the J2EE Connector Architecture specification. These specifications are available at http://java.sun.com/j2ee/download.html#platformspec.

The connector specification provides for deployment descriptors to specify additional security policies using the <security-permission> tag (see Listing 7-1):

Listing 7-1 Security-Permission Tag Sample

```xml
<security-permission>
<description> Optional explanation goes here </description>
<security-permission-spec>
```
<!—
A single grant statement following the syntax of
http://java.sun.com/j2se/1.4.2/docs/guide/security/PolicyFiles.html#FileSyntax
without the "codebase" and "signedBy" clauses goes here. For example:
-->
grant {
permission java.net.SocketPermission "*", "resolve";
};
</security-permission-spec>
</security-permission>

Besides support of the <security-permission> tag in the rar.xml file, WebLogic Server adds
the <security-permission> tag to the weblogic.xml and weblogic-ejb-jar.xml files.
This extends the connector model to the two other application types, Web applications and EJBs,
provides a uniform interface to security policies across all component types, and anticipates
future J2EE specification changes.

Using the Java Security Manager to Protect WebLogic Resources

The Java Security Manager can be used with WebLogic Server to provide additional protection
for resources running in a Java Virtual Machine (JVM). Using a Java Security Manager is an
optional security step. The following sections describe how to use the Java Security Manager
with WebLogic Server:

- “Setting Up the Java Security Manager” on page 7-3
- “Using the Recording Security Manager Utility” on page 7-6
- “Using the Java Authorization Contract for Containers” on page 7-6

For more information on Java Security Manager, see the Java Security Web page at
http://java.sun.com/j2se/1.5.0/docs/guide/security/index.html.
Setting Up the Java Security Manager

When you run WebLogic Server under Java 2 (SDK 1.2 or later), WebLogic Server can use the Java Security Manager in Java 2, which prevents untrusted code from performing actions that are restricted by the Java security policy file.

The JVM has security mechanisms built into it that allow you to define restrictions to code through a Java security policy file. The Java Security Manager uses the Java security policy file to enforce a set of permissions granted to classes. The permissions allow specified classes running in that instance of the JVM to permit or not permit certain runtime operations. In many cases, where the threat model does not include malicious code being run in the JVM, the Java Security Manager is unnecessary. However, when untrusted third-parties use WebLogic Server and untrusted classes are being run, the Java Security Manager may be useful.

To use the Java Security Manager with WebLogic Server, specify the `-Djava.security.policy` and `-Djava.security.manager` arguments when starting WebLogic Server. The `-Djava.security.policy` argument specifies a filename (using a relative or fully-qualified pathname) that contains Java 2 security policies.

WebLogic Server provides a sample Java security policy file, which you can edit and use. The file is located at `WL_HOME\server\lib\weblogic.policy`.

If you enable the Java Security Manager but do not specify a security policy file, the Java Security Manager uses the default security policies defined in the `java.policy` file in the `$JAVA_HOME\jre\lib\security` directory.

Define security policies for the Java Security Manager in one of the following ways:

- “Modifying the `weblogic.policy` file for General Use” on page 7-3
- “Setting Application-Type Security Policies” on page 7-4
- “Setting Application-Specific Security Policies” on page 7-5

Modifying the `weblogic.policy` file for General Use

To use the Java Security Manager security policy file with your WebLogic Server deployment, you must specify the location of the `weblogic.policy` file to the Java Security Manager when you start WebLogic Server. To do this, you set the following arguments on the Java command line you use to start the server:

- `java.security.manager` tells the JVM to use a Java security policy file.
Using Java Security to Protect WebLogic Resources

- `java.security.policy` tells the JVM the location of the Java security policy file to use. The argument is the fully qualified name of the Java security policy, which in this case is `weblogic.policy`.

For example:

```
java...-Djava.security.manager \\
- Djava.security.policy==c:\weblogic\weblogic.policy
```

**Note:** Be sure to use `==` instead of `=` when specifying the `java.security.policy` argument so that only the `weblogic.policy` file is used by the Java Security Manager. The `==` causes the `weblogic.policy` file to override any default security policy. A single equal sign (`=`) causes the `weblogic.policy` file to be appended to an existing security policy.

