Business Processes and Rules: Siebel Enterprise Application Integration

Siebel Innovation Pack 2013
Version 8.1/8.2
September 2013
Contents

Chapter 1: What’s New in This Release

Chapter 2: Defining Workflows for Siebel EAI

Sample Integration Workflows 9
  Import Account (File) 9
  Export Account (File) 11
  Import Employee (MQSeries) 12
  Export Employee (MQSeries) 15

Testing the Workflow Integration Process 17
  Exporting the Workflow Process to an XML File 17
  Importing the XML File Into Siebel Tools 18
  Running the Workflow Process Simulator 18

Chapter 3: Creating and Using Dispatch Rules

Overview of EAI Dispatch Service 21
  EAI Dispatch Service Rule Hierarchy 22
  EAI Dispatch Service Methods 23
  Search Expression Grammar 24

Output Transformation 24

EAI Dispatch Service 26
  Inbound Requests 26
  Outbound Requests 28

Implementing EAI Dispatch Service 28
  Creating a Workflow 29
  Defining Rule Sets 30
  Defining Rules 30
  Defining Transforms 30
  Invoking a Workflow Process From an EAI Dispatch Service 31

Testing Your EAI Dispatch Service Using Argument Tracing 32

Differences Between EAI Dispatch Service and Workflow 32

ProcessAggregateRequest Method 33

EAI Dispatch Service Scenarios 34
Chapter 4: Data Mapping Using the Siebel Data Mapper

Siebel Data Mapper Overview 44
EAI Data Mapping Engine 44
  EAI Data Mapping Engine Methods 45
  Using the EAI Data Mapping Engine 46
The Siebel Data Mapper 46
  Integration Object Maps 47
  Integration Component Maps 47
  Integration Field Maps 48
Creating Data Maps 48
  Define Integration Objects 48
  Determining Required Maps 49
  Creating New Data Maps 49
  Creating Integration Component Maps 50
  Creating Integration Field Maps 51
  Validating the Data Map 51
Examples of Workflow Processes 51
  Outbound Workflow Process 51
  Inbound Workflow Process 54
  About Executing Workflows 55
EAI Data Mapping Engine Expressions 56
Addressing Fields in Components 58
Data Mapping Scenario 58

Chapter 5: Data Mapping Using Scripts

Overview 61
EAI Data Transformation 62
DTE Business Service Method Arguments 64
Map Functions 65
Data Transformation Functions 67
Siebel Message Objects and Methods  68
  Integration Message Objects  68
  CSSEAIIntMsgIn  68
  CSSEAIIntMsgOut  71
  Integration Object Objects  73
  CSSEAIIntObjIn  73
  CSSEAIIntObjOut  75
  Primary Integration Component Objects  76
  CSSEAIPrimaryIntCompIn  76
  CSSEAIPrimaryIntCompOut  79
  Integration Component Objects  82
  CSSEAIIntCompIn  82
  CSSEAIIntCompOut  85

MIME Message Objects and Methods  88
  CSSEAIMimeMsgIn  88
  CSSEAIMimeMsgOut  91

Attachments and Content Identifiers in MIME Messages  93

XML Property Set Functions  94
  Top-Level Property Set Functions  94

  CSSEAIValueMap Translate Method  104
  EAIGetValueMap unmappedKeyHandler Argument  104
  EAIGetValueMap() Method  105

Exception Handling Considerations  106
  Error Codes and Error Symbols  107
  Data Transformation Error Processing  107
  Exception Handling Functions  108

Sample Siebel eScript  109

Index
What’s New in This Release

No new features have been added to this guide for this release. This guide has been updated to reflect only product name changes.
This chapter explains workflow integration processes and how to use them to develop your integration projects. The chapter depends on several sample workflows that are included in the Siebel Business Applications. It contains the following topics:

- "Sample Integration Workflows" on page 9
- "Testing the Workflow Integration Process" on page 17

**NOTE:** In version 8.0 and higher of Siebel Business Applications, workflow processes are created in Siebel Tools. However, the sample workflows in this chapter are found in the Administration - Business Process screen, then the Workflow Processes view in the Siebel client.

For information on creating workflow processes, see *Siebel Business Process Framework: Workflow Guide*.

**Sample Integration Workflows**

Siebel EAI includes several sample workflows that illustrate how you can receive, process, and send integration messages. This chapter includes four of those samples, along with brief descriptions that are intended to help you understand the workflow elements specific to Siebel EAI.

**NOTE:** One of the methods of invoking a workflow process is through a workflow policy. To invoke a workflow process that includes steps that call EAI adapters from a workflow policy, you must create a workflow policy action using the Run Workflow Process workflow policy program. The workflow policy action will invoke the Workflow Process Manager component. For information on creating workflow policies, see *Siebel Business Process Framework: Workflow Guide*.

The sample workflows explained in this chapter include:

- "Import Account (File)" on page 9
- "Export Account (File)" on page 11
- "Import Employee (MQSeries)" on page 12
- "Export Employee (MQSeries)" on page 15

**Import Account (File)**

This is a sample workflow process that reads an XML file (c:\account.xml) and imports the account information into the Siebel environment using the EAI XML Read from File business service. The EAI XML Read from File business service converts the data and the EAI Siebel Adapter updates the Siebel database.
To review the Import Account (File) sample workflow process

1. Navigate to Administration - Business Process, then Workflow Processes.

2. Query for Import Account (File).

3. With the Import Account (File) workflow process selected, click the Process Properties tab in the bottom applet to review the process properties for this workflow process.

Workflow process properties are global to the entire workflow. For example, as shown in the following table, the Import Account (File) workflow has several properties. The Account Message is defined to identify the output of the Read File step (a parsed version of the XML Account Message) as a hierarchical structure. The Error Message, Error Code, Object Id, and Siebel Operation Object Id properties are included in the workflow by default.

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>In/Out</th>
</tr>
</thead>
<tbody>
<tr>
<td>Account Message</td>
<td>Hierarchy</td>
<td>In/Out</td>
</tr>
<tr>
<td>Error Code</td>
<td>String</td>
<td>In/Out</td>
</tr>
<tr>
<td>Error Message</td>
<td>String</td>
<td>In/Out</td>
</tr>
<tr>
<td>Object Id</td>
<td>String</td>
<td>In/Out</td>
</tr>
<tr>
<td>Siebel Operation Object Id</td>
<td>String</td>
<td>In/Out</td>
</tr>
</tbody>
</table>

4. Click the Process Designer tab in the bottom applet to review the process design for this workflow process.

5. Double-click the Read File step to review its method and arguments.

This step uses the Read Siebel Message method of the EAI XML Read from File business service to convert XML from a file into an integration object hierarchy, with the following input argument.

<table>
<thead>
<tr>
<th>Input Arguments</th>
<th>Type</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>File Names</td>
<td>Literal</td>
<td>c:\account.xml</td>
</tr>
</tbody>
</table>

Note how the path and file name are specified as a string in the Value field of the Input Arguments applet.

Also note the following output property for this step.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Output Argument</th>
</tr>
</thead>
<tbody>
<tr>
<td>Account Message</td>
<td>Output Argument</td>
<td>Siebel Message</td>
</tr>
</tbody>
</table>
Double-click the Update Account step to review its method and arguments. This step uses the EAI Siebel Adapter business service with the Insert or Update method to read the Siebel Message and update or insert the Account object in the Siebel Database. The EAI Siebel Adapter uses the information in the XML file and the following input argument to accomplish this task.

<table>
<thead>
<tr>
<th>Arguments</th>
<th>Type</th>
<th>Property Name</th>
<th>Property Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Siebel Message</td>
<td>Process Property</td>
<td>Account Message</td>
<td>Hierarchy</td>
</tr>
</tbody>
</table>

Because the Insert or Update method is specified on the EAI Siebel Adapter business service, this step checks the Siebel Database to see if the Account object defined in the XML file already exists in the database. If the account exists, then it updates the account in the database with the account instance from the XML file; otherwise, it inserts the account into the database.

**Export Account (File)**

This sample workflow process exports an account to a file in an XML format. This workflow uses the EAI Siebel Adapter and the EAI XML Write to File business service to query the data and then convert the data from the Siebel business object to an XML document.

To review the Export Account (File) sample workflow process

1. Navigate to Administration - Business Process, then Workflow Processes.
2. Query for Export Account (File).
3. With the Export Account (File) workflow process selected, click the Process Properties tab to review the process properties for this workflow process.

Workflow process properties are global to the entire workflow. For example, as shown in the following table, the Export Account (File) workflow has several properties. The Output Message property is defined to identify the outbound account as a hierarchical structure. The Object Id property is included in each workflow by default.

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>In/Out</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object Id</td>
<td>String</td>
<td>In/Out</td>
</tr>
<tr>
<td>Output Message</td>
<td>Hierarchy</td>
<td>In/Out</td>
</tr>
</tbody>
</table>

4. Click the Process Designer tab in the bottom applet to review the process design for this workflow process.
5 Double-click the Get Account step to review its method and arguments.

This step uses the EAI Siebel Adapter business service to query an account from your Siebel Database. The EAI Siebel Adapter uses the following input arguments.

<table>
<thead>
<tr>
<th>Input Arguments</th>
<th>Type</th>
<th>Value</th>
<th>Property Name</th>
<th>Property Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Output Integration Object Name</td>
<td>Literal</td>
<td>Sample Account</td>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td>Object Id</td>
<td>Process Property</td>
<td>-</td>
<td>Object Id</td>
<td>String</td>
</tr>
</tbody>
</table>

Note that Output Integration Object Name of Sample Account is part of the query criteria. The Sample Account integration object describes the structure of the Account business object and was created using the Integration Object Builder. The other part of the query criteria is the Object Id, which is a process property that includes the account number 1-6 defined as a process property before.

Also note the following output property for this step.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Output Argument</th>
</tr>
</thead>
<tbody>
<tr>
<td>Output Message</td>
<td>Output Argument</td>
<td>Siebel Message</td>
</tr>
</tbody>
</table>

The output from this step is Output Message. Output Message is a process property that will include the Siebel Message, which contains data for the account. The format is specified by the Sample Account integration object.

6 Double-click the Write to File step to review its method and arguments.

This step invokes the EAI XML Write to File business service with the Write Siebel Message method. The EAI XML Write to File uses the following input arguments.

<table>
<thead>
<tr>
<th>Input Arguments</th>
<th>Type</th>
<th>Value</th>
<th>Property Name</th>
<th>Property Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>File Name</td>
<td>Literal</td>
<td>c:\account.xml</td>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td>Siebel Message</td>
<td>Process Property</td>
<td>-</td>
<td>Output Message</td>
<td>Hierarchy</td>
</tr>
</tbody>
</table>

The EAI XML Write to File business service converts the hierarchical message to XML and writes the resulting document to the file named in the File Name argument.

**Import Employee (MQSeries)**

This is a sample workflow process that receives an XML string from an IBM MQSeries queue and updates the Employee instance in the Siebel Database.
To review the Import Employee (MQSeries) sample workflow process

1. Navigate to Administration - Business Process, then Workflow Processes.
2. Query for Import Employee (MQSeries).
3. With the Import Employee (MQSeries) process selected, click the Process Properties tab to review its process properties.

Workflow process properties are global to the entire workflow. For example, as shown in the following table, the Import Employee (MQSeries) workflow has several properties. The Employee Message contains the object as an integration object hierarchy, when converted. The object must be in that format before it can be inserted or updated in the Siebel environment. The Employee XML property defines the MQSeries message as XML recognizable by Siebel applications. The Error Code, Error Message, Object Id, and Siebel Operation Object Id properties are included in the workflow by default.

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>In/Out</th>
</tr>
</thead>
<tbody>
<tr>
<td>Employee Message</td>
<td>Hierarchy</td>
<td>In/Out</td>
</tr>
<tr>
<td>Employee XML</td>
<td>Binary</td>
<td>In/Out</td>
</tr>
<tr>
<td>Error Code</td>
<td>String</td>
<td>In/Out</td>
</tr>
<tr>
<td>Error Message</td>
<td>String</td>
<td>In/Out</td>
</tr>
<tr>
<td>Object Id</td>
<td>String</td>
<td>In/Out</td>
</tr>
<tr>
<td>Siebel Operation Object Id</td>
<td>String</td>
<td>In/Out</td>
</tr>
</tbody>
</table>

4. Click the Process Designer tab in the bottom applet to review the process design for this workflow process.

**NOTE:** When using the MQSeries Receiver, remember that the MQ Receiver task will read the message from the queue and pass it into your workflow process in the <Value> field. This means your workflow process does not need to read the message from the MQSeries Queue. To get the XML string that has been read, you need to create a process property and set its default value as follows: Name=MyXMLStringProperty and Default=<Value>. You should use this process property as the input to the EAI XML Converter business service.
5 Double-click the Receive step to review its method and arguments.

This step uses the Receive method of the EAI MQSeries Server Transport to get the inbound message from the Employee physical queue named in the Physical Queue Name argument. This step uses the following input arguments.

<table>
<thead>
<tr>
<th>Input Arguments</th>
<th>Type</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Physical Queue Name</td>
<td>Literal</td>
<td>Employee</td>
</tr>
<tr>
<td>Queue Manager Name</td>
<td>Literal</td>
<td>Siebel</td>
</tr>
</tbody>
</table>

As shown in the following table, the output from this step is put into the Employee XML process property with the assumption that the inbound message is already in XML format.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Output Argument</th>
</tr>
</thead>
<tbody>
<tr>
<td>Employee XML</td>
<td>Output Argument</td>
<td>Message Text</td>
</tr>
</tbody>
</table>

6 Double-click the Convert to Internal step to review its method and arguments.

This step uses the XML to Property Set method of the EAI XML Converter to convert the inbound message to the Siebel business object format. The step uses the following input argument.

<table>
<thead>
<tr>
<th>Input Arguments</th>
<th>Type</th>
<th>Property Name</th>
<th>Property Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>XML Document</td>
<td>Process Property</td>
<td>Employee XML</td>
<td>Binary</td>
</tr>
</tbody>
</table>

The output from this step is passed in the Employee Message output argument as described in the following table.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Output Argument</th>
</tr>
</thead>
<tbody>
<tr>
<td>Employee Message</td>
<td>Output Argument</td>
<td>Siebel Message</td>
</tr>
</tbody>
</table>

7 Double-click the Update Employee step to review its method and arguments.

This step uses the EAI Siebel Adapter business service with the Insert or Update method and the following input argument to update the database.

<table>
<thead>
<tr>
<th>Input Arguments</th>
<th>Type</th>
<th>Property Name</th>
<th>Property Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Siebel Message</td>
<td>Process Property</td>
<td>Employee Message</td>
<td>Hierarchy</td>
</tr>
</tbody>
</table>

The EAI Siebel Adapter checks the Siebel Database for an Employee record that matches the current instance of Employee in the Employee Message property. If an Employee record matching the current instance does not exist in the database, the EAI Siebel Adapter inserts the record into the database; otherwise, it updates the existing record with the instance.
Export Employee (MQSeries)

This is a sample workflow process that sends an XML string for an employee to an IBM MQSeries queue.

**To review the Export Employee (MQSeries) sample workflow process**

1. Navigate to Administration - Business Process, then Workflow Processes.
2. Query for Export Employee (MQSeries).
3. With the Export Employee (MQSeries) workflow process selected, click the Process Properties tab to review the process properties defined for this workflow process.

Workflow process properties are global to the entire workflow. For example, as shown in the following table, the Export Employee (MQSeries) workflow has multiple properties. The Employee Message contains the object as an integration object hierarchy, before conversion. The Employee XML property specifies the Siebel object that has been converted to XML. The Error Code, Error Message, Object Id, and Siebel Operation Object Id properties are included in each workflow by default.

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
<th>In/Out</th>
<th>Default String</th>
</tr>
</thead>
<tbody>
<tr>
<td>Employee Message</td>
<td>Hierarchy</td>
<td>In/Out</td>
<td>-</td>
</tr>
<tr>
<td>Employee XML</td>
<td>Binary</td>
<td>In/Out</td>
<td>-</td>
</tr>
<tr>
<td>Error Code</td>
<td>String</td>
<td>In/Out</td>
<td>-</td>
</tr>
<tr>
<td>Error Message</td>
<td>String</td>
<td>In/Out</td>
<td>-</td>
</tr>
<tr>
<td>Object Id</td>
<td>String</td>
<td>In/Out</td>
<td>1-548</td>
</tr>
<tr>
<td>Siebel Operation Object Id</td>
<td>String</td>
<td>In/Out</td>
<td>-</td>
</tr>
</tbody>
</table>

Note that the Object Id process property is set to 1-548 in the Default String column. This string identifies an actual employee record in the Siebel Database by its Row Id. You can set this workflow to use the active employee record instead of specifying a hard-coded employee number. You can accomplish this by creating a button that invokes this workflow from the Administration - User, then the Employees view, or you can pass the value of the Object Id into the workflow process as an input argument.

