This software and related documentation are provided under a license agreement containing restrictions on use and disclosure and are protected by intellectual property laws. Except as expressly permitted in your license agreement or allowed by law, you may not use, copy, reproduce, translate, broadcast, modify, license, transmit, distribute, exhibit, perform, publish, or display any part, in any form, or by any means. Reverse engineering, disassembly, or decompilation of this software, unless required by law for interoperability, is prohibited.

The information contained herein is subject to change without notice and is not warranted to be error-free. If you find any errors, please report them to us in writing.

If this software or related documentation is delivered to the U.S. Government or anyone licensing it on behalf of the U.S. Government, the following notice is applicable:

U.S. GOVERNMENT RIGHTS Programs, software, databases, and related documentation and technical data delivered to U.S. Government customers are "commercial computer software" or "commercial technical data" pursuant to the applicable Federal Acquisition Regulation and agency-specific supplemental regulations. As such, the use, duplication, disclosure, modification, and adaptation shall be subject to the restrictions and license terms set forth in the applicable Government contract, and, to the extent applicable by the terms of the Government contract, the additional rights set forth in FAR 52.227-19, Commercial Computer Software License (December 2007). Oracle USA, Inc., 500 Oracle Parkway, Redwood City, CA 94065.

This software is developed for general use in a variety of information management applications. It is not developed or intended for use in any inherently dangerous applications, including applications which may create a risk of personal injury. If you use this software in dangerous applications, then you shall be responsible to take all appropriate fail-safe, backup, redundancy, and other measures to ensure the safe use of this software. Oracle Corporation and its affiliates disclaim any liability for any damages caused by use of this software in dangerous applications.

Oracle is a registered trademark of Oracle Corporation and/or its affiliates. Other names may be trademarks of their respective owners.

This software and documentation may provide access to or information on content, products, and services from third parties. Oracle Corporation and its affiliates are not responsible for and expressly disclaim all warranties of any kind with respect to third-party content, products, and services. Oracle Corporation and its affiliates will not be responsible for any loss, costs, or damages incurred due to your access to or use of third-party content, products, or services.

Part I Getting Started with Fusion Web Applications	
1 Introduction to Building Fusion Web Applications with Oracle ADF	
1.1 Introduction to Oracle ADF.....	1-1
1.2 Oracle ADF Architecture	1-2
1.2.1 ADF Business Components.....	1-3
1.2.2 ADF Model Layer	1-4
1.2.3 ADF Controller.....	1-5
1.2.4 ADF Faces Rich Client.....	1-5
1.3 Overview of Building and Application with Oracle ADF	1-6
1.3.1 Creating an Application Workspace.....	1-7
1.3.2 Modeling with Database Object Definitions.....	1-10
1.3.3 Creating Use Cases	1-12
1.3.4 Designing Application Control and Navigation Using ADF Task Flows.....	1-13
1.3.5 Identifying Shared Resources	1-15
1.3.6 Creating a Data Model to Access Data with ADF Business Components	1-15
1.3.6.1 Creating a Layer of Business Domain Objects for Tables.....	1-16
1.3.6.2 Building the Business Services	1-17
1.3.6.3 Testing and Debugging Business Services with the Oracle ADF Model Tester	1-18
1.3.7 Implementing the User Interface with JSF.....	1-18
1.3.8 Data Binding with ADF Model Layer.....	1-20
1.3.9 Validation and Error Handling.....	1-23
1.3.10 Adding Security	1-24

1.3.11	Testing and Debugging the Web Client Application	1-24
1.3.12	Refactoring Application Artifacts.....	1-25
1.3.13	Deploying a Fusion Web Application	1-25
1.3.14	Integrating a Fusion Web Application	1-25
1.4	Working Productively in Teams.....	1-25
1.4.1	Enforcing Standards	1-26
1.4.2	Using a Source Control System	1-27
1.5	Other Resources for Learning Oracle ADF	1-28
1.6	Generation of Complete Web Tier Using Oracle JHeadstart.....	1-29

2 Introduction to the ADF Sample Application

2.1	About the Oracle Fusion Order Demo.....	2-1
2.2	Setting Up the Fusion Order Demo Application.....	2-1
2.2.1	How to Download the Application Resources.....	2-2
2.2.2	How to Install the Fusion Order Demo Schema	2-3
2.2.3	Overview of the Fusion Order Demo Schema.....	2-4
2.2.3.1	Translation Support in the Fusion Order Demo Schema	2-6
2.2.3.2	Lookup Tables in the Fusion Order Demo Schema.....	2-7
2.3	Running the Fusion Order Demo Application StoreFront Module	2-8
2.4	Running the Fusion Order Demo Standalone Applications.....	2-11
2.4.1	How to Run the Standalone Applications.....	2-11
2.4.2	Standalone Applications in the DevGuideExamples Application Workspace	2-13
2.4.3	Standalone Applications in the AdvancedExamples Application Workspace	2-16
2.4.4	Standalone Applications in the AdvancedEntityExamples Application Workspace.....	2-18
2.4.5	Standalone Applications in the AdvancedViewObjectExamples Application Workspace	2-20
2.4.6	Standalone Applications in the AdvancedUIExamples Application Workspaces .	2-22
2.5	Taking a Look at the Fusion Order Demo Application.....	2-23
2.5.1	Anonymous Browsing	2-25
2.5.1.1	Viewing Product Details.....	2-27
2.5.1.2	Browsing the Product Catalog.....	2-29
2.5.1.3	Searching for Products.....	2-30
2.5.2	The Login Process	2-33
2.5.3	The Ordering Process	2-34
2.5.4	The Customer Registration Process	2-39

Part II Building Your Business Services

3 Getting Started with ADF Business Components

3.1	About ADF Business Components.....	3-1
3.1.1	ADF Business Components Features.....	3-2
3.1.2	ADF Business Components Core Objects	3-3
3.2	Comparison to Familiar 4GL Tools	3-3
3.2.1	Familiar Concepts for Oracle Forms Developers	3-3
3.2.1.1	Similarities Between the Application Module and a "Headless" Form Module .	3-4
3.2.1.2	Similarities Between the Entity Object and a Forms Record Manager	3-5

3.2.1.3	Similarities Between the View Object and a Data Block.....	3-5
3.2.2	Familiar Concepts for PeopleTools Developers	3-5
3.2.2.1	Similarities Between the Application Module and a "Headless" Component.....	3-5
3.2.2.2	Similarities Between the Entity Object and a Record Definition	3-6
3.2.2.3	Similarities Between the View Object and a Row Set.....	3-6
3.2.3	Familiar Concepts for Siebel Tools Developers.....	3-6
3.2.3.1	Similarities Between the entity Object and a Table Object	3-6
3.2.3.2	Similarities Between the View Object and a Business Component.....	3-7
3.2.3.3	Similarities Between the Application Module and a Business Object	3-7
3.2.4	Familiar Functionality for ADO.NET Developers	3-7
3.2.4.1	Similarities Between the Application Module and a Data Set	3-7
3.2.4.2	Similarities Between the Entity Object and a Data Adapter	3-7
3.2.4.3	Similarities Between the View Object and a Data Table	3-8
3.3	Overview of Design Time Facilities	3-8
3.3.1	Choosing a Connection, SQL Platform, and Data Type Map	3-8
3.3.2	Creating New Components Using Wizards	3-9
3.3.3	Creating New Components Using the Context Menu	3-10
3.3.4	Editing Components Using the Component Overview Editor.....	3-10
3.3.5	Displaying Related Components Using Diagrams.....	3-10
3.3.6	Visualizing, Creating, and Editing Components Using UML Diagrams	3-11
3.3.7	Testing Application Modules Using the Oracle ADF Model Tester	3-11
3.3.8	Refactoring Components	3-12
3.4	Overview of the Oracle ADF Active Data Model	3-12
3.4.1	A More Generic Business Service Solution	3-12
3.4.2	Typical Scenarios for an Active Data Model	3-13
3.4.3	Active Data Model Support for Custom Code	3-13
3.5	Overview of the ADF Business Components Implementation.....	3-14
3.5.1	Standard Java and XML.....	3-14
3.5.2	Application Server or Database Independence.....	3-14
3.5.3	Java EE Design Pattern Support	3-15
3.5.4	Source Code Organization	3-15
3.5.5	Package Naming Conventions.....	3-16
3.5.6	Metadata with Optional Custom Java Code.....	3-17
3.5.6.1	Example of an XML-Only Component.....	3-18
3.5.6.2	Example of a Component with Custom Java Class.....	3-18
3.5.7	Basic Data Types	3-19
3.5.8	Generic Versus Strongly-Typed APIs.....	3-21
3.5.9	Custom Interface Support for Client-Accessible Components	3-21
3.5.9.1	Framework Client Interfaces for Components.....	3-22
3.5.9.2	Custom Client Interfaces for Components	3-22
3.6	Overview of Groovy Scripting Language Support.....	3-22
3.6.1	Referencing Business Components Objects in Groovy Expressions	3-25
3.6.2	Referencing Custom Business Components Methods and Attributes in Groovy Expressions 3-26	
3.6.2.1	Referencing Members of the Same Business Component	3-27
3.6.2.2	Referencing Members of Other Business Components	3-28
3.6.3	Manipulating Business Component Attribute Values in Groovy Expressions	3-28

4 Creating a Business Domain Layer Using Entity Objects

4.1	About Entity Objects	4-1
4.1.1	Entity Object Use Cases and Examples	4-2
4.1.2	Additional Functionality for Entity Objects.....	4-2
4.2	Creating Entity Objects and Associations	4-2
4.2.1	How to Create Multiple Entity Objects and Associations from Existing Tables.....	4-3
4.2.2	How to Create Single Entity Objects Using the Create Entity Wizard	4-5
4.2.3	What Happens When You Create Entity Objects and Associations from Existing Tables 4-5	
4.2.3.1	What Happens When Tables Have Foreign Key Relationships	4-6
4.2.3.2	What Happens When a Table Has No Primary Key	4-7
4.2.4	What Happens When You Create an Entity Object for a Synonym or View	4-7
4.2.5	How to Edit an Existing Entity Object or Association	4-7
4.2.6	How to Create Database Tables from Entity Objects	4-8
4.2.7	How to Synchronize an Entity with Changes to Its Database Table.....	4-8
4.2.7.1	Removing an Attribute Associated with a Dropped Column	4-9
4.2.7.2	Addressing a Data Type Change in the Underlying Table	4-9
4.2.8	How to Store Data Pertaining to a Specific Point in Time	4-10
4.2.9	What Happens When You Create Effective Dated Entity Objects	4-11
4.2.10	What You May Need to Know About Creating Entities from Tables.....	4-12
4.3	Creating and Configuring Associations	4-12
4.3.1	How to Create an Association	4-12
4.3.2	What Happens When You Create an Association	4-14
4.3.3	How to Change Entity Association Accessor Names.....	4-14
4.3.4	How to Rename and Move Associations to a Different Package	4-15
4.3.5	What You May Need to Know About Using a Custom View Object in an Association... 4-16	
4.3.6	What You May Need to Know About Composition Associations	4-17
4.4	Creating an Entity Diagram for Your Business Layer.....	4-17
4.4.1	How to Create an Entity Diagram.....	4-18
4.4.2	What Happens When You Create an Entity Diagram	4-19
4.4.3	What You May Need to Know About the XML Component Descriptors	4-20
4.4.4	What You May Need to Know About Changing the Names of Components.....	4-20
4.5	Defining Property Sets	4-20
4.5.1	How to Define a Property Set	4-21
4.5.2	How to Apply a Property Set	4-21
4.6	Defining Attribute Control Hints for Entity Objects	4-22
4.6.1	How to Add Attribute Control Hints	4-22
4.6.2	What Happens When You Add Attribute Control Hints	4-23
4.6.3	How to Define Formatters and Masks.....	4-23
4.7	Working with Resource Bundles	4-25
4.7.1	How to Set Message Bundle Options	4-26
4.7.2	How to Use Multiple Resource Bundles	4-27
4.7.3	How to Internationalize the Date Format	4-27
4.8	Defining Business Logic Groups	4-28
4.8.1	How to Create a Business Logic Group.....	4-29
4.8.2	How to Create a Business Logic Unit	4-30

4.8.3	How to Add Logic to a Business Logic Unit.....	4-30
4.8.4	How to Override Attributes in a Business Logic Unit	4-31
4.8.5	What Happens When You Create a Business Logic Group	4-31
4.8.6	What Happens at Runtime: Invoking a Business Logic Group	4-32
4.9	Configuring Runtime Behavior Declaratively	4-33
4.9.1	How to Configure Declarative Runtime Behavior.....	4-33
4.9.2	What Happens When You Configure Declarative Runtime Behavior	4-34
4.9.3	How to Use Update Batching	4-34
4.10	Setting Attribute Properties.....	4-35
4.10.1	How to Set Database and Java Data Types for an Entity Object Attribute	4-35
4.10.2	How to Indicate Data Type Length, Precision, and Scale.....	4-37
4.10.3	How to Control the Updatability of an Attribute	4-37
4.10.4	How to Make an Attribute Mandatory.....	4-37
4.10.5	How to Define the Primary Key for the Entity.....	4-37
4.10.6	How to Define a Static Default Value	4-38
4.10.7	How to Define a Default Value Using a Groovy Expression	4-38
4.10.8	What Happens When You Create a Default Value Using a Groovy expression....	4-39
4.10.9	How to Synchronize with Trigger-Assigned Values.....	4-39
4.10.10	How to Get Trigger-Assigned Primary Key Values from a Database Sequence....	4-39
4.10.11	How to Protect Against Losing Simultaneously Updated Data	4-40
4.10.12	How to Track Created and Modified Dates Using the History Column.....	4-41
4.10.13	How to Configure Composition Behavior	4-41
4.10.13.1	Orphan-Row Protection for New Composed Entities	4-42
4.10.13.2	Ordering of Changes Saved to the Database	4-42
4.10.13.3	Cascade Update of Composed Details from Refresh-On-Insert Primary Keys	4-42
4.10.13.4	Cascade Delete Support.....	4-42
4.10.13.5	Cascade Update of Foreign Key Attributes When Primary Key Changes.....	4-43
4.10.13.6	Locking of Composite Parent Entities	4-43
4.10.13.7	Updating of Composing Parent History Attributes	4-43
4.10.14	How to Set the Discriminator Attribute for Entity Object Inheritance Hierarchies	4-43
4.10.15	How to Define Alternate Key Values	4-44
4.10.16	What Happens When You Define Alternate Key Values	4-44
4.10.17	What You May Need to Know About Alternate Key Values.....	4-44
4.11	Adding Transient and Calculated Attributes to an Entity Object	4-44
4.11.1	How to Add a Transient Attribute	4-45
4.11.2	What Happens When You Add a Transient Attribute.....	4-45
4.11.3	How to Base a Transient Attribute on a Groovy Expression	4-46
4.11.4	What Happens When You Base a Transient Attribute on a Groovy Expression	4-48
4.11.5	How to Add Java Code in the Entity Class to Perform Calculation	4-48
4.12	Creating Business Events.....	4-48
4.12.1	Introducing Event Definitions	4-49
4.12.2	Introducing Event Points.....	4-49
4.12.3	What You May Need to Know About Event Points	4-50
4.12.4	How to Create a Business Event.....	4-50
4.12.5	What Happens When You Create a Business Event.....	4-51
4.12.6	What You May Need to Know About Payload.....	4-52
4.12.7	How to Publish a Business Event.....	4-52

4.12.8	How to Subscribe to Business Events	4-53
4.13	Generating Custom Java Classes for an Entity Object.....	4-54
4.13.1	How to Generate Custom Classes	4-54
4.13.2	What Happens When You Generate Custom Classes.....	4-55
4.13.3	What Happens When You Generate Entity Attribute Accessors	4-55
4.13.4	How to Navigate to Custom Java Files.....	4-56
4.13.5	What You May Need to Know About Custom Java Classes.....	4-57
4.13.5.1	Framework Base Classes for an Entity Object.....	4-57
4.13.5.2	Safely Adding Code to the Custom Component File.....	4-57
4.13.5.3	Configuring Default Java Generation Preferences	4-58
4.13.5.4	Attribute Indexes and InvokeAccessor Generated Code	4-58
4.13.6	Programmatic Example for Comparison Using Custom Entity Classes	4-59
4.14	Working Programmatically with Entity Objects and Associations	4-62
4.14.1	How to Find an Entity Object by Primary Key	4-62
4.14.2	How to Access an Associated Entity Using the Accessor Attribute	4-63
4.14.3	How to Update or Remove an Existing Entity Row	4-65
4.14.4	How to Create a New Entity Row	4-66
4.14.5	Assigning the Primary Key Value Using an Oracle Sequence.....	4-67
4.14.6	How to Update a Deleted Flag Instead of Deleting Rows.....	4-68
4.14.6.1	Updating a Deleted Flag When a Row Is Removed	4-69
4.14.6.2	Forcing an Update DML Operation Instead of a Delete	4-69
4.14.7	How to Control Entity Posting Order to Prevent Constraint Violations.....	4-70
4.14.7.1	Default Post Processing Order.....	4-70
4.14.7.2	Compositions and Default Post Processing Order	4-70
4.14.7.3	Overriding postChanges() to Control Post Order	4-70
4.14.8	Advanced Entity Association Techniques	4-75
4.14.8.1	Modifying Association SQL Clause to Implement Complex Associations.....	4-75
4.14.8.2	Exposing View Link Accessor Attributes at the Entity Level	4-75
4.14.8.3	Optimizing Entity Accessor Access by Retaining the Row Set.....	4-76
4.15	Creating Custom, Validated Data Types Using Domains	4-77
4.15.1	How to Create a Domain	4-77
4.15.2	What Happens When You Create a Domain	4-78
4.15.3	What You May Need to Know About Domains	4-78
4.15.3.1	Domains as Entity and View Object Attributes	4-78
4.15.3.2	DataCreationException in Custom validate() Method	4-79
4.15.3.3	String Domains and String Value Aggregation	4-79
4.15.3.4	Simple Domains and Built-In Types.....	4-80
4.15.3.5	Simple Domains As Immutable Java Classes.....	4-80
4.15.3.6	Creating Domains for Oracle Object Types When Useful.....	4-80
4.15.3.7	Quickly Navigating to the Domain Class	4-82
4.15.3.8	Domains Packaged in the Common JAR	4-82
4.15.3.9	Custom Domain Properties and Attributes in Entity and View Objects	4-82
4.15.3.10	Inherited Restrictive Properties of Domains in Entity and View Objects	4-82
4.16	Creating New History Types	4-82
4.16.1	How to Create New History Types.....	4-82
4.16.2	How to Remove a History Type.....	4-84
4.17	Basing an Entity Object on a PL/SQL Package API	4-85

4.17.1	How to Create an Entity Object Based on a View.....	4-86
4.17.2	What Happens When You Create an Entity Object Based on a View	4-87
4.17.3	How to Centralize Details for PL/SQL-Based Entities into a Base Class.....	4-87
4.17.4	How to Implement the Stored Procedure Calls for DML Operations	4-88
4.17.5	How to Add Select and Lock Handling	4-89
4.17.5.1	Updating PLSQLEntityImpl Base Class to Handle Lock and Select.....	4-90
4.17.5.2	Implementing Lock and Select for the Product Entity.....	4-91
4.17.5.3	Refreshing the Entity Object After RowInconsistentException.....	4-93
4.18	Basing an Entity Object on a Join View or Remote DBLink	4-94
4.18.1	How to Disable the Use of the RETURNING Clause	4-94
4.18.2	What Happens at Runtime: Disabling the RETURNING Clause.....	4-94
4.19	Using Inheritance in Your Business Domain Layer.....	4-94
4.19.1	Understanding When Inheritance Can Be Useful.....	4-95
4.19.2	How to Create Entity Objects in an Inheritance Hierarchy	4-96
4.19.2.1	Identifying the Discriminator Column and Distinct Values	4-97
4.19.2.2	Identifying the Subset of Attributes Relevant to Each Kind of Entity	4-97
4.19.2.3	Creating the Base Entity Object in an Inheritance Hierarchy	4-98
4.19.2.4	Creating a Subtype Entity Object in an Inheritance Hierarchy	4-99
4.19.3	How to Add Methods to Entity Objects in an Inheritance Hierarchy	4-100
4.19.3.1	Adding Methods Common to All Entity Objects in the Hierarchy	4-100
4.19.3.2	Overriding Common Methods in a Subtype Entity Object.....	4-101
4.19.3.3	Adding Methods Specific to a Subtype Entity Object.....	4-102
4.19.4	What You May Need to Know About Using Inheritance.....	4-103
4.19.4.1	When to Introduce a New Base Entity	4-103
4.19.4.2	Subtype Entity Objects and the findByPrimaryKey() Method	4-103
4.19.4.3	View Objects with Polymorphic Entity Usages	4-103

5 Defining SQL Queries Using View Objects

5.1	About View Objects.....	5-1
5.1.1	View Object Use Cases and Examples.....	5-2
5.1.2	Additional Functionality for View Objects.....	5-4
5.2	Populating View Object Rows from a Single Database Table.....	5-4
5.2.1	How to Create an Entity-Based View Object.....	5-5
5.2.1.1	Creating an Entity-Based View Object from a Single Table.....	5-6
5.2.1.2	Creating a View Object with All the Attributes of an Entity Object	5-8
5.2.2	What Happens When You Create an Entity-Based View Object.....	5-9
5.2.3	How to Create an Expert Mode, Read-Only View Object	5-10
5.2.4	What Happens When You Create a Read-Only View Object	5-12
5.2.5	How to Edit a View Object	5-13
5.2.5.1	Overriding the Inherit Properties from Underlying Entity Object Attributes .	5-13
5.2.5.2	Controlling the Length, Precision, and Scale of View Object Attributes	5-14
5.2.5.3	Converting a Read-Only View Object to Allow Attribute Updates	5-15
5.2.5.4	Customizing View Object Attribute Display in the Overview Editor.....	5-16
5.2.5.5	Modifying the Order of Attributes in the View Object Source File	5-18
5.2.6	How to Show View Objects in a Business Components Diagram.....	5-18
5.3	Populating View Object Rows with Static Data	5-19
5.3.1	How to Create Static View Objects with Data You Enter	5-19

5.3.2	How to Create Static View Objects with Data You Import	5-20
5.3.3	What Happens When You Create a Static List View Object	5-22
5.3.4	How to Edit Static List View Objects	5-23
5.3.5	What You May Need to Know About Static List View Objects	5-23
5.4	Limiting View Object Rows Using Effective Date Ranges.....	5-23
5.4.1	How to Create an Date-Effective View Object	5-24
5.4.2	How to Create New View Rows Using Date-Effective View Objects.....	5-25
5.4.3	How to Update Date-Effective View Rows	5-25
5.4.4	How to Delete Date-Effective View Rows	5-26
5.4.5	What Happens When You Create a Date-Effective View Object	5-26
5.4.6	What You May Need to Know About Date-Effective View Objects and View Links.....	5-27
5.5	Working with Multiple Tables in Join Query Results	5-28
5.5.1	How to Create Joins for Entity-Based View Objects.....	5-28
5.5.2	How to Select Additional Attributes from Reference Entity Usages	5-32
5.5.3	How to Remove Unnecessary Key Attributes from Reference Entity Usages	5-33
5.5.4	How to Hide the Primary Key Attributes from Reference Entity Usages.....	5-33
5.5.5	How to Modify a Default Join Clause to Be an Outer Join When Appropriate	5-34
5.5.6	What Happens When You Reference Entities in a View Object.....	5-36
5.5.7	How to Create Joins for Read-Only View Objects	5-37
5.5.8	How to Test the Join View	5-37
5.5.9	How to Use the Query Builder with Read-Only View Objects.....	5-38
5.5.10	What You May Need to Know About Join View Objects	5-39
5.6	Working with Multiple Tables in a Master-Detail Hierarchy	5-39
5.6.1	How to Create a Master-Detail Hierarchy for Read-Only View Objects.....	5-39
5.6.2	How to Create a Master-Detail Hierarchy for Entity-Based View Objects	5-42
5.6.3	What Happens When You Create Master-Detail Hierarchies Using View Links...	5-43
5.6.4	How to Enable Active Master-Detail Coordination in the Data Model	5-44
5.6.5	How to Test Master-Detail Coordination.....	5-46
5.6.6	How to Access the Detail Collection Using the View Link Accessor	5-46
5.6.6.1	Accessing Attributes of Row by Name	5-46
5.6.6.2	Programmatically Accessing a Detail Collection Using the View Link Accessor.....	5-47
5.6.7	How to Create a Master-Detail Hierarchy for Entity Objects with Transient-Only Attributes	5-47
5.7	Working with a Single Table in a Recursive Master-Detail Hierarchy	5-48
5.7.1	How to Create a Recursive Master-Detail Hierarchy for an Entity-Based View Object ...	5-48
5.7.1.1	Creating an Association-Based, Self-Referential View Link	5-49
5.7.1.2	Exposing the View Instance and Filter with a View Criteria	5-51
5.7.2	What Happens When You Create a Recursive Master-Detail Hierarchy.....	5-53
5.8	Working with View Objects in Declarative SQL Mode.....	5-54
5.8.1	How to Create SQL-Independent View Objects with Declarative SQL Mode	5-55
5.8.1.1	Enabling Declarative SQL Mode for All New View Objects.....	5-56
5.8.1.2	Enabling Declarative SQL Mode for Specific View Objects.....	5-56
5.8.2	How to Filter Declarative SQL-Based View Objects When Table Joins Apply	5-58
5.8.3	How to Filter Master-Detail Related View Objects with Declarative SQL Mode ...	5-60

5.8.4	How to Support Programmatic Execution of Declarative SQL Mode View Objects.....	5-60
5.8.4.1	Forcing Attribute Queries for All Declarative SQL Mode View Objects	5-61
5.8.4.2	Forcing Attribute Queries for Specific Declarative SQL Mode View Objects ..	5-61
5.8.5	What Happens When You Create a View Object in Declarative SQL Mode	5-62
5.8.6	What Happens at Runtime: Declarative SQL Mode Queries.....	5-63
5.8.7	What You May Need to Know About Overriding Declarative SQL Mode Defaults	5-63
5.8.8	What You May Need to Know About Working Programmatically with Declarative SQL Mode View Objects	5-64
5.9	Working with View Objects in Expert Mode.....	5-65
5.9.1	How to Customize SQL Statements in Expert Mode	5-65
5.9.2	How to Name Attributes in Expert Mode.....	5-65
5.9.3	What Happens When You Enable Expert Mode.....	5-66
5.9.4	What You May Need to Know About Expert Mode	5-66
5.9.4.1	Expert Mode Provides Limited Attribute Mapping Assistance	5-67
5.9.4.2	Expert Mode Drops Custom Edits	5-67
5.9.4.3	Expert Mode Ignores Changes to SQL Expressions	5-68
5.9.4.4	Expert Mode Returns Error for SQL Calculations that Change Entity Attributes.....	5-68
5.9.4.5	Expert Mode Retains Formatting of SQL Statement	5-69
5.9.4.6	Expert Mode Wraps Queries as Inline Views.....	5-70
5.9.4.7	Limitation of Inline View Wrapping at Runtime.....	5-70
5.9.4.8	Expert Mode Changes May Affect Dependent Objects	5-71
5.10	Working with Bind Variables.....	5-71
5.10.1	How to Add Bind Variables to a View Object Definition	5-72
5.10.2	How to Reference the Current User in a Named Bind Variable Using Groovy	5-73
5.10.3	What Happens When You Add Named Bind Variables.....	5-74
5.10.4	How to Test Named Bind Variables	5-74
5.10.5	How to Add a WHERE Clause with Named Bind Variables at Runtime	5-75
5.10.6	How to Set Existing Bind Variable Values at Runtime	5-77
5.10.7	What Happens at Runtime: Dynamic Read-Only View Object WHERE Clause	5-78
5.10.8	What You May Need to Know About Named Bind Variables	5-80
5.10.8.1	An Error Related to Clearing Bind Variables	5-80
5.10.8.2	A Helper Method to Remove Named Bind Variables	5-80
5.10.8.3	Errors Related to Naming Bind Variables.....	5-81
5.10.8.4	Default Value of NULL for Bind Variables.....	5-82
5.11	Working with Named View Criteria.....	5-82
5.11.1	How to Create Named View Criteria Declaratively	5-83
5.11.2	What Happens When You Create a Named View Criteria	5-88
5.11.3	What You May Need to Know About Bind Variable Options.....	5-89
5.11.4	What You May Need to Know About Nested Expressions.....	5-90
5.11.5	How to Set User Interface Hints on View Criteria to Support Search Forms.....	5-90
5.11.6	How to Test View Criteria Using the Oracle ADF Model Tester	5-94
5.11.7	How to Create View Criteria Programmatically	5-95
5.11.8	What Happens at Runtime: How the View Criteria Is Applied to a View Object..	5-96
5.11.9	What You May Need to Know About the View Criteria API.....	5-97
5.11.9.1	Referencing Attribute Names in View Criteria.....	5-97

5.11.9.2	Referencing Bind Variables in View Criteria.....	5-97
5.11.9.3	Altering Compound Search Conditions Using Multiple View Criteria.....	5-98
5.11.9.4	Searching for a Row Whose Attribute Value Is NULL Value.....	5-99
5.11.9.5	Searching for Rows Whose Attribute Value Matches a Value in a List.....	5-99
5.11.9.6	Searching Case-Insensitively	5-99
5.11.9.7	Clearing View Criteria in Effect	5-99
5.11.10	What You May Need to Know About Query-by-Example Criteria.....	5-100
5.12	Working with List of Values (LOV) in View Object Attributes	5-100
5.12.1	How to Define a Single LOV-Enabled View Object Attribute	5-102
5.12.2	How to Define Cascading Lists for LOV-Enabled View Object Attributes	5-103
5.12.2.1	Creating a Data Source View Object to Control the Cascading List.....	5-104
5.12.2.2	Creating a View Accessor to Filter the Cascading List	5-105
5.12.3	How to Specify Multiple LOVs for an LOV-Enabled View Object Attribute.....	5-107
5.12.4	How to Define an LOV to Display a Reference Attribute	5-109
5.12.5	How to Set User Interface Hints on a View Object LOV-Enabled Attribute	5-111
5.12.6	How to Handle Date Conversion for List Type UI Components	5-115
5.12.7	How to Automatically Refresh the View Object of the View Accessor.....	5-115
5.12.8	How to Test LOV-Enabled Attributes Using the Oracle ADF Model Tester.....	5-117
5.12.9	What Happens When You Define an LOV for a View Object Attribute	5-118
5.12.10	What Happens at Runtime: How an LOV Queries the List Data Source.....	5-119
5.12.11	What You May Need to Know About Lists.....	5-120
5.12.11.1	Inheritance of AttributeDef Properties from Parent View Object Attributes.	5-120
5.12.11.2	Using Validators to Validate Attribute Values	5-121
5.13	Defining Attribute UI Hints for View Objects.....	5-121
5.13.1	How to Add Attribute UI Hints	5-121
5.13.2	What Happens When You Add Attribute UI Hints	5-122
5.13.3	How to Define UI Category Hints.....	5-123
5.13.4	What Happens When You Assign Attributes to UI Categories.....	5-126
5.13.5	What You May Need to Know About Resource Bundles.....	5-128
5.14	Adding Calculated and Transient Attributes to a View Object	5-128
5.14.1	How to Add a SQL-Calculated Attribute.....	5-128
5.14.2	What Happens When You Add a SQL-Calculated Attribute	5-129
5.14.3	How to Add a Transient Attribute	5-130
5.14.4	How to Add a Validation Rule to a Transient Attribute.....	5-132
5.14.5	What Happens When You Add a Transient Attribute.....	5-133
5.14.6	Adding Java Code in the View Row Class to Perform Calculation	5-134
5.14.7	What You May Need to Know About Transient Attributes.....	5-134

6 Testing View Instance Queries

6.1	About View Instance Queries	6-1
6.1.1	View Instance Use Cases and Examples	6-1
6.1.2	Additional Functionality for View Instances.....	6-1
6.2	Creating an Application Module to Test View Instances	6-2
6.2.1	How to Create the Application Module with Individual View Object Instances	6-2
6.2.2	How to Create the Application Module with Master-Detail View Object Instances.	6-3
6.3	Testing View Object Instances Using the Oracle ADF Model Tester	6-5
6.3.1	How to Run the Oracle ADF Model Tester.....	6-6

6.3.2	How to Test Entity-Based View Objects Interactively	6-8
6.3.3	How to Update the Oracle ADF Model Tester to Display Project Changes	6-10
6.3.4	What Happens When You Use the Oracle ADF Model Tester	6-10
6.3.5	How to Simulate End-User Interaction in the Oracle ADF Model Tester	6-11
6.3.5.1	Testing Master-Detail Coordination	6-13
6.3.5.2	Testing UI Hints.....	6-13
6.3.5.3	Testing Business Domain Layer Validation.....	6-13
6.3.5.4	Testing Alternate Language Message Bundles and UI Hints	6-14
6.3.5.5	Testing View Objects That Reference Entity Usages.....	6-14
6.3.5.6	Testing Row Creation and Default Value Generation	6-14
6.3.5.7	Testing That New Detail Rows Have Correct Foreign Keys.....	6-15
6.3.6	How to Test Multiuser Scenarios in the Oracle ADF Model Tester	6-15
6.3.7	How to Customize Configuration Options Before Running the Tester	6-15
6.3.8	How to Enable ADF Business Components Debug Diagnostics.....	6-16
6.3.9	What Happens at Runtime: How View Objects and Entity Objects Cooperate	6-17
6.3.9.1	What Happens at Runtime: After a View Object Executes Its Query	6-17
6.3.9.2	What Happens at Runtime: After a View Row Attribute Is Modified	6-19
6.3.9.3	What Happens at Runtime: After a Foreign Key Attribute is Changed.....	6-20
6.3.9.4	What Happens at Runtime: After a Transaction is Committed.....	6-21
6.3.9.5	What Happens at Runtime: After a View Object Requeries Data	6-22
6.3.10	What You May Need to Know About Optimizing View Object Runtime Performance .. 6-23	
6.4	Testing View Object Instances Programmatically.....	6-26
6.4.1	ViewObject Interface Methods for Working with the View Object's Default RowSet..... 6-26	
6.4.1.1	The Role of the Key Object in a View Row or Entity Row	6-27
6.4.1.2	The Role of the Entity Cache in the Transaction.....	6-28
6.4.2	How to Create a Command-Line Java Test Client.....	6-29
6.4.2.1	Generating a Test Client with Skeleton Code.....	6-29
6.4.2.2	Modifying the Skeleton Code to Create the Test Client	6-30
6.4.3	What Happens When You Run a Test Client Program.....	6-32
6.4.4	What You May Need to Know About Running a Test Client.....	6-32
6.4.5	How to Count the Number of Rows in a Row Set	6-32
6.4.6	How to Access a Detail Collection Using the View Link Accessor	6-33
6.4.7	How to Iterate Over a Master-Detail-Detail Hierarchy.....	6-35
6.4.8	How to Find a Row and Update a Foreign Key Value.....	6-37
6.4.9	How to Create a New Row for a View Object Instance	6-38
6.4.10	How to Retrieve the Row Key Identifying a Row	6-39
6.4.11	How to Authenticate Test Users in the Test Client.....	6-41

7 Defining Validation and Business Rules Declaratively

7.1	About Declarative Validation	7-1
7.1.1	Declarative Validation Use Cases and Examples.....	7-2
7.1.2	Additional Functionality for Declarative Validation	7-2
7.2	Understanding the Validation Cycle	7-2
7.2.1	Types of Entity Object Validation Rules	7-3
7.2.1.1	Attribute-Level Validation Rules	7-3

7.2.1.2	Entity-Level Validation Rules.....	7-3
7.2.2	Understanding Commit Processing and Validation	7-3
7.2.3	Understanding the Impact of Composition on Validation Order	7-4
7.2.4	Avoiding Infinite Validation Cycles	7-4
7.2.5	What Happens When Validations Fail	7-4
7.2.6	Understanding Entity Objects Row States	7-5
7.2.7	Understanding Bundled Exception Mode	7-6
7.3	Adding Validation Rules to Entity Objects and Attributes	7-6
7.3.1	How to Add a Validation Rule to an Entity or Attribute	7-6
7.3.2	How to View and Edit a Validation Rule on an Entity Object or Attribute.....	7-7
7.3.3	What Happens When You Add a Validation Rule	7-7
7.3.4	What You May Need to Know About Entity and Attribute Validation Rules.....	7-8
7.4	Using the Built-in Declarative Validation Rules	7-9
7.4.1	How to Ensure That Key Values Are Unique.....	7-9
7.4.2	What Happens When You Use a Unique Key Validator	7-10
7.4.3	How to Validate Based on a Comparison	7-10
7.4.4	What Happens When You Validate Based on a Comparison.....	7-12
7.4.5	How to Validate Using a List of Values	7-13
7.4.6	What Happens When You Validate Using a List of Values	7-14
7.4.7	What You May Need to Know About the List Validator	7-15
7.4.8	How to Make Sure a Value Falls Within a Certain Range.....	7-15
7.4.9	What Happens When You Use a Range Validator	7-16
7.4.10	How to Validate Against a Number of Bytes or Characters	7-16
7.4.11	What Happens When You Validate Against a Number of Bytes or Characters	7-17
7.4.12	How to Validate Using a Regular Expression	7-17
7.4.13	What Happens When You Validate Using a Regular Expression.....	7-19
7.4.14	How to Use the Average, Count, or Sum to Validate a Collection	7-19
7.4.15	What Happens When You Use Collection Validation	7-20
7.4.16	How to Determine Whether a Key Exists	7-20
7.4.17	What Happens When You Use a Key Exists Validator	7-22
7.4.18	What You May Need to Know About Declarative Validators and View Accessors	7-22
7.5	Using Groovy Expressions For Validation and Business Rules.....	7-23
7.5.1	How to Reference Entity Object Methods in Groovy Validation Expressions	7-23
7.5.2	How to Validate Using a True/False Expression	7-25
7.5.3	What Happens When You Add a Groovy Expression.....	7-26
7.6	Triggering Validation Execution	7-27
7.6.1	How to Specify Which Attributes Fire Validation.....	7-28
7.6.2	What Happens When You Constrain Validation Execution with Triggering Attributes .	7-29
7.6.3	How to Set Preconditions for Validation	7-30
7.6.4	How to Set Transaction-Level Validation	7-30
7.6.5	What You May Need to Know About the Order of Validation Execution	7-30
7.7	Creating Validation Error Messages	7-31
7.7.1	How to Create Validation Error Messages	7-31
7.7.2	How to Localize Validation Messages.....	7-31
7.7.3	How to Conditionally Raise Error Messages Using Groovy.....	7-32
7.7.4	How to Embed a Groovy Expression in an Error Message	7-32

7.8	Setting the Severity Level for Validation Exceptions	7-34
7.9	Bulk Validation in SQL	7-34

8 Implementing Validation and Business Rules Programmatically

8.1	About Programmatic Business Rules.....	8-1
8.1.1	Programmatic Business Rules Use Cases and Examples.....	8-2
8.1.2	Additional Functionality for Programmatic Business Rules.....	8-3
8.2	Using Method Validators.....	8-3
8.2.1	How to Create an Attribute-Level Method Validator	8-4
8.2.2	What Happens When You Create an Attribute-Level Method Validator.....	8-5
8.2.3	How to Create an Entity-Level Method Validator.....	8-6
8.2.4	What Happens When You Create an Entity-Level Method Validator	8-7
8.2.5	What You May Need to Know About Translating Validation Rule Error Messages	8-7
8.3	Assigning Programmatically Derived Attribute Values	8-8
8.3.1	How to Provide Default Values for New Rows at Create Time	8-8
8.3.1.1	Choosing Between create() and initDefaultExpressionAttributes() Methods.....	8-8
8.3.1.2	Eagerly Defaulting an Attribute Value from a Database Sequence	8-8
8.3.2	How to Assign Derived Values Before Saving.....	8-9
8.3.3	How to Assign Derived Values When an Attribute Value Is Set	8-10
8.4	Undoing Pending Changes to an Entity Using the Refresh Method	8-10
8.4.1	How to Control What Happens to New Rows During a Refresh	8-11
8.4.2	How to Cascade Refresh to Composed Children Entity Rows.....	8-11
8.5	Using View Objects for Validation	8-11
8.5.1	How to Use View Accessors for Validation Against View Objects.....	8-11
8.5.2	How to Validate Conditions Related to All Entities of a Given Type.....	8-12
8.5.3	What You May Need to Know About Row Set Access with View Accessors	8-14
8.6	Accessing Related Entity Rows Using Association Accessors	8-14
8.6.1	How to Access Related Entity Rows.....	8-14
8.6.2	How to Access Related Entity Row Sets	8-15
8.7	Referencing Information About the Authenticated User.....	8-16
8.8	Accessing Original Attribute Values.....	8-16
8.9	Storing Information About the Current User Session	8-16
8.9.1	How to Store Information About the Current User Session	8-16
8.9.2	How to Use Groovy to Access Information About the Current User Session.....	8-17
8.10	Accessing the Current Date and Time	8-18
8.11	Sending Notifications Upon a Successful Commit	8-18
8.12	Conditionally Preventing an Entity Row from Being Removed.....	8-18
8.13	Determining Conditional Updatability for Attributes	8-19
8.14	Implementing Custom Validation Rules.....	8-19
8.14.1	How to Create a Custom Validation Rule.....	8-20
8.14.2	Adding a Design Time Bean Customizer for Your Rule.....	8-22
8.14.3	How to Register and Using a Custom Rule in JDeveloper.....	8-22
8.14.3.1	Registering a Custom Validator at the Project Level.....	8-23
8.14.3.2	Registering a Custom Validator at the IDE Level.....	8-23

9 Implementing Business Services with Application Modules

9.1	About Application Modules.....	9-1
9.1.1	Application Module Use Cases and Examples.....	9-2
9.1.2	Additional Functionality for Application Modules.....	9-3
9.2	Creating and Modifying an Application Module	9-3
9.2.1	How to Create an Application Module	9-4
9.2.2	What Happens When You Create an Application Module	9-5
9.2.3	How to Add a View Object to an Application Module.....	9-5
9.2.3.1	Adding a View Object Instance to an Existing Application Module	9-5
9.2.3.2	Adding Master-Detail View Object Instances to an Application Module	9-6
9.2.3.3	Customizing a View Object Instance that You Add to an Application Module .	9-9
9.2.4	What Happens When You Add a View Object to an Application Module	9-11
9.2.5	How to Edit an Existing Application Module	9-11
9.2.6	How to Change the Data Control Name Before You Begin Building Pages.....	9-12
9.2.7	What You May Need to Know About Application Module Granularity.....	9-12
9.2.8	What You May Need to Know About View Object Components and View Object Instances	9-13
9.3	Configuring Your Application Module Database Connection	9-13
9.3.1	How to Use a JDBC Data Source Connection Type.....	9-14
9.3.2	How to Use a JDBC URL Connection Type.....	9-15
9.3.3	What Happens When You Create an Application Module Database Connection .	9-15
9.3.4	How to Change Your Application Module's Runtime Configuration.....	9-17
9.3.5	How to Change the Database Connection for Your Project	9-18
9.4	Defining Nested Application Modules.....	9-18
9.4.1	How to Define a Nested Application Module.....	9-19
9.4.2	What You May Need to Know About Root Application Modules Versus Nested Application Module Usages	9-20
9.5	Creating an Application Module Diagram for Your Business Service	9-21
9.5.1	How to Create an Application Module Diagram.....	9-21
9.5.2	What Happens When You Create an Application Module Diagram	9-22
9.5.3	How to Use the Diagram to Edit the Application Module.....	9-22
9.5.4	How to Control Diagram Display Options.....	9-22
9.5.5	How to Filtering Method Names Displayed in the Diagram.....	9-23
9.5.6	How to Show Related Objects and Implementation Files in the Diagram.....	9-23
9.5.7	How to Publish the Application Module Diagram	9-24
9.5.8	How to Test the Application Module from the Diagram	9-24
9.6	Supporting Multipage Units of Work.....	9-24
9.6.1	How to Simulate State Management in the Oracle ADF Model Tester.....	9-25
9.6.2	What Happens at Runtime: How the Application Uses Application Module Pooling and State Management	9-25
9.7	Customizing an Application Module with Service Methods.....	9-27
9.7.1	How to Generate a Custom Class for an Application Module	9-27
9.7.2	What Happens When You Generate a Custom Class for an Application Module .	9-28
9.7.3	What You May Need to Know About Default Code Generation	9-28
9.7.4	How to Add a Custom Service Method to an Application Module.....	9-29
9.7.5	How to Test the Custom Application Module Using a Static Main Method.....	9-30
9.7.6	What You May Need to Know About Programmatic Row Set Iteration	9-32

9.8	Customizing Application Module Message Strings	9-33
9.8.1	How to Add a Resource Bundle to an Application Module	9-33
9.8.2	What Happens When You Add a Resource Bundle to an Application Module	9-35
9.9	Publishing Custom Service Methods to UI Clients.....	9-35
9.9.1	How to Publish a Custom Method on the Application Module's Client Interface.	9-35
9.9.2	What Happens When You Publish Custom Service Methods	9-36
9.9.3	How to Generate Client Interfaces for View Objects and View Rows.....	9-37
9.9.4	How to Test Custom Service Methods Using the Oracle ADF Model Tester	9-38
9.9.5	What You May Need to Know About Method Signatures on the Client Interface	9-39
9.9.6	What You May Need to Know About Passing Information from the Data Model	9-40
9.10	Working Programmatically with an Application Module's Client Interface.....	9-40
9.10.1	How to Work Programmatically with an Application Module's Client Interface..	9-40
9.10.2	What Happens at Runtime: How the Application Module's Client Interface is Accessed	9-42
9.10.3	How to Access an Application Module Client Interface in a Fusion Web Application....	9-43
9.11	Overriding Built-in Framework Methods	9-45
9.11.1	How to Override a Built-in Framework Method	9-45
9.11.2	What Happens When You Override a Built-in Framework Method.....	9-46
9.11.3	How to Override prepareSession() to Set Up an Application Module for a New User Session	9-47
9.12	Calling a Web Service from an Application Module.....	9-48
9.12.1	How to Call an External Service Programmatically	9-49
9.12.1.1	Creating a Web Service Proxy Class to Programmatically Access the Service	9-50
9.12.1.2	Calling the Web Service Proxy Template to Invoke the Service.....	9-50
9.12.1.3	Calling a Web Service Method Using the Proxy Class in an Application Module....	9-51
9.12.2	What Happens When You Create the Web Service Proxy	9-51
9.12.3	What Happens at Runtime: When You Call a Web Service Using a Web Service Proxy Class	9-52
9.12.4	What You May Need to Know About Web Service Proxies	9-52
9.12.4.1	Using a Try-Catch Block to Handle Web Service Exceptions	9-52
9.12.4.2	Separating Application Module and Web Services Transactions	9-53
9.12.4.3	Setting Browser Proxy Information	9-53
9.12.4.4	Invoking Application Modules with a Web Service Proxy Class.....	9-53

10 Sharing Application Module View Instances

10.1	About Shared Application Modules	10-1
10.1.1	Shared Application Module Use Cases and Examples	10-1
10.1.2	Additional Functionality for Shared Application Modules	10-2
10.2	Sharing an Application Module Instance.....	10-2
10.2.1	How to Create a Shared Application Module Instance	10-3
10.2.2	What Happens When You Define a Shared Application Module.....	10-4
10.2.3	What You May Need to Know About Design Time Scope of the Shared Application Module	10-6
10.2.4	What You May Need to Know About the Design Time Scope of View Instances of the Shared Application Module	10-6

10.2.5	What You May Need to Know About Managing the Number of Shared Query Collections	10-6
10.2.6	What You May Need to Know About Shared Application Modules and Connection Pooling	10-7
10.3	Defining a Base View Object for Use with Lookup Tables	10-7
10.3.1	How to Create a Base View Object Definition for a Lookup Table	10-8
10.3.2	What Happens When You Create a Base View Object	10-9
10.3.3	How to Define the WHERE Clause of the Lookup View Object Using View Criteria	10-12
10.3.4	What Happens When You Create a View Criteria with the Editor	10-13
10.3.5	What Happens at Runtime: How a View Instance Accesses Lookup Data	10-14
10.4	Accessing View Instances of the Shared Service	10-14
10.4.1	How to Create a View Accessor for an Entity Object or View Object	10-15
10.4.2	How to Validate Against the Attribute Values Specified by a View Accessor	10-17
10.4.3	What Happens When You Define a View Accessor Validator	10-18
10.4.4	What You May Need to Know About Dynamic Filtering with View Accessors	10-19
10.4.5	How to Create an LOV Based on a Lookup Table	10-19
10.4.6	What Happens When You Define an LOV for a View Object Attribute	10-21
10.4.7	How to Automatically Refresh the View Object of the View Accessor	10-22
10.4.8	What Happens at Runtime: How the Attribute Displays the List of Values	10-22
10.4.9	What You May Need to Know About Programmatically Invoking Database Change Notifications	10-23
10.4.10	What You May Need to Know About Inheritance of AttributeDef Properties	10-23
10.4.11	What You May Need to Know About Using Validators	10-24
10.5	Testing View Object Instances in a Shared Application Module	10-24
10.5.1	How to Test the Base View Object Using the Oracle ADF Model Tester	10-24
10.5.2	How to Test LOV-Enabled Attributes Using the Oracle ADF Model Tester	10-25
10.5.3	What Happens When You Use the Oracle ADF Model Tester	10-25
10.5.4	What Happens at Runtime: How Another Service Accesses the Shared Application Module Cache	10-26

11 Integrating Service-Enabled Application Modules

11.1	About Service-Enabled Application Modules	11-1
11.1.1	Service-Enabled Application Module Use Cases and Examples	11-2
11.1.2	Additional Functionality for Service-Enabled Application Modules	11-2
11.2	Publishing Service-Enabled Application Modules	11-2
11.2.1	How to Enable the Application Module Service Interface	11-3
11.2.2	What Happens When You Create an Application Module Service Interface	11-8
11.2.2.1	Remote Common Interface	11-10
11.2.2.2	Remote Service Schema File	11-11
11.2.2.3	Remote Service Definition File	11-11
11.2.2.4	Remote Server Class	11-12
11.2.2.5	connections.xml	11-13
11.2.3	What You May Need to Know About Method Signatures on the ADF Web Service Interface	11-14
11.2.4	How to Service-Enable Individual View Objects	11-15
11.2.5	How to Customize the SDO Properties of Service-Enabled View Objects	11-17
11.2.5.1	Excluding Individual SDO Properties in a Generated SDO Component	11-17

11.2.5.2	Associating Related SDO Properties Using Complex Data Types.....	11-17
11.2.6	How to Support Nested Processing in Service-Enabled Master-Detail View Objects	11-19
11.2.7	What Happens When You Create SDO Classes.....	11-21
11.2.7.1	Service Data Object Interface	11-21
11.2.7.2	Service Data Object Class	11-21
11.2.7.3	Service Data Object Schema File.....	11-21
11.2.7.4	Service Data Object Result Class and Interface.....	11-22
11.2.8	How to Expose a Declarative Find Operation Filtered By a Required Bind Variable.....	11-23
11.2.9	How to Expose a Custom Find Method Filtered By a Required Bind Variable	11-24
11.2.10	How to Generate Asynchronous ADF Web Service Methods	11-25
11.2.11	What Happens When You Generate Asynchronous ADF Web Service Methods	11-25
11.2.12	What Happens at Runtime: How the Asynchronous Call Is Made	11-27
11.2.13	How to Set Preferences for Generating the ADF Web Service Interface.....	11-28
11.2.14	How to Secure the ADF Web Service for Access By SOAP Clients	11-29
11.2.15	How to Secure the ADF Web Service for Access By RMI Clients	11-32
11.2.15.1	Enabling Authentication for RMI Clients	11-32
11.2.15.2	Enabling Authorization for RMI Clients.....	11-35
11.2.16	How to Grant Test Users Access to the Service.....	11-36
11.2.17	How to Enable Support for Binary Attachments for SOAP Clients.....	11-39
11.2.18	How to Test the Web Service Using Integrated WebLogic Server	11-40
11.2.19	How to Prevent Custom Service Methods from Timing Out.....	11-41
11.2.20	How to Deploy Web Services to Oracle WebLogic Server	11-43
11.3	Accessing Remote Data Over the Service-Enabled Application Module.....	11-45
11.3.1	How to Use Service-Enabled Entity Objects and View Objects.....	11-46
11.3.1.1	Creating Entity Objects Backed by SDO Services.....	11-46
11.3.1.2	Creating View Objects Backed by SDO Services	11-48
11.3.2	What Happens When You Create Service-Backed Business Components	11-48
11.3.3	How to Update the Data Model for Service-Backed Business Components	11-49
11.3.4	How to Configure the Service-Backed Business Components Runtime	11-51
11.3.4.1	Adding the SDO Client Library to the Classpath.....	11-52
11.3.4.2	Registering the ADF Business Components Service in the Consuming Application's connections.xml for the EJB RMI Protocol	11-53
11.3.4.3	Registering the ADF Business Components Service in the Consuming Application's connections.xml for the SOAP Protocol	11-55
11.3.4.4	Registering the ADF Business Components Service in the Consuming Application's connections.xml for Fabric SDO Binding	11-58
11.3.5	How to Test the Service-Backed Components in the Oracle ADF Model Tester ..	11-59
11.3.6	How to Invoke Operations of the Service-Backed Components in the Consuming Application	11-60
11.3.7	What You May Need to Know About Creating Service Data Objects in the Consuming Application	11-61
11.3.8	What Happens at Runtime: How the Application Accesses the Published Application Module	11-61
11.3.9	What You May Need to Know About Service-Backed Entity Objects and View Objects.	11-61

12 Extending Business Components Functionality

12.1	About Extending Business Components Functionality	12-1
12.1.1	Extending Business Components Use Cases and Examples	12-2
12.1.2	Additional Functionality for Extending Business Components	12-2
12.2	Globally Extending ADF Business Components Functionality	12-2
12.2.1	How To Create a Framework Extension Class.....	12-2
12.2.2	What Happens When You Create a Framework Extension Class.....	12-4
12.2.3	How to Base an ADF Component on a Framework Extension Class	12-4
12.2.4	How to Define Framework Extension Classes for All New Components	12-6
12.2.5	How to Define Framework Extension Classes for All New Projects	12-7
12.2.6	What Happens When You Base a Component on a Framework Extension Class..	12-7
12.2.6.1	XML-Only Components	12-7
12.2.6.2	Components with Custom Java Classes.....	12-8
12.2.7	What You May Need to Know About Updating the Extends Clause in Custom Component Java Files	12-9
12.3	Creating a Layer of Framework Extensions.....	12-9
12.3.1	How to Create Your Layer of Framework Extension Layer Classes.....	12-10
12.3.2	How to Package Your Framework Extension Layer in a JAR File	12-11
12.3.3	How to Create a Library Definition for Your Framework Extension JAR File.....	12-11
12.4	Customizing Framework Behavior with Extension Classes.....	12-12
12.4.1	How to Access Runtime Metadata For View Objects and Entity Objects	12-12
12.4.2	How to Implement Generic Functionality Using Runtime Metadata.....	12-13
12.4.3	How to Implement Generic Functionality Driven by Custom Properties	12-14
12.4.4	What You May Need to Know About the Kinds of Attributes.....	12-15
12.4.5	What You May Need to Know About Custom Properties	12-15
12.5	Creating Generic Extension Interfaces.....	12-15
12.6	Invoking Stored Procedures and Functions.....	12-18
12.6.1	How to Invoke Stored Procedures with No Arguments	12-18
12.6.2	How to Invoke Stored Procedure with Only IN Arguments	12-18
12.6.3	How to Invoke Stored Function with Only IN Arguments.....	12-19
12.6.4	How to Call Other Types of Stored Procedures.....	12-21
12.7	Accessing the Current Database Transaction	12-22
12.8	Customizing Business Components Error Messages	12-23
12.8.1	How to Customize Base ADF Business Components Error Messages	12-24
12.8.2	What Happens When You Customize Base ADF Business Components Error Messages 12-26	
12.8.3	How to Customize Error Messages for Database Constraint Violations	12-26
12.8.4	How to Implement a Custom Constraint Error Handling Routine	12-26
12.8.4.1	Creating a Custom Database Transaction Framework Extension Class	12-27
12.8.4.2	Configuring an Application Module to Use a Custom Database Transaction Class . 12-27	
12.9	Creating Extended Components Using Inheritance	12-28
12.9.1	How To Create a Component That Extends Another	12-29
12.9.2	How To Extend a Component After Creation.....	12-29
12.9.3	What Happens When You Create a Component That Extends Another	12-29
12.9.3.1	Understanding an Extended Component's XML Descriptor.....	12-30
12.9.3.2	Understanding Java Code Generation for an Extended Component	12-30

12.9.4	What You May Need to Know.....	12-31
12.9.4.1	You Can Use Parent Classes and Interfaces to Work with Extended Components ... 12-31	
12.9.4.2	Class Extends is Disabled for Extended Components	12-33
12.9.4.3	Interesting Aspects You Can Extend for Key Component Types	12-33
12.9.4.4	Extended Components Have Attribute Indices Relative to Parent.....	12-33
12.10	Substituting Extended Components in a Delivered Application	12-34
12.10.1	How To Substitute an Extended Component.....	12-34
12.10.2	What Happens When You Substitute	12-35
12.10.3	How to Enable the Substituted Components in the Base Application	12-36

Part III Using the ADF Model Layer

13 Using ADF Model in a Fusion Web Application

13.1	About ADF Data Binding	13-1
13.2	Additional Functionality.....	13-3
13.3	Exposing Application Modules with Oracle ADF Data Controls.....	13-3
13.3.1	How an Application Module Data Control Appears in the Data Controls Panel... 13-4	
13.3.1.1	How the Data Model and Service Methods Appear in the Data Controls Panel..... 13-6	
13.3.1.2	How Transaction Control Operations Appear in the Data Controls Panel	13-6
13.3.1.3	How View Objects Appear in the Data Controls Panel	13-7
13.3.1.4	How Nested Application Modules Appear in the Data Controls Panel	13-9
13.3.2	How to Open the Data Controls Panel	13-10
13.3.3	How to Refresh the Data Controls Panel	13-10
13.3.4	Packaging a Data Control for Use in Another Project.....	13-11
13.4	Using the Data Controls Panel.....	13-11
13.4.1	How to Use the Data Controls Panel	13-14
13.4.2	What Happens When You Use the Data Controls Panel.....	13-16
13.4.3	What Happens at Runtime: How the Binding Context Works.....	13-17
13.5	Working with the DataBindings.cpx File	13-18
13.5.1	How JDeveloper Creates a DataBindings.cpx File	13-18
13.5.2	What Happens When JDeveloper Creates a DataBindings.cpx File	13-18
13.6	Configuring the ADF Binding Filter	13-20
13.6.1	How JDeveloper Configures the ADF Binding Filter.....	13-21
13.6.2	What Happens When JDeveloper Configures an ADF Binding Filter	13-21
13.6.3	What Happens at Runtime: How the ADF Binding Filter Works	13-21
13.7	Working with Page Definition Files	13-22
13.7.1	How JDeveloper Creates a Page Definition File	13-22
13.7.2	What Happens When JDeveloper Creates a Page Definition File.....	13-23
13.7.2.1	Bindings Binding Objects Defined in the Page Definition File.....	13-26
13.7.2.2	Executable Binding Objects Defined in the Page Definition File.....	13-28
13.8	Creating ADF Data Binding EL Expressions	13-31
13.8.1	How to Create an ADF Data Binding EL Expression.....	13-31
13.8.1.1	Opening the Expression Builder from the Property Inspector	13-32
13.8.1.2	Using the Expression Builder	13-32
13.8.2	What You May Need to Know About ADF Binding Properties.....	13-33

13.9	Using Simple UI First Development	13-34
13.9.1	How to Apply ADF Model Data Binding to Existing UI Components	13-35
13.9.2	What Happens When You Apply ADF Model Data Binding to UI Components	13-36

14 Exposing Web Services Using the ADF Model Layer

14.1	About Web Services in Fusion Web Applications	14-1
14.1.1	Web Services Use Cases and Examples.....	14-1
14.1.2	Additional Functionality for Web Services in Fusion Applications.....	14-2
14.2	Creating Web Service Data Controls.....	14-2
14.2.1	How to Create a Web Service Data Control.....	14-2
14.2.2	How to Adjust the Endpoint for a Web Service Data Control	14-3
14.2.3	How to Refresh a Web Service Data Control.....	14-3
14.2.4	What You May Need to Know About Web Service Data Controls.....	14-4
14.3	Creating a New Web Service Connection	14-6
14.3.1	How to Create a New Web Service Connection.....	14-6
14.4	Securing Web Service Data Controls	14-7
14.4.1	WS-Security Specification.....	14-8
14.4.2	Using Key Stores.....	14-8
14.4.3	How to Define Web Service Data Control Security	14-8

15 Exposing URL Services Using the ADF Model Layer

15.1	About Using ADF Model with URL Services	15-1
15.1.1	URL Services Use Cases and Examples.....	15-1
15.1.2	Additional Functionality for URL Services.....	15-2
15.2	Exposing URL Services with ADF Data Controls	15-2
15.2.1	How to Create a URL Connection.....	15-2
15.2.2	How to Create a URL Service Data Control	15-3
15.2.3	What You May Need to Know About URL Service Data Controls.....	15-4
15.3	Using URL Service Data Controls	15-4

16 Using Validation in the ADF Model Layer

16.1	About ADF Model Layer Validation.....	16-1
16.1.1	ADF Model Layer Validation Use Cases and Examples.....	16-1
16.1.2	Additional Functionality for ADF Model Layer Validation.....	16-2
16.2	Defining Validation Rules in the ADF Model Layer	16-2
16.2.1	How to Add Validation	16-2
16.2.2	What Happens at Runtime: Model Validation Rules	16-3
16.3	Customizing Error Handling	16-3
16.3.1	How to Customize the Detail Portion of a Message.....	16-4
16.3.2	How to Write an Error Handler to Deal with Multiple Threads	16-6