If you have extra directories in your `CLASSPATH` or if you are deploying applications in extra directories, add specific permissions for those directories to your `weblogic.policy` file.

BEA recommends taking the following precautions when using the `weblogic.policy` file:

- Make a backup copy of the `weblogic.policy` file and put the backup copy in a secure location.
- Set the permissions on the `weblogic.policy` file via the operating system such that the administrator of the WebLogic Server deployment has write and read privileges and no other users have access to the file.

**Caution:** The Java Security Manager is partially disabled during the booting of Administration and Managed Servers. During the boot sequence, the current Java Security Manager is disabled and replaced with a variation of the Java Security Manager that has the `checkRead()` method disabled. While disabling this method greatly improves the performance of the boot sequence, it also minimally diminishes security. The startup classes for WebLogic Server are run with this partially disabled Java Security Manager and therefore the classes need to be carefully scrutinized for security considerations involving the reading of files.

For more information about the Java Security Manager, see the Javadoc for the `java.lang.SecurityManager` class.

### Setting Application-Type Security Policies

Set default security policies for Servlets, EJBs, and J2EE Connector Resource Adapters in the Java security policy file. The default security policies for Servlets, EJBs, and Resource Adapters are defined in the Java security policy file under the following codebases:

- **Servlets**—"file:/weblogic/application/defaults/Web"
Using the Java Security Manager to Protect WebLogic Resources

- **EJBs**—“file:/weblogic/application/defaults/EJB”
- **Resource Adapters**—“file:/weblogic/application/defaults/Connector”

**Note:** These security policies apply to all Servlets, EJBs, and Resource Adapters deployed in the particular instance of WebLogic Server.

### Setting Application-Specific Security Policies

Set security policies for a specific Servlet, EJB, or Resource Adapter by adding security policies to their deployment descriptors. Deployment descriptors are defined in the following files:

- **Servlets**—weblogic.xml
- **EJBs**—weblogic-ejb-jar.xml
- **Resource Adapters**—rar.xml

**Note:** The security policies for Resource Adapters follow the J2EE standard while the security policies for Servlets and EJBs follow the WebLogic Server extension to the J2EE standard.

**Listing 7-2** shows the syntax for adding a security policy to a deployment descriptor:

**Listing 7-2   Security Policy Syntax**

```xml
<security-permission>
  <description>
    Allow getting the J2EEJ2SETest4 property
  </description>
  <security-permission-spec>
    grant {
      permission java.util.PropertyPermission "welcome.J2EEJ2SETest4","read";
    };
  </security-permission-spec>
</security-permission>
```

**Note:** The `<security-permission-spec>` tag cannot currently be added to a `weblogic-application.xml` file, you are limited to using this tag within a
weblogic-ejb-jar.xml, rar.xml, or weblogic.xml file. Also, variables are not supported in the `<security-permission-spec>` attribute.

### Using the Recording Security Manager Utility

The Recording Security Manager utility can be used to detect permission problems that occur when starting and running WebLogic Server. The utility outputs permissions that can be added to your Java security policy file to resolve the permission problems that the utility finds. The Recording Security Manager is available at the [BEA dev2dev Online](https://bea.dev2dev.com).

### Using the Java Authorization Contract for Containers

The Java Authorization Contract for Containers (JACC) is part of J2EE 1.4. JACC extends the Java 2 permission-based security model to EJBs and Servlets. JACC is defined by [JSR-115](https://jcp.org/en/jsr/detail?id=115).

JACC provides an alternate authorization mechanism for the EJB and Servlet containers in a WebLogic Server domain. When JACC is configured, the WebLogic Security framework access decisions, adjudication, and role mapping functions are not used for EJB and Servlet authorization decisions.

**Note:** You cannot use the JACC framework in conjunction with the WebLogic Security framework. The JACC classes used by WebLogic Server do not include an implementation of a Policy object for rendering decisions but instead rely on the `java.security.Policy` object.