4. Click the Process Designer tab in the bottom applet to review the process design for this workflow process.
5 Double-click the Get Employee step to review its method and arguments.

This step uses the Query method of the EAI Siebel Adapter business service, with the following input arguments to get an instance of an Employee record from the Siebel Database. The Sample Employee integration object describes the structure of the Employee business object and was created using the Integration Object Builder wizard. The other part of the query criteria is the Object Id, which is a process property containing value 1-548.

<table>
<thead>
<tr>
<th>Input Arguments</th>
<th>Type</th>
<th>Value</th>
<th>Property Name</th>
<th>Property Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Output Integration Object Name</td>
<td>Literal</td>
<td>Sample Employee</td>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td>Object Id</td>
<td>Process Property</td>
<td>-</td>
<td>Object Id</td>
<td>String</td>
</tr>
</tbody>
</table>

The output from this step is passed in the Employee Message output argument as described in the following table.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Output Argument</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Employee Message</td>
<td>Output Argument</td>
<td>Siebel Message</td>
<td>-</td>
</tr>
</tbody>
</table>

6 Double-click the Convert to XML step to review its method and arguments.

This step uses the Property Set to XML method of the EAI XML Converter business service to convert the outbound Siebel Message to XML. The converter stores the outbound Siebel Message in the Employee XML output argument with the following input argument.

<table>
<thead>
<tr>
<th>Input Arguments</th>
<th>Type</th>
<th>Property Name</th>
<th>Property Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Siebel Message</td>
<td>Process Property</td>
<td>Employee Message</td>
<td>Hierarchy</td>
</tr>
</tbody>
</table>

The output from this step is passed in to the Employee XML output argument as shown in the following table.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Value</th>
<th>Output Argument</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Employee XML</td>
<td>Output Argument</td>
<td>-</td>
<td>XML Document</td>
<td>-</td>
</tr>
</tbody>
</table>
Double-click the Send step to review its method and arguments.

This step invokes the EAI MQSeries Server Transport business service with the Send method to put the XML message onto the MQSeries queue, Employee. The message is represented by the Message Text argument, as shown in the following table.

<table>
<thead>
<tr>
<th>Input Arguments</th>
<th>Type</th>
<th>Value</th>
<th>Property Name</th>
<th>Property Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Message Text</td>
<td>Process Property</td>
<td>-</td>
<td>Employee XML</td>
<td>String</td>
</tr>
<tr>
<td>Physical Queue Name</td>
<td>Literal</td>
<td>Employee</td>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td>Queue Manager Name</td>
<td>Literal</td>
<td>Siebel</td>
<td>-</td>
<td>-</td>
</tr>
</tbody>
</table>

The Queue Manager that handles the request is called Siebel. The XML message is put onto the Employee queue, where it remains until another application retrieves it from the queue.

Testing the Workflow Integration Process

When you have finished defining your integration workflow process, you can use the Workflow Process Simulator to test its behavior.

The Workflow Process Simulator, included in the Workflow Process Manager, allows you to validate your processes before deploying them in production environments.

When you simulate an integration process that performs some external action—for example, the Export Account (File) workflow writes an XML file to a disk location—you can verify the end result by checking if the output object exists, or if a predetermined event has occurred.

NOTE: You can also enable detailed client logging and use the /s option for creating SQL spool scripts. This option provides more detailed information when running the integration workflow process in the Workflow Process Simulator. For details, see Siebel Remote and Replication Manager Administration Guide.

To test the workflow processes described in this chapter using the Workflow Process Simulator, you must export them to an XML file from the Workflow Processes view in the Siebel client, and then import the XML file into the Workflow Processes list in Siebel Tools. The Workflow Process Simulator runs from Siebel Tools.

Exporting the Workflow Process to an XML File

You export the workflow process from the Workflow Processes view in the Siebel client. In this example, Export Account (File) is exported.
Defining Workflows for Siebel EAI ■ Testing the Workflow Integration Process

To export a workflow process to an XML file
1 Navigate to Administration - Business Process, then Workflow Processes.
2 Query for Export Account (File).
3 From the pull-down menu, choose Export Workflow.
4 Choose a location to save the XML file.
The workflow process XML file, in this example Export Account (File).xml, is created.

Importing the XML File Into Siebel Tools
You import the workflow process XML file into the Workflow Processes list in Siebel Tools.

To import the XML file into Siebel Tools
1 In the Object Explorer in Siebel Tools, select Workflow Process.
2 Right-click inside the Workflow Processes list in the Object List Editor, then choose Import Workflow Process.
3 Browse for the workflow process XML file, then click Open.
The workflow process is imported into Siebel Tools.

Running the Workflow Process Simulator
You run the Workflow Process Simulator from the Workflow Process list in Siebel Tools.

To simulate a workflow process
1 In Siebel Tools, choose Toolbars, then the Simulate view to activate the Simulator.
2 In the Object Explorer in Siebel Tools, select Workflow Process.
3 Query for Export Account* in the Object List Editor.
4 Right-click on Export Account (File), then choose Simulate Workflow Process.
The Workflow Process Designer appears, with the border of the Start shape red to indicate that it is the active element.
5 Click Start Simulation in the Simulate toolbar.
A new instance of the Siebel Debugger starts and then runs the Simulator.
6 Click Simulate Next to activate the next step.
As you step through the process, the border of each active shape turns red in turn, unless the simulator encounters an error, in which case it displays an error message alert.
7 Click Complete Simulation to pause.
8 Click Stop Simulation to stop.

For more information about running the Workflow Process Simulator, reviewing process values, and using Workflow Process Manager and Workflow Batch Manager, see *Siebel Business Process Framework: Workflow Guide*.

**NOTE:** Use the Workflow Process Simulator only for testing purposes. Do not use the Workflow Process Simulator to load data.
Creating and Using Dispatch Rules

This chapter gives an overview on the EAI Dispatch Service, transforming output, and implementing a new dispatch service. It contains the following topics:

- "Overview of EAI Dispatch Service" on page 21
- "Output Transformation" on page 24
- "EAI Dispatch Service" on page 26
- "Implementing EAI Dispatch Service" on page 28
- "Testing Your EAI Dispatch Service Using Argument Tracing" on page 32
- "Differences Between EAI Dispatch Service and Workflow" on page 32
- "ProcessAggregateRequest Method" on page 33
- "EAI Dispatch Service Scenarios" on page 34
- "Examples of Search Expression Grammar" on page 38
- "Examples of Dispatch Output Property Sets" on page 40

Overview of EAI Dispatch Service

The EAI Dispatch Service is a rule-based dispatching business service that invokes business services based on the properties of its input property set. The EAI Dispatch Service can execute transformations on an input property set before dispatching it to the target business service. Such transformations can be useful for setting business service arguments or workflow process properties. They can also be used to do limited hierarchy manipulation such as discarding the envelope of an XML document. Figure 1 illustrates the EAI Dispatch Service process.

Figure 1. EAI Dispatch Service Process
Although the EAI Dispatch Service is a utility to invoke one business service from another business service based on specified rules, one of its primary uses is to accomplish inbound and outbound integration. The EAI Dispatch Service can be the first business service of the inbound integration to decide which business service should process an incoming document. It can also be the last step of the outbound integration to send the outgoing document to the right transport. The EAI Dispatch Service is similar to the branching in Siebel Workflow. To determine whether to use Siebel Workflow or the EAI Dispatch Service, see “Differences Between EAI Dispatch Service and Workflow” on page 32.

**EAI Dispatch Service Rule Hierarchy**

The EAI Dispatch Service has a three-layer rules hierarchy as illustrated in Figure 2.

**Figure 2. EAI Dispatch Service Rule Hierarchy**

**Rule Sets**

Rule Sets are sets of rules that you define in a particular sequence. EAI Dispatch Service parses the input document using these rules in sequence until it finds a rule that matches the input.

**Rules**

Rules are individual entities in a rule set. Each rule consists of data transformations, search expression grammar, and zero or more rule transforms. You define rules by using search expression grammar to establish how you want an input message to be routed. For details, see “Search Expression Grammar” on page 24.
Creating and Using Dispatch Rules

Overview of EAI Dispatch Service

Data Transformation
A transform specifies how the intermediate output is going to be generated before it is dispatched to the service and the method you specified in the rule. For details, see “Output Transformation” on page 24.

EAI Dispatch Service Methods

EAI Dispatch Service uses the methods described in Table 1.

Table 1. EAI Dispatch Service Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dispatch</td>
<td>This method parses the input against the rules and dispatches it to the appropriate business service and business service method for further processing.</td>
</tr>
<tr>
<td>Lookup</td>
<td>This method returns the intermediate output generation as specified by the rule output properties without dispatching it to any business service. You use this method for debugging purposes, as well as manipulating property sets within business service or workflow.</td>
</tr>
<tr>
<td>ProcessAggregateRequest</td>
<td>This method allows multiple invocations of business services in a single request. The output for each request will be combined into a single Siebel property set or XML document. The input to this method is an XML document. For details, see “ProcessAggregateRequest Method” on page 33.</td>
</tr>
<tr>
<td>Purge</td>
<td>The Purge method clears any data that has been cached by the EAI Dispatch Service and does not take in any input arguments.</td>
</tr>
</tbody>
</table>

The EAI Dispatch Service executes the following at run time:

- Matches the input with a dispatch rule.
- Evaluates the transforms.
- Dispatches the output to a business service if the method is set to Dispatch.
**Search Expression Grammar**

Search expression grammar is used by the EAI Dispatch Service to parse incoming messages and determine the course of action. Search expression grammar is based on the XPath standard. Table 2 presents the definitions you use to construct a search expression.

Table 2. Definitions for Constructing Search Expressions

<table>
<thead>
<tr>
<th>Symbols</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>/</td>
<td>A forward slash indicates a new level in the hierarchy. The first slash indicates the root of the hierarchy.</td>
</tr>
<tr>
<td>@</td>
<td>An at symbol indicates the attribute.</td>
</tr>
<tr>
<td>*</td>
<td>An asterisk indicates no specific criteria and that everything matches in the input. Asterisks cannot be used with attributes.</td>
</tr>
<tr>
<td>Name</td>
<td>This is the literal value for which the EAI Dispatch Service searches the document.</td>
</tr>
</tbody>
</table>

NOTE: See “Examples of Search Expression Grammar” on page 38 for additional information and examples.

**Output Transformation**

Before dispatching the incoming hierarchy to the business service, EAI Dispatch Service can be used to perform some transformations to the hierarchy to make it appropriate for the target business service. A transform specifies how the intermediate output, in the memory, is going to be generated before it is dispatched to the service and the method you specified in the rule.

If you do not define any transforms, the EAI Dispatch Service will send the input directly to the business service. However, if you define transforms, the EAI Dispatch Service will create intermediate output based on the values of the transforms before sending the input to the business service you have defined in your rule.

Transforms are specified using one or more of the following targets in permissible combination.

**RootHierarchy**

This target creates a new output root hierarchy based on the source expression. The source expression specifies a node in the input hierarchy. The hierarchy rooted at this node is copied as the target root hierarchy. You can use the root hierarchy for minor modifications, such as adding a property, to the input hierarchy.

Only one root hierarchy transform can be specified because this transform always creates a new hierarchy. The root hierarchy transform is always executed before any other transforms in the combination.

NOTE: For the following targets, if an output hierarchy does not exist at the time of invoking the target, an output hierarchy is first created with just an empty root node before the target is applied.
ChildHierarchy
This target creates a new hierarchy as a child of the current output root hierarchy, based on the source expression. The source expression specifies a node in the input hierarchy. The hierarchy rooted at this node is copied as a new child hierarchy. You can use the child hierarchy for adding service arguments to an incoming document before dispatching to workflow or business service.

Type
This target sets the Type field to Source Expression in the root node of output hierarchy.

Value
This target sets the Value field to Source Expression in the root node of output hierarchy.

Property
This target creates or overwrites a property with name Property Name and value Source Expression in the root node of output hierarchy. You can use property to add business service arguments or workflow process properties.

As described in Table 3, for certain targets, in addition to the dispatch grammar, literal values can be used for the Source Expression property to retrieve the data from the input message.

Table 3. Literal Values for Source Expression.

<table>
<thead>
<tr>
<th>Target</th>
<th>Source Expression</th>
<th>Property Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property</td>
<td>Dispatch grammar or a literal value enclosed in quotes to search for a value</td>
<td>Name of the Property</td>
</tr>
<tr>
<td>ChildHierarchy</td>
<td>Grammar to search for the hierarchy</td>
<td>N/A</td>
</tr>
<tr>
<td>RootHierarchy</td>
<td>Grammar to search for the hierarchy</td>
<td>N/A</td>
</tr>
<tr>
<td>Type</td>
<td>Dispatch grammar or Literal value enclosed in quotes to search for a value</td>
<td>N/A</td>
</tr>
<tr>
<td>Value</td>
<td>Literal value enclosed in quotes</td>
<td>N/A</td>
</tr>
</tbody>
</table>

**NOTE:** You can combine one or more of the preceding transforms to achieve the desired transformation. The combination should not include more than one Root Hierarchy transform, Type transform, or Value transforms. However, it can include multiple Property transforms, as long as the names of the properties are different. Also if you do not want to transform the input data, but need to add an entry in transform—for example the process name of the dispatching workflow, you have to add another entry to the transform with Target: RootHierarchy, Source Expression: /*, and no Property Name. If you do not have a RootHierarchy transform, an empty PropertySet will be created and the called dispatching service will receive an invalid hierarchy data.
EAI Dispatch Service

You can use the EAI Dispatch Service to:

■ Respond to a request from an external system. This can be a request to query data or a request to insert data into the Siebel Database. See “Inbound Requests” on page 26.

■ Send data to an external system based on an event in Siebel applications. See “Outbound Requests” on page 28.

The EAI Dispatch Service works with the hierarchy in the property set, which may be in some cases different from the hierarchy in your document. When dispatching XML documents, you should use the XML Hierarchy Converter because it generates a hierarchy matching the hierarchy in the XML document.

NOTE: For details on the XML Hierarchy Converter, see XML Reference: Siebel Enterprise Application Integration.

Use the business service argument tracing facility provided by the EAI Dispatch Service to understand the input property set hierarchy. This facility dumps the input and the output of the EAI Dispatch Service as XML. For details, see “Testing Your EAI Dispatch Service Using Argument Tracing” on page 32.

Inbound Requests

The steps for creating an inbound or an outbound EAI Dispatch Service are very similar, as illustrated in the following figures.
Figure 3 illustrates the high-level architecture of an inbound EAI Dispatch Service.
Outbound Requests

The steps for creating an outbound EAI Dispatch Service are the same as the steps for an inbound EAI Dispatch Service with some differences in the workflow. Figure 4 illustrates the high-level architecture of an outbound Dispatch Service. For details on how to create an outbound workflow, see "Outbound Scenario" on page 34.

Implementing EAI Dispatch Service

The following checklist lists the steps you need to take to implement a new EAI Dispatch Service. These steps are the same whether an external system is requesting data from a Siebel application, or inserting data into a Siebel application, or when a Siebel application sends a request to an external system.

**Checklist**

- Create a workflow to be called by the EAI Dispatch Service.
  
  For details, see "Creating a Workflow" on page 29.
Creating and Using Dispatch Rules ▶ Implementing EAI Dispatch Service

<table>
<thead>
<tr>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Define a Rule Set.</td>

<tr>
<td>Set up the EAI Dispatch Service to invoke the workflow.</td>
<td>For details, see “Creating a Workflow” on page 29.</td>
</tr>
<tr>
<td>Test your EAI Dispatch Service.</td>
<td>For details, see “Testing Your EAI Dispatch Service Using Argument Tracing” on page 32.</td>
</tr>
</tbody>
</table>

Creating a Workflow

Design a workflow process to be called by EAI Dispatch Service upon receiving a request from an external system.

**NOTE:** For details on how to use Workflow Process Manager, see *Siebel Business Process Framework: Workflow Guide*.

To design a workflow to receive a request from an external system

1. In Siebel Tools, set up a workflow process to include the following steps: Start, EAI Data Mapping Engine, EAI Siebel Adapter, End.

2. Create process properties to pass incoming data from the EAI Dispatch Service.

   Because you have to pass data (as a hierarchy) from the EAI Dispatch Service to the workflow, you need to create a process property of type Hierarchy to receive this data. The name of the property should match the root tag of the hierarchy you are passing. If you use XML Hierarchy Converter with the EAI Dispatch Service, then you use the property XMLHierarchy.

   Also, you may want to pass other parameters, such as what data map to use, from the EAI Dispatch Service. Create process properties of type String to receive such parameters. The name of the property should match the Property Name used in your dispatch transform.
Defining Rule Sets
Rule sets are used by the EAI Dispatch Service to search the incoming data for specific criteria.

To define a rule set
1. Navigate to Administration - Integration, then the EAI Dispatch Service View.
2. Click New on the Rule Sets list applet to create a new rule set.
3. Give this rule set a meaningful name such as AribaAccountToSiebel.
4. Save the rule set.