17 Designing a Page Using Placeholder Data Controls

17.1	About Placeholder Data Controls.....	17-1
17.1.1	Placeholder Data Controls Use Cases and Examples.....	17-2
17.1.2	Additional Functionality for Placeholder Data Controls.....	17-2
17.2	Creating Placeholder Data Controls.....	17-3

17.2.1	How to Create a Placeholder Data Control.....	17-3
17.2.2	What Happens When You Create a Placeholder Data Control	17-4
17.3	Creating Placeholder Data Types	17-5
17.3.1	How to Create a Placeholder Data Type	17-6
17.3.2	What Happens When You Create a Placeholder Data Type.....	17-9
17.3.3	How to Configure a Placeholder Data Type Attribute to Be an LOV	17-10
17.3.3.1	Configuring an Attribute to Be a Fixed LOV.....	17-10
17.3.3.2	Configuring an Attribute to Be a Dynamic LOV	17-11
17.3.4	How to Create Master-Detail Data Types	17-13
17.3.5	What Happens When You Create a Master-Detail Data Type.....	17-15
17.3.6	How to Add Sample Data	17-15
17.3.6.1	Adding Sample Data Manually.....	17-15
17.3.6.2	Importing Sample Data	17-16
17.3.7	What Happens When You Add Sample Data	17-18
17.4	Using Placeholder Data Controls	17-18
17.4.1	Limitations of Placeholder Data Controls.....	17-18
17.4.2	Creating Layout	17-19
17.4.3	Creating a Search Form.....	17-19
17.4.4	Binding Components	17-19
17.4.5	Rebinding Components	17-19
17.4.6	Packaging Placeholder Data Controls to ADF Library JARs	17-19

Part IV Creating ADF Task Flows

18 Getting Started with ADF Task Flows

18.1	About ADF Task Flows.....	18-1
18.1.1	About Unbounded Task Flows.....	18-3
18.1.2	About Bounded Task Flows.....	18-4
18.1.3	About Control Flows.....	18-7
18.1.4	ADF Task Flow Use Cases and Examples.....	18-8
18.1.5	Additional Functionality for ADF Task Flows.....	18-9
18.2	Creating a Task Flow	18-10
18.2.1	How to Create a Task Flow	18-10
18.2.2	What Happens When You Create a Task Flow	18-13
18.2.3	What You May Need to Know About the Default Activity in a Bounded Task Flow	18-14
18.2.4	What You May Need to Know About Memory Scope for Task Flows.....	18-15
18.2.5	What Happens at Runtime: Using Task Flows	18-17
18.3	Adding Activities to a Task Flow	18-17
18.3.1	How to Add an Activity to a Task Flow.....	18-18
18.3.2	What Happens When You Add an Activity to a Task Flow	18-19
18.4	Adding Control Flow Rules to Task Flows	18-19
18.4.1	How to Add a Control Flow Rule to a Task Flow.....	18-20
18.4.2	How to Add a Wildcard Control Flow Rule	18-22
18.4.3	What Happens When You Create a Control Flow Rule.....	18-22
18.4.4	What Happens at Runtime: Evaluating Control Flow Rules	18-24
18.5	Testing Task Flows	18-24

18.5.1	How to Run a Bounded Task Flow That Contains Pages	18-25
18.5.2	How to Run a Bounded Task Flow That Uses Page Fragments	18-26
18.5.3	How to Run a Bounded Task Flow That Has Parameters	18-26
18.5.4	How to Run a JSF Page When Testing a Task Flow	18-27
18.5.5	How to Run the Unbounded Task Flow	18-27
18.5.6	How to Set a Run Configuration for a Project	18-28
18.6	Refactoring to Create New Task Flows and Task Flow Templates	18-29
18.6.1	How to Create a Bounded Task Flow from Selected Activities	18-29
18.6.2	How to Create a Task Flow from JSF Pages.....	18-30
18.6.3	How to Convert Bounded Task Flows	18-31
18.7	What You Should Know About Task Flow Constraints	18-32

19 Working with Task Flow Activities

19.1	About Task Flow Activities	19-1
19.1.1	Task Flow Activities Use Cases and Examples	19-3
19.1.2	Additional Functionality for Task Flow Activities	19-4
19.2	Using View Activities.....	19-4
19.2.1	Passing Control Between View Activities.....	19-6
19.2.1.1	How to Pass Control Between View Activities	19-6
19.2.1.2	What Happens When You Pass Control Between View Activities.....	19-7
19.2.2	Bookmarking View Activities	19-8
19.2.2.1	How to Create a Bookmarkable View Activity	19-9
19.2.2.2	What Happens When You Designate a View as Bookmarkable	19-10
19.2.3	Specifying HTTP Redirect for a View Activity.....	19-10
19.2.3.1	How to Specify HTTP Redirect for a View Activity.....	19-10
19.2.3.2	What Happens When You Specify HTTP Redirect for a View Activity	19-11
19.3	Using URL View Activities.....	19-11
19.3.1	How to Add a URL View Activity to a Task Flow	19-12
19.3.2	What You May Need to Know About URL View Activities.....	19-13
19.4	Using Router Activities	19-13
19.4.1	How to Configure Control Flow Using a Router Activity.....	19-15
19.4.2	What Happens When You Configure Control Flow Using a Router Activity	19-16
19.5	Using Method Call Activities.....	19-16
19.5.1	How to Add a Method Call Activity.....	19-18
19.5.2	How to Specify Method Parameters and Return Values.....	19-20
19.5.3	What Happens When You Add a Method Call Activity	19-21
19.6	Using Task Flow Call Activities.....	19-22
19.6.1	How to Call a Bounded Task Flow Using a Task Flow Call Activity	19-22
19.6.2	What Happens When You Call a Bounded Task Flow Using a Task Flow Call Activity. 19-24	
19.6.3	How to Specify Input Parameters on a Task Flow Call Activity	19-24
19.6.4	How to Call a Bounded Task Flow Using a URL.....	19-25
19.6.5	What Happens When You Configure a Bounded Task Flow to be Invoked by a URL 19-27	
19.6.6	What You May Need to Know About Calling a Bounded Task Flow Using a URL	19-27
19.6.7	How to Specify Before and After Listeners.....	19-29

19.6.8	What Happens When You Add a Task Flow Call Activity	19-30
19.6.9	What Happens at Runtime When a Task Flow Call Activity Invokes a Task Flow	19-31
19.7	Using Task Flow Return Activities	19-31
19.8	Using Save Point Restore Activities	19-34
19.9	Using Parent Action Activities.....	19-34
19.10	Using Task Flow Activities with Page Definition Files	19-34
19.10.1	How to Associate a Page Definition File with a Task Flow Activity	19-35
19.10.2	What Happens When You Associate a Page Definition File with a Task Flow Activity ..	19-36

20 Using Parameters in Task Flows

20.1	About Using Parameters in Task Flows	20-1
20.1.1	Task Flow Parameters Use Cases and Examples	20-1
20.1.2	Additional Functionality for Task Flows Using Parameters.....	20-2
20.2	Passing Parameters to a View Activity	20-2
20.2.1	How to Pass Parameters to a View Activity	20-2
20.2.2	What Happens When You Pass Parameters to a View Activity.....	20-3
20.2.3	What You May Need to Know About Specifying Parameter Values	20-4
20.3	Passing Parameters to a Bounded Task Flow	20-4
20.3.1	How to Pass an Input Parameter to a Bounded Task Flow	20-5
20.3.2	What Happens When You Pass an Input Parameter to a Bounded Task Flow.....	20-7
20.4	Sharing Data Controls Between Task Flows	20-8
20.4.1	How to Share a Data Control Between Task Flows.....	20-9
20.4.2	What Happens When You Share a Data Control Between Task Flows.....	20-9
20.4.3	What You May Need to Know About Managing Transactions.....	20-10
20.5	Specifying a Return Value from a Bounded Task Flow	20-10
20.5.1	How to Specify a Return Value from a Bounded Task Flow	20-11
20.5.2	What Happens When You Specify a Return Value from a Bounded Task Flow ..	20-12

21 Using Task Flows as Regions

21.1	About Using Task Flows in ADF Regions.....	21-1
21.1.1	About Page Fragments and ADF Regions	21-2
21.1.2	About View Ports and ADF Regions	21-3
21.1.3	Task Flows and ADF Region Use Cases and Examples.....	21-4
21.1.4	Additional Functionality for Task Flows that Render in ADF Regions	21-5
21.2	Creating an ADF Region.....	21-5
21.2.1	How to Create an ADF Region	21-6
21.2.2	What Happens When You Create an ADF Region	21-7
21.3	Specifying Parameters for an ADF Region.....	21-8
21.3.1	How to Specify Parameters for an ADF Region.....	21-8
21.3.2	What Happens When You Specify Parameters for an ADF Region.....	21-9
21.4	Specifying Parameters for ADF Regions Using Parameter Maps.....	21-10
21.4.1	How to Create a Parameter Map to Specify Input Parameters for an ADF Region	21-10
21.4.2	What Happens When You Create a Parameter Map to Specify Input Parameters.....	21-11

21.5	Refreshing an ADF Region	21-12
21.5.1	How to Configure the Refresh of an ADF Region	21-13
21.5.2	What You May Need to Know About Refreshing an ADF Region	21-14
21.6	Configuring Activation of an ADF Region	21-15
21.6.1	How to Configure Activation of an ADF Region.....	21-15
21.6.2	What Happens When You Configure Activation of an ADF Region	21-17
21.7	Navigating Outside an ADF Region’s Task Flow	21-18
21.7.1	How to Trigger Navigation Outside of an ADF Region’s Task Flow	21-18
21.7.2	What Happens When You Configure Navigation Outside a Task Flow	21-19
21.7.3	What You May Need to Know About How a Page Determines the Capabilities of an ADF Region 21-20	
21.8	Creating ADF Dynamic Regions	21-20
21.8.1	How to Create an ADF Dynamic Region	21-21
21.8.2	What Happens When You Create an ADF Dynamic Region.....	21-23
21.9	Adding Additional Task Flows to an ADF Dynamic Region.....	21-24
21.9.1	How to Create an ADF Dynamic Region Link.....	21-25
21.9.2	What Happens When You Create an ADF Dynamic Region	21-26
21.10	Configuring a Page To Render an Unknown Number of Regions.....	21-26
21.10.1	How to Configure a Page to Render an Unknown Number of Regions	21-27
21.10.2	What Happens When You Configure a Page to Render an Unknown Number of Regions 21-28	
21.10.3	What You May Need to Know About Configuring a Page to Render an Unknown Number of Regions 21-29	

22 Creating Complex Task Flows

22.1	About Creating Complex Task Flows.....	22-1
22.1.1	Complex Task Flows Use Cases and Examples	22-2
22.1.2	Additional Functionality for Complex Task Flows	22-3
22.2	Managing Transactions in Task Flows	22-4
22.2.1	How to Enable Transactions in a Bounded Task Flow	22-5
22.2.2	What Happens When You Specify Transaction Options	22-6
22.2.3	What You May Need to Know About Data Control Scoping with Task Flows	22-7
22.3	Reentering Bounded Task Flows	22-8
22.3.1	How to Set Reentry Behavior	22-8
22.3.2	How to Set Outcome-Dependent Options	22-9
22.3.3	What You Should Know About Managed Bean Values Upon Task Flow Reentry	22-10
22.4	Handling Exceptions in Task Flows.....	22-10
22.4.1	How to Designate an Activity as an Exception Handler	22-11
22.4.2	What Happens When You Designate an Activity as an Exception Handler	22-12
22.4.3	How to Designate Custom Code as an Exception Handler.....	22-12
22.4.4	What Happens When You Designate Custom Code as an Exception Handler	22-13
22.4.5	What You May Need to Know About Handling Exceptions During Transactions	22-14
22.4.6	What You May Need to Know About Handling Validation Errors	22-14
22.5	Configuring Your Application to Use Save Points	22-14
22.5.1	How to Configure Your Fusion Web Application to Use Save Points	22-14

22.5.2	What Happens When You Configure a Fusion Web Application to Use Save Points	22-15
22.6	Using Save Points in Task Flows	22-15
22.6.1	How to Add a Save Point to a Task Flow	22-17
22.6.2	What Happens When You Add Save Points to a Task Flow	22-18
22.6.3	How to Restore a Save Point	22-18
22.6.4	What Happens When You Restore a Save Point	22-19
22.6.5	How to Use the Save Point Restore Finalizer	22-19
22.6.6	What Happens When a Task Flow Invokes a Save Point Restore Finalizer	22-19
22.6.7	How to Enable Implicit Save Points	22-20
22.6.8	What You May Need to Know About Enabling Implicit Save Points	22-21
22.6.9	What You May Need to Know About the Time-to-Live Period for a Save Point	22-21
22.7	Using Train Components in Bounded Task Flows	22-21
22.7.1	Creating a Task Flow as a Train	22-23
22.7.1.1	How to Create a Train in a Bounded Task Flow	22-24
22.7.1.2	What Happens When You Create a Task Flow as a Train	22-25
22.7.2	Invoking a Child Bounded Task Flow from a Train Stop	22-25
22.7.2.1	How to Invoke a Child Bounded Task Flow From a Train Stop	22-26
22.7.3	Grouping Task Flow Activities to Execute Between Train Stops	22-26
22.7.4	Disabling the Sequential Behavior of Train Stops in a Train	22-27
22.7.4.1	How to Disable the Sequential Behavior of a Train	22-28
22.7.4.2	What Happens When You Disable the Sequential Behavior a Train Stop	22-28
22.7.5	Changing the Label of a Train Stop	22-29
22.7.5.1	How to Change the Label of a Train Stop	22-29
22.7.5.2	What Happens When You Change the Label of a Train Stop	22-29
22.7.6	Configuring a Train to Skip a Train Stop	22-30
22.7.6.1	How to Configure a Train to Skip a Train Stop	22-30
22.7.6.2	What Happens When You Configure a Train to Skip a Train Stop	22-30
22.8	Creating Task Flow Templates	22-31
22.8.1	How to Create a Task Flow Template	22-33
22.8.2	What Happens When You Create a Task Flow Template	22-33
22.8.3	What You May Need to Know About Task Flow Templates	22-34
22.9	Creating a Page Hierarchy Using Task Flows	22-34
22.9.1	How to Create a Page Hierarchy	22-35
22.9.1.1	How to Create an XMLMenuModel Metadata File	22-37
22.9.1.2	How to Create a Submenu with a Hierarchy of Group and Child Nodes	22-38
22.9.1.3	How to Attach a Menu Hierarchy to Another Menu Hierarchy	22-39
22.9.2	What Happens When You Create a Page Hierarchy	22-40

23 Using Dialogs in Your Application

23.1	About Using Dialogs in Your Application	23-1
23.1.1	Using Dialogs in Your Application Use Cases and Examples	23-1
23.1.2	Additional Functionality for Using Dialogs in Your Application	23-1
23.2	Running a Bounded Task Flow in a Modal Dialog	23-2
23.2.1	How to Run a Bounded Task Flow in a Modal Dialog	23-3
23.2.2	How to Return a Value From a Modal Dialog	23-4
23.2.3	How to Refresh a Page After a Modal Dialog Returns	23-5

23.2.4	What You May Need to Know About Dialogs in an Application that Uses Task Flows .	23-6
23.3	Using the ADF Faces Dialog Framework.....	23-7
23.3.1	How to Define a JSF Navigation Rule for Opening a Dialog.....	23-10
23.3.2	How to Create the JSF Page That Opens a Dialog	23-11
23.3.3	How to Create the Dialog Page and Return a Dialog Value	23-12
23.3.4	What Happens at Runtime: Raising the Return Event from the Dialog.....	23-14
23.3.5	How to Pass a Value into a Dialog.....	23-14
23.3.6	What Happens at Runtime: Handling the LaunchEvent	23-16
23.3.7	How to Handle the Return Value.....	23-16
23.3.8	What Happens at Runtime: Handling the ReturnEvent on the Launching Component..	23-17

Part V Creating a Databound Web User Interface

24 Getting Started with Your Web Interface

24.1	About Developing a Web Application with ADF Faces	24-1
24.1.1	Page Template and Managed Beans Use Cases and Examples	24-2
24.1.2	Additional Functionality for Page Templates and Managed Beans	24-2
24.2	Using Page Templates.....	24-2
24.2.1	How to Use ADF Data Binding in ADF Page Templates	24-4
24.2.2	What Happens When You Use ADF Model Layer Bindings on a Page Template .	24-6
24.2.3	How to Add a Databound Page Template to a Page Dynamically	24-7
24.2.4	What Happens at Runtime: How Pages Use Templates.....	24-8
24.3	Creating a Web Page	24-9
24.4	Using a Managed Bean in a Fusion Web Application.....	24-9
24.4.1	How to Use a Managed Bean to Store Information.....	24-12
24.4.2	What Happens When You Create a Managed Bean.....	24-14
24.4.3	How to Set Managed Bean Memory Scopes in a Server-Cluster Environment	24-15

25 Understanding the Fusion Page Lifecycle

25.1	About the Fusion Page Lifecycle	25-1
25.2	About the JSF and ADF Page Lifecycles.....	25-3
25.2.1	What You May Need to Know About Partial Page Rendering and Iterator Bindings.....	25-7
25.2.2	What You May Need to Know About Using the Refresh Property Correctly.....	25-10
25.2.3	What You May Need to Know About Task Flows and the Lifecycle	25-12
25.3	About Object Scope Lifecycles	25-13
25.3.1	What You May Need to Know About Object Scopes and Task Flows	25-15
25.4	Customizing the ADF Page Lifecycle	25-16
25.4.1	How to Create a Custom Phase Listener.....	25-16
25.4.2	How to Register a Listener Globally.....	25-17
25.4.3	What You May Need to Know About Listener Order	25-18
25.4.4	How to Register a Lifecycle Listener for a Single Page.....	25-18
25.4.5	What You May Need to Know About Extending RegionController for Page Fragments	25-19

26 Creating a Basic Databound Page

26.1	About Creating a Basic Databound Page	26-1
26.1.1	ADF Databound Forms Use Cases and Examples.....	26-1
26.1.2	Additional Functionality for Databound Forms	26-3
26.2	Using Attributes to Create Text Fields.....	26-4
26.2.1	How to Create a Text Field	26-4
26.2.2	What Happens When You Create a Text Field	26-5
26.2.2.1	Creating and Using Iterator Bindings	26-5
26.2.2.2	Creating and Using Value Bindings	26-6
26.2.2.3	Using EL Expressions to Bind UI Components	26-7
26.3	Creating a Basic Form.....	26-8
26.3.1	How to Create a Form	26-8
26.3.2	What Happens When You Create a Form	26-10
26.4	Incorporating Range Navigation into Forms.....	26-11
26.4.1	How to Insert Navigation Controls into a Form	26-11
26.4.2	What Happens When You Create Command Buttons.....	26-12
26.4.2.1	Action Bindings for Built-in Navigation Operations	26-12
26.4.2.2	Iterator RangeSize Attribute	26-13
26.4.2.3	EL Expressions Used to Bind to Navigation Operations.....	26-14
26.4.3	What Happens at Runtime: How Action Events and Action Listeners Work	26-15
26.4.4	What You May Need to Know About the Browser Back Button and Navigating Through Records 26-16	
26.5	Creating a Form to Edit an Existing Record	26-16
26.5.1	How to Create Edit Forms	26-16
26.5.2	What Happens When You Use Built-in Operations to Change Data	26-18
26.6	Creating an Input Form	26-19
26.6.1	How to Create an Input Form Using a Task Flow	26-20
26.6.2	What Happens When You Create an Input Form Using a Task Flow	26-21
26.6.3	What Happens at Runtime: CreateInsert Action from the Method Activity	26-22
26.6.4	What You May Need to Know About Displaying Sequence Numbers.....	26-23
26.7	Using a Dynamic Form to Determine Data to Display at Runtime.....	26-23
26.7.1	How to Use Dynamic Forms.....	26-24
26.7.2	What Happens When You Use Dynamic Components	26-25
26.7.3	What Happens at Runtime: How Attribute Values Are Dynamically Determined	26-26
26.8	Modifying the UI Components and Bindings on a Form	26-26
26.8.1	How to Modify the UI Components and Bindings.....	26-26
26.8.2	What Happens When You Modify Attributes and Bindings	26-27

27 Creating ADF Databound Tables

27.1	About Creating ADF Databound Tables	27-1
27.1.1	ADF Databound Tables Use Cases and Examples.....	27-1
27.1.2	Additional Functionality for Databound Tables.....	27-2
27.2	Creating a Basic Table	27-3
27.2.1	How to Create a Basic Table.....	27-3
27.2.2	What Happens When You Create a Table	27-6

27.2.2.1	Iterator and Value Bindings for Tables	27-6
27.2.2.2	Code on the JSF Page for an ADF Faces Table	27-7
27.2.3	What You May Need to Know About Setting the Current Row in a Table	27-10
27.3	Creating an Editable Table	27-11
27.3.1	How to Create an Editable Table.....	27-12
27.3.2	What Happens When You Create an Editable Table	27-14
27.4	Creating an Input Table	27-15
27.4.1	How to Create an Input Table.....	27-15
27.4.2	What Happens When You Create an Input Table	27-16
27.4.3	What Happens at Runtime: How CreateInsert and Partial Page Refresh Work ...	27-17
27.4.4	What You May Need to Know About Creating a Row and Sorting Columns.....	27-17
27.4.5	What You May Need to Know About Create and CreateInsert	27-18
27.5	Modifying the Attributes Displayed in the Table	27-18
27.5.1	How to Modify the Displayed Attributes	27-18
27.5.2	How to Change the Binding for a Table.....	27-19
27.5.3	What Happens When You Modify Bindings or Displayed Attributes	27-19

28 Command Components to Invoke Functionality in the View Layer

28.1	About Command Components.....	28-1
28.1.1	Command Component Use Cases and Examples.....	28-1
28.1.2	Additional Functionality for Command Components.....	28-2
28.2	Creating Command Components to Execute Methods.....	28-2
28.2.1	How to Create a Command Component Bound to a Custom Method	28-3
28.2.2	What Happens When You Create Command Components Using a Method	28-3
28.2.2.1	Defining Method Action Binding.....	28-4
28.2.2.2	Using Parameters in a Method	28-4
28.2.2.3	Adding ADF Faces Component Code to JSF Page	28-4
28.2.2.4	Using EL Expressions to Bind to Methods	28-4
28.2.2.5	Using the Return Value from a Method Call.....	28-5
28.2.3	What Happens at Runtime: Command Button Method Bindings	28-6
28.3	Setting Parameter Values Using a Command Component	28-6
28.3.1	How to Set Parameters Using setPropertyListener Within a Command Component	28-6
28.3.2	What Happens When You Set Parameters	28-7
28.3.3	What Happens at Runtime: setPropertyListener for a Command Component	28-7
28.4	Overriding Declarative Methods.....	28-8
28.4.1	How to Override a Declarative Method.....	28-8
28.4.2	What Happens When You Override a Declarative Method.....	28-11

29 Displaying Master-Detail Data

29.1	About Displaying Master-Detail Data	29-1
29.1.1	Master-Detail Tables, Forms, and Trees Use Cases and Examples	29-2
29.1.2	Additional Functionality for Master-Detail Tables, Forms, and Trees	29-5
29.2	Common Functionality for Master-Detail Tables, Forms, and Trees	29-5
29.2.1	Identifying Master-Detail Objects on the Data Controls Panel.....	29-6
29.3	Using Tables and Forms to Display Master-Detail Objects	29-7
29.3.1	How to Display Master-Detail Objects in Tables and Forms	29-8

29.3.2	What Happens When You Create Master-Detail Tables and Forms	29-9
29.3.2.1	Code Generated in the JSF Page.....	29-9
29.3.2.2	Binding Objects Defined in the Page Definition File.....	29-10
29.3.3	What Happens at Runtime: ADF Iterator for Master-Detail Tables and Forms ...	29-11
29.3.4	What You May Need to Know About Displaying Master-Detail Widgets on Separate Pages	29-12
29.4	Using Trees to Display Master-Detail Objects.....	29-12
29.4.1	How to Display Master-Detail Objects in Trees.....	29-13
29.4.2	What Happens When You Create an ADF Databound Tree.....	29-16
29.4.2.1	Code Generated in the JSF Page.....	29-16
29.4.2.2	Binding Objects Defined in the Page Definition File.....	29-17
29.4.3	What Happens at Runtime: Displaying an ADF Databound Tree	29-18
29.5	Using Tree Tables to Display Master-Detail Objects	29-18
29.5.1	How to Display Master-Detail Objects in Tree Tables	29-19
29.5.2	What Happens When You Create a Databound Tree Table.....	29-19
29.5.2.1	Code Generated in the JSF Page.....	29-19
29.5.2.2	Binding Objects Defined in the Page Definition File.....	29-20
29.5.3	What Happens at Runtime: Events.....	29-20
29.5.4	How to Use the TargetIterator Property	29-21
29.6	Using Selection Events with Trees and Tables	29-22
29.6.1	How to Use Selection Events with Trees and Tables	29-22
29.6.2	What Happens at Runtime: RowKeySet Objects and SelectionEvent Events.....	29-24

30 Creating Databound Selection Lists and Shuttles

30.1	About Selection Lists and Shuttles	30-1
30.1.1	Selection Lists and Shuttles Use Cases and Examples	30-2
30.1.2	Additional Functionality for Selection Lists and Shuttles	30-2
30.2	Creating List of Values (LOV) Components	30-3
30.2.1	How to Create an LOV.....	30-8
30.2.2	What Happens When You Create an LOV	30-9
30.3	Creating a Selection List.....	30-10
30.3.1	How to Create a Model-Driven List.....	30-11
30.3.2	How to Create a Selection List Containing Fixed Values	30-13
30.3.3	How to Create a Selection List Containing Dynamically Generated Values.....	30-14
30.3.4	What Happens When You Create a Model-Driven Selection List.....	30-15
30.3.5	What Happens When You Create a Fixed Selection List.....	30-16
30.3.6	What You May Need to Know About Values in a Selection List	30-17
30.3.7	What Happens When You Create a Dynamic Selection List.....	30-17
30.4	Creating a List with Navigation List Binding.....	30-18
30.5	Creating a Databound Shuttle.....	30-19

31 Creating ADF Databound Search Forms

31.1	About Creating Search Forms	31-1
31.1.1	Implicit and Named View Criteria.....	31-2
31.1.2	List of Values (LOV) Input Fields.....	31-2
31.1.3	Search Form Use Cases and Examples	31-3

31.1.4	Additional Functionality for Search Forms	31-4
31.2	Creating Query Search Forms	31-4
31.2.1	Named Bind Variables in Query Search Forms	31-11
31.2.2	How to Create a Query Search Form with a Results Table or Tree Table.....	31-12
31.2.3	How to Create a Query Search Form and Add a Results Component Later	31-13
31.2.4	How to Persist Saved Searches into MDS	31-14
31.2.5	How to Set Default Search Binding Behavior.....	31-14
31.2.6	What You May Need to Know About Dependent Criterion.....	31-16
31.2.7	What Happens When You Create a Query Form	31-17
31.2.8	What Happens at Runtime: Search Forms	31-18
31.3	Setting Up Search Form Properties	31-18
31.3.1	How to Set Search Form Properties on the View Criteria	31-19
31.3.2	How to Set Search Form Properties on the Query Component.....	31-20
31.3.3	How to Create Custom Operators or Remove Standard Operators	31-21
31.4	Creating Quick Query Search Forms	31-23
31.4.1	How to Create a Quick Query Search Form with a Results Table or Tree Table ..	31-24
31.4.2	How to Create a Quick Query Search Form and Add a Results Component Later	31-25
31.4.3	How to Set the Quick Query Layout Format.....	31-26
31.4.4	What Happens When You Create a Quick Query Search Form.....	31-26
31.4.5	What Happens at Runtime: Quick Query	31-26
31.5	Creating Standalone Filtered Search Tables from Named View Criteria.....	31-27
31.5.1	How to Create Filtered Table and Query-by-Example Searches	31-28

32 Using More Complex Databound ADF Faces Components

32.1	About More Complex Databound ADF Faces Components	32-1
32.1.1	Complex Databound ADF Faces Components Use Cases and Examples.....	32-1
32.1.2	Additional Functionality of Complex Databound ADF Faces Components	32-2
32.2	Using the ADF Faces Calendar Component	32-2
32.2.1	How to Use the ADF Faces Calendar	32-4
32.2.2	What Happens When You Create a Calendar	32-6
32.2.3	What Happens at Runtime: How the Calendar Binding Works	32-8
32.3	Using the ADF Faces Carousel Component.....	32-8
32.3.1	How to Create a Databound Carousel Component.....	32-9
32.3.2	What Happens When You Create a Carousel	32-12

33 Creating Databound ADF Data Visualization Components

33.1	About ADF Data Visualization Components	33-1
33.1.1	End User and Presentation Features.....	33-3
33.1.2	Data Visualization Components Use Cases and Examples.....	33-3
33.1.3	Additional Functionality for Data Visualization Components.....	33-4
33.2	Creating Databound Graphs	33-4
33.2.1	How to Create a Graph	33-7
33.2.2	What Happens When You Use the Data Controls Panel to Create a Graph.....	33-10
33.2.3	What You May Need to Know About Using a Graph's Row Selection Listener for Master-Detail Processing	33-11
33.2.4	What You May Need to Know About Using Name-Value Pairs	33-12

33.2.5	How to Create a Graph Using Name-Value Pairs	33-13
33.2.6	How to Create a Databound Spark Chart	33-15
33.3	Creating Databound Gauges	33-17
33.3.1	How to Create a Databound Dial Gauge	33-19
33.3.2	What Happens When You Create a Dial Gauge from a Data Control.....	33-21
33.3.3	How to Create a Databound Status Meter Gauge Set	33-22
33.3.4	What Happens When You Create a Status Meter Gauge from a Data Control.....	33-25
33.4	Creating Databound Pivot Tables	33-26
33.4.1	How to Create a Pivot Table	33-27
33.4.2	What Happens When You Use the Data Controls Panel to Create a Pivot Table.	33-38
33.4.2.1	Bindings for Pivot Tables	33-39
33.4.2.2	Code on the JSF Page for a Pivot Table and Pivot Filter Bar.....	33-40
33.4.3	What You May Need to Know About Aggregating Attributes in the Pivot Table	33-41
33.4.3.1	Default Aggregation of Duplicate Data Rows.....	33-41
33.4.3.2	Custom Aggregation of Duplicate Rows	33-41
33.4.4	What You May Need to Know About Specifying an Initial Sort for a Pivot Table	33-42
33.5	Creating Databound Geographic Maps.....	33-43
33.5.1	How to Create a Geographic Map with a Point Theme.....	33-44
33.5.2	How to Create Point Style Items for a Point Theme.....	33-47
33.5.3	What Happens When You Create a Geographic Map with a Point Theme.....	33-49
33.5.3.1	Binding XML for a Point Theme	33-49
33.5.3.2	XML Code on the JSF Page for a Geographic Map and Point Theme	33-49
33.5.4	What You May Need to Know About Adding Custom Point Style Items to a Map Point Theme	33-50
33.5.5	How to Add a Databound Color Theme to a Geographic Map.....	33-51
33.5.6	What Happens When You Add a Color Theme to a Geographic Map	33-53
33.5.6.1	Binding XML for a Color Theme	33-53
33.5.6.2	XML Code on the JSF Page for a Color Theme	33-54
33.5.7	What You May Need to Know About Customizing Colors in a Map Color Theme	33-54
33.5.8	How to Add a Databound Pie Graph Theme to a Geographic Map.....	33-54
33.5.9	What Happens When You Add a Pie Graph Theme to a Geographic Map	33-56
33.5.9.1	Binding XML for a Pie Graph Theme	33-56
33.5.9.2	Code on the JSF Page for a Pie Graph Theme	33-57
33.6	Creating Databound Thematic Maps.....	33-57
33.6.1	How to Create a Thematic Map Using ADF Data Controls	33-57
33.6.2	What Happens When You Use Data Controls to Create a Thematic Map.....	33-64
33.6.3	What You May Need to Know About Base Map Location Ids	33-65
33.6.4	How to Add Data Layers to Thematic Maps.....	33-66
33.6.5	How to Configure Drilling in Thematic Maps	33-71
33.6.6	What You May Need to Know About Configuring Master-Detail Relationships	33-73
33.6.7	Styling Areas, Markers, and Images to Display Data.....	33-74
33.6.7.1	How to Style Areas to Display Data	33-74
33.6.7.2	How to Style Markers to Display Data.....	33-77
33.6.7.3	What You May Need to Know About Styling Markers.....	33-84
33.6.7.4	What You May Need to Know About Default Style Values for Attribute Groups	33-84

33.6.7.5	How to Style Images to Display Data.....	33-85
33.6.7.6	What You May Need to Know About SVG Files.....	33-87
33.6.8	Creating Databound Legends.....	33-87
33.6.9	How to Define a Custom Map Layer.....	33-90
33.7	Creating Databound Gantt Charts.....	33-94
33.7.1	How to Create a Databound Project Gantt Chart.....	33-95
33.7.2	What Happens When You Create a Project Gantt Chart from a Data Control.....	33-98
33.7.3	What You May Need to Know About Summary Tasks in a Project Gantt Chart.....	33-100
33.7.4	What You May Need to Know About Percent Complete in a Project Gantt Chart.....	33-100
33.7.5	What You May Need to Know About Variance in a Project Gantt Chart.....	33-101
33.7.6	How to Create a Databound Resource Utilization Gantt Chart.....	33-101
33.7.7	What Happens When You Create a Resource Utilization Gantt Chart.....	33-103
33.7.8	How to Create a Databound Scheduling Gantt Chart.....	33-105
33.7.9	What Happens When You Create a Scheduling Gantt Chart.....	33-108
33.8	Creating Databound Hierarchy Viewers.....	33-109
33.8.1	How to Create a Hierarchy Viewer Using ADF Data Controls.....	33-110
33.8.2	What Happens When You Create a Databound Hierarchy Viewer.....	33-114
33.8.3	How to Create a Databound Search in a Hierarchy Viewer.....	33-118

34 Using Contextual Events

34.1	About Creating Contextual Events.....	34-1
34.1.1	Contextual Events Use Cases and Examples.....	34-4
34.1.2	Additional Functionality for Contextual Events.....	34-5
34.2	Creating Contextual Events Declaratively.....	34-5
34.2.1	How to Publish Contextual Events.....	34-5
34.2.2	How to Subscribe to and Consume Contextual Events.....	34-7
34.2.3	What Happens When You Create Contextual Events.....	34-9
34.2.4	How to Control Contextual Events Dispatch.....	34-10
34.2.5	What Happens at Runtime: Contextual Events.....	34-11
34.3	Creating Contextual Events Manually.....	34-11
34.3.1	How to Create Contextual Events Manually.....	34-11
34.4	Creating Contextual Events Using Managed Beans.....	34-13
34.5	Creating Contextual Events Using JavaScript.....	34-14
34.6	Creating the Event Map Manually.....	34-14
34.6.1	How to Create the Event Map Manually.....	34-15
34.7	Registering a Custom Dispatcher.....	34-15
34.7.1	How to Register a Custom Dispatcher.....	34-16

Part VI Completing Your Application

35 Enabling ADF Security in a Fusion Web Application

35.1	About ADF Security.....	35-1
35.1.1	Integration of ADF Security and Java Security.....	35-3
35.1.2	ADF Security Use Cases and Examples.....	35-4
35.1.3	Additional Functionality for ADF Security.....	35-5
35.2	ADF Security Process Overview.....	35-6

35.3	Enabling ADF Security.....	35-9
35.3.1	How to Enable ADF Security	35-9
35.3.2	What Happens When You Enable ADF Security	35-13
35.3.3	What Happens When You Generate a Default Form-Based Login Page	35-17
35.3.4	What You May Need to Know About the Configure ADF Security Wizard.....	35-17
35.3.5	What You May Need to Know About ADF Authentication	35-17
35.3.6	What You May Need to Know About the Built-In test-all Role	35-17
35.3.7	What You May Need to Know About the valid-users Role	35-18
35.4	Creating Application Roles	35-18
35.4.1	How to Create Application Roles.....	35-19
35.4.2	What Happens When You Create Application Roles.....	35-19
35.4.3	What You May Need to Know About Enterprise Roles and Application Roles...	35-20
35.5	Defining ADF Security Policies.....	35-21
35.5.1	How to Make an ADF Resource Public.....	35-21
35.5.2	What Happens When You Make an ADF Resource Public.....	35-24
35.5.3	What Happens at Runtime: How the Built-in Roles Are Used.....	35-24
35.5.4	How to Define Policies for ADF Bounded Task Flows	35-25
35.5.5	How to Define Policies for Web Pages That Reference a Page Definition	35-28
35.5.6	What Happens When You Define the Security Policy	35-31
35.5.7	What Happens at Runtime: How ADF Security Policies Are Enforced	35-32
35.5.8	What You May Need to Know About Defining Policies for Pages with No ADF Bindings	35-33
35.5.9	How to Use Regular Expressions to Define Policies on Groups of Resources	35-34
35.5.10	How to Define Policies for Data	35-35
35.5.10.1	Defining Permission Maps on ADF Entity Objects	35-36
35.5.10.2	Granting Permissions on ADF Entity Objects	35-37
35.5.11	How to Aggregate Resource Grants as Entitlement Grants	35-39
35.5.12	What Happens After You Create an Entitlement Grant	35-41
35.6	Creating Test Users.....	35-43
35.6.1	How to Create Test Users in JDeveloper.....	35-43
35.6.2	What Happens When You Create Test Users.....	35-45
35.6.3	How to Associate Test Users with Application Roles.....	35-46
35.6.4	What Happens When You Configure Application Roles	35-47
35.7	Creating a Login Page	35-48
35.7.1	How to Create a Login Link Component and Add it to a Public Web Page	35-48
35.7.2	How to Create a Login Page	35-50
35.7.2.1	Creating Login Code for the Backing Bean	35-51
35.7.2.2	Creating an ADF Faces-Based Login Page.....	35-55
35.7.2.3	Configuring the web.xml File for an ADF Faces-Based Login Page.....	35-58
35.7.2.4	Ensuring That the Login Page Is Public	35-59
35.7.2.5	Ensuring That the Login Page's Resources Are Accessible.....	35-59
35.7.3	How to Create a Public Welcome Page	35-60
35.7.3.1	Ensuring That the Welcome Page Is Public	35-60
35.7.3.2	Adding Login and Logout Links.....	35-60
35.7.3.3	Hiding Links to Secured Pages.....	35-61
35.7.4	How to Redirect a User After Authentication	35-61

35.7.5	What You May Need to Know About ADF Servlet Logout and Browser Caching.....	35-63
35.8	Testing Security in JDeveloper.....	35-63
35.8.1	How to Configure, Deploy, and Run a Secure Application in JDeveloper.....	35-63
35.8.2	What Happens When You Configure Security Deployment Options.....	35-64
35.8.3	How to Use the Built-In test-all Application Role.....	35-66
35.8.4	What Happens at Runtime: How ADF Security Handles Authentication.....	35-66
35.8.5	What Happens at Runtime: How ADF Security Handles Authorization.....	35-69
35.9	Preparing the Secure Application for Deployment.....	35-70
35.9.1	How to Remove the test-all Role from the Application Policy Store.....	35-71
35.9.2	How to Remove Test Users from the Application Identity Store.....	35-72
35.9.3	How to Secure Resource Files Using a URL Constraint.....	35-73
35.10	Disabling ADF Security.....	35-74
35.10.1	How to Disable ADF Security.....	35-74
35.10.2	What Happens When You Disable ADF Security.....	35-75
35.11	Advanced Topics and Best Practices.....	35-75
35.11.1	Using Expression Language (EL) with ADF Security.....	35-75
35.11.1.1	How to Evaluate Policies Using EL.....	35-75
35.11.1.2	What Happens When You Use the Expression Builder Dialog.....	35-79
35.11.1.3	What You May Need to Know About Delayed Evaluation of EL.....	35-80
35.11.2	How to Evaluate Policies Using Custom JAAS Permissions and EL.....	35-80
35.11.2.1	Creating the Custom JAAS Permission Class.....	35-81
35.11.2.2	Creating the ADF Security Policy Using a Custom Permission.....	35-82
35.11.2.3	Associating the Rendering of a UI Component with a Custom Permission...	35-83
35.11.3	Getting Information from the ADF Security Context.....	35-85
35.11.3.1	How to Determine Whether Security Is Enabled.....	35-85
35.11.3.2	How to Determine Whether the User Is Authenticated.....	35-85
35.11.3.3	How to Determine the Current User Name, Enterprise Name, or Enterprise ID.....	35-86
35.11.3.4	How to Determine Membership of a Java EE Security Role.....	35-87
35.11.3.5	How to Determine Permission Using Java.....	35-87
35.11.4	Best Practices for Working with ADF Security.....	35-88

36 Testing and Debugging ADF Components

36.1	About ADF Debugging.....	36-1
36.2	Correcting Simple Oracle ADF Compilation Errors.....	36-2
36.3	Correcting Simple Oracle ADF Runtime Errors.....	36-4
36.4	Reloading Oracle ADF Metadata in Integrated WebLogic Server.....	36-6
36.5	Validating ADF Controller Metadata.....	36-6
36.6	Using the ADF Logger.....	36-7
36.6.1	How to Set ADF Logging Levels.....	36-7
36.6.2	How to Turn On Diagnostic Logging.....	36-10
36.6.3	How to Create an Oracle ADF Debugging Configuration.....	36-10
36.6.4	How to Use the Log Analyzer to View Log Messages.....	36-11
36.6.4.1	Viewing Diagnostic Messages in the Log Analyzer.....	36-12
36.6.4.2	Using the Log Analyzer to Analyze the ADF Request.....	36-14
36.6.4.3	Sorting Diagnostic Messages By ADF Events.....	36-18

36.6.5	What You May Need to Know About the Logging.xml File.....	36-21
36.6.6	What You May Need to Know About ADF Logging and Oracle WebLogic Server	36-22
36.7	Using the Oracle ADF Model Tester for Testing and Debugging	36-23
36.7.1	How to Run in Debug Mode and Test with the Oracle ADF Model Tester.....	36-23
36.7.2	How to Run the Oracle ADF Model Tester and Test with a Specific Configuration.....	36-23
36.7.3	What Happens When You Run the Oracle ADF Model Tester in Debug Mode...	36-24
36.7.4	How to Verify Runtime Artifacts in the Oracle ADF Model Tester	36-24
36.7.5	How to Refresh the Oracle ADF Model Tester with Application Changes	36-25
36.8	Using the ADF Declarative Debugger	36-25
36.8.1	Using ADF Source Code with the Debugger.....	36-27
36.8.2	How to Set Up the ADF Source User Library.....	36-27
36.8.3	How to Add the ADF Source Library to a Project	36-28
36.8.4	How to Use the EL Expression Evaluator	36-28
36.8.5	How to View and Export Stack Trace Information	36-29
36.9	Setting ADF Declarative Breakpoints	36-30
36.9.1	How to Set and Use Task Flow Activity Breakpoints	36-39
36.9.2	How to Set and Use Page Definition Executable Breakpoints	36-40
36.9.3	How to Set and Use Page Definition Action Binding Breakpoints	36-42
36.9.4	How to Set and Use Page Definition Value Binding Breakpoints.....	36-43
36.9.5	How to Set and Use Page Definition Contextual Event Breakpoints.....	36-44
36.9.6	How to Set and Use ADF Lifecycle Phase Breakpoints	36-45
36.9.7	How to Use the ADF Structure Window	36-48
36.9.8	How to Use the ADF Data Window	36-51
36.9.9	What Happens When You Set an ADF Declarative Breakpoint.....	36-61
36.10	Setting Java Code Breakpoints.....	36-62
36.10.1	How to Set Java Breakpoints on Classes and Methods.....	36-62
36.10.2	How to Optimize Use of the Source Editor	36-63
36.10.3	How to Set Breakpoints and Debug Using ADF Source Code	36-64
36.10.4	How to Use Debug Libraries for Symbolic Debugging	36-64
36.10.5	How to Use Different Kinds of Java Code Breakpoints	36-66
36.10.6	How to Edit Breakpoints for Improved Control.....	36-67
36.10.7	How to Filter Your View of Class Members.....	36-68
36.10.8	How to Use Common Oracle ADF Breakpoints	36-68
36.11	Regression Testing with JUnit.....	36-69
36.11.1	How to Obtain the JUnit Extension.....	36-70
36.11.2	How to Create a JUnit Test Case	36-71
36.11.3	How to Create a JUnit Test Fixture	36-73
36.11.4	How to Create a JUnit Test Suite.....	36-73
36.11.5	How to Create a Business Components Test Suite	36-74
36.11.6	How to a Create Business Components Test Fixture	36-76
36.11.7	How to Run a JUnit Test Suite as Part of an Ant Build Script	36-77

37 Refactoring a Fusion Web Application

37.1	About Refactoring a Fusion Web Application	37-1
37.1.1	Refactoring Use Cases and Examples	37-1

37.2	Renaming Files	37-2
37.3	Moving JSF Pages	37-2
37.4	Refactoring pagedef.xml Bindings Objects	37-2
37.5	Refactoring ADF Business Components	37-3
37.6	Refactoring ADF Business Component Object Attributes.....	37-4
37.7	Refactoring Named Elements	37-5
37.8	Refactoring ADF Task Flows.....	37-6
37.9	Refactoring the DataBindings.cpx File.....	37-6
37.10	Refactoring Limitations	37-7
37.11	Moving the ADF Business Components Project Configuration File (.jpx).....	37-8

38 Reusing Application Components

38.1	About Reusable Components.....	38-1
38.1.1	Creating Reusable Components	38-3
38.1.1.1	Naming Conventions	38-3
38.1.1.2	The Naming Process for the ADF Library JAR Deployment Profile	38-5
38.1.1.3	Keeping the Relevant Project.....	38-6
38.1.1.4	Selecting the Relevant Feature.....	38-6
38.1.1.5	Selecting Paths and Folders	38-6
38.1.1.6	Including Connections Within Reusable Components.....	38-6
38.1.2	Reusable ADF Components Use Cases and Examples	38-7
38.1.3	Additional Functionality for Reusable ADF Components	38-8
38.2	Common Functionality of Reusable ADF Components	38-8
38.2.1	Using Extension Libraries.....	38-8
38.2.2	Using the Resource Palette	38-12
38.3	Packaging a Reusable ADF Component into an ADF Library.....	38-13
38.3.1	How to Package a Component into an ADF Library JAR	38-14
38.3.2	What Happens When You Package a Project to an ADF Library JAR	38-19
38.3.2.1	Application Modules	38-19
38.3.2.2	Data Controls	38-20
38.3.2.3	Task Flows	38-20
38.3.2.4	Page Templates	38-20
38.3.2.5	Declarative Components	38-20
38.3.3	How to Place and Access JDeveloper JAR Files.....	38-20
38.4	Adding ADF Library Components into Projects.....	38-21
38.4.1	How to Add an ADF Library JAR into a Project using the Resource Palette	38-22
38.4.2	How to Add an ADF Library JAR into a Project Manually.....	38-24
38.4.3	What Happens When You Add an ADF Library JAR to a Project	38-25
38.4.4	What You May Need to Know About Using ADF Library Components	38-27
38.4.4.1	Using Data Controls.....	38-27
38.4.4.2	Using Application Modules.....	38-27
38.4.4.3	Using Business Components	38-27
38.4.4.4	Using Task Flows.....	38-28
38.4.4.5	Using Page Templates.....	38-29
38.4.4.6	Using Declarative Components.....	38-30
38.4.5	What You May Need to Know About Differentiating ADF Library Components.....	38-30

38.4.6	What Happens at Runtime: Adding ADF Libraries	38-30
38.5	Removing an ADF Library JAR from a Project	38-31
38.5.1	How to Remove an ADF Library JAR from a Project Using the Resource Palette	38-31
38.5.2	How to Remove an ADF Library JAR from a Project Manually.....	38-32

39 Customizing Applications with MDS

39.1	About Customization and MDS	39-1
39.1.1	Customization and Layers: Use Cases and Examples.....	39-2
39.1.2	Static and Dynamic Customization Content	39-3
39.1.3	Additional Functionality for Customization	39-4
39.2	Developing a Customizable Application	39-4
39.2.1	How to Create Customization Classes	39-4
39.2.1.1	Customization Classes	39-4
39.2.1.2	Implementing the getValue() Method in Your Customization Class	39-7
39.2.1.3	Creating a Customization Class	39-9
39.2.2	What You May Need to Know About Customization Classes	39-10
39.2.3	How to Consume Customization Classes	39-10
39.2.3.1	Making Customization Classes Available to JDeveloper at Design Time	39-11
39.2.3.2	Making Customization Classes Available to the Application at Run Time ..	39-12
39.2.4	How to Enable Seeded Customizations for View Projects	39-12
39.2.5	How to Enable Seeded Customizations in Existing Pages	39-13
39.2.6	How to Enable Customizations in Resource Bundles	39-14
39.2.7	How to Configure the adf-config.xml file	39-14
39.2.8	What Happens When You Create a Customizable Application	39-16
39.2.9	What You May Need to Know About Customizable Objects and Applications .	39-16
39.3	Customizing an Application	39-16
39.3.1	Introducing the Customization Developer Role	39-16
39.3.2	How to Switch to the Customization Developer Role in JDeveloper	39-17
39.3.3	Introducing the Tip Layer	39-18
39.3.4	How to Configure Customization Layers	39-18
39.3.4.1	Configuring Layer Values Globally	39-19
39.3.4.2	Configuring Workspace-Level Layer Values from the Studio Developer Role	39-20
39.3.4.3	Configuring Workspace-Level Layer Values from the Customization Developer Role	39-21
39.3.5	How to Customize Metadata in JDeveloper	39-22
39.3.6	What Happens When You Customize an Application	39-24
39.3.7	How to Customize ADF Library Artifacts in JDeveloper.....	39-24
39.3.7.1	Specifying a Location for ADF Library Customizations.....	39-26
39.3.8	How to View ADF Library Runtime Customizations from Exported JARs	39-26
39.3.9	What Happens When You Customize ADF Library Artifacts.....	39-27
39.3.10	How to Package and Deploy Customized Applications	39-28
39.3.10.1	Implicitly Creating a MAR Profile	39-29
39.3.10.2	Explicitly Creating a MAR Profile.....	39-29
39.3.11	What Happens at Runtime in a Customized Application.....	39-30
39.3.12	What You May Need to Know About Customized Applications	39-30
39.3.12.1	Customization and Integrated Source Control	39-30

39.3.12.2	Editing Resource Bundles in Customized Applications.....	39-31
39.4	Extended Metadata Properties.....	39-31
39.4.1	How to Edit Extended Metadata Properties.....	39-32
39.4.2	How to Enable Customization for Design Time at Runtime.....	39-33
39.4.2.1	Editing Customization Properties in the Property Inspector.....	39-33
39.4.2.2	Using a Standalone Annotations File to Specify Type-Level Customization Properties 39-34	
39.5	Enabling Runtime Modification of Customization Configuration.....	39-35

40 Allowing User Customizations at Runtime

40.1	About User Customizations	40-1
40.1.1	Runtime User Customization Use Cases and Examples.....	40-7
40.1.2	Additional Functionality for Runtime User Customization.....	40-8
40.2	Enabling Runtime User Customizations for a Fusion Web Application.....	40-8
40.2.1	How to Enable User Customizations.....	40-8
40.2.2	What Happens When You Enable User Customizations.....	40-9
40.3	Configuring User Customizations.....	40-10
40.3.1	How to Configure Change Persistence.....	40-11
40.3.2	What Happens When You Configure Change Persistence	40-12
40.4	Controlling User Customizations in Individual JSF Pages.....	40-13
40.4.1	How to Control User Customizations on a JSF Page.....	40-13
40.4.2	What Happens at Runtime.....	40-15
40.4.3	What You May Need to Know About Using Change Persistence on Templates and Regions 40-15	
40.5	Implementing Custom User Customizations	40-16
40.5.1	Change Persistence Framework API	40-16
40.5.2	How to Create Code for Custom User Customizations.....	40-18
40.6	Creating Implicit Change Persistence in Custom Components.....	40-21
40.6.1	How to Set Implicit Change Persistence For Attribute Values that Use Events ...	40-22
40.6.2	How to Set Implicit Change Persistence For Other Attribute Values.....	40-22

41 Deploying Fusion Web Applications

41.1	About Deploying Fusion Web Applications.....	41-1
41.1.1	Developing Applications with Integrated WebLogic Server	41-3
41.1.2	Developing Applications to Deploy to Standalone Application Server.....	41-3
41.2	Running an ADF Application in Integrated WebLogic Server	41-5
41.2.1	How to Run an Application in Integrated WebLogic Server	41-6
41.2.2	How to Run an Application with Metadata in Integrated WebLogic Server	41-6
41.3	Preparing the Application	41-8
41.3.1	How to Create a Connection to the Target Application Server	41-9
41.3.2	How to Create Deployment Profiles.....	41-12
41.3.2.1	Creating a WAR Deployment Profile	41-12
41.3.2.2	Creating a MAR Deployment Profile	41-13
41.3.2.3	Creating an Application-Level EAR Deployment Profile	41-16
41.3.2.4	Delivering Customization Classes as a Shared Library	41-17
41.3.2.5	Viewing and Changing Deployment Profile Properties.....	41-18
41.3.2.6	Adding Customization Classes into a JAR.....	41-19

41.3.3	How to Create and Edit Deployment Descriptors.....	41-20
41.3.3.1	Creating Deployment Descriptors	41-21
41.3.3.2	Viewing or Modifying Deployment Descriptor Properties	41-22
41.3.3.3	Configuring the application.xml File for Application Server Compatibility..	41-22
41.3.3.4	Configuring the web.xml File for Application Server Compatibility	41-23
41.3.3.5	Enabling the Application for Real User Experience Insight.....	41-23
41.3.4	How to Deploy Applications with ADF Security Enabled.....	41-24
41.3.4.1	Applications That Will Run Using Oracle Single Sign-On (SSO).....	41-24
41.3.4.2	Configuring Security for Weblogic Server.....	41-25
41.3.4.3	Configuring Security for Websphere Application Server	41-27
41.3.5	How to Replicate Memory Scopes in a Clustered Environment	41-28
41.3.6	How to Enable the Application for ADF MBeans.....	41-28
41.3.7	What You May Need to Know About JDBC Data Source for Oracle WebLogic Server ...	41-29
41.4	Deploying the Application	41-30
41.4.1	How to Deploy to the Application Server from JDeveloper	41-33
41.4.2	How to Create an EAR File for Deployment	41-35
41.4.3	How to Deploy New Customizations Applied to ADF Library.....	41-36
41.4.3.1	Exporting Customization to a Deployed Application	41-36
41.4.3.2	Deploying Customizations to a JAR.....	41-37
41.4.4	What You May Need to Know About ADF Libraries	41-38
41.4.5	What You May Need to Know About EAR Files and Packaging.....	41-38
41.4.6	How to Deploy the Application Using Scripts and Ant	41-38
41.4.7	What You May Need to Know About JDeveloper Runtime Libraries	41-38
41.5	Postdeployment Configuration	41-38
41.5.1	How to Migrate an Application.....	41-39
41.5.2	How to Configure the Application Using ADF MBeans	41-39
41.6	Testing the Application and Verifying Deployment	41-39

Part VII Advanced Topics

42 Advanced View Object Techniques

42.1	Advanced View Object Concepts and Features	42-1
42.1.1	Limiting the View Object Max Fetch Size to Fetch the First n Rows	42-1
42.1.2	Maintaining New Row Consistency in View Objects Based on the Same Entity....	42-2
42.1.2.1	What Happens at Runtime When View Link Consistency is Enabled.....	42-3
42.1.2.2	How to Change the Default View Link Consistency Setting.....	42-3
42.1.2.3	How to Use a RowMatch to Qualify Which New, Unposted Rows Get Added to a Row Set 42-4	
42.1.2.4	What You May Need to Know About the Dynamic WHERE Clause and View Link Consistency 42-5	
42.1.3	Understanding View Link Accessors Versus Data Model View Link Instances.....	42-5
42.1.3.1	Enabling a Dynamic Detail Row Set with Active Master-Detail Coordination	42-5
42.1.3.2	Accessing a Stable Detail Row Set Using View Link Accessor Attributes.....	42-6
42.1.3.3	Accessor Attributes Create Distinct Row Sets Based on an Internal View Object.....	42-6
42.1.4	Presenting and Scrolling Data a Page at a Time Using the Range	42-7

42.1.5	Efficiently Scrolling Through Large Result Sets Using Range Paging.....	42-8
42.1.5.1	Understanding How to Oracle Supports "TOP-N" Queries.....	42-9
42.1.5.2	How to Enable Range Paging for a View Object	42-10
42.1.5.3	What Happens When You Enable Range Paging.....	42-11
42.1.5.4	What Happens When View Rows are Cached When Using Range Paging ...	42-12
42.1.5.5	How to Scroll to a Given Page Number Using Range Paging	42-12
42.1.5.6	Estimating the Number of Pages in the Row Set Using Range Paging.....	42-12
42.1.5.7	Understanding the Tradeoffs of Using a Range Paging Mode.....	42-12
42.1.6	Setting Up a Data Model with Multiple Masters	42-13
42.1.7	Understanding When You Can Use Partial Keys with findByKey().....	42-14
42.1.8	Handling View Object Queries with Primary Keys Defined by Transient Attributes	42-15
42.1.9	Creating Dynamic Attributes to Store UI State	42-16
42.1.10	Working with Multiple Row Sets and Row Set Iterators.....	42-16
42.1.11	Optimizing View Link Accessor Access By Retaining the Row Set	42-16
42.2	Tuning Your View Objects for Best Performance	42-18
42.2.1	Use Bind Variables for Parameterized Queries.....	42-18
42.2.1.1	Use Bind Variables to Avoid Re-parsing of Queries	42-18
42.2.1.2	Use Bind Variables to Prevent SQL-Injection Attacks	42-18
42.2.2	Consider Using Entity-Based View Objects for Read-Only Data	42-19
42.2.3	Use SQL Tracing to Identify Ill-Performing Queries.....	42-21
42.2.4	Consider the Appropriate Tuning Settings for Every View Object	42-22
42.2.4.1	Set the Database Retrieval Options Appropriately	42-22
42.2.4.2	Consider Whether Fetching One Row at a Time is Appropriate	42-23
42.2.4.3	Specify a Query Optimizer Hint if Necessary	42-23
42.2.5	Using Care When Creating View Objects at Runtime.....	42-24
42.2.6	Use Forward Only Mode to Avoid Caching View Rows.....	42-24
42.3	Generating Custom Java Classes for a View Object	42-24
42.3.1	How To Generate Custom Classes.....	42-25
42.3.1.1	Generating Bind Variable Accessors.....	42-25
42.3.1.2	Generating View Row Attribute Accessors	42-26
42.3.1.3	Exposing View Row Accessors to Clients.....	42-27
42.3.1.4	Configuring Default Java Generation Preferences	42-28
42.3.2	What Happens When You Generate Custom Classes.....	42-28
42.3.2.1	Seeing and Navigating to Custom Java Files	42-28
42.3.3	What You May Need to Know About Custom Classes	42-29
42.3.3.1	About the Framework Base Classes for a View Object	42-29
42.3.3.2	You Can Safely Add Code to the Custom Component File	42-29
42.3.3.3	Attribute Indexes and InvokeAccessor Generated Code	42-29
42.4	Working Programmatically with Multiple Named View Criteria	42-31
42.4.1	Applying One or More Named View Criteria.....	42-31
42.4.2	Removing All Applied Named View Criteria.....	42-32
42.4.3	Using the Named Criteria at Runtime.....	42-33
42.5	Performing In-Memory Sorting and Filtering of Row Sets.....	42-34
42.5.1	Understanding the View Object's SQL Mode.....	42-34
42.5.2	Sorting View Object Rows In Memory	42-35
42.5.2.1	Combining setSortBy and setQueryMode for In-Memory Sorting.....	42-35
42.5.2.2	Extensibility Points for In-Memory Sorting.....	42-37

42.5.3	Performing In-Memory Filtering with View Criteria.....	42-37
42.5.4	Performing In-Memory Filtering with RowMatch	42-40
42.5.4.1	Applying a RowMatch to a View Object.....	42-40
42.5.4.2	Using RowMatch to Test an Individual Row	42-42
42.5.4.3	How a RowMatch Affects Rows Fetched from the Database	42-42
42.6	Using View Objects to Work with Multiple Row Types.....	42-42
42.6.1	Working with Polymorphic Entity Usages	42-42
42.6.2	How to Create a View Object with a Polymorphic Entity Usage.....	42-43
42.6.3	What Happens When You Create a View Object with a Polymorphic Entity Usage.....	42-45
42.6.4	What You May Need to Know About Entity Usages.....	42-45
42.6.4.1	Your Query Must Limit Rows to Expected Entity Subtypes	42-45
42.6.4.2	Exposing Selected Entity Methods in View Rows Using Delegation	42-45
42.6.4.3	Creating New Rows With the Desired Entity Subtype.....	42-46
42.6.5	Working with Polymorphic View Rows	42-47
42.6.6	How to Create a View Object with Polymorphic View Rows.....	42-48
42.6.7	What You May Need to Know About Polymorphic View Rows	42-49
42.6.7.1	Selecting Subtype-Specific Attributes in Extended View Objects	42-49
42.6.7.2	Delegating to Subtype-Specific Methods After Overriding the Entity Usage	42-50
42.6.7.3	Working with Different View Row Interface Types in Client Code	42-50
42.6.7.4	View Row Polymorphism and Polymorphic Entity Usage are Orthogonal... ..	42-51
42.7	Reading and Writing XML	42-52
42.7.1	How to Produce XML for Queried Data	42-52
42.7.2	What Happens When You Produce XML	42-53
42.7.3	What You May Need to Know About Reading and Writing XML	42-55
42.7.3.1	Controlling XML Element Names.....	42-55
42.7.3.2	Controlling Element Suppression for Null-Valued Attributes.....	42-56
42.7.3.3	Printing or Searching the Generated XML Using XPath	42-56
42.7.3.4	Using the Attribute Map For Fine Control Over Generated XML	42-57
42.7.3.5	Use the Attribute Map Approach with Bi-Directional View Links.....	42-58
42.7.3.6	Transforming Generated XML Using an XSLT Stylesheet.....	42-58
42.7.3.7	Generating XML for a Single Row	42-60
42.7.4	How to Consume XML Documents to Apply Changes.....	42-60
42.7.5	What Happens When You Consume XML Documents.....	42-60
42.7.5.1	How ViewObject.readXML() Processes an XML Document	42-60
42.7.5.2	Using readXML() to Processes XML for a Single Row.....	42-61
42.8	Using Programmatic View Objects for Alternative Data Sources	42-64
42.8.1	How to Create a Read-Only Programmatic View Object	42-65
42.8.2	How to Create an Entity-Based Programmatic View Object.....	42-65
42.8.3	Key Framework Methods to Override for Programmatic View Objects.....	42-65
42.8.4	How to Create a View Object on a REF CURSOR	42-66
42.8.4.1	The Overridden create() Method	42-67
42.8.4.2	The Overridden executeQueryForCollection() Method	42-67
42.8.4.3	The Overridden createRowFromResultSet() Method	42-68
42.8.4.4	The Overridden hasNextForCollectionMethod()	42-69
42.8.4.5	The Overridden releaseUserDataForCollection() Method	42-69
42.8.4.6	The Overridden getQueryHitCount() Method	42-69

42.9	Creating a View Object with Multiple Updatable Entities	42-70
42.9.1	How to Programmatically Create New Rows With Multiple Updatable Entity Usages..	42-71
42.9.2	What Happens at Runtime: View Row Creation	42-73
42.10	Declaratively Preventing Insert, Update, and Delete	42-74

43 Application State Management

43.1	Understanding Why State Management is Necessary	43-1
43.1.1	Examples of Multi-Step Tasks.....	43-1
43.1.2	Stateless HTTP Protocol Complicates Stateful Applications.....	43-2
43.1.3	How Cookies Are Used to Track a User Session.....	43-2
43.1.4	Performance and Reliability Impact of Using HttpSession	43-3
43.2	Introduction to Fusion Web Application State Management	43-5
43.2.1	Basic Architecture of the Save for Later Facility	43-5
43.2.2	Basic Architecture of the Application Module State Management Facility	43-5
43.2.2.1	Understanding When Passivation and Activation Occurs.....	43-6
43.2.2.2	How Passivation Changes When Optional Failover Mode is Enabled	43-8
43.2.2.3	About State Management Release Levels	43-9
43.2.2.4	State Management and Subclassed Entity Objects	43-11
43.3	Using Save For Later	43-11
43.4	Setting the Application Module Release Level at Runtime	43-11
43.4.1	How to Set Unmanaged Level	43-11
43.4.2	How to Set Reserved Level.....	43-12
43.4.3	How to Set Managed Level	43-12
43.4.4	How to Set Release Level in a JSF Backing Bean.....	43-12
43.4.5	How to Set Release Level in an ADF PagePhaseListener	43-13
43.4.6	How to Set Release Level in an ADF PageController.....	43-13
43.4.7	How to Set Release Level in a Custom ADF PageLifecycle	43-14
43.5	What Model State Is Saved and When It Is Cleaned Up.....	43-14
43.5.1	State Information Saved During Passivation.....	43-15
43.5.2	Where the Model State Is Saved	43-15
43.5.2.1	How Database-Backed Passivation Works	43-15
43.5.2.2	Controlling the Schema Where the State Management Table Resides.....	43-16
43.5.2.3	Configuring the Type of Passivation Store	43-16
43.5.3	Cleaning Up the Model State	43-17
43.5.3.1	Previous Snapshot Removed When Next One Taken.....	43-17
43.5.3.2	Passivation Snapshot Removed on Unmanaged Release	43-17
43.5.3.3	Passivation Snapshot Retained in Failover Mode	43-18
43.5.4	Cleaning Up Temporary Storage Tables	43-18
43.6	Timing Out the HttpSession.....	43-19
43.6.1	How to Configure the Implicit Timeout Due to User Inactivity.....	43-19
43.6.2	How to Code an Explicit HttpSession Timeout	43-19
43.7	Managing Custom User-Specific Information.....	43-20
43.7.1	How to Passivate Custom User-Specific Information.....	43-20
43.7.1.1	What Happens When You Passivate Custom Information.....	43-21
43.8	Managing the State of View Objects	43-22
43.8.1	How to Manage the State of View Objects.....	43-22

43.8.2	What You May Need to Know About Passivating View Objects	43-22
43.8.3	How to Manage the State of Transient View Objects and Attributes	43-24
43.8.4	What You May Need to Know About Passivating Transient View Objects	43-24
43.8.5	How to Use Transient View Objects to Store Session-level Global Variables	43-24
43.9	Using State Management for Middle-Tier Savepoints	43-26
43.9.1	How to Use State Management for Savepoints.....	43-26
43.10	Testing to Ensure Your Application Module is Activation-Safe.....	43-26
43.10.1	Understanding the jbo.ampool.doampooling Configuration Parameter	43-26
43.10.2	Disabling Application Module Pooling to Test Activation	43-27
43.11	Keeping Pending Changes in the Middle Tier	43-27
43.11.1	How to Confirm That Applications Use Optimistic Locking	43-28
43.11.2	How to Avoid Clashes Using the postChanges() Method.....	43-29
43.11.3	How to Use the Reserved Level For Pending Database States	43-29

44 Tuning Application Module Pools and Connection Pools

44.1	About Application Module Pooling.....	44-1
44.1.1	Types of Pools Created When Running the Fusion Web Application.....	44-2
44.1.1.1	Application Module Pools.....	44-2
44.1.1.2	Database Connection Pools.....	44-2
44.1.2	Understanding Application Module and Connection Pools.....	44-3
44.1.2.1	Single Oracle Application Server Instance, Single Oracle WebLogic Server Instance, Single JVM	44-3
44.1.2.2	Multiple Oracle Application Server Instances, Single Oracle WebLogic Server Instance, Multiple JVMs	44-3
44.2	Setting Pool Configuration Parameters	44-4
44.2.1	How to Set Configuration Properties Declaratively	44-5
44.2.2	What Happens When You Set Configuration Properties Declaratively.....	44-5
44.2.3	How to Set Configuration Properties as System Parameters	44-6
44.2.4	How to Programmatically Set Configuration Properties.....	44-7
44.2.5	What You May Need to Know About Configuration Property Scopes.....	44-8
44.2.6	What You May Need to Know About How Database and Application Module Pools Cooperate	44-9
44.2.7	What You May Need to Know About Application Module Pool Parameters	44-11
44.2.7.1	Pool Behavior Parameters	44-11
44.2.7.2	Pool Sizing Parameters	44-14
44.2.7.3	Pool Cleanup Parameters	44-15
44.2.8	What You May Need to Know About Data Source Configuration.....	44-17
44.2.9	What You May Need to Know About Database Connection Pool Parameters.....	44-18
44.3	Initializing Database State and Pooling Considerations	44-20
44.3.1	How to Set Database State Per User.....	44-20
44.3.2	What You May Need to Know About Database User State and jbo.doconnectionpooling = true	44-21

45 Using the Active Data Service

45.1	About the Active Data Service	45-1
45.1.1	Active Data Service Use Cases and Examples.....	45-1
45.1.2	Limitations of the Active Data Service Framework.....	45-2

45.1.3	Active Data Service Framework	45-2
45.1.4	Data Transport Modes	45-4
45.2	Configuring the Active Data Service.....	45-5
45.2.1	How to Configure the Active Data Service.....	45-6
45.2.2	What You May Need to Know About Transport Modes.....	45-7
45.3	Configuring Components to Use the Active Data Service.....	45-9
45.3.1	How to Configure Components to Use the Active Data Service Without the Active Data Proxy 45-10	
45.3.2	How to Configure Components to Use the Active Data Service with the Active Data Proxy 45-10	
45.3.3	What You May Need to Know About Displaying Active Data in ADF Trees	45-11
45.3.4	What Happens at Runtime: How Components Render When Bound to Active Data.....	45-11
45.3.5	What You May Need to Know About ADS and Google Chrome	45-11
45.4	Using the Active Data Proxy	45-12
45.4.1	What You May Need to Know About Read Consistency	45-17
45.5	Using the Active Data with a Scalar Model	45-17

Glossary

Preface

Welcome to the *Oracle Fusion Middleware Fusion Developer's Guide for Oracle Application Development Framework*.