WebLogic Server implements a JACC provider which, although fully compliant with JSR-115, is not as optimized as the WebLogic Authentication provider. The Java JACC classes are used for rendering access decisions. Because JSR-115 does not define how to address role mapping, WebLogic JACC classes are used for role-to-principal mapping. See [http://java.sun.com/j2ee/javaacc](http://java.sun.com/j2ee/javaacc) for information on developing a JACC provider.

This section discusses the following topics:

- “Comparing the WebLogic JACC Provider with the WebLogic Authentication Provider” on page 7-7
- “Enabling the WebLogic JACC Provider” on page 7-8

Table 7-1 shows which providers are used for role mapping when JACC is enabled.
Using the Java Security Manager to Protect WebLogic Resources

Note: In a domain, either enable JACC on all servers or on none. The reason is that JACC is server-specific while the WebLogic Security Framework is realm/domain specific. If you enable JACC, either by using the WebLogic JACC provider or (recommended) by creating your own JACC provider, you are responsible for keeping EJB and Servlet authorization policies synchronized across the domain. For example, applications are redeployed each time a server boots. If a server configured for JACC reboots without specifying the JACC options on the command line, the server will use the default WebLogic Authorization provider for EJB and Servlet role mapping and authorization decisions.

Comparing the WebLogic JACC Provider with the WebLogic Authentication Provider

The WebLogic JACC provider fully complies with JSR-115; however, it does not support dynamic role mapping, nor does it address authorization decisions for resources other than EJBs and Servlets. For better performance, and for more flexibility regarding security features, BEA recommends using SSPI-based providers.

Table 7-2 compares the features provided by the WebLogic JACC provider with those of the WebLogic Authorization provider.

<table>
<thead>
<tr>
<th>JACC is enabled</th>
<th>Provider used for EJB/Servlet Authorization and Role Mapping</th>
<th>Provider used for all other Authorization and Role Mapping</th>
<th>EJB/Servlet Roles and Policies Can be Viewed and Modified by the Administration Console</th>
</tr>
</thead>
<tbody>
<tr>
<td>JACC is enabled</td>
<td>JACC provider</td>
<td>WebLogic Security Framework providers</td>
<td>No</td>
</tr>
<tr>
<td>JACC is not enabled</td>
<td>WebLogic Security Framework providers</td>
<td>WebLogic Security Framework providers</td>
<td>Yes, depending on settings</td>
</tr>
</tbody>
</table>

Table 7-1 When JACC is Enabled
Enabling the WebLogic JACC Provider

To enable the WebLogic JACC Provider from the command line, you must specify the following system property/value pairs:

- **Property**: `java.security.manager`  
  **Value**: No value required.

- **Property**: `java.security.policy`  
  **Value**: A valid `weblogic.policy` file, specified using either a relative or an absolute pathname

- **Property**: `javax.security.jacc.PolicyConfigurationFactory`  
  **Value**: `weblogic.security.jacc.PolicyConfigurationFactoryImpl`

- **Property**: `javax.security.jacc.PolicyConfigurationFactory`  
  **Value**: `weblogic.security.jacc.PolicyConfigurationFactoryImpl`

---

Table 7-2 Comparing the WebLogic JACC Provider with the WebLogic Authorization Provider

<table>
<thead>
<tr>
<th>WebLogic JACC Provider</th>
<th>WebLogic Authorization Provider</th>
</tr>
</thead>
<tbody>
<tr>
<td>Implements the JACC specification (JSR-115)</td>
<td>Value-added security framework</td>
</tr>
<tr>
<td>Addresses only EJB and Servlet deployment/authorization decisions</td>
<td>Addresses deployment/authorization decisions</td>
</tr>
<tr>
<td>Uses the <code>java.security.Policy</code> object to render decisions</td>
<td>Allows for multiple authorization/role providers</td>
</tr>
<tr>
<td>Static role mapping at deployment time</td>
<td>Dynamic role mapping</td>
</tr>
<tr>
<td>J2SE permissions control access</td>
<td>Entitlements engine controls access</td>
</tr>
<tr>
<td>Roles, policies, and role-to-principal mappings are modifiable only through deployment descriptors</td>
<td>Roles, policies, and role-to-principal mappings are modifiable through deployment descriptors and the Administration Console</td>
</tr>
</tbody>
</table>
For example, assuming a properly configured `weblogic.policy` file, the following command line will enable the WebLogic JACC provider:

```
# ./startWebLogic.sh -Djava.security.manager
-Djava.security.policy=<pathname>/weblogic.policy \
-Djavax.security.jacc.policy.provider=\ 
weblogic.security.jacc.simpleprovider.SimpleJACCPolicy \
-Djavax.security.jacc.PolicyConfigurationFactory.provider=\ 
weblogic.security.jacc.simpleprovider.PolicyConfigurationFactoryImpl \
-Dweblogic.security.jacc.RoleMapperFactory.provider=\ 
weblogic.security.jacc.simpleprovider.RoleMapperFactoryImpl
```