Defining Rules

To define rules
1. Click New on the Rules list applet on the EAI Dispatch Service View.
2. Provide the following fields for this record:
   - **Sequence.** Enter a sequence number. This determines the sequence in which the application evaluates the rules.
   - **Search Expression.** Actual logic behind what the rule is looking for in the input. Define the Search Expression using Dispatch Rule Grammar. For details, see “Search Expression Grammar” on page 24.
   - **Property Value (Optional).** Populate this field with the value for the property that the input is to be matched with.
   - **Dispatch Service.** The business service that you want to dispatch the input to. You leave this blank if you intend to use the Lookup method.
   - **Dispatch Method.** Pick a method for the business service you defined in the Dispatch Service field.
3. Save your rules.
   
   The system validates search expression grammar. If you have not set your rules properly, you will receive an error message. See Table 5 on page 39 for examples of valid search expressions.

Defining Transforms

To define transforms
1. Click New on the Transforms list applet on the EAI Dispatch Service View to create a new transform.
2 Provide the following fields for the new record:

- **Target.** Defines how the intermediate output is going to be generated before it is dispatched to the service and the method you specified in the rule. For details, see “Output Transformation” on page 24.

- **Source Expression.** The source expression is used to assign a value to the target. You can either use a search expression pointing to a node in the input hierarchy or a literal value enclosed in quotes. For details, see “Search Expression Grammar” on page 24.

- **Property Name.** The name of the property to be set. This value is only used when the Target is set to Property. For the other Target types this field is inactive.

**NOTE:** See “EAI Dispatch Service Scenarios” on page 34 and “Examples of Search Expression Grammar” on page 38 for more details on these parameters.

3 Save your transform.

This saves and validates your transform.

### Invoking a Workflow Process From an EAI Dispatch Service

Once you created your workflow, you need to set up your EAI Dispatch Service to invoke it.

**To invoke a workflow process with an EAI Dispatch Service**

1. Navigate to Administration - Integration, then the EAI Dispatch Service View.
2. Select the target rule set.
3. Select the rule that invokes the workflow process.
4. For the selected rule set the following values:
   - **Dispatch Service.** Workflow Process Manager
   - **Dispatch Method.** Execute Process
5. For the selected rule insert a new record in the Transforms applet and fill in the following values:
   - **Target.** Property. You can select the Property value from a list of values.
   - **Source Expression.** Name of the workflow process to run. Make sure you include double quotes around the name, for example, "my workflow process".
   - **Property Name.** Process Name. You can select the Property Name value from a list applet.
Testing Your EAI Dispatch Service Using Argument Tracing

You should use the Business Service Simulator to test your EAI Dispatch Service before using it in your production environment. You can use argument tracing to write the input and the output of the EAI Dispatch Service as XML.

**NOTE:** For details on how to use the Business Service Simulator, see *Integration Platform Technologies: Siebel Enterprise Application Integration*.

**To use the EAI dispatch service argument tracing**

1. Set the server parameter EnableServiceArgTracing to true.
2. Set the appropriate event level for EAIDispatchSvcArgTrc on your server component:
   - **Event level 3.** Leads to input arguments being written out when errors occur.
   - **Event level 4.** Leads to both input and output being written out.

   If arguments are written out, there will be a trace log entry indicating the filename in the log directory. The filenames will have the following form:

   service name_input or output_args_a big number.dmp

   For example:

   EAIDispatchService_input_args_270613751.dmp

   **NOTE:** To open the file in a XML editor, you can rename the extension to XML.

Differences Between EAI Dispatch Service and Workflow

Although the EAI Dispatch Service is very similar to Siebel Workflow in initiating a task based on a condition, there are some limitations in Siebel Workflow that you can overcome using the EAI Dispatch Service. Siebel Workflow operates on business components as opposed to property sets, so Siebel Workflow can only branch based on fields in a business component. Furthermore, with Siebel Workflow you cannot route incoming documents based on property sets, because the workflow decision points cannot search inside of arbitrary property sets.
Creating and Using Dispatch Rules

Table 4 provides some guidance to help you determine the best method for your business requirements.

Table 4. Siebel EAI Dispatch Methods and Workflow

<table>
<thead>
<tr>
<th>Requirements</th>
<th>EAI Dispatch Service</th>
<th>Workflow</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Need to route the incoming document based on its structure or content</td>
<td>✓</td>
<td></td>
<td>The EAI Dispatch Service can route incoming documents based on property sets, whereas workflow can only branch based on fields in a business component.</td>
</tr>
<tr>
<td>Multiple dispatch targets</td>
<td>✓</td>
<td></td>
<td>The EAI Dispatch Service is a better choice because writing a workflow to include every branch can be unwieldy, but you can have many EAI Dispatch Service rules.</td>
</tr>
<tr>
<td>Need to change input property set before dispatching</td>
<td>✓</td>
<td></td>
<td>The EAI Dispatch Service is the better choice since it has more powerful mapping capabilities than workflow.</td>
</tr>
<tr>
<td>Need more complex processing on the input message before dispatching</td>
<td>✓</td>
<td></td>
<td>The EAI Dispatch Service can branch based on the content of the input document, whereas workflow can branch based on business service.</td>
</tr>
<tr>
<td>Workflow options are sufficient for your requirements</td>
<td>✓</td>
<td></td>
<td>In this case, Siebel Workflow is the best choice.</td>
</tr>
</tbody>
</table>

ProcessAggregateRequest Method

The ProcessAggregateRequest method allows you to perform multiple invocations of business services in a single request. The method bundles the output for each request into a single Siebel property set or XML document.

When using the ProcessAggregateRequest method with the EAI Dispatch Service business service, you need to define an input argument called AggregatedServiceRequest, with type Hierarchy for the EAI Dispatch Service to use to store the incoming data.

The following example is the input argument for this method, using XML to represent the PropertySet.

```
<PropertySet>
  <AggregatedServiceRequest>
```
This is the input/output method argument for the ProcessAggregatedRequest method. The EAI Dispatch Service with ProcessAggregateRequest Method looks for this XML tag within the XML document to determine where it needs to start reading the document.

```xml
<BusinessServiceWrapper
wrapper around the business service. The name of the wrapper has no effect on the EAI Dispatch Service.
    BusinessServiceName=...
XML tag for business service
    BusinessServiceMethod=...>
XML tag for business service method
<ArgumentWrapper
wrapper around the business service arguments. The name of the wrapper has no effect on the EAI Dispatch Service.
    XMLTagArgument1=...
XML tag for the first argument. Replace this tag with the correct XML tag for the argument your business service method is using.
    XMLTagArgument2=...
XML tag for the second argument. Replace this tag with the correct XML tag for the argument your business service method is using.
    .../>
</BusinessServiceWrapper>
```

**NOTE:** For examples, see “Outbound Scenarios Using ProcessAggregateRequest” on page 36.

### EAI Dispatch Service Scenarios

The following business scenarios explains how you might accomplish commonly performed tasks using the EAI Dispatch Service.

#### Outbound Scenario

For this scenario, you want to dispatch a service request as soon as it is created. The scenario assumes that:

- You are only interested in service requests logged against EAI.
- You know how to design a workflow that gets triggered as a new service request is created.

**NOTE:** There are number of different ways to trigger a workflow process. For details, see *Siebel Business Process Framework: Workflow Guide*.
You want the other non-EAI service requests to be sent to an MQSeries.

Figure 5 illustrates this scenario.

![Diagram](image)

**Figure 5. Dispatching Service Request**

**To create this scenario**

1. Create a rule set with a search expression to check if the Service Request Area is set to EAI.
2. Create a workflow that is triggered when the criterion defined in Step 1 is matched.

   Your workflow should contain the following steps:
   - Start
   - EAI Dispatch Service
   - End

**Inbound Scenario**

For this scenario, you want to receive an XML document from an external system through MQ, HTTP, MSMQ, or other means and have the EAI Dispatch Service write to an error file if certain criteria are not met, as illustrated in Figure 6. The scenario assumes that:

- You are only interested in the message if it contains an OrderReport element; otherwise, you want an error written to the error log.
You know how to create a workflow.

To create this scenario
1. Create a rule set with a rule that searches the message for the OrderReport element.
2. Create a workflow that contains the following steps:
   - Start
   - EAI Data Mapping Engine
   - EAI Siebel Adapter
   - End
3. Create an EAI Dispatch Service that triggers your workflow, once the criteria in Step 1 are matched.

Outbound Scenarios Using ProcessAggregateRequest

The ProcessAggregateRequest method allows you to have multiple invocation of one or more methods in one or more business services using a single request. The following examples illustrate the use of this method to query account and employee information.

Querying the Account Integration Object

The following example shows how you can invoke multiple business services and setting arguments for each of the services. This is done using simple arguments for the services and by having the aggregate request invoke the QueryPage method of the EAI Siebel Adapter twice, with different searchespces.
Creating and Using Dispatch Rules  ■  EAI Dispatch Service Scenarios

<?xml version="1.0" encoding="UTF-8"?>
<?Siebel-Property-Set EscapeNames="true"?>
<PropertySet>
  <AggregatedServiceRequest>
    <BusinessServiceWrapper
        BusinessServiceName="EAI Siebel Adapter"
        BusinessServiceMethod="QueryPage">
      <ArgumentWrapper
          PageSize="4"
          StartRowNum="0"
          OutputIntObjectName="Sample Account"
          SearchSpec="[Account.Name] LIKE 'Aa*'/">
        </ArgumentWrapper>
    </BusinessServiceWrapper>
    <BusinessServiceWrapper
        BusinessServiceName="EAI Siebel Adapter"
        BusinessServiceMethod="QueryPage">
      <ArgumentWrapper
          PageSize="4"
          StartRowNum="0"
          OutputIntObjectName="Sample Account"
          SearchSpec="[Account.Name] LIKE 'Bb*'/">
        </ArgumentWrapper>
    </BusinessServiceWrapper>
  </AggregatedServiceRequest>
</PropertySet>

Querying the Employee Integration Object
The following example shows how you can set complex type business service method arguments. The aggregate request invokes the EAI Siebel Adapter twice, and, instead of using searchspec, uses query by example by passing in a SiebelMessage.

NOTE: All simple arguments are attributes of the ArgumentWrapper element, and the complex argument is a child element.

<?xml version="1.0" encoding="UTF-8" ?>
<?Siebel-Property-Set EscapeNames="true"?>
<PropertySet>
  <AggregatedServiceRequest>
    <BusinessServiceWrapper
        BusinessServiceName="EAI Siebel Adapter"
        BusinessServiceMethod="Query">
      <ArgumentWrapper>
        <SiebelMessage
            MessageType="Integration Object"
            IntObjectName="Sample Employee"
            IntObjectFormat="Siebel Hierarchical">
          <ListOfSampleEmployee>
            <Employee
                EMailAddr="firstname.lastname@oracle.com" />
          </ListOfSampleEmployee>
        </SiebelMessage>
      </ArgumentWrapper>
    </BusinessServiceWrapper>
    <BusinessServiceWrapper
        BusinessServiceName="EAI Siebel Adapter"
        BusinessServiceMethod="Query">
      <ArgumentWrapper>
        <SiebelMessage
            MessageType="Integration Object"
            IntObjectName="Sample Employee"
            IntObjectFormat="Siebel Hierarchical">
          <ListOfSampleEmployee>
            <Employee
                EMailAddr="firstname.lastname@oracle.com" />
          </ListOfSampleEmployee>
        </SiebelMessage>
      </ArgumentWrapper>
    </BusinessServiceWrapper>
  </AggregatedServiceRequest>
</PropertySet>
Creating and Using Dispatch Rules

Examples of Search Expression Grammar

In the following example, assume that the XML document is a typical document your system receives and that you want to set some rules for the EAI Dispatch Service to use to parse this document.

```xml
<?xml version="1.0" encoding="UTF-8" ?>
- <cXML payloadID="3223232@ariba.acme.com" timestamp="1999-03-12T18:39:09-08:00" xml:lang="en-US">
  - <Header>
    - <From>
      - <Credential domain="AribaNetworkUserId">
        <Identity>admin@acme.com</Identity>
      </Credential>
      - <Credential domain="AribaNetworkUserId" type="marketplace">
        <Identity>bigadmin@marketplace.org</Identity>
      </Credential>
      - <Credential domain="BT">
        <Identity>2323</Identity>
      </Credential>
    </From>
    - <To>
      - <Credential domain="DUNS">
        <Identity>942888711</Identity>
      </Credential>
    </To>
    - <Sender>
      - <Credential domain="AribaNetworkUserId">
        <Identity>admin@acme.com</Identity>
      </Credential>
      - <SharedSecret>abracadabra</SharedSecret>
    </Sender>
  </Header>
  - <Request deploymentMode="test">
    - <OrderRequest>
      - <OrderRequestHeader orderID="DO1234" orderDate="1999-03-12" type="new">
```
Creating and Using Dispatch Rules  □ Examples of Search Expression Grammar

- `<Total>`
  `<Money currency='USD'>12.34</Money>
- `<ShipTo>`

Table 5 provides some valid search expression examples.

### Table 5. Dispatch Rule Grammar

<table>
<thead>
<tr>
<th>Search Expression</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>/<em>/</em>/Header</td>
<td>Go to the second level and look at the type value of each property set and check whether it is of value Header.</td>
</tr>
<tr>
<td>/<em>/</em>/DeploymentMode</td>
<td>Go to the second level and look at the properties of each property set and check whether any of them has the name (not the value) of DeploymentMode.</td>
</tr>
<tr>
<td>/<em>/</em>/RequestDeploymentMode</td>
<td>Go to the third level and look at each property set for type of value Request and property of name DeploymentMode.</td>
</tr>
<tr>
<td>/cXML/*/OrderRequest</td>
<td>Search at the top level for type of value cXML and then upon matching, find a grandchild (not child) of type of value OrderRequest.</td>
</tr>
</tbody>
</table>

Following are examples of invalid rules:

**Rule**

`/*@DeploymentMode/Request/SiebelMessage`

**Description**

This is not a valid rule. A search for a property value must be specified at the very end. A correct form would be the following, which will have a different result.

`/*@DeploymentMode/Request`
Creating and Using Dispatch Rules ■ Examples of Dispatch Output Property Sets

Examples of Dispatch Output Property Sets

This example shows different output property sets generated by EAI Dispatch Service based on the hierarchy input shown in Figure 7 and certain Target and Source Expression as shown in Table 6.

Table 6 presents the intermediate output based on the value of the Target.

<table>
<thead>
<tr>
<th>Target</th>
<th>Source Expression</th>
<th>Property Name</th>
<th>Output Property Set</th>
</tr>
</thead>
<tbody>
<tr>
<td>RootHierarchy</td>

![Diagram](https://example.com/diagram2.png)
This chapter describes the process of using the Siebel Data Mapper to convert your external data to the Siebel format and your Siebel data to your external data specifications. It contains the following topics:

- "Siebel Data Mapper Overview" on page 44
- "EAI Data Mapping Engine" on page 44
- "The Siebel Data Mapper" on page 46
- "Creating Data Maps" on page 48
- "Examples of Workflow Processes" on page 51
- "About Executing Workflows" on page 55
- "EAI Data Mapping Engine Expressions" on page 56
- "Addressing Fields in Components" on page 58
- "Data Mapping Scenario" on page 58
**Siebel Data Mapper Overview**

The Siebel Data Mapper provides you with a declarative interface to specify maps for both inbound and outbound data transformation. The maps you set up using the Siebel Data Mapper call the EAI Data Mapping Engine to complete the data transformation. Using the Siebel Data Mapper can often reduce or even eliminate the number of scripts you need to write. Figure 8 illustrates the Siebel Data Mapper architecture.

![Siebel Data Mapper Architecture](image)

For data mapping within Siebel Business Applications, Siebel applications now support two data mapping solutions, the Siebel Data Mapper and Siebel eScript Data Mapping. The Siebel Data Mapper has a declarative interface and requires no programming skills. The Siebel eScript Data Mapping uses scripts programmed in eScript as data maps. Because the Siebel Data Mapper is based on a declarative interface, it does not have the flexibility that script-based data mapping has. Use Siebel Data Mapper for most of your integration needs, except for complex mapping situations requiring aggregation, joins, or programmatic flow control.

## EAI Data Mapping Engine

To use the EAI Data Mapping Engine, you must enable the following component groups:
NOTE: The display name of the EAI Data Transformation Engine business service in Siebel Tools is EAI Data Mapping Engine. Throughout this guide, it is referred to by both names interchangeably.

EAI Data Mapping Engine Methods

The EAI Data Mapping Engine business service has two methods: Execute and Purge.

**Execute**

Use the Execute method when your integration requires data transformation. Input and output arguments for the Execute method are shown in Table 8 and Table 9.