Audience

This document is intended for enterprise developers who need to create and deploy database-centric Java EE applications with a service-oriented architecture using the Oracle Application Development Framework (Oracle ADF). This guide explains how to build Fusion web applications using ADF Business Components, ADF Controller, ADF Faces, and JavaServer Faces.

Documentation Accessibility

Our goal is to make Oracle products, services, and supporting documentation accessible to all users, including users that are disabled. To that end, our documentation includes features that make information available to users of assistive technology. This documentation is available in HTML format, and contains markup to facilitate access by the disabled community. Accessibility standards will continue to evolve over time, and Oracle is actively engaged with other market-leading technology vendors to address technical obstacles so that our documentation can be accessible to all of our customers. For more information, visit the Oracle Accessibility Program Web site at <http://www.oracle.com/accessibility/>.

Accessibility of Code Examples in Documentation

Screen readers may not always correctly read the code examples in this document. The conventions for writing code require that closing braces should appear on an otherwise empty line; however, some screen readers may not always read a line of text that consists solely of a bracket or brace.

Accessibility of Links to External Web Sites in Documentation

This documentation may contain links to Web sites of other companies or organizations that Oracle does not own or control. Oracle neither evaluates nor makes any representations regarding the accessibility of these Web sites.

Deaf/Hard of Hearing Access to Oracle Support Services

To reach Oracle Support Services, use a telecommunications relay service (TRS) to call Oracle Support at 1.800.223.1711. An Oracle Support Services engineer will handle technical issues and provide customer support according to the Oracle service request process. Information about TRS is available at

<http://www.fcc.gov/cgb/consumerfacts/trs.html>, and a list of phone numbers is available at <http://www.fcc.gov/cgb/dro/trsphonebk.html>.

Conventions

The following text conventions are used in this document:

Convention	Meaning
boldface	Boldface type indicates graphical user interface elements (for example, menus and menu items, buttons, tabs, dialog controls), including options that you select.
<i>italic</i>	Italic type indicates book titles, emphasis, or placeholder variables for which you supply particular values.
monospace	Monospace type indicates language and syntax elements, directory and file names, URLs, text that appears on the screen, or text that you enter.

What's New in This Guide in Release 11.1.2.0.0

For Release 11.1.2.0.0, this guide has been updated in several ways. The following table lists the sections that have been added or changed.

For changes made to Oracle JDeveloper and Oracle Application Development Framework (Oracle ADF) for this release, see the What's New page on the Oracle Technology Network at <http://www.oracle.com/technetwork/developer-tools/jdev/documentation/index.html>.

Sections	Change Description
Chapter 1 Introduction to Building Fusion Web Applications with Oracle ADF	
Chapter 1, "Introduction to Building Fusion Web Applications with Oracle ADF"	Updated chapter to reflect basic UI and FOD updates in 11.1.2.0.0.
Chapter 2 Introduction to the ADF Sample Application	
Section 2.4.6, "Standalone Applications in the AdvancedUIExamples Application Workspaces"	Created a new section to describe several new standalone samples.
Chapter 3 Getting Started with ADF Business Components	
Section 3.3.1, "Choosing a Connection, SQL Platform, and Data Type Map"	Revised section to describe new Java Extended for Oracle type map default.
Section 3.3.5, "Displaying Related Components Using Diagrams"	Created a new section to describe the use of the new Diagram page in all overview editors for business components.
Section 3.6, "Overview of Groovy Scripting Language Support"	Revised section to describe use of Business Rules page in overview editors to filter the display to show expressions.
Chapter 4 Creating a Business Domain Layer Using Entity Objects	

Sections	Change Description
Chapter 4, "Creating a Business Domain Layer Using Entity Objects"	Merged the entire advanced entity object chapter (previously shown in the advanced part). Also, updated to reflect improvements to the JDeveloper UI.
Chapter 5 Defining SQL Queries Using View Objects	
Section 5.6.7, "How to Create a Master-Detail Hierarchy for Entity Objects with Transient-Only Attributes"	Created a new section to describe use case for entity objects with non-persistent attributes.
Section 5.12.4, "How to Define an LOV to Display a Reference Attribute"	Created a new section to describe LOV use case with reference attributes.
Section 5.13.3, "How to Define UI Category Hints"	Created a new section to describe use of UI Categories page in view object editor.
Chapter 6 Working with View Object Query Results	
Section 6.3.10, "What You May Need to Know About Optimizing View Object Runtime Performance"	Revised table to mention how the new Row Fetch Limit property can be used with view object tuning properties.
Section 6.4.11, "How to Authenticate Test Users in the Test Client"	Created a new section to describe how to pass user credentials into a test client.
Chapter 7 Defining Validation and Business Rules Declaratively	
Section 7.3, "Adding Validation Rules to Entity Objects and Attributes"	Revised section to provide additional information: clarification on usage of declarative validation definitions.
Chapter 8 Implementing Validation and Business Rules Programmatically	
Section 8.14, "Implementing Custom Validation Rules"	Created a new section to describe creating a custom validator.
Chapter 9 Implementing Business Services with Application Modules	
Section 9.3, "Configuring Your Application Module Database Connection"	Revised section to describe default connection type based on a JDBC data source.
Chapter 10 Sharing Application Module View Instances	
Section 10.2.6, "What You May Need to Know About Shared Application Modules and Connection Pooling"	Revised section to describe optimization of shared application modules through use of <code>jbo.shared.txn</code> property setting.
Chapter 11 Integrating Service-Enabled Application Modules	

Sections	Change Description
Section 11.2.5, "How to Customize the SDO Properties of Service-Enabled View Objects"	Created a new section to describe how to exclude individual attributes from SDO and how to use complex data types.
Chapter 12 Extending Business Components Functionality	
Chapter 12, "Extending Business Components Functionality"	Moved advanced chapter (previously titled "Advanced Business Components Techniques") into the Building Business Services part.
Chapter 13 Using ADF Model in a Fusion Web Application	
Section 13.7.2.2, "Executable Binding Objects Defined in the Page Definition File"	Revised section to describe PPR is the new default for iterator bindings and added multi task flow executable binding object.
Chapter 15 Exposing URL Services Using the ADF Model Layer	
Chapter 15, "Exposing URL Services Using the ADF Model Layer"	Created a new chapter that describes how to consume a data stream from a URL service.
Chapter 16 Using Validation in the ADF Model Layer	
Chapter 16, "Using Validation in the ADF Model Layer"	Created a new chapter that describes how and when to use model layer validation.
Chapter 18 Getting Started with ADF Task Flows	
Section 18.4, "Adding Control Flow Rules to Task Flows"	Revised section to describe new If condition to control flow cases.
Section 18.4.4, "What Happens at Runtime: Evaluating Control Flow Rules"	Revised section to describe implementation of new <code>javax.faces.application.ConfigurableNavigationHandler</code> interface.
Chapter 20 Using Parameters in Task Flows	
Section 20.3, "Passing Parameters to a Bounded Task Flow"	Revised section to make clear that application developers should not configure their applications to invoke task flows using URLs if they plan to expose their application in a JSF portlet.
Chapter 21 Using Task Flows as Regions	
Section 21.6, "Configuring Activation of an ADF Region"	Revised section to describe conditional activation of task flow bindings.
Section 21.10, "Configuring a Page To Render an Unknown Number of Regions"	Revised section to describe how to use multi task flow binding.

Sections	Change Description
Chapter 22 Creating Complex Task Flows	
Section 22.2, "Managing Transactions in Task Flows"	Revised section to recommend against usage of the <No Controller Transaction> setting.
Section 22.4.3, "How to Designate Custom Code as an Exception Handler"	Created new section to describe how to write custom code that you can designate as an exception handler for a task flow.
Section 22.7, "Using Train Components in Bounded Task Flows"	Revised section to describe how to label train components that render in a task.
Chapter 23 Using Dialogs in Your Application	
Section 23.2.1, "How to Run a Bounded Task Flow in a Modal Dialog"	Revised section to clarify the property changes you need to make to the command button that invokes a task flow to run in a modal dialog.
Chapter 25 Understanding the Fusion Page Lifecycle	
Section 25.2, "About the JSF and ADF Page Lifecycles"	Revised section to provide simplified lifecycle example.
Section 25.2.1, "What You May Need to Know About Partial Page Rendering and Iterator Bindings"	Created a new section to describe PPR iterator bindings.
Chapter 28 Using Command Components to Invoke Functionality in the View Layer	
Chapter 28, "Command Components to Invoke Functionality in the View Layer"	Moved entire chapter here from previous "Complex Pages" chapter.
Chapter 32 Using More Complex Databound ADF Faces Components	
Chapter 32, "Using More Complex Databound ADF Faces Components"	Updated procedures in this chapter to describe the use of the emptyText attribute to specify the text to display when there is no data to return in the graph.
Chapter 33 Creating Databound ADF Data Visualization Components	
Section 33.2.6, "How to Create a Databound Spark Chart"	Revised section to describe adding a sparkchart from the Data Controls panel.
Section 33.8.1, "How to Create a Hierarchy Viewer Using ADF Data Controls"	Revised section to describe updated databinding dialog.
Section 33.6, "Creating Databound Thematic Maps"	Created new section to describe using the Data Controls panel to create a thematic map.
Chapter 35 Enabling ADF Security in Fusion Web Applications	

Sections	Change Description
Section 35.5.11, "How to Aggregate Resource Grants as Entitlement Grants"	Created a new section to describe use of entitlement grants in security policy overview editor.
Section 35.11.4, "Best Practices for Working with ADF Security"	Revised section to clarify best practice for using JDeveloper to create test users.
Chapter 36 Testing and Debugging ADF Components	
Section 36.4, "Reloading Oracle ADF Metadata in Integrated WebLogic Server"	Created a new section to describe the ability to reload application metadata at runtime without restarting the application.
Section 36.9.4, "How to Set and Use Page Definition Value Binding Breakpoints"	Revised section to describe breakpoints for tree and table bindings.
Section 36.9.5, "How to Set and Use Page Definition Contextual Event Breakpoints"	Created a new section to describe breakpoints for contextual events.
Chapter 39 Customizing Applications with MDS	
Section 39.2.1.3, "Creating a Customization Class" and Section 39.2.3, "How to Consume Customization Classes"	Revised sections to remove constraint that customization classes must be in JDeveloper class path.
Section 39.3.4, "How to Configure Customization Layers"	Revised section to describe the use of a workspace-level CustomizationLayerValues.xml file.
Section 39.4.2.2, "Using a Standalone Annotations File to Specify Type-Level Customization Properties"	Created section to describe the use of a standalone annotations file.
Chapter 43 Application State Management	
Section 43.2.2.2, "How Passivation Changes When Optional Failover Mode is Enabled"	Revised section to clarify best practice for <code>jbo.doFailover</code> property.
Section 43.2.2.4, "State Management and Subclassed Entity Objects"	Created section to describe the need to prepopulate the key for subclassed entity objects.
Section 43.11.1, "How to Confirm That Applications Use Optimistic Locking"	Revised section to clarify use of optimistic locking.
Chapter 44 Tuning Application Module Pools and Connection Pools	
Section 44.2.7, "What You May Need to Know About Application Module Pool Parameters"	Updated table to document new default value for <code>jbo.txn.disconnect_level</code> property. The new transaction state defaults to 0 to better support Fusion web applications.
Chapter 45 Using the Active Data Service	

Sections	Change Description
Section 45.1.2, "Limitations of the Active Data Service Framework"	Created a new section to describe limitations of ADS.
Section 45.3.3, "What You May Need to Know About Displaying Active Data in ADF Trees"	Created a new section to describe support for active data and tree components.
Section 45.5, "Using the Active Data with a Scalar Model"	Created a new section to describe support for active data and scalar models.
Appendix A Oracle ADF XML Files	
Section A.11, "adf-config.xml"	Revised to describe how you can disable automatic partial page rendering as the default behavior for an application.
Section A.12, "adf-settings.xml"	Revised section to describe how JDeveloper automatically creates the <code>adf-settings.xml</code> file when you create an application using the Fusion Web Application template or add ADF Page Flow to the technology scope of your project.
Section A.13, "web.xml"	Revised to describe how to override the staleness period setting of 364 days for all static web application resources in ADF Libraries by adding initialization parameters to the <code>web.xml</code> file.
Appendix H Data Controls in Fusion Web Applications	
Section H.1, "Introduction to Data Controls"	Revised section to describe support for JMX data control.

Part I

Getting Started with Fusion Web Applications

Part I contains the following chapters:

- [Chapter 1, "Introduction to Building Fusion Web Applications with Oracle ADF"](#)
- [Chapter 2, "Introduction to the ADF Sample Application"](#)

Introduction to Building Fusion Web Applications with Oracle ADF

This chapter describes the architecture and key functionality of the Oracle Application Development Framework (Oracle ADF) when used to build a Fusion web application that uses ADF Business Components, ADF Model, ADF Controller, and ADF Faces rich client, along with high-level development practices.

This chapter includes the following sections:

- [Section 1.1, "Introduction to Oracle ADF"](#)
- [Section 1.2, "Oracle ADF Architecture"](#)
- [Section 1.3, "Overview of Building and Application with Oracle ADF"](#)
- [Section 1.4, "Working Productively in Teams"](#)
- [Section 1.5, "Other Resources for Learning Oracle ADF"](#)
- [Section 1.6, "Generation of Complete Web Tier Using Oracle JHeadstart"](#)

1.1 Introduction to Oracle ADF

The Oracle Application Development Framework (Oracle ADF) is an end-to-end application framework that builds on Java Platform, Enterprise Edition (Java EE) standards and open-source technologies. You can use Oracle ADF to implement enterprise solutions that search, display, create, modify, and validate data using web, wireless, desktop, or web services interfaces. Because of its declarative nature, Oracle ADF simplifies and accelerates development by allowing users to focus on the logic of application creation rather than coding details. Used in tandem, Oracle JDeveloper and Oracle ADF give you an environment that covers the full development lifecycle from design to deployment, with drag and drop data binding, visual UI design, and team development features built in.

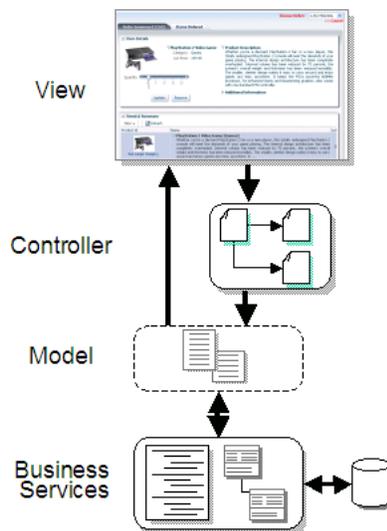

As a companion to this guide, you can download and view the Fusion Order demo application, which helps to illustrate the concepts and procedures in this guide (and other Oracle Fusion Middleware developer guides). The StoreFront module of this application is built using the Fusion web application technology stack, which includes ADF Business Components, ADF Model, ADF Controller, and JavaServer Faces pages with ADF Faces rich client components. Screenshots and code samples from this module are used throughout this guide to provide you with real-world examples of using the Oracle ADF technologies in an application that uses the Fusion web technology stack. For more information about downloading and using the StoreFront module of the Fusion Order Demo application, see [Chapter 2, "Introduction to the ADF Sample Application."](#)

1.2 Oracle ADF Architecture

In line with community best practices, applications you build using the Fusion web technology stack achieve a clean separation of business logic, page navigation, and user interface by adhering to a model-view-controller architecture. As shown in [Figure 1-1](#), in an MVC architecture:

- The model layer represents the data values related to the current page
- The view layer contains the UI pages used to view or modify that data
- The controller layer processes user input and determines page navigation
- The business service layer handles data access and encapsulates business logic

Figure 1-1 MVC Architecture Cleanly Separates UI, Business Logic and Page Navigation

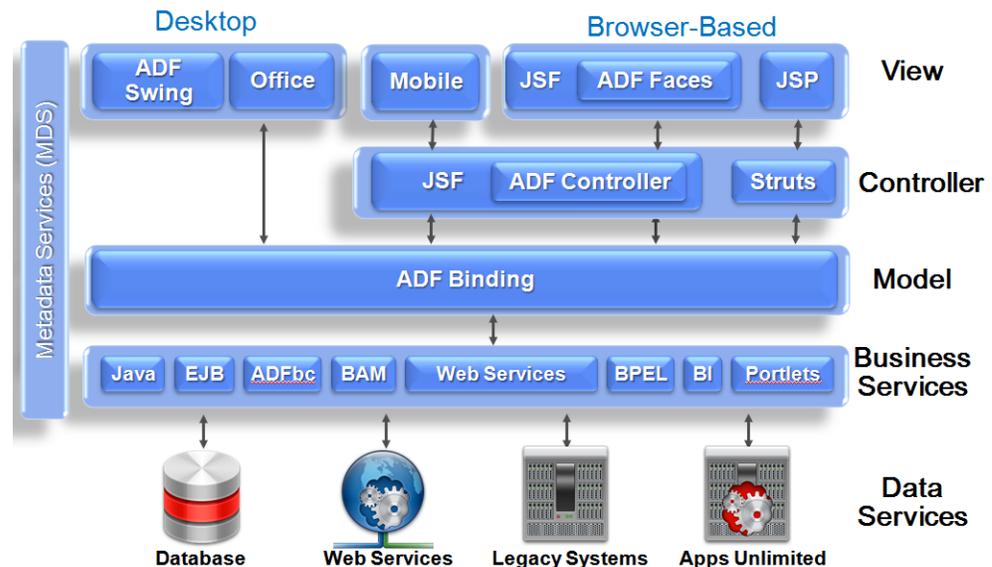

[Figure 1-2](#) illustrates where each ADF module fits in the Fusion web application architecture. The core module in the framework is ADF Model, a data binding facility that implements the JSR-227 specification (for more information, see <http://jcp.org/en/jsr/detail?id=227>). The ADF Model layer enables a unified approach to bind any user interface to any business service, without the need to write code. The other modules that make up a Fusion web application technology stack are:

- ADF Business Components, which simplifies building business services.
- ADF Faces rich client, which offers a rich library of ajax-enabled UI components for web applications built with JavaServer Faces (JSF).
- ADF Controller, which integrates JSF with ADF Model. ADF Controller extends the standard JSF controller by providing additional functionality, such as reusable task flows that pass control not only between JSF pages, but also between other activities, for instance method calls or other task flows.

Note: In addition to ADF Faces, Oracle ADF also supports using the Swing, JSP, and standard JSF view technologies. For more information about these technologies, see the *Oracle Fusion Middleware User Guide for Oracle JDeveloper*. Oracle ADF also provides support for using Microsoft Excel as a view layer for your application. For more information, see the *Oracle Fusion Middleware Desktop Integration Developer's Guide for Oracle Application Development Framework*.

Figure 1–2 Simple Oracle ADF Architecture

1.2.1 ADF Business Components

When building service-oriented Java EE applications, you implement your core business logic as one or more business services. These backend services provide clients with a way to query, insert, update, and delete business data as required while enforcing appropriate business rules. ADF Business Components are prebuilt application objects that accelerate the job of delivering and maintaining high-performance, richly functional, database-centric services. They provide you with a ready-to-use implementation of Java EE design patterns and best practices.

As illustrated in [Figure 1–3](#), Oracle ADF provides the following key components to simplify building database-centric business services:

- Entity object

An entity object represents a row in a database table and simplifies modifying its data by handling all data manipulation language (DML) operations for you. It can encapsulate business logic to ensure that your business rules are consistently enforced. You associate an entity object with others to reflect relationships in the underlying database schema to create a layer of business domain objects to reuse in multiple applications.

- View object

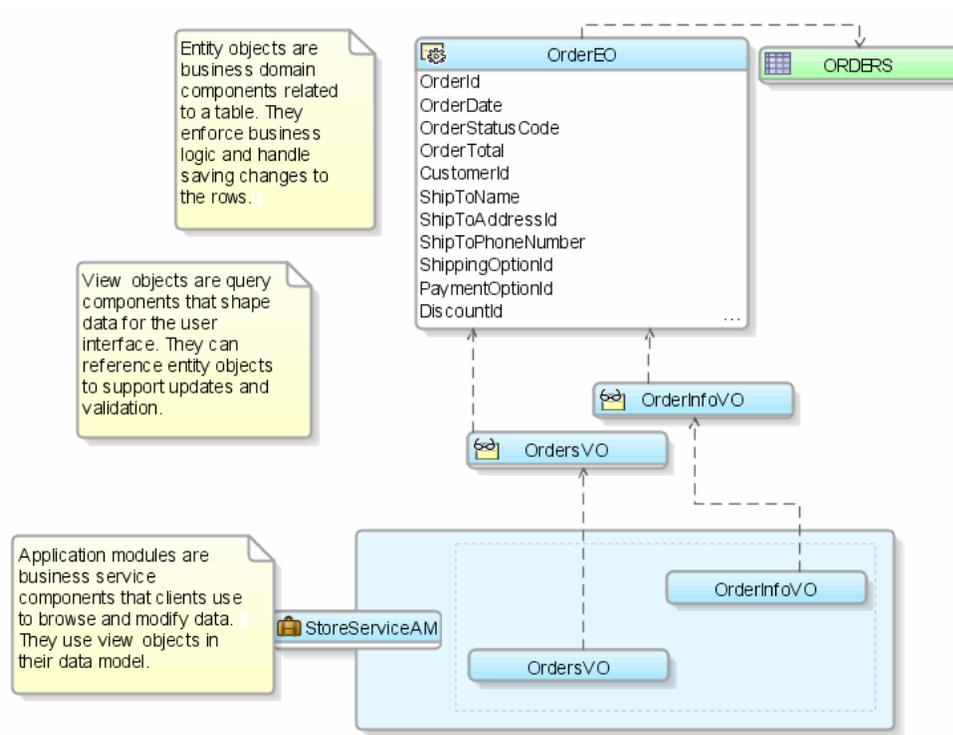

A view object represents a SQL query and simplifies working with its results. You use the SQL language to join, filter, sort, and aggregate data into the shape required by the end-user task being represented in the user interface. This includes

the ability to link a view object with other view objects to create master-detail hierarchies of any complexity. When end users modify data in the user interface, your view objects collaborate with entity objects to consistently validate and save the changes.

- Application module

An application module is the transactional component that UI clients use to work with application data. It defines an updateable data model along with top-level procedures and functions (called service methods) related to a logical unit of work related to an end-user task.

Figure 1–3 ADF Business Components Simplify Data Access and Validation

Tip: If you have previously worked with Oracle Forms, note that this combined functionality is the same set of data-centric features provided by the form, data blocks, record manager, and form-level procedures or functions. The key difference in Oracle ADF is that the user interface is cleanly separated from data access and validation functionality. For more information, see [Appendix G, "Performing Common Oracle Forms Tasks in Oracle ADF."](#)

1.2.2 ADF Model Layer

The ADF model abstracts the business service implementation according to JSR-227, providing a single programming interface for different types of services. Data controls provide this interface by using standard metadata interfaces to describe the service's operations and data collections, including information about the properties, methods, and types involved. In JDeveloper, the functionality and attributes exposed by a business service are indicated by icons in the Data Controls panel. You can drag and drop onto a page to create UI components. JDeveloper automatically creates the bindings from the page and the UI components to the services. At runtime, the ADF

Model layer reads the information describing your data controls and data bindings from appropriate XML files and implements the two-way connection between your user interface and your business service.

Oracle ADF provides out-of-the-box data control implementations for the most common business service technologies. Using JDeveloper and Oracle ADF together provides you with a drag and drop data binding experience as you build your user interfaces. Along with support for ADF application modules, ADF Model also provides support for the following service technologies:

- Enterprise JavaBeans (EJB) session beans and JPA entities
- JavaBeans
- Web services
- XML
- CSV files

1.2.3 ADF Controller

In the controller layer, where handling page flow of your web applications is a key concern, ADF Controller provides an enhanced navigation and state management model on top of JSF. JDeveloper allows you to declaratively create task flows where you can pass application control between different types of activities, such as pages, methods on managed beans, case statements, or calls to other task flows.

These task flows can be reused, and can also be nested, both within themselves and within pages. Task flows nested in pages become regions that contain their own set of navigable pages, allowing users to view a number of different pages and functionality without leaving the main page.

1.2.4 ADF Faces Rich Client

ADF Faces rich client (ADF Faces for short), is a set of standard JSF components that include built-in AJAX functionality. AJAX is a combination of asynchronous JavaScript, dynamic HTML (DHTML), XML, and `XmlHttpRequest` communication channels. This combination allows requests to be made to the server without fully re-rendering the page. While AJAX allows rich client-like applications to use standard internet technologies, JSF provides server-side control, which reduces the dependency on an abundance of JavaScript often found in typical AJAX applications. To achieve these front-end capabilities, ADF Faces components use a rendering kit that handles displaying the component and also provides the JavaScript objects needed for the rich functionality. This built-in support enables you to build rich applications without needing to code JavaScript, or needing extensive knowledge of the individual technologies on the front or back end.

ADF Faces provides over 150 rich components, including hierarchical data tables, tree menus, in-page dialogs, accordions, dividers, and sortable tables. ADF Faces also provides ADF Data Visualization components, which are Flash- and PNG-enabled components capable of rendering dynamic charts, graphs, gauges, and other graphics that can provide a real-time view of underlying data. Each component also supports customization and skinning, along with internationalization and accessibility.

ADF Faces can also be used in an application that uses the Facelets library. Facelets is a JSF-centric XML view definition technology that provides an alternative to using the JSP engine. For more information about ADF Faces, including the architecture and detailed information about each of the components, see the *Oracle Fusion Middleware Web User Interface Developer's Guide for Oracle Application Development Framework*.

Along with ADF Faces, Oracle ADF also supports the following view technologies:

- Apache MyFaces Trinidad: This is the open source code donation from Oracle to the Apache Software Foundation. ADF Faces components are based on these Trinidad components.
- Java Swing and ADF Swing: ADF Swing is the development environment for building Java Swing applications that use the ADF Model layer.
- ADF Mobile: This is a standards-based framework for building mobile applications built on the component model of JSF.
- Microsoft Excel: You can create spreadsheets that are bound to data using the same binding principals as do other view technologies. For more information, see the *Oracle Fusion Middleware Desktop Integration Developer's Guide for Oracle Application Development Framework*.

1.3 Overview of Building and Application with Oracle ADF

Oracle ADF emphasizes the use of the declarative programming paradigm throughout the development process to allow users to focus on the logic of application creation without having to get into implementation details. Using JDeveloper with Oracle ADF, you benefit from a high-productivity environment that automatically manages your application's declarative metadata for data access, validation, page control and navigation, user interface design, and data binding.

At a high level, the development process for a Fusion web application usually involves the following:

- Creating an application workspace: Using a wizard, JDeveloper automatically adds the libraries and configuration needed for the technologies you select, and structures your application into projects with packages and directories.
- Modeling the database objects: You can create an offline replica of any database, and use JDeveloper editors and diagrammers to edit definitions and update schemas.
- Creating use cases: Using the UML modeler, you can create use cases for your application.
- Designing application control and navigation: You use diagrammers to visually determine the flow of application control and navigation. JDeveloper creates the underlying XML for you.
- Identifying shared resources: You use a resource library that allows you to view and use imported libraries by simply dragging and dropping them into your application.
- Creating business components to access data: From your database tables, you create entity objects using wizards or dialogs. From those entity objects, you create the view objects used by the pages in your application. You can implement validation rules and other types of business logic using editors.
- Implementing the user interface with JSF: The Data Controls panel in JDeveloper contains a representation of the view objects in your application. Creating a user interface is as simple as dragging an object onto a page and selecting the UI component you want to display the underlying data. For UI components that are not databound, you use the Component Palette to drag and drop components. JDeveloper creates all the page code for you.

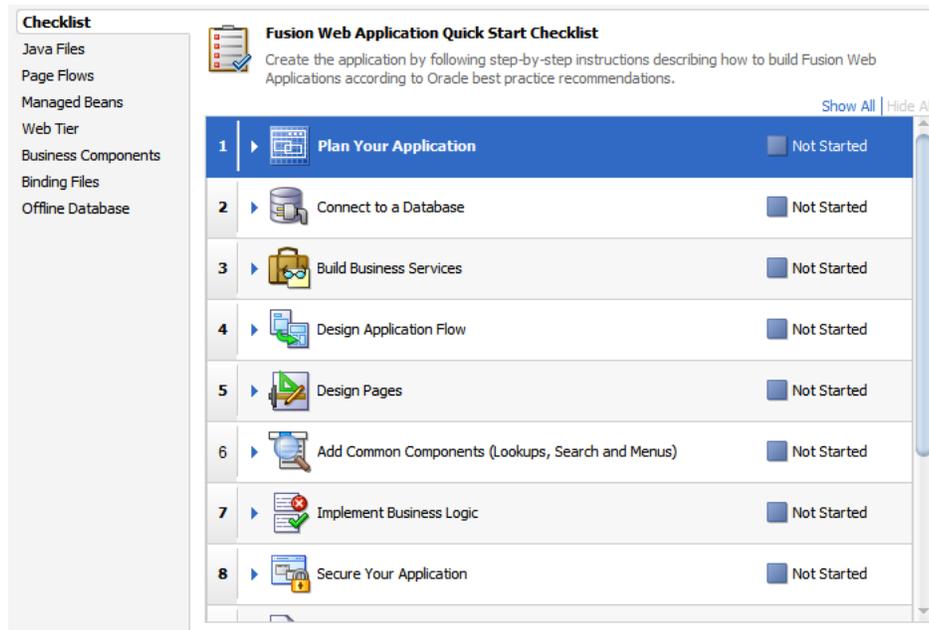

- Binding UI components to data using the ADF Model layer: When you drag an object from the Data Controls panel, JDeveloper automatically creates the bindings between the page and the data model.
- Incorporating validation and error handling: Once your application is created, you use editors to add additional validation and to define error handling.
- Securing the application: You use editors to create roles and populate these with test users. You then use a flat file editor to define security policies for these roles and assign them to specific resources in your application.
- Testing and debugging: JDeveloper includes an integrated application server that allows you to fully test your application without needing to package it up and deploy it. JDeveloper also includes the ADF Declarative Debugger, a tool that allows you to set breakpoints and examine the data.
- Deploying the application: You use wizards and editors to create and edit deployment descriptors, JAR files, and application server connections.

1.3.1 Creating an Application Workspace

The first step in building a new application is to assign it a name and to specify the directory where its source files will be saved. When you create an application using the application templates provided by JDeveloper, it organizes your workspace into projects and creates and organizes many of the configuration files required by the type of application you are creating.

One of these templates is the Fusion Web Application (ADF) template, which provides the correctly configured set of projects you need to create a web application that uses ADF Faces for the view, ADF Controller for the page flow, and ADF Business Components for business services. When you create an application workspace using this template, JDeveloper automatically creates the JSF and ADF configuration files needed for the application.

One part of the application overview is the Fusion Web Application Quick Start Checklist. This checklist provides you with the basic steps for creating a Fusion web application. Included are links to pertinent documentation, prerequisites, and the ability to keep track of status for each step in the checklist, as shown in [Figure 1-4](#).

Figure 1–4 Fusion Web Application Quick Start Checklist

JDeveloper also creates a project named `Model` that will contain all the source files related to the business services in your application, and a project named `ViewController` that will contain all the source files for your ADF Faces view layer, including files for the controller.

JDeveloper adds the following libraries to the data model project:

- ADF Model Runtime
- BC4J Oracle Domains
- BC4J Runtime
- BC4J Security
- MDS Runtime
- MDS Runtime Dependencies
- Oracle JDBC

JDeveloper also adds the following libraries to the view project:

- JSP Runtime
- JSF 2.0
- JSTL 1.2
- ADF Page Flow Runtime
- ADF Controller Runtime
- ADF Controller Schema
- ADF Faces Runtime 11
- ADF Common Runtime
- ADF Web Runtime
- MDS Runtime

- MDS Runtime Dependencies
- Commons Beautils 1.6
- Commons Logging 1.0.4
- Commons Collections 3.1
- ADF DVT Faces Runtime
- ADF DVT Faces Databinding Runtime
- ADF DVT Faces Databinding MDS Runtime

Once you add a JSF page, JDeveloper adds the Oracle JJWT library.

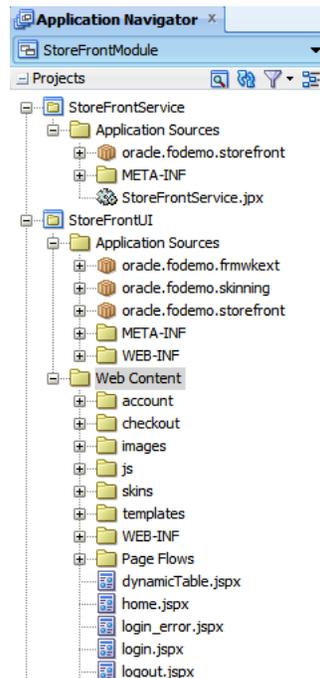

Once the projects are created for you, you can rename them as you need. You can then use JDeveloper to create additional projects, and add the packages and files needed for your application.

Note: If you plan to reuse artifacts in your application (for example, task flows), then you should follow the naming guidelines presented in [Chapter 38, "Reusing Application Components"](#) in order to prevent naming conflicts.

Tip: You can edit the default values used in application templates, as well as create your own templates. To do so, choose **Application > Manage Templates**.

Figure 1–5 shows the different projects, packages, directories, and files for the `StoreFrontModule` application, as displayed in the Application Navigator.

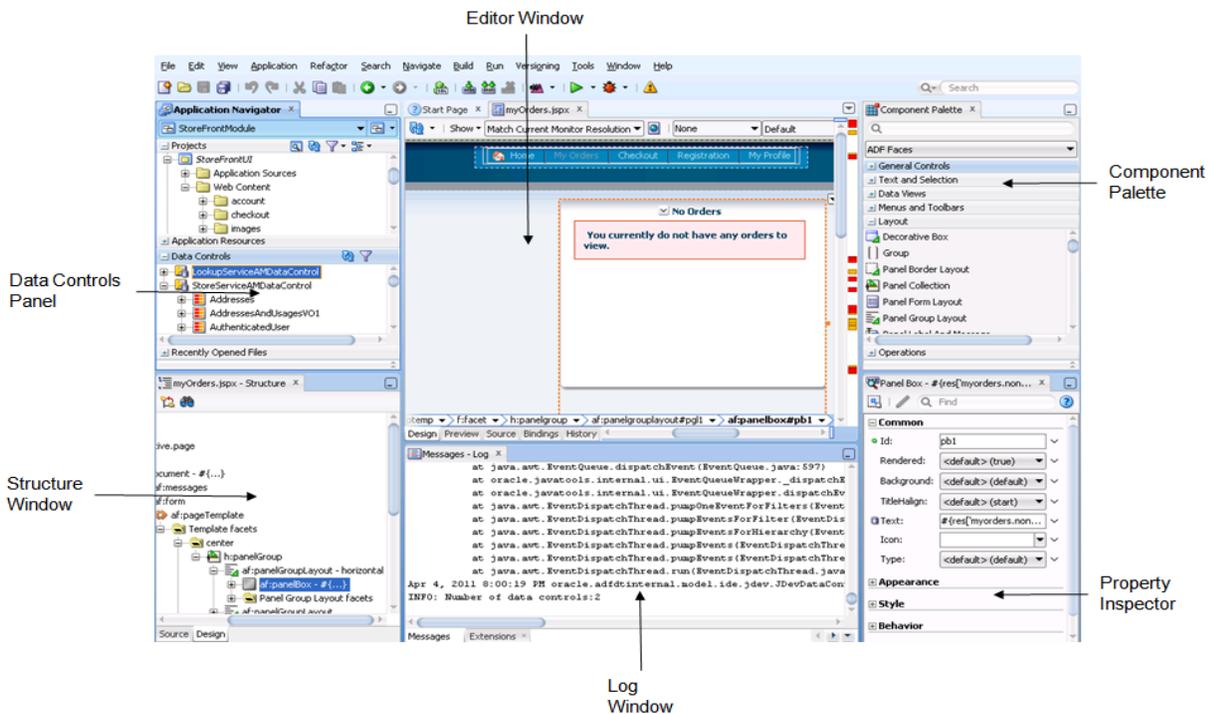

Figure 1–5 StoreFrontModule Application Projects, Packages, and Directories

For more information, see "Managing Applications and Projects" section of the *Oracle Fusion Middleware User Guide for Oracle JDeveloper*.

When you work with your files, you use mostly the editor window, the Structure window, and the Property Inspector, as shown in Figure 1–6. The editor window allows you to view many of your files in a WYSIWYG environment, or you can view a file in an overview editor where you can declaratively make changes, or you can view the source code for the file. The Structure window shows the structure of the currently selected file. You can select objects in this window and then edit the properties for the selection in the Property Inspector.

Figure 1–6 The JDeveloper Workspace

1.3.2 Modeling with Database Object Definitions

In JDeveloper, after you create your application workspace, you can copy database objects from a database schema to an offline database or project where they become available as offline database objects, saved as .xml files. You can then create and edit database object definitions within a project using the same editors that you use to create and edit database objects on live database connections. You can also compare your offline database objects with other offline or live database schemas and generate SQL statements (including CREATE, REPLACE, and ALTER).

For example, you can drag a table from a database connection that your application defines onto a database diagram and JDeveloper will give you the choice to model the database object live or offline (to create the .xml file representation of the object). Modeling database definitions, such as tables and foreign keys, visually captures the essential information about a schema. You can use the diagram to drag and drop columns and keys to duplicate, move, and create foreign key relationships. Working in offline mode, whenever you model a node on a diagram, JDeveloper creates the underlying offline object and lists it in the Application Navigator. Working with a live schema, JDeveloper updates the live database object as you amend the diagram. You

can create multiple diagrams from the same offline database objects and spread your offline database across multiple projects.

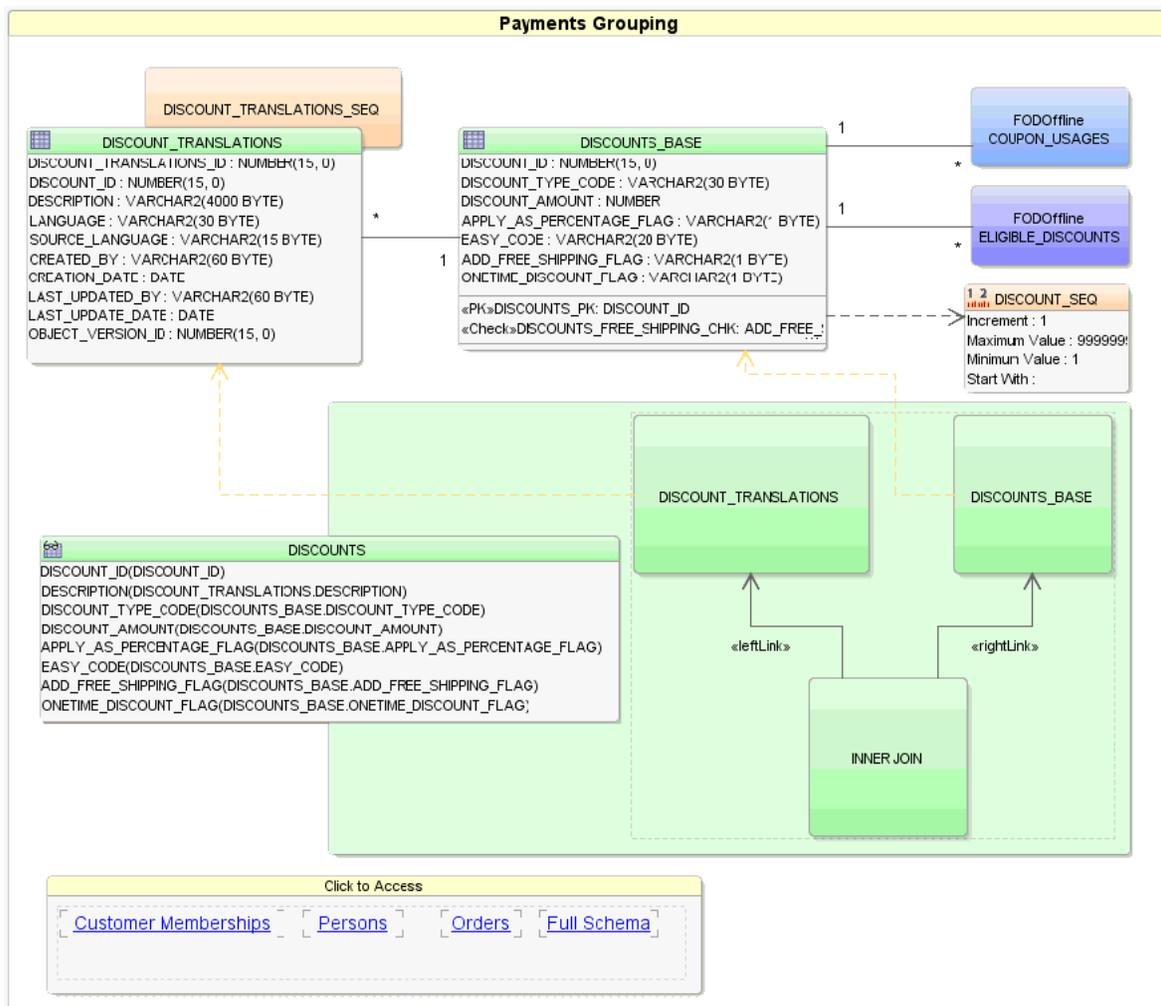

Using a database diagram like the one shown in [Figure 1-7](#) you can visualize the following:

- Tables and their columns
- Foreign key relationships between tables
- Views
- Offline sequences and synonyms

In addition to using the diagram directly to create and edit database objects, you can work with specific database object editors. After you have finished working with the offline database objects, you can generate new and updated database definitions to online database schemas.

When you work with the database diagram you can customize the diagram to change the layout, change how objects are represented and grouped, add diagram annotations to specify dependencies or links (such as URLs), and change visual properties, such as color and font of diagram elements.

Figure 1-7 Database Diagram for Payments Grouping

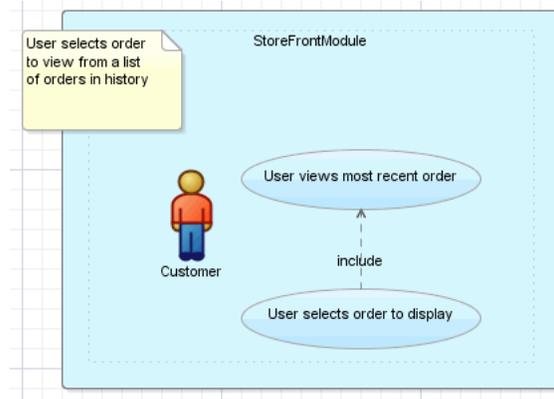

Specifically, the following customizations were made to the database diagram shown in [Figure 1-7](#):

- DISCOUNT_TRANSLATIONS element show the table with constraints not displayed.
- DISCOUNTS_BASE element shows the table with some column definitions hidden (such as CREATED_BY, CREATION_DATE, and LASTUPDATED_BY) plus the diagram element has been sized to fit within the overall diagram (thus truncating some of the detail).
- DISCOUNT_TRANSLATIONS_SEQ element shows a sequence displayed in compact view in contrast to DISCOUNTS_SEQ which shows the sequence properties.
- COUPON_USAGES and ELIGIBLE_DISCOUNTS elements use different colors both in compact view and each identifies their database schema (FODOffline).
- DISCOUNTS element is a view displayed. The element identifies the tables that comprise the view in compact mode and the JOIN type (INNER JOIN). It also identifies the usage relationships on tables with a dotted line.
- DISCOUNTS_BASE and DISCOUNT_TRANSLATIONS elements show a foreign key relationship.
- DISCOUNT_SEQ element uses an annotation (dashed arrow) to represent the dependency with DISCOUNTS_BASE table.
- Payments Grouping element uses HTML link annotations (for example, Customer Memberships) to display other diagrams from the project.
- Payments Grouping element nests elements with group shapes (Click to Access).

For more information about modeling database definitions with database diagrams, see "Creating, Editing, and Dropping Database Objects" in the *Oracle Fusion Middleware User Guide for Oracle JDeveloper*.

1.3.3 Creating Use Cases

After creating an application workspace, you may decide to begin the development process by doing use case modeling to capture and communicate end-user requirements for the application to be built. [Figure 1-8](#) shows a simple diagram created using the UML modeler in JDeveloper. The diagram represents an end user viewing a list of his orders and then drilling down to view the details of an order. Using diagram annotations, you can capture particular requirements about what end users might need to see on the screens that will implement the use case. For example, in this use case, it is noted that the user will select order details for each order listed.

Figure 1–8 Use Case Diagram for Viewing Order History

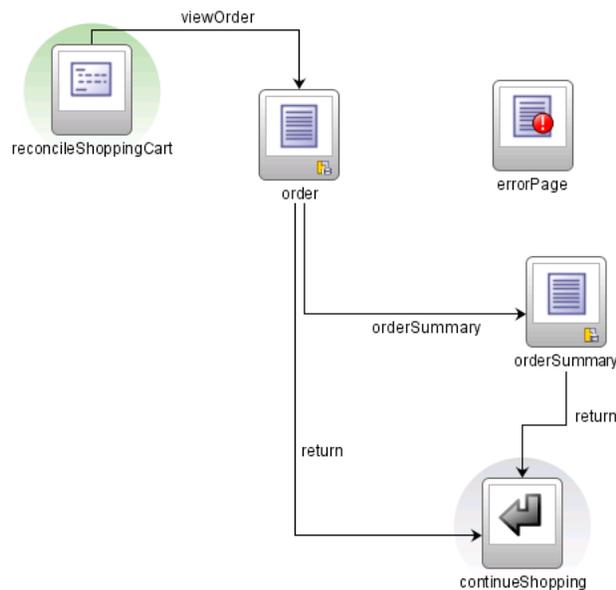

For more information about creating use case diagrams, see the "Getting Started With Application Modeling Using Diagrams" chapter of the *Oracle Fusion Middleware User Guide for Oracle JDeveloper*.

1.3.4 Designing Application Control and Navigation Using ADF Task Flows

By modeling the use cases, you begin to understand the kinds of user interface pages that will be required to implement end-user requirements. At this point, you can begin to design the flow of your application. In a Fusion web application, you use ADF task flows instead of standard JSF navigation flows. Task flows provide a more modular and transaction-aware approach to navigation and application control. Like standard JSF navigation flows, task flows contain mostly viewable pages. However, instead of describing navigation between pages, task flows facilitate transitions between activities. Aside from navigation, task flows can also have nonvisual activities that can be chained together to affect the page flow and application behavior. For example, these nonvisual activities can call methods on managed beans, evaluate an EL expression, or call another task flow. This facilitates reuse, as business logic can be invoked independently of the page being displayed.

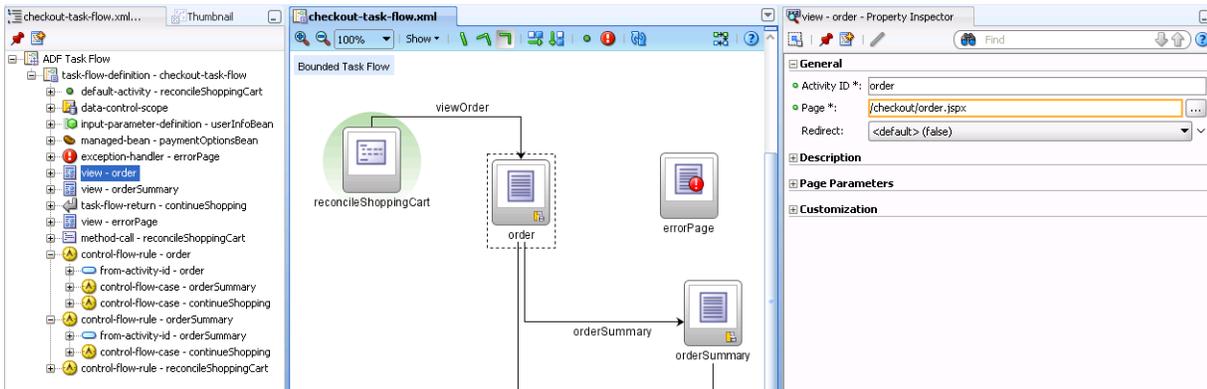

Figure 1–9 shows the `checkout-task-flow` task flow from the `StoreFront` module of the Fusion Order Demo application. In this task flow, `order` and `orderSummary` are view activities that represent pages, while `reconcileShoppingCart` is a method call activity. When the user enters this flow, the `reconcileShoppingCart` activity is invoked (because it is the entry point for the flow, as denoted by the green circle) and the corresponding method is called. From there, the flow continues to the `order` page. From the `order` page, control can be passed to the `orderSummary` page, or to the `continueShopping` return activity that is the exit point of the flow and passes control back to the home page.

Figure 1–9 Task Flow in the StoreFrontModule Application

ADF Controller provides a mechanism to define navigation using control flow rules. The control flow rule information, along with other information regarding the flow, is saved in a configuration file. [Figure 1–10](#) shows the Structure window for the `checkout-task-flow` task flow. This window shows each of the items configured in the flow, such as the control flow rules. The Property Inspector (by default, located at the bottom right) allows you to set values for the different elements in the flow.

Figure 1–10 Task Flow Elements in the Structure Window and Property Inspector

Aside from pages, task flows can also coordinate page fragments. Page fragments are JSF JSP documents that are rendered as content in other JSF pages. You can create page fragments and the control between them in a bounded task flow as you would create pages, and then insert the entire task flow into another page as a region. Because it is simply another task flow, the region can independently execute methods, evaluate expressions, and display content, while the remaining content on the containing page remains the same. For example, before registering a new user, the application needs to determine what kind of user needs to be created. All the logic to do this is handled in the `user-registration-task-flow` task flow, which is used as a region in the `registerUser` page.

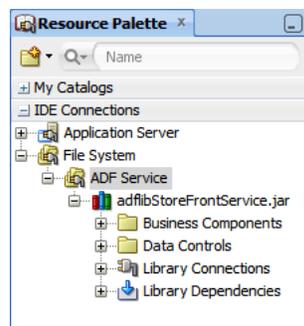

Regions also facilitate reuse. You can create a task flow as a region, determine the pieces of information required by a task and the pieces of information it might return, define those as parameters and return values of the region, then drop the region on any page in an application. Depending on the value of the parameter, a different view can display.

The chapters in [Part IV, "Creating ADF Task Flows"](#) contain information about using task flows. For general information about task flows and creating them, see [Chapter 18, "Getting Started with ADF Task Flows."](#) For information about task flow activities, see [Chapter 19, "Working with Task Flow Activities."](#) If you need to pass parameters into or out of task flows, see [Chapter 20, "Using Parameters in Task Flows."](#) For more information about regions, see [Chapter 21, "Using Task Flows as Regions."](#) For information about advanced functionality that task flows can provide, such as transactional capabilities and creating mandatory sequences of pages (known as *trains*), see [Chapter 22, "Creating Complex Task Flows."](#) For information about using task flows to create dialogs, see [Chapter 23, "Using Dialogs in Your Application."](#)

1.3.5 Identifying Shared Resources

You may find that some aspects of your application can be reused throughout the application. For example, you might have one developer that creates the business components, and another that creates the web interface. The business component developer can then save the project and package it as a library. The library can be sent to other developers who can add it to their resource catalog, from which they can drag and drop it onto any page where it's needed. [Figure 1–11](#) shows the Resource Palette in JDeveloper.

Figure 1–11 Resource Palette in JDeveloper

When designing the application, be sure to note all the tasks that can possibly become candidates for reuse. [Chapter 38, "Reusing Application Components"](#) provides more information about the ADF artifacts that can be packaged and reused as an ADF library, along with procedures both for creating and using the libraries.

1.3.6 Creating a Data Model to Access Data with ADF Business Components

Typically, when you implement business logic as ADF Business Components, you do the following:

- Create entity objects to represent tables that you expect your application to perform a transaction against. Add validation and business rules as needed.
- Create view objects that work with the entity objects to query and update the database. These view objects will be used to make the data available for display at your view layer. You can also create read-only view objects, which you might use to display static lists.

- Create the application module, which provides the interface to the business services that a consumer of those services (such as the UI layer of your application) will use. This application module contains view object instances in its data model along with any custom methods that users will interact with through the application's web pages.
- If needed, publish your services as web services for remote invocation.

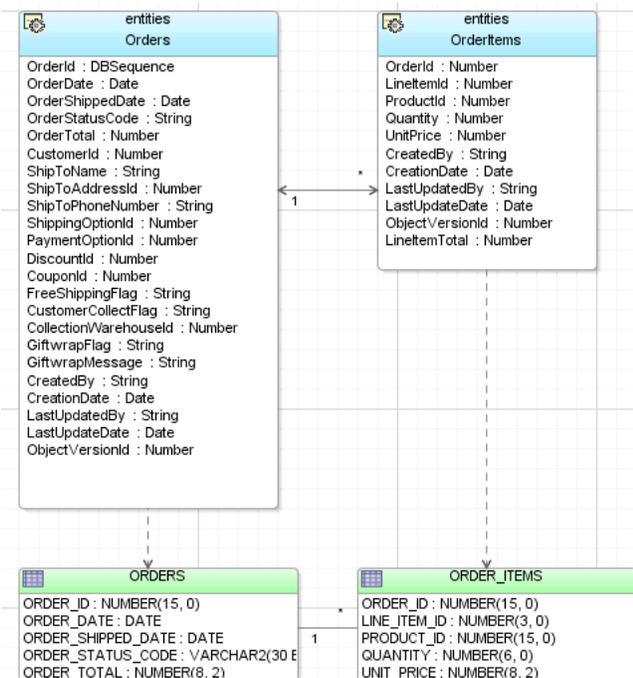

The chapters contained in [Part II, "Building Your Business Services"](#) provide information on creating each of these artifacts. The chapters in [Part VII, "Advanced Topics"](#) provide additional information, such as extending business objects, tuning, and state management.