**Note:** Use `-Djava.security.policy=<pathname>/weblogic.security` if you want to override any default security policy. A single equal sign (=) causes the `weblogic.policy` file to be appended to an existing security policy.
Using Java Security to Protect WebLogic Resources
The Security Assertion Markup Language, SAML, is an XML-based protocol for exchanging security information between disparate entities. SAML provides single sign-on capabilities; users can authenticate at one location and then access service providers at other locations without having to log in multiple times. For a general description of SAML and SAML assertions in a WebLogic Server environment, see *Understanding WebLogic Security*. For access to the SAML specifications, go to http://www.oasis-open.org.

WebLogic Server supports SAML version 1.1. The WebLogic Server implementation:

- Supports both the Browser/POST and Browser/Artifact Profiles
- Supports SAML authentication and attribute statements (does not support SAML authorization statements)

Table 8-1 lists and describes the WebLogic SAML APIs

<table>
<thead>
<tr>

<td>The WebLogic SAML package.</td>
</tr>
</tbody>
</table>
SAML APIs

Table 8-1 WebLogic SAML APIs

<table>
<thead>
<tr>
<th>Interface</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>SAMLAssertionStore</strong></td>
<td>Interface which defines methods for storing and retrieving assertions for the Artifact profile. initStore(Properties props) initializes a store. Although the store will normally be instantiated and initialized only once, at server start time, an implementation should be robust in the face of multiple instantiations and multiple calls to init. The props parameter is a Properties object containing properties the store needs to initialize. It can be empty or null. flushStore() removes all entries from the store. releaseStore() releases the store. This method is not guaranteed to be called at server shutdown. Although the store will normally be instantiated and initialized only once, at server start time, an implementation should be robust in the face of multiple instantiations and multiple calls to init and release. storeAssertion() stores an assertion for later retrieval using the specified artifact as a key. retrieveAssertion() returns the assertion to the caller and removes the assertion from the store.</td>
</tr>
<tr>
<td><strong>SAMLCredentialNameMapper</strong></td>
<td>Interface which defines methods used to map subject information to fields in a SAML assertion. Described in the Javadocs.</td>
</tr>
<tr>
<td><strong>SAMLIdentityAssertionNameMapper</strong></td>
<td>Interface which defines methods used to map information from a SAML assertion to user and group names. Described in the Javadocs.</td>
</tr>
</tbody>
</table>
SAMLUsedAssertionCache

Interface which defines methods for caching assertion IDs so that the POST profile one-use policy can be enforced.

Classes implementing this interface must have a public no-arg constructor.

initCache(Properties prop) initializes the cache. Although the cache will normally be instantiated and initialized only once, at server start time, an implementation should be robust in the face of multiple instantiations and multiple calls to init and release. The props parameter is a Properties object containing properties the cache needs to initialize. It can be empty or null.

flushCache() flushes all cache entries.

releaseCache() releases the cache. This method is not guaranteed to be called at server shutdown. Although the cache will normally be instantiated and initialized only once, at server start time, an implementation should be robust in the face of multiple instantiations and multiple calls to init and release.

cacheAssertion(String assertionId, String issuer, long expire)
caches the assertion ID and issuer of a consumed assertion. This method must return false if this ID/Issuer combination has already been cached (the one-use policy has failed for the referenced assertion). Otherwise, this method must cache the ID/Issuer and return true. The expire parameter is the NotOnOrAfter time of the to-be-cached assertion. After this time, the cache entry may be discarded, as the assertion is no longer valid and hence cannot be re-used. The method returns true if the referenced assertion was successfully cached; false if the referenced assertion was already in cache.