<table>
<thead>
<tr>
<th>Input Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Map Name</td>
<td>Name of your data map.</td>
</tr>
<tr>
<td>Output Integration Object Name (Optional)</td>
<td>The target integration object in your map. If you use this argument you have to match it with the data map.</td>
</tr>
<tr>
<td>Siebel Message</td>
<td>The instance of your source integration object.</td>
</tr>
<tr>
<td>Map Arguments (Optional)</td>
<td>Used as an argument when you call your map from a workflow.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name of the property</td>
<td>The output integration object in Siebel Message format.</td>
</tr>
</tbody>
</table>

**Purge**

This method is only for development mode. Use the Purge method to purge the database of an existing map. Use this method when you have made a change to a map and you would like to run Execute after these changes. This method does not require any input or output arguments.
Using the EAI Data Mapping Engine

The following checklist outlines the main steps required to use the EAI Data Mapping Engine.

**Checklist**

- Create integration objects.
  
  For details, see “Define Integration Objects” on page 48.

- Create data maps.
  
  For details, see “Creating New Data Maps” on page 49.

- Validate data maps.
  
  For details, see “Validating the Data Map” on page 51.

**The Siebel Data Mapper**

The Siebel Data Mapper maps one integration object, source, to another integration object, target. Integration objects contain one or more integration components, which in turn contain one or more integration fields. For details on integration objects, see *Integration Platform Technologies: Siebel Enterprise Application Integration*.

Figure 9 illustrates the Siebel Data Mapping Engine architecture.
A data map defines the relationship between source and target object format. The map controls the transformation process. Transformation maps are stored in the Siebel Database as explained in Table 10.

Table 10. Maps and Data Table Relationship

Integration Object Maps

An integration object map is the top-level data map specifying mapping from one integration object to another. An integration object map contains one or more integration component maps and can optionally contain integration map arguments.

Integration Map Arguments

Data maps can be parameterized using integration map arguments. Map arguments can be referenced in any expression, including the integration field map expression, source search expression, precondition expression, and postcondition expression. For example, you may want to have a field map that creates an Order Number in the target object by prefixing the Order Number in the source object with a constant.

You may want to use this map for orders coming from multiple partners and use a different prefix for each partner. To achieve this with a single data map, you can define an argument Prefix in the Integration Map Argument List, and use this argument Prefix in the field map source expression: [Prefix]+[Order Number]. Then in the input method arguments in EAI Data Mapping Engine business service, you can specify any value for Prefix.

Integration Component Maps

Integration component maps specify how integration components in the source object get mapped to integration objects in the target object. For every occurrence of the source component in the source integration object instance, an instance of the target component is created in the target object instance. An integration component map contains one or more integration field maps. For details on integration component maps, see “Creating Integration Component Maps” on page 50.
Integration Field Maps

Integration field maps specify how fields in the source integration object are mapped to fields in the target integration component. An integration field map target is always a field in the target component of the parent component. An integration field map source can be a constant, a reference to a map argument, a field in the source component, or other legally addressable components such as ancestors of the source component. It can also be a Siebel Query Language expression using one or more of the preceding elements.

**NOTE:** For details on integration field maps, see “Creating Integration Field Maps” on page 51. For details on addressing fields in components other than the source component, see “Addressing Fields in Components” on page 58. For details on Source Expression, see “Source Expression” on page 56.

Creating Data Maps

The following checklist provides the high-level steps for creating data maps.

<table>
<thead>
<tr>
<th>Checklist</th>
</tr>
</thead>
<tbody>
<tr>
<td>□ Define and validate integration objects and determine the required maps.</td>
</tr>
<tr>
<td>For details, see “Define Integration Objects.”</td>
</tr>
<tr>
<td>□ List components and fields within the Siebel object to use.</td>
</tr>
<tr>
<td>For details, see “Define Integration Objects.”</td>
</tr>
<tr>
<td>□ Create a map between the two integration objects.</td>
</tr>
<tr>
<td>For details, see “Creating New Data Maps” on page 49.</td>
</tr>
<tr>
<td>□ Create maps between the components of the objects you mapped.</td>
</tr>
<tr>
<td>For details, see “Creating Integration Component Maps” on page 50.</td>
</tr>
<tr>
<td>□ Create maps between individual fields within the components you mapped.</td>
</tr>
<tr>
<td>For details, see “Creating Integration Field Maps” on page 51.</td>
</tr>
<tr>
<td>□ Validate the data maps.</td>
</tr>
<tr>
<td>For details, see “Validating the Data Map” on page 51.</td>
</tr>
</tbody>
</table>

Define Integration Objects

Before you create a data map, you need to verify that valid integration objects exist for the source and the target data you want to map. For details on creating and validating integration objects, see Integration Platform Technologies: Siebel Enterprise Application Integration.
Determining Required Maps

The Integration Object Browser lists the existing integration object maps. Use this browser to determine which maps you need to create.

To determine which maps to create
1. Navigate to Administration - Integration, then Data Maps.
2. In the Data Maps list, query for the integration objects you want to map.

Creating New Data Maps

Once you determine what objects you need to map, use the Data Map form to create data maps. See “Define Integration Objects” on page 48.

To create a new data map
1. Navigate to Administration - Integration, then Data Maps.
2. In the Integration Object Map list, click New to create a new map.
3. Provide the necessary fields:
   - **Name.** Enter a name for the map you are creating.
   - **Source Object Name.** From the list of values, select the source integration object you want to create the data mapping for.
   - **Target Object Name.** From the list of values, select the target integration object into which you want the data to be transferred.

Creating Maps Using Auto-Map

Once you have created your integration object map, you can use the Auto-Map button to have the Siebel application create the necessary mappings between the underlying components. The root components are always mapped by Auto-Map, whether or not they have the same name. Once the root components are mapped, the Auto-Map recursively walks through every component and their fields to map them. If the components have the same name, the Auto-Map continues to map their fields and their children components. However, if the components have different names, the Auto-Map ignores the current components, their fields, and their children components, and moves on to map the next component. In cases where only the field names are different, the Auto-Map only ignores that one field and continues with its recursive mapping.

**NOTE:** You can also use the Auto-Map on an existing mapping when you modify the integration object. The Auto-Map does not overwrite your manual mappings.
Defining Arguments for a Data Map (Optional)
After you create a data map, you can define the arguments for your map. You can then use these arguments when you call the map within workflow. To define arguments, use the Integration Map Argument list on the Integration Object Map form.

To define integration map arguments
1. Create a new record in the Integration Map Argument list.
2. Provide the following fields:
   - **Name.** Enter a name for the argument.
   - **Data Type.** From the list of values, select the Siebel Data Type for the argument.
   - **Display Name.** Enter the name that you want displayed.

Creating Integration Component Maps
Once you have defined a data map (see "Creating New Data Maps" on page 49), you need to set up the mapping between the components and the fields within the objects you have mapped. You do this using the Data Map Editor form. The Integration Object Editor list displays existing object maps and provides views in which you can define maps for components and for fields. You use the Integration Component Map view to create integration component maps.

To define integration component maps
1. Navigate to Administration - Integration, then Data Map Editor.
2. In the Integration Object Map list, select the map for which you want to define integration component maps.
3. Create a new record in the Integration Component Map list.
4. Provide the following fields:
   - **Name.** Name of the map you are creating.
   - **Source Component Name.** The component where you are getting the data.
   - **Target Component Name.** The component where you want to store the data.
   - **Source Search Specification (optional).** The search criteria based on which the records are filtered. See "Source Search Specification" on page 56 for details.
   - **Parent Component Map Name (optional).** The parent component field is used when there is a mapping to two target components that share multiple parent components. You can exclude data from one of these child objects by choosing a parent component.
   - **Precondition (optional).** See "Preconditions" on page 57 for details.
   - **Postcondition (optional).** See "Postconditions" on page 57 for details.
Creating Integration Field Maps

You define the integration field map between your source and target fields using the Integration Field Map form.

To define a integration field map
1. Create a new record in the Integration Field Map list.
2. Provide the following fields:
   - **Target Field Name.** Name of the field in the Target Component where the value will be assigned.
   - **Source Expression.** An expression that is used to calculate a value for the Destination Field. See "Source Expression" on page 56 for details.

Validating the Data Map

Once you have created your data map, you need to validate your data map.

To validate your data map
1. Navigate to Administration - Integration, then Data Maps.
2. Select your data map.
3. Click Validate to validate your data map.
4. Take the necessary actions to fix the problems with your map or the associated integration objects.

Examples of Workflow Processes

Depending on whether you are preparing for an outbound or an inbound data exchange, you need to design different workflow processes as described in the following two procedures.

Outbound Workflow Process

To execute the map for an outbound process create a workflow process to query the database, purge the data map, execute the data map, and then write the XML into a file. The following examples illustrate integration between contact and employee business objects.
To create an outbound workflow process

1. In Siebel Tools, create a workflow process consisting of Start, End, and four business service steps. Set up each business service according to the task it needs to accomplish.

   **NOTE:** Use the EAI Data Mapping Engine Purge step only in a development environment.

2. Define the following process properties:

<table>
<thead>
<tr>
<th>Input Argument</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Employee Message</td>
<td>Hierarchy</td>
</tr>
<tr>
<td>IntObjName</td>
<td>Hierarchy</td>
</tr>
<tr>
<td>Process Instance Id</td>
<td>String</td>
</tr>
<tr>
<td>Error Code</td>
<td>String</td>
</tr>
<tr>
<td>Error Message</td>
<td>String</td>
</tr>
<tr>
<td>Object Id</td>
<td>String</td>
</tr>
<tr>
<td>Siebel Operation Object Id</td>
<td>String</td>
</tr>
</tbody>
</table>

3. The Read DTE from File step uses the EAI Siebel Adapter business service with the Query method, to query the information from the database. The business service uses the following input and output arguments.

<table>
<thead>
<tr>
<th>Input Argument</th>
<th>Type</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Output Integration Object Name</td>
<td>literal</td>
<td>An Employee</td>
</tr>
<tr>
<td>Search Specification</td>
<td>Literal</td>
<td>[Employee.Last Name] LIKE &quot;Peterson&quot;</td>
</tr>
</tbody>
</table>

   **NOTE:** For more information on using the EAI Siebel Adapter, see *Integration Platform Technologies: Siebel Enterprise Application Integration*.

4. The second business service step purges the map using the EAI Data Transformation Engine business service (display name is EAI Data Mapping Engine) with the Purge method. This step is only for development mode so that the latest map is picked for the process and should not be used in a production environment. This step does not require any input or output arguments.
The third business service step uses the EAI Data Transformation Engine business service with the Execute method to execute the data map. The business service uses the following input and output arguments.

<table>
<thead>
<tr>
<th>Input Argument</th>
<th>Type</th>
<th>Value</th>
<th>Property Name</th>
<th>Property Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Map Name</td>
<td>Literal</td>
<td>Outbound DDTE Map</td>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td>Output Integration Object Name</td>
<td>Literal</td>
<td>My DTE</td>
<td>-</td>
<td>-</td>
</tr>
</tbody>
</table>

The output argument for this step is optional and can be defined as follows.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Output Argument</th>
</tr>
</thead>
<tbody>
<tr>
<td>IntObjName</td>
<td>Output Argument</td>
<td>Siebel Message</td>
</tr>
</tbody>
</table>

The Siebel Query step uses the EAI XML Write to File business service with the Write Siebel Message method to write the XML into a file. The business service uses the following input and output arguments.

<table>
<thead>
<tr>
<th>Input Argument</th>
<th>Type</th>
<th>Value</th>
<th>Property Name</th>
<th>Property Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>File Name</td>
<td>Literal</td>
<td>c:\emp.xml</td>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td>Siebel Message</td>
<td>Process Property</td>
<td>-</td>
<td>IntObjName</td>
<td>Hierarchy</td>
</tr>
</tbody>
</table>

The output argument for this step is optional and can be defined as follows.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Value</th>
<th>Output Argument</th>
</tr>
</thead>
<tbody>
<tr>
<td>IntObjName</td>
<td>Output Argument</td>
<td>-</td>
<td>Siebel Message</td>
</tr>
</tbody>
</table>

You can use this argument to put the Siebel Message into a Hierarchy type process property.

Use the Workflow Process Simulator to test your workflow process.

**NOTE:** For details on creating a workflow process and using the Workflow Process Simulator to test your workflow process, see *Siebel Business Process Framework: Workflow Guide.*
Inbound Workflow Process

To execute the map for an inbound process you need to create a workflow process to read the data from a file, purge the data map, execute the data map, and then write the XML into a file.

To create an inbound workflow process

1. In Siebel Tools, create a workflow process consisting of Start, End and four business service steps. Set up each business service according to the task it needs to accomplish.
   
   **NOTE:** The EAI Data Mapping Engine Purge step should only be used in a development environment.

2. Define the following process properties:

<table>
<thead>
<tr>
<th>Name</th>
<th>Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Contact Message</td>
<td>Hierarchy</td>
</tr>
<tr>
<td>DTE Message</td>
<td>Hierarchy</td>
</tr>
<tr>
<td>Process Instance Id</td>
<td>String</td>
</tr>
<tr>
<td>Error Code</td>
<td>String</td>
</tr>
<tr>
<td>Error Message</td>
<td>String</td>
</tr>
<tr>
<td>Object Id</td>
<td>String</td>
</tr>
<tr>
<td>Siebel Operation Id</td>
<td>String</td>
</tr>
</tbody>
</table>

3. The Read DTE from File step uses the EAI XML Read from File business service with the Read Siebel Message method, to read the information from a file. The business service uses the following input and output arguments.

<table>
<thead>
<tr>
<th>Input Argument</th>
<th>Type</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>File Name</td>
<td>Literal</td>
<td>c:\emp.xml</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Type</th>
<th>Output Argument</th>
</tr>
</thead>
<tbody>
<tr>
<td>DTE Message</td>
<td>Output Argument</td>
<td>Siebel Message</td>
</tr>
</tbody>
</table>
4 The second business service step purges the map using the EAI Data Transformation Engine business service (display name is EAI Data Mapping Engine) with the Purge method. This step is only for development mode so that the latest map is picked for the process and should not be used in a production environment. This step does not require any input or output arguments.

5 The third business service step uses the EAI Data Transformation Engine business service with the Execute method, to execute the data map. The business service uses the following input and output arguments.

<table>
<thead>
<tr>
<th>Input Argument</th>
<th>Type</th>
<th>Value</th>
<th>Property Name</th>
<th>Property Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Map Name</td>
<td>Literal</td>
<td>Inbound DDTE Map</td>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td>Output Integration Object Name</td>
<td>Literal</td>
<td>A Contact</td>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td>Siebel Message</td>
<td>Process Property</td>
<td>-</td>
<td>DTE Message</td>
<td>Hierarchy</td>
</tr>
</tbody>
</table>

6 The Upsert Contact step uses the EAI Siebel Adapter business service with Insert or Update method to write the data into the database. This business service uses the following input argument.

<table>
<thead>
<tr>
<th>Input Argument</th>
<th>Type</th>
<th>Property Name</th>
<th>Property Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Siebel Message</td>
<td>Process Property</td>
<td>Contact Message</td>
<td>Hierarchy</td>
</tr>
</tbody>
</table>

This step does not have any output arguments.

**NOTE:** For more information on using the EAI Siebel Adapter, see *Integration Platform Technologies: Siebel Enterprise Application Integration*.

7 Use the Workflow Process Simulator to test your workflow process.

**NOTE:** For details on creating a workflow process and using the Workflow Process Simulator to test your workflow process, see *Siebel Business Process Framework: Workflow Guide*.

### About Executing Workflows

Once you have designed and tested your workflows, you can run them in your production environment using Workflow Process Manager Server.

**NOTE:** For details on how to activate and execute a workflow, see *Siebel Business Process Framework: Workflow Guide*.
EAI Data Mapping Engine Expressions

The EAI Data Mapping Engine uses four categories of expressions:

- Source expressions
- Source search specifications
- Preconditions
- Postconditions

These expressions support Siebel Query Language expressions. These expressions can address fields in the source component, map arguments, and constants. In addition to fields in the source component, fields in certain other components in the source integration object can be addressed. For details, see “Addressing Fields in Components” on page 58. These expressions are just like Siebel Query Language support invocations of predefined functions and custom business services.

**NOTE:** For details on the Siebel Query Language, see *Siebel Tools Online Help*.

**Source Expression**

Source Expression is a required field for every integration field map. The source expression can be a literal or, based on scripting if you need to parse data or query the database for a specific value. The source expression is associated with an instance of the input integration component named in the integration component map, which is the parent of the integration field map that contains the source expression. An example of a source expression is:

\[ \text{[First Name]} + \ " \ + \ \text{[Last Name]} \]

This expression concatenates the First Name and the Last Name and separates them with a space to be moved into a target field such as Full Name.

**NOTE:** Only a subset of Siebel Query Language Expressions that do not require context of a business component, is supported by EAI Data Mapping Engine. You can not use the following Siebel Query Language Expressions that require context of a business component in the Source Expression: BCName(), Count(mvlink), IsPrimary(), Min(mvfield), Max(mvfield), ParentBCName(), ParentFieldValue(field_name), Sum(mvfield), GetXAVal(), GetXAValAsNum(), GetXAValAsInt(), GetXAValAsDate(), and XAIsClass().