1.3.6.1 Creating a Layer of Business Domain Objects for Tables

Once you have an understanding of the data that will be presented and manipulated in your application, if you haven't already done so, you can build your database (for more information, see the "Designing Databases Within Oracle JDeveloper" chapter of the *Oracle Fusion Middleware User Guide for Oracle JDeveloper*). Once the database tables are in place, you can create a set of entity objects that represents them and simplifies modifying the data they contain. When you use entity objects to encapsulate data access and validation related to the tables, any pages you build today or in the future that work with these tables are consistently validated. As you work, JDeveloper automatically configures your project to reference any necessary Oracle ADF runtime libraries your application will need at runtime.

For example, the `StoreFrontService` project of the `StoreFrontModule` application contains the business services needed by the application. [Figure 1–12](#) shows two of the entity objects that represent the database tables in that application.

Figure 1–12 Business Components Diagram Showing Entity Objects and Related Tables

To create the business layer, you first create the entity objects based on your database tables. Any relationships between the tables will be reflected as associations between the corresponding entity objects.

Once the entity objects are created, you can define control and attribute hints that simplify the display of the entities in the UI, and you can also add behaviors to the objects. For more information, see [Chapter 4, "Creating a Business Domain Layer Using Entity Objects."](#)

1.3.6.2 Building the Business Services

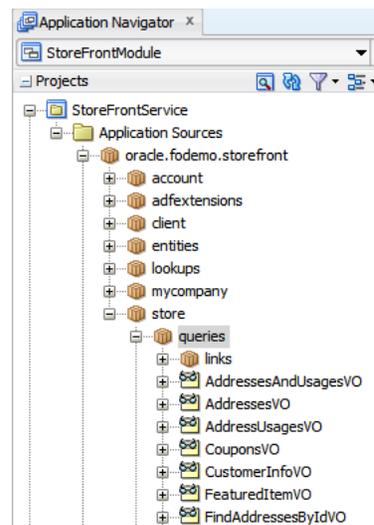

Once the reusable layer of business objects is created, you can implement the application module's data model and service methods with which a UI client can work.

The application module's data model is composed of instances of the view object components you create that encapsulate the necessary queries. View objects can join, project, filter, sort, and aggregate data into the shape required by the end-user task being represented in the user interface. When the end user needs to update the data, your view objects reference entity objects in your reusable business domain layer. View objects are reusable and can be used in multiple application modules.

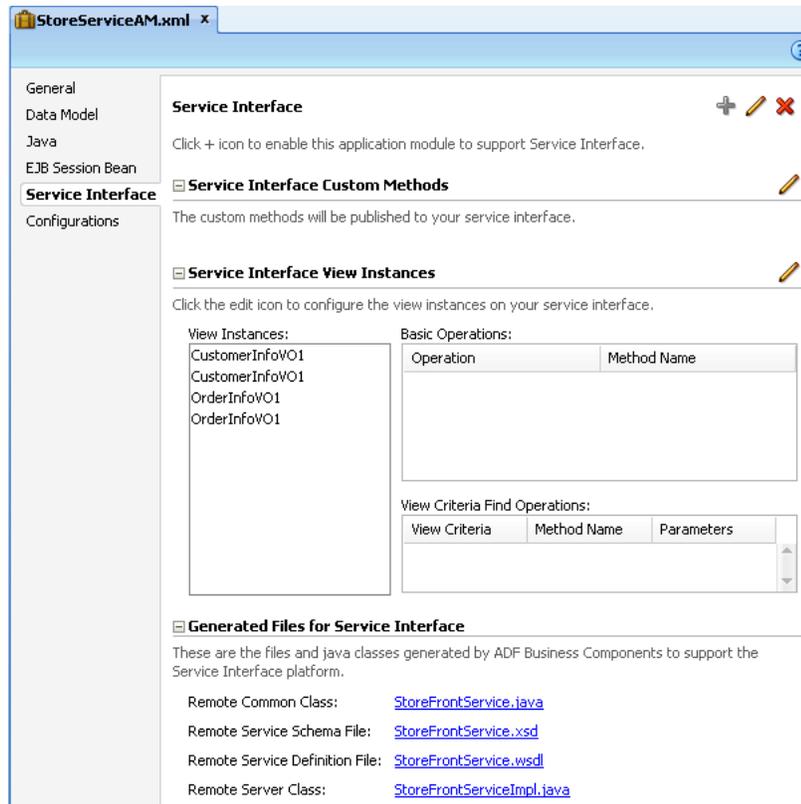

When you want the data to display in a consistent manner across all view pages that access that data, you can configure metadata on the view object to determine display properties. The metadata allows you to set display properties in one place and then change them as needed, so that you make the change only in one place instead of on all pages that display the data. Conversely, you can also have the query controlled by the data the page requires. All display functionality is handled by the page. For more information, see [Chapter 5, "Defining SQL Queries Using View Objects."](#)

For example, the `StoreFrontService` project contains the `oracle.fodemo.storefront.store.queries` package, which contains many of the queries needed by the `StoreFrontModule` application, as shown in [Figure 1–13](#).

Figure 1–13 View Objects in the StoreFrontModule Application

Additionally, you may find that you need to expose functionality to external applications. You can do this by exposing this functionality through a service interface. For example, the `StoreServiceAM` application module is exposed as a web service. This web service exposes the `CustomerInfo` and `OrderInfo` view instances, as shown in [Figure 1–14](#). For more information, see [Chapter 11, "Integrating Service-Enabled Application Modules."](#)

Figure 1–14 StoreFrontModule Application in the Fusion Order Demo Application

1.3.6.3 Testing and Debugging Business Services with the Oracle ADF Model Tester

While you develop your application, you can iteratively test your business services using the Oracle ADF Model Tester. The tester allows you to test the queries, business logic, and validation of your business services without having to use or create a user interface or other client to test your services. Using the tester allows you to test out the latest queries or business rules you've added, and can save you time when you're trying to diagnose problems. For more information about developing and testing application modules, see [Chapter 9, "Implementing Business Services with Application Modules."](#)

The tester also interacts with the ADF Declarative Debugger to allow debug your business services. You can set breakpoints on any custom methods you create. For more information, see [Section 36.7, "Using the Oracle ADF Model Tester for Testing and Debugging."](#)

1.3.7 Implementing the User Interface with JSF

From the page flows you created during the planning stages, you can double-click the page icons to create the actual JSP files. When you create a JSP for an ADF Faces application, you can choose to create an XML-based JSP document (which uses the extension `*.jspx`) rather than a `*.jsp` file.

Best Practice: Using an XML-based document has the following advantages:

- Simplifies treating your page as a well-formed tree of UI component tags.
- Discourages you from mixing Java code and component tags.
- Allows you to easily parse the page to create documentation or audit reports.

If you want to use Facelets instead of JSP in your application, you can instead create XHTML files. Facelets is a JSF-centric XML view definition technology that provides an alternative to using the JSP engine.

Tip: While Facelet pages can use any well formed XML file, including `.jspx`, when you create a Facelet page in JDeveloper, it is created as an XHTML file.

Best Practice: Use Facelets to take advantage of the following:

- The Facelets layer was created specifically for JSF, which results in reduced overhead and improved performance during tag compilation and execution.
- Facelets is considered the primary view definition technology in JSF 2.0.
- Some future performance enhancements will only be available with Facelets

ADF Faces provides a number of components that you can use to define the overall layout of the page. JDeveloper contains predefined quick start layouts that use these components to provide you with an efficient way to correctly determine the layout of your pages. You can choose from one-, two-, or three-column layouts, and then determine how you want the columns to behave. You can also choose to apply themes to the layouts, which adds color to some of the components for you. For more information see the "Using Quick Layouts" section of the *Oracle Fusion Middleware Web User Interface Developer's Guide for Oracle Application Development Framework*.

Oracle ADF also allows you to create and use your own page templates. When creating templates, a developer can determine the layout of the page (either using one of the quick layout templates or creating the layout manually), provide static content that must appear on all pages, and create placeholder attributes that can be replaced with valid values for each page. Each time the template is changed, for example if the layout changes, any page that uses the template will reflect the update.

Most pages in the `StoreFrontModule` application use the `StoreFrontTemplate` template, which provides an area for branding and navigation, a main content area divided into three panes, and a footer area. If the template designer decides to switch the location of the branding and the navigation, all pages that use the template will automatically reflect that change at runtime.

The chapters in [Part V, "Creating a Databound Web User Interface"](#) provide information on creating different types of UI functionality, from basic forms to more complex search capabilities.

1.3.8 Data Binding with ADF Model Layer

In JSF, you use a simple *expression language* (called EL) to bind to the information you want to present and/or modify (for more information, see <http://www.oracle.com/technetwork/java/unifiedel-139263.html>). Example expressions look like `#{userInfoBean.principalName}` to reference a particular user's name, or `#{userInfoBean.principalName eq 'SKING'}` to evaluate whether a user's name is SKING or not. At runtime, a generic expression evaluator returns the `String` and `boolean` value of these respective expressions, automating access to the individual objects and their properties without requiring code.

At runtime, the value of certain JSF UI components is determined by the `value` attribute. While a component can have static text as its value, typically the `value` attribute will contain a binding that is an EL expression that the runtime infrastructure evaluates to determine what data to display. For example, an `outputText` component that displays the name of the currently logged-in user might have its `value` attribute set to the expression `#{userInfoBean.principalName}`. Since any attribute of a component can be assigned a value using an EL expression, it's easy to build dynamic, data-driven user interfaces. For example, you could hide a component when a user is not logged in by using a boolean-valued expression like `#{userInfoBean.principalName != null}` in the UI component's `rendered` attribute. If there is no principal name in the current instantiation of the `userInfoBean`, the `rendered` attribute evaluates to `false` and the component disappears from the page.

In a typical JSF application, you would create objects like the `userInfoBean` object as a managed bean. The JSF runtime manages instantiating these beans on demand when any EL expression references them for the first time. However, in an application that uses the ADF Model layer, instead of binding the UI component attributes to properties or methods on managed beans, JDeveloper automatically binds the UI component attributes to the ADF Model layer, which uses XML configuration files that drive generic data binding features. It implements the two concepts in JSR-227 that enable decoupling the user interface technology from the business service implementation: *data controls* and *declarative bindings*.

Data controls use XML configuration files to describe a service. At design time, visual tools like JDeveloper can leverage that metadata to allow you to declaratively bind UI components to any data control operation or data collection, creating bindings. For example, [Figure 1-15](#) shows the `StoreServiceAMDataControl` data control as it appears in the Data Controls panel of JDeveloper.

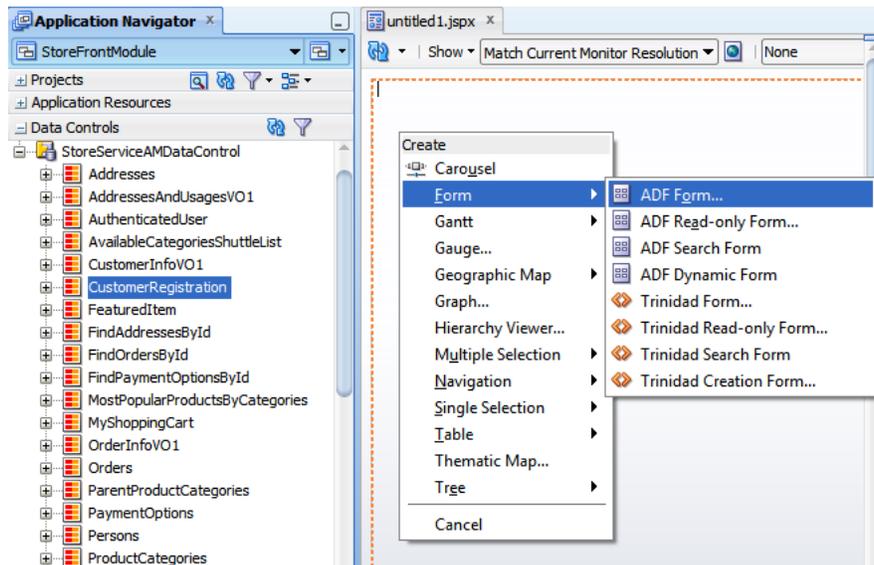

Figure 1–15 StoreFrontServiceAMDataControl

Note that the collections that display in the panel represent the set of rows returned by the query in each view object instance contained in the *StoreServiceAM* application module. For example, the *CustomerRegistration* data collection in the Data Controls panel represents the *CustomerRegistrationVO* view object instance in the *StoreServiceAM*'s data model. The *CustomerAddress* data collection appears as a child, reflecting the master-detail relationship set up while building the business service. The attributes available in each row of the respective data collections appear as child nodes. The data collection level *Operations* node contains the built-in operations that the ADF Model layer supports on data collections, such as *previous*, *next*, *first*, *last*, and so on.

Note: If you create other kinds of data controls for working with web services, XML data retrieved from a URL, JavaBeans, or EJBs, these would also appear in the Data Controls panel with an appropriate display. When you create one of these data controls in a project, JDeveloper creates metadata files that contain configuration information. These additional files do not need to be explicitly created when you are working with Oracle ADF application modules, because application modules are already metadata-driven components, and so contain all the information necessary to be exposed automatically as JSR 227 data controls.

Using the Data Controls panel, you can drag and drop a data collection onto a page in the visual editor, and JDeveloper creates the necessary bindings for you. [Figure 1–16](#) shows the `CustomerRegistration` collection from the `StoreServiceAMDataControl` data control being dragged from the Data Controls panel, and dropped as a form onto a JSF page.

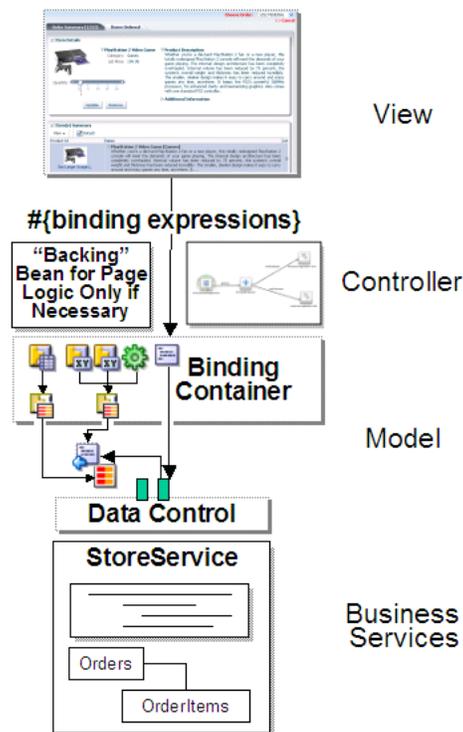

Figure 1–16 Declaratively Creating a Form Using the Data Controls Panel

The first time you drop a databound component from the Data Controls panel on a page, JDeveloper creates an associated page definition file. This XML file describes the group of bindings supporting the UI components on a page. The ADF Model uses this file at runtime to instantiate the page's bindings. These bindings are held in a request-scoped map called the *binding container*. Each time you add components to the page using the Data Controls panel, JDeveloper adds appropriate binding entries into this page definition file. Additionally, as you perform drag and drop data binding operations, JDeveloper creates the required tags representing the JSF UI components on the JSF page. For more information about using the Data Controls panel, see [Chapter 13, "Using ADF Model in a Fusion Web Application."](#)

Note: You can use dynamic UI components that create the bindings at runtime instead of design time. To use dynamic components, you set control hints on your view objects that determine how the data is to be displayed each time the view object is accessed by a page. This ensures that data is displayed consistently across pages, and also allows you to change in a single location, how the data is displayed instead of having to update each individual page. For more information, see [Section 26.7, "Using a Dynamic Form to Determine Data to Display at Runtime."](#)

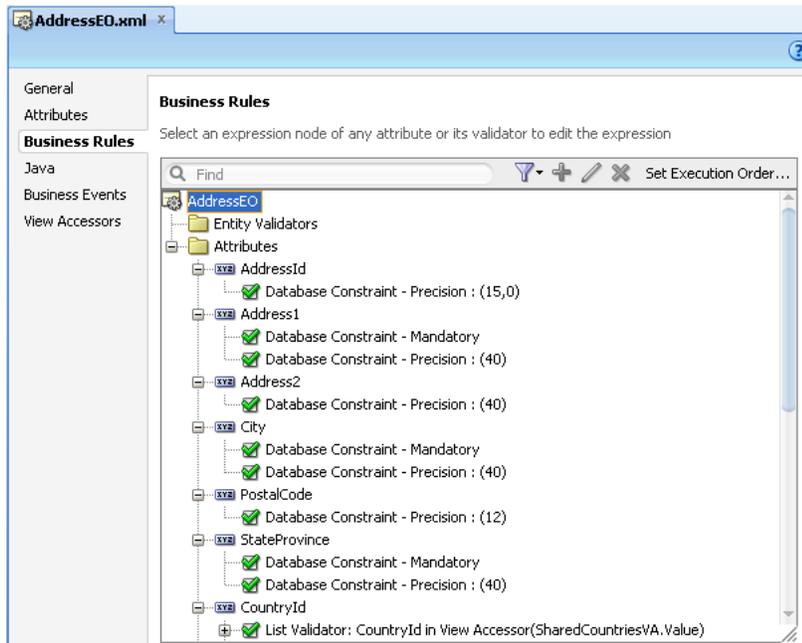

[Figure 1–17](#) illustrates the architecture of a JSF application when you leverage ADF Model for declarative data binding. By combining ADF Model with JSF, you avoid having to write a lot of the typical managed bean code that would be required for real-world applications.

Figure 1–17 Architecture of a JSF Application Using ADF Model Data Binding

Aside from forms and tables that display or update data, you can also create search forms, and databound charts and graphs. For more information about using data controls to create different types of pages, see the chapters contained in [Part V, "Creating a Databound Web User Interface"](#). For more information about the Data Controls panel and how to use it to create any UI data bound component, see [Chapter 13, "Using ADF Model in a Fusion Web Application."](#)

1.3.9 Validation and Error Handling

You can add validation to your business objects declaratively using the overview editors for entity and view objects. [Figure 1–18](#) shows the **Business Rules** page of the overview editor for the `AddressEO` entity object.

Figure 1–18 Setting Validation in the Overview Editor

Along with providing the validation rules, you also set the error messages to display when validation fails. To supplement this declarative validation, you can also use Groovy-scripted expressions. For more information about creating validation at the service level, see [Chapter 7, "Defining Validation and Business Rules Declaratively."](#)

Additionally, ADF Faces input components have built-in validation capabilities. You set one or more validators on a component either by setting the `required` attribute or by using the prebuilt ADF Faces validators. You can also create your own custom validators to suit your business needs. For more information, see the "Validating and Converting Input" chapter of the *Oracle Fusion Middleware Web User Interface Developer's Guide for Oracle Application Development Framework*.

You can create a custom error handler to report errors that occur during execution of an ADF application. Once you create the error handler, you only need to register the handler in one of the application's configuration files.

1.3.10 Adding Security

Oracle ADF provides a security implementation that is based on Java Authentication and Authorization Service (JAAS). JAAS is a standard security Application Programming Interface (API) that is added to the Java language through the Java Community Process. It enables applications to authenticate users and enforce authorization. The Oracle ADF implementation of JAAS is permission-based. You define these permissions and then grant them on application roles that you associate with users of the application. For more information about securing your application, see [Chapter 35, "Enabling ADF Security in a Fusion Web Application."](#)

1.3.11 Testing and Debugging the Web Client Application

Testing an Oracle ADF web application is similar to testing and debugging any other Java EE application. Most errors result from simple and easy-to-fix problems in the declarative information that the application defines or in the EL expressions that

access the runtime objects of the page's ADF binding container. In many cases, examination of the declarative files and EL expressions resolve most problems.

For errors not caused by the declarative files or EL expressions, JDeveloper includes the ADF Logger, which captures runtime trace messages from the ADF Model layer API. The trace includes runtime messages that may help you to quickly identify the origin of an application error. You can also search the log output for specific errors.

JDeveloper also includes the ADF Declarative Debugger, a tool that allows you to set breakpoints on declarative aspects of Oracle ADF, such as the binding layer, taskflows and more. When a breakpoint is reached, the execution of the application is paused and you can examine the data that the ADF binding container has to work with, and compare it to what you expect the data to be. [Chapter 36, "Testing and Debugging ADF Components"](#) contains useful information and tips on how to successfully debug a Fusion web application.

For testing purposes, JDeveloper provides integration with JUnit. You use a wizard to generate regression test cases. For more information, see [Section 36.11, "Regression Testing with JUnit."](#)

1.3.12 Refactoring Application Artifacts

Using JDeveloper, you can easily rename or move the different components in your application. For example, you may find that you need to change the name of your view objects after you have already created them. JDeveloper allows you to easily do this and then propagates the change to all affected metadata XML files. For more information, see [Chapter 37, "Refactoring a Fusion Web Application."](#)

1.3.13 Deploying a Fusion Web Application

You can deploy a Fusion web application to either the integrated WebLogic server within JDeveloper or to a standalone instance. For more information about deployment, see [Chapter 41, "Deploying Fusion Web Applications."](#)

1.3.14 Integrating a Fusion Web Application

You can build your Fusion web application so that it can easily integrate with other applications. You can publish your application modules as services. You can also create events that can be used for example, to initiate business processes. For more information, see [Chapter 11, "Integrating Service-Enabled Application Modules."](#) Your application modules can also call other web services directly. For more information, see [Section 9.12, "Calling a Web Service from an Application Module."](#) You can also integrate your application using task flows. For example, a task flow can be used to initiate a business process flow.

1.4 Working Productively in Teams

Often, applications are built in a team development environment. While a team-based development process follows the development cycle outlined in [Section 1.3, "Overview of Building and Application with Oracle ADF,"](#) many times developers are creating the different parts of the application simultaneously. Working productively means team members divide the work, understand how to enforce standards, and manage source files with a source control system, in order to ensure efficient application development.

Before beginning development on any large application, a design phase is typically required to assess use cases, plan task flows and screens, and identify resources that can be shared.

The following list shows how the work for a typical Fusion web application might be broken up once an initial design is in place:

- Infrastructure

An administrator creates Ant scripts (or other script files) for building and deploying the finished application. SQL scripts are developed to create the database schema used by the application.

- Entity objects

In a large development environment, a separate development group builds all entity objects for the application. Because the rest of the application depends on these objects, entity objects should be one of the first steps completed in development of the application.

Once the entity objects are finished, they can be shared with other teams using Oracle ADF libraries (see [Section 38.3, "Packaging a Reusable ADF Component into an ADF Library"](#) for more information). The other teams then access the objects by adding to them to a catalog in the Resource Palette. In your own application development process, you may choose not to divide the work this way. In many applications, entity objects and view objects might be developed by the same team (or even one person) and would be stored within one project.

- View objects

After the entity objects are created and provided either in a library or within the project itself, view objects can be created as needed to display data (in the case of building the UI) or supply service data objects (when data is needed by other applications in a SOA infrastructure).

When building the Fusion Order Demo application, each developer of a particular page or service was in charge of creating the view objects for that page or service. This was needed because of the tight integration between the view object and its use by a page in the Fusion Order demo; the team who built the UI also built the corresponding view objects.

During development, you may find that two or more view objects are providing the same functionality. In some cases, these view objects can be easily combined by altering the query in one of the objects so that it meets the needs of each developer's page or service.

Once the view objects are in place, you can create the application module, data controls, and add any needed custom methods. The process of creating view objects, reviewing for redundancy, and then adding them to the application module can be an iterative one.

- User interface (UI) creation

With a UI design in place, the view objects in place and the data controls created, the UI can be built either by the team that created the view objects (as described in the previous bullet point) or by a separate team. You can also develop using a UI-first strategy, which would allow UI designers to create pages before the data controls are in place. Oracle ADF provides placeholder data controls that UI designers can use early in the development cycle. For more information, see [Chapter 17, "Designing a Page Using Placeholder Data Controls."](#)

1.4.1 Enforcing Standards

Because numerous individuals divided into separate teams will be developing the application, you should enforce a number of standards before development begins to

ensure that all components of the application will work together efficiently. The following are areas within an application where it is important to have standardization in place when working in a team environment:

- Code layout style

So that more than one person can work efficiently in the code, it helps to follow specific code styles. JDeveloper allows you to choose how the built-in code editor behaves. While many of the settings affect how the user interacts with the code editor (such as display settings), others affect how the code is formatted. For example, you can select a code style that determines things like the placement of opening brackets and the size of indents. You can also import any existing code styles you may have, or you can create your own and export them for use by the team. For more information, see "How to Set Preferences for the Source Editor" in the *Oracle Fusion Middleware User Guide for Oracle JDeveloper*.

- Package naming conventions

You should determine not only how packages should be named, but also the granularity of how many and what kinds of objects will go into each package. For example, all managed beans in the StoreFront module are in the `view.managed` package. All beans that contain helper-type methods accessed by other beans are in `util` packages (one for Oracle ADF and one for JSF). All property files are in the `common` package.

- Pages

You can create templates to be used by all developers working on the UI, as described in [Section 1.3.7, "Implementing the User Interface with JSF."](#) This not only ensures that all pages will have the same look and feel, but also allows you to make a change in the template and have the change appear on all pages that use it. For more information, see [Section 24.2, "Using Page Templates."](#)

Aside from using templates, you should also devise a naming standard for pages. For example, you may want to have names reflect where the page is used in the application. To achieve this goal, you can create subdirectories to provide a further layer of organization.

- Connection names: Unlike most JDeveloper and Oracle ADF objects that are created only once per project and by definition have the same name regardless of who sees or uses them, database connection names might be created by individual team members, even though they map to the same connection details. Naming discrepancies may cause unnecessary conflicts. Team members should agree in advance on common, case-sensitive connection names that should be used by every member of the team.

1.4.2 Using a Source Control System

When working in a team environment, you will need to use a source control system. By default, JDeveloper provides support for the Subversion source control system, and others (such as CVS) are available through extensions. You can also create an extension that allows you to work with another system in JDeveloper. For information about using these systems within JDeveloper, see the "Versioning Applications with Source Control" chapter of the *Oracle Fusion Middleware User Guide for Oracle JDeveloper*.

Following are suggestions for using source control with a Fusion web application:

- Checking out files

Using JDeveloper, you can create a connection to the source control server and use the source control window to check out the source. When you work locally in the files, the pending changes window notifies you of any changed files. You can create a script using Apache Ant (which is integrated into JDeveloper). You can then use the script to build all application workspaces locally. This can ensure that the source files compile before you check the changed files into the source control repository. To find out how to use Apache Ant to create scripts, see the "Building With Apache Ant" section of the *Oracle Fusion Middleware User Guide for Oracle JDeveloper*.

- Automating builds

Consider running a continuous integration tool. Once files are checked into the source server, the tool can be used to recognize either that files have changed or to check for changed files at determined intervals. At that point, the tool can run an Ant script on the server that copies the full source (note that this should be a copy, and not a checkout), compiles those files, and if the compilation is successful, creates a zip file for consumers (not developers) of the application to use. The script should then clean up the source directory. Running a continuous integration tool will improve confidence in the quality of the code in the repository, encourage developers to update more often, and lead to smaller updates and fewer conflicts. Hudson (<http://hudson-ci.org/>) is one example of a continuous integration tool.

- Updating and committing files

When working with Subversion, updates and commits should be done at the Working Copy level, not on individual files. If you attempt to commit and update an individual file, there is a chance you will miss a supporting metadata file and thereby corrupt the committed copy of the application.

- Resolving merge conflicts

When you add or remove business components in a data model project with ADF Business Components, JDeveloper reflects it in the project file (.jpx). When you create (or refactor) a component into a new package, JDeveloper reflects that in the project file and in the ADF Business Components project configuration file (.jpx). Although the XML format of these project control files has been optimized to reduce occurrences of merge conflicts, merge conflicts may still arise and you will need to resolve them in JDeveloper using the **Resolve Conflicts** option on the context menu of each affected file.

After resolving merge conflicts in any ADF Business Components XML component descriptor files, the project file (.jpx) for a data model project, or the corresponding ADF Business Components project configuration file (.jpx), close and reopen the project to ensure that you're working with latest version of the component definitions. To do this, select the project in the Application Navigator, choose **File > Close** from the JDeveloper main menu, and then expand the project again in the Application Navigator.

1.5 Other Resources for Learning Oracle ADF

In addition to this developers guide, Oracle also offers the following resources to help you learn how you can best use Oracle ADF in your applications:

- Cue Cards in JDeveloper: JDeveloper cue cards provide step-by-step support for the application development process using Oracle ADF. They are designed to be used either with the included examples and a sample schema, or with your own data. Cue cards also include topics that provide more detailed background

information, viewlets that demonstrate how to complete the steps in the card, and code samples. Cue cards provide a fast, easy way to become familiar with the basic features of Oracle ADF, and to work through a simple end-to-end task.

- Tutorials, technical papers, samples, and more on Oracle Technology Network.
- Oracle Press publishes a number of books on JDeveloper and Oracle ADF.
- Other developer guides for supporting Oracle ADF technology: Oracle provides developer guides for ADF Faces, Oracle ADF Desktop Integration, and Oracle Mobile Browser, to name a few. For more information about related guides, see [Related Documents](#), in this book's Preface.

1.6 Generation of Complete Web Tier Using Oracle JHeadstart

As you'll learn throughout the rest of this guide, JDeveloper and Oracle ADF give you a productive, visual environment for building richly functional, database-centric Java EE applications with a maximally declarative development experience. However, if you are used to working with tools like Oracle Designer that offer *complete* user interface generation based on a higher-level application structure definition, you may be looking for a similar facility for your Java EE development. If so, then the Oracle JHeadstart application generator may be of interest to you. It is an additional extension for JDeveloper that uses Oracle ADF's built-in features to offer complete web-tier generation for your application modules. Starting with the data model you've designed for your ADF business service, you use the integrated editors that JHeadstart adds to the JDeveloper environment to iteratively refine a higher-level application structure definition. These editors controls the functionality and organization of the view objects' information in your generated web user interface. By checking boxes and choosing various options from dropdown lists, you describe a logical hierarchy of pages that can include multiple styles of search regions, list of values (LOVs) with validation, shuttle controls, nested tables, and other features. These declarative choices use terminology familiar to Oracle Forms and Designer users, further simplifying web development. Based on the application structure definition, you generate a complete web application that automatically implements the best practices described in this guide, easily leveraging the most sophisticated features that Oracle ADF and JSF have to offer.

Whenever you run the JHeadstart application generator, rather than generating *code*, it creates (or regenerates) all of the declarative view and controller layer artifacts of your Oracle ADF-based web application. These artifacts use the ADF Model layer and work with your ADF application module as their business service. The generated files are the same kinds you produce when using the JDeveloper built-in visual editors. The key difference is that JHeadstart creates them in bulk, based on a higher-level definition that you can iteratively refine until the generated pages match your end users' requirements as closely as possible. The generated files include:

- JSF Pages with databound ADF Faces UI components
- ADF Model page definition XML files describing each page's data bindings
- JSF navigation rules to handle page flow
- Resource files containing localizable UI strings

Once you've generated a maximal amount of your application's web user interface, you can spend your time using the productive environment of JDeveloper to tailor the results or to concentrate your effort on additional showcase pages that need special attention. Once you've modified a generated page, you can adjust a setting to avoid regenerating that page on subsequent runs of the application generator. Of course,

since both the generated pages and your custom designed ones leverage the same ADF Faces UI components, all of your pages automatically inherit a consistent look and feel. For more information on how to get a fully functional trial of JHeadstart for evaluation, including details on pricing, support, and additional services, see the JHeadstart page on the Oracle Technology Network at <http://www.oracle.com/technetwork/developer-tools/jheadstart/overview/index.html>

Introduction to the ADF Sample Application

As a companion to this guide, the StoreFront module of the Fusion Order Demo application was created to demonstrate the use of the Fusion web application technology stack to create transaction-based web applications as required for a web shopping storefront. The demonstration application is used as an example throughout this guide to illustrate points and provide code samples.

Before examining the individual components and their source code in depth, you may find it helpful to install and become familiar with the functionality of the Fusion Order Demo application.

This chapter includes the following sections:

- [Section 2.1, "About the Oracle Fusion Order Demo"](#)
- [Section 2.2, "Setting Up the Fusion Order Demo Application"](#)
- [Section 2.3, "Running the Fusion Order Demo Application StoreFront Module"](#)
- [Section 2.4, "Running the Fusion Order Demo Standalone Applications"](#)
- [Section 2.5, "Taking a Look at the Fusion Order Demo Application"](#)

2.1 About the Oracle Fusion Order Demo

In this sample application, electronic devices are sold through a storefront-type web application. Customers can visit the web site, register, and place orders for the products. In order to register customers and fulfill orders, currently only a single application is in place. In a future release, several applications, will cooperate. For a detailed description of how the application works at runtime, see [Section 2.5, "Taking a Look at the Fusion Order Demo Application."](#)

In order to view and run the demo, you need to install Oracle JDeveloper Studio. You then need to download the application for this demonstration. Instructions to complete these tasks appear in this chapter. For complete details, see [Section 2.2, "Setting Up the Fusion Order Demo Application."](#)

Once the application is installed and running, you can view the code using JDeveloper. You can view the application at runtime by logging in as an existing customer and placing an order.

2.2 Setting Up the Fusion Order Demo Application

The Fusion Order Demo application runs using an Oracle database and JDeveloper. The platforms supported are the same as those supported by JDeveloper.

To prepare the environment and run the Fusion Order Demo application, you must:

1. Install Oracle JDeveloper Studio and meet the installation prerequisites. The Fusion Order Demo application requires an existing Oracle database. For details, see [Section 2.2.1, "How to Download the Application Resources."](#)
2. Install the Fusion Order Demo application from the Oracle Technology Network. For details, see [Section 2.2.2, "How to Install the Fusion Order Demo Schema."](#)
3. Install Mozilla FireFox, version 2.0 or higher, or Internet Explorer, version 7.0 or higher.
4. Run the application on a monitor that supports a screen resolution of 1024 X 768 or higher. For details, see [Section 2.3, "Running the Fusion Order Demo Application StoreFront Module."](#)

2.2.1 How to Download the Application Resources

The Fusion Order Demo application requires an existing Oracle database. You run the Fusion Order Demo application using JDeveloper.

Do the following before installing the Fusion Order Demo application:

- Install JDeveloper, as described in the *Oracle Fusion Middleware Installation Guide for Oracle JDeveloper*. You will need to install the Studio configuration of Oracle JDeveloper to view the application's projects and run the application in Integrated WebLogic Server. You can download JDeveloper from:

<http://www.oracle.com/technetwork/developer-tools/jdev/overview/index.html>

Note: When you download and install JDeveloper, ensure that it is the Studio configuration, not the Java configuration. You can verify these details in JDeveloper from the **Help > About** menu option.

- Download the Fusion Order Demo application ZIP file (FusionOrderDemo.zip). You can download the ZIP file from:
<http://www.oracle.com/technetwork/developer-tools/jdev/index-095536.html>
- Install an Oracle database. The Fusion Order Demo application requires a database for its data.

The SQL scripts were written for an Oracle database, so you will need some version of an Oracle RDBMS, such as 11g, or XE. The scripts will not install into Oracle Lite. If you wish to use Oracle Lite or some other database, then you will need to modify the database scripts accordingly. You can download an Oracle database from:

<http://www.oracle.com/technetwork/index.html>

Specifically, the small footprint of the Oracle Express Edition (XE) is ideally suited for setting up the database on your local machine. You can download it from:

<http://www.oracle.com/technetwork/database/express-edition/overview/index.html>

2.2.2 How to Install the Fusion Order Demo Schema

You can download the Fusion Order Demo application from the Oracle Technology Network (OTN) web site.

To download the demo and install the FOD schema to your database:

1. Navigate to <http://www.oracle.com/technetwork/developer-tools/jdev/index-095536.html> and download the ZIP file to a local directory.
2. Start JDeveloper and from the main menu choose **File > Open**.
3. In the Open dialog, browse to the location where you extracted the ZIP file to in Step 1 and select **Infrastructure.jws** from the **infrastructure** directory. Click **Open**.
4. In the Application Navigator, expand **MasterBuildScript** and then **Resources**, and double-click **build.properties**.
5. In the editor, modify the properties shown in [Table 2-1](#) for your environment.

Table 2-1 Properties Required to Install the Fusion Order Demo Application

Property	Description
<code>jdeveloper.home</code>	The root directory where you have JDeveloper installed. For example: <code>C:/JDeveloper/11/jdeveloper</code>
<code>jdbc.urlBase</code>	The base JDBC URL for your database in the format <code>jdbc:oracle:thin:@<yourhostname></code> . For example: <code>jdbc:oracle:thin:@localhost</code>
<code>jdbc.port</code>	The port for your database. For example: 1521
<code>jdbc.sid</code>	The SID of your database. For example: ORCL or XE
<code>db.adminUser</code>	The administrative user for your database. For example: system
<code>db.demoUser.tablespace</code>	The table space name where FOD users will be installed. For example: USERS

6. From the main menu, choose **File > Save All**.
7. In the Application Navigator, under the **Resources** node, right-click **build.xml** and choose **Run Ant Target > buildAll**.
8. In the Enter Property dialog, enter the password for the database system user and click **Continue**.

Once you enter the password, the Ant build script creates the FOD users and populates the tables in the FOD schema. In the Apache Ant - Log window, you will see a series of SQL scripts and finally:

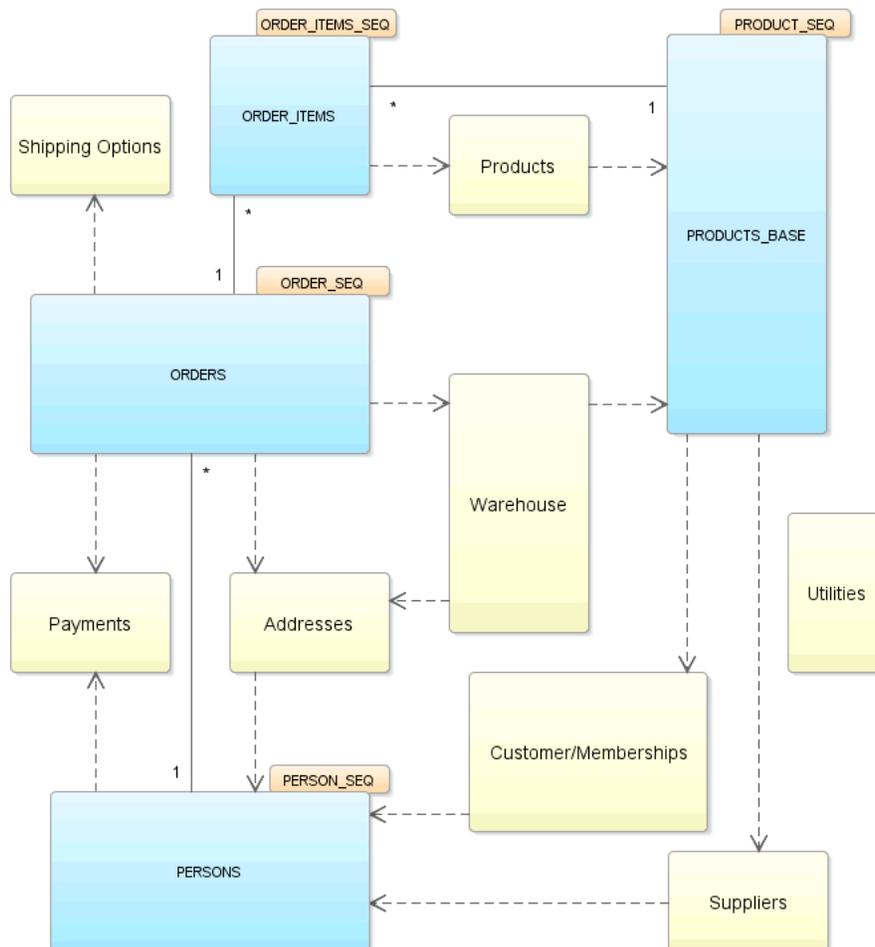

```
buildAll:
BUILD SUCCESSFUL
Total time: nn minutes nn seconds
```

For more information on the demo schema and scripts, see the `README.txt` file in the `MasterBuildScript` project.

2.2.3 Overview of the Fusion Order Demo Schema

Figure 2–1 shows a simplified representation of the schema for the Fusion Order Demo application. The blue shapes in the diagram represent the four core tables. The other tables and views are shown as yellow shapes that sometimes represent several tables to help simplify the diagram. Some of the tables use sequences, but only those used by the core tables are shown.

Figure 2–1 Schema Diagram for the Fusion Order Demo Application

The core tables represented by the blue diagram elements include:

- PERSONS:** This table stores all the users who interact with the system, including customers, staff, and suppliers. The first and last name, email address, and person type code of each user is stored. A user is uniquely identified by an ID. Other IDs provide foreign keys to tables with address information and, in the case of customer's, membership information.
- ORDERS:** This table represents activity by specific customers. When an order is created, the date of the order, the total amount of the order, the ID of the customer who created it, and the status of the order are all recorded. After the order is

fulfilled, the order status and order shipped date are updated. All orders are uniquely identified by a sequence-assigned ID.

- **ORDER_ITEMS:** For each order, there may be many order items recorded. The unit price and quantity of each order item are recorded. The order line item and its order ID uniquely identify each order item.
- **PRODUCTS_BASE:** This table stores all of the products available in the store. For each product, the name and cost are recorded. All products are uniquely identified by a sequence-assigned ID. The image of the product and its description are stored in separate tables, which each reference the product ID. The columns `ATTRIBUTEx` are reserved for future use with descriptive flexfields (commonly required by Oracle E-Business Suite schema).

The sequences that the core tables use include:

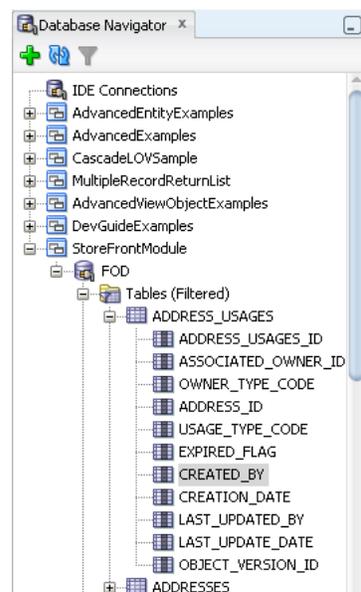

- **PERSON_SEQ:** Populates the ID for for each new person.
- **ORDER_SEQ:** Populates the ID for each new order.
- **ORDERS_ITEMS_SEQ:** Populates the ID for each new order item.
- **PRODUCTS_SEQ:** Populates the ID for each product.

The PL/SQL package `USER_CONTEXT_PKG` contains a procedure `set_app_user_lang()` used to illustrate a simple example of how to set per-user database state from inside an application module.

Note the `SHIPPING_OPTIONS` view is reserved for future use and is not currently used in the Fusion Order Demo application.

To support tracking of change history in the Fusion Order Demo application, every table contains the history column `CREATED_BY`, `CREATION_DATE`, `LAST_UPDATED_BY`, `LAST_UPDATED_DATE`, and `OBJECT_VERSION_ID`, as shown in [Figure 2-2](#).

Figure 2-2 History Columns for Tables in FOD Schema

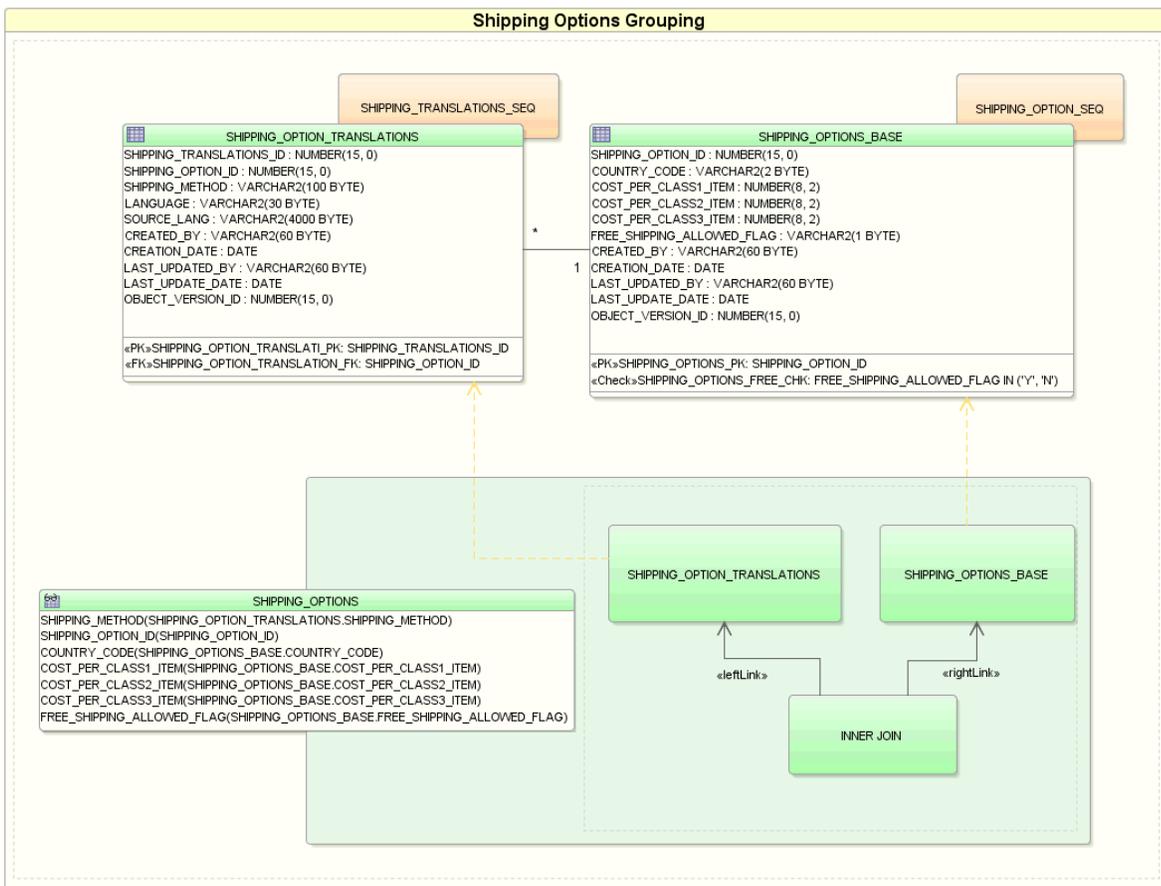

2.2.3.1 Translation Support in the Fusion Order Demo Schema

To support localization of the Fusion Order Demo, the AVAILABLE_LANGUAGES table lists all available languages. In this table, only one row will have the DEFAULT_FLAG set to Y corresponding to the current user's language.

Translations exist for the following base tables: PRODUCTS_BASE (PRODUCT_TRANSLATIONS), PRODUCT_CATEGORIES_BASE (CATEGORY_TRANSLATIONS), SHIPPING_OPTIONS_BASE (SHIPPING_OPTION_TRANSLATIONS), MEMBERSHIPS_BASE (MEMBERSHIP_TRANSLATIONS) and DISCOUNTS_BASE (DISCOUNT_TRANSLATIONS).

Taking the Shipping Options group, as shown in Figure 2-3: SHIPPING_OPTION_TRANSLATIONS is fully populated so that each product has one row for each language. The column LANGUAGE holds the translation language identifier. The entry itself may not yet be translated, in which case the SOURCE_LANGUAGE column holds the language that the entry is currently in. When a value has been translated, SOURCE_LANGUAGE and LANGUAGE will hold the same value. The PL/SQL package USER_CONTEXT_PKG creates the custom USERENV('CLIENT_INFO') variable that specifies the runtime locale used to pull the correct translations from SHIPPING_OPTION_TRANSLATIONS into the SHIPPING_OPTIONS view along with the SHIPPING_OPTIONS_BASE table data. Each order has one set of Shipping Options associated with it.

Figure 2-3 Shipping Options Grouping for the Fusion Order Demo Schema

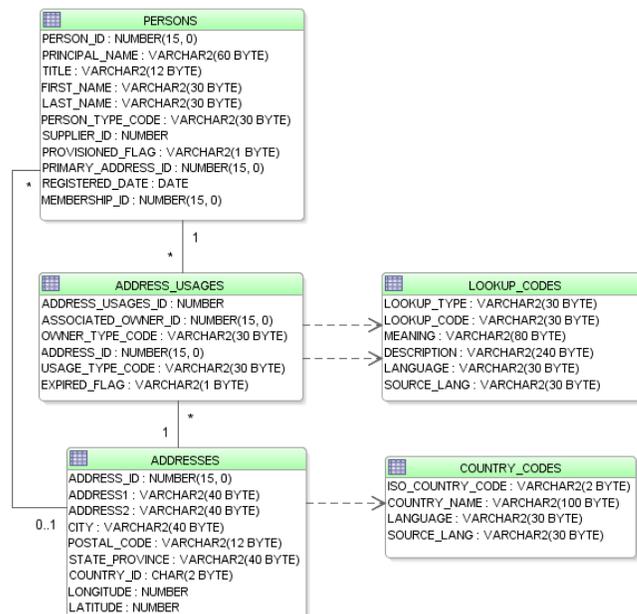

2.2.3.2 Lookup Tables in the Fusion Order Demo Schema

The code lookup table `LOOKUP_CODES` table contains codes that are used throughout the Fusion Order Demo application. For example, the `PERSONS` table contains the columns `person_type_code`, `marital_status_code`, and `gender`. These codes have corresponding rows in the `LOOKUP_CODES` table, discriminating on the `lookup_type` column. Foreign keys are not defined for these rows, but instead are enforced in the user interface by populating user interface components with `LOOKUP_CODES` values for a particular lookup type. For example, when creating a new registration (also known as a person) in the user interface, the values that can be used for the `person_type_code` are populated in a dropdown list from the `lookup_code` values with `lookup_type=person_type_code`.

The `LOOKUP_CODES` table also supports the localization of the user interface. The table uses a combined key of code and language (obtained from runtime locale or preference) to determine the code's meaning. Each code has an entry for each supported language, as described in [Section 2.2.3.1, "Translation Support in the Fusion Order Demo Schema."](#)

Using addresses as an example, as shown in [Figure 2-4](#): `PERSONS` uses an intersection `ADDRESS_USAGES` to accommodate multiple address information. In addition `ADDRESS_USAGES` uses `LOOKUP_CODES` to store both `OWNER_TYPE_CODE` and `USAGE_TYPE_CODE` information, returning the `MEANING` (see table extract in [Figure 2-5](#)). `ADDRESSES` directly accesses `COUNTRY_CODES` to look up and use the `COUNTRY_NAME` associated with the `COUNTRY_ID` stored in `ADDRESSES`. The `PERSONS` table also directly stores `PRIMARY_ADDRESS_ID` by a direct lookup to `ADDRESSES`.

Figure 2-4 *LOOKUP_CODES Usage in the Fusion Order Demo Schema*

The correct translation is applied by using the `LANGUAGE` columns in both `LOOKUP_CODES` and `COUNTRY_CODES` with the runtime locale/preference.

Figure 2–5 LOOKUP_CODES Sample Data in the Fusion Order Demo Schema

LOOKUP_TYPE	LOOKUP_CODE	MEANING
OWNER_TYPE_CODE	CUST	Customer
OWNER_TYPE_CODE	SUPP	Supplier
OWNER_TYPE_CODE	STAFF	Staff
USAGE_TYPE_CODE	IN	Invoice Address
USAGE_TYPE_CODE	SH	Shipping Address

The lookup table DEMO_OPTIONS defines the various options within the Fusion Order Demo application that are switched on. It also caches general configuration information such as email addresses and phone numbers to use as overrides in this demonstration scenario (for example, where email addresses are fictitious). This table is reserved for future use.

2.3 Running the Fusion Order Demo Application StoreFront Module

The Fusion Order Demo application consists of a web user interface and a business service layer. Specifically, the following projects are part of the Fusion Order Demo application:

- **StoreFrontService:** Provides access to the storefront data and provides transaction support to update data for customer information and orders.
- **StoreFrontUI:** Provides web pages that the customer uses to browse the storefront, place orders, register on the site, view order information, and update the user profile.

You run the StoreFront module of the Fusion Order Demo application in JDeveloper by running the `home.jspx` page in the `StoreFrontUI` project. The `StoreFrontUI` project uses JavaServer Faces (JSF) as the view technology, and relies on the ADF Model layer to interact with ADF Business Components in the `StoreFrontService` project. To learn more about the Fusion Order Demo application and to understand its implementation details, see [Section 2.5, "Taking a Look at the Fusion Order Demo Application."](#)

A second module of the Fusion Order Demo application is available to process the orders that you place using the StoreFront module. For example, the WebLogic Fusion Order Demo module uses various internal and external applications, including a customer service application, a credit validation system, and both an internal vendor and external vendor. These composite services are the subject of another developer's guide and are not addressed in the *Oracle Fusion Middleware Fusion Developer's Guide for Oracle Application Development Framework*. For details about the WebLogic Fusion Order Demo module used to demonstrate the capabilities of Oracle SOA Suite, see the *Oracle Fusion Middleware Developer's Guide for Oracle SOA Suite*.

You cannot run the WebLogic Fusion Order Demo module in JDeveloper. When you want to integrate the storefront portion with the composite services portion of the application, you must deploy the Fusion Order Demo application to a SOA-enabled Oracle WebLogic Server. Instructions to deploy any SOA web application to Oracle WebLogic Server, are addressed in the Fusion Order Demo home page on OTN at this link

<http://www.oracle.com/technetwork/developer-tools/jdev/index-095536.html>.

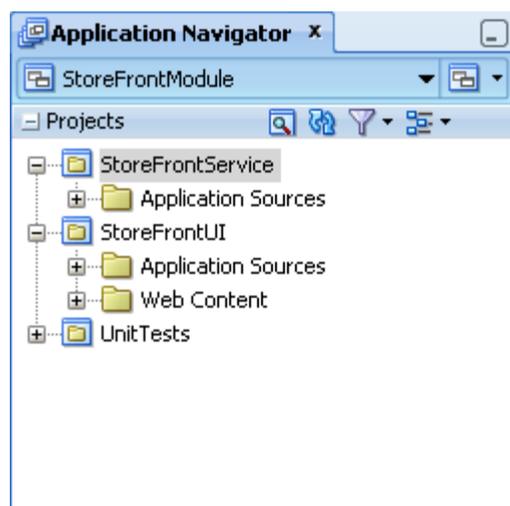

The easiest way to run the Fusion Order Demo application is to open only the StoreFront module in JDeveloper and run the `home.jspx` page in the `StoreFrontUI` project.

To run the StoreFront module of the Fusion Order Demo application:

1. Open the application in JDeveloper:
 - a. From the main menu, choose **File > Open**.
 - b. Navigate to the location where you extracted the demo ZIP file to and select the **StoreFrontModule.jws** application workspace from the **StoreFrontModule** directory. Click **Open**.

Figure 2–6 shows the Application Navigator after you open the file for the application workspace. For a description of each of the projects in the workspace, see Section 2.5, "Taking a Look at the Fusion Order Demo Application."

Figure 2–6 The Fusion Order Demo Projects in JDeveloper

2. In the Application Navigator, click the **Application Resources** accordion title to expand the panel.
3. In the Application Resources panel, expand the **Connections** and **Database** nodes.
4. Right-click **FOD** connection and choose **Properties**.
5. In the Edit Database Connection dialog, modify the connection information shown in Table 2–2 for your environment.

Table 2–2 Connection Properties Required to Run the Fusion Order Demo Application

Property	Description
Host Name	The host name for your database. For example: localhost
JDBC Port	The port for your database. For example: 1521
SID	The SID of your database. For example: ORCL or XE

Do not modify the user name and password **fod/fusion**. These must remain unchanged. Click **OK**.

6. In the Application Navigator, right-click **StoreFrontService** and choose **Rebuild**.

7. In the Application Navigator, right-click **StoreFrontUI** and choose **Run**.

The Configure Default Domain dialog displays the first time you run the application and start a new domain in Integrated WebLogic Server. Use the dialog to define an administrator password for the new domain. Passwords you enter can be eight characters or more and must have a numeric character.

The `home.jspx` page within the `StoreFrontUI` project is the default run target. When you run the default target, JDeveloper will launch the browser and display the Fusion Order Demo application home page.

Once the home page appears, you can browse the web site as an anonymous user, or you can choose to log in and place orders (may require registering as a customer first). Because the Fusion Order Demo application implements ADF Security to manage access to Oracle Application Development Framework (Oracle ADF) resources, only the authenticated user will be able to view orders in their cart. [Table 2–3](#) shows the users who are authorized as members of the `fod-users` role to log into the Fusion Order Demo application.

Note: The Fusion Order Demo application ships with predefined user data. The schema for the application defines different types of users including customer, supplier, and staff types. All users are members of the `fod-users` role and are authorized to log in. However, only `ngreenbe` is the user type `CUST` (customer). When you log in as any other user, you will need to register as a customer before you can place an order. These additional users were created to support roles in other modules of the Fusion Order Demo application.

Table 2–3 *Supplied Users in the Fusion Order Demo Application*

Username	Password	Application Role	Notes
ngreenbe	welcome1	fod-users	Can add items to cart, check out, and view order information. This is the only user who is preregistered as a customer in the StoreFront module of Fusion Order Demo.
sking	welcome1	fod-users, fod-admin	Can add items to cart, but must register as a customer to check out and view order information. This user also has administration privileges (<code>fod-admin</code>) in the MasterPriceList module of Fusion Order Demo.
ahunold	welcome1	fod-users, fod-manager	Can add items to cart, but must register as a customer to check out and view order information. This user also has read-only privileges (<code>fod-manager</code>) in the MasterPriceList module of Fusion Order Demo.
pbrown / fdaviet	welcome1	fod-users	Can add items to cart, but must register as a customer to check out and view order information. These users may be added to other roles in a future version of Fusion Order Demo.

2.4 Running the Fusion Order Demo Standalone Applications

The Fusion Order Demo application includes a set of sample applications that allow you to investigate Oracle ADF functionality that does not appear in the StoreFront module. Collectively, these sample applications are referred to as standalone applications. The standalone sample applications appear in five application workspaces, each consisting of several projects, located in the `StandaloneExamples` folder where you extracted the demo ZIP file.

In general, almost all of the standalone applications demonstrate concepts of ADF Business Components and data model projects. References to these standalone applications appear throughout the chapters contained in [Part II, "Building Your Business Services"](#) and [Part VII, "Advanced Topics"](#) of this developer's guide. As you read sections this guide, you may want to run the corresponding standalone application to investigate the concepts further. For a brief description of each application workspace and links to the documentation, refer to the tables in [Section 2.4.2](#) through [Section 2.4.5](#).

2.4.1 How to Run the Standalone Applications

How you use JDeveloper to run a standalone application depends on the individual application. Some applications are set up to use the interactive testing tool JDeveloper provides for the ADF Business Components data model project (this tool is known as the Oracle ADF Model Tester). Other applications provide Java test clients (with file names like `TestClientXxx.java`) that use the ADF Business Components API to execute queries and display results. In the case of the Oracle ADF Model Tester, you work entirely in the tool, which essentially provides a convenient user interface for interacting with business components. In the case of the Java clients, the program files output their results and print statements to the JDeveloper Log window.

Familiarize yourself with the following general procedures about how to run the standalone applications. The first procedure describes how to run an application with its provided test client. The second describes how to launch the Oracle ADF Model Tester on the data model project's ADF application module. Then read [Section 2.4.2](#) through [Section 2.4.5](#) for more details about the individual standalone applications.

Before you begin:

- In the Database Navigator, modify the connection information for the FOD database connection so it has the connection information for your environment, as described in [Section 2.3, "Running the Fusion Order Demo Application StoreFront Module."](#)
- Some of the standalone applications work with a modified version of the FOD schema. For standalone applications that require schema changes, the application's project will contain a SQL script that you must run within JDeveloper.

Once you are through investigating a standalone application, you can use the script to back out the schema changes.

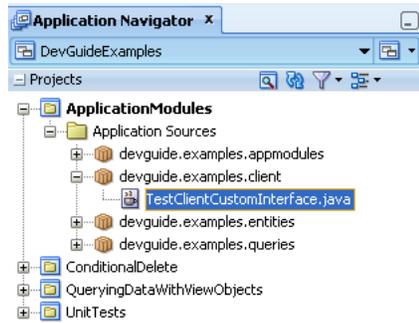

To run a standalone application from its provided test client:

1. Open the application in JDeveloper:
 - a. From the main menu, choose **File > Open**.
 - b. Navigate to the location where you extracted the demo ZIP file to, open the **StandaloneExamples** directory, then open the desired standalone application directory and then select the application workspace (**.jws**) and click **Open**.

2. In the Application Navigator, expand the project node and locate the test client (.java) file node. In some cases, the test client is added to a package located under the **Application Sources** node. In other cases, the **Resources** node contains the test client.

For example, [Figure 2–7](#) shows the expanded **ApplicationModules** node with the Java file node **TestClientCustomInterface.java** selected.

Figure 2–7 Test Client Selected in Application Navigator

3. Right-click the test client and choose **Run**.

For the names and location of the test clients provided with the standalone applications, see the tables in [Section 2.4.2](#) through [Section 2.4.5](#).

The Configure Default Domain dialog displays the first time you run your application and start a new domain in Integrated WebLogic Server. Use the dialog to define an administrator password for the new domain. Passwords you enter can be eight characters or more and must have a numeric character.

4. Examine the JDeveloper Log window for the test client's output.

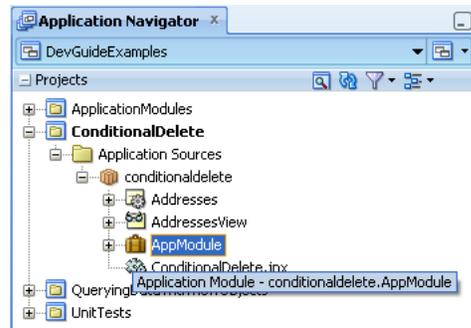

Refer to the referenced documentation for details about the expected results.

When the standalone application does not provide a test client to programmatically exercise the ADF Business Components API, you will use the interactive testing tool, known as the Oracle ADF Model Tester.