SAMLNameMapperInfo

Instances of this class are used to pass user and group information to and from the name mappers. The class also defines several useful constants.

Described in the Javadocs.

<table>

SAML APIs
The WebLogic Security service provides the Certificate Lookup and Validation (CLV) API that finds and validates X509 certificate chains.

A CertPath is a JDK class that stores a certificate chain in memory. The term CertPath is also used to refer to the JDK architecture and framework that is used to locate and validate certificate chains. The CLV framework extends and completes the JDK CertPath functionality. CertPath providers rely on a tightly-coupled integration of WebLogic and JDK interfaces.

Your application code can use the default CertPath providers provided by WebLogic Server to build and validate certificate chains, or any custom CertPath providers.

The following topics are covered in this section:

- “CertPath Building” on page 9-2
- “CertPath Validation” on page 9-6
- “Instantiate a CertPathSelector” on page 9-2
- “Instantiate a CertPathBuilderParameters” on page 9-3
- “Use the JDK CertPathBuilder Interface” on page 9-4
- “Instantiate a CertPathValidatorParameters” on page 9-6
- “Use the JDK CertPathValidator Interface” on page 9-8
CertPath Building

To use a CertPath Builder in your application, follow these steps:

1. “Instantiate a CertPathSelector” on page 9-2
2. “Instantiate a CertPathBuilderParameters” on page 9-3
3. “Use the JDK CertPathBuilder Interface” on page 9-4

Instantiate a CertPathSelector

The CertPathSelector interface (weblogic.security.pk.CertPathSelector) contains the selection criteria for locating and validating a certification path. Because there are many ways to look up certification paths, a derived class is implemented for each type of selection criteria. Each selector class has one or more methods to retrieve the selection data and a constructor.

The classes in weblogic.security.pk that implement the CertPathSelector interface, one for each supported type of certificate chain lookup, are as follows:

- EndCertificateSelector - used to find and validate a certificate chain given its end certificate.
- IssuerDNSerialNumberSelector - used to find and validate a certificate chain from its end certificate's issuer DN and serial number.
- SubjectDNSelector - used to find and validate a certificate chain from its end certificate's subject DN.
- SubjectKeyIdentifierSelector - used to find and validate a certificate chain from its end certificate's subject key identifier (an optional field in X509 certificates).

Notes: The selectors that are supported depend on the configured CertPath providers. The configured CertPath providers are determined by the administrator.

The WebLogic CertPath provider uses only the EndCertificateSelector selector. Listing 9-1 shows an example of choosing a selector.

Listing 9-1  Make a certificate chain selector

```java
// you already have the end certificate
// and want to use it to lookup and
```

// validate the corresponding chain
X509Certificate endCertificate = ...

// make a cert chain selector
CertPathSelector selector = new EndCertificateSelector(endCertificate);

### Instantiate a CertPathBuilderParameters

You pass an instance of `CertPathBuilderParameters` as the `CertPathParameters` object to the JDK's `CertPathBuilder.build()` method.

The following constructor and method are provided:

**CertPathBuilderParameters**

```java
public CertPathBuilderParameters(String realmName,
                                 CertPathSelector selector,
                                 X509Certificate[] trustedCAs,
                                 ContextHandler context)
```

Constructs a `CertPathBuilderParameters`.

You must provide the realm name. To do this, get the domain’s `SecurityConfigurationMBean`. Then, get the `SecurityConfigurationMBean`’s default `realm` attribute, which is a realm MBean. Finally, get the realm MBean’s `name` attribute. You must use the runtime JMX MBean server to get the realm name.

You must provide the `selector`. You use one of the `weblogic.security.pk.CertPathSelector` interfaces derived classes, described in “Instantiate a CertPathSelector” on page 9-2 to specify the selection criteria for locating and validating a certification path.

Specify trusted CAs if you have them. Otherwise, the server’s trusted CAs are used. These are just a hint to the configured CertPath builder and CertPath validators which, depending on their lookup/validation algorithm, may or may not use these trusted CAs.