**Source Search Specification**

Source Search Specification is a Boolean expression that is used to determine if a given component instance satisfies given criteria. It may only appear in an integration object map or a integration component map together with an integration component name. Defining a source search specification is optional, and if you do not define it, then it does not apply any criteria and returns True.

If a field in the current integration component has the same name as a field in a parent component, then you can only address the parent component field by using dot (’.’) notation. An example of a source search specification is:

\[ \text{[Role]} = \text{"Billing"} \]
The expression returns True only if the current input integration component has the value Billing in the Role field.

**NOTE:** If a source search specification is not provided, then every input integration component whose type matches the input component of the integration component map is processed.

**Preconditions**

You can use preconditions to make sure that a field of the input object has a certain value or otherwise terminate the process. An error is generated if the field in the input object has any other value, or no value. Preconditions are evaluated immediately before their containing integration component map is executed. If the condition is true then the process continues. If the condition is false then the whole transformation is aborted and EAI Data Mapping Engine returns an error to the caller. An example of a precondition is:

```
(Role)="Billing" Or (Role)="Shipping"
```

This precondition makes sure that the field Role of the input object either has a value Billing or a value Shipping before it proceeds with the process of data transformation.

The precondition is only applied to the input components that are selected by the source search specification. The input components that fail to match the source search specification will not be checked against the precondition.

A precondition expression may address any field in the current input component, and any of its parent components. It can also address any service call parameter that has been declared as a map argument.

**NOTE:** The default value for the precondition is True. If the precondition is omitted from an integration component map then no constraint is enforced.

**Postconditions**

Postconditions are evaluated and applied to the newly created objects when you execute the containing integration component map. If the result of the postcondition is true then the process continues. If the result is false, the whole transformation is aborted and EAI Data Mapping Engine returns an error. Here is an example of a postcondition:

```
(Object Id)<>"" Or ([First Name]<>"" And [Last Name]<>"")
```

This postcondition checks the output component for a value in the Object Id or in the First Name and the Last Name.

**NOTE:** Because there is no search specification for output components, the postcondition is applied only once for every output component instantiated because it executes its containing integration component map.

The type of the expression may be any type that can be assigned to the Destination Field type either directly or after applying standard conversions to the result of the expression.
You may want to address fields in components other than the source component. This is because your target component may depend on more than one component in the source object. In such cases, you cannot use different component maps with different source components, and the same target component, because each component map creates a different instance of the target component. Data Mapping Engine expressions allow you to use the dot notation to address fields, other than the source component, in source integration object components—for example, [Component Name.Field Name].

NOTE: The picklist for the source expression in the Data Mapper View does not list fields in components other than the source component. Such fields should be typed in using the dot notation.

Addressing fields in other components is legal only if the cardinality of the component is less than or equal to one relative to the source component—that is, only if the component can be uniquely identified from the context of the source component without using any qualifiers other than the component name. If a field in a component that is not legally addressable is used in the source expression then it leads to a runtime error to the effect that such a field does not exist. Any component that is an ancestor of the source component in the integration object hierarchy has a relative cardinality of 1 which means it can always be uniquely identified from the source component. Therefore, fields in ancestor components can always be legally addressed.

Sibling components can be uniquely identified from the context of the source component only if they do not occur multiple times—that is have a cardinality of less than or equal to 1. Only such siblings can be legally addressed. Therefore, it is not legal to address repeated sibling components. Components that are descendants of a sibling component can be legally addressed only if there is no repeated component in the hierarchical path from the sibling component to the component.

Further, components that are descendants of a sibling of some ancestor of a source component can be legally addressed only if there is no multiply-occurring component in the hierarchical path from the sibling-of-ancestor-of-source component to the component.

The following scenarios concern an IT developer named Chris Conway, who works for a computing company, PCS Computing. One of his responsibilities is creating and maintaining the data mappings between Siebel and the other applications in use at PCS. He is assigned to create mapping between Siebel applications and the external application they need to integrate with.

Mapping Between Siebel and an External Application

Chris is in charge of integrating PCS’s Siebel implementation with a custom in-house application. The purpose is to exchange customer information between the two systems.

After weighing various options, Chris decides to use the Siebel Data Mapper instead of scripts to perform the data mapping. He creates the internal integration object using the Siebel Integration Object Wizard in Siebel Tools. He also creates an external integration object using the external application’s DTD.
When Chris is ready to map the two integration objects, he navigates to the Data Mapper and creates a new entry by supplying the name of the map and associating the internal integration object with the external integration object, as explained in "Creating New Data Maps" on page 49. He then uses the Map Editor form to create object, component, and field maps, as explained in "Creating Integration Component Maps" on page 50.

When he finishes creating the map, Chris creates a workflow process in Siebel Tools to define the integration flow. For one of the workflow steps, he defines an invocation of the Siebel Data Mapper. He supplies the appropriate parameters, including the name of the map, and saves his work.
This chapter describes the process of using the Siebel eScript Data Mapping to convert your external data to the Siebel format and your Siebel data to your external data specifications. It contains the following topics:

- "Overview" on page 61
- "EAI Data Transformation" on page 62
- "DTE Business Service Method Arguments" on page 64
- "Map Functions" on page 65
- "Data Transformation Functions" on page 67
- "Siebel Message Objects and Methods" on page 68
- "MIME Message Objects and Methods" on page 88
- "Attachments and Content Identifiers in MIME Messages" on page 93
- "XML Property Set Functions" on page 94
- "EAI Value Maps" on page 102
- "Exception Handling Considerations" on page 106
- "Sample Siebel eScript" on page 109

**Overview**

You can accomplish your data transformation requirements in Siebel Business applications by using the Data Transformation Function or Siebel Data Mapper, as illustrated in Figure 10.

---

Figure 10. Data Transformation Options
For customers who want to do data mapping within Siebel applications, Siebel applications now support two data mapping solutions—Siebel Data Mapper and Siebel eScript Data Mapping. Siebel Data Mapper has a declarative interface and requires no programming skills. Siebel eScript Data Mapping uses scripts programmed in eScript as data maps.

Data maps defined using Siebel Data Mapper are easy to maintain and upgrade. These maps also perform better than eScript Data Maps. Because Siebel Data Mapper is based on a declarative interface, it does not have the full flexibility and power that the data mapping using eScript has. Siebel Data Mapper should suffice for most integration needs except some complex mapping situations requiring aggregation, joins, or programmatic flow control.

The following checklist outlines the main steps required to accomplish your data transformation requirements using the Data Transformation Functions.

<table>
<thead>
<tr>
<th>Checklist</th>
</tr>
</thead>
</table>
| Define integration objects in Siebel Tools—one to represent Siebel objects and another to represent external data.  
For details, see *Integration Platform Technologies: Siebel Enterprise Application Integration*. |
| Set up the Data Transformation Map.  
For details, see "Setting Up a Data Transformation Map" on page 62. |
| Write the Siebel eScript code to perform the data transformation.  
For details, see "To write a script for the DTE business service" on page 63. |

**EAI Data Transformation**

The Siebel Data Transformation Functions are a framework for building data transformation maps. Data transformation maps act as import and export filters, preparing data from an external system for entry into Siebel applications and preparing data in Siebel applications for export.

Data transformation maps are created as business services using Siebel eScript. You invoke them as part of an EAI workflow process.

A data transformation map reads data from an input structure and transfers it to an output structure, transforming it along the way. The map developer creates a custom eScript function to do the transformation. The Data Transformation Functions provide a convenient way to read the input data and generate results. They also provide a framework for invoking your map functions, handling errors, and accessing other EAI resources.

**Setting Up a Data Transformation Map**

You create your data transformation map in Siebel Tools in a business service, then you compile it into an .srf file. You can organize your maps in many different ways. Each business service you create can contain one or more maps. You can, in fact, use several business services to organize a large number of maps into logical groups.
To define a data transformation business service in Siebel Tools

1. In Siebel Tools, create a new business service associated with a locked project.
2. Choose the CSSEAIIDTEScriptService class for the business service.
3. Double-click the Business Services Methods folder and add the method Execute.
4. Select the Business Service Method Arg folder and add the arguments for the Execute method. For a list of arguments and their description, see “DTE Business Service Method Arguments” on page 64. The arguments to include are:
   - MapName
     - An input argument. Select one of SiebelMessage, XMLHierarchy, or MIMEHierarchy as the argument name, based on the type of input.
   - An output argument. Required if the output object is a different type than the input argument. Select one of SiebelMessage, XMLHierarchy, or MIMEHierarchy as the argument name.
     **NOTE:** If the input and output types are the same then the same argument entry is used for both.
   - OutputType
   - InputType(Optional). This is required only when passing the business service input property set to the map function without interpretation. This is done by specifying the InputType as ServiceArguments.
     **NOTE:** Most transform maps use SiebelMessage for both the input and output arguments. This is for mapping one integration object to another. For details, see “DTE Business Service Method Arguments” on page 64.

Once you have created the business service you need to write the Siebel eScript code to perform the data transformation.

To write a script for the DTE business service

1. In Siebel Tools, select the business service you want to contain the transformation map.
2. Right-click, then choose Edit Server Scripts
3. Choose eScripts as the scripting language if you are prompted to select a scripting language.
4. In the (declarations) procedure of the (general) object, add the line:
   ```
   #include "eaisiebel.js"
   ```
5. In the Service_PreInvokeMethod function of the service, change the function to the following:
function Service_PreInvokeMethod (MethodName, Inputs, Outputs)
{
    return EAIExecuteMap (MethodName, Inputs, Outputs);
}

Your data transformation map is run as a business service invoked from a workflow process. Business service scripts have a standard entry point, Service_PreInvokeMethod. Although the script environment provides you with a boilerplate function by this name, you need to modify it, as described in the preceding steps, to include the call to the EAIExecuteMap function.

a The MethodName must be Execute and is used by Siebel Workflow. The name of your function is the name you supply for the MapName argument to the Execute method.

b Inputs is the input message from workflow containing service arguments—for example, MapName and Output Integration Object Name—and the integration message to be transformed. Outputs is the argument used to return data—for example, Siebel Message. MapName specifies the map function to be executed and must be the name of one of the functions you defined in the business service.

For examples of DTE business services, select the Business Service object in Siebel Tools, and then query for CSSEAITEScriptService in the Class field in the Object List Editor.

DTE Business Service Method Arguments

Table 11 presents the arguments for the Execute method of the DTE business services.

</table>

You can set the following arguments in Siebel Tools:
Map Functions

A map function has the following signature:

```
function MapFnName (objectIn, objectOut)
```

The function name signified by MapFnName is the name of your transformation function. It is the value passed as the MapName argument to the business service. The Input Type and Output Type business service arguments determine the types of the objectIn and objectOut arguments and default to the type Integration Message. You should name these arguments according to type. For example, to use the default values, you would specify a function that transforms one integration object to another as:

```
function MapFnName (intMsgIn, intMsgOut)
```

If you define a function that transforms an XML property set to an integration object, you might specify it as:

```
function MapFnName (xmlPropSetIn, intMsgOut)
```
Data Mapping Using Scripts  ▪ Map Functions

The arguments to these functions are contained within the input and output arguments to the business service's Service_PreInvokeMethod function. The EAIExecuteMap function—called by Service_PreInvokeMethod—interprets the arguments and passes them to MapFnName. MapFnName reads from the input object and writes to the output object using the appropriate API for each type of object.

If you define a function to access input integration object, you might specify it as:

```javascript
function myMapFn (ObjectIn, ObjectOut) {
  inIntObj = ObjectIn.GetIntObj(); // Get Integration Object
  // Iterate over all Integration Object Instances
  while (inIntObj.NextInstance()) {
    // Get the Primary Component which is called "Order Entry - Orders"
    primaryIntComp = inIntObj.GetPrimaryIntComp("Order Entry - Orders");
    // Iterate over all instances of Primary Component
    while (primaryIntComp.NextRecord()) {
      OrderId = primaryIntComp.GetFieldValue("Id");
      // Get component "Order Entry - Line Items" which is child of "Order Entry - Orders"
      comp = primaryIntComp.GetIntComp("Order Entry - Line Items");
      // Process component similar to primary component
      while (comp.NextRecord()) {
        OrderItemld = comp.GetFieldValue("Id");
      }
    }
  }
}
```

And to define a function to create output integration object, you might specify it as:

```javascript
function myMapFn (ObjectIn, ObjectOut) {
  outIntObj = ObjectOut.CreateIntObj("Sample Order");
  while (Need new integration object instances) {
    outIntObj.CreateInstance();
    // Create Primary Component which is called "Order Entry - Orders"
    primaryIntComp = outIntObj.CreatePrimaryIntComp("Order Entry - Orders");
    while (Need new instances of primary int component) {
      primaryIntComp.NewRecord();
      primaryIntComp.SetFieldValue("Id", OrderItemld);
      // Create component Order Item which is child of Order
      comp = primaryIntComp.CreateIntComp("Order Entry - Order Items");
    }
  }
}
```
// Process component similar to primary component
while (need new instances of component) {
    comp.NewRecord();
    comp.SetFieldValue("Id", OrdertemId);
}

**EAIExecuteMap() Method**
This method executes a user-defined data transformation function. Table 12 presents the parameters for this method.

**Syntax**
EAIExecuteMap(methodName, inputPropSet, outputPropSet)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>methodName</td>
<td>The business service method should be Execute.</td>
</tr>
<tr>
<td>inputPropSet</td>
<td>Input message and service arguments.</td>
</tr>
<tr>
<td>outputPropSet</td>
<td>Output message and service arguments.</td>
</tr>
</tbody>
</table>

**Returns**
CancelOperation or ContinueOperation. The Service_PreInvokeMethod function should return the value returned by the EAIExecuteMap.

**Usage**
See “Setting Up a Data Transformation Map” on page 62.

## Data Transformation Functions
The data transformation API consists of global functions and classes that represent the different parts of input and output data. The data transformation functions are implemented as Siebel eScript. You must use Siebel eScript to create your data transformation maps.

Three different top-level data types are supported:

- **Siebel Messages.** See “Siebel Message Objects and Methods” on page 68.
- **MIME Messages.** See “MIME Message Objects and Methods” on page 88.
- **XML Property Sets.** See “XML Property Set Functions” on page 94.

The data type is determined by the InputType and OutputType arguments, as described in “DTE Business Service Method Arguments” on page 64.
Siebel Messages are the most common data type. Siebel Messages are a hierarchical type represented at the top level by an Integration Message message. See “Siebel Message Objects and Methods” on page 68.

It is also possible to operate directly on the business service input and output property sets. This is accomplished by specifying the InputType or OutputType as ServiceArguments. In this case the business service property set arguments are passed directly to the map function. The standard property set functions can be used to access them.

### Siebel Message Objects and Methods

A Siebel Message is a message containing the data of individual integration object instances. It is hierarchically structured and composed of several different types of objects.

The data transform API uses several different eScript classes to represent a Siebel Message:

- **An integration message.** This represents the top-level message container. See “Integration Message Objects” on page 68.

- **An integration object.** See “Integration Object Objects” on page 73.

- **A primary integration component.** See “Primary Integration Component Objects” on page 76.

- **Integration components.** See “Integration Component Objects” on page 82.

Each of these parts of a Siebel Message has two classes: one for input and one for output. Each class provides methods for specific purposes.

### Integration Message Objects

The integration message is the top-level piece of a message. The workflow process passes the integration message to the Data Mapping Engine as input. The Data Mapping Engine returns another message as output. The integration message object provides access to workflow arguments, integration message arguments, and the integration object that is contained in the message.

The following integration message objects are provided:

- CSSEAIIntMsgIn
- CSSEAIIntMsgOut

#### CSSEAIIntMsgIn

This object represents an integration message that is open for reading. The object provides GetArgument and GetIntObj methods.

**GetArgument() Method**

This method gets the value of a business service argument. For example, this could get the name of a map function in the business service. *Table 13* presents the parameters for this method.
Syntax
GetArgument(name [, defaultIfNull [, defaultIfEmpty]])

Table 13. Parameters for GetArgument() Method

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of a business service argument.</td>
</tr>
<tr>
<td>defaultIfNull</td>
<td>Returned if a service argument of the specified name does not exist.</td>
</tr>
<tr>
<td>defaultIfEmpty</td>
<td>Returned if the service argument is set to an empty string.</td>
</tr>
</tbody>
</table>

Returns
String or null.

Usage
Use this method to get the value of an argument passed to the business service. For example, if the MapName argument passed to the business service is MapExtOrderToOrder, the call:

```java
int MsIn.GetArgument('MapName');
```

returns the name of the map, MapExtOrderToOrder, passed to the business service.

If the named argument does not exist, `null` is returned. If the named argument exists but the value is the empty string, the empty string is returned. You can use the defaultIfNull and defaultIfEmpty optional arguments to change this behavior.

The arguments defaultIfNull and defaultIfEmpty are optional; however, if you specify defaultIfEmpty, you must also specify the defaultIfNull argument.