To run a standalone application in the Oracle ADF Model Tester:

1. Open the application in JDeveloper:
 - a. From the main menu, choose **File > Open**.
 - b. Navigate to the location where you extracted the demo ZIP file to, open the **StandaloneExamples** directory, then open the desired standalone application directory, and then select the application workspace (.jws) and click **Open**.
2. In the Application Navigator, expand the project node and locate the application module in a package under the **Application Sources** node.

For example, [Figure 2–8](#) shows the expanded **ConditionalDelete** project with the application module **AppModule** selected and a tooltip for the node displayed.

Figure 2–8 Application Module Node Selected in Application Navigator

3. Right-click the application module node and choose **Run**.

For the names of the runnable application modules, see the tables in [Section 2.4.2](#) through [Section 2.4.5](#).

The Configure Default Domain dialog displays the first time you run your application and start a new domain in Integrated WebLogic Server. Use the dialog to define an administrator password for the new domain. Passwords you enter can be eight characters or more and must have a numeric character.

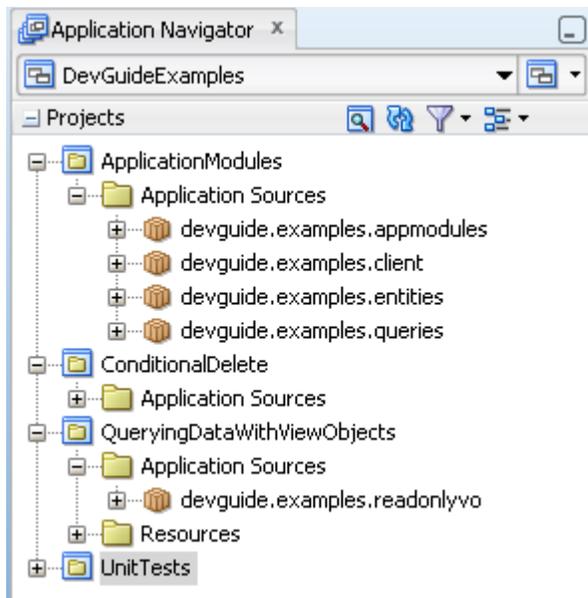

4. Use the Oracle ADF Model Tester to interact with the view instances of the standalone application.

Refer to the referenced documentation for details about the application. For details about using the tester to interact with the data model, see [Section 6.3, "Testing View Object Instances Using the Oracle ADF Model Tester."](#)

2.4.2 Standalone Applications in the DevGuideExamples Application Workspace

Two of the standalone applications in the application workspace `DevGuideExamples` use programmatic test clients to demonstrate concepts related to the ADF Business Components framework. The third application demonstrates framework functionality when you run the application in the Oracle ADF Model Tester.

[Figure 2–9](#) shows the Application Navigator after you open the `DevGuideExamples` application workspace.

Figure 2–9 *Runnable Applications in the DevGuideExamples Application Workspace*

Note that the test clients for the `DevGuideExamples` standalone applications provide a good starting point for understanding how to exercise methods of the ADF Business Components API. They also make good samples for test clients that you may want to create to test business component queries in a data model project. For background on working with test clients, see [Section 6.4, "Testing View Object Instances Programmatically."](#)

Note: The ADF Business Components API is available when you need to generate custom classes to augment the default runtime behavior of the business components. For background about the ADF Business Components framework, see [Section 3.5, "Overview of the ADF Business Components Implementation."](#)

[Table 2–4](#) describes the standalone applications in the `DevGuideExamples` application workspace. Examples from these applications appear throughout the chapters contained in [Part II, "Building Your Business Services"](#) of this guide.

Table 2–4 Standalone Applications in the DevGuideExamples Application Workspace

Project Name	Runnable Class or Project Target	Documentation
ApplicationModule	<p>Run TestClientCustomInterface.java in the devguide.examples.client package under the Application Sources node.</p> <p>Exercises custom methods of StoreFrontService application module's client interface and prints to the JDeveloper Log window to indicate the results.</p>	<p>For details about the test client, see Section 9.10.1, "How to Work Programmatically with an Application Module's Client Interface."</p> <p>For details about the methods of the client interface, see the examples in Section 4.14, "Working Programmatically with Entity Objects and Associations."</p>
ConditionalDelete	<p>Launch the Oracle ADF Model Tester on AppModule under the Application Sources node.</p> <p>Overrides a method in the generated entity class that conditionally prevents deletion of entity rows. In the Oracle ADF Model Tester, click Delete the Current Row and observe the exception statement. Then, click Insert a New Row and delete the new row.</p>	<p>For a description of overriding the <code>remove()</code> method that you generate in the entity implementation class file, see Section 8.12, "Conditionally Preventing an Entity Row from Being Removed."</p>

Table 2–4 (Cont.) Standalone Applications in the DevGuideExamples Application Workspace

Project Name	Runnable Class or Project Target	Documentation
QueryingDataWithViewObjects	Run TestClient.java under the Resources node of the Application Navigator. Programmatically iterates over the <code>PersonList</code> view instance using methods of the Business Components API <code>RowIterator</code> interface and prints to the JDeveloper Log window.	For details about iterating over a collection, see Section 6.4.5, "How to Count the Number of Rows in a Row Set." For details about how to create test clients, see Section 6.4, "Testing View Object Instances Programmatically."
	Run TestClient2.java under the Resources node of the Application Navigator. Programmatically iterates over the <code>PersonList</code> view instance, accesses the detail collection <code>OrdersToShipToCustomers</code> using a view link accessor attribute, and prints to the JDeveloper Log window.	For details about iterating over a detail collection, see Section 5.6.6, "How to Access the Detail Collection Using the View Link Accessor." For more details about the test client, see Section 6.4.6, "How to Access a Detail Collection Using the View Link Accessor."
	Run TestClient3.java under the Resources node of the Application Navigator. Programmatically iterates over the <code>PersonList</code> view instance using a strongly-typed <code>PersonsRow</code> interface and prints to the JDeveloper Log window.	For details about iterating over a collection using the view row accessor attribute, see Section 42.3.1.3, "Exposing View Row Accessors to Clients."
	Run TestClientBindVars.java under the Resources node of the Application Navigator. Programmatically sets the <code>WHERE</code> clause for the <code>PersonList</code> view instance using bind variables to filter the collection and prints to the JDeveloper Log window.	For details about setting bind variables, see Section 5.10.6, "How to Set Existing Bind Variable Values at Runtime." For more details about the test client, see Section 5.10.5, "How to Add a WHERE Clause with Named Bind Variables at Runtime."
	Run TestClientViewCriteria.java under the Resources node of the Application Navigator. Programmatically sets a view criteria for the <code>PersonList</code> view instance to filter the collection and prints to the JDeveloper Log window.	For details about the ADF Business Component's view criteria API, see Section 5.11.9, "What You May Need to Know About the View Criteria API." For more details about the test client, see Section 5.11.7, "How to Create View Criteria Programmatically."

2.4.3 Standalone Applications in the AdvancedExamples Application Workspace

The standalone applications assembled in the application workspace `AdvancedExamples` demonstrate advanced concepts that apply to the entire ADF Business Components framework.

[Figure 2–10](#) shows the Application Navigator after you open the `AdvancedExamples` application workspace.

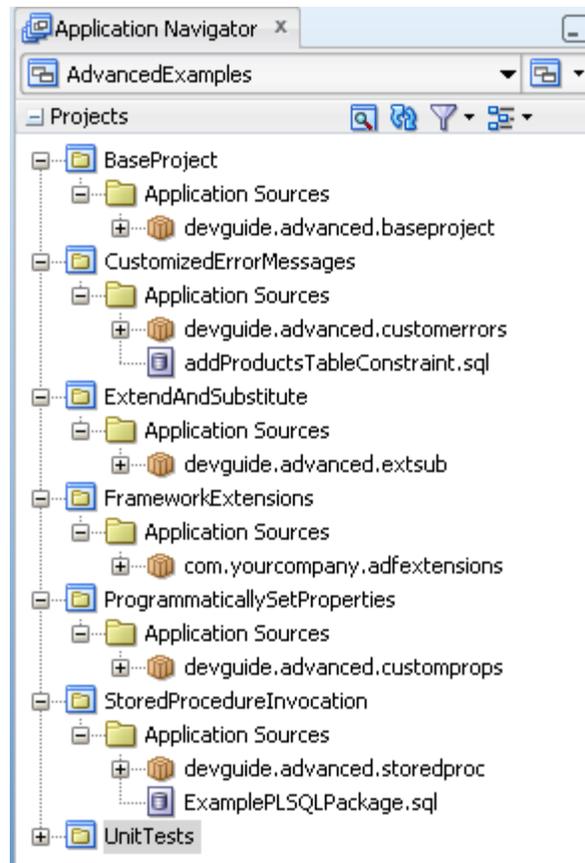

Figure 2–10 *Runnable Applications in the AdvancedExamples Application Workspace*

Table 2–5 describes the standalone applications in the `AdvancedExamples` application workspace. Examples from this application workspace are described in Chapter 12, "Extending Business Components Functionality."

Table 2–5 Standalone Applications in the AdvancedExamples Application Workspace

Project Name	Runnable Class or Project Target	Documentation
BaseProject	Run TestClient.java under the Application Sources node of the Application Navigator.	For details about how to extend business components to create a customized versions of the original, see Section 12.9, "Creating Extended Components Using Inheritance."
CustomizedErrorMessage	Run the addProductsTableConstraint.sql script under the Application Sources node of the Application Navigator against the FOD connection to set up the additional database objects required for the project. Launch the Oracle ADF Model Tester on ProductModule under the Application Sources node of the Application Navigator.	For details about how to provide an alternative message string for the builtin error codes in a custom message bundle, see Section 12.8, "Customizing Business Components Error Messages."
ExtendAndSubstitute	Not runnable. Programmatically iterates over the PersonList view instance using methods of the Business Components API RowIterator interface and prints to the JDeveloper Log window.	For details about how to substitute business components, see Section 12.10, "Substituting Extended Components in a Delivered Application."
FrameworkExtensions	Not runnable. Provides template class files that you can use to modify your own generated ADF Business Components classes.	For details about framework extensions, see Section 12.3, "Creating a Layer of Framework Extensions."
ProgrammaticallySetProperties	Run TestClient.java under the Application Sources node of the Application Navigator.	For details about how to communicate custom declarative information about business components to the generic code in framework extension classes, see Section 12.4, "Customizing Framework Behavior with Extension Classes."
StoredProcedureInvocation	Run the ExampleSQLPackage.sql script under the Application Sources node of the Application Navigator against the FOD connection to set up the additional database objects required for the project. Run TestClient.java under the Application Sources node of the Application Navigator.	For details about how to code custom Java classes for business components that invoke database stored procedures and functions, see Section 12.6, "Invoking Stored Procedures and Functions."

2.4.4 Standalone Applications in the AdvancedEntityExamples Application Workspace

The standalone applications assembled in the application workspace **AdvancedEntityExamples** demonstrate advanced concepts that apply to ADF Business Components entity objects.

[Figure 2–11](#) shows the Application Navigator after you open the **AdvancedEntityExamples** application workspace.

Figure 2–11 Runnable Applications in the AdvancedEntityExamples Application Workspace

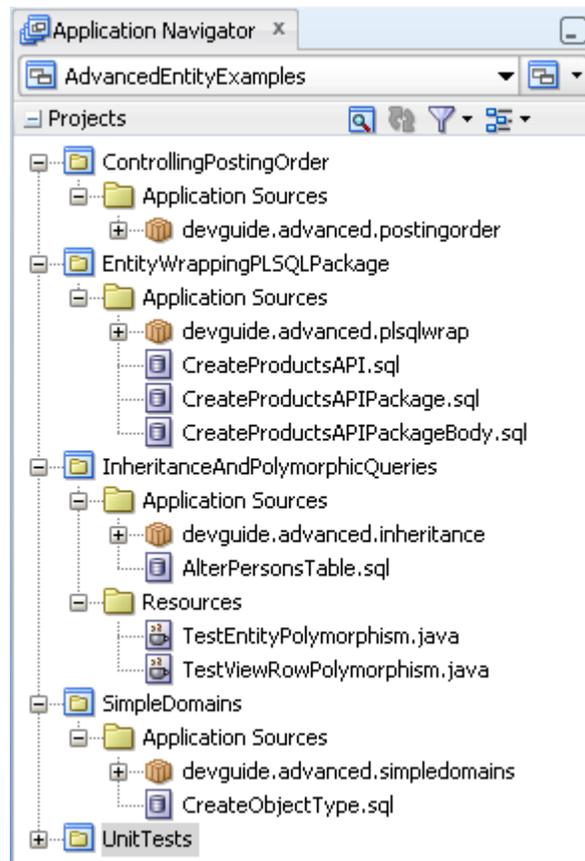

Table 2–6 describes the standalone applications in the `AdvancedEntityExamples` application workspace. Examples from this application workspace are described in Chapter 4, "Creating a Business Domain Layer Using Entity Objects."

Table 2–6 Standalone Applications in the AdvancedEntityExamples Application Workspace

Project Name	Runnable Class or Project Target	Documentation
ControllingPostingOrder	Launch the Oracle ADF Model Tester on ProductsModule under the Application Sources node of the Application Navigator.	For details about controlling the posting order resulting from DML operations to save changes to a number of related entity objects, see Section 4.14.7, "How to Control Entity Posting Order to Prevent Constraint Violations."
EntityWrappingPLSQLPackage	Run the CreateProductsXXX.sql scripts under the Application Sources node of the Application Navigator against the FOD connection to set up the additional database objects required for the project. Launch the Oracle ADF Model Tester on ProductsModule under the Application Sources node of the Application Navigator.	For details about overriding the default DML processing event for an entity object to invoke methods in a PL/SQL API PL/SQL package that encapsulates insert, update, and delete access to an underlying table, see Section 4.17, "Basing an Entity Object on a PL/SQL Package API."
InheritanceAndPolymorphicQueries	Run the AlterPersonsTable.sql script under the Application Sources node of the Application Navigator against the FOD connection to set up the additional database objects required for the project. Run TestEntityPolymorphism.java under the Resources node of the Application Navigator. Also, run TestViewRowPolymorphism.java under the Resources node of the Application Navigator.	For details about creating an entity object inheritance hierarchy, see Section 4.19, "Using Inheritance in Your Business Domain Layer."
SimpleDomains	Run the CreateObjectType.sql script under the Application Sources node of the Application Navigator against the FOD connection to set up the additional database objects required for the project. Launch the Oracle ADF Model Tester on PersonModule under the Application Sources node of the Application Navigator.	For details about creating custom data types, see Section 4.15, "Creating Custom, Validated Data Types Using Domains."

2.4.5 Standalone Applications in the AdvancedViewObjectExamples Application Workspace

The standalone applications assembled in the application workspace `AdvancedViewObjectExamples` demonstrate advanced concepts that apply to ADF Business Components view objects.

[Figure 2–12](#) shows the Application Navigator after you open the `AdvancedViewObjectExamples` application workspace.

Figure 2–12 *Runnable Applications in the AdvancedViewObjectExamples Application Workspace*

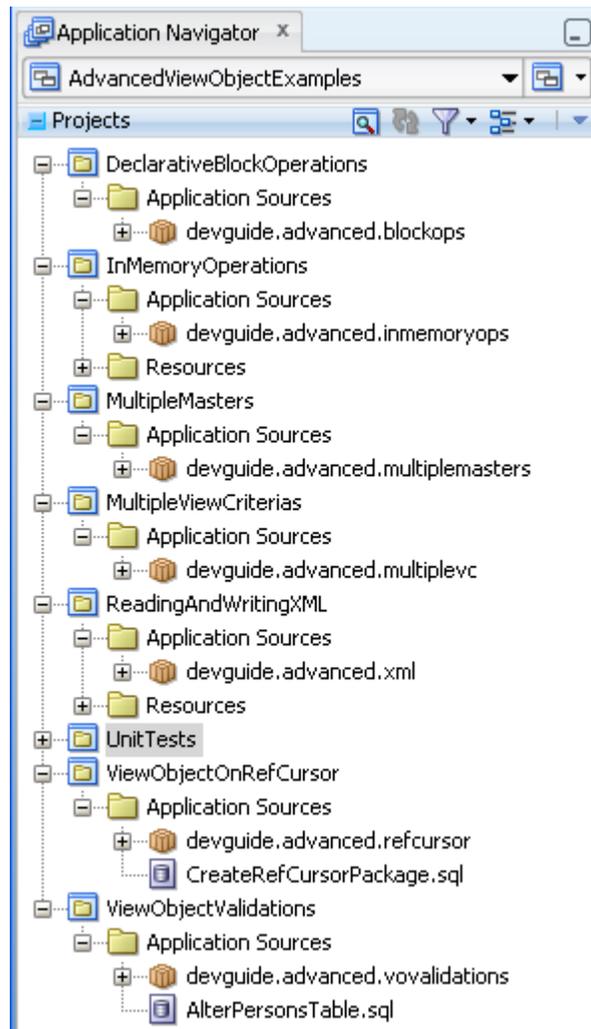

Table 2–4 describes the standalone applications in the AdvancedViewObjectExamples application workspace. Examples from this application workspace are described in [Chapter 42, "Advanced View Object Techniques."](#)

Table 2–7 Standalone Applications in the AdvancedViewObjectExamples Application Workspace

Project Name	Runnable Class or Project Target	Documentation
DeclarativeBlockOperations	Launch the Oracle ADF Model Tester on AppModule under the Application Sources node of the Application Navigator.	For details about how to use custom metadata properties to control insert, update, or delete on a view object, see Section 42.10, "Declaratively Preventing Insert, Update, and Delete."
InMemoryOperations	Launch the Oracle ADF Model Tester on AppModule under the Application Sources node of the Application Navigator. Illustrates using the in-memory sorting and filtering functionality from the client side using methods on the interfaces in the <code>oracle.jbo</code> package.	For details about how to use view objects to perform in-memory searches and sorting to avoid unnecessary trips to the database, see Section 42.5, "Performing In-Memory Sorting and Filtering of Row Sets."
MultipleMasters	Launch the Oracle ADF Model Tester on AppModule under the Application Sources node of the Application Navigator.	For details about creating a view object with multiple updatable entities to support creating new rows, see Section 42.9, "Creating a View Object with Multiple Updatable Entities."
MultipleViewCriteria	Run TestClientMultipleViewCriteria.java under the Application Sources node of the Application Navigator.	For details about how to programmatically filter query results, see Section 42.4, "Working Programmatically with Multiple Named View Criteria."
ReadingAndWritingXML	Run TestClientReadXML.java under the Resources node of the Application Navigator. Then run TestClientWriteXML.java under the Resources node of the Application Navigator.	For details about how to produce XML from queried data, see Section 42.7, "Reading and Writing XML."
ViewObjectOnRefCursor	Run the CreateRefCursorPackage.sql script under the Application Sources node of the Application Navigator against the FOD connection to set up the additional database objects required for the project, Launch the Oracle ADF Model Tester on OrdersModule under the Application Sources node of the Application Navigator.	For details about how to use PL/SQL to open a cursor to iterate through the results of a query, see Section 42.8.4, "How to Create a View Object on a REF CURSOR."

2.4.6 Standalone Applications in the AdvancedUIExamples Application Workspaces

The standalone applications assembled in the application workspaces in the `AdvancedUIExamples` folder demonstrate advanced concepts that apply to databound ADF Faces components.

[Figure 2–13](#) shows the Application Navigator after you open the application workspaces in the `AdvancedUIExamples` folder.

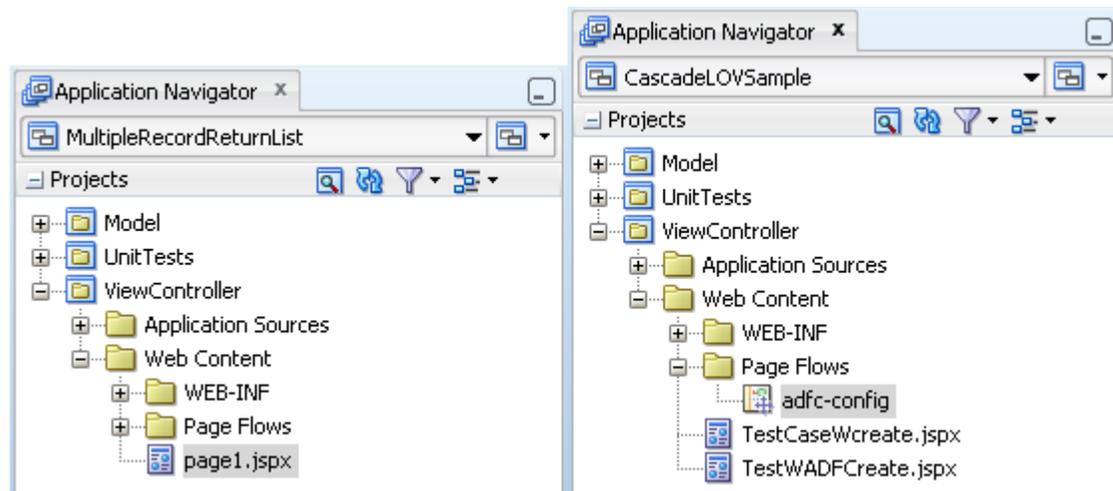

Figure 2–13 Runnable Applications in the AdvancedUIExamples Application Workspaces

Table 2–4 describes the standalone applications in the AdvancedUIExamples folder.

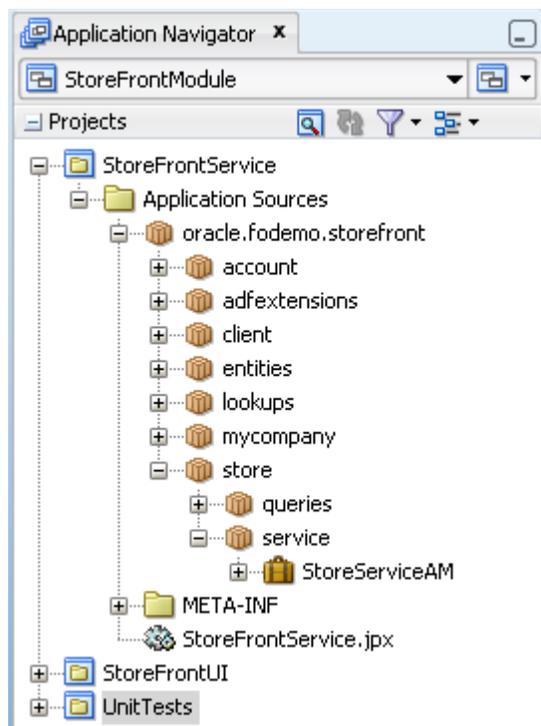

Table 2–8 Standalone Applications in the AdvancedUIExamples Application Workspaces

Workspace Name	Runnable Project Target	Documentation
MultipleRecordReturnList	Run the page1.jspx node under the Web Content node in the ViewController project displayed in the Application Navigator.	For details about how to use <code>selectOneChoice</code> components to return multiple records, see Section 30.3, "Creating a Selection List."
CascadeLOVSample	Run the adfc-config node under the Page Flows node in the ViewController project displayed in the Application Navigator.	For details about how to use cascading LOVs, see Section 30.2, "Creating List of Values (LOV) Components."

2.5 Taking a Look at the Fusion Order Demo Application

Once you have opened the projects in JDeveloper, you can then begin to review the artifacts within each project. The development environment for the Fusion Order Demo application is divided into two projects: the `StoreFrontService` project and the `StoreFrontUI` project.

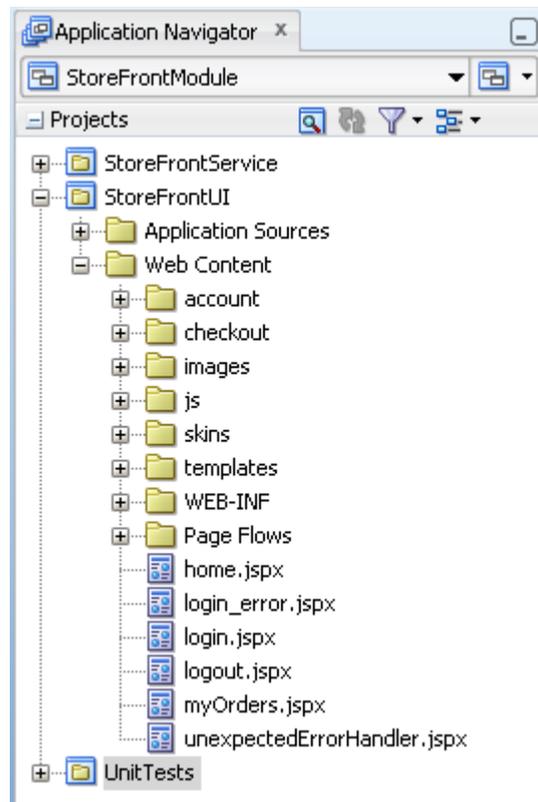

The `StoreFrontService` project contains the classes that allow the product data to be displayed in the web application. [Figure 2–14](#) shows the `StoreFrontService` project and its associated directories.

Figure 2–14 The StoreFrontService Project

The StoreFrontService project contains the following directories:

- Application Sources: Contains the files used to access the product data. Included are the metadata files used by Oracle Application Development Framework (Oracle ADF) to bind the data to the view.
- META-INF: Contains a file used in deployment.

The StoreFrontUI project contains the files for the web interface, including the backing beans, deployment files, and JSPX files. [Figure 2–15](#) shows the StoreFrontUI project and its associated directories.

Figure 2–15 The StoreFrontUI Project

The StoreFrontUI project contains the following directories:

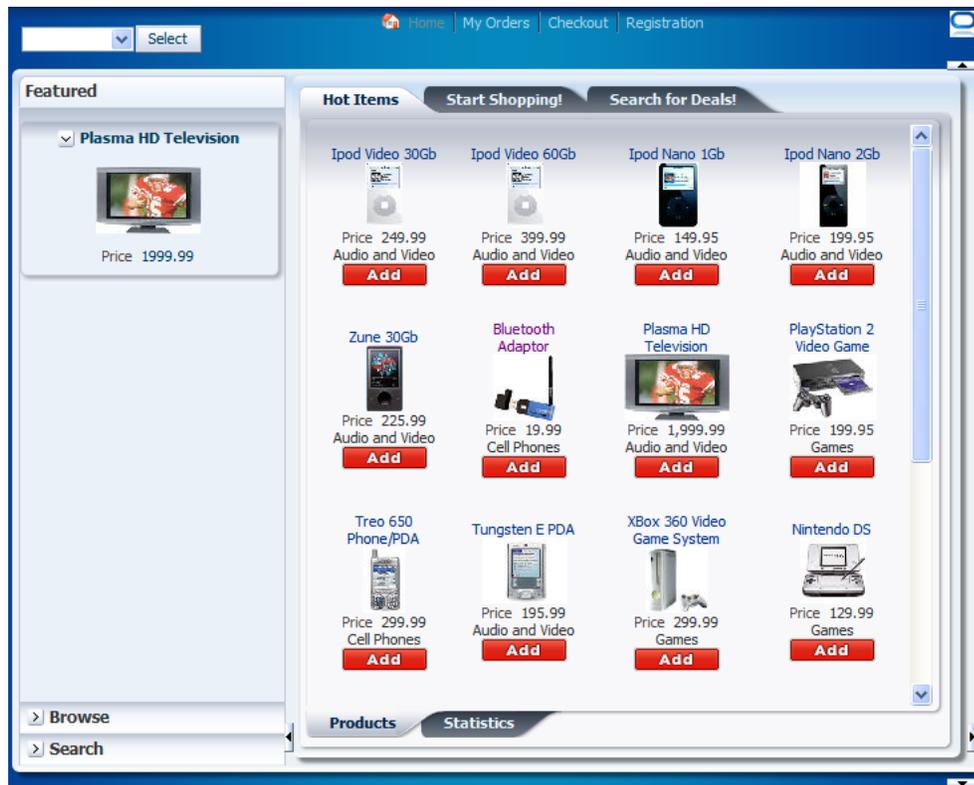

- **Application Sources:** Contains the code used by the web client, including the managed and backing beans, property files used for internationalization, and the metadata used by Oracle ADF to display bound data.
- **Web Content:** Contains the web files, including the JSP files, images, skin files, deployment descriptors, and libraries.

2.5.1 Anonymous Browsing

You start the Fusion Order Demo application by running the `home.jspx` page in the StoreFrontUI project. For details about running the application using the default target, `home.jspx` page, see [Section 2.3, "Running the Fusion Order Demo Application StoreFront Module."](#)

When you enter the storefront site, the site is available for anonymous browsing. You can use this page to browse the catalog of products without logging into an account. The initial view shows the featured products that the site wishes to promote and gives you access to the full catalog of items. Products are presented as images along with the name of the product. Page regions divide the product catalog area from other features that the site offers.

[Figure 2–16](#) shows the home page.

Figure 2–16 Home Page with Multiple Regions

Where to Find Implementation Details

Following are the sections of the *Oracle Fusion Middleware Fusion Developer's Guide for Oracle Application Development Framework* that describe how to create a databound web page:

- Providing the structure for the web page

The home page separates features of the site into regions that are implemented using a combination of ADF Faces templates and JavaServer Faces (JSF) page fragments. ADF Faces templates and the fragments allow you to add ADF databound components. For information about the steps you perform before adding databound user interface components to a web page, see [Section 24.1, "About Developing a Web Application with ADF Faces."](#)

- Displaying information on a web page

To support data binding, the featured items on the tabbed region of the home page use EL (Expression Language) expressions to reference ADF data control usages in the declarative ADF page definition file. The page definition file, which JDeveloper creates for you when you work with the Data Controls panel to drag and drop databound ADF Faces components, is unique to each web page or page fragment. The ADF data control usages enable queries to the database and ultimately work with the JSF runtime to render the databound ADF Faces components, such as the ADF Faces image component used to display images from the `PRODUCT_IMAGES` table. For information about creating a databound web page that references the ADF page definition file, see [Section 26.1, "About Creating a Basic Databound Page."](#)

- Managing entry points to the application

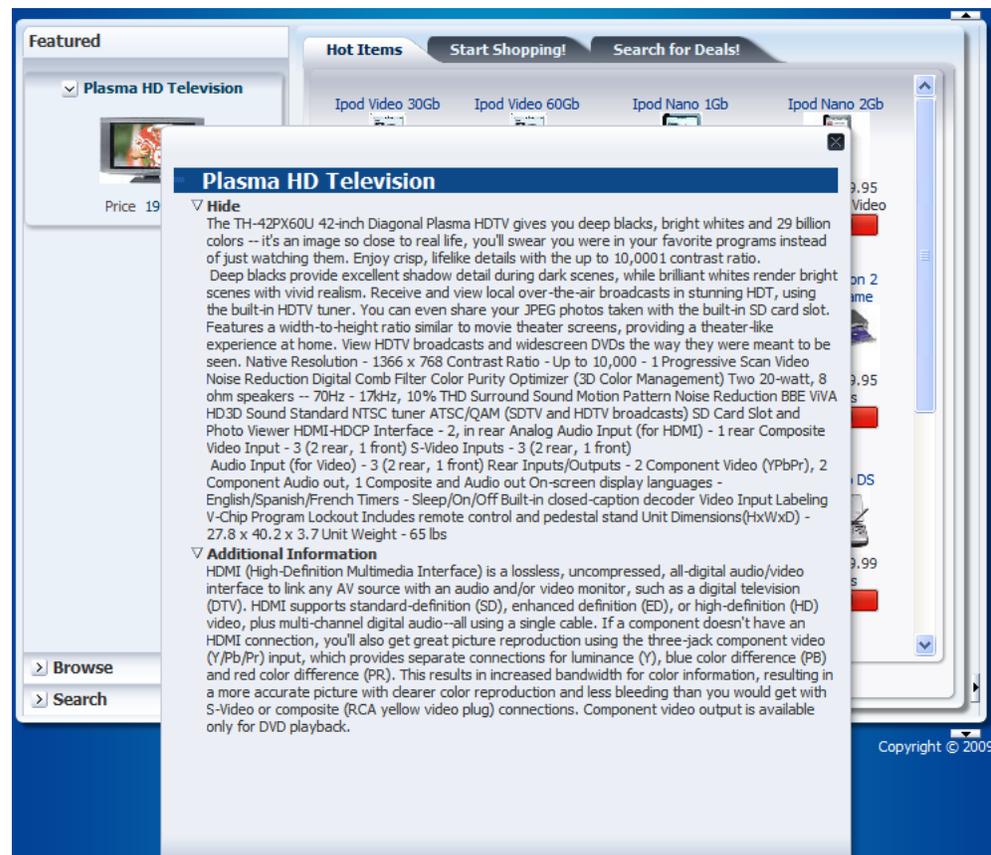

The home page is supported by an ADF unbounded task flow. In general, the Fusion web application relies on this ADF Controller feature to define entry points to the application. The unbounded task flow for the entire home page and its page fragments describes view activities for displaying the home page, displaying the orders page, displaying the register user page, and it defines a task flow reference to manage the checkout process. JDeveloper helps you to create the task flow with visual design elements that you drag and drop from the Component Palette. When you create an unbounded task flow, the elements allow you to identify how to pass control from one activity in the application to the next. Because a view activity must be associated with a web page or page fragment, JDeveloper allows you also to create the files for the web page or fragment directly from the task flow diagram. The process of creating a task flow adds declarative definitions to an ADF task flow configuration file. The resulting diagram lets you work with a visual control flow map of the pages and referenced task flows for your application. For more information about specifying the entry points to the application using an ADF unbounded task flows, see [Section 18.1, "About ADF Task Flows."](#)

2.5.1.1 Viewing Product Details

To view detailed product information, you can click the product name link for any product in the home page. The product information is laid out with collapsing nodes organized by categories.

[Figure 2-17](#) shows the detail dialog that you can view for a product.

Figure 2-17 Home Page - Product Details Popup

You can also select the **Statistics** subtab on the home page to view a graphical representation of the number of orders that customers have placed for the featured items. To present the information so that quantities are easily compared, the graph sorts the products by the number of items ordered, in descending order.

Figure 2–18 shows the bar graph used to display the featured products' current order details.

Figure 2–18 Home Page - Statistics for Featured Items

Where to Find Implementation Details

Following are the sections of the *Oracle Fusion Middleware Fusion Developer's Guide for Oracle Application Development Framework* that describe how to develop the components used to support browsing product details:

- Triggering an action to display data

To display data from the data model, user interface components in the web page are bound to ADF Model layer binding objects using JSF Expression Language (EL) expressions. For example, when the user clicks on a link to display an informational dialog, the JSF runtime evaluates the EL expression for the dialog's UI component and pulls the value from the ADF Model layer. At design time, when you work with the Data Controls panel to drag an attribute for an item of a data collection into your web page, and then choose an ADF Faces component to display the value, JDeveloper creates all the necessary JSF tag and binding code needed to display and update the associated data. For more information about the Data Controls panel and the declarative binding experience, see [Section 13.1, "About ADF Data Binding."](#)
- Displaying data in graphical format

JDeveloper allows you to create databound components declaratively for your JSF pages, meaning you can design most aspects of your pages without needing to look at the code. By dragging and dropping items from the Data Controls panel, JDeveloper declaratively binds ADF Faces UI components and ADF Data Visualization graph components to attributes on a data control using an ADF

binding. For more information, see [Section 33.1, "About ADF Data Visualization Components."](#)

2.5.1.2 Browsing the Product Catalog

To begin browsing, click the **Start Shopping** tab in the home page. This action changes the region of the page used to display details about featured products to a region that displays a product categories tree. You can collapse and expand the branch nodes of the tree to view the various product categories that make up the product catalog. The tree displays the product categories in alphabetical order, by category names. When you want to view all the products in a particular category, click its category node in the tree (for example, click **Electronics**, **Media**, or **Office**). The site refreshes the product information region to display the list of products organized as they appear in the database with an image and an accompanying description.

[Figure 2–19](#) shows the home page with all the products in the **Electronics** category displayed.

Figure 2–19 Home Page - Product Categories View

Where to Find Implementation Details

Following are the sections of the *Oracle Fusion Middleware Fusion Developer's Guide for Oracle Application Development Framework* that describe how to use tables and forms to display master-detail related objects:

- Dragging and dropping master and detail components

You can create pages that display master-detail data using the Data Controls panel. The Data Controls panel displays master-detail related objects in a hierarchy that mirrors the one you defined in the data model for the ADF application module, where the detail objects are children of the master objects. All you have to do is drop the collections on the page and choose the type of component you want to use. For example, in the Fusion Order Demo application, the page `home.jspx` displays the master list of product categories in an `af:tree` component and displays the detail list of products in an `af:table` component. For more information about the data model, see [Section 3.4, "Overview of the](#)

[Oracle ADF Active Data Model.](#) For more information about various types of pages that display master-detail related data, see [Section 29.1, "About Displaying Master-Detail Data."](#)

- Sorting data that displays in tables

When you create an ADF Faces table component you bind the table to the complete collection or to a range of data objects from the collection. The specific components that display the data in the columns are then bound to the attributes of the collection. The iterator binding handles displaying the correct data for each object, while the table component handles displaying each object in a row. You can set the **Sort** property for any column when you want the iterator to perform an order-by query to determine the order. You can also specify an `ORDER BY` clause for the query that the view object in the data model project defines. For more information about binding table components to a collection, see [Section 27.1, "About Creating ADF Databound Tables."](#) For more information about creating queries that sort data in the data model, see [Section 5.2, "Populating View Object Rows from a Single Database Table."](#)

2.5.1.3 Searching for Products

To search the product catalog, you have several choices. You can begin either by clicking the disclosure icon (a + symbol) on the **Search** tab on the panel accordion or by clicking the **Search for Deals** tab in the main region. When you click either of these, the home page displays both regions at once to allow you to enter a search criteria and view the search results. You use the **Search** tab on the accordion panel to perform a simple keyword search against the attributes common to all products, such as product names or product descriptions. When you select the attribute to search on from the dropdown list, the panel renders a search field using an appropriate input component to accept the search criteria. For example, in the case of the default searchable attribute **ProductId**, where a numeric value is expected, the search field uses a spinbox (the ADF Faces component `inputNumberSpinBox`) to return the product ID.

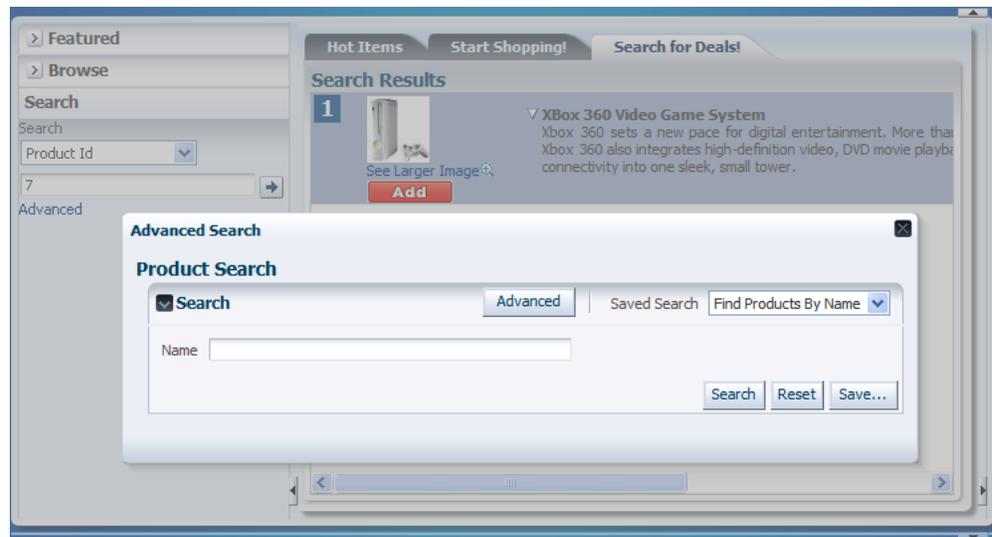

[Figure 2–20](#) shows the home page with the search results returned for the product with an ID equal to 7.

Figure 2–20 Home Page - Search View

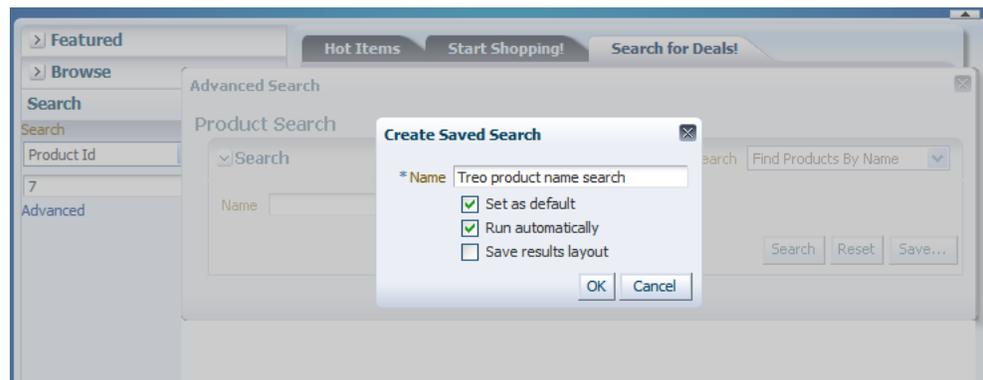

As an alternative to entering a simple search, you can use the advanced search feature to define and save search criteria based on any combination of searchable fields that you select for the product. Click the **Advanced** link to open the Advanced Search dialog. Developer-defined saved searches like **Find Products By Name** appear in the **Saved Search** dropdown list.

[Figure 2–21](#) shows the Advanced Search dialog with a single search criteria, **Name**, that the **Find Products By Name** saved search defines.

Figure 2–21 Home Page - Advanced Search Dialog

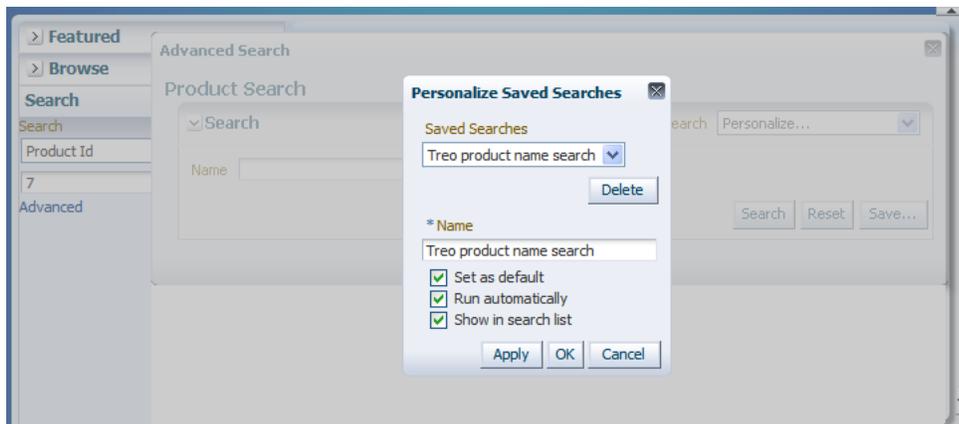

In addition to the developer-defined saved searches available in the Advanced Search dialog, the end user can create saved searches that will persist for the duration of their session. Enter the product search criteria in the Advanced Search dialog, then click the **Save** button to open the Create Saved Search dialog.

Figure 2–22 shows the Create Saved Search dialog that you use to specify how you want to save the search criteria you entered in the Advanced Search dialog. You can name the search, for example, **Treo product name search**, so that it will display in the **Saved Search** dropdown list of the Advanced Search dialog.

Figure 2–22 Home Page - Advanced Search Dialog - Saved Searches Option

You can also manage your saved searches by selecting the **Personalize** function in the **Saved Search** dropdown list of the Advanced Search dialog.

Figure 2–23 shows the Personalize Saved Search dialog for the **Find Products By Name** search, with **Show in Search List** enabled so that it will appear in the **Saved Search** dropdown list. Note that because this search is not a user-defined saved search, the personalization options appear disabled.

Figure 2–23 Home Page - Advanced Search Dialog - Personalization Option

Where to Find Implementation Details

Following are the sections of the *Oracle Fusion Middleware Fusion Developer's Guide for Oracle Application Development Framework* that describe how to define queries and create query search forms:

- Defining the query for the search form to display

A query is associated with an ADF Business Components view object that you create for the data model project to define a particular query against the database. In particular, a query component is the visual representation of the view criteria defined on that view object. If there are multiple view criteria defined, each of the view criteria can be selected from the **Saved Search** dropdown list. These saved searches are created at design time by the developer. For example, in the Fusion Order Demo application, the `ProductsVO` view object defines two view criteria. When the query associated with that view object is run, both view criteria are available for selection. For more information, see [Section 31.1, "About Creating Search Forms."](#)
- Creating a quick search form

A quick query search form has one search criteria field with a dropdown list of the available searchable attributes from the associated data collection. By default, the searchable attributes are all the attributes in the associated view object. You can exclude attributes by setting the attribute's **Display** control hint to **Hide** in the view object. The user can search against the selected attribute or search against all the displayed attributes. The search criteria field type will automatically match the type of its corresponding attribute type. For more information, see [Section 31.4, "Creating Quick Query Search Forms."](#)
- Creating a search form

You create a query search form by dropping a named view criteria item from the Data Controls panel onto a page. You have a choice of dropping only a search panel, dropping a search panel with a results table, or dropping a search panel with a tree table. For more information, see [Section 31.2, "Creating Query Search Forms."](#)
- Displaying the results of a query search

Normally, you would drop a query search panel with the results table or tree table. JDeveloper will automatically wire up the results table or tree table with the query panel. If you drop a query panel by itself and want a separate results component, you can set the query component's `resultComponentId` attribute to

the relative expression of the results component. For example, in the Fusion Order Demo application, the page `home.jsp` displays an `af:table` with the ID `searchT` and the results ID of the advanced search dialog is assigned this ID. For more information, see [Section 31.2.3, "How to Create a Query Search Form and Add a Results Component Later."](#)

2.5.2 The Login Process

Until you attempt to access secure resources in the storefront site, you are free to browse the product catalog and update the shopping cart as an anonymous user. However, when you click the **My Orders** or **Checkout** links that appear at the top of the home page, you will be challenged by the web container running the site to supply login credentials. The site requires that you enter a valid user name and password before it completes your request to display the linked page.

Note: The Fusion Order Demo application supports the new customer registration process, but that user is not added to the security implementation. Thus, you must use a predefined customer's user name and password to log in, as shown in [Table 2-3](#).

[Figure 2-24](#) shows the login page fragment that displays before you can view order details or purchase items from the store. For demonstration purposes, log in as a customer by entering `ngreenbe` and `welcome1` for the **Username** and **Password**, respectively.

Figure 2-24 Login Region

The screenshot shows a login form titled "Log in" with a dropdown arrow. It contains two input fields: "Username" with the text "ngreenbe" and "Password" with seven dots. A "Log In" button is positioned to the right of the password field. Below the form, there is a link that reads "Not a user? Create an account now! >> Continue Shopping".

When you click the **Log In** button, the web container will compare your entries with the credential information stored in its identity store. If the web container is able to authenticate you (because you have entered the user name and password for a registered user), then the web container redirects to the web page specified by your link selection; otherwise, the site prompts you to create an account or to continue browsing as an unauthenticated user.

Where to Find Implementation Details

Following are the sections of the *Oracle Fusion Middleware Fusion Developer's Guide for Oracle Application Development Framework* that describe how to secure Oracle ADF resources so that users are required to log in to access those resources:

- Enabling fine-grained security to secure Oracle ADF resources

ADF Security is a framework that provides a security implementation that is based on Java Authentication and Authorization Service (JAAS). The Oracle ADF implementation of JAAS is role-based. You define these roles in JDeveloper and then make permission grants based on these roles to enable fine-grained security

for Oracle ADF resources. JDeveloper supports declaratively defining the Oracle ADF policy store for an ADF bounded task flow or individual web pages associated with their ADF page definition. For information about securing Oracle ADF resources, see [Section 35.5, "Defining ADF Security Policies."](#)

- Triggering dynamic user authentication

When you use ADF Security, authentication is triggered automatically if the user is not yet authenticated and tries to access a page that is not granted to the `anonymous-role` role. After successfully logging in, another check will be done to verify if the authenticated user has view access to the requested page. For more information, see [Section 35.3.5, "What You May Need to Know About ADF Authentication."](#)

- Performing permission checking within the web page

At runtime, the security policy you define for ADF resources is enforced using standard JAAS permission authorization to determine the user's access rights. If your application requires it, you can use Expression Language (EL) to perform runtime permission checks within the web page to hide components that should not be visible to the user. For example, in the Fusion Order Demo application, the page `myOrders.jsp` uses an expression with the value `userGrantedPermission` to test the user's authorization privileges before displaying their account number. For more information, see [Section 35.11.1, "Using Expression Language \(EL\) with ADF Security."](#)

2.5.3 The Ordering Process

You begin the order process by browsing the product catalog. When you click **Add** next to a product, the site updates the shopping cart region to display the item.

[Figure 2-25](#) shows the cart summary with a single item added. The summary shows a subtotal for the items that appear in the cart.

Figure 2–25 Home Page - Shopping Cart Summary

When you are satisfied with the items in the cart, you can complete the order by clicking the **Checkout** link at the top of the home page. To check out and complete the order, you must become an authenticated user, as described in [Section 2.5.2, "The Login Process."](#)

After you log in, the site displays the checkout page with order details, such as the name and address of the user you registered as. The order is identified by an **Order Information** number that is generated at runtime and assigned to the order. An Order Summary region displays the order items that comprise the new order. This region is similar to the cart summary on the home page, except that it adds the cost of shipping and deducts any discounts that apply to the order to calculate the total purchase amount.

[Figure 2–26](#) shows the checkout page with an order comprising four order items.

Figure 2–26 Checkout Page - Order Details Form

The screenshot displays the checkout page for order #1316. It is divided into several sections:

- Shipping Details:**
 - Customer Information:** Nancy Greenberg, Member Since, Email Address: NGREENBE, Mobile Phone: 865.555.0102.
 - Primary Address:** Address Line 1: 2549 Yonge Street, City: Toronto, Postal Code or ZIP: M4P 2H9, State / Province: ON, Country: CA.
- Order Information - #1316:**
 - Shipping Information:** Ship to, Shipping Address (1100 N Peach St Philadelphia PA 19139 US), Phone Number.
 - Payment Options:** Payment Option Code: 536267 MSTR.
 - Shipping Options:** Standard Shipping (3-5 business days), Two-Day Shipping, One-Day Shipping, Pick-up.
 - Discounts:** Coupon Code field.
 - Gift Options:** Gift Wrapping Message: None.
- Order Summary:**
 - Items: ≈1,221.82
 - Shipping & Handling: ≈63.05
 - Discounts: ≈20.00
 - Your Total: ≈1,264.87
 - Submit Order button.

You can use the checkout page to customize details of the order information. For example, click the **Edit** icon next to the **Payment Option Code** field to display and edit payment funding information for the order.

Figure 2–27 shows the detail dialog for the **Payment Option Code** field.

Figure 2–27 Checkout Page - Payment Option Detail Dialog

The screenshot shows the Payment Option Detail Dialog for the Payment Option Code 536267 MSTR. The dialog contains the following fields:

- * Payment Type: PayPal
- * Billing Address: 1100 N Peach St Philadelphia PA US 19139
- * Account Number: 536267
- Card Type: MasterCard
- Expiration Date: 06-FEB-2009 10:47:21
- Check Digits: [Empty]
- Routing Identifier: [Empty]
- Institution Name: [Empty]
- Valid From Date: [Empty]
- Valid To Date: [Empty]

At the bottom, there is a note: "Valid sample credit card numbers include: Visa: 4012888888881881, MC: 5105105105105100, AMEX: 3434343434343434. Valid routing numbers include: 9874321 and 789456124." There are OK and Cancel buttons at the bottom right.

Many of the fields of the payment options dialog offer user interface hints that guide you to enter specific information.

Figure 2–28 shows an example of a date entry (06-FEB-2009 10:47:21) that the format mask (dd-MMM-yyyy hh:mm:ss) defines for the **Expiration Date** field.

Figure 2–28 Checkout Page - Payment Options Detail Dialog - Date Format Mask

The screenshot shows a dialog box with the following fields and values:

- * Payment Type: PayPal
- * Billing Address: 1100 N Peach St Philadelphia PA US 19139
- * Account Number: 536267
- Card Type: MasterCard
- Expiration Date: 06-FEB-2009 10:47:21
- Check Digits: (empty)
- Routing Identifier: (empty)
- Institution Name: (empty)
- Valid From Date: (empty)
- Valid To Date: (empty)

A tooltip next to the Expiration Date field displays the example: **Example: 29-Nov-1998 15:45:38**.

At the bottom of the dialog, there is a list of valid sample credit card numbers and routing numbers:

- Valid sample credit card numbers include:
 - Visa: 4012888888881881
 - MC: 5105105105105100
 - AMEX: 343434343434343
- Valid routing numbers include: 9874321 and 789456124

Buttons for OK and Cancel are located at the bottom right.

The **Card Type** field displays a dropdown list that allows you to select from a valid list of credit card types.

Figure 2–29 displays the list of values for the **Card Type** field.

Figure 2–29 Checkout Page - Payment Options Detail Dialog - List of Values (LOV) Choice List

The screenshot shows the same dialog box as Figure 2–28, but with the **Card Type** dropdown list open. The list contains the following options:

- American Express
- Diners Club
- MasterCard
- Visa

The **Visa** option is currently selected and highlighted in blue.

The rest of the dialog fields and the list of valid sample credit card numbers and routing numbers are the same as in Figure 2–28.

If you close the payment options dialog and click the **Submit Order** button in the checkout page, the purchase order is created and sent into a process flow.

After you place an order using the StoreFront module, a second module of the Fusion Order Demo application is available to process the order. For details about the WebLogic Fusion Order Demo module used to demonstrate the capabilities of Oracle

SOA Suite, see *Oracle Fusion Middleware Developer's Guide for Oracle SOA Suite*. For information about running this portion of the Fusion Order Demo application, see [Section 2.3, "Running the Fusion Order Demo Application StoreFront Module."](#)

Where to Find Implementation Details

Following are the sections of the *Oracle Fusion Middleware Fusion Developer's Guide for Oracle Application Development Framework* that describe how to develop forms like the ones used in the order checkout process:

- **Creating a databound edit form**

When you want to create a basic form that collects values from the user, instead of having to drop individual attributes, JDeveloper allows you to drop all attributes for an object at once as an input form. You can create forms that display values, forms that allow users to edit values, and forms that collect values. For example, in the Fusion Order Demo application, the checkout page `orderSummary.jspx` displays one form to display user information and another form to collect shipping information for the user's order. For more information, see [Section 26.6, "Creating an Input Form."](#)
- **Defining format masks for input forms**

Format masks help ensure the user supplies attribute values in the required format. To facilitate this task, ADF Business Components provides declarative support known as control hints for attributes in the data model project. For example, in the Fusion Order Demo application, the attribute for the `CustomerPaymentOptionVO` view object used to assign the user's credit card expiration date is configured with a format mask hint and enforced in the Payment Options page fragment `paymentOptionsDetails.jsff`. For information on defining format masks for input form components, see [Section 5.13, "Defining Attribute UI Hints for View Objects."](#)
- **Defining a list of values for selection lists**

Input forms displayed in the user interface can utilize databound ADF Faces selection components to display a list of values (LOV) for individual attributes of the data collection. To facilitate this common design task, ADF Business Components provides declarative support to specify the LOV usage for attributes in the data model project. For example, in the Fusion Order Demo application, the three `af:selectOneChoice` components displayed in the Payment Options page fragment `paymentOptionsDetails.jsff` are bound to LOV-enabled attributes configured for the `CustomerPaymentOptionVO` view object. For more information about configuring attributes for LOV usage, see [Section 5.12, "Working with List of Values \(LOV\) in View Object Attributes."](#)
- **Keeping track of transient session information**

When you create a data model project that maps attributes to columns in an underlying table, your ADF view objects can include transient attributes that display calculated values (for example, using Java or Groovy expressions) or that are value holders. For example, in the Fusion Order Demo application, the order summary page `orderSummary.jspx` displays the value of the `InvoiceTotal` attribute calculated by the expression defined on the `OrderVO` view object. For more information about defining transient attributes in the data model project, see [Section 4.11, "Adding Transient and Calculated Attributes to an Entity Object."](#)

2.5.4 The Customer Registration Process

The site requires that you become an authenticated user before you can display the checkout page. To make it possible for new customers complete the order process, the site needs to provide a way to guide users through customer registration. To begin, click the registration link on the home page and then click **Register as a customer**.

Customer registration progresses in steps, with one screen dedicated to each step. To represent the progression of these steps, the registration page displays a series of train stops labelled **Basic Information**, **Address**, **Payment Options**, and **Review**. To navigate the customer registration process, you can click certain train stops or you can click the **Next** button.

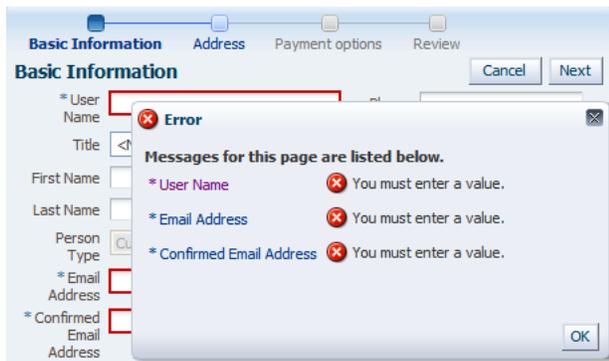

Figure 2–30 shows the first screen in the customer registration process. The **Basic Information** stop of the train is enabled and selected to identify it as the current stop. Notice that the next train stop icon, **Address**, is enabled but not highlighted, while the **Payment options** and **Review** train stop icons appear disabled and grayed out. Together, these train stops signify that you must complete the activity in a sequential flow.

Figure 2–30 Customer Registration Page - Basic Information Form

Before you enter any information into the Basic Information form, click the **Address** train stop. The page displays an error dialog to inform you that specific fields require a value before you can progress to the next step.

Figure 2–31 shows the error dialog with messages stating that the Basic Information form requires a user name and an email address.

Figure 2–31 Customer Registration Page - Basic Information Form with Validation Error Popup

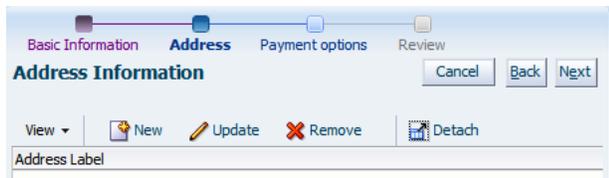

Click **OK** to dismiss the error dialog. Then enter a user name and email address. Be sure to confirm the email address in the form.

Again, click **Next** to progress to the next task. This time, the site should display the Address screen with icon buttons that you can select to create a new address record in the database (or, in the case of an existing customer, to update an existing address record).

Figure 2–32 shows the Address screen with one column for **Address Label** and no row information. Because you are entering information as a new customer, no address record currently exists, so no rows are available to display below these columns.

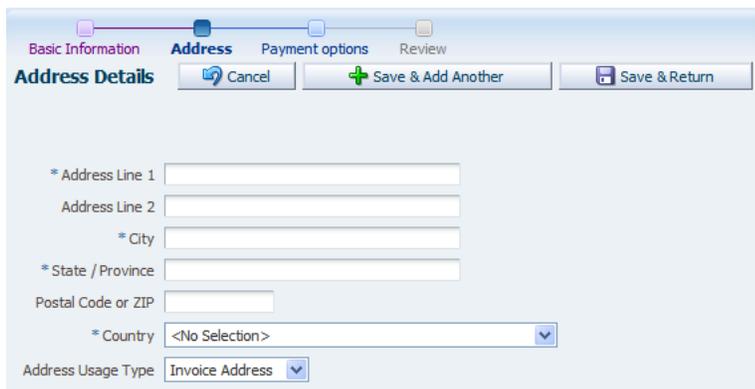

Figure 2–32 Customer Registration Page - Address Input Task

Click **New**. The registration page changes to display an address input form and the current train stop remains on **Address**.

Figure 2–33 shows the empty address input form.

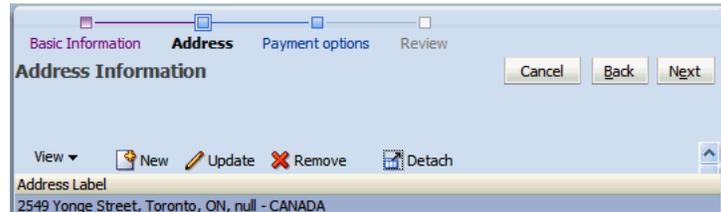

Figure 2–33 Customer Registration Page - Address Input Form

For the fields with an asterisk symbol (*), enter the address information specified. The asterisk symbol indicates that the value is required. Note that you must also select a country from the dropdown list since this information is required by the database. Then click **Save & Return** to create the new address record in the database.

Figure 2–34 shows the Address screen with the row information for the new address record.

Figure 2–34 Customer Registration Page - Address Record Complete

This concludes the tour of the Fusion Order Demo application.