`ContextHandler` is used to pass in an optional list of name/value pairs that the configured CertPathBuilder and CertPathValidators may use to look up and validate the chain. It is symmetrical with the context handler passed to other types of security providers. Setting context to null indicates that there are no context parameters.

**clone**

```java
Object clone()
```
This interface is not cloneable.

Listing 9-2 shows an example of passing an instance of CertPathBuilderParameters.

```
// make a cert chain selector
CertPathSelector selector = new EndCertificateSelector(endCertificate);
String realm = _;
// create and populate a context handler if desired, or null
ContextHandler context = _;
// pass in a list of trusted CAs if desired, or null
X509Certificate[] trustedCAs = _;
// make the params
CertPathBuilderParams params =
new CertPathBuilderParameters(realm, selector, context, trustedCAs);
```

Use the JDK CertPathBuilder Interface

The java.security.cert.CertPathBuilder interface is the API for the CertPathBuilder class. To use the JDK CertPathBuilder interface, do the following:

1. Call the static CertPathBuilder.getInstance method to retrieve the CLV framework’s CertPathBuilder. You must specify “WLSCertPathBuilder” as the algorithm name that’s passed to the call

2. Once the CertPathBuilder object has been obtained, call the “build” method on the returned CertPathBuilder. This method takes one argument - a CertPathParameters that indicates which chain to find and how it should be validated.

You must pass an instance of weblogic.security.pk.CertPathBuilderParameters as the CertPathParameters object to the JDK’s CertPathBuilder.build() method, as described in “Instantiate a CertPathBuilderParameters” on page 9-3.
3. If successful, the result (including the CertPath that was built) is returned in an object that implements the CertPathBuilderResult interface. The builder determines how much of the CertPath is returned.

4. If not successful, the CertPathBuilder build method throws
   InvalidAlgorithmParameterException if the params is not a WebLogic CertPathBuilderParameters, if the configured CertPathBuilder does not support the selector, or if the realm name does not match the realm name of the default realm from when the server was booted.

   The CertPathBuilder build method throws CertPathBuilderException if the cert path could not be located or if the located cert path is not valid

Example Code Flow for Looking Up a Certificate Chain

Listing 9-3  Looking up a Certificate Chain

```java
import weblogic.security.pk.CertPathBuilderParameters;
import weblogic.security.pk.CertPathSelector;
import weblogic.security.pk.EndCertificateSelector;
import weblogic.security.service.ContextHandler;
import java.security.cert.CertPath;
import java.security.cert.CertPathBuilder;
import java.security.cert.X509Certificate;

// you already have the end certificate
// and want to use it to lookup and
// validate the corresponding chain
X509Certificate endCertificate = ...;

// make a cert chain selector
CertPathSelector selector = new EndCertificateSelector(endCertificate);

String realm = __;
```
Using CertPath Building and Validation

// create and populate a context handler if desired
ContextHandler context = _;

// pass in a list of trusted CAs if desired
X509Certificate[] trustedCAs = _;

// make the params
CertPathBuilderParams params =
    new CertPathBuilderParameters(realm, selector, context, trustedCAs);

// get the WLS CertPathBuilder
CertPathBuilder builder =
    CertPathBuilder.getInstance("WLSCertPathBuilder");

// use it to look up and validate the chain
CertPath certpath = builder.build(params).getCertPath();
X509Certificate[] chain =
    certpath.getCertificates().toArray(new X509Certificate[0]);

CertPath Validation

To use a CertPath Validator in your application, follow these steps:

1. “Instantiate a CertPathValidatorParameters” on page 9-6
2. “Use the JDK CertPathValidator Interface” on page 9-8

Instantiate a CertPathValidatorParameters

You pass an instance of CertPathValidatorParameters as the CertPathParameters object to the JDK's CertPathValidator.validate() method.

The following constructor and method are provided:

CertPathValidatorParameters
    public CertPathValidatorParameters(String realmName,
Constructs a CertPathValidatorParameters.