GetIntObj() Method
This method returns an instance of the integration object and opens it for reading. Table 14 presents the parameter for this method.

Syntax
GetIntObj(name)

Table 14. Parameter for GetIntObj() Method

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of an integration object in the active integration message.</td>
</tr>
</tbody>
</table>

Returns
CSSEAIIntObjIn Integration Object
**Usage**
An integration object instance is always returned even if the integration object does not exist. Call the returned object’s Exist method to test for this before calling other methods on the object. An error is raised if an integration object is present but the name is not correct.

**NOTE:** Currently an integration message can contain only one integration object.

**GetAttachmentCount() Method**
This method returns the number of attachments in the input integration message.

**Syntax**
GetAttachmentCount()

**Returns**
The number of attachments in the input integration message.

**GetAttachment() Method**
This method returns the attachment specified by the index. Table 15 presents the parameter for this method.

**Syntax**
GetAttachment(index)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>index</td>
<td>The index of the attachment to return.</td>
</tr>
</tbody>
</table>

**Returns**
The attachment (a PropertySet) specified by the index. The index is zero based. Returns null if index is out of bounds.

**GetAttachmentByCID() Method**
This method retrieves an attachment based on the Content Identifier (CID). Table 16 presents the parameter for this method.
**Syntax**
GetAttachmentByCID(cid)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cid</td>
<td>The Content Identifier of the attachment.</td>
</tr>
</tbody>
</table>

**Returns**
The attachment (a PropertySet) specified by the CID. Returns null if there is no attachment with the specified CID.

**CSSEAIIntMsgOut**
This object represents an output integration message that is open for writing. The object provides CreateIntObj and SetArgument methods:

**CreateIntObj() Method**
This method creates a new integration object. Table 17 presents the parameter for this method.

**Syntax**
CreateIntObj(name)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Creates a new integration object and adds it to the integration message.</td>
</tr>
</tbody>
</table>

**Returns**
CSSEAIIntObjOut Output Integration Object

**Usage**
An integration message can contain only one integration object, so multiple calls to this method on one integration message raises an error. The name must agree with the business service argument OutputIntObjName, if that argument is passed to the service.

**SetArgument() Method**
This method sets the value of a business service argument. Table 18 presents the parameters for this method.
**Syntax**
SetArgument(name, value)

Table 18. Parameters for SetArgument() Method

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of an argument in the active business service.</td>
</tr>
<tr>
<td>value</td>
<td>The string value corresponding to the argument named by the name parameter.</td>
</tr>
</tbody>
</table>

**Returns**
Not applicable

**Usage**
You can call the SetArgument method to establish the value of a given output argument for the business service method invocation.

**SetAttachmentSource() Method**
This method establishes the source object to copy attachment objects from. The source object must be a CSSEAIIntMsgIn, CSSEAI MimeMsgIn, or other object implementing the GetAttachmentByCID method. Table 19 presents the parameter for this method.

**Syntax**
SetAttachmentSource(source)

Table 19. Parameters for SetAttachmentSource() Method

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>source</td>
<td>The attachment source.</td>
</tr>
</tbody>
</table>

**CopyAttachment() Method**
This method copies an attachment from the attachment source to the output integration object. The attachment is referenced by the MIME Content Identifier (CID). The attachment source must be established by calling CSSEAIIntMsgOut.SetAttachmentSource before calling this method. Table 20 presents the parameter for this method.
Syntax
CopyAttachment(cid)

Table 20. Parameters for CopyAttachment() Method

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cid</td>
<td>MIME content identifier.</td>
</tr>
</tbody>
</table>

Returns
The attachment copy is returned as a property set. This method returns null if the attachment source does not contain an attachment with the specified CID.

Integration Object Objects
The integration object contains one or more integration components. The following integration object objects are provided:
- CSSEAIIntObjIn
- CSSEAIIntObjOut

CSSEAIIntObjIn
This object represents an input integration object, open for reading, that is contained in the integration message. The integration object has a name and contains zero or more instances of actual integration objects. Integration object instances are accessed one at a time, similar to accessing database records. Each instance has a primary integration component that contains data and every subordinate integration components. This object provides the Exists, FirstInstance, GetPrimaryIntComp, and NextInstance methods.

Exists() Method
This method checks to see if the integration object is actually present in the input data. It takes no parameters.

Syntax
Exists()

Returns
Boolean
**Usage**
Call Exists after retrieving the integration object from the integration message. If the integration object was found and is open for reading, the Exists method returns true.

**FirstInstance() Method**
This method moves to the first integration object instance and sets it as the active instance.

**Syntax**
FirstInstance()

**Returns**
Boolean

**Usage**
The FirstInstance method returns true if the instance exists, false otherwise.

**GetPrimaryIntComp() Method**
This method returns the primary integration component of the active instance of the integration object. **Table 21** presents the parameter for this method.

**Syntax**
GetPrimaryIntComp(name)

**Table 21. Parameter for GetPrimaryIntComp() Method**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of a primary integration component in the active integration object instance.</td>
</tr>
</tbody>
</table>

**Returns**
CSSEAIPrimaryIntCompIn Input Primary Integration Component

**Usage**
Gets the primary integration component of the active instance of the integration object and opens it for input.

This method always returns an input primary integration component object, even if the component does not exist. Call the Exists method on the returned object to test for this condition. If there is no active instance, a call to this method raises an error.
**NextInstance() Method**
This method moves a pointer to the next logical integration object instance in the active integration message.

**Syntax**
NextInstance()

**Returns**
Boolean

**Usage**
Moves to the next integration object instance and makes it the active instance. This method returns true if the instance exists, or false if there are no more instances. If neither the NextInstance or the FirstInstance method has been called previously, the NextInstance method moves to the first instance in the message.

**CSSEAIIntObjOut**
This object represents an output integration object, open for writing, that is contained in the integration message. It provides CreatePrimaryIntComp and NewInstance methods as an interface to the output integration object.

**CreatePrimaryIntComp() Method**
This method creates a new primary integration component. Table 22 presents the parameter for this method.

**Syntax**
CreatePrimaryIntComp(name)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Assigned as the name of the Primary Integration Component.</td>
</tr>
</tbody>
</table>

**Returns**
CSSEAIPrimaryIntCompOut Primary Integration Component, open for output
Usage
Use the Exists method to test for existence of the integration object instance, then create a new integration object instance and set it as the active instance, using the NewInstance method. You must perform these tasks before calling the CreatePrimaryIntComp() method.

NewInstance() Method
This method creates a new instance of an integration object and makes it the active instance.

Syntax
NewInstance()

Returns
Not applicable

Primary Integration Component Objects
A primary integration component represents the integration component contained within an integration object instance. It has a name and contains records with data from actual integration components. Each record may have fields and subordinate integration components.

The following primary integration component objects are provided:
- CSSEAIPrimaryIntCompIn
- CSSEAIPrimaryIntCompOut

CSSEAIPrimaryIntCompIn
This object represents the input primary integration component, open for reading. Your data transformation maps can use this object’s methods to traverse integration components. This object provides Exists, FirstRecord, GetFieldValue, GetIntComp, and NextRecord methods:

Exists() Method
This method checks to see if the primary integration component is actually present in the input data. It takes no parameters.

Syntax
Exists()

Returns
Boolean
Data Mapping Using Scripts

Siebel Message Objects and Methods

Usage
Call Exists after retrieving the primary integration component with the CSSEAIIntObjIn.GetPrimaryIntComp method, and before invoking the primary integration component’s other methods.

If the primary integration component was found and is open for reading, the Exists method returns true.

FirstRecord() Method
This method moves a pointer to the first component record in the primary integration component.

Syntax
FirstRecord()

Returns
Boolean

Usage
Moves to the first integration component record and sets it as the active record. This method returns true if the record exists, false if the integration component has no records.

GetFieldValue() Method
This method returns the value of the primary integration component field from the active record. Table 23 presents the parameters for this method.

Syntax
GetFieldValue(name [, defaultIfNull [, defaultIfEmpty]])

Table 23. Parameters for GetFieldValue() Method

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of a primary integration component field.</td>
</tr>
<tr>
<td>defaultIfNull</td>
<td>Optional. Sets the default value if the field does not exist.</td>
</tr>
<tr>
<td>defaultIfEmpty</td>
<td>Optional. Sets the default value if the field is set to an empty string.</td>
</tr>
</tbody>
</table>

Returns
String or null
Usage
A null value is returned if the active record does not contain the field. Otherwise, a string containing
the value in the field is returned. If there is no active record, this method raises an error.

If the named argument does not exist, null is returned. If the named argument exists but the value
is the empty string, the empty string is returned. You can use the defaultIfNull and defaultIfEmpty
optional arguments to change this behavior.

The arguments defaultIfNull and defaultIfEmpty are optional; however, if you specify defaultIfEmpty,
you must also specify the defaultIfNull argument.

GetIntComp() Method
This method returns the named integration component from the active record and opens it for input.
Table 24 presents the parameter for this method.

Syntax
GetIntComp(name)

Table 24. Parameter for GetIntComp() Method

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of an integration component in the active record.</td>
</tr>
</tbody>
</table>

Returns
CSSEAIIntCompIn Input Integration Component

Usage
This method always returns an input integration component object, even if the component does not
exist. Call the Exists method on the returned object to test for this condition. If there is no active
record, a call to this method raises an error.

NextRecord() Method
This method moves a pointer to the next logical record in the active integration component.

Syntax
NextRecord()

Returns
Boolean
Data Mapping Using Scripts

■ Siebel Message Objects and Methods

Usage
Moves to the next record and makes it the active record. Returns true if the record exists, or false if there are no more records. Moves to the first record if neither the NextRecord method nor the FirstRecord method has been called previously.

CSSEAIPrimaryIntCompOut

This object represents the output primary integration component. You can use the object’s methods to create output integration components and records and to copy input data records to output data records. This object provides CopyFieldValue, CreateIntComp, NewRecord, SetCopySource, and SetFieldValue methods.

CopyFieldValue() Method
This method sets the value of a field in the active record to the value of a field in the current source record. Table 25 presents the parameters for this method.

Syntax
CopyFieldValue(targetName, sourceName [, defaultIfNull [, defaultIfEmpty]])

Table 25. Parameters for CopyFieldValue() Method

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>targetName</td>
<td>Name of the field to set in the output integration component.</td>
</tr>
<tr>
<td>sourceName</td>
<td>Name of the field to retrieve from the input integration component.</td>
</tr>
<tr>
<td>defaultIfNull</td>
<td>Optional value that specifies what should be inserted into the target, if the source field does not exist.</td>
</tr>
<tr>
<td>defaultIfEmpty</td>
<td>Optional value that specifies what to use as a source value if the source field is empty.</td>
</tr>
</tbody>
</table>

Returns
Not applicable.

Usage
Use this method to copy a field from an input integration component to the output primary integration component. You could achieve the same results by calling the GetFieldValue method on the input component and the SetFieldValue on the output component; however, using CopyFieldValue is easier.

You must call the SetCopySource method first to specify the source integration component. CopyFieldValue uses the active records of the input and output components of the active integration component.
If the integration component is not set with the `SetCopySource` method first, a call to the `CopyFieldValue` method raises an error. An error also occurs if either input or output component does not have an active record.

If you set the copy source using the following statement:

```java
outIntComp.SetCopySource (inIntComp);
```

the following two statements are equivalent:

```java
outIntComp.SetFieldValue("Fld-A", inIntComp.GetFieldValue("X"));
outIntComp.CopyFieldValue("Fld-A", "X");
```

Using the second convention is convenient if you are copying many fields between the same components.

**CreateIntComp() Method**

This method creates a new integration component. Table 26 presents the parameters for this method.

**Syntax**

CreateIntComp(name [, createNow])

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of the new integration component.</td>
</tr>
<tr>
<td>createNow</td>
<td>Defaults to true. This is an optional parameter. By default, the underlying data object is created in the output data object at the time this method is called. To change this behavior, specify the optional createNow argument as false. If you specify createNow as false, the underlying data object is not created until you make the first NewRecord call on the newly created integration component.</td>
</tr>
</tbody>
</table>

**Returns**

CSSEAIIntCompOut. Output Integration Component

**Usage**

Use this method to create a new integration component, open it for writing, and add it to the active record of the integration component.

**NOTE:** This method raises an error if you call it without an active integration component record. Use the NewRecord method to create a new record and set the active record.

**NewRecord() Method**

This method creates a new record in a primary integration component.
Syntax
NewRecord()

Returns
Not applicable

Usage
This method adds a new primary integration component record and makes it the active record.

SetCopySource() Method
This method establishes the integration component from which a field value will be copied. Table 27 presents the parameter for this method.

Syntax
SetCopySource(IntComp)

Table 27. Parameter for SetCopySource() Method

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IntComp</td>
<td>The integration component object—either CSSEAIPrimaryIntCompIn or CSSEAIIntCompIn.</td>
</tr>
</tbody>
</table>

Returns
Not applicable

Usage
Call this method before a call to the CopyFieldValue method.

SetFieldValue() Method
This method sets the value of the named field in the active integration component record. Table 28 presents the parameters for this method.
Syntax

SetFieldValue(name, value)

### Table 28. Parameters for SetFieldValue() Method

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of a field in the active record of the primary integration component.</td>
</tr>
<tr>
<td>value</td>
<td>The string value to be put into the field given in the name parameter.</td>
</tr>
</tbody>
</table>

Returns

Not applicable

Usage

Both the name and value arguments should be strings.

The field is not set if the value is `null`. This method provides no return value.

This method raises an error if called while there is no active record.

**NOTE:** Siebel eScript automatically converts most types to strings as necessary.

### Integration Component Objects

An integration component object represents integration components. The following integration component objects are provided:

- CSSEAIIntCompIn
- CSSEAIIntCompOut

#### CSSEAIIntCompIn

This object represents the input integration component, open for reading. You can use the object’s methods to traverse actual integration components and to retrieve data from those integration components. This object provides Exists, FirstRecord, GetFieldValue, GetIntComp, and NextRecord methods.

**Exists() Method**

This method checks to see if the integration component is actually present in the input data. It takes no parameters.

**Syntax**

Exists()
**Returns**
Boolean

**Usage**
Call Exists after retrieving the integration component from its parent object using the GetIntComp method, and before invoking the integration component’s other methods.

If the integration component is found and is open for reading, the Exists method returns true.

**FirstRecord() Method**
This method moves a pointer to the first component record in the integration component.

**Syntax**
FirstRecord()

**Returns**
Boolean

**Usage**
Moves to the first integration component record and sets it as the active record. This method returns true if the record exists, false if the integration component has no records.

**GetFieldValue() Method**
This method returns the value of the integration component field from the active record. Table 29 presents the parameters for this method.

**Syntax**
GetFieldValue(name [, defaultIfNull [, defaultIfEmpty]])

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of an integration component field.</td>
</tr>
<tr>
<td>defaultIfNull</td>
<td>Optional. Value to return if the field does not exist.</td>
</tr>
<tr>
<td>defaultIfEmpty</td>
<td>Optional. Value to return if the field is set to an empty string.</td>
</tr>
</tbody>
</table>

**Returns**
String or null
Usage
A null value is returned if the active record does not contain the field. Otherwise, a string containing the value in the field is returned. If there is no active record, this method raises an error.

If the named argument does not exist, null is returned. If the named argument exists but the value is the empty string, the empty string is returned. You can use the defaultIfNull and defaultIfEmpty arguments to change this behavior.

NOTE: The arguments defaultIfNull and defaultIfEmpty are optional. However, if you specify defaultIfEmpty, you must also specify the defaultIfNull argument.

GetIntComp() Method
This method returns the integration component from the active record and opens it for input. Table 30 presents the parameter for this method.

Syntax
GetIntComp(name)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of an integration component in the active record.</td>
</tr>
</tbody>
</table>

Returns
CSSEAIIntCompIn Input Integration Component

Usage
This method always returns an input integration component object, even if the component does not exist. Call the Exists method on the returned object to test for this condition.

NOTE: If there is no active record, a call to this method raises an error.

NextRecord() Method
This method moves a pointer to the next logical record in the active integration component.

Syntax
NextRecord()

Returns
Boolean
Usage
Moves to the next record and makes it the active record. Returns true if the record exists, or false if there are no more records. Moves to the first record if neither the NextRecord method nor the FirstRecord method has been called previously.

CSSEAIIntCompOut
This object represents the output integration object, open for writing. You can use this object’s methods to create new output integration components and to copy or set actual data in the records of the integration components. This object provides CopyFieldValue, CreateIntComp, NewRecord, SetCopySource, and SetFieldValue methods.

CopyFieldValue() Method
This method sets the value of a field in the active record to the value of a field in the current source record. Table 31 presents the parameters for this method.