Where to Find Implementation Details

Following are the sections of the *Oracle Fusion Middleware Fusion Developer's Guide for Oracle Application Development Framework* that describe how to use complex components like the ADF Faces Train component used in the registration process:

- Grouping activities using a bounded task flow

Every Fusion web application contains an unbounded task flow, which contains the entry points to the application. The application can then call bounded task flows from activities within the unbounded task flow. For example, in the Fusion Order Demo application, the bounded task flow `checkout-task-flow` controls the flow of the checkout process and calls another bounded task flow `customer-registration-task-flow` to control the flow of the registration process. For information about the bounded task flow, see [Section 18.1, "About ADF Task Flows."](#)

- Displaying a progression of related activities using a train component that you associate with a bounded task flow

You configure train stops based on activities that you select in an ADF bounded task flow and then you add the `af:train` component to your JSF pages. For example, in the Fusion Order Demo application, the bounded task flow `customer-registration-task-flow` defines four train stops for the page fragments `basicInformation.jsff`, `defineAddresses.jsff`, `paymentOptions.jsff`, and `reviewCustomerInfo.jsff`. The page `register.jspx` displays the fragments and each page fragment displays the train component bound to the activities that define the four stops. For information about the bounded task flow and how you can use it to define train stops, see [Section 22.7.1, "Creating a Task Flow as a Train."](#)

- Requiring values to complete an input form

The input form displays attributes of a data collection that you drop from the Data Controls panel. You can set the `required` property of individual components in the form to control whether an attribute value is mandatory. For details about how to customize the `required` property, see [Section 26.2, "Using Attributes to Create Text Fields."](#) Alternatively, you can set a display control hint property directly on the attribute where it is defined by an ADF Business Components entity object. The entity object is a data model component that represents a row from a specific

table in the database and that simplifies modifying its associated attributes. For details about using control hints to make an attribute mandatory, see [Section 4.10, "Setting Attribute Properties."](#)

Part II

Building Your Business Services

Part II contains the following chapters:

- [Chapter 3, "Getting Started with ADF Business Components"](#)
- [Chapter 4, "Creating a Business Domain Layer Using Entity Objects"](#)
- [Chapter 5, "Defining SQL Queries Using View Objects"](#)
- [Chapter 6, "Testing View Instance Queries"](#)
- [Chapter 7, "Defining Validation and Business Rules Declaratively"](#)
- [Chapter 8, "Implementing Validation and Business Rules Programmatically"](#)
- [Chapter 9, "Implementing Business Services with Application Modules"](#)
- [Chapter 10, "Sharing Application Module View Instances"](#)
- [Chapter 11, "Integrating Service-Enabled Application Modules"](#)
- [Chapter 12, "Extending Business Components Functionality"](#)

Getting Started with ADF Business Components

This chapter provides an overview of ADF Business Components, including a description of the key features they provide for building your business services.

This chapter includes the following sections:

- [Section 3.1, "About ADF Business Components"](#)
- [Section 3.2, "Comparison to Familiar 4GL Tools"](#)
- [Section 3.3, "Overview of Design Time Facilities"](#)
- [Section 3.4, "Overview of the Oracle ADF Active Data Model"](#)
- [Section 3.5, "Overview of the ADF Business Components Implementation"](#)
- [Section 3.6, "Overview of Groovy Scripting Language Support"](#)

3.1 About ADF Business Components

ADF Business Components and JDeveloper simplify the development, delivery, and customization of business applications for the Java EE platform. With ADF Business Components, developers aren't required to write the application infrastructure code required by the typical Java EE application to:

- Connect to the database
- Retrieve data
- Lock database records
- Manage transactions

ADF Business Components addresses these tasks through its library of reusable software components and through the supporting design time facilities in JDeveloper. Most importantly, developers save time using ADF Business Components since the JDeveloper design time makes typical development tasks entirely declarative. In particular, JDeveloper supports declarative development with ADF Business Components to:

- Author and test business logic in components which automatically integrate with databases
- Reuse business logic through multiple SQL-based views of data, supporting different application tasks
- Access and update the views from browser, desktop, mobile, and web service clients

- Customize application functionality in layers without requiring modification of the delivered application

The goal of ADF Business Components is to make the business services developer more productive.

3.1.1 ADF Business Components Features

ADF Business Components provides a foundation of Java classes that allow your business-tier application components to leverage the functionality provided in the following areas:

Simplifying Data Access

- Design a data model for client displays, including only necessary data
- Include master-detail hierarchies of any complexity as part of the data model
- Implement end-user Query-by-Example data filtering without code
- Automatically coordinate data model changes with business services layer
- Automatically validate and save any changes to the database

Enforcing Business Domain Validation and Business Logic

- Declaratively enforce required fields, primary key uniqueness, data precision-scale, and foreign key references
- Easily capture and enforce both simple and complex business rules, programmatically or declaratively, with multilevel validation support
- Navigate relationships between business domain objects and enforce constraints related to compound components

Supporting Sophisticated UIs with Multipage Units of Work

- Automatically reflect changes made by business service application logic in the user interface
- Retrieve reference information from related tables, and automatically maintain the information when the user changes foreign-key values
- Simplify multistep web-based business transactions with automatic web-tier state management
- Handle images, video, sound, and documents without having to use code
- Synchronize pending data changes across multiple views of data
- Consistently apply prompts, tooltips, format masks, and error messages in any application
- Define custom metadata for any business components to support metadata-driven user interface or application functionality
- Add dynamic attributes at runtime to simplify per-row state management

Implementing High-Performance Service-Oriented Architecture

- Support highly functional web service interfaces for business integration without writing code
- Enforce best-practice interface-based programming style
- Simplify application security with automatic JAAS integration and audit maintenance

- "Write once, run anywhere": use the same business service as plain Java class, EJB session bean, or web service

Streamlining Application Customization

- Extend component functionality after delivery without modifying source code
- Globally substitute delivered components with extended ones without modifying the application
- Deliver application upgrades without losing or having to reapply downstream customizations manually

3.1.2 ADF Business Components Core Objects

ADF Business Components implements the business service through the following set of cooperating components:

- Entity object

An *entity object* represents a row in a database table and simplifies modifying its data by handling all data manipulation language (DML) operations for you. It can encapsulate business logic for the row to ensure that your business rules are consistently enforced. You associate an entity object with others to reflect relationships in the underlying database schema to create a layer of business domain objects to reuse in multiple applications.

- View object

A *view object* represents a SQL query. You use the full power of the familiar SQL language to join, filter, sort, and aggregate data into exactly the shape required by the end-user task. This includes the ability to link a view object with others to create master-detail hierarchies of any complexity. When end users modify data in the user interface, your view objects collaborate with entity objects to consistently validate and save the changes.

- Application module

An *application module* is the transactional component that UI clients use to work with application data. It defines an updatable data model and top-level procedures and functions (called *service methods*) related to a logical unit of work related to an end-user task.

While the base components handle all the common cases through built-in behavior, customization is always possible and the default behavior provided by the base components can be easily overridden or augmented.

3.2 Comparison to Familiar 4GL Tools

ADF Business Components provides components that implement functionality similar to that offered by enterprise 4GL tools. Several key components in ADF Business Components have concepts you may be familiar with in other 4GL tools.

3.2.1 Familiar Concepts for Oracle Forms Developers

ADF Business Components implements all of the data-centric aspects of the familiar Oracle Forms runtime functionality, but in a way that is independent of the user interface. In Oracle Forms, each *form* contains both visual objects (like canvases, windows, alerts, and LOVs), as well as nonvisual objects (like data blocks, relations, and record groups). Individual data block *items* have both visual properties like `Foreground Color` and `Bevel`, as well as nonvisual properties like `Data Type` and

Maximum Length. Even the different event-handling triggers that Forms defines fall into visual and nonvisual categories. For example, it's clear that triggers like `WHEN-BUTTON-PRESSED` and `WHEN-MOUSE-CLICKED` are visual in nature, relating to the front-end UI, while triggers like `WHEN-VALIDATE-ITEM` and `ON-INSERT` are more related to the backend data processing. While merging visual and nonvisual aspects definitely simplifies the learning curve, the flip side is that it can complicate reuse. With a cleaner separation of UI-related and data-related elements, it would be easier to redesign the user interface without disturbing backend business logic and easier to repurpose back-end business logic in multiple different forms.

In order to imagine this separation of UI and data, consider reducing a form as you know it to only its nonvisual, data-related aspects. This reduces the form to a container of data blocks, relations, and record groups. This container would continue to provide a database connection for the data blocks to share and would be responsible for coordinating transaction commits or rollbacks. Of course, you could still use the *nonvisual* validation and transactional triggers to augment or change the default data-processing behavior as well. This nonvisual object you are considering is a kind of a "smart data model" or a generic application module, with data and business logic, but no user interface elements. The goal of separating this application module from anything visual is to allow any kind of user interface you need in the future to use it as a data service.

Focus a moment on the role the data blocks would play in this application module. They would query rows of data from the database using SQL, coordinate master/detail relationships with other data blocks, validate user data entry with `WHEN-VALIDATE-RECORD` and `WHEN-VALIDATE-ITEM` triggers, and communicate valid user changes back to the database with `INSERT`, `UPDATE`, and `DELETE` statements when you commit the data service's transaction.

Experience tells you that you need to filter, join, order, and group data for your end-users in a variety of ways to suit the many different tasks. On the other hand, the validation rules that you apply to your business domain data remain basically the same over time. Given these observations, it would be genuinely useful to write business entity validation exactly once, and leverage it consistently anywhere that data is manipulated by users in your applications.

Enabling this flexibility requires further "factoring" of your data block functionality. You need one kind of "SQL query" object to represent each of the many different views of data your application requires, and you need another kind of "business entity" object to enforce business rules and communicate changes to your base table in a consistent way. By splitting things like this, you can have multiple "view objects" with specific SQL queries that present the same business data yet each working with the same underlying "entity object."

Oracle Application Development Framework (Oracle ADF) addresses the UI/data split by providing ready-to-use Java components that implement typical Forms functionality. Responsibilities between the querying and entity-related functions are cleanly separated, resulting in better reuse.

3.2.1.1 Similarities Between the Application Module and a "Headless" Form Module

The application module component is the "data portion" of the form. The application module is a smart data service containing a data model of master-detail-related queries that your client interface needs to work with. It also provides a transaction and database connection used by the components it contains. It can contain form-level procedures and functions, referred to as service methods, that are encapsulated within the service implementation. You can decide which of these procedures and functions should be private and which ones should be public.

3.2.1.2 Similarities Between the Entity Object and a Forms Record Manager

The entity object component implements the "validation and database changes" portion of the data block functionality. In the Forms runtime, this duty is performed by the record manager. The record manager is responsible for keeping track of which of the rows in the data block have changed, for firing the block-level and item-level validation triggers when appropriate, and for coordinating the saving of changes to the database. This is exactly what an entity object does for you. The entity object is a component that represents your business domain entity through an underlying database table. The entity object gives you a single place to encapsulate business logic related to validation, defaulting, and database modification behavior for that business object.

3.2.1.3 Similarities Between the View Object and a Data Block

The `ViewObject` component performs the "data retrieval" portion of the data block functionality. Each view object encapsulates a SQL query, and at runtime each one manages its own query result set. If you connect two or more view objects in master-detail relationships, that coordination is handled automatically. While defining a view object, you can link any of its query columns to underlying entity objects. By capturing this information, the view object and entity object can cooperate automatically for you at runtime to enforce your domain business logic, regardless of the "shape" of the business data required by the user's task.

3.2.2 Familiar Concepts for PeopleTools Developers

If you have developed solutions in the past with PeopleTools, you are familiar with the PeopleTools component structure. ADF Business Components implement the data access functionality you are familiar with from PeopleTools.

3.2.2.1 Similarities Between the Application Module and a "Headless" Component

Oracle ADF adheres to an MVC pattern and separates the model from the view. Pages, which you are familiar with in the PeopleTools Component, are defined in the view layer, using standard technologies like JSF and ADF Faces components for web-based applications or Swing for desktop-fidelity client displays.

The ADF application module defines the data structure, just like the PeopleTools Component Buffer does. By defining master-detail relationships between ADF query components that produce row sets of data, you ensure that any application module that works with the data can reuse the natural hierarchy as required, similar to the scroll levels in the Component Buffer.

Similar to the Component Interface you are familiar with, the application module is a service object that provides access to standard methods, as well as additional developer-defined business logic. In order to present a "headless" data service for a particular user interface, the Component Interface restricts a number of PeopleTools functions that are related to UI interaction. The application module is similar to the Component Interface in that it provides a "headless" data service, but in contrast it does not do this by wrapping a restricted view of an existing user interface. Instead, the application module is designed to deal exclusively with business logic and data access. Rather than building a Component Interface on top of the component, with ADF Business Components you first build the application module service that is independent of user interface, and then build one or more pages on top of this service to accomplish some end-user task in your application.

The application module is associated with a transaction object in the same way that the PeopleTools Component Buffer is. The application module also provides a database

connection for the components it contains. Any logic you associate today with the transaction as Component PeopleCode, in ADF Business Components you would define as logic on the application module.

Logic associated with records in the transaction, that today you write as Component Record PeopleCode or Component Record Field PeopleCode, should probably *not* be defined on the application module. ADF Business Components has view objects that allow for better re-use when the same record appears in different components.

In summary, PeopleTools uses the component for the container concept, whereas ADF Business Components uses the application module. That is where the similarity ends. Do not assume that all of your component code will migrate to an application module. First, understand the concept of the view object, which is the layer between the entity object and the application module. Then, decide which of your component code is suitable for an application module and which is suitable for view objects.

3.2.2.2 Similarities Between the Entity Object and a Record Definition

The entity object is the mapping to the underlying data structure, just like the PeopleTools Record Definition maps to the underlying table or view. You'll often create one entity object for each of the tables that you need to manipulate your application.

Similar to how you declare a set of valid values for fields like "Customer Status" using PeopleTools' translate values, in ADF Business Components you can add declarative validations to the individual attributes of an entity object. Any logic you associate with the record that applies throughout your applications, which today you write as Record PeopleCode or Record Field PeopleCode, can be defined in ADF Business Components on the entity object.

3.2.2.3 Similarities Between the View Object and a Row Set

Just like a PeopleTools row set, a view object can be populated by a SQL query. Unlike a row set, a view object definition can contain business logic.

Any logic which you would find in Component Record PeopleCode is a likely candidate to define on the view object. Component Record PeopleCode is directly tied to the component, but a view object can be associated with different application modules. Whereas you can use the same record definition in many PeopleTools components, Oracle ADF allows you to reuse the business logic across multiple applications.

The view object queries data in exactly the "shape" that is useful for the current application. Many view objects can be built on top of the same entity object.

You can define relationships between view objects to create master-detail structures, just as you find them in the scroll levels in the PeopleTools component.

3.2.3 Familiar Concepts for Siebel Tools Developers

If you have developed solutions in the past with Siebel Tools version 7.0 or earlier, you will find that ADF Business Components implements all of the familiar data access functionality you are familiar with, with numerous enhancements.

3.2.3.1 Similarities Between the entity Object and a Table Object

Like the Siebel Table object, the ADF entity object describes the physical characteristics of a single table, including column names and physical data types. Both objects contain sufficient information to generate the DDL (data definition language) statements to create the physical tables in the database. In ADF Business Components you define associations between entity objects to reflect the foreign keys present in the underlying

tables. These associations allow view object queries used by user interface pages to automatically join business information. ADF Business Components handles list of values (LOV) objects that you reference from data columns through a combination of declarative entity-level validation rules and view object attribute-level LOV definitions. You can also encapsulate other declarative or programmatic business logic with these entity object "table" handlers that is automatically reused in any view of the data you create.

3.2.3.2 Similarities Between the View Object and a Business Component

Like the Siebel Business Component, the ADF view object describes a logical mapping on top of the underlying physical table representation. Both the Siebel Business Component and the ADF view object allow you to provide logical field names, data, and calculated fields that match the needs of the user interface. As with the Siebel Business Component, with the ADF view object you can define view objects that join information from various underlying tables. The related ADF view link is similar to the Siebel Link object and allows you to define master-detail relationships. In ADF Business Components, your view object definitions can exploit the full power of the SQL language to shape the data as required by the user interface.

3.2.3.3 Similarities Between the Application Module and a Business Object

The Siebel Business Object lets you define a collection of business components. The ADF application module performs a similar task, allowing you to create a collection of master-detail view objects that act as a "data model" for a set of related user interface pages. In addition, the application module provides a transaction and database connection context for this group of data views. You can make multiple requests to objects obtained from the application module and these participate in the same transaction.

3.2.4 Familiar Functionality for ADO.NET Developers

If you have developed solutions in the past with Visual Studio 2003 or 2005, you are familiar with using the ADO.NET framework for data access. ADF Business Components implements all of the data access functionality you are familiar with from ADO.NET, with numerous enhancements.

3.2.4.1 Similarities Between the Application Module and a Data Set

The application module component plays the same role as the ADO.NET data set. It is a strongly typed service component that represents a collection of row sets called view object instances, which are similar to ADO.NET data tables. An application module exposes a service interface that surfaces the rows of data in a developer-configurable set of its view instances as an SDO-compatible service (accessible as a web service, or as an SCA composite). The application module works with a related transaction object to provide the context for the SQL queries that the view objects execute. The application module also provides the context for modifications saved to the database by the entity objects, which play the role of the ADO.NET data adapter.

3.2.4.2 Similarities Between the Entity Object and a Data Adapter

The entity object component is like a strongly-typed ADO.NET data adapter. It represents the rows in a particular table and handles the find-by-primary-key, insert, update, delete, and lock operations for those rows. In ADF Business Components, you don't have to specify these statements yourself, but you can override them if you need to. The entity object encapsulates validation or other business logic related to attributes or entire rows in the underlying table. This validation is enforced when data

is modified and saved by the end user using any view object query that references the underlying entity object. One difference in ADF Business Components is that the arbitrary, flexible querying is performed by SQL statements at the view object instance level, but the view objects and entity objects coordinate automatically at runtime.

3.2.4.3 Similarities Between the View Object and a Data Table

The view object component encapsulates a SQL query and manages the set of resulting rows. It can be related to an underlying entity object to automatically coordinate validation and saving of modifications made by the user to those rows. This cooperation between a view object's queried data and an entity object's encapsulated business logic offers all of the benefits of the data table with the clean encapsulation of business logic into a layer of business domain objects. Like ADO.NET data tables, you can easily work with a view object's data as XML or have a view object read XML data to automatically insert, update, or delete rows based on the information it contains.

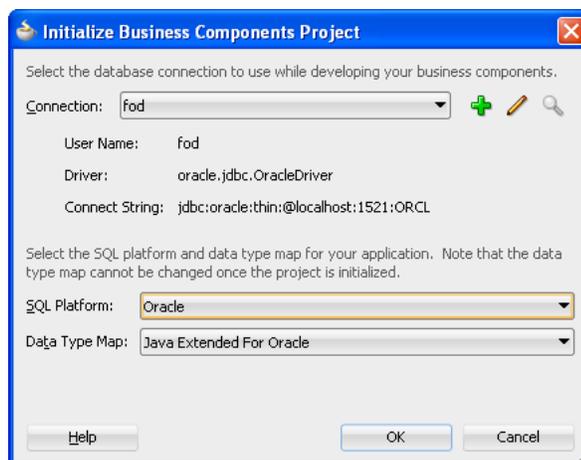

3.3 Overview of Design Time Facilities

JDeveloper includes comprehensive design time support for ADF Business Components. Collectively, these facilities let you create, edit, diagram, test, and refactor the business components.

3.3.1 Choosing a Connection, SQL Platform, and Data Type Map

The first time you create a component, you'll see the Initialize Business Components Project dialog shown in [Figure 3-1](#). You use this dialog to select a design time application resource connection to use while working on your business components in this data model project (the term used in this guide for a project created for ADF Business Components) or to create a new application resource connection by copying an existing IDE-level connection.

Figure 3-1 Initialize Business Components Project Dialog

Since this dialog appears before you create your first business component, you also use it to globally control the SQL platform that the view objects will use to formulate SQL statements. Although the default for an Oracle database connection is always the Oracle SQL platform, other SQL platforms you can choose include OLite (for the Oracle Lite database), SQLServer for a Microsoft SQLServer database, DB2 for an IBM DB2 database, and SQL92 for any other supported SQL92-compliant database.

Note: If you plan to have your application run against both Oracle and non-Oracle databases, you should select the **SQL92** SQL platform when you begin building your application, not later. While this sacrifices some of the Oracle-specific optimizations that are inherent in using the Oracle SQL platform, it makes the application portable to both Oracle and non-Oracle databases.

Additionally, the dialog lets you determine which set of data types that you want the data model project to use. If JDeveloper detects you are using an Oracle database driver, it defaults the **Data Type Map** setting to the **Java Extended for Oracle** type map which uses standard Java types and the optimized types in the `oracle.jbo.domain` package for common data types. When you create a SQL92-compliant application that will run on a non-Oracle database, you can change the data type map to the **Java** setting to globally use only the basic Java data types.

The **Java Extended for Oracle** type map and the **Oracle Domains** type map handle numeric data differently. When you create a new application the default type map **Java Extended for Oracle** maps numeric data to the `java.math.BigDecimal` class, which inherits from `java.math.Number`. The `java.math.BigDecimal` default matches the way the Fusion web application view layer, consisting of ADF Faces components, preserves alignment of numeric data (such as numeric values displayed by ADF Faces input fields in a web page). Whereas the **Oracle Domains** type map, which maps numeric data to the `oracle.jbo.domain.Number` class, may not display the data with the alignment expected by certain ADF Faces components. Aside from this alignment issue, the **Oracle Domains** type map remains a valid choice and applications without ADF Faces components will function without issue.

New Fusion web applications should use the default **Java Extended for Oracle** type. The **Oracle Domains** type map is provided for backward compatibility and for applications that do not use ADF Faces as the view layer technology. Please note that when you migrate an application developed with JDeveloper version 11.1.1.4.0 or earlier, your application will continue to use the **Oracle Domains** type map and will not change to the current default type map **Java Extended for Oracle**.

Note that you cannot change the data type map after you've initialized a data model project. After you have initialized a data model project, you can you can override the SQL platform in the overview editor for the `adf-config.xml` file. Specifying the database type in the `adf-config.xml` file supports generating SQL statements during runtime that can require the actual database type. You can locate the file in the Application Resources panel by expanding the **Descriptors > ADF META-INF** node.

3.3.2 Creating New Components Using Wizards

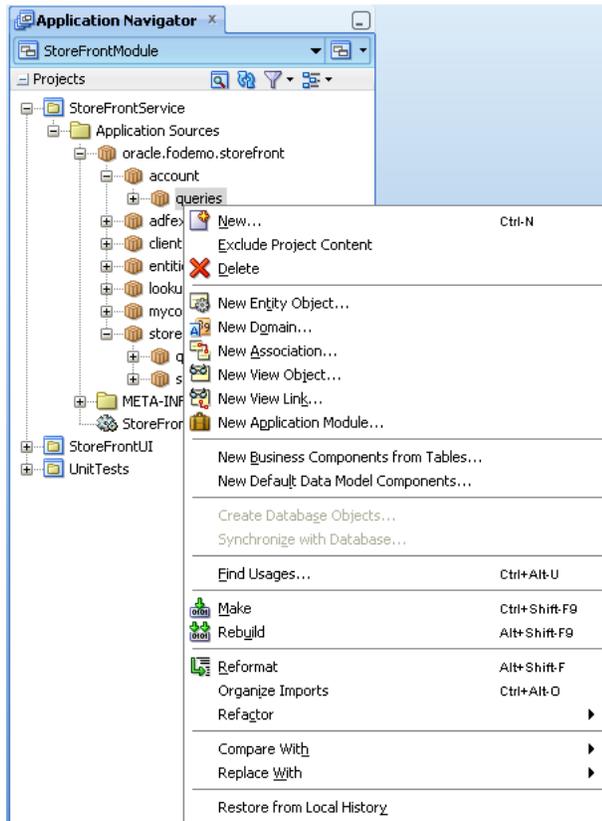

In the New Gallery in the **ADF Business Components** category, JDeveloper offers a wizard to create each kind of business component. Each wizard allows you to specify the component name for the new component and to select the package into which you'd like to organize the component. If the package does not yet exist, the new component becomes the first component in that new package.

The wizard presents a series of panels that capture the necessary information to create the component type. When you click **Finish**, JDeveloper creates the new component by saving its XML component definition file. If you have set your Java generation options to generate classes by default, JDeveloper also creates the initial custom Java class files.

3.3.3 Creating New Components Using the Context Menu

Once a package exists in the Application Navigator, you can quickly create additional business components of any type in the package by selecting it in the Application Navigator and using one of the options on the context menu shown in [Figure 3–2](#).

Figure 3–2 Context Menu Options on a Package to Create Any Kind of Business Component

3.3.4 Editing Components Using the Component Overview Editor

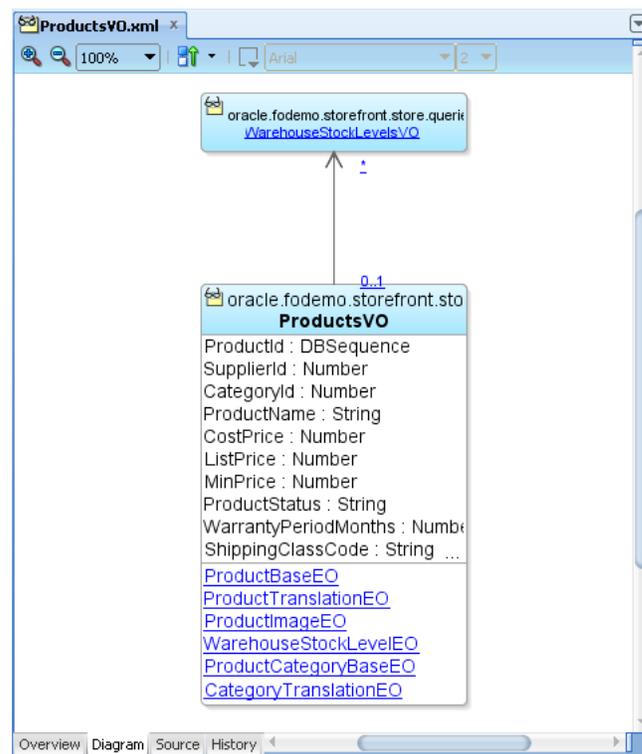

Once a component exists, you can edit it using the respective overview editor that you access either by double-clicking the component in the Application Navigator or by selecting it and choosing the **Edit** option from the context menu. The overview editor presents the same editing options that you see in the wizard but it may arrange them differently. The overview editor allows you to change any aspect of the component. When you click **OK**, JDeveloper updates the component's XML component definition file and, if necessary, any of its related custom Java files. Because the overview editor is a JDeveloper editor window, rather than a modal dialog, you can open and view the overview editor for as many components as you require.

3.3.5 Displaying Related Components Using Diagrams

As the number of business components that your project defines increases, you may decide to refactor components to change the relationships that you originally created. To help you understand the relationship between components in the data model project, open any component in the editor window and click the **Diagram** tab. The relationship diagram in the editor identifies the component you are editing in bold text. Related components appear as link text that you can click to display the

relationship diagram for the component identified by the link. For example, [Figure 3–3](#) displays the **Diagram** tab in the editor for the view object `ProductsVO`. The diagram identifies the list of entity objects that `ProductsVO` can access (for example, `ProductBaseEO` and `ProductTranslationEO` and so on), the view link (`ProductsToWarehouseStockLevels`) that defines the view object's relationship to a related view object, and the related view object (`WarehouseStockLevelsVO`) named by the view link. Each of these related components displays as a link that you can click to open the component in the **Diagram** tab for its editor. By clicking on related component links, you can use the diagrams to navigate the component relationships that your project defines.

Figure 3–3 Relationship Diagram Displays Main Object and All Related Components in Component Editor's Diagram Tab

3.3.6 Visualizing, Creating, and Editing Components Using UML Diagrams

JDeveloper offers extensive UML diagramming support for ADF Business Components. You can drop components that you've already created onto a business components diagram to visualize them. You can also use the diagram to create and modify components. The diagrams are kept in sync with changes you make in the editors.

To create a new business components diagram, use the **Business Components Diagram** item in the **ADF Business Components** category of the JDeveloper New Gallery. This category is part of the **Business Tier** choices.

3.3.7 Testing Application Modules Using the Oracle ADF Model Tester

Once you have created an application module component, you can test it interactively using the built-in Oracle ADF Model Tester. To launch the Oracle ADF Model Tester,

select the application module in the Application Navigator or in the business components diagram and choose either **Run** or **Debug** from the context menu.

The Oracle ADF Model Tester presents the view object instances in the application module's data model and allows you to interact with them using a dynamically generated user interface. The tool also provides a list of the application module's client interface methods that you can test interactively by double-clicking the application module node. This tool is invaluable for testing or debugging your business service both before and after you create the web page view layer.

3.3.8 Refactoring Components

At any time, you can select a component in the Application Navigator and choose **Refactor > Rename** from the context menu to rename the component. The Structure window also provides a **Rename** context menu option for details of components, such as view object attributes or view instances of the application module data model, that do not display in the Application Navigator. You can also select one or more components in the navigator by using Ctrl + click and then choosing **Refactor > Move** from the context menu to move the selected components to a new package. References to the old component names or packages in the current data model project are adjusted automatically.

3.4 Overview of the Oracle ADF Active Data Model

One of the key simplifying benefits of using ADF Business Components for your business service implementation is the application module's support for an "active data model" of row sets. The data model defines the business objects specific to your application, while the row sets of each business object contain the data. In the UI portion of the application, the UI components interact with these business objects to perform retrieve, create, edit, and delete operations. When you use ADF Business Components in combination with the ADF Model layer and ADF Faces UI components, the data model is "active" because your UI components will automatically update to reflect any changes to the row sets of these business objects.

Thus, the active data model represents a solution that works across application technology layers to ensure that the UI and data model remain synchronized.

3.4.1 A More Generic Business Service Solution

Using a typical Java EE business service implementation makes the client developer responsible for:

- Invoking service methods to return data to present
- Tracking what data the client has created, deleted, or modified
- Passing the changes back to one or more different service methods to validate and save them

Retrieving, creating, editing, deleting, and saving is a typical sequence of tasks performed during application development. As a result, the ADF application module represents a smarter, more generic solution. Using the application module for your business service, you simply bind client UI components like fields, tables, and trees to the active view object instances in the application module's data model. Your UI components in JSP or JSF pages for the web or mobile devices (as well as desktop-fidelity UIs comprising windows and panels that use Swing) automatically update to reflect any changes to the rows in the view object row sets of the data model. Additionally, if you define custom business service methods for the application

module that happen to produce changes to the data model view instances, those changes will also be automatically reflected in the UI components.

Under the covers, the application module component implements a set of *generic* service methods that allow users to leverage its active data model in a service-oriented architecture (SOA). Both web service and UI clients can easily access an application module's data model using simple APIs. These APIs enable you to search for and modify any information that the application module makes available.

When you build UIs that take advantage of the ADF Model layer for declarative data binding, you generally won't need to write client-side code. The active data model supports declaratively binding UI components in your web pages to view objects in the data model and to custom business service methods. Additionally, when you create web services in a SOA environment they can be bound declaratively to the data model through the data model's web service interface.

3.4.2 Typical Scenarios for an Active Data Model

Without an active data model, you would need to write more code in the client or web service to handle the straightforward, everyday CRUD-style operations. In addition, to keep pages up to date, you would need to manage "refresh flags" that clue the controller layer in to requesting a "repull" of data from the business service to reflect data that might have been modified. When using an ADF application module to implement your business service, you can focus on the business logic at hand, instead of the plumbing to make your business work as your end users expect.

Consider the following three simple, concrete examples of the active data model:

- New data appears in relevant displays without requerying

A customer logs into the Fusion Order Demo application and displays a list of items in their shopping cart. Then if the customer visits some product pages and creates a new order item, when they return back to display their shopping cart, the new item appears in their list without requiring the application to query the database.
- Changes caused by business domain logic automatically reflected

A back office application causes an update to the order status. Business logic encapsulated in the `Orders` entity object in the business domain layer contains a simple rule that updates the last update date whenever the order status attribute is changed. The user interface updates to automatically reflect the last update date that was changed by the logic in the business domain layer.
- Invocation of a business service method by the ADF Model layer binding requeries data and sets current rows

In a tree display, the user clicks on a specific node in a tree. This action declaratively invokes a business service method by the ADF tree binding on your application module that requeries master-detail information and sets the current rows to an appropriate row in the row set. The display updates to reflect the new master-detail data and current row displayed.

3.4.3 Active Data Model Support for Custom Code

Because the application module supports the active data model, your client user interface will remain up to date. This means you will not need to write code in the client that is related to setting up or manipulating the data model.

Another typical type of client-side code you no longer have to write using ADF Business Components is code that coordinates detail data collections when a row in the master changes. By linking the view objects, you can have the coordination performed automatically for you.

However, when you do need to write custom code, encapsulate that code inside custom methods of your application module component. For example, whenever the programmatic code that manipulates view objects is a logical aspect of implementing your complete business service functionality, you should encapsulate the details by writing a custom method in your application module's Java class. This includes, but is not limited to, code that:

- Configures view object properties to query the correct data to display
- Iterates over view object rows to return an aggregate calculation
- Performs any kind of multistep procedural logic with one or more view objects

By centralizing these implementation details in your application module, you gain the following benefits:

- You make the intent of your code more clear to clients.
- You allow multiple client pages to easily call the same code if needed.
- You simplify regression-testing of your complete business service functionality.
- You keep the option open to improve your implementation without affecting clients.
- You enable *declarative* invocation of logical business functionality in your pages.

3.5 Overview of the ADF Business Components Implementation

Before you begin implementing specific ADF business components, it is a good idea to have some familiarity with ADF Business Components design and implementation.

3.5.1 Standard Java and XML

As is the case with all Oracle ADF technologies, ADF Business Components is implemented in Java. The working, tested components in the framework provide generic, metadata-driven functionality from a rich layer of robust code. ADF Business Components follows the Java EE community best practice of using cleanly separated XML files to store metadata that you define to configure each component's runtime behavior.

Since ADF Business Components is often used for business critical applications, it's important to understand that the full source for Oracle ADF, including ADF Business Components, is available to supported customers through Oracle Worldwide Support. The full source code for Oracle ADF can be an important tool to assist you in diagnosing problems, as described in [Section 36.8, "Using the ADF Declarative Debugger."](#) Working with the full source code for Oracle ADF also helps you understand how to correctly extend the base framework functionality to suit your needs, as described in [Section 12.4, "Customizing Framework Behavior with Extension Classes."](#)

3.5.2 Application Server or Database Independence

Applications built using ADF Business Components can run on any Java-capable application server, including any Java EE-compliant application server. Because

business components are implemented using plain Java classes and XML files, you can use them in any runtime environment where a Java Virtual Machine is present. This means that services built using ADF Business Components are easy to use both inside a Java EE server — known as the "container" of your application at runtime — and outside.

Customers routinely use application modules in such diverse configurations as command-line batch programs, web services, custom servlets, JSP pages, and desktop-fidelity clients built using Swing.

You can also build applications that work with non-Oracle databases, as described in [Section 3.3.1, "Choosing a Connection, SQL Platform, and Data Type Map."](#) However, applications that target Oracle databases will find numerous optimizations built into ADF Business Components.

3.5.3 Java EE Design Pattern Support

ADF Business Components implements all of the popular Java EE design patterns that you would normally need to understand, implement, and debug yourself to create a real-world enterprise Java EE application. If it is important to you to cross-reference the names of these design patterns from the Java EE specifications with their ADF Business Components counterparts, you can refer to [Appendix E, "ADF Business Components Java EE Design Pattern Catalog."](#)

3.5.4 Source Code Organization

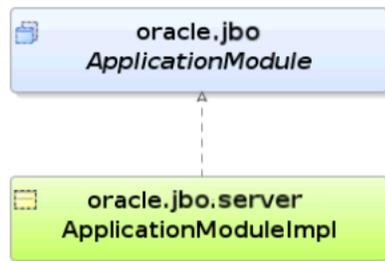

Since ADF Business Components is implemented in Java, its classes and interfaces are organized into packages. Java packages are identified by dot-separated names that developers use to arrange code into a hierarchical naming structure.

The classes and interfaces that comprise the source code provided by ADF Business Components reside in the `oracle.jbo` package and numerous subpackages. However, in day to day work with ADF Business Components, you'll work typically with classes and interfaces in these two key packages:

- The `oracle.jbo` package, which contains all of the interfaces that are designed for the business service client to work with
- The `oracle.jbo.server` package, which contains the classes that implement these interfaces

Note: The term *client* here refers to any code in the model, view, or controller layers that accesses the application module component as a business service.

[Figure 3–4](#) shows a concrete example of the application module component. The client interface for the application module is the `ApplicationModule` interface in the `oracle.jbo` package. This interface defines the names and signatures of methods that clients can use while working with the application module, but it does not include any specifics about the implementation of that functionality. The class that implements the base functionality of the application module component resides in the `oracle.jbo.server` package and is named `ApplicationModuleImpl`.

Figure 3–4 ADF Business Components Separate Interface and Implementation

3.5.5 Package Naming Conventions

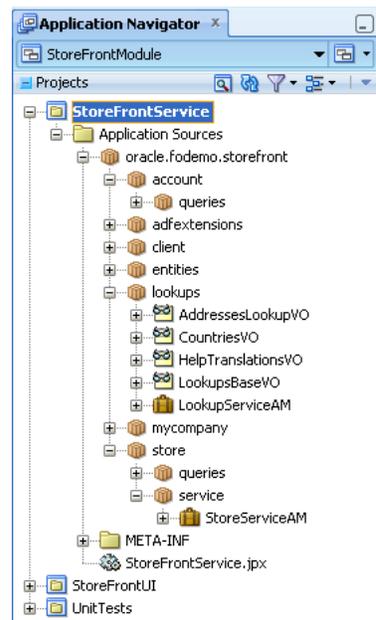

Since ADF Business Components is implemented in Java, the components of your application (including their classes, interfaces, and metadata files) will also be organized into packages.

To ensure that your components won't clash with reusable components from other organizations, choose package names that begin with your organization's name or web domain name. So, for example, the Apache organization chose `org.apache.tomcat` for a package name related to its Tomcat web server, while Oracle picked `oracle.xml.parser` as a package name for its XML parser. Components you create for your own applications might reside in packages with names like `com.yourcompany.yourapp` and subpackages of these.

As a specific example, the ADF Business Components that make up the main business service for the Fusion Order Demo application are organized into the `oracle.fodemo.storefront` package and its subpackages. As shown in [Figure 3–5](#), these components reside in the `StoreFrontService` project in the `StoreFrontModule` application, and are organized broadly as follows:

- `oracle.fodemo.storefront.account.queries` contains the view objects used in the customer registration process
- `oracle.fodemo.storefront.client` contains test client `.java` files
- `oracle.fodemo.storefront.entities` contains the entity objects
- `oracle.fodemo.storefront.lookups` contains static data view objects and the `LookupServiceAM` shared application module
- `oracle.fodemo.storefront.store.queries` contains the view objects used to manage the storefront
- `oracle.fodemo.storefront.store.service` contains the `StoreServiceAM` application module

Figure 3–5 Organization of ADF Business Components in the Fusion Order Demo Application

In your own applications, you can choose any package organization that you believe best. In particular, keep in mind that you are not constrained to organize components of the same type into a single package.

Because JDeveloper supports component refactoring, you can easily rename components or move them to a different package at any time. This flexibility allows you to easily incorporate inevitable changes into the application as your application evolves.

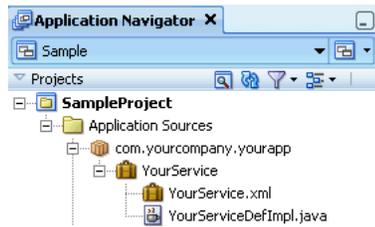

There is no optimal number of components in a package. However, with experience, you'll realize that the best structure for your team falls somewhere between the two extremes of placing all components in a single package and placing each component in its own, separate package.

One thing to consider is that the project is the unit of granularity that JDeveloper supports for reuse in other data model projects. So, you might factor this consideration into how you choose to organize components. For more information, see [Section 38.3, "Packaging a Reusable ADF Component into an ADF Library."](#)

3.5.6 Metadata with Optional Custom Java Code

Each kind of component in ADF Business Components comes with built-in runtime functionality that you control through declarative settings. These settings are stored in an XML component definition file with the same name as the component that it represents. When you need to write custom code for a component, for example to augment the component's behavior, you can enable an optional custom Java class for the component in question. [Figure 3–6](#) shows how the Application Navigator displays the XML component definition and optional custom Java class for an application module.

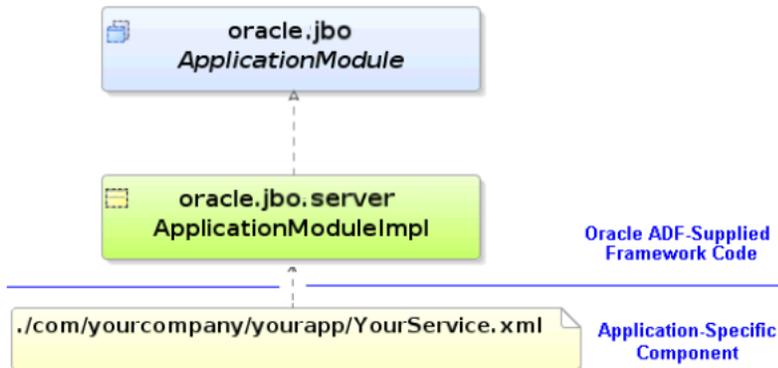

Figure 3–6 Application Navigator Displays Component XML File and Optional Class Files

3.5.6.1 Example of an XML-Only Component

Figure 3–7 illustrates the XML component definition file for an application-specific component like an application module named *YourService* that you create in a package named *com.yourcompany.yourapp*. The corresponding XML component definition resides in a *./com/yourcompany/yourapp* subdirectory of the data model project's source path root directory. That XML file records the name of the Java class it should use at runtime to provide the application module implementation. In this case, the XML records the name of the base `oracle.jbo.server.ApplicationModuleImpl` class provided by Oracle ADF.

Figure 3–7 XML Component Definition File for an Application Module

When used without customization, your component is completely defined by its XML component definition and it will be fully functional without custom Java code or even a Java class file for the component. If you have no need to extend the built-in functionality of a component in ADF Business Components, and no need to write any custom code to handle its built-in events, you can use the component in this XML-only fashion.

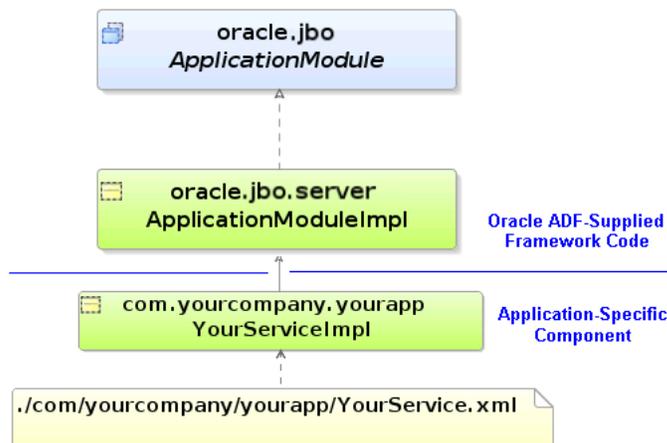

3.5.6.2 Example of a Component with Custom Java Class

When you need to add custom code to extend the base functionality of a component or to handle events, you can enable a custom Java class for any of the key types of ADF Business Components you create. You enable the generation of custom classes for a component on the Java page of its respective overview editor in JDeveloper. When you enable this option, JDeveloper creates a Java source file for a custom class related to the component whose name follows a configurable naming standard. This class, whose name is recorded in the component's XML component definition, provides a place where you can write the custom Java code required by that component. Once you've enabled a custom Java class for a component, you can navigate to it using a

corresponding **Go To *componentName* Class** option in the component's Application Navigator context menu.

Figure 3–8 illustrates what occurs when you enable a custom Java class for the *YourService* application module. A *YourServiceImpl.java* source code file is created in the same source path directory as your component's XML component definition file. The *YourServiceImpl.xml* file is updated to reflect the fact that at runtime the component should use the *com.yourcompany.yourapp.YourServiceImpl* class instead of the base *ApplicationModuleImpl* class.

Figure 3–8 Component with Custom Java Class

Note: The examples in this guide use default settings for generated names of custom component classes and interfaces. If you want to change these defaults for your own applications, use the ADF Business Components: Class Naming page of the JDeveloper Preferences dialog. Changes you make only affect newly created components.

3.5.7 Basic Data Types

The Java language provides a number of built-in data types for working with strings, dates, numbers, and other data. When working with ADF Business Components, you can use these types, but by default you'll use an optimized set of types in the *oracle.jbo.domain* and *oracle.ord.im* packages. These types, shown in Table 3–1, allow data accessed from the Oracle database to remain in its native, internal format. You will achieve better performance using the optimized data types provided by ADF Business Components by avoiding costly type conversions when they are not necessary.

There are two cases where an optimized data type is not used by default and a Java built-in data type is used instead. To work with string-based data, by default ADF Business Components uses the regular *java.lang.String* type. Additionally, to work with numeric data, by default ADF Business Components uses the *java.math.BigDecimal* type, which formats numerals in a way that is consistent with the alignment expected by ADF Faces components. For backward compatibility, and for applications that do not use ADF Faces components, the optimized data type *oracle.jbo.domain.Number* provided in previous releases remains an alternative data type for numeric data.

Table 3–1 Basic Data Types in the *oracle.jbo.domain* and *oracle.ord.im* Packages

Data Type	Package	Represents
Number (not used by default)	<code>oracle.jbo.domain</code>	Any numerical data. By default, ADF Business Components uses the <code>java.math.BigDecimal</code> type to support formatting of numeric values with the alignment expected by ADF Faces components. The <code>java.math.BigDecimal</code> type should be used whenever ADF Faces is the chosen view layer technology.
Date	<code>oracle.jbo.domain</code>	Date with optional time
DBSequence	<code>oracle.jbo.domain</code>	Sequential integer assigned by a database trigger
RowID	<code>oracle.jbo.domain</code>	Oracle database ROWID
Timestamp	<code>oracle.jbo.domain</code>	Timestamp value
TimestampTZ	<code>oracle.jbo.domain</code>	Timestamp value with time zone information
TimestampLTZ	<code>oracle.jbo.domain</code>	Timestamp value with local time zone information retrieved from JavaVM or from the ADF Context when configured in the application's <code>adf-config.xml</code> with an EL expression: <pre><user-time-zone-config xmlns= "http://xmlns.oracle.com/adf/usertimezone/config"> <user-timezone expression= "EL exp" /> </user-time-zone-config></pre> The EL expression will be evaluated to determine the time zone of the current user; otherwise, the value defaults to the time zone of the JavaVM.
BFileDomain	<code>oracle.jbo.domain</code>	Binary File (BFILE) object
BlobDomain	<code>oracle.jbo.domain</code>	Binary Large Object (BLOB)
ClobDomain	<code>oracle.jbo.domain</code>	Character Large Object (CLOB)
OrdImageDomain	<code>oracle.ord.im</code>	Oracle Intermedia Image (ORDIMAGE)
OrdAudioDomain	<code>oracle.ord.im</code>	Oracle Intermedia Audio (ORDAUDIO)
OrdVideoDomain	<code>oracle.ord.im</code>	Oracle Intermedia Video (ORDVIDEO)
OrdDocDomain	<code>oracle.ord.im</code>	Oracle Intermedia Document (ORDDOC)
Struct	<code>oracle.jbo.domain</code>	User-defined object type
Array	<code>oracle.jbo.domain</code>	User-defined collection type (e.g. VARRAY)

Note: If you are not using ADF Faces as your view layer technology, you may use either the `java.math.BigDecimal` type or the `oracle.jbo.domain.Number` type. Be aware, however, that the `oracle.jbo.domain.Number` class has the same class name as the built-in `java.lang.Number` type. Since the Java compiler *implicitly* imports `java.lang.*` into every class, you will need to explicitly import the `oracle.jbo.domain.Number` class into any class that references it. Typically, JDeveloper will follow this practice for you, but if you receive compiler or runtime errors related to "Number is an abstract class" it means you are using `java.lang.Number` instead of `oracle.jbo.domain.Number`. Adding the:

```
import oracle.jbo.domain.Number;
```

line at the top of your class, after the package line, prevents these kinds of errors.

3.5.8 Generic Versus Strongly-Typed APIs

When working with application modules, view objects, and entity objects, you can choose to use a set of generic APIs or you can have JDeveloper generate code into a custom Java class to enable a strongly-typed API for that component. For example, when working with an view object, if you wanted to access the value of an attribute in any row of its result, the generic API would look like this:

```
Row row = ordersVO.getCurrentRow();
Date shippedDate = (Date)row.getAttribute("OrderShippedDate");
```

Notice that using the generic APIs, you pass string names for parameters to the accessor, and you have to cast the return type to the expected type, as with `Date` shown in the example.

Alternatively, when you enable the strongly typed style of working you can write code like this:

```
OrdersRow row = (OrdersRow)ordersVO.getCurrentRow();
Date shippedDate = row.getOrderShippedDate();
```

In this case, you work with generated method names whose return type is known at compile time, instead of passing string names and having to cast the results. Typically, it is necessary to use strongly typed accessors when you need to invoke the methods from the business logic code without sacrificing compile-time safety. This can also be useful when you are writing custom validation logic in setter methods, although in this case, you may want to consider using Groovy expressions instead of generating entity and view row implementation classes for Business Components. Subsequent chapters explain how to enable this strongly typed style of working by generating Java classes for business logic that you choose to implement using Java.

3.5.9 Custom Interface Support for Client-Accessible Components

Only these components of the business service as visible to the client:

- Application module, representing the service itself
- View objects, representing the query components
- View rows, representing each row in a given query component's results

The entity objects in the business service implementation is intentionally not designed to be referenced directly by clients. Instead, clients work with the data queried by view objects as part of an application module's data model. Behind the scenes, the view object cooperates automatically with entity objects in the business services layer to coordinate validating and saving data that the user changes. For more information about this runtime interaction, see [Section 6.3.9, "What Happens at Runtime: How View Objects and Entity Objects Cooperate."](#)

3.5.9.1 Framework Client Interfaces for Components

The Java interfaces of the `oracle.jbo` package provide a client-accessible API for your business service. This package intentionally does not contain an `Entity` interface, or any methods that would allow clients to directly work with entity objects. Instead, client code works with interfaces like:

- `ApplicationModule`, to work with the application module
- `ViewObject`, to work with the view objects
- `Row`, to work with the view rows

3.5.9.2 Custom Client Interfaces for Components

When you begin adding custom code to your ADF business components that you want clients to be able to call, you can "publish" that functionality to clients for any client-visible component. For each of your components that publishes at least one custom method to clients on its client interface, JDeveloper automatically maintains the related Java interface file. So, assuming you were working with an application module like `StoreServiceAM` in the Fusion Order Demo application, you could have custom interfaces like:

- Custom application module interface
`StoreServiceAM` extends `ApplicationModule`
- Custom view object interface
`OrderItemsInfo` extends `ViewObject`
- Custom view row interface
`OrderItemsInfoRowClient` extends `Row`

Client code can then cast one of the generic client interfaces to the more specific one that includes the selected set of client-accessible methods you've selected for your particular component.

3.6 Overview of Groovy Scripting Language Support

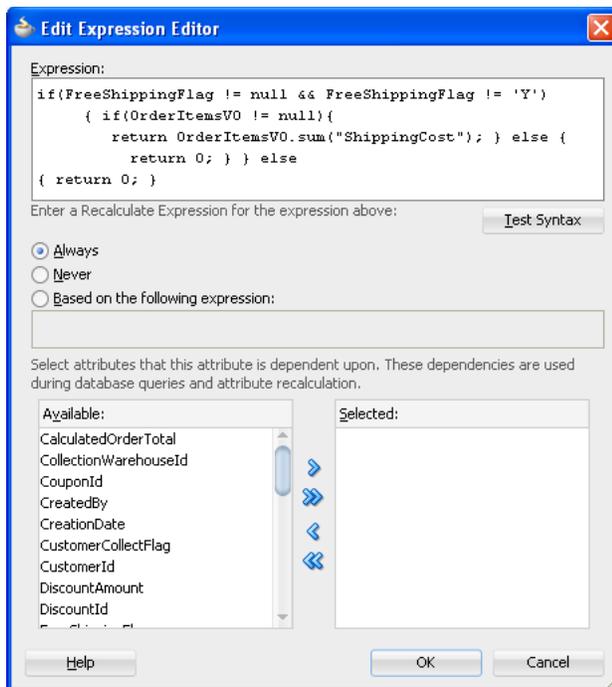

Groovy is a scripting language with Java-like syntax for the Java platform. The Groovy scripting language simplifies the authoring of code by employing dot-separated notation, yet still supporting syntax to manipulate collections, Strings, and JavaBeans. Groovy language expressions in ADF Business Components differs from the Java code that you might use in a Business Components custom Java class because Groovy expressions are executed at runtime, while the strongly typed language of Java is executed at compile-time. Additionally, because Groovy expressions are dynamically compiled, they are stored in the XML definition files of the business components where you use it.

ADF Business Components supports the use of the Groovy scripting language in places where access to entity object and view object attributes is useful, including attribute validators (for entity objects), attribute default values (for either entity objects or view objects), transient attribute value calculations (for either entity objects or view objects), bind variable default values (in view object query statements and view criteria filters), and placeholders for error messages (in entity object validation rules). Additionally, ADF Business Components provides a limited set of built-in keywords that can be used in Groovy expressions.

Specifically, the ADF Business Components framework provides support for the use of Groovy language expressions to perform the following tasks:

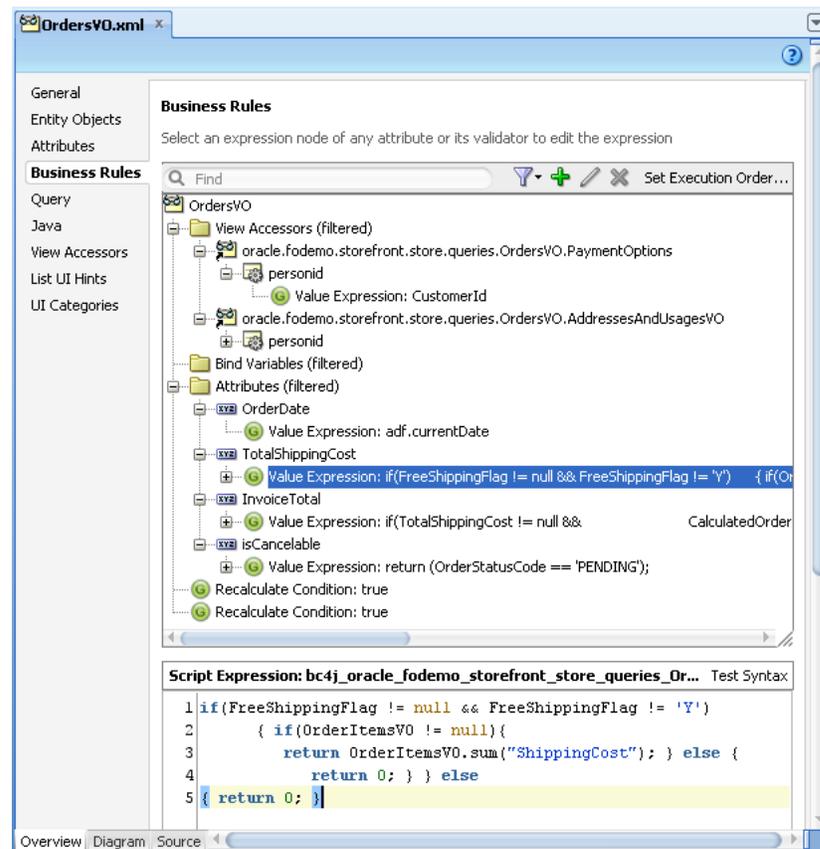

- Define a Script Expression validator or Compare validator (see [Section 7.5, "Using Groovy Expressions For Validation and Business Rules"](#))
- Define error message tokens for handling validation failure (see [Section 7.7.4, "How to Embed a Groovy Expression in an Error Message"](#))
- Handle conditional execution of validators (see [Section 7.7.3, "How to Conditionally Raise Error Messages Using Groovy"](#))
- Set the default value of a bind variable in the view object query statement (see [Section 5.10, "Working with Bind Variables"](#))
- Set the default value of a bind variable that specifies a criteria item in the view criteria statement (see [Section 5.11, "Working with Named View Criteria"](#)).
- Define the default value and optional recalculate condition for an entity object attribute (see [Section 4.10.6, "How to Define a Static Default Value"](#))
- Determine the value of a transient attribute of an entity object or view object (see [Section 4.11, "Adding Transient and Calculated Attributes to an Entity Object"](#) and [Section 5.14, "Adding Calculated and Transient Attributes to a View Object"](#))

To perform these tasks in JDeveloper, you use expression editor dialogs that are specific to the task. For example, when you want to create a default value for a transient view object attribute, you use the attribute's Edit Expression Editor dialog to enter an expression that determines a runtime value for the attribute. The same dialog also lets you specify when the value should be calculated (known as a *recalculate condition*), as shown in [Figure 3-9](#).

Figure 3–9 Dialog to Edit Expression for Default Attribute Values

Additionally, the overview editor that you use to edit entity objects and view objects displays the Business Rules page, where you can view and edit all expressions used by a single business component. For example, the Business Rules page that you display for a view object lets you view all expressions that the view object uses on its view accessors, bind variables, and attributes. You can filter the display to show only those items with Groovy expressions defined, as shown in [Figure 3–10](#). Although expressions cannot be verified at design time, all expression editors let you test the syntax of the expression before you save it.

Figure 3–10 Overview Editor's Business Rules Page Shows All Expressions Used by a Business Component

For more information about the Groovy language, refer to the following web site:

- <http://groovy.codehaus.org/>

3.6.1 Referencing Business Components Objects in Groovy Expressions

There is one top-level object named `adf` that allows you access to objects that the framework makes available to the Groovy script. When you reference an Oracle ADF object in a Groovy expression, the Oracle ADF runtime returns wrapper objects that do not correspond to the actual concrete type of the classes. These wrapper objects support all of the method and field types of the wrapped object. Your expressions can use wrapped objects as if they were the actual object. Note, however, any attempt to cast wrapped objects to its concrete type will fail with a `ClassCastException`. In general, when working with the Groovy language it is not necessary to use explicit casting, and in the case of these wrapped ADF Business Components objects, doing so will cause an exception.

The accessible Oracle ADF objects consist of the following:

- `adf.context` - to reference the `ADFContext` object
- `adf.object` - to reference the object on which the expression is being applied (which can also be referenced using the keyword `object`, without the `adf` prefix). Other accessible member names come from the context in which the Groovy script is applied.

- Entity object attributes: The context is an instance of the entity implementation class. Through this object you can reference custom methods of the custom entity implementation class, any methods defined by the base implementation class as specified by the JavaDoc for `EntityImpl`, and you can reference the attributes of the entity instance.
- Entity object script validation rules: The context is the validator object (`JboValidatorContext`) merged with the entity on which the validator is applied. For details about keywords that you can use in this context, see [Section 3.6.2.1, "Referencing Members of the Same Business Component."](#)
- View object attributes: The context is an instance of the view row implementation class. Through this object, you can reference custom methods of the custom view row implementation class, any methods defined by the base implementation class as specified by the JavaDoc for `ViewRowImpl`, and you can reference the attributes of the view row instance as defined by the query row set.
- Bind variable in view objects: The context is the variable object itself not the view row. You can reference the `structureDef` property to access other information as well as the `viewObject` property to access the view object in which the bind variable participates. However, access to view object attributes is not supported.
- Bind variable in view accessors: The context is the current view row. The view accessor with bind variable is used to create a cascading List of Value (LOV). The view accessor can derive Groovy-driven values from the current view row in the view accessor view object used to formulate the list of valid choices.
- Transient attributes: The context is the current entity or view row. You can reference attributes by name in the entity or view row in which the attribute appears, as well as public methods on that entity or view row. To access methods on the current object, you must use the `object` keyword to reference the current object (for example, `object.methodName()`). The `object` keyword is equivalent to the `this` keyword in Java. Without it, in transient expressions, the method will be assumed to exist on the dynamically compiled Groovy script object itself.
- `adf.error` - in validation rules, to access the error handler that allows the validation expression to generate exceptions or warnings
- `adf.userSession` - returns a reference to the ADF Business Components user session (which you can use to reference values in the `userData` hashmap that is part of the session)

You can also reference the current date (time truncated) or current date and time using the following expressions:

- `adf.currentDate`
- `adf.currentDateTime`

3.6.2 Referencing Custom Business Components Methods and Attributes in Groovy Expressions

Groovy script language simplifies the authoring of code that you might write to access methods and attributes of your entity object and view objects.

3.6.2.1 Referencing Members of the Same Business Component

The simplest example of referencing business component members, including methods and attributes that the entity object and view object define, is to reference attributes that exist in the same entity object or view object as the attribute that you apply the expression.

For example, you could define a Groovy expression to calculate the value of a transient attribute `AnnualSalary` on an entity object with an attribute `Sal` that specifies the employee's monthly salary:

```
Sal * 12
```

Or, with Groovy you can write a simple validation rule to compare the attributes of a single view object using syntax like:

```
PromotionDate > HireDate
```

Using Java, this same comparison would look like:

```
((Date)getAttribute("PromotionDate")).compareTo((Date)getAttribute("HireDate")) > 0
```

Note that the current object is passed in to the script as the `this` object, so you can reference an attribute in the current object by simply using the attribute name. For example, in an attribute-level or entity-level Script Expression validator, to refer to an attribute named "HireDate", the script can simply reference `HireDate`.

Similar to referencing attributes, when you define custom methods in an entity implementation class, you can invoke those methods as part of your expression. For example, to define an attribute default value:

```
adf.object.getDefaultSalaryForGrade()
```

A method reference requires the prefix `adf.object` which allows you to reference the same entity that defines the attribute on which the expression is applied. This same prefix also allows you to reference the methods of the base class of the entity implementation class (`EntityImpl.java`) that your custom implementation class extends.

Note that when you want to reference the method of an entity implementation class in a validation rule, you use the `source` prefix:

```
source.getDefaultSalaryForGrade()
```

Use of the `source` prefix is necessary in validators because the `object` keyword implies the validation rule object instead of the entity object (where the method is defined).

To allow you to reference members of the validator object (`JboValidatorContext`), you can use these keywords in your validation rule expression:

- `newValue`: in an attribute-level validator, to access the attribute value being set
- `oldValue`: in an attribute-level validator, to access the current value of the attribute being set

For example, you might use the following expression to specify a dynamic validation rule check of the salary for a salesman.

```
if (Job == "SALESMAN")
{
    return newValue < source.getMaxSalaryForGrade(Job)
}
else
```

```
return true
```

3.6.2.2 Referencing Members of Other Business Components

You can also reference the methods and attributes that entity objects and view objects defines in the expressions you apply to a different entity object attribute or validation rule. This is accomplished by referencing the accessor in the entity association.