You must provide the realm name. To do this, get the domain’s SecurityConfigurationMBean. Then, get the SecurityConfigurationMBean’s default realm attribute, which is a realm MBean. Finally, get the realm MBean’s name attribute. You must use the runtime JMX MBean server to get the realm name.

Specify trusted CAs if you have them. Otherwise, the server’s trusted CAs are used. These are just a hint to the configured CertPath builder and CertPath validators which, depending on their lookup/validation algorithm, may or may not use these trusted CAs.

ContextHandler is used to pass in an optional list of name/value pairs that the configured CertPathBuilder and CertPathValidators may use to look up and validate the chain. It is symmetrical with the context handler passed to other types of security providers. Setting context to null indicates that there are no context parameters.

clone

Object clone()

This interface is not cloneable.

Listing 9-4 shows an example of passing an instance of CertPathValidatorParameters.

Listing 9-4 Pass an Instance of CertPathValidatorParameters

// get the WLS CertPathValidator
CertPathValidator validator =
    CertPathValidator.getInstance("WLSCertPathValidator");

String realm = _;

// create and populate a context handler if desired, or null
ContextHandler context = _;

// pass in a list of trusted CAs if desired, or null
X509Certificate[] trustedCAs = _;
// make the params (for the default security realm)
CertPathValidatorParams params =
new CertPathValidatorParams(realm, context, trustedCAs);

### Use the JDK CertPathValidator Interface

The `java.security.cert.CertPathValidator` interface is the API for the `CertPathValidator` class. To use the JDK CertPathValidator interface, do the following:

1. Call the static `CertPathValidator.getInstance` method to retrieve the CLV framework’s `CertPathValidator`. You must specify “WLSCertPathValidator” as the algorithm name that’s passed to the call.

2. Once the `CertPathValidator` object has been obtained, call the “validate” method on the returned `CertPathValidator`. This method takes one argument - a `CertPathParameters` that indicates how it should be validated.

   You must pass an instance of `weblogic.security.pk.CertPathValidatorParameters` as the `CertPathParameters` object to the JDK’s `CertPathValidator.validate()` method, as described in “Instantiate a CertPathValidatorParameters” on page 9-6.

3. If successful, the result is returned in an object that implements the `CertPathValidatorResult` interface.

4. If not successful, the `CertPathValidator.validate()` method throws `InvalidAlgorithmParameterException` if params is not a WebLogic `CertPathValidatorParameters` or if the realm name does not match the realm name of the default realm from when the server was booted.

   The `CertPathValidator validate` method throws `CertPathValidatorException` if the certificates in the `CertPath` are not ordered (the end certificate must be the first cert) or if the `CertPath` is not valid.
Example Code Flow for Validating a Certificate Chain

Listing 9-5  Performing Extra Validation

```java
import weblogic.security.pk.CertPathValidatorParams;
import weblogic.security.service.ContextHandler;
import java.security.cert.CertPath;
import java.security.cert.CertPathValidator;
import java.security.cert.X509Certificate;

// you already have an unvalidated X509 certificate chain
// and you want to get it validated
X509Certificate[] chain = ...

// convert the chain to a CertPath
CertPathFactory factory = CertPathFactory.getInstance("X509");
ArrayList list = new ArrayList(chain.length);
for (int i = 0; i < chain.length; i++) {
    list.add(chain[i]);
}
CertPath certPath = factory.generateCertPath(list);

// get the WLS CertPathValidator
CertPathValidator validator =
    CertPathValidator.getInstance("WLSCertPathValidator");

String realm = _;

// create and populate a context handler if desired, or null
ContextHandler context = _;
```
Using CertPath Building and Validation

// pass in a list of trusted CAs if desired, or null
X509Certificate[] trustedCAs = _;

// make the params (for the default security realm)
CertPathValidatorParams params =
new CertPathValidatorParams(realm, context, trustedCAs);

// use it to validate the chain
validator.validate(certPath, params);
Some or all of the Security interfaces, classes, and exceptions in the following WebLogic security packages were deprecated in this release of WebLogic Server:

- `weblogic.security.service`
- `weblogic.security.SSL`

For specific information on the interfaces, classes, and exceptions deprecated in each package, see the Javadocs for WebLogic Classes.