Syntax
CopyFieldValue(targetName, sourceName [, defaultIfNull [, defaultIfEmpty]])

Table 31. Parameters for CopyFieldValue() Method

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>targetName</td>
<td>Name of the field to set in the output integration component.</td>
</tr>
<tr>
<td>sourceName</td>
<td>Name of the field to retrieve from the input integration component.</td>
</tr>
<tr>
<td>defaultIfNull</td>
<td>Optional value that specifies what should be inserted into the target, if the source field does not exist.</td>
</tr>
<tr>
<td>defaultIfEmpty</td>
<td>Optional value that specifies what to use as a source value if the source field is empty.</td>
</tr>
</tbody>
</table>

Returns
Not applicable

Usage
Use this method to copy a field from an input integration component to the output integration component. You could achieve the same results by calling the GetFieldValue method on the input component and the SetFieldValue on the output component; however, using CopyFieldValue is easier.

You must call the SetCopySource method first to specify the source integration component. CopyFieldValue uses the active records of the input and output components of the active integration component.
If the integration component is not set with the SetCopySource method first, a call to the CopyFieldValue method raises an error. An error also occurs if either input or output component does not have an active record.

If you set the copy source using the following statement:

```java
outIntComp.SetCopySource(inIntComp);
```

the following two statements are equivalent:

```java
outIntComp.SetFieldValue("Fld-A", inIntComp.GetFieldValue("X"));
outIntComp.CopyFieldValue("Fld-A", "X");
```

Using the second convention is convenient if you are copying many fields between the same components.

**CreateIntComp() Method**
This method creates a new integration component. Table 32 presents the parameters for this method.

**Syntax**

CreateIntComp(name [, createNow])

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of the new integration component.</td>
</tr>
<tr>
<td>createNow</td>
<td>Defaults to true. This is an optional parameter. By default, the underlying data object is created in the output data object at the time this method is called. To change this behavior, specify the optional createNow argument as false. If you specify createNow as false, the underlying data object is not created until you make the first NewRecord call on the newly created integration component.</td>
</tr>
</tbody>
</table>

**Returns**

CSSEAIIntCompOut. Output Integration Component

**Usage**

Use this method to create a new integration component, open it for writing, and add it to the active record of the integration component.

This method raises an error if you call it without an active integration component record. Use the NewRecord method to create a new record and set the active record.

**SetCopySource() Method**

This method establishes the integration component from which a field value will be copied. Table 33 presents the parameter for this method.
Syntax
SetCopySource(IntComp)

Table 33. Parameter for SetCopySource() Method

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IntComp</td>
<td>The integration component object—either CSSEAIPrimaryIntCompIn or CSSEAIIntCompIn.</td>
</tr>
</tbody>
</table>

Returns
Not applicable

Usage
Call this method before calling the CopyFieldValue method.

SetFieldValue() Method
This method sets the value of the named field in the active integration component record. Table 34 presents the parameters for this method.

Syntax
SetFieldValue(name, value)

Table 34. Parameters for SetFieldValue() Method

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of a field in the active record of the integration component.</td>
</tr>
<tr>
<td>value</td>
<td>The string value to be put into the field given in the name parameter.</td>
</tr>
</tbody>
</table>

Returns
Not applicable

Usage
Both the name and value arguments should be strings.
The field is not set if the value is null. This method provides no return value.
This method raises an error if called while there is no active record.

NOTE: Siebel eScript automatically converts most types to strings as necessary.
MIME Message Objects and Methods

Siebel EAI represents MIME documents using a property set format. This is the format used by the EAI MIME Doc Converter Business Service. The objects and methods described here provide access to this property set format, and are intended for use in conjunction with transforming pieces of the MIME message to and from Siebel Integration Messages.

NOTE: The EAI MIME Hierarchy Converter Business Service is the preferred method of converting between the property set representation Siebel Messages.

The following MIME message objects are provided:
- CSSEAIMimeMsgIn
- CSSEAIMimeMsgOut

CSSEAIMimeMsgIn

This object represents an input MIME Message, open for reading. The MIME message is in the property set format generated by the EAI MIME Doc Converter. The object consists of a series of MIME parts forming the different pieces of the message.

This object provides GetArgument, GetPartCount, GetPart, GetPartByCID, GetAttachmentByCID, and GetXMLRootPart methods.

GetArgument() Method

This method gets the value of a business service argument. For example, this could get the name of a map function in the business service. Table 35 presents the parameters for this method.

Syntax

GetArgument(name [, defaultIfNull [, defaultIfEmpty]])

Table 35. Parameters for GetArgument() Method

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of a business service argument.</td>
</tr>
<tr>
<td>defaultIfNull</td>
<td>Returned if a service argument of the specified name does not exist.</td>
</tr>
<tr>
<td>defaultIfEmpty</td>
<td>Returned if the service argument is set to an empty string.</td>
</tr>
</tbody>
</table>

Returns

String or null
Data Mapping Using Scripts  ■  MIME Message Objects and Methods

Usage
Use this method to get the value of an argument passed to the business service. For example, if the MapName argument passed to the business service is MapExtOrderToOrder, the call:

```csharp
int MsgIn.GetArgument("MapName");
```
returns the name of the map, MapExtOrderToOrder, passed to the business service.

If the named argument does not exist, null is returned. If the named argument exists but the value is the empty string, the empty string is returned. You can use the defaultIfNull and defaultIfEmpty optional arguments to change this behavior.

The arguments defaultIfNull and defaultIfEmpty are optional; however, if you specify defaultIfEmpty, you must also specify the defaultIfNull argument.

GetPartCount() Method
This method returns the number of parts in the MIME message. Table 36 presents the parameter for this method.

Syntax
GetPartCount()

Returns
This method returns the number of parts in the MIME message.

GetPart() Method

Syntax
GetPart(index)

Table 36. Parameters for GetPart() Method

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>index</td>
<td>Index of the MIME part to return.</td>
</tr>
</tbody>
</table>

Returns
Property set. Returns the part, a property set, specified by the index. The index is zero based. Returns null if the index is out of bounds.

GetPartByCID() Method
Retrieves a MIME part based on the MIME Content Identifier (CID). Table 37 presents the parameter for this method.
Syntax
GetPartByCID(cid)

Table 37. Parameters for GetPartByCID() Method

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cid</td>
<td>MIME Content Identifier to retrieve.</td>
</tr>
</tbody>
</table>

Returns
Returns null if there is no part with the specified CID.

GetAttachmentByCID() Method
The same functionality as CSSEAIMimeMsgIn.GetPartByCID. Supports using a CSSEAIMimeMsgIn as an attachment source for copying attachments to output objects. Table 38 presents the parameter for this method.

Syntax
GetAttachmentByCID(cid)

Table 38. Parameters for GetAttachmentByCID() Method

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cid</td>
<td>MIME Content Identifier to retrieve.</td>
</tr>
</tbody>
</table>

Returns
The attachment (a property set) specified by the CID. Returns null if there is no attachment with the specified CID.

GetXMLRootPart() Method
Finds the first MIME part that is an XML message in property set format and returns the root element of the XML document. The XML message must be in property set format as produced by the XML Hierarchy Converter Business Service. An error is raised if the XML message is not found. The method is intended for use with MIME messages that consist of an XML message and a series of related attachments. The property set returned is consistent with what XPSGetRootElement returns, and can be accessed with the XML Property Set functions. See “XML Property Set Functions” on page 94.

Syntax
GetXMLRootPart()
Returns
MIME body part representing an XML document.

CSSEAIMimeMsgOut
This object represents an output MIME message, open for writing. This object provides SetArgument, CreateXMLPart, SetAttachmentSource, and CopyAttachment methods:

SetArgument() Method
This method sets the value of a business service argument. Table 39 presents the parameters for this method.

Syntax
SetArgument(name, value)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of an argument in the active business service.</td>
</tr>
<tr>
<td>value</td>
<td>The string value corresponding to the argument named by the name parameter.</td>
</tr>
</tbody>
</table>

Usage
You can call the SetArgument method to establish the value of a given output argument for the business service method invocation.

CreateXMLPart() Method
This method is similar to XPSCreateRootElement. See "XPSCreateRootElement()" on page 95. CreateXMLPart() Method creates an XML MIME part and adds it to the MIME document. The property set representing the XML root element is returned. The property set returned can be populated using the XML Property Set functions. See "XML Property Set Functions" on page 94. Table 40 on page 92 presents the parameter for this method.
Syntax
CreateXMLPart(xmlRootTagName)

Table 40. Parameters for CreateXMLPart() Method

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xmlRootTagName</td>
<td>The name you want to supply as the root element name in the XML document.</td>
</tr>
</tbody>
</table>

Returns
Property set

SetAttachmentSource() Method
This method establishes the source object from which to copy attachment objects. The source object must be a CSSEAIIntMsgIn, CSSEAIMimeMsgIn, or other object implementing the GetAttachmentByCID method. Table 41 presents the parameter for this method.

Syntax
SetAttachmentSource(source)

Table 41. Parameters for SetAttachmentSource() Method

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>source</td>
<td>The attachment source.</td>
</tr>
</tbody>
</table>

CopyAttachment() Method
This method copies an attachment from the attachment source to the output MIME message object. The attachment is referenced by the MIME Content Identifier (CID). The attachment copy, a property set, is returned. The attachment source must be established by calling CSSEAIMimeMsgOut.SetAttachmentSource before calling this method. Table 42 presents the parameter for this method.

Syntax
CopyAttachment(cid)

Table 42. Parameters for CopyAttachment() Method

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cid</td>
<td>MIME Content Identifier of the attachment to copy.</td>
</tr>
</tbody>
</table>
Returns
Property set. This method returns null if the attachment source does not contain an attachment with the specified CID.

Attachments and Content Identifiers in MIME Messages

A MIME message contains one or more parts, each representing a separate piece of the message. One common use of multipart MIME messages is to include attachments with a message.

NOTE: All the examples have to be typed single-spaced and without word wrap.

Each MIME body part has an optional Content Identifier (CID) used to identify it. The Content Id is part of the MIME part header, for example:

```
--unique_boundary_123
Content-Type: image/jpeg
Content-ID: <001110.102215@abc.com>
```

Then the CID is 001110.102215@abc.com. The CID is usually referenced from another part of the MIME message. A common scheme is to use an XML document as the main part of the MIME message, and use Content Ids to reference the other attachments in the message. The following is an example of a MIME message with attachment.

```
MIME-Version: 1.0
Content-Type: multipart/related;
    boundary="unique_boundary_123";
    type="application/xml"
Content-Transfer-Encoding: binary
--unique_boundary_123
Content-Type: application/xml; charset="UTF-8"
Content-Transfer-Encoding: binary
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE Memo SYSTEM "Memo.dtd">
<Memo>
    <To>All Employees</To>
    <Subject>Map and Directions</Subject>
    <Body>Maps to company headquarters are attached.</Body>
    <ListOfAttachments>
```
XML Property Set Functions

Siebel EAI represents XML documents using the property set format. While Siebel EAI does not always require using the property set format, this representation is used by EAI Business Services such as the EAI XML Converter. The functions described in this section provide a simple interface for manipulating XML documents using the property set format.

Top-Level Property Set Functions

These functions are used to manipulate the top-level property set passed to the Map function.
**XPSGetRootElement()**
This function returns the property set representing the root element of the XML document. If the root element is not present, the system raises an error. Table 43 presents the parameter for this function.

**Syntax**
XPSGetRootElement(xmlPropSetIn)

**Table 43. Parameter for XPSGetRootElement() Method**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xmlPropSetIn</td>
<td>The name of the property set representing the root element of the XML document.</td>
</tr>
</tbody>
</table>

**Returns**
Property set

**Usage**
Use this function to return the root element of an XML document.

**XPSCreateRootElement()**
This function creates the root element in an output XML document and returns the property set representing it. The element tag in the XML document is set to the value of the tagName argument. Table 44 presents the parameters for this function.

**Syntax**
XPSCreateRootElement(xmlPropSetOut, tagName)

**Table 44. Parameters for XPSCreateRootElement() Method**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xmlPropSetOut</td>
<td>The output property set.</td>
</tr>
<tr>
<td>tagName</td>
<td>The name you want to supply as the root element name in the XML document.</td>
</tr>
</tbody>
</table>

**Returns**
Property set

**Usage**
Use this function to create the root element of an XML document that represents a property set. Because the root element does not directly map to a component in the property set, you can give it any representative name.
As an example of how the "XPSGetRootElement()" and "XPSCreateRootElement()" functions work, consider the following XML document:

```xml
<?xml version='1.0'?>
<!DOCTYPE LETTER SYSTEM "letter.dtd">
<letter>
  <from>Mary Smith</from>
  <to>Paul Jones</to>
  <text>Hello!</text>
</letter>
```

The root element is `<letter>`. The property set for the `<letter>` element can be retrieved from the input property set using EAIXPS_GetRootElement, or it can be created in the output property set using EAIXPS_CreateRootElement.

A map function that converts a letter to a memo might start with the following code:

```javascript
function ConvertLetterToMemo (xmlPropSetIn, xmlPropSetOut)
{
  var xmlLetter = XPSGetRootElement (xmlPropSetIn);
  var xmlMemo = XPSCreateRootElement (xmlPropSetOut, "memo");
  ... Code to fill in the 'memo' from the 'letter' ...
}
```

### XML Element Accessors

These functions provide access to elements represented by property sets. Table 45 presents the parameter for this function.

**XPSGetTagName()**

Retrieves the tag name of an XML element.

**Syntax**

XPSGetTagName (xmlPropSet)

**Table 45. Parameter for XPSGetTagName() Method**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xmlPropSet</td>
<td>The output property set.</td>
</tr>
</tbody>
</table>

**Returns**

String. If xmlPropSet is null, XPSGetTagName returns `null`.  

**XPSSetTagName()**

This function sets the tag name of an XML element. Table 46 presents the parameters for this function.

**Syntax**

XPSSetTagName (xmlPropSet, tagName)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xmlPropSet</td>
<td>The property set.</td>
</tr>
<tr>
<td>tagName</td>
<td>The name you want to supply as the current element name in the XML document.</td>
</tr>
</tbody>
</table>

**Returns**

String

**XPSGetTextValue()**

This function returns the text value of an XML element as a string. Table 47 presents the parameters for this function.

**Syntax**

XPSGetTextValue (xmlPropSet [, defaultIfNull [, defaultIfEmpty]])

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xmlPropSet</td>
<td>The output property set.</td>
</tr>
<tr>
<td>defaultIfNull</td>
<td>Specify a value to override the null default value that results if xmlPropSet is null.</td>
</tr>
<tr>
<td>defaultIfEmpty</td>
<td>Specify a value to override an empty string (&quot;&quot;) contained in xmlPropSet.</td>
</tr>
</tbody>
</table>

**Returns**

String or null

**Usage**

If xmlPropSet is null then null is returned. You can use the optional defaultIfNull and defaultIfEmpty arguments to override null and empty string ("") return values. An element’s text value is the text between an XML element’s start and end tags, excluding child elements.
**XPSSetTextValue()**

This function sets the text value of an XML element. Table 48 presents the parameters for this function.

**Syntax**

```
XPSSetTextValue (xmlPropSet, text)
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xmlPropSet</td>
<td>The property set.</td>
</tr>
<tr>
<td>text</td>
<td>A string you want inserted between start and end tags of an XML element.</td>
</tr>
</tbody>
</table>

**Returns**

Not applicable

**Usage**

The text argument should be a string. An element’s text value is the text between the element’s start and end tags, excluding child elements.

**XPSGetAttribute()**

This function retrieves an element’s attribute of the given name and returns it as a string. Table 49 presents the parameters for this function.

**Syntax**

```
XPSGetAttribute (xmlPropSet, name [, defaultIfNull [, defaultIfEmpty]])
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xmlPropSet</td>
<td>The output property set.</td>
</tr>
<tr>
<td>name</td>
<td>The name you want to supply as the root element name in the XML document.</td>
</tr>
<tr>
<td>defaultIfNull</td>
<td>Specify a value to override the null default value that results if xmlPropSet is null.</td>
</tr>
<tr>
<td>defaultIfEmpty</td>
<td>Specify a value to override an empty string (&quot;&quot;&quot;) contained in xmlPropSet.</td>
</tr>
</tbody>
</table>

**Returns**

String
Usage
A null value is returned if xmlPropSet is null or the element does not have the named attribute. The optional defaultIfNull and defaultIfEmpty arguments can be used to override null and empty string (""") return values.

XPSSetAttribute()
This function sets an element attribute value. Table 50 presents the parameters for this function.

Syntax
XPSSetAttribute (xmlPropSet, name, value)

Table 50. Parameters for XPSSetAttribute() Method

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xmlPropSet</td>
<td>The output property set.</td>
</tr>
<tr>
<td>name</td>
<td>Attribute name.</td>
</tr>
<tr>
<td>value</td>
<td>String value you want to supply as the attribute value.</td>
</tr>
</tbody>
</table>

Returns
String

Usage
No action is taken if any of the arguments are null.

XPSGetChildCount()
This function returns the number of children of an element. Table 51 presents the parameter for this function.