For example, if you define an entity with a master-detail association for `Dept` and `Emp`, by default the accessor for the entity association will be named `Dept` and `Emp`, to identity the source and destination data source. Using that accessor in a Groovy expression to set the default value for a new employee's salary based on the location of their department:

```
adf.object.getDefaultSalaryForGrade(Dept.Loc)
```

This expression does not reference the entity even though it has the same name (`Dept`) as the accessor for the association. Instead, assuming a master-detail relationship between departments and employees, referencing the accessor allows the Groovy expression for the employee entity object to walk back to the master department entity and pass in the value of `Loc` from that master.

3.6.3 Manipulating Business Component Attribute Values in Groovy Expressions

You can use the following built-in aggregate functions on Oracle Business Components `RowSet` objects:

- `rowSetAttr.sum(GroovyExpr)`
- `rowSetAttr.count(GroovyExpr)`
- `rowSetAttr.avg(GroovyExpr)`
- `rowSetAttr.min(GroovyExpr)`
- `rowSetAttr.max(GroovyExpr)`

These aggregate functions accept a string-value argument that is interpreted as a Groovy expression that is evaluated in the context of each row in the row set as the aggregate is being computed. The Groovy expression must return a numeric value (or number domain).

For example, in a `Dept` entity object you could add a transient attribute that displays the sum of all employee salaries that is calculated by this expression:

```
EmployeesInDept.sum("Sal")
```

To reference the employees of a specific department, the expression supplies the name of the master-detail association's accessor for the destination `Emp` entity. In this case, the accessor is `EmployeesInDept` and salary is interpreted for each record of the `Emp` entity object.

Or, assume that you want the calculation of the salary total for specific departments to include each employee's benefits package, which varies with job role:

```
EmployeesInDept.sum("Sal + adf.object.getBenefitsValue(Job)")
```

Creating a Business Domain Layer Using Entity Objects

This chapter describes how to use entity objects to create a reusable layer of business domain objects for use in your Java EE applications.

This chapter includes the following sections:

- [Section 4.1, "About Entity Objects"](#)
- [Section 4.2, "Creating Entity Objects and Associations"](#)
- [Section 4.3, "Creating and Configuring Associations"](#)
- [Section 4.4, "Creating an Entity Diagram for Your Business Layer"](#)
- [Section 4.5, "Defining Property Sets"](#)
- [Section 4.6, "Defining Attribute Control Hints for Entity Objects"](#)
- [Section 4.7, "Working with Resource Bundles"](#)
- [Section 4.8, "Defining Business Logic Groups"](#)
- [Section 4.9, "Configuring Runtime Behavior Declaratively"](#)
- [Section 4.10, "Setting Attribute Properties"](#)
- [Section 4.11, "Adding Transient and Calculated Attributes to an Entity Object"](#)
- [Section 4.12, "Creating Business Events"](#)
- [Section 4.13, "Generating Custom Java Classes for an Entity Object"](#)
- [Section 4.14, "Working Programmatically with Entity Objects and Associations"](#)
- [Section 4.15, "Creating Custom, Validated Data Types Using Domains"](#)
- [Section 4.16, "Creating New History Types"](#)
- [Section 4.17, "Basing an Entity Object on a PL/SQL Package API"](#)
- [Section 4.18, "Basing an Entity Object on a Join View or Remote DBLink"](#)
- [Section 4.19, "Using Inheritance in Your Business Domain Layer"](#)

4.1 About Entity Objects

An entity object is the ADF Business Components component that represents a row in the specified data source and simplifies modifying its associated attributes. Importantly, it allows you to encapsulate domain business logic to ensure that your business policies and rules are consistently validated.

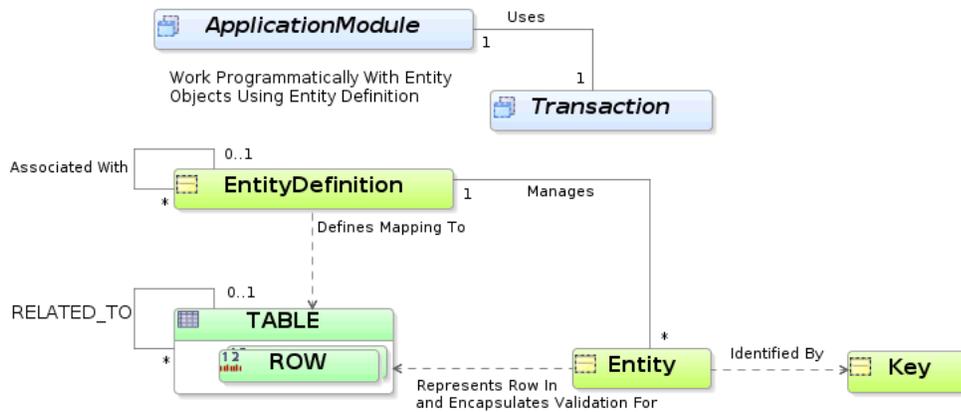

4.1.1 Entity Object Use Cases and Examples

Entity objects support numerous declarative business logic features to enforce the validity of your data. You will typically complement declarative validation with additional custom application logic and business rules to cleanly encapsulate a maximum amount of domain business logic into each entity object. Your associated set of entity objects forms a reusable business domain layer that you can exploit in multiple applications.

The key concepts of entity objects (as illustrated in [Figure 4-1](#)) are the following:

- You define an entity object by specifying the database table whose rows it will represent.
- You can create associations to reflect relationships between entity objects.
- At runtime, entity rows are managed by a related entity definition object.
- Each entity row is identified by a related row key.
- You retrieve and modify entity rows in the context of an application module that provides the database transaction.

Figure 4-1 Entity Object Encapsulates Business Logic for a Table

4.1.2 Additional Functionality for Entity Objects

You may find it helpful to understand other ADF features before you start working with entity objects. Following are links to other functionality that may be of interest.

- For information about using declarative validation in entity objects, see [Chapter 7, "Defining Validation and Business Rules Declaratively."](#)
- For API documentation related to the `oracle.jbo` package, see the following Javadoc reference document:
 - *Oracle Fusion Middleware Java API Reference for Oracle ADF Model*

4.2 Creating Entity Objects and Associations

If you already have a database schema to work from, the simplest way to create entity objects and associations is to reverse-engineer them from existing tables. When needed, you can also create an entity object from scratch, and then generate a table for it later.

4.2.1 How to Create Multiple Entity Objects and Associations from Existing Tables

To create one or more entity objects, use the Business Components from Tables wizard, which is available from the New Gallery.

Before you begin:

It may be helpful to have an understanding of the options you have for creating entity objects. For more information, see [Section 4.2, "Creating Entity Objects and Associations."](#)

You may also find it helpful to understand additional functionality that can be added using other entity object features. For more information, see [Section 4.1.2, "Additional Functionality for Entity Objects."](#)

To create one or more entity objects and associations from existing tables:

1. In the Application Navigator, right-click the project in which you want to create the entity objects and choose **New**.
2. In the New Gallery, expand **Business Tier**, select **ADF Business Components** and then **Business Components from Tables**, and click **OK**.

If this is the first component you're creating in the project, the Initialize Business Components Project dialog appears to allow you to select a database connection.

3. In the Initialize Business Components Project dialog, select the database connection or choose **New** to create a connection. Click **OK**.
4. On the Entity Objects page, do the following to create the entity objects:
 - Enter the package name in which all of the entity objects will be created.
 - Select the tables from the **Available** list for which you want to create entity objects.

If the **Auto-Query** checkbox is selected, then the list of available tables appears immediately. In the **Name Filter** field, you can optionally enter a full or partial table name to filter the available tables list in real time. As an alternative to the auto-query feature, click the **Query** button to retrieve the list based on an optional table name filter. When no name filter is entered, JDeveloper retrieves all table objects for the chosen schema.

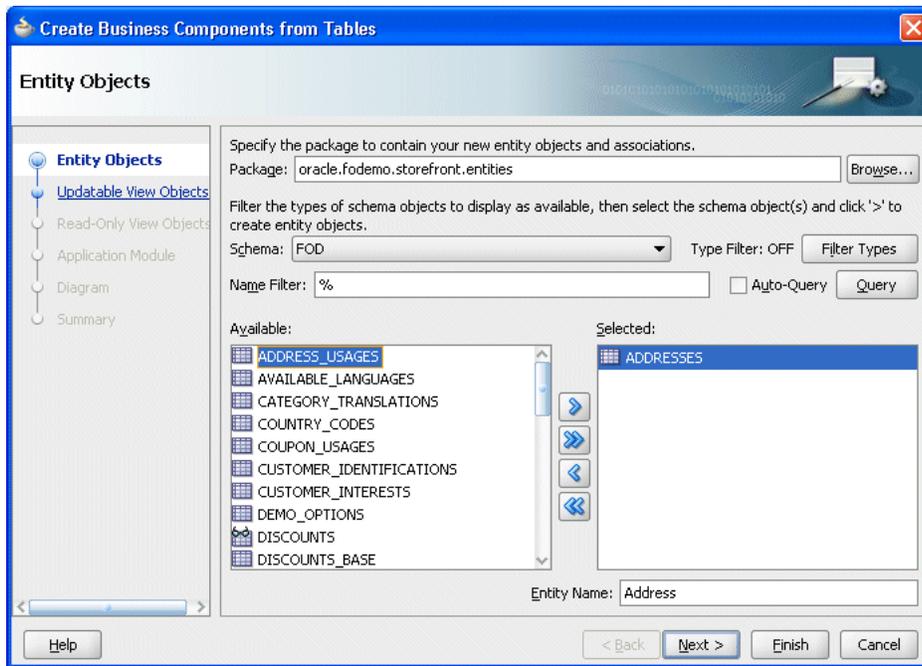

- Click **Filter Types** if you want to see only a subset of the database objects available. You can filter out tables, views, or synonyms.

Once you have selected a table from the **Available** list, the proposed entity object name for that table appears in the **Selected** list with the related table name in parenthesis.

- Select an entity object name in the **Selected** list and use the **Entity Name** field to change the default entity object name.

Best Practice: Because each entity object instance represents a *single* row in a particular table, name the entity objects with a singular noun (like Address, Order, and Person), instead of their plural counterparts. [Figure 4–2](#) shows what the wizard page looks like after selecting the ADDRESSES table in the FOD schema, setting a package name of `oracle.fodemo.storefront.entities`, and renaming the entity object in the singular.

Figure 4–2 Create Business Components from Tables Wizard, Entity Objects Page

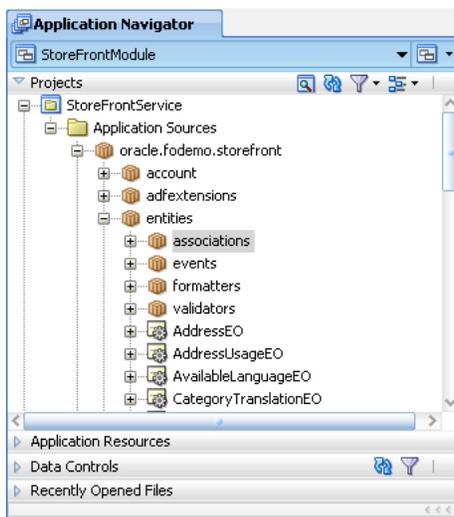

5. When you are satisfied with the selected table objects and their corresponding entity object names, click **Finish**.

The Application Navigator displays the entity objects in the package you specified.

Best Practice: After you create associations, move all of your associations to a separate package so that you can view and manage them separately from the entity objects. In [Figure 4–3](#), the associations have been moved to a subpackage (associations) and do not appear in the entities package in the Application Navigator. For more information, see [Section 4.3.4, "How to Rename and Move Associations to a Different Package."](#)

Figure 4–3 New Entity Objects in Application Navigator

4.2.2 How to Create Single Entity Objects Using the Create Entity Wizard

To create a single entity object, you can use the Create Entity Object wizard, which is available in the New Gallery.

Note: Associations are not generated when you use the Create Entity Object wizard. However, the Business Components from Tables wizard does generate associations. If you use the Create Entity Object wizard to create entity objects, you will need to create the corresponding associations manually.

Before you begin:

It may be helpful to have an understanding of the options you have for creating entity objects. For more information, see [Section 4.2, "Creating Entity Objects and Associations."](#)

You may also find it helpful to understand additional functionality that can be added using other entity object features. For more information, see [Section 4.1.2, "Additional Functionality for Entity Objects."](#)

To create a single entity object:

1. In the Application Navigator, right-click the project in which you want to create the entity object and choose **New**.
2. In the New Gallery, expand **Business Tier**, select **ADF Business Components** and then **Entity Object**, and click **OK**.

If this is the first component you're creating in the project, the Initialize Business Components Project dialog appears to allow you to select a database connection.

3. In the Initialize Business Components Project dialog, select the database connection or choose **New** to create a connection. Click **OK**.
4. On the Name page, do the following to create the entity object:
 - Enter a name for the entity object.
 - Enter the package name in which the entity object will be created.
 - Click **Browse** (next to the **Schema Object** field) to select the table for which you want to create the entity object.

Or, if you plan to create the table later, you can enter a name of a table that does not exist.

5. If you manually entered a table name in the **Schema Object** field, you will need to define each attribute on the Attributes page of the wizard. Click **Next**.

You can create the table manually or generate it, as described in [Section 4.2.6, "How to Create Database Tables from Entity Objects."](#)

6. When you are satisfied with the table object and its corresponding entity object name, click **Finish**.

4.2.3 What Happens When You Create Entity Objects and Associations from Existing Tables

When you create an entity object from an existing table, first JDeveloper interrogates the data dictionary to infer the following information:

- The Java-friendly entity attribute names from the names of the table's columns (for example, `USER_ID` -> `UserId`)
- The SQL and Java data types of each attribute based on those of the underlying column
- The length and precision of each attribute
- The primary and unique key attributes
- The mandatory flag on attributes, based on `NOT NULL` constraints
- The relationships between the new entity object and other entities based on foreign key constraints

Note: Since an entity object represents a database row, it seems natural to call it an *entity row*. Alternatively, since at runtime the entity row is an instance of a Java object that encapsulates business logic for that database row, the more object-oriented term *entity instance* is also appropriate. Therefore, these two terms are interchangeable.

JDeveloper then creates the XML component definition file that represents its declarative settings and saves it in the directory that corresponds to the name of its package. For example, when an entity named `Order` appears in the `genericbcmodel.entities` package, JDeveloper will create the XML file `genericbcmodel/entities/Order.xml` under the project's source path. This XML file contains the name of the table, the names and data types of each entity attribute, and the column name for each attribute.

You can inspect the XML description for the entity object by opening the object in the overview editor and clicking the **Source** tab.

Note: If your IDE-level Business Components Java generation preferences so indicate, the wizard may also create an optional custom entity object class (for example, `OrderImpl.java`).

4.2.3.1 What Happens When Tables Have Foreign Key Relationships

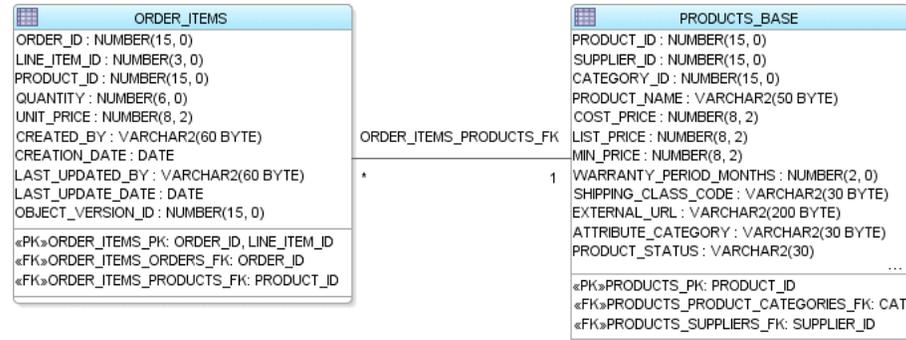

In addition to the entity objects, the Business Components from Tables wizard also generates named association components that capture information about the relationships between entity objects. For example, the database diagram in [Figure 4-4](#) shows that JDeveloper derives default association names like `OrderItemsProductsFkAssoc` by converting the foreign key constraint names to a Java-friendly name and adding the `Assoc` suffix. For each association created, JDeveloper creates an appropriate XML component definition file and saves it in the directory that corresponds to the name of its package.

Note: Associations are generated when you use the Business Components from Tables wizard. However, the Create Entity Object wizard does not generate associations. If you use the Create Entity Object wizard to create entity objects, you will need to create the corresponding associations manually.

By default the associations reverse-engineered from foreign keys are created in the same package as the entities. For example, for the association

OrderItemsProductsFkAssoc with entities in the `fodemo.storefront.entities` package, JDeveloper creates the association XML file named `./fodemo/storefront/entities/OrderItemsProductsFkAssoc.xml`.

Figure 4–4 *ORDER_ITEMS and PRODUCTS_BASE Tables Related by Foreign Key*

4.2.3.2 What Happens When a Table Has No Primary Key

If a table has no primary key constraint, then JDeveloper cannot infer the primary key for the entity object. Since every entity object must have at least one attribute marked as a primary key, the wizard will create an attribute named `RowID` and use the database `ROWID` value as the primary key for the entity. If appropriate, you can edit the entity object later to mark a different attribute as a primary key and remove the `RowID` attribute. When you use the Create Entity Object wizard and you have not set any other attribute as primary key, you will be prompted to use `RowID` as the primary key.

4.2.4 What Happens When You Create an Entity Object for a Synonym or View

When you create an entity object using the Business Components from Tables wizard or the Create Entity Object wizard, the object can represent an underlying table, synonym, or view. The framework can infer the primary key and related associations for a table or synonym by inspecting database primary and foreign key constraints in the data dictionary.

However, when your selected schema object is a database view, then neither the primary key nor associations can be inferred since database views do not have database constraints. In this case, if you use the Business Components from Tables wizard, the primary key defaults to `RowID`. If you use the Create Entity Object wizard, you'll need to specify the primary key manually by marking at least one of its attributes as a primary key. For more information, see [Section 4.2.3.2, "What Happens When a Table Has No Primary Key."](#)

When your selected schema object is a synonym, there are two possible outcomes. If the synonym is a synonym for a table, then the wizard and editor behave as if you had specified a table. If instead the synonym refers to a database view, then they behave as if you had specified a view.

4.2.5 How to Edit an Existing Entity Object or Association

After you've created a new entity object or association, you can edit any of its settings in the overview editor. To launch the editor, choose **Open** from the context menu for the entity object or association in the Application Navigator or double-click the object.

By clicking the different tabs of the editor, you can adjust the settings that define the object and govern its runtime behavior.

4.2.6 How to Create Database Tables from Entity Objects

To create database tables based on entity objects, right-click the package in the Application Navigator that contains the entity objects and choose **Create Database Objects** from the context menu. A dialog appears to let you select the entities whose tables you'd like to create. This tool can be used to generate a table for an entity object you created from scratch, or to drop and re-create an existing table.

Caution: This feature does *not* generate a DDL script to run later. It performs its operations directly against the database and will drop existing tables. A dialog appears to confirm that you want to do this before proceeding. For entities based on existing tables, use with caution.

In the overview editor for an association, the **Use Database Key Constraints** checkbox on the Association Properties page controls whether the related foreign key constraint will be generated when creating the tables for entity objects. Selecting this option does not have any runtime implications.

4.2.7 How to Synchronize an Entity with Changes to Its Database Table

Inevitably you (or your DBA) might alter a table for which you've already created an entity object. Your existing entity will not be disturbed by the presence of additional attributes in its underlying table; however, if you want to access the new column in the table in your Java EE application, you'll need to synchronize the entity object with the database table.

For example, suppose you had done the following at the SQL*Plus command prompt to add a new `SECURITY_QUESTION` column to the `PERSONS` table:

```
ALTER TABLE PERSONS ADD (security_question VARCHAR2(60));
```

Then you can use the synchronization feature to add the new column as an attribute on the entity object.

Before you begin:

It may be helpful to have an understanding of the options you have for creating entity objects. For more information, see [Section 4.2, "Creating Entity Objects and Associations."](#)

You may also find it helpful to understand additional functionality that can be added using other entity object features. For more information, see [Section 4.1.2, "Additional Functionality for Entity Objects."](#)

To synchronize an entity with changes to its database table:

1. In the Application Navigator, right-click the desired entity object and choose **Synchronize with Database**.

The Synchronize with Database dialog shows the list of the actions that can be taken to synchronize the business logic tier with the database.

2. Select the action you want to take:

- Select one or more actions from the list, and click **Synchronize** to synchronize the selected items.
 - Click **Synchronize All** to perform all actions in the list.
 - Click **Write to File** to save the action list to a text file. This feature helps you keep track of the changes you make.
3. When finished, click **OK** to close the dialog.

4.2.7.1 Removing an Attribute Associated with a Dropped Column

The synchronize feature does not handle dropped columns. When a column is dropped from the underlying database after an entity object has been created, you can delete the corresponding attribute from the entity object. If the attribute is used in other parts of your application, you must remove those usages as well.

Before you begin:

It may be helpful to have an understanding of the options you have for creating entity objects. For more information, see [Section 4.2, "Creating Entity Objects and Associations."](#)

You may also find it helpful to understand additional functionality that can be added using other entity object features. For more information, see [Section 4.1.2, "Additional Functionality for Entity Objects."](#)

To remove an entity attribute:

1. In the Application Navigator, double-click the entity.
2. In the overview editor, click the **Attributes** navigation tab.
3. On the Attributes page, right-click the attribute, and choose **Delete Safely**.
If there are other usages, the Delete Attributes dialog displays the message "Usages were found."
4. If usages were found, click **View Usages**.
The Log window shows all usages of the attribute.
5. Work through the list in the Log window to delete all usages of the entity attribute.

4.2.7.2 Addressing a Data Type Change in the Underlying Table

The synchronize feature does not handle changed data types. For a data type change in the underlying table (for example, precision increased), you must locate all usages of the attribute and manually make changes, as necessary.

Before you begin:

It may be helpful to have an understanding of the options you have for creating entity objects. For more information, see [Section 4.2, "Creating Entity Objects and Associations."](#)

You may also find it helpful to understand additional functionality that can be added using other entity object features. For more information, see [Section 4.1.2, "Additional Functionality for Entity Objects."](#)

To locate all usages of an entity attribute:

1. In the Application Navigator, double-click the entity.
2. In the overview editor, click the **Attributes** navigation tab.

3. On the Attributes page, right-click the attribute and choose **Find Usages**.

If there are other usages, they are displayed in the Log window.

4.2.8 How to Store Data Pertaining to a Specific Point in Time

Effective dated tables are used to provide a view into the data set pertaining to a specific point in time. Effective dated tables are widely used in applications like HRMS and Payroll to answer queries like:

- What was the tax rate for an employee on August 31st, 2005?
- What are the employee's benefits as of October 2004?

In either case, the employee's data may have changed to a different value since then.

The primary difference between the effective dated entity type and the dated entity type is that the dated entity does not cause row splits during update and delete.

When you create an effective dated entity object, you identify the entity as effective dated and specify the attributes of the entity that represent the start and end dates. The start date and end date attributes must be of the Date type.

Additionally, you can specify an attribute that represents the sequence for the effective dated entity and an attribute that represents a flag for the sequence. These attributes allow for tracking of multiple changes in a single day.

Before you begin:

It may be helpful to have an understanding of the options you have for creating entity objects. For more information, see [Section 4.2, "Creating Entity Objects and Associations."](#)

You may also find it helpful to understand additional functionality that can be added using other entity object features. For more information, see [Section 4.1.2, "Additional Functionality for Entity Objects."](#)

To create an effective dated entity object

1. In the Application Navigator, double-click the entity on which you want enable effective dating.
2. In the Property Inspector, expand the **Type** category.

If necessary, choose **Property Inspector** from the **View** menu to display the Property Inspector.

If the **Type** category is not displayed in the Property Inspector, click the **General** tab in the overview editor to set the proper focus.

3. From the context menu for the **Effective Date Type** property, choose **Edit**.

To display the context menu, click the down arrow next to the property field.

4. In the Edit Property dialog, specify the following settings:
 - For **Effective Date Type**, select **EffectiveDated**.
 - For **Start Date Attribute**, select the attribute that corresponds to the start date.
 - For **End Date Attribute**, select the attribute that corresponds to the end date.
5. You can optionally specify attributes that allow for tracking of multiple changes in a single day.

- For **Effective Date Sequence**, select the attribute that stores the sequence of changes.
- For **Effective Date Sequence Flag**, select the attribute that stores a flag indicating the most recent change in the sequence.

Without specifying the **Effective Date Sequence** and **Effective Date Sequence Flag** attributes, the default granularity of effective dating is one day. For this reason, multiple changes in a single day are not allowed. An attempt to update the entity a second time in a single day will result in an exception being thrown. After these two attributes are specified, the framework inserts and updates their values as necessary to track multiple changes in a single day.

6. Click **OK**.

Note: You can also identify the start and end date attributes using the Property Inspector for the appropriate attributes. To do so, select the appropriate attribute in the overview editor and set the **IsEffectiveStartDate** or **IsEffectiveEndDate** property to **true** in the Property Inspector.

4.2.9 What Happens When You Create Effective Dated Entity Objects

When you create an effective dated entity object, JDeveloper creates a transient attribute called `SysEffectiveDate` to store the effective date for the row. Typically the Insert, Update, and Delete operations modify the transient attribute while the ADF Business Components framework decides the appropriate values for the effective start date and the effective end date.

[Example 4–1](#) show some sample XML entries that are generated when you create an effective dated entity. For more information about working with effective dated objects, see [Section 5.4, "Limiting View Object Rows Using Effective Date Ranges."](#)

Example 4–1 XML Entries for Effective Dated Entities

```
// In the effective dated entity
<Entity
  ...
  EffectiveDateType="EffectiveDated">

// In the attribute identified as the start date
  <Attribute
    ...
    IsEffectiveStartDate="true">

// In the attribute identified as the end date
  <Attribute
    ...
    IsEffectiveEndDate="true">

// The SysEffectiveDate transient attribute
  <Attribute
    Name="SysEffectiveDate"
    IsQueryable="false"
    IsPersistent="false"
    ColumnName="$none$"
    Type="oracle.jbo.domain.Date"
    ColumnType="$none$"
    SQLType="DATE" />
```

4.2.10 What You May Need to Know About Creating Entities from Tables

The Business Components from Tables wizard makes it easy to quickly generate many business components at the same time. In practice, this does not mean that you should use it to immediately create entity objects for every table in your database schema just because it is possible to do so. If your application requires all of the tables, then that strategy might be appropriate. But because you can use the wizard whenever needed, you should create the entity objects for the tables that you know will be involved in the application.

[Section 9.4, "Defining Nested Application Modules,"](#) describes a use case-driven design approach for your business services that can assist you in understanding which entity objects are required to support your application's business logic needs. You can always add more entity objects later as necessary.

4.3 Creating and Configuring Associations

If your database tables have no foreign key constraints defined, JDeveloper won't be able to infer the associations between the entity objects that you create. Since several ADF Business Components runtime features depend on the presence of entity associations, create them manually if the foreign key constraints don't exist.

4.3.1 How to Create an Association

To create an association, use the Create New Association wizard, which is available in the New Gallery.

Before you begin:

It may be helpful to have an understanding of why you create associations. For more information, see [Section 4.3, "Creating and Configuring Associations."](#)

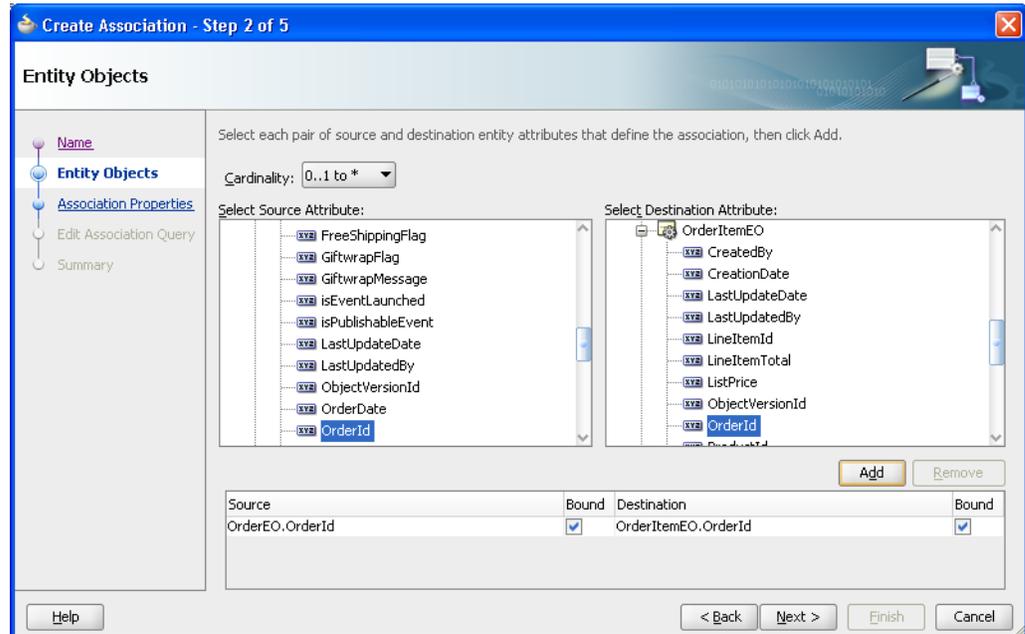

You may also find it helpful to understand additional functionality that can be added using other entity object features. For more information, see [Section 4.1.2, "Additional Functionality for Entity Objects."](#)

To create an association:

1. In the Application Navigator, right-click the project in which you want to create the association and choose **New**.
2. In the New Gallery, expand **Business Tier**, select **ADF Business Components** and then **Association**, and click **OK**.
3. On the Name page, do the following to create the association:
 - Enter the package name in which the association will be created.
 - Enter the name of the association component.
 - Click **Next**.
4. On the Entity Objects page, select the source and destination entity attributes:
 - Select a source attribute from one of the entity objects that is involved in the association to act as the master.
 - Select a corresponding destination attribute from the other entity object involved in the association.

For example, [Figure 4–5](#) shows the selected `OrderId` attribute from the `OrderEO` entity object as the source entity attribute. Because the `OrderItemEO` rows contain an order ID that relates them to a specific `OrderEO` row, you would select this `OrderId` foreign key attribute in the `OrderItemEO` entity object as the destination attribute.

Figure 4–5 Create Association Wizard, Attribute Pairs That Relate Two Entity Objects Defined

5. Click **Add** to add the matching attribute pair to the table of source and destination attribute pairs below.

By default, the **Bound** checkbox is selected for both the source and destination attribute. This checkbox allows you to specify whether or not the value will be bound into the association SQL statement that is created internally when navigating from source entity to target entity or from target entity to source entity (depending on which side you select).

Typically, you would deselect the checkbox for an attribute in the relationship that is a transient entity attribute whose value is a constant and therefore should not participate in the association SQL statement to retrieve the entity.

6. If the association requires multiple attribute pairs to define it, you can repeat the preceding steps to add additional source/target attribute pairs.
7. Finally, ensure that the **Cardinality** dropdown correctly reflects the cardinality of the association. The default is a one-to-many relationship. Click **Next**.

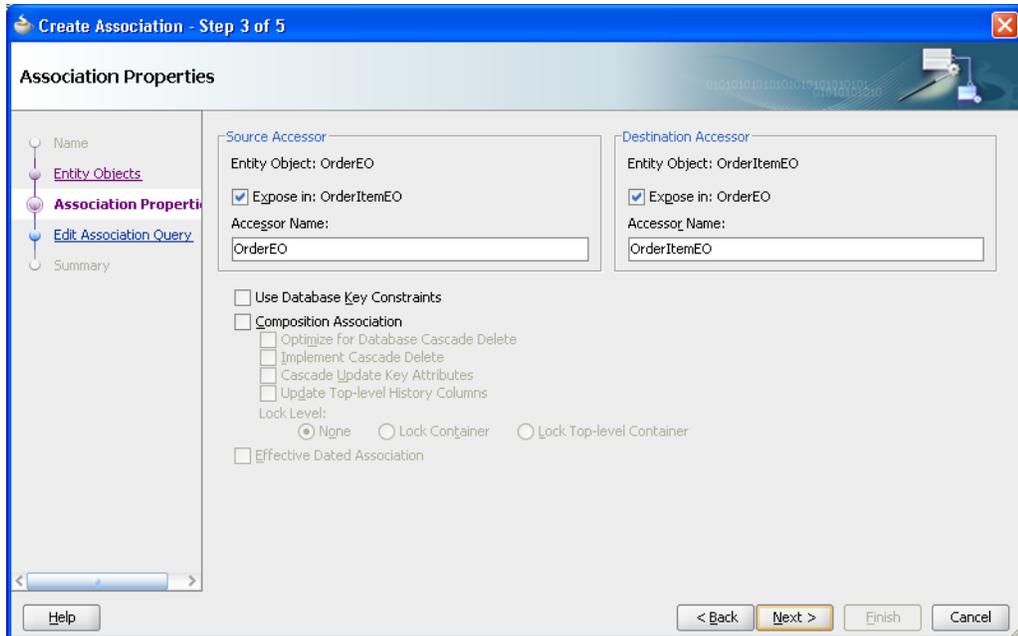

For example, since the relationship between a `OrderEO` row and its related `OrderItemEO` rows is one-to-many, you can leave the default setting.

8. On the Association SQL page, you can preview the association SQL predicate that will be used at runtime to access the related destination entity objects for a given instance of the source entity object.
9. On the Association Properties page, disable the **Expose Accessor** checkbox on either the **Source** or the **Destination** entity object when you want to create an association that represents a one-way relationship. The default, bidirectional

navigation is more convenient for writing business validation logic, so in practice, you typically leave these default checkbox settings.

For example, Figure 4–6 shows an association that represents a bidirectional relationship, permitting either entity object to access the related entity row(s) on the other side when needed. In this example, this means that if you are working with an instance of an `OrderEO` entity object, you can easily access the collection of its related `OrderItemEO` rows. With any instance of a `OrderItemEO` entity object, you can also easily access the `Order` to which it belongs.

Figure 4–6 Association Properties Control Runtime Behavior

10. When you are satisfied with the association definition, click **Finish**.

4.3.2 What Happens When You Create an Association

When you create an association, JDeveloper creates an appropriate XML component definition file and saves it in the directory that corresponds to the name of its package. For example, if you created an association named `OrderItemsOrdersFkAssoc` in the `oracle.fodemo.storefront.entities.associations` subpackage, then the association XML file would be created in the `./oracle/fodemo/storefront/entities/associations` directory with the name `OrderItemsOrdersFkAssoc.xml`. At runtime, the entity object uses the association information to automate working with related sets of entities.

4.3.3 How to Change Entity Association Accessor Names

You should consider the default settings for the accessor names on the Association Properties page and decide whether changing the names to something more intuitive is appropriate. The default settings define the names of the accessor attributes you will use at runtime to programmatically access the entities on the other side of the relationship. By default, the accessor names will be the names of the entity object on the other side. Since the accessor names on an entity must be unique among entity object attributes and other accessors, if one entity is related to another entity in *multiple*

ways, then the default accessor names are modified with a numeric suffix to make the name unique.

In an existing association, you can rename the accessor using the Association Properties dialog.

Before you begin:

It may be helpful to have an understanding of why you create associations. For more information, see [Section 4.3, "Creating and Configuring Associations."](#)

You may also find it helpful to understand additional functionality that can be added using other entity object features. For more information, see [Section 4.1.2, "Additional Functionality for Entity Objects."](#)

To rename the entity accessor in an association:

1. In the Application Navigator, double-click the association.
2. In the overview editor, click the **Relationships** navigation tab.
3. On the Relationships page, expand the **Accessors** category and click the **Edit** icon.
The Association Properties dialog displays the current settings for the association's accessors.
4. Modify the name as necessary, and click **OK** to apply your changes and close the dialog.

4.3.4 How to Rename and Move Associations to a Different Package

Since associations are a component that you typically configure at the outset of your project and don't change frequently thereafter, you might want to move the associations to a different package so that your entity objects are easier to see. Both renaming components and moving them to a different package is straightforward using JDeveloper's refactoring functionality.

Before you begin:

It may be helpful to have an understanding of why you create associations. For more information, see [Section 4.3, "Creating and Configuring Associations."](#)

You may also find it helpful to understand additional functionality that can be added using other entity object features. For more information, see [Section 4.1.2, "Additional Functionality for Entity Objects."](#)

To move a set of business components to a different package:

1. In the Application Navigator, select the components you want to move.
2. Right-click one of the selected components, and choose **Refactor > Move**.
3. In the Move Business Components dialog, enter the name of the package to move the component(s) to, or click **Browse** to navigate to and select the package.
4. Click **OK** to apply your changes and close the dialog.

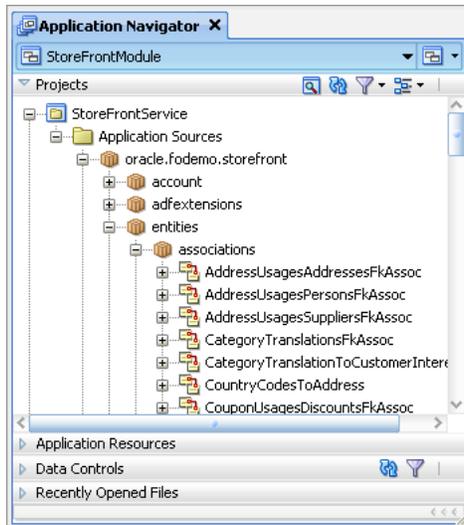

To rename a component:

1. In the Application Navigator, right-click the component you want to rename, and choose **Refactor > Rename**.
2. In the Rename dialog, enter the new name for the component and click **OK**.

When you refactor ADF Business Components, JDeveloper moves the XML and Java files related to the components, and updates any other components that might reference them.

Figure 4–7 shows what the Application Navigator would look like after renaming all of the associations and moving them to the `oracle.fodemo.storefront.associations` subpackage. While you can refactor the associations into any package name you choose, picking a subpackage keeps them logically related to the entities, and allows you to collapse the package of associations to better manage which files display in the Application Navigator.

Figure 4–7 Application Navigator After Association Refactoring

4.3.5 What You May Need to Know About Using a Custom View Object in an Association

You can associate a custom view object with the source end or destination end (or both) of an entity association.

When you traverse entity associations in your code, if the entities are not already in the cache, then the ADF Business Components framework performs a query to bring the entity (or entities) into the cache. By default, the query performed to bring an entity into the cache is the find-by-primary-key query that selects values for all persistent entity attributes from the underlying table. If the application performs a lot of programmatic entity association traversal, you could find that retrieving all of the attributes might be heavy-handed for your use cases.

Entity associations support the ability to associate a custom, entity-based view object with the source entity or destination entity in the association, or both. The primary entity usage of the entity-based view object you supply must match the entity type of the association end for which you use it.

Using a custom view object can be useful because the custom view object's query can include fewer columns and it can include an `ORDER BY` clause. This allows you to control how much data is retrieved when an entity is brought into the cache due to association traversal, as well as the order in which any collections of related entities will appear.

For more information about creating a custom view object, see [Section 42.8.2, "How to Create an Entity-Based Programmatic View Object."](#)

4.3.6 What You May Need to Know About Composition Associations

A *composition association* represents a relationship between entities, such as `Person` referenced by an `Order` or a `OrderItem` contained in a `Order`. When you create composition associations, it is useful to know about the kinds of relationships you can represent, and the various options.

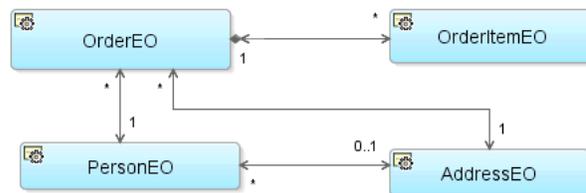

Associations between entity objects can represent two styles of relationships depending on whether the source entity:

- *References* the destination entity
- *Contains* the destination entity as a logical, nested part

Figure 4–8 depicts an application business layer that represents both styles of relationships. For example, an `OrderEO` entry references a `PersonEO`. This relationship represents the first kind of association, reflecting that a `PersonEO` or an `OrderEO` entity object can exist independent from each other. In addition, the removal of an `Order` does not imply the cascade removal of the `Person` to which it was referring.

In contrast, the relationship between `OrderEO` and its collection of related `OrderItemEO` details is stronger than a simple reference. The `OrderItemEO` entries comprise a logical part of the overall `OrderEO`. In other words, a `OrderEO` is composed of `OrderItemEO` entries. It does not make sense for a `OrderItemEO` entity row to exist independently from an `OrderEO`, and when an `OrderEO` is removed — assuming the removal is allowed — all of its composed parts should be removed as well. This kind of logical containership represents the second kind of association, called a *composition*. The UML diagram in Figure 4–8 illustrates the stronger composition relationship using the solid diamond shape on the side of the association which composes the other side of the association.

Figure 4–8 *OrderEO Composed of OrderItemEO Entries and References Both PersonEO and AddressEO*

The Business Components from Tables Wizard creates composition associations by default for any foreign keys that have the `ON DELETE CASCADE` option. You can use the Create Association wizard or the overview editor for the association to indicate that an association is a composition association. Select the **Composition Association** checkbox on either the Association Properties page of the Create Association wizard or the Relationships page of the overview editor. An entity object offers additional runtime behavior in the presence of a composition. For the settings that control the behavior, see [Section 4.10.13, "How to Configure Composition Behavior."](#)

4.4 Creating an Entity Diagram for Your Business Layer

Since your layer of business domain objects represents a key reusable asset for your team, it is often convenient to visualize the business domain layer using a UML model. JDeveloper supports easily creating a diagram for your business domain layer that you and your colleagues can use for reference.

The UML diagram of business components is not just a static picture that reflects the point in time when you dropped the entity objects onto the diagram. Rather, it is a UML-based rendering of the current component definitions, that will always reflect the current state of affairs. What's more, the UML diagram is both a visualization aid and a visual navigation and editing tool. To open the overview editor for any entity object in a diagram, right-click the desired object and choose **Properties** from the context menu or double-click the desired object. You can also perform some entity object editing tasks directly on the diagram, like renaming entities and entity attributes, and adding or removing attributes.

4.4.1 How to Create an Entity Diagram

To create a diagram of your entity objects, you can use the Create Business Components Diagram dialog, which is available in the New Gallery.

Before you begin:

It may be helpful to have an understanding of how entity diagrams are used in the application. For more information, see [Section 4.4, "Creating an Entity Diagram for Your Business Layer."](#)

You may also find it helpful to understand additional functionality that can be added using other entity object features. For more information, see [Section 4.1.2, "Additional Functionality for Entity Objects."](#)

To create an entity diagram that models existing entity objects:

1. In the Application Navigator, right-click the project in which you want to create the entity diagram and choose **New**.
2. In the New Gallery, expand **Business Tier**, select **ADF Business Components** and then **Business Components Diagram**, and click **OK**.
3. In the dialog, do the following to create the diagram:
 - Enter a name for the diagram, for example `Business Domain Objects`.
 - Enter the package name in which the diagram will be created. For example, you might create it in a subpackage like `myproject.model.design`.
4. Click **OK**.
5. To add existing entity objects to the diagram, select them in the Application Navigator and drop them onto the diagram surface.

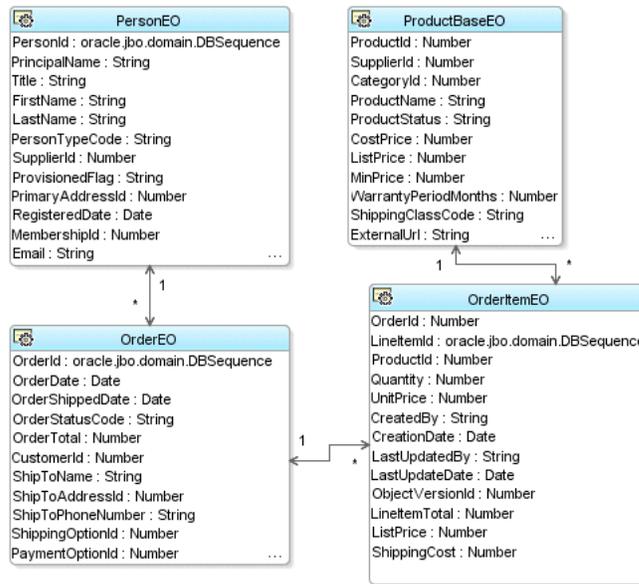

After you have created the diagram you can use the Property Inspector to adjust visual properties of the diagram. For example you can:

- Hide or show the package name
- Change the font
- Toggle the grid and page breaks on or off
- Display association names that may otherwise be ambiguous

You can also create an image of the diagram in PNG, JPG, SVG, or compressed SVG format, by choosing **Publish Diagram** from the context menu on the diagram surface.

[Figure 4–9](#) shows a sample diagram that models various entity objects from the business domain layer.

Figure 4–9 UML Diagram of Business Domain Layer

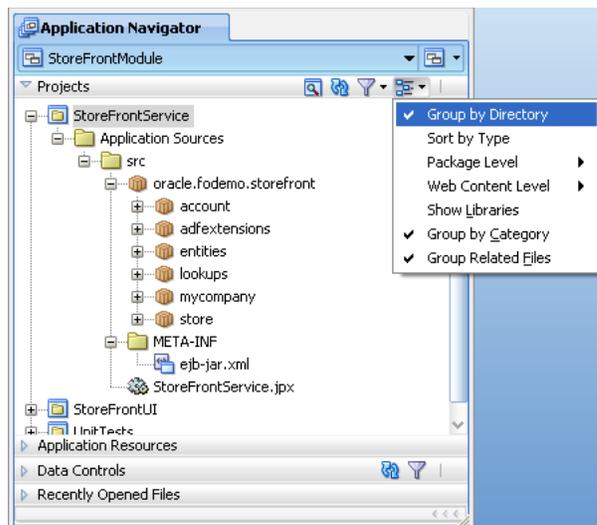

4.4.2 What Happens When You Create an Entity Diagram

When you create a business components diagram, JDeveloper creates an XML file * .oxd_bc4j representing the diagram in a subdirectory of the project's model path that matches the package name in which the diagram resides.

By default, the Application Navigator unifies the display of the project contents paths so that ADF components and Java files in the source path appear in the same package tree as the UML model artifacts in the project model path. However, as shown in [Figure 4–10](#), using the **Navigator Display Options** toolbar button on the Application Navigator, you can see the distinct project content path root directories when you prefer.

Figure 4–10 Toggling the Display of Separate Content Path Directories

4.4.3 What You May Need to Know About the XML Component Descriptors

When you include a business component like an entity object to a UML diagram, JDeveloper adds extra metadata to a <Data> section of the component's XML component descriptor as shown in [Example 4-2](#). This additional information is used at design time only.

Example 4-2 Additional UML Metadata Added to an Entity Object XML Descriptor

```
<Entity Name="OrderEO" ... >
  <Data>
    <Property Name ="COMPLETE_LIBRARY" Value ="FALSE" />
    <Property Name ="ID"
      Value ="ff16fca0-0109-1000-80f2-8d9081ce706f:::EntityObject" />
    <Property Name ="IS_ABSTRACT" Value ="FALSE" />
    <Property Name ="IS_ACTIVE" Value ="FALSE" />
    <Property Name ="IS_LEAF" Value ="FALSE" />
    <Property Name ="IS_ROOT" Value ="FALSE" />
    <Property Name ="VISIBILITY" Value ="PUBLIC" />
  </Data>
  :
</Entity>
```

4.4.4 What You May Need to Know About Changing the Names of Components

On an entity diagram, the names of entity objects, attributes, and associations can be changed for clarity. Changing names on a diagram does not affect the underlying data names. The name change persists for the diagram only. The new name may contain spaces and mixed case for readability. To change the actual entity object names, attribute names, or association names, open the entity object or association in the overview editor.

4.5 Defining Property Sets

A property set is a named collection of properties, where a property is defined as a name/value pair. Property sets are a convenience mechanism to group properties and then reference them from other ADF Business Components objects. Properties defined in a property set can be configured to be translatable, in which case the translations are stored in a message bundle file owned by the property set.

Property sets can be used for a variety of functions, such as control hints and error messages. A property set may contain control hints and other custom properties, and you can associate them with multiple attributes of different objects.

Note: Take care when defining property sets that contain translatable content. Be sure not to "overload" common terms in different contexts. For example, the term "Name" might be applied to both an object and a person in one language, but then translated into two different terms in a target language. Even though a term in several contexts might be the same in the source language, a separate distinguishable term should be used for each context.

Property sets can be used with entity objects and their attributes, view objects and their attributes, and application modules.

4.5.1 How to Define a Property Set

To define a property set, you create a new property set using a dialog and then specify properties using the Property Inspector.

Before you begin:

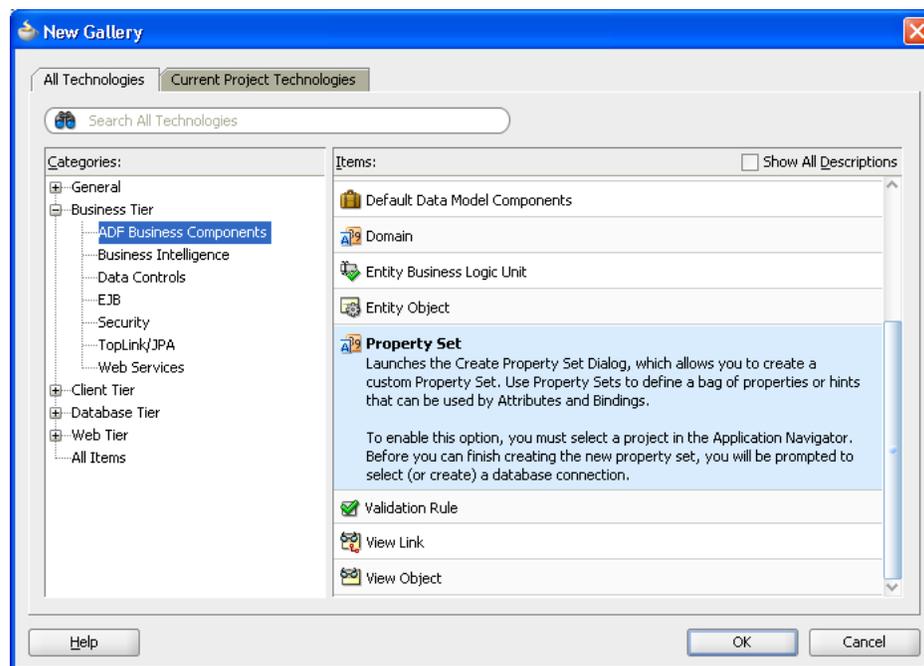

It may be helpful to have an understanding of how property sets can be used. For more information, see [Section 4.5, "Defining Property Sets."](#)

You may also find it helpful to understand additional functionality that can be added using other entity object features. For more information, see [Section 4.1.2, "Additional Functionality for Entity Objects."](#)

To define a property set:

1. In the Application Navigator, right-click the project where you want to create the property set, and choose **New**.
2. In the New Gallery, expand **Business Tier**, select **ADF Business Components** and then **Property Set**, and click **OK**.

Figure 4–11 Property Set in New Gallery

3. In the Create Property Set dialog, enter the name and location of the property set and click **OK**.
4. From the **View** menu, choose **Property Inspector**.
5. In the Property Inspector, define the properties for the property set.

4.5.2 How to Apply a Property Set

After you have created the property set, you can apply the property set to an entity object or attribute, and use the defined properties (or override them, if necessary).

Before you begin:

It may be helpful to have an understanding of how property sets can be used. For more information, see [Section 4.5, "Defining Property Sets."](#)

You may also find it helpful to understand additional functionality that can be added using other entity object features. For more information, see [Section 4.1.2, "Additional Functionality for Entity Objects."](#)

To apply a property set to an entity object or view object:

1. In the Application Navigator, double-click the desired object (entity object or view object).
2. In the overview editor, click the **General** navigation tab and then click the **Edit** icon next to the **Property Set** line.
3. Select the appropriate property set, and click **OK**.

To apply a property set to an attribute:

1. In the Application Navigator, double-click the object (entity object or view object) that contains the attribute.
2. In the overview editor, click the **Attributes** navigation tab, select the attribute you want to edit, and then click the **Details** tab.
3. In the **Property Set** dropdown list, select the appropriate property set.

4.6 Defining Attribute Control Hints for Entity Objects

If you are familiar with previous versions of ADF Business Components, you may have used control hints. Control hints allow you to define label text, tooltip, and format mask hints for entity object attributes. The UI hints you define on your business domain layer are inherited by any entity-based view objects as well. You can also set additional control hints on view objects and application modules in a similar manner.

4.6.1 How to Add Attribute Control Hints

To add attribute control hints to an entity object, use the overview editor.

Before you begin:

It may be helpful to have an understanding of how control hints are used in an entity object. For more information, see [Section 4.6, "Defining Attribute Control Hints for Entity Objects."](#)

You may also find it helpful to understand additional functionality that can be added using other entity object features. For more information, see [Section 4.1.2, "Additional Functionality for Entity Objects."](#)

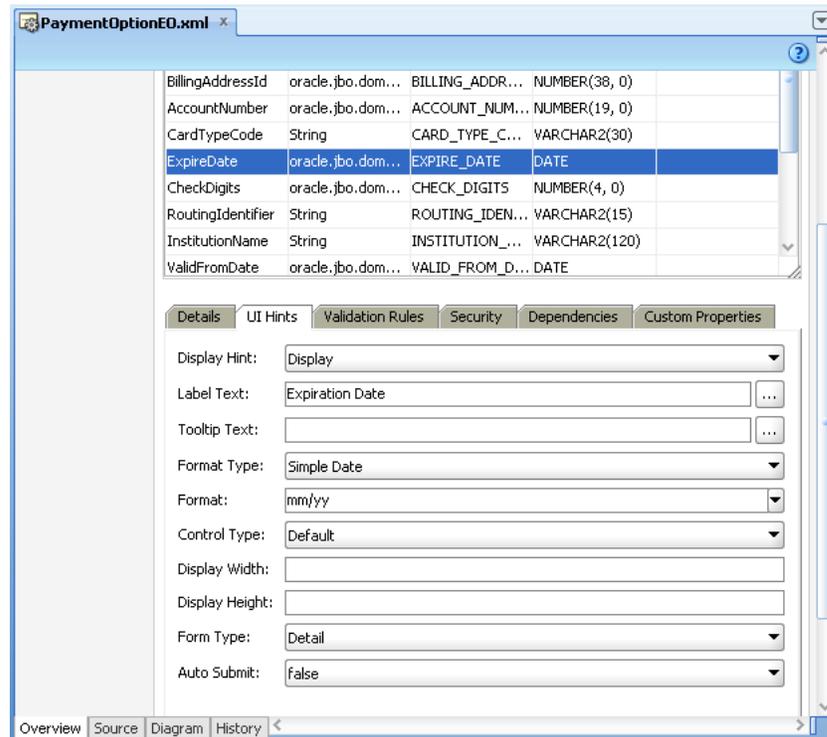

To add attribute control hints to an entity object:

1. In the Application Navigator, double-click the desired entity object.
2. In the overview editor, click the **Attributes** navigation tab, select the attribute you want to edit, and then click the **UI Hints** tab.
3. Specify control hints as necessary.

For example, [Figure 4–12](#) shows control hints defined for the attribute `ExpireDate` of the `PaymentOptionEO` entity object. The defined hints include the following:

- **Format Type** of Simple Date
- **Format** mask of `mm/yy`

Figure 4–12 Overview Editor, Attributes Page, UI Hints Tab

Note: Java defines a standard set of format masks for numbers and dates that are different from those used by the Oracle database's SQL and PL/SQL languages. For reference, see the Javadoc for the `java.text.DecimalFormat` and `java.text.SimpleDateFormat` classes.

4.6.2 What Happens When You Add Attribute Control Hints

When you define attribute control hints for an entity object, JDeveloper creates a resource bundle file in which to store them. The hints that you define can be used by generated forms and tables in associated view clients. The type of file and its granularity are determined by Resource Bundle options in the Project Properties dialog. For more information, see [Section 4.7, "Working with Resource Bundles."](#)

4.6.3 How to Define Formatters and Masks

When you set the **Format Type** control hint (on the **UI Hints** tab) for an attribute (for example, to **Simple Date**), you can also specify a format mask for the attribute to customize how the UI displays the value. If the mask you want to use is not listed in the **Format** dropdown list, you can simply type it into the field.

Not all formatters require format masks. Specifying a format mask is only needed if that formatter type requires it. For example, the date formatter requires a format mask, but the currency formatter does not. In fact the currency formatter does not support format mask at all.

The mask elements that you can use are defined by the associated Java format class. For information about the mask elements for the Simple Date format type, see the Javadoc for `java.text.SimpleDateFormat`. For information about the mask elements for the Number format type, see the Javadoc for `java.text.DecimalFormat`.

If you have a format mask that you will continue to use on multiple occasions, you can add it to the `formatinfo.xml` file, so that it is available from the **Format** dropdown list on the **UI Hints** tab. The entries in this file define the format masks and formatter classes for a domain class. [Example 4–3](#) shows the format definitions for the `java.util.Date` domain.

Note: You can find the `formatinfo.xml` file in the BC4J subdirectory of the JDeveloper system directory (for example, `C:\Documents and Settings\username\Application Data\JDeveloper\system##\o.BC4J\formatinfo.xml`).

Example 4–3 Format Definitions for `java.util.Date` in `formatinfo.xml`

```
<?xml version="1.0"?>
<FORMATTERS>
. . .
  <DOMAIN CLASS="java.util.Date">
    <FORMATTER name="Simple Date" class="oracle.jbo.format.DefaultDateFormatter">
      <FORMAT text="yyyy-MM-dd" />
      <FORMAT text="EEE, MMM d, ''yy" />
      <FORMAT text="dd-MM-yy" />
      <FORMAT text="dd-MMM-yyyy" />
      <FORMAT text="dd/MMM/yyyy" />
    </FORMATTER>
  </DOMAIN>
. . .
</FORMATTERS>
```

The definition of the format mask belongs to a formatter and a domain class, and includes the text specification of the mask as it appears on the **UI Hints** tab. When you specify the **Format Type** (`FORMATTER name`) for an attribute of a given type (`DOMAIN CLASS`), the masks (`FORMAT text`) appear in the **Format** dropdown list.

To map a formatter to a domain for use with control hints, you can either amend one of the default formatters provided in the `oracle.jbo.format` package, or create a new formatter class by extending the `oracle.jbo.format.Formatter` class. The default formatters provided with JDeveloper aggregate the formatters provided in the `java.text` package.

It is not necessary to create new domain to map a formatter. You can use an existing domain when the business components project contains a domain of the same data type as the formatter.

Before you begin:

It may be helpful to have an understanding of how control hints are used in an entity object. For more information, see [Section 4.6, "Defining Attribute Control Hints for Entity Objects."](#)

You may also find it helpful to understand additional functionality that can be added using other entity object features. For more information, see [Section 4.1.2, "Additional Functionality for Entity Objects."](#)

To define a new format mask:

1. Open the `formatinfo.xml` file in a text editor.
2. Find the domain class and formatter name for which you want to add a format mask.
3. Insert a new `FORMAT` entry within the `FORMATTER` element.

After defining a format mask, you can select the new format mask from the **Format** dropdown list on the **UI Hints** tab.

Note: If you create a new domain for the format mask, the XML definition of the formatter must include a `DOMAIN CLASS` (which can be a new or existing one), the `FORMATTER` (which includes the name and class), and the list of `FORMAT` definitions the formatter class specifies.

4.7 Working with Resource Bundles

When you define translatable strings (such as validator error messages, or attribute control hints for an entity object or view object), by default JDeveloper creates a project-level resource bundle file in which to store them. For example, when you define control hints for an entity object in the `StoreFront` project, JDeveloper creates the message bundle file named `StoreFrontBundle.xxx` for the package. The hints that you define can be used by generated forms and tables in associated view clients.

The resource bundle option that JDeveloper uses is determined by an option on the Resource Bundle page of the Project Properties dialog. By default JDeveloper sets the option to **Properties Bundle**, which produces a `.properties` file. For more information on this and other resource bundle options, see [Section 4.7.1, "How to Set Message Bundle Options."](#)

You can inspect the message bundle file for the entity object by selecting the object in the Application Navigator and looking in the corresponding **Sources** node in the Structure window. The Structure window shows the implementation files for the component you select in the Application Navigator.

[Example 4-4](#) shows a sample message bundle file where the control hint information appears. The first entry in each `String` array is a message key; the second entry is the locale-specific `String` value corresponding to that key.

Example 4-4 Project Message Bundle Stores Locale-Sensitive Control Hints

```
AddressUsageEO_OwnerTypeCode_Error_0=Invalid OwnerTypeCode.
AddressUsageEO_UsageTypeCode_Error_0=Invalid UsageTypeCode.
OwnerTypeCode_CONTROLTYPE=105
PaymentOptionEO_RoutingIdentifier_Error_0=Please enter a valid routing identifier.
PaymentOptionsEO_PaymentTypeCode_Error_0=Invalid PaymentTypeCode.
PaymentTypeCode_CONTROLTYPE=105
PaymentOption_AccountNumber=Please enter a valid Account Number
MinPrice_FMT_FORMATTER=oracle.jbo.format.DefaultCurrencyFormatter
CostPrice_FMT_FORMATTER=oracle.jbo.format.DefaultCurrencyFormatter
UnitPrice_FMT_FORMATTER=oracle.jbo.format.DefaultCurrencyFormatter
OrderEO_GiftMessage=Please supply a message shorter than 200 characters
```

```
OrderEO=Please supply a gift message
DiscountBaseEO_DiscountAmount=Discount must be between 0 and 40%

oracle.fodemo.storefront.entities.PaymentOptionEO.ExpireDate_FMT_FORMAT=mm/yy
#Date range validation for ValidFrom and ValidTo dates
PaymentOptionEO_invalidDateRange_Error_0=Date range is invalid. {0} must be
greater than {1}.
PaymentOptionEO_DateRange_Error_0=Invalid date range.{0} should be greater than
{1}.

oracle.fodemo.storefront.entities.PaymentOptionEO.ValidFromDate_LABEL=Valid From
Date
oracle.fodemo.storefront.entities.PaymentOptionEO.ValidToDate_LABEL=Valid To Date
OrderItemsVO_ImageId_Rule_0=ImageId not found
oracle.fodemo.storefront.store.queries.AddressesVO.Address1_LABEL=Address
oracle.fodemo.storefront.store.queries.AddressesVO.PostalCode_LABEL=Post Code or
ZIP
. . .
```

4.7.1 How to Set Message Bundle Options

The resource bundle option JDeveloper uses to save control hints and other translatable strings is determined by an option on the Resource Bundle page of the Project Properties dialog. By default JDeveloper sets the option to **Properties Bundle** which produces a `.properties` file.