Syntax
XPSGetChildCount(xmlPropSet)

Table 51. Parameter for XPSGetChildCount() Method

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xmlPropSet</td>
<td>The property set.</td>
</tr>
</tbody>
</table>

Returns
Number
**Data Mapping Using Scripts**

**XML Property Set Functions**

**Usage**

All children of an element are also elements.

**XPSGetChild()**

This function returns the $n$th child element as specified by the index. **Table 52** presents the parameters for this function.

**Syntax**

XPSGetChild(xmlPropSet, index)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xmlPropSet</td>
<td>The property set.</td>
</tr>
<tr>
<td>index</td>
<td>Number, starting at zero, of child elements of another element in an XML document.</td>
</tr>
</tbody>
</table>

**Returns**

Property set

**Usage**

Child elements are specified using a zero-based index. A value of `null` is returned if the index is invalid.

**XPSFindChild()**

This function returns the first child element with the `tagName`. **Table 53** presents the parameters for this function.

**Syntax**

XPSFindChild (xmlPropSet, tagName)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xmlPropSet</td>
<td>The property set.</td>
</tr>
<tr>
<td>tagName</td>
<td>An XML element tag that signifies the first child element of another XML element.</td>
</tr>
</tbody>
</table>

**Returns**

Property set.
Usage
A value of null is returned if there is no child with the specified tag name.

XPSAddChild()
This function creates a new child element with the tagName and appends it to the list of xmlPropSet’s children. Table 54 presents the parameters for this function.

Syntax
XPSAddChild (xmlPropSet, tagName [, textValue])

Table 54. Parameters for XPSAddChild() Method

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xmlPropSet</td>
<td>The property set.</td>
</tr>
<tr>
<td>tagName</td>
<td>The name you want to give to the new child element.</td>
</tr>
<tr>
<td>textValue</td>
<td>Optional. Sets the text value of the new element.</td>
</tr>
</tbody>
</table>

Returns
Property set

Examples
The following example converts a <letter> to a <memo>.

NOTE: The input letter in this example is slightly different from the previous example.

The input XML document is:

```xml
<letter
    from="Mary Smith"
    to="Paul Jones">
    <text>Hello!</text>
</letter>
```

The conversion function converts this to a memo format, as follows:

```xml
<memo>
    <type>Interoffice Memo</type>
    <header>
        <from>Mary Smith</from>
        <to>Paul Jones</to>
    </header>
    <body>Hello!</body>
</memo>
```

The map function that performs this conversion is:
function ConvertLetterToMemo (xmlPropSetIn, xmlPropSetOut) {
    var letter = XPSGetRootElement (xmlPropSetIn);
    var memo = XPSCreateRootElement (xmlPropSetOut, "memo");
    XPSAddChild (memo, "type", "Interoffice Memo");
    var header = XPSAddChild (memo, "header");
    XPSAddChild (header, "from", XPSGetAttribute (letter, "from"));
    XPSAddChild (header, "to", XPSGetAttribute (letter, "to"));
    XPSAddChild (memo, "body", XPSGetTextValue (XPSFindChild (letter, "text")));
}

EAI Value Maps

EAI Value Maps correlate Siebel data values with external data values.

If you are:

- Sending and receiving data, you can create inbound and outbound maps for the same data
- Receiving data only, you need only to define an inbound map
- Sending data only, you need only to define an outbound map

Consider an example of how EAI Value Maps provide correlations between Siebel applications and the SAP R/3 system. SAP country codes, which are represented as two-character codes, are different from Siebel country codes, represented by the country name spelled out. An EAI Value Map provides a lookup table that lists these two sets of data side by side.

The EAI Value Map entries are stored in the EAI Value Map table. You can view and administer this table from the EAI Value Maps view in the Administration-Integration screens in the Siebel client. The Siebel client groups the entries logically based on the Type and Direction columns.

Figure 11 shows the entries form two logical groupings, with entries for the Siebel inbound and Siebel outbound entries.

Figure 11. EAI Value Maps for Country Codes
The Direction field determines the direction of the mapping and is either Siebel Outbound or Siebel Inbound. In a Siebel Outbound mapping, the Siebel Value field is the lookup key; the External System Value is the translation. In a Siebel Inbound mapping, the External System Value field is the lookup key; the Siebel Value is the translation.

You can add, remove, or modify entries in the Type group on the EAI Lookup Map view in the Siebel client. The EAI_LOOKUP_MAP_TYPE list of values defines type values. You can modify the list from the Application Administration views in the Siebel client.

**NOTE:** You cannot change the values of the Direction field, which must be Siebel Outbound or Siebel Inbound.

The data transformation methods include an interface to EAI Value Maps for translating the codes of one database to another. You use the EAIGetValueMap function to obtain an interface to the mappings of specific Type-Direction pairs. You use the interface object’s Translate method to find specific keys in the Type-Direction map and retrieve the translated values.

### EAIGetValueMap Function

You use the following statement in your Siebel eScript code to return a value map:

```plaintext
EAIGetValueMap (type, direction [, unmappedKeyHandler])
```

This object returns a value map for translating lookup keys using the Type-Direction combination.

- The type argument is a string found in the Type field of the EAI Value Map table.
- The direction argument must be either Siebel Inbound or Siebel Outbound string values.

A call to this function returns a CSSEAIValueMap object.

You can use the optional unmappedKeyHandler argument to control the behavior of the Translate method when it gets keys that do not have mappings in the table. The unmappedKeyHandler argument can be either a literal value or a function. If you pass a literal value, it is used as the default value. Otherwise, if you pass a function, the method calls that function, then uses the value returned by the function.

The unmappedKeyHandler defaults to an empty string (""").

### EAILookupSiebel Search Function

This function returns an EAI Value Map, with inbound direction that has the external value matching the value in the[]. The general format for this function is as follows:

```plaintext
EAILookupSiebel ("EAI Value Type", [Source field that lookup will be based on]).
```

### EAILookupExternal Search Function

This function returns an EAI Value Map, with outbound direction that has the Siebel value matching the value in the[]. The general format for this function is as follows:
EAI Lookup External ("EAI Value Type", [Source field that lookup will be based on]).

CSSEAIValueMap Translate Method

The CSSEAIValueMap object has one method: Translate. The Translate method takes one argument, as follows:

    Translate (key)

The Translate method looks up the key value in the EAI Value Map and returns the translated value. The EAIGetValueMap call establishes the set of mappings for the translation using the type and direction arguments. The call looks for the key in either the Siebel Value column or in the External System Value column, depending on the value of the type argument.

- If the type is Siebel Outbound, the method returns the key found in the Siebel Value column. The translated value is in the External System Value column.
- If the type is Siebel Inbound, the method returns the key found in the External System Value column. The translated value is in the Siebel Value column.
- If key is null then the return value is null.
- If key is an empty string, the lookup is performed.
If there is no mapping, an empty string is returned.
If a nonempty string does not have a mapping, the unmappedKeyHandler value specified in the call to the EAIGetValueMap function is used to determine the translation.

EAIGetValueMap unmappedKeyHandler Argument

The unmappedKeyHandler provides a flexible mechanism for handling cases where keys are not found in the EAI Value Map. In most situations, you can use literal values for defaults or you can use one of several predefined handler functions. However, you can also provide your own handler function.

The technique you use for handling unmapped values depends on the data being mapped.

Typical strategies include:

- Use the empty string as the translation.
  This is the default strategy. It clears the field if the data is being imported into your Siebel application. To follow this approach, omit the unmappedKeyHandler argument or pass it as an empty string. For example:

```
var langMap = EAIGetValueMap("SAP Language","Siebel Inbound","");
```

This example looks up a nonexistent language code and returns an empty string. For example:

```
var translatedValue= langMap.Translate ("ABC"); // returns an empty string
```
Use `null` as the translation.

This technique makes the result unspecified rather than empty. For data imported to Siebel applications, this keeps the existing value from being overridden when performing updates. Use `null` as the unmappedKeyHandler—for example:

```javascript
var langMap = EAIGetValueMap("SAP Language", "Siebel Inbound", null);
```

Use a literal string as the translation.

Specify the string as the unmappedKeyHandler. For example:

```javascript
var langMap = EAIGetValueMap("SAP Language", "Siebel Inbound", "Unknown Language");
```

Raise an error.

This may be the best strategy if the Value Map should contain mappings for every key. You can use the `EAIValueMap_NoEntry.RaiseError` function. For example:

```javascript
var langMap = EAIGetValueMap("SAP Language", "Siebel Inbound", EAIValueMap_NoEntry.RaiseError);
```

Use the untranslated value.

The predefined function `EAIValueMap_NoEntry.ReturnLookupKey` implements this strategy. For example:

```javascript
var langMap = EAIGetValueMap("SAP Language", "Siebel Inbound", EAIValueMap_NoEntry.ReturnLookupKey);
```

Trying to look up a nonexistent language code (for example, ABC) will return the original key. For example:

```javascript
var translatedValue = langMap.Translate("ABC"); // returns 'ABC'
```

You can also write a custom handler function. You need to write a function taking three arguments: key, type, and direction. The value your function returns is used as the translation. For example:

```javascript
function MyUnmappedLangHandler (key, type, direction)
{
    return ('Unknown Language: ' + key);
}
var langMap = EAIGetValueMap("SAP Language", "Siebel Inbound", MyUnmappedLangHandler);
```

// Lookup a nonexistent language code.

```javascript
var translatedValue = langMap.Translate("ABC"); // returns 'Unknown Language: ABC'
```

**EAIGetValueMap() Method**

This method retrieves objects for the required Type-Direction mapping. **Table 55** presents the parameters for this method.
Syntax
EAIGetValueMap(type, direction [, unmappedKeyHandler])

Table 55. Parameters for EAIGetValueMap() Method

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>

<tr>
<td></td>
<td>empty string, null, a literal, or the name of a predefined function.</td>
</tr>
</tbody>
</table>

Returns
An object you can use to access the EAI Value Maps.

Usage
Use this method at the beginning of a script function to retrieve objects for the required Type-Direction mapping. Then call the object's Translate method to get the translation of a code from the map table as needed within the function.

NOTE: Providing a Type-Direction pair that does not have an entry in the EAI Value Map raises an error at the first call to the Translate method.

Exception Handling Considerations

There are three categories of errors you might encounter in the data transformation area of your integration. These categories are:

- **Siebel errors.** Errors signaled by the built-in facilities that execute a map; for example, run-time Siebel eScript errors, business service invocation errors, BusComp errors, and errors in the data transformation functions.
  - Siebel errors are fatal, terminating execution of the map immediately.
  - The business service returns an error code other than OK. No specific error code is guaranteed, and they are not intended for workflow branching. Workflow processes can branch on the indication of an error occurrence, but not on a specific code.
  - The CSSService error stack will contain useful error information. In particular, data transformation function errors will generate error stacks describing the particular error.

- **User errors.** Errors signaled in custom maps using the EAIRaiseErrorCode call. These are similar to Siebel Framework errors, except that the map developer selects the error code and uses them for workflow branching.
User errors are fatal, terminating execution of the map immediately.

The service returns the error code specified in the call to EAIRaiseErrorCode. Your workflow can branch on this code.

Available error codes are those in the Workflow generic error set.

You specify the entire error text for these generic errors in the call to EAIRaiseErrorCode.

You can use the function EAIRaiseError to raise an error without specifying a particular error code.

**Map status flags.** The map developer can use the SetArgument method to set custom status information in the output property set. For example, you can use the SetArgument method to indicate that a required field is missing. This can be used for workflow branching, if desired. This mechanism is independent of calls made to EAIRaiseError.

### Error Codes and Error Symbols

All errors each have an error code, which is a unique integer. A subset of errors also each have an error symbol. An error symbol is a text string that allows you to reference specific error codes in Siebel Workflow and in Siebel eScript. Errors that do not have an error symbol cannot be used for branch decisions and cannot be raised as user errors.

Error codes returned by a data transformation service may or may not have an associated error symbol. User errors will have error symbols. Currently, errors generated by Data Transformation Functions have error symbols. Errors occurring outside the data transformation framework often will not have error symbols.

### Data Transformation Error Processing

This section describes how the Data Transformation Functions handle errors, and how the top-level error code returned by the data transformation business service invocation is determined.

**Framework errors occurring outside the Data Transformation Context.** These errors are passed through without change to the CSSService script invocation mechanism. That mechanism takes control and returns an error of its choice. For example, if your map invokes a BusComp and the BusComp signals an error, an exception is thrown that will be ignored by the Data Mapping Engine but passed to the CSSService script invocation mechanism, which sets up the error state and returns an error from the business service invocation.

**Framework errors generated by Data Transformation Functions.** These are caught by an exception handler that sets up the state in the output PropertySet and passes control to the CSSEAITEScriptService class. CSSEAITEScriptService sets the error code on the business service as in the state, transforming error symbols to error codes in the process. Error symbols are specific to the failure.

**User errors.** These are processed the same way as errors generated by the Data Transformation Functions, except that you specify the error symbols and error text in your maps.
Exception Handling Functions

When writing your data transformation scripts, you can use the following functions to handle error conditions:

- EAIRaiseError
- EAIRaiseErrorCode
- EAIFormatMessage

**NOTE:** Before proceeding, read “Exception Handling Considerations” on page 106.

**EAIRaiseError() Method**

This method raises a fatal error and terminates the script. Table 56 presents the parameters for this method.

**Syntax**

EAIRaiseError(msg [, formatParameters])

**Table 56. Parameters for EAIRaiseError() Method**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>msg</td>
<td>Error message text from the Data Mapping Engine.</td>
</tr>
<tr>
<td>formatParameters</td>
<td>Optional string arguments inserted in the return value in the positions specified by the positional arguments in the msg parameter. A maximum of nine format parameters are allowed.</td>
</tr>
</tbody>
</table>

**Usage**

You can provide format parameters to format the message text. For details, see “EAIFormatMessage() Method” on page 109.

**EAIRaiseErrorCode() Method**

This method raises a fatal error, terminates the script, and returns an error symbol that it receives from the business service.

**Syntax**

EAIRaiseErrorCode(errorSymbol, msg)

**Usage**

You can use this function when you want to pass an error symbol to a workflow as an indication to branch on an exception. If you are not branching on the specific error code in your workflow, use EAIRaiseError instead.
**EAIFormatMessage() Method**

This method formats strings that have position-independent arguments. Table 57 presents the parameters for this method.

**Syntax**

EAIFormatMessage(msg [, formatParameters])

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>msg</td>
<td>A string that contains positional arguments. The substitution operation replaces the percent sign followed by a digit with the corresponding format parameter.</td>
</tr>
<tr>
<td>formatParameters</td>
<td>Optional string arguments inserted in the return value in the positions specified by the positional arguments in the msg parameter. A maximum of nine format parameters are allowed.</td>
</tr>
</tbody>
</table>

**Returns**

A string of the formatParameters argument values in the positions specified by the positional arguments included in the msg parameter.

**Usage**

You can use this function to generate messages from strings that are translated and whose positions have changed as a result of the translation.

**Example**

EAIFormatMessage("Data: '%2', '%3', '%1'", "A", "B", "C")

returns the string:

"Data: 'B', 'C', 'A'"

---

**Sample Siebel eScript**

This section provides a sample Siebel eScript map for transforming data from a Siebel Account to SAP to retrieve an order list. The map is used to convert between Oracle’s Siebel Account object and the equivalent SAP R/3 objects.

```eScript
function GetSAPOrderStatus_SiebelToBAPI (inputMsg, outputMsg) {
    /* Input Objects' Integration Components: */
    /* Order Object (Order - Get SAP Order Status (Siebel)) */
    /* Order */
    /* Output Object's Integration Components: */
}
```
* BAPI Import (Order - Get SAP Order Status (BAPI Input))
  * Import Parameters
*/

/*
 * Set up EAI Lookup objects
*/

/*
 * Set up EAI Input Message objects
*/

var iOrderObj; // Siebel Order instance
var iOrderComp; // Order

/*
 * Set up EAI Output Message objects
*/

var oGSObj;     // BAPI instance
var oGSImportComp; // Import Parameters

/*
 * Find and create top-level integration object
*/

iOrderObj = inputMsg.GetIntObj("Order - Get SAP Order Status (Siebel)");

oGSObj = outputMsg.CreateInstance("Order - Get SAP Order Status (BAPI Input)");

/*
 * Read int object instances from EAI message
*/

while (iOrderObj.NextInstance()) {

  /*
   * Create "Get Status" object
   */

  oGSObj.CreateInstance();

  /*
   * Read "Order" component
   */

  iOrderComp = iOrderObj.GetPrimaryIntComp("Order");
oGSImportComp = oGSOBJ.CreatePrimaryIntComp
("Import Parameters");
if (iOrderComp.NextRecord())
{
    /*
    * Write "Import Parameters" component
    */
    oGSImportComp.NewRecord();
oGSImportComp.SetCopySource (iOrderComp);
oGSImportComp.CopyFieldsValue("SALESDOCUMENT",
                      "Integration Id");
}