Before you begin:

It may be helpful to have an understanding of how resource bundles are used. For more information, see [Section 4.7, "Working with Resource Bundles."](#)

You may also find it helpful to understand additional functionality that can be added using other entity object features. For more information, see [Section 4.1.2, "Additional Functionality for Entity Objects."](#)

To set resource bundle options for your project

1. In the Application Navigator, right-click the project and choose **Project Properties**.
2. Click **Resource Bundle**.
3. Select whether to use project or custom settings.

If you select **Use Custom Settings**, the settings apply only to your work with the current project. They are preserved between sessions, but are not recorded with the project and cannot be shared with other users. If you select **Use Project Settings**, your choices are recorded with the project and can be shared with others who use the project.

4. Specify your preference with the following options by selecting or deselecting the option:
 - **Automatically Synchronize Bundle**
 - **Warn About Hard-coded Translatable Strings**
 - **Always Prompt for Description**For more information on these options, click **Help** to see the online help.
5. Select your choice of resource bundle granularity.
 - **One Bundle Per Project** (default)

- **One Bundle Per File**
 - **Multiple Shared Bundles** (not available for ADF Business Components)
6. Select the type of file to use.
 - **List Resource Bundle**
The `ListResourceBundle` class manages resources in a name/value array. Each `ListResourceBundle` class is contained within a Java class file. You can store any locale-specific object in a `ListResourceBundle` class.
 - **Properties Bundle** (default)
A text file containing translatable text in name/value pairs. Property files (like the one shown in [Example 4-4](#)) can contain values only for String objects. If you need to store other types of objects, you must use a `ListResourceBundle` instead.
 - **Xliff Resource Bundle**
The XML Localization Interchange File Format (XLIFF) is an XML-based format for exchanging localization data.
 7. Click **OK** to apply your settings and close the dialog.

4.7.2 How to Use Multiple Resource Bundles

When you define translatable strings (for example, for attribute control hints), the Select Text Resource dialog allows you to enter a new string or select one that is already defined in the default resource bundle for the object. You can also use a different resource bundle if necessary. This is helpful when you use a common resource bundle that is shared between projects.

Before you begin:

It may be helpful to have an understanding of how resource bundles are used. For more information, see [Section 4.7, "Working with Resource Bundles."](#)

You may also find it helpful to understand additional functionality that can be added using other entity object features. For more information, see [Section 4.1.2, "Additional Functionality for Entity Objects."](#)

To use strings in a nondefault resource bundle:

1. In the Select Text Resource dialog, select the bundle you want to use from the **Resource Bundle** dropdown list.

If the desired resource bundle is not included in the **Resource Bundle** dropdown list, click the **Browse** icon to locate and select the resource bundle you want to use.

The dialog displays the strings that are currently defined in the selected resource bundle.

2. Select an existing string and click **Select**, or enter a new string and click **Save and Select**.

If you entered a new string it is written to the selected resource bundle.

4.7.3 How to Internationalize the Date Format

Internationalizing the model layer of an application built using ADF Business Components entails producing translated versions of each component message bundle file. For example, the Italian version of the `OrdersImplMsgBundle` message bundle

would be a class named `OrdersImplMsgBundle_it` and a more specific *Swiss* Italian version would have the name `OrdersImplMsgBundle_it_ch`. These classes typically extend the base message bundle class, and contain entries for the message keys that need to be localized, together with their localized translation.

Example 4-5 shows the Italian version of an entity object message bundle. Notice that in the Italian translation, the format masks for `RequestDate` and `AssignedDate` have been changed to `dd/MM/yyyy HH:mm`. This ensures that an Italian user will see a date value like May 3rd, 2006, as `03/05/2006 15:55`, instead of `05/03/2006 15:55`, which the format mask in the default message bundle would produce. Notice the overridden `getContents()` method. It returns an array of messages with the more *specific* translated strings merged together with those that are not overridden from the superclass bundle. At runtime, the appropriate message bundles are used automatically, based on the current user's locale settings.

Example 4-5 Localized Entity Object Component Message Bundle for Italian

```
package devguide.model.entities.common;
import oracle.jbo.common.JboResourceBundle;
public class ServiceRequestImplMsgBundle_it
    extends ServiceRequestImplMsgBundle {
    static final Object[][] sMessageStrings = {
        { "AssignedDate_FMT_FORMAT", "dd/MM/yyyy HH:mm" },
        { "AssignedDate_LABEL", "Assegnato il" },
        { "AssignedTo_LABEL", "Assegnato a" },
        { "CreatedBy_LABEL", "Aperto da" },
        { "ProblemDescription_LABEL", "Problema" },
        { "RequestDate_FMT_FORMAT", "dd/MM/yyyy HH:mm" },
        { "RequestDate_LABEL", "Aperto il" },
        { "RequestDate_TOOLTIP", "La data in cui il ticket è stato aperto" },
        { "Status_LABEL", "Stato" },
        { "SvrId_LABEL", "Ticket" }
    };
    public Object[][] getContents() {
        return super.getMergedArray(sMessageStrings, super.getContents());
    }
}
```

4.8 Defining Business Logic Groups

Business logic groups allow you to encapsulate a set of related control hints, default values, and validation logic. A business logic group is maintained separate from the base entity in its own file, and can be enabled dynamically based on context values of the current row.

This is useful, for example, for an HR application that defines many locale-specific validations (like national identifier or tax law checks) that are maintained by a dedicated team for each locale. The business logic group eases maintenance by storing these validations in separate files, and optimizes performance by loading them only when they are needed.

Each business logic group contains a set of business logic units. Each unit identifies the set of business logic that is loaded for the entity, based on the value of the attribute associated with the business logic group.

For example, you can define a business logic group for an `Employee` entity object, specifying the `EmpRegion` attribute as the discriminator. Then define a business logic unit for each region, one that specifies a range validator for the employee's salary. When the application loads a row from the `Employee` entity, the appropriate validator

for the `EmpSalary` attribute is loaded (based on the value of the `EmpRegion` attribute).

In another example, from the `StoreFront` module of the `Fusion Order Demo` application, the `PersonEO` entity object has a business logic group called `PersonTypeCodeGroup` that uses `PersonTypeCode` as the discriminator attribute. Because this attribute has three valid values (`CUST`, `STAFF`, and `SUPP`), there are three corresponding business logic units.

In this scenario, each business logic unit contains new or modified business logic that pertains only to that person type:

- The `CUST` business logic unit contains logic that pertains to customers. For example, it contains a validator that checks for a phone number because all customers must have a phone number.
- The `STAFF` business logic unit contains logic that pertains to staff members. For example, it contains a validator that constrains the credit limit.
- The `SUPP` business logic unit contains logic that pertains to suppliers. For example, it contains a validator that makes sure the `ContactByAffiliatesFlag` attribute is set to `N`, because suppliers cannot be contacted by affiliates.

4.8.1 How to Create a Business Logic Group

You create the business logic group for an entity object from the overview editor.

Before you begin:

It may be helpful to have an understanding of how business logic groups are used. For more information, see [Section 4.8, "Defining Business Logic Groups."](#)

You may also find it helpful to understand additional functionality that can be added using other entity object features. For more information, see [Section 4.1.2, "Additional Functionality for Entity Objects."](#)

To create a business logic group:

1. In the Application Navigator, double-click the entity for which you want to create a business logic group.
2. In the overview editor, click the **General** navigation tab.
3. On the General page, expand the **Business Logic Groups** section, and click the **Add** icon.
4. In the creation dialog, select the appropriate group discriminator attribute and specify a name for the group.

Tip: To enhance the readability of your code, you can name the group to reflect the discriminator. For example, if the group discriminator attribute is `PersonTypeCode`, you can name the business logic group `PersonTypeCodeGroup`.

5. Click **OK**.

The new business logic group is added to the table in the overview editor. After you have created the group, you can add business logic units to it.

4.8.2 How to Create a Business Logic Unit

You can create a business logic unit from the New Gallery, or directly from the context menu of the entity that contains the business logic group.

Before you begin:

It may be helpful to have an understanding of how business logic groups are used. For more information, see [Section 4.8, "Defining Business Logic Groups."](#)

You may also find it helpful to understand additional functionality that can be added using other entity object features. For more information, see [Section 4.1.2, "Additional Functionality for Entity Objects."](#)

To create a business logic unit:

1. In the Application Navigator, right-click the entity that contains the business logic group and choose **New Entity Business Logic Unit** from the context menu.
2. In the Create Business Logic Unit dialog, specify the name of the base entity and select the appropriate business logic group.
3. Enter a name for the business logic unit.

The name of each business logic unit must reflect a valid value of the group discriminator attribute with which this business logic unit will be associated. For example, if the group discriminator attribute is `PersonTypeCode`, the name of the business logic unit associated with the `PersonTypeCode` value of `STAFF` must be `STAFF`.

4. Specify the package for the business logic unit.

Note: The package for the business logic unit does not need to be the same as the package for the base entity or the business logic group. This allows you to develop and deliver business logic units separately from the core application.

5. Click **OK**.

JDeveloper creates the business logic unit and opens it in the overview editor. The name displayed for the business logic unit in the Application Navigator contains the name of the entity object and business logic group in the format `EntityName_BusLogicGroupName_BusLogicUnitName`. For example, when you create a business logic unit with the name `CUST` in the `PersonTypeCodeGroup` business logic group of the `PersonEO` entity object, the displayed name of the business logic unit is `PersonEO_PersonTypeCodeGroup_CUST`.

After you have created the unit, you can redefine the business logic for it.

4.8.3 How to Add Logic to a Business Logic Unit

After you have created a business logic unit, you can open it in the overview editor and add business logic (such as adding an entity-level validator) just as you would in the base entity.

Before you begin:

It may be helpful to have an understanding of how business logic groups are used. For more information, see [Section 4.8, "Defining Business Logic Groups."](#)

You may also find it helpful to understand additional functionality that can be added using other entity object features. For more information, see [Section 4.1.2, "Additional Functionality for Entity Objects."](#)

To add an entity validator to a business logic unit:

1. In the Application Navigator, double-click the business logic unit.
2. In the overview editor, click the **Business Rules** navigation tab.
3. On the Business Rules page, select the Entity Validators node and click the **Add** icon.
4. Define your validation rule, and click **OK**.

For example, the `PersonEO` entity object in the StoreFront module of the Fusion Order Demo application has a business logic unit called `PersonEO_PersonTypeCodeGroup_CUST`. This business logic unit has an entity validator that checks for the presence of a phone number to ensure that all persons who are customers have a phone number.

4.8.4 How to Override Attributes in a Business Logic Unit

When you view the Attributes page for the business logic unit (in the overview editor), you can see that the **Extends** column in the attributes table shows that the attributes are "extended" in the business logic unit. Extended attributes are editable only in the base entity, not in the business logic unit. To implement changes in the business logic unit rather than the base entity, you must define attributes as overridden in the business logic unit before you edit them.

Before you begin:

It may be helpful to have an understanding of how business logic groups are used. For more information, see [Section 4.8, "Defining Business Logic Groups."](#)

You may also find it helpful to understand additional functionality that can be added using other entity object features. For more information, see [Section 4.1.2, "Additional Functionality for Entity Objects."](#)

To override attributes in a business logic unit:

1. In the Application Navigator, double-click the business logic unit.
2. In the overview editor, click the **Attributes** navigation tab.
3. On the Attributes page, select the desired attribute and click the **Override** button.

After you make an attribute overridden, you can edit the attribute as you normally would in the tabs below the table. You will notice that in an overridden attribute, you are limited to making modifications to only control hints, validators, and default values.

4.8.5 What Happens When You Create a Business Logic Group

When you create a business logic group, JDeveloper adds a reference to the group in the base entity's XML file. [Example 4-6](#) shows the code added to the base entity's XML file for the business logic group.

Example 4-6 XML Code in the Base Entity for a Business Logic Group

```
<BusLogicGroup
  Name="PersonTypeCodeGroup"
```

```
DiscrAttrName="PersonTypeCode"/>
```

When you create a business logic unit, JDeveloper generates an XML file similar to that of an entity object. [Example 4-7](#) shows XML code for a business logic unit.

Note: The package for the business logic unit does not need to be the same as the package for the base entity or the business logic group. This allows you to develop and deliver business logic units separately from the core application.

Example 4-7 XML Code for a Business Logic Unit

```
<Entity
  xmlns="http://xmlns.oracle.com/bc4j"
  Name="PersonEO_PersonTypeCodeGroup_CUST"
  Version="11.1.1.54.6"
  Extends="oracle.fodemo.storefront.entities.PersonEO"
  DBObjectType="table"
  DBObjectName="PERSONS"
  BindingStyle="OracleName"
  UseGlueCode="false"
  BusLogicGroupName="PersonTypeCodeGroup"
  BusLogicUnitName="CUST"
  xmlns:validation="http://xmlns.oracle.com/adfm/validation">
  <DesignTime>
    <Attr Name="_codeGenFlag2" Value="Access"/>
    <AttrArray Name="_publishEvents"/>
  </DesignTime>
  <validation:ExpressionValidationBean
    Name="PersonEO_PersonTypeCodeGroup_CUST_Rule_0"
    OperandType="EXPR"
    Inverse="false">
    <validation:MsgIds>
      <validation:Item
        Value="CUST_PHONE_REQUIRED"/>
    </validation:MsgIds>
    <validation:TransientExpression>
      <![CDATA[if (PhoneNumber == null && MobilePhoneNumber == null)
        return false;
        else return true;]]>
    </validation:TransientExpression>
  </validation:ExpressionValidationBean>
  <ResourceBundle>
    <PropertiesBundle
      PropertiesFile="oracle.fodemo.storefront.entities.common.PersonEO_
PersonTypeCodeGroup_CUSTMsgBundle"/>
    </ResourceBundle>
  </Entity>
```

4.8.6 What Happens at Runtime: Invoking a Business Logic Group

When a row is loaded in the application at runtime, the entity object decides which business logic units to apply to it.

The base entity maintains a list of business logic groups. Each group references the value of an attribute on the entity, and this value determines which business logic unit to load for that group. This evaluation is performed for each row that is loaded.

If the logic for determining which business logic unit to load is more complex than just a simple attribute value, you can create a transient attribute on the entity object, and use a Groovy expression to determine the value of the transient attribute.

4.9 Configuring Runtime Behavior Declaratively

Entity objects offer numerous declarative features to simplify implementing typical enterprise business applications. Depending on the task, sometimes the declarative facilities *alone* may satisfy your needs. The declarative runtime features that describe the basic persistence features of an entity object are covered in this section, while declarative validation and business rules are covered in [Chapter 7, "Defining Validation and Business Rules Declaratively."](#)

Note: It is possible to go beyond the declarative behavior to implement more complex business logic or validation rules for your business domain layer when needed. In [Chapter 8, "Implementing Validation and Business Rules Programmatically,"](#) you'll see some of the most typical ways that you extend entity objects with custom code.

Also, it is important to note as you develop your application that the business logic you implement, either programmatically or declaratively, should not assume that the attributes of an entity object or view row will be set in a particular order. This will cause problems if the end user enters values for the attributes in an order other than the assumed one.

4.9.1 How to Configure Declarative Runtime Behavior

To configure the declarative runtime behavior of an entity object, use the overview editor.

Before you begin:

It may be helpful to have an understanding of declarative configuration of runtime behavior. For more information, see [Section 4.9, "Configuring Runtime Behavior Declaratively."](#)

You may also find it helpful to understand additional functionality that can be added using other entity object features. For more information, see [Section 4.1.2, "Additional Functionality for Entity Objects."](#)

To configure the declarative runtime behavior of an entity object:

1. In the Application Navigator, double-click an entity object.
2. In the overview editor, click the **General** navigation tab to view the name and package of the entity object, and configure aspects of the object at the entity level, such as its associated schema, alternative keys, custom properties, and security.
 - The **Alternate Keys** section allows you to select entity object attributes mapped to the database that can serve as an alternative primary key. For information on alternative keys, see [Section 4.10.15, "How to Define Alternate Key Values."](#)
 - The **Tuning** section allows you to set options to make database operations more efficient when you create, modify, or delete multiple entities of the same

type in a single transaction. For more information, see [Section 4.9.3, "How to Use Update Batching."](#)

- The **Custom Properties** section allows you to define custom metadata that you can access at runtime on the entity.
 - The **Security** section allows you to define role-based updatability permissions for the entity. For more information, see [Chapter 35, "Enabling ADF Security in a Fusion Web Application."](#)
 - The **Business Logic Groups** section allows you to add and edit business logic groups. For more information, see [Section 4.8, "Defining Business Logic Groups."](#)
3. Click the **Attributes** navigation tab to create or delete attributes that represent the data relevant to an entity object, and configure aspects of the attribute, such as validation rules, custom properties, and security.

Select an attribute and click the **Edit** icon to access the properties of the attribute. For information on how to set these properties, see [Section 4.10, "Setting Attribute Properties."](#)

Tip: If your entity has a long list of attribute names, there's a quick way to find the one you're looking for. In the Structure window with the **Attributes** node expanded, you can begin to type the letters of the attribute name and JDeveloper performs an incremental search to take you to its name in the tree.

4. Click the **Business Rules** navigation tab to define declarative validators for the entity object and its attributes. For more information, see [Chapter 7, "Defining Validation and Business Rules Declaratively."](#)
5. Click the **Java** navigation tab to select the classes you generate for custom Java implementation. You can use the Java classes for such things as defining programmatic business rules, as in [Chapter 8, "Implementing Validation and Business Rules Programmatically."](#)
6. Click the **Business Events** navigation tab to define events that your entity object can use to notify others of interesting changes in its state, optionally including some or all of the entity object's attributes in the delivered event. For more information about business events, see [Section 4.12, "Creating Business Events."](#)
7. Click the **View Accessors** navigation tab to create and manage view accessors. For more information, see [Section 10.4.1, "How to Create a View Accessor for an Entity Object or View Object."](#)

4.9.2 What Happens When You Configure Declarative Runtime Behavior

The declarative settings that describe and control an entity object's runtime behavior are stored in its XML component definition file. When you use the overview editor to modify settings of your entity, JDeveloper updates the component's XML definition file and optional custom Java files.

4.9.3 How to Use Update Batching

You can use update batching to reduce the number of DML statements issued with multiple entity modifications.

By default, the ADF Business Components framework performs a single DML statement (INSERT, UPDATE, DELETE) for each modified entity of a given entity definition type. For example, say you have an Employee entity object type for which multiple instances are modified during typical use of the application. If two instances were created, three existing instances modified, and four existing instances deleted, then at transaction commit time the framework issues nine DML statements (2 INSERTS, 3 UPDATES, and 4 DELETES) to save these changes.

If you will frequently be updating more than one entity of a given type in a transaction, consider using the update batching feature for that entity definition type. In the example, update batching (with a threshold of 1) causes the framework to issue just three DML statements: one bulk INSERT statement processing two inserts, one bulk UPDATE statement processing three updates, and one bulk DELETE statement processing four deletes.

Note: If the entity object has any attributes that are set to **Refresh After Insert** or **Refresh After Update**, then the batch update feature is disabled.

Before you begin:

It may be helpful to have an understanding of the declarative configuration of runtime behavior. For more information, see [Section 4.9, "Configuring Runtime Behavior Declaratively."](#)

You may also find it useful to understand additional functionality that can be added using other entity object features. For more information, see [Section 4.1.2, "Additional Functionality for Entity Objects."](#)

To enable update batching for an entity

1. In the Application Navigator, double-click the appropriate entity.
2. In the overview editor, click the **General** navigation tab.
3. On the General page of the overview editor, expand the **Tuning** section, select the **Use Update Batching** checkbox, and specify the appropriate threshold.

This establishes a batch processing threshold beyond which Oracle ADF will process the modifications in a bulk DML operation.

4.10 Setting Attribute Properties

The declarative framework helps you set attribute properties easily. In all cases, you set these properties on the Attributes page of the overview editor.

4.10.1 How to Set Database and Java Data Types for an Entity Object Attribute

The **Persistent** property controls whether the attribute value corresponds to a column in the underlying table, or whether it is just a transient value. If the attribute is persistent, the **Database Column** area lets you change the name of the underlying column that corresponds to the attribute and indicate its column type with precision and scale information (e.g. VARCHAR2 (40) or NUMBER (4, 2)). Based on this information, at runtime the entity object enforces the maximum length and precision/scale of the attribute value, and throws an exception if a value does not meet the requirements.

Both the Business Components from Tables wizard and the Create Entity Object wizard infer the Java type of each entity object attribute from the SQL type of the database column type of the column to which it is related.

Note: The project's Type Map setting also plays a role in determining the Java data type. You specify the Type Map setting when you initialize your business components project, before any business components are created. For more information, see [Section 3.3.1, "Choosing a Connection, SQL Platform, and Data Type Map."](#)

The **Type** field (on the **Details** tab) allows you to change the Java type of the entity attribute to any type you might need. The **Column Type** field reflects the SQL type of the underlying database column to which the attribute is mapped. The value of the **Column Name** field controls the column to which the attribute is mapped.

Your entity object can handle tables with various column types, as listed in [Table 4-1](#). With the exception of the `java.lang.String` class, the default Java attribute types are all in the `oracle.jbo.domain` and `oracle.ord.im` packages and support efficiently working with Oracle database data of the corresponding type. The dropdown list for the **Type** field includes a number of other common Java types that are also supported.

Table 4-1 Default Entity Object Attribute Type Mappings

Oracle Column Type	Entity Column Type	Entity Java Type
NVARCHAR2 (n), VARCHAR2 (n), NCHAR VARYING (n), VARCHAR (n)	VARCHAR2	<code>java.lang.String</code>
NUMBER	NUMBER	<code>oracle.jbo.domain.Number</code>
DATE	DATE	<code>oracle.jbo.domain.Date</code>
TIMESTAMP (n), TIMESTAMP (n) WITH TIME ZONE, TIMESTAMP (n) WITH LOCAL TIME ZONE	TIMESTAMP	<code>java.sql.Timestamp</code>
LONG	LONG	<code>java.lang.String</code>
RAW (n)	RAW	<code>oracle.jbo.domain.Raw</code>
LONG RAW	LONG RAW	<code>oracle.jbo.domain.Raw</code>
ROWID	ROWID	<code>oracle.jbo.domain.RowID</code>
NCHAR, CHAR	CHAR	<code>oracle.jbo.domain.Char</code>
CLOB	CLOB	<code>oracle.jbo.domain.ClobDomain</code>
NCLOB	NCLOB	<code>oracle.jbo.domain.NClobDomain</code>
BLOB	BLOB	<code>oracle.jbo.domain.BlobDomain</code>
BFILE	BFILE	<code>oracle.jbo.domain.BFileDomain</code>
ORDSYS.ORDIMAGE	ORDSYS.ORDIMAGE	<code>oracle.ord.im.OrdImageDomain</code>
ORDSYS.ORDVIDEO	ORDSYS.ORDVIDEO	<code>oracle.ord.im.OrdVideoDomain</code>
ORDSYS.ORDAUDIO	ORDSYS.ORDAUDIO	<code>oracle.ord.im.OrdAudioDomain</code>
ORDSYS.ORDDOC	ORDSYS.ORDDOC	<code>oracle.ord.im.OrdDocDomain</code>

Note: In addition to the types mentioned here, you can use any Java object type as an entity object attribute's type, provided it implements the `java.io.Serializable` interface.

4.10.2 How to Indicate Data Type Length, Precision, and Scale

When working with types that support defining a maximum length like `VARCHAR2 (n)`, the **Column Type** field (on the **Details** tab) includes the maximum attribute length as part of the value. For example, an attribute based on a `VARCHAR2 (10)` column in the database will initially reflect the maximum length of 10 characters by showing `VARCHAR2 (10)` as the database column type. If for some reason you want to restrict the maximum length of the `String`-valued attribute to fewer characters than the underlying column will allow, just change the maximum length of the **Column Type** value.

For example, if the `EMAIL` column in the `PERSONS` table is `VARCHAR2 (50)`, then by default the `Email` attribute in the `Persons` entity object defaults to the same. But if you know that the actual email addresses are always 8 characters or fewer, you can update the database column type for the `Email` attribute to be `VARCHAR2 (8)` to enforce a maximum length of 8 characters at the entity object level.

The same holds for attributes related to database column types that support defining a precision and scale like `NUMBER (p [, s])`. For example, to restrict an attribute based on a `NUMBER (7, 2)` column in the database to instead have a precision of 5 and a scale of 1, just update the value of the **Column Type** field to be `NUMBER (5, 1)`.

4.10.3 How to Control the Updatability of an Attribute

The `Updatable` property controls when the value of a given attribute can be updated. You can select the following values:

- **Always**, the attribute is always updatable
- **Never**, the attribute is read-only
- **While New**, the attribute can be set during the transaction that creates the entity row for the first time, but after being successfully committed to the database the attribute is read-only

Note: In addition to the static declaration of updatability, you can also add custom code in the `isAttributeUpdateable()` method of the entity to determine the updatability of an attribute at runtime.

4.10.4 How to Make an Attribute Mandatory

Select the **Mandatory** checkbox if the field is required. The mandatory property is enforced during entity-level validation at runtime (and not when the attribute validators are run).

4.10.5 How to Define the Primary Key for the Entity

The `Primary Key` property indicates whether the attribute is part of the key that uniquely identifies the entity. Typically, you use a single attribute for the primary key, but multiattribute primary keys are fully supported.

At runtime, when you access the related `Key` object for any entity row using the `getKey()` method, this `Key` object contains the value of the primary key attribute for the entity object. If your entity object has multiple primary key attributes, the `Key` object contains each of their values. It is important to understand that these values appear in the same *relative* sequential order as the corresponding primary key attributes in the entity object definition.

For example, if the `OrderItemEO` entity object has multiple primary key attributes `OrderId` and `LineItemId`. On the Entity Attribute page of the overview editor, `OrderId` is first, and `LineItemId` is second. An array of values encapsulated by the `Key` object for an entity row of type `OrderItemEO` will have these two attribute values in exactly this order.

It is crucial to be aware of the order in which multiple primary key attributes appear on the Entity Attributes page. If you try to use `findByPrimaryKey()` to find an entity with a multiattribute primary key, and the `Key` object you construct has these multiple primary key attributes in the wrong order, the entity row will not be found as expected.

In addition, to populate the primary key in new rows, you might want to use a trigger to assign the value from the database. For more information, see [Section 4.10.10, "How to Get Trigger-Assigned Primary Key Values from a Database Sequence"](#)

4.10.6 How to Define a Static Default Value

The value field on the **Details** tab allows you to specify a static default value for the attribute when the value type is set to **Literal**. For example, you can set the default value of the `ServiceRequest` entity object's `Status` attribute to `Open`, or set the default value of the `User` entity object's `UserRole` attribute to `user`.

Note: When more than one attribute is defaulted for an entity object, the attributes are defaulted in the order in which they appear in the entity object's XML file.

4.10.7 How to Define a Default Value Using a Groovy Expression

You can use a Groovy expression to define a default value for an attribute. This approach is useful if you want to be able to change default values at runtime, but if the default value is always the same, the value is easier to see and maintain using a value field with the **Literal** type (on the **Details** tab). For general information about using Groovy, see [Section 3.6, "Overview of Groovy Scripting Language Support."](#)

Before you begin:

It may be helpful to have an understanding of how you set attribute properties. For more information, see [Section 4.10, "Setting Attribute Properties."](#)

You may also find it helpful to understand additional functionality that can be added using other entity object features. For more information, see [Section 4.1.2, "Additional Functionality for Entity Objects."](#)

To define a default value using a Groovy expression:

1. In the Application Navigator, double-click the desired entity object.
2. In the overview editor, click the **Attributes** navigation tab.
3. On the Attributes page, select the attribute you want to edit, and then click the **Details** tab.

4. Select **Expression** for the value type, and click the **Edit** icon (next to the value field).
5. Enter a Groovy expression in the field provided, and click **OK**.

4.10.8 What Happens When You Create a Default Value Using a Groovy expression

When you define a default value using a Groovy expression, a `<TransientExpression>` tag is added to the entity object's XML file within the appropriate attribute. [Example 4–8](#) shows sample XML code for a Groovy expression that returns the current date for a default value.

Example 4–8 Default Date Value

```
<TransientExpression>
  <![CDATA[
    adf.currentDate
  ]]>
</TransientExpression>
```

4.10.9 How to Synchronize with Trigger-Assigned Values

If you know that the underlying column value will be updated by a database trigger during insert or update operations, you can enable the respective **Refresh on Insert** or **Refresh on Update** checkboxes on the **Details** tab to ensure that the framework automatically retrieves the modified value and keeps the entity object and database row in sync. The entity object will use the Oracle SQL `RETURNING INTO` feature, while performing the `INSERT` or `UPDATE` to return the modified column back to your application in a single database roundtrip.

Note: If you create an entity object for a synonym that resolves to a remote table over a `DBLINK`, use of this feature will give an error at runtime like:

```
JBO-26041: Failed to post data to database during "Update"
## Detail 0 ##
ORA-22816: unsupported feature with RETURNING clause
```

[Section 4.18, "Basing an Entity Object on a Join View or Remote Dblink"](#) describes a technique to circumvent this database limitation.

4.10.10 How to Get Trigger-Assigned Primary Key Values from a Database Sequence

One common case for refreshing an attribute after insert occurs when a primary key attribute value is assigned by a `BEFORE INSERT FOR EACH ROW` trigger. Often the trigger assigns the primary key from a database sequence using PL/SQL logic. [Example 4–9](#) shows an example of this.

Example 4–9 PL/SQL Code Assigning a Primary Key from a Database Sequence

```
CREATE OR REPLACE TRIGGER ASSIGN_SVR_ID
BEFORE INSERT ON SERVICE_REQUESTS FOR EACH ROW
BEGIN
  IF :NEW.SVR_ID IS NULL OR :NEW.SVR_ID < 0 THEN
    SELECT SERVICE_REQUESTS_SEQ.NEXTVAL
    INTO :NEW.SVR_ID
    FROM DUAL;
```

```
END IF;  
END;
```

On the **Details** tab (on the Attributes page of the overview editor), you can set the value of the **Type** field to the built-in data type named `DBSequence`, and the primary key will be assigned automatically by the database sequence. Setting this data type automatically selects the **Refresh on Insert** checkbox.

Note: The sequence name shown on the **Sequence** tab is used only at design time when you use the **Create Database Tables** feature described in [Section 4.2.6, "How to Create Database Tables from Entity Objects."](#) The sequence indicated here will be created along with the table on which the entity object is based.

When you create a new entity row whose primary key is a `DBSequence`, a unique negative number is assigned as its temporary value. This value acts as the primary key for the duration of the transaction in which it is created. If you are creating a set of interrelated entities in the same transaction, you can assign this temporary value as a foreign key value on other new, related entity rows. At transaction commit time, the entity object issues its `INSERT` operation using the `RETURNING INTO` clause to retrieve the actual database trigger-assigned primary key value. In a composition relationship, any related new entities that previously used the temporary negative value as a foreign key will get that value updated to reflect the actual new primary key of the master.

You will typically also set the **Updatable** property of a `DBSequence`-valued primary key to **Never**. The entity object assigns the temporary ID, and then refreshes it with the actual ID value after the `INSERT` operation. The end user never needs to update this value.

For information on how to implement this functionality for an association that is not a composition, see [Section 4.14.7.3.3, "Associations Based on DBSequence-Valued Primary Keys."](#)

Note: For a metadata-driven alternative to the `DBSequence` approach, see [Section 4.14.5, "Assigning the Primary Key Value Using an Oracle Sequence."](#)

4.10.11 How to Protect Against Losing Simultaneously Updated Data

At runtime, the framework provides automatic "lost update" detection for entity objects to ensure that a user cannot unknowingly modify data that another user has updated and committed in the meantime. Typically, this check is performed by comparing the original values of each persistent entity attribute against the corresponding current column values in the database at the time the underlying row is locked. Before updating a row, the entity object verifies that the row to be updated is still consistent with the current state of the database. If the row and database state are inconsistent, then the entity object raises the `RowInconsistentException`.

You can make the lost update detection more efficient by identifying any attributes of your entity whose values you know will be updated whenever the entity is modified. Typical candidates include a version number column or an updated date column in the row. The change-indicator attribute's value might be assigned by a database trigger you've written and refreshed in the entity object, because you selected the **Refresh on Insert** or **Refresh on Update** option (on the **Details** tab). Alternatively, you can

indicate that the entity object should manage updating the change-indicator attribute's value using the history attribute feature described in [Section 4.10.12, "How to Track Created and Modified Dates Using the History Column."](#) To detect whether the row has been modified since the user queried it in the most efficient way, select the **Change Indicator** option to compare only the change-indicator attribute values.

4.10.12 How to Track Created and Modified Dates Using the History Column

If you need to keep track of historical information in your entity object, such as when an entity was created or modified and by whom, or the number of times the entity has been modified, you specify an attribute with the **Track Change History** option selected (on the **Details** tab).

If an attribute's data type is `Number`, `String`, or `Date`, and if it is not part of the primary key, then you can enable this property to have your entity automatically maintain the attribute's value for historical auditing. How the framework handles the attribute depends which type of history attribute you indicate:

- **Created On:** This attribute is populated with the time stamp of when the row was created. The time stamp is obtained from the database.
- **Created By:** The attribute is populated with the name of the user who created the row. The user name is obtained using the `getUserPrincipalName()` method on the `Session` object.
- **Modified On:** This attribute is populated with the time stamp whenever the row is updated/created.
- **Modified By:** This attribute is populated with the name of the user who creates or updates the row.
- **Version Number:** This attribute is populated with a long value that is incremented whenever a row is created or updated.

4.10.13 How to Configure Composition Behavior

An entity object exhibits composition behavior when it creates (or composes) other entities, such as an `OrderEO` entity creating a `OrderItemEO` entity. This additional runtime behavior determines its role as a logical container of other nested entity object parts.

Note: Composition also affects the order in which entities are validated. For more information, see [Section 7.2.3, "Understanding the Impact of Composition on Validation Order."](#)

The features that are always enabled for composing entity objects are described in the following sections:

- [Section 4.10.13.1, "Orphan-Row Protection for New Composed Entities"](#)
- [Section 4.10.13.2, "Ordering of Changes Saved to the Database"](#)
- [Section 4.10.13.3, "Cascade Update of Composed Details from Refresh-On-Insert Primary Keys"](#)

The additional features, and the properties that affect their behavior, are described in the following sections:

- [Section 4.10.13.4, "Cascade Delete Support"](#)

- [Section 4.10.13.5, "Cascade Update of Foreign Key Attributes When Primary Key Changes"](#)
- [Section 4.10.13.6, "Locking of Composite Parent Entities"](#)
- [Section 4.10.13.7, "Updating of Composing Parent History Attributes"](#)

4.10.13.1 Orphan-Row Protection for New Composed Entities

When a composed entity object is created, it performs an existence check on the value of its foreign key attribute to ensure that it identifies an existing entity as its owning parent entity. At create time, if no foreign key is found or else a value that does not identify an existing entity object is found, the entity object throws an `InvalidOwnerException` instead of allowing an orphaned child row to be created without a well-identified parent entity.

Note: The existence check finds new pending entities in the current transaction, as well as existing ones in the database if necessary.

4.10.13.2 Ordering of Changes Saved to the Database

Composition behavior ensures that the sequence of data manipulation language (DML) operations performed in a transaction involving both composing and composed entity objects is performed in the correct order. For example, an `INSERT` statement for a new composing parent entity object will be performed before the DML operations related to any composed children.

4.10.13.3 Cascade Update of Composed Details from Refresh-On-Insert Primary Keys

When a new entity row having a primary key configured to refresh on insert is saved, then after its trigger-assigned primary value is retrieved, any composed entities will have their foreign key attribute values updated to reflect the new primary key value.

There are a number of additional composition related features that you can control through settings on the Association Properties page of the Create Association wizard or the overview editor. [Figure 4–13](#) shows the Relationships page for the `OrderItemsOrdersFkAssoc` association between two entity objects: `OrderItemEO` and `OrderEO`.

4.10.13.4 Cascade Delete Support

You can either enable or prevent the deletion of a composing parent while composed children entities exist. When the **Implement Cascade Delete** option (see [Figure 4–13](#)) is deselected, the removal of the composing entity object is prevented if it contains any composed children.

Figure 4–13 Composition Settings on Relationship Page of Overview Editor for Associations

Behavior
Specify the behavioral aspects of this association.

- Use Database Key Constraints
- Composition Association
 - Optimize for Database Cascade Delete
 - Implement Cascade Delete
 - Cascade Update Key Attributes
 - Update Top-level History Columns
- Lock Level:
 - None
 - Lock Container
 - Lock Top-level Container
- Effective Dated Association

When selected, this option allows the composing entity object to be removed unconditionally together with any composed children entities. If the related **Optimize for Database Cascade Delete** option is deselected, then the composed entity objects perform their normal DELETE statement at transaction commit time to make the changes permanent. If the option is selected, then the composed entities do not perform the DELETE statement on the assumption that the database ON DELETE CASCADE constraint will handle the deletion of the corresponding rows.

4.10.13.5 Cascade Update of Foreign Key Attributes When Primary Key Changes

Select the **Cascade Update Key Attributes** option (see [Figure 4–13](#)) to enable the automatic update of the foreign key attribute values in composed entities when the primary key value of the composing entity is changed.

4.10.13.6 Locking of Composite Parent Entities

Select the **Lock Top-Level Container** option (see [Figure 4–13](#)) to control whether adding, removing, or modifying a composed detail entity row should attempt to lock the composing entity before allowing the changes to be saved.

4.10.13.7 Updating of Composing Parent History Attributes

Select the **Update Top-Level History Columns** option (see [Figure 4–13](#)) to control whether adding, removing, or modifying a composed detail entity object should update the **Modified By** and **Modified On** history attributes of the composing parent entity.

4.10.14 How to Set the Discriminator Attribute for Entity Object Inheritance Hierarchies

Sometimes a single database table stores information about several different kinds of logically related objects. For example, a payroll application might work with hourly, salaried, and contract employees all stored in a single EMPLOYEES table with an EMPLOYEE_TYPE column. In this case, the value of the EMPLOYEE_TYPE column contains values like H, S, or C to indicate respectively whether a given row represents an hourly, salaried, or contract employee. And while it is possible that many attributes and behavior are the same for all employees, certain properties and business logic may also depend on the type of employee.

In situations where common information exists across related objects, it may be convenient to represent these different types of entity objects using an inheritance hierarchy. For example, attributes and methods common to all employees can be part of a base Employee entity object, while subtype entity objects like HourlyEmployee, SalariedEmployee, and ContractEmployee extend the base Employee object and add additional properties and behavior. The **Discriminator** attribute setting is used to indicate which attribute's value distinguishes the type of row. [Section 4.19](#),

"[Using Inheritance in Your Business Domain Layer](#)," explains how to set up and use inheritance.

4.10.15 How to Define Alternate Key Values

Database primary keys are often generated from a sequence and may not be data you want to expose to the user for a variety of reasons. For this reason, it's often helpful to have alternate key values that are unique. For example, you might want to enforce that every customer have a unique email address. Because a customer may change their email address, you won't want to use that value as a primary key, but you still want the user to have a unique field they can use for login or other purposes.

Alternate keys are useful for direct row lookups via the `findByKey` class of methods. Alternate keys are frequently used for efficient uniqueness checks in the middle tier. For information on how to find out if a value is unique, see [Section 7.4.1, "How to Ensure That Key Values Are Unique."](#)

To define an alternate key, you use the Create Entity Constraint wizard.

Before you begin:

It may be helpful to have an understanding of how you set attribute properties. For more information, see [Section 4.10, "Setting Attribute Properties."](#)

You may also find it helpful to understand additional functionality that can be added using other entity object features. For more information, see [Section 4.1.2, "Additional Functionality for Entity Objects."](#)

To define alternate key values:

1. In the Application Navigator, right-click an entity object and choose **New Entity Constraint**.
2. Follow the steps in the Create Entity Constraint wizard to name your constraint and select the attribute or attributes that participate in the key.
3. On the Properties page, select **Alternate Key** and choose the appropriate **Key Properties** options.

For more information about the **Key Properties** options, press the F1 key or click **Help**.

4.10.16 What Happens When You Define Alternate Key Values

When you define alternate key values, a hash map is created for fast access to entities that are already in memory.

4.10.17 What You May Need to Know About Alternate Key Values

The Unique key constraint is used only for forward generation of `UNIQUE` constraints in the database, not for alternate key values.

4.11 Adding Transient and Calculated Attributes to an Entity Object

In addition to having attributes that map to columns in an underlying table, your entity objects can include transient attributes that display values calculated (for example, using Java or Groovy) or that are value holders. For example, a transient attribute you create, such as `FullName`, could be calculated based on the concatenated values of `FirstName` and `LastName` attributes.

Once you create the transient attribute, you can perform a calculation in the entity object Java class, or use a Groovy expression in the attribute definition to specify a default value.

If you want to be able to change the value at runtime, you can use a Groovy expression. If the calculated value is not likely to change (for example, if it's a sum of the line items), you can perform the calculation directly in the entity object Java class.

4.11.1 How to Add a Transient Attribute

Use the Attributes page of the overview editor to create a transient attribute.

Before you begin:

It may be helpful to have an understanding of the use of transient and calculated attributes. For more information, see [Section 4.11, "Adding Transient and Calculated Attributes to an Entity Object."](#)

You may also find it helpful to understand additional functionality that can be added using other entity object features. For more information, see [Section 4.1.2, "Additional Functionality for Entity Objects."](#)

To add a transient attribute to an entity object:

1. In the Application Navigator, double-click the entity object.
2. In the overview editor, click the **Attributes** navigation tab, and then click the **New** icon.
3. In the New Entity Attribute dialog, enter a name for the attribute and click **OK**.
4. On the Details tab (in the overview editor), set the Java attribute type and select the **Transient** option.
5. If the value will be calculated, set **Updatable** to **Never**.

4.11.2 What Happens When You Add a Transient Attribute

When you add a transient attribute, JDeveloper updates the XML component definition for the entity object to reflect the new attribute.

The `<Attribute>` tag of a transient attribute has no `TableName` and a `ColumnName` of `$none$`, as shown in [Example 4-10](#).

Example 4-10 XML Code for a Transient Attribute

```
<Attribute
  Name="FullName"
  IsUpdateable="false"
  IsQueryable="false"
  IsPersistent="false"
  ColumnName="$none$"
  Type="java.lang.String"
  ColumnType="$none$"
  SQLType="VARCHAR" >
</Attribute>
```

In contrast, a persistent entity attribute has both a `TableName` and a `ColumnName`, as shown in [Example 4-11](#).

Example 4–11 XML Code for a Persistent Attribute

```
<Attribute
  Name="FirstName"
  IsNotNull="true"
  Precision="30"
  ColumnName="FIRST_NAME"
  Type="java.lang.String"
  ColumnType="VARCHAR2"
  SQLType="VARCHAR"
  TableName="USERS" >
</Attribute>
```

4.11.3 How to Base a Transient Attribute on a Groovy Expression

When creating a transient attribute, you can use a Groovy expression to provide the default value.

Before you begin:

It may be helpful to have an understanding of transient and calculated attributes. For more information, see [Section 4.11, "Adding Transient and Calculated Attributes to an Entity Object."](#)

You may also find it helpful to understand additional functionality that can be added using other entity object features. For more information, see [Section 4.1.2, "Additional Functionality for Entity Objects."](#)

To create a transient attribute based on a Groovy expression:

1. In the Application Navigator, double-click the entity object.
2. In the overview editor, click the **Attributes** navigation tab, and then click the **New** icon.
3. In the New Entity Attribute dialog, enter a name for the attribute and click **OK**.
4. On the Details tab (in the overview editor), set the Java attribute type and select the **Transient** option.
5. If the value will be calculated, set **Updatable** to **Never**.
6. Select **Expression** for the default value type, and click the **Edit** button next to the value field.

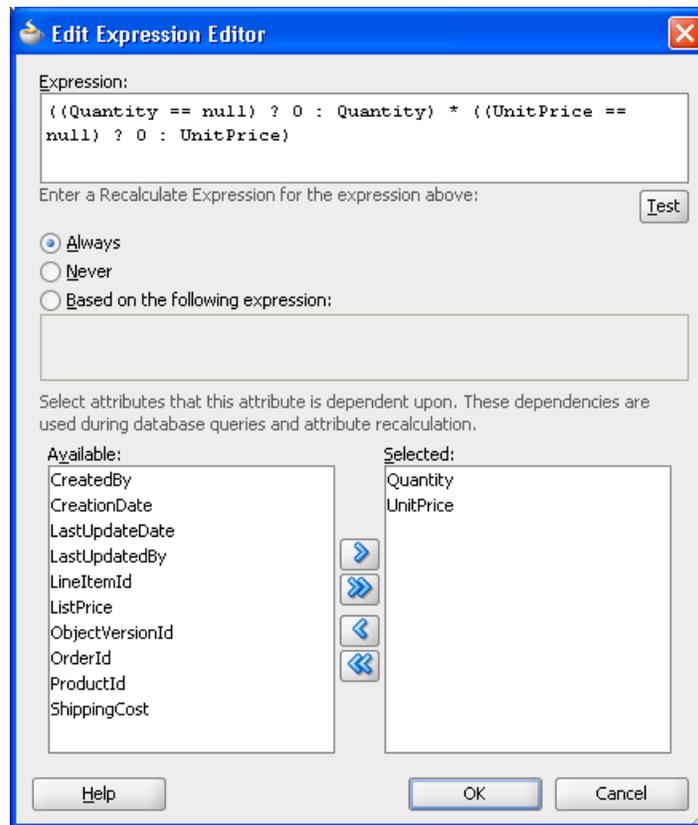

Expressions that you define are evaluated using the Groovy scripting language, as described in [Section 3.6, "Overview of Groovy Scripting Language Support."](#)

Groovy lets you insert expressions and variables into strings. The expression is saved as part of the entity object definition.

7. In the Edit Expression dialog, enter an expression in the field provided, as shown in [Figure 4–14](#).

Attributes that you reference can include any attribute that the entity object defines. Do not reference attributes in the expression that are not defined by the entity object.

Figure 4–14 Edit Expression Dialog

8. Select the appropriate recalculate setting.

If you select **Always** (default), the expression is evaluated each time any attribute in the row changes. If you select **Never**, the expression is evaluated only when the row is created.

9. You can optionally provide a condition for when to recalculate the expression.

For example, the following expression in the **Based on the following expression** field causes the attribute to be recalculated when either the `Quantity` attribute or the `UnitPrice` attribute are changed:

```
return (adf.object.isAttributeChanged("Quantity") ||
adf.object.isAttributeChanged("UnitPrice"));
```

10. You can also list attributes on which this attribute is dependent.

In [Figure 4–14](#), the `Quantity` and `UnitPrice` attributes are selected, which causes the attribute to be recalculated when either attribute is changed.

11. Click **OK** to save the expression.
12. Then click **OK** to create the attribute.

Note: If either the value expression or the optional recalculate expression that you define references an attribute from the base entity object, you must define this as a dependency on the **Dependencies** tab (on the **Attributes** page). On the **Dependencies** tab, locate the attributes in the **Available** list and shuttle each to the **Selected** list.

4.11.4 What Happens When You Base a Transient Attribute on a Groovy Expression

When you base a transient attribute on a Groovy expression, a `<TransientExpression>` tag is added to the entity object's XML file within the appropriate attribute, as shown in [Example 4-12](#).

Example 4-12 Calculating a Transient Attribute Using a Groovy Expression

```
<TransientExpression>
  <![CDATA[
    ((Quantity == null) ? 0 : Quantity) * ((UnitPrice == null) ? 0 : UnitPrice)
  ]]>
</TransientExpression>
```

4.11.5 How to Add Java Code in the Entity Class to Perform Calculation

A transient attribute is a placeholder for a data value. If you change the **Updatable** property of the transient attribute to **While New** or **Always**, then the end user can enter a value for the attribute. If you want the transient attribute to display a calculated value, then you'll typically leave the **Updatable** property set to **Never** and write custom Java code that calculates the value.

After adding a transient attribute to the entity object, to make it a *calculated* attribute you need to:

- Enable a custom entity object class on the Java page of the overview editor, choosing to generate accessor methods
- Write Java code inside the accessor method for the transient attribute to return the calculated value
- Specify each dependent attribute for the transient attribute on the **Dependencies** tab of the Attributes page

For example, after generating the view row class, the Java code to return the transient attribute's calculated value would reside in the getter method for the attribute (such as `FullName`), as shown in [Example 4-13](#).

Example 4-13 Getter Method for a Transient Attribute

```
// Getter method for FullName calculated attribute in UserImpl.java
public String getFullName() {
    // Commented out original line since we'll always calculate the value
    // return (String)getAttributeInternal(FULLNAME);
    return getFirstName()+" "+getLastName();
}
```

To ensure that the transient attribute is reevaluated whenever the attributes to be concatenated (such as `LastName` and `FirstName`) might be changed by the end user, specify the dependent attributes for the transient attribute. On the **Dependencies** tab of the Attributes page, locate the attributes in the **Available** list and shuttle each to the **Selected** list.

4.12 Creating Business Events

Business events raised from the model layer are useful for launching business processes and triggering external systems synchronization by way of the Oracle Mediator.

Oracle Mediator supports declarative subscriptions which map business events to actions. In other words, you can define and publish a business event (such as a new customer being created) in one component, and then subscribe to that event in another component so that a business process is notified when it occurs. You can then, in the subscribing component, proceed with an action you assign to that event (such as sending a welcome new customer email).

You declaratively define business events at the entity level. You may also specify conditions under which those events should be raised. Business events that meet the specified criteria are raised upon successful commit of the changed data. A business event is raised to the Mediator on a successful create, update, or delete of an entity object.

To implement a business event, you perform the following tasks:

1. Create an event definition, as described in [Section 4.12.4, "How to Create a Business Event."](#)
2. Map the event definition to an event point and publish the event definition, as described in [Section 4.12.7, "How to Publish a Business Event."](#)

After the business event is published, you can subscribe to the event from another component, as described in [Section 4.12.8, "How to Subscribe to Business Events."](#)

4.12.1 Introducing Event Definitions

An event definition describes an event that will be published and raised with an event system Mediator. An event definition is stored in an entity object's XML file with the elements shown in [Table 4-2](#).

Table 4-2 Event Definition Elements for Entity Objects

Element	Description
Event Name	Name of the event, for example, OrderUpdated
Payload	A list of attributes sent to the subscriber. Attributes marked as optional appear on payload only if changed.

4.12.2 Introducing Event Points

An event point is a place from which an event can be raised. On a successful commit, one of the event points shown in [Table 4-3](#) can be raised to the Mediator for each entity in a transaction.

Table 4-3 Example Event Points Raised to the Mediator

DML Type	Event Name	Event Description
CREATE	<i>EntityCreated</i>	A new <i>Entity</i> has been created.
UPDATE	<i>EntityUpdated</i>	An existing <i>Entity</i> has been updated.
DELETE	<i>EntityDeleted</i>	An existing <i>Entity</i> has been deleted.

Note that no events are raised by default; all events are custom. When you create the event, you can specify the name and DML operation appropriately.

For each event point, you must specify which event definitions should be raised on a particular event point. In other words, you must declaratively map each event definition to an event point.

4.12.3 What You May Need to Know About Event Points

Transactional event delivery, where event delivery is part of the transaction, is not supported by the framework.

Synchronous events, where the publisher waits for further processing until the subscriber has confirmed event reception, is not supported by the framework.

4.12.4 How to Create a Business Event

To create a business event, use the Business Events page of the overview editor.

Before you begin:

It may be helpful to have an understanding of how business events work. For more information, see [Section 4.12, "Creating Business Events."](#)

You may also find it helpful to understand additional functionality that can be added using other entity object features. For more information, see [Section 4.1.2, "Additional Functionality for Entity Objects."](#)

To create a business event:

1. In the Application Navigator, double-click an entity object.
2. In the overview editor, click the **Business Events** navigation tab.
3. On the Business Events page, expand the **Event Definitions** section and click the **New** icon.
4. In the Create Business Event Definition dialog, provide a name that describes this event, such as `EmployeeContactInfoChanged`.
5. In the payload table, click **New** and **Delete** to select the appropriate attributes for this event.

Alternatively, you can double-click the cell and pick the attributes you want.

Note: Only attributes of supported types are displayed in the Entity Attribute column. While `ClobDomain` attributes are supported, very large clob data can impact performance.

6. In the **Value Sent** field, choose whether the value should **Always** be sent, or **Only if changed**.

The **Only if changed** option provides the best performance because the attribute will be considered optional for the payload. If you leave the default **Always**, the payload will require the attribute whether or not the value has changed. For more details about payload efficiency, see [Section 4.12.6, "What You May Need to Know About Payload."](#)

7. Use the arrow buttons to rearrange the order of attributes.

The order that the attributes appear in defines their order in the generated XSD. Since you'll be using the XSD to build your Fabric mediator and BPEL process, you might want the most frequently accessed attributes at the top.

8. Click **OK**.

Repeat the procedure for each business event that you want to define. To publish an event, see [Section 4.12.7, "How to Publish a Business Event."](#)

4.12.5 What Happens When You Create a Business Event

When you create a business event, the entity object's XML file is updated with the event definition. [Example 4–14](#) shows an example of the XML code for a business event. JDeveloper also generates an associated XSD file for the event schema that allows specification of required attributes and optional attributes. Required attributes correspond to **Value Sent - Always** in the Create Business Event Definition dialog, whereas optional attributes are those for which you changed **Value Sent** to **Only if changed**.

Example 4–14 XML Code for a Business Event

```
<EventDef
  Name="CustBusEvent1">
  <Payload>
    <PayloadItem
      AttrName="Order.OrderId"/>
    <PayloadItem
      AttrName="LineItemId"/>
    <PayloadItem
      AttrName="ProductBase.ProductId"
      SendOnlyIfChanged="true"/>
  </Payload>
</EventDef>
```

[Example 4–15](#) shows an example of the XSD event schema for a business event.

Example 4–15 XSD Event Schema for a Business Event

```
<?xml version = '1.0' encoding = 'UTF-8'?>
<xs:schema
targetNamespace="/oracle/fodemo/storefront/entities/events/schema/OrderItemEO"
xmlns="/oracle/fodemo/storefront/entities/events/schema/OrderItemEO"
elementFormDefault="qualified" attributeFormDefault="unqualified"
xmlns:xs="http://www.w3.org/2001/XMLSchema">
  <xs:element name="CustBusEvent1Info">
    <xs:complexType>
      <xs:sequence>
        <xs:element name="Order.OrderId" type="DecimalValuePair" minOccurs="1"/>
        <xs:element name="LineItemId" type="DecimalValuePair" minOccurs="1"/>
        <xs:element name="ProductBase.ProductId" type="DecimalValuePair" minOccurs="0"/>
      </xs:sequence>
    </xs:complexType>
  </xs:element>
  <xs:complexType name="ValuePair" abstract="true"/>
  <xs:complexType name="DecimalValuePair">
    <xs:complexContent>
      <xs:extension base="ValuePair">
        <xs:sequence>
          <xs:element name="newValue" minOccurs="0">
            <xs:complexType>
              <xs:complexContent>
                <xs:extension base="xs:anyType">
                  <xs:attribute name="value" type="xs:decimal"/>
                </xs:extension>
              </xs:complexContent>
            </xs:complexType>
          </xs:element>
          <xs:element name="oldValue" minOccurs="0">
            <xs:complexType>
```

```

        <xs:complexContent>
            <xs:extension base="xs:anyType">
                <xs:attribute name="value" type="xs:decimal" />
            </xs:extension>
        </xs:complexContent>
    </xs:complexType>
</xs:element>
</xs:sequence>
</xs:extension>
</xs:complexContent>
</xs:complexType>
</xs:schema>

```

Example 4–16 shows an example of the EDL event definition for the entity object.

Example 4–16 EDL Event Definition for the Entity Object

```

<definitions
  targetNamespace="/oracle/fodemo/storefront/entities/events/edl/OrderItemEO"
  xmlns:ns0="/oracle/fodemo/storefront/entities/events/schema/OrderItemEO"
  xmlns="http://schemas.oracle.com/events/edl">
  <schema-import
    namespace="/oracle/fodemo/storefront/entities/events/schema/OrderItemEO"
    location="OrderItemEO.xsd" />
  <event-definition name="CustBusEvent1">
    <content element="ns0:CustBusEvent1Info" />
  </event-definition>
</definitions>

```

4.12.6 What You May Need to Know About Payload

The attributes of the associated entity object constitute the payload of a business event. The payload attributes for a business event are defined by the creator of the event. It isn't automatically optimized. When the event is defined, an attribute can be marked as sent **Always** or **Only if changed**. For events fired during creation, only new values are sent. For events fired during an update or delete, the new and old values are sent and only the attributes that should be based on the **Value Sent** setting. For best performance, you should include only the primary key attribute for delete events.

To support composition scenarios (such as a purchase order with line items), a child entity can raise events defined on the parent entity, and events defined on the child entity can include attributes from the parent entity. When a child entity raises an event on a parent entity, only a single event is raised for a particular top-level entity per transaction, regardless of how many times the child entity raises it.

In the case of entity subtypes (for example, a `Staff` entity object is a subtype of the `Persons` entity), ADF Business Components does not support the overriding of business events. Because the subscriber to a business event listens to the event using the event name, overriding of events could cause the event subscriber to receive payload data unintended for that subscriber. Therefore, this capability is not supported.

When defining business events, remember that while `ClobDomain` attributes are supported, very large clob data can have performance implications.

4.12.7 How to Publish a Business Event

To publish a business event, use the Business Events page of the entity objects overview editor.

Before you begin:

It may be helpful to have an understanding of how business events are used in the application. For more information, see [Section 4.12, "Creating Business Events."](#)

You may also find it helpful to understand additional functionality that can be added using other entity object features. For more information, see [Section 4.1.2, "Additional Functionality for Entity Objects."](#)

You need to have already created the event definition, as described in [Section 4.12.4, "How to Create a Business Event,"](#) before you can publish it.

To publish a business event:

1. In the Application Navigator, double-click an entity object.
2. In the overview editor, click the **Business Events** navigation tab.
3. On the Business Events page, expand the **Event Publication** section and click the **Edit event publications** icon.
4. In the Edit Event Publications dialog, click **New** to create a new event.
5. Double-click the new cell in **Event** column, and select the appropriate event.
6. Double-click the corresponding cell in **Event Point** column, and select the appropriate event point action.
7. You can optionally define conditions for raising the event using the **Raise Conditions** table.
8. Click **OK**.

4.12.8 How to Subscribe to Business Events

After you have created a business event, you can subscribe and respond to the event.

Before you begin:

It may be helpful to have an understanding of business events. For more information, see [Section 4.12, "Creating Business Events."](#)

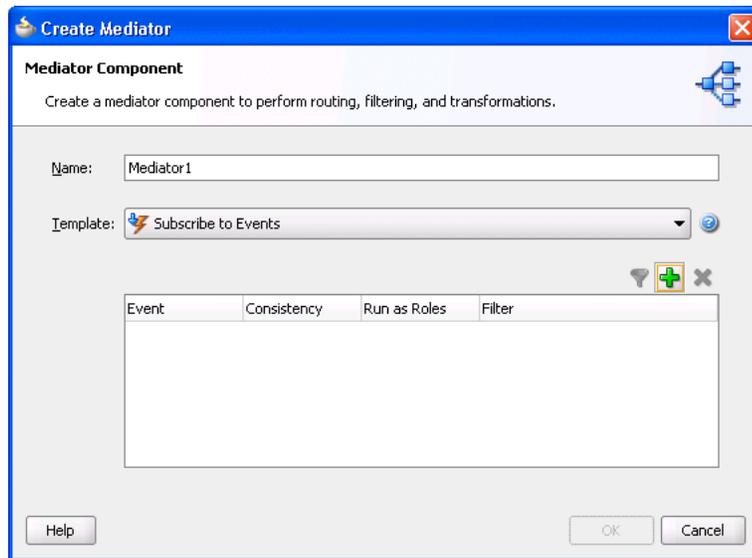

You may also find it helpful to understand additional functionality that can be added using other entity object features. For more information, see [Section 4.1.2, "Additional Functionality for Entity Objects."](#)

You will also need to complete the following tasks:

- Publish the business event, as described in [Section 4.12.7, "How to Publish a Business Event."](#)
- Open the SCA project that will subscribe to the business event.

To subscribe to a business event:

1. Using the file system, copy the XSD and event definition files for the business event into your SCA project's source path.
2. In the Application Navigator, right-click the project, and choose **New**.
3. In the New Gallery, expand **SOA Tier**, select **Service Components** and then **Mediator**, and click **OK**.
4. In the Create Mediator dialog, select the **Subscribe to Events** template, as shown in [Figure 4–15](#).

Figure 4–15 Create Mediator Dialog, Subscribe to Events

5. Click the **Add** icon to add an event.
6. In the Event Chooser dialog, click the **Browse** icon to navigate to and select the event's definition file, and then click **OK**.
7. In the Create Mediator dialog, you can optionally change the **Consistency** option and specify a **Filter** for the event.
8. Click **OK** to generate the mediator.

The resulting mediator (.mp1an file) is displayed in the overview editor.

9. You can now click the **Add** icon in the **Routing Rules** section to add a rule for how to respond to the event.

4.13 Generating Custom Java Classes for an Entity Object

As described in this chapter, all of the database interaction and a large amount of declarative runtime functionality of an entity object can be achieved without using custom Java code. When you need to go beyond the declarative features to implement custom business logic for your entities, you'll need to enable custom Java generation for the entities that require custom code. [Appendix D, "Most Commonly Used ADF Business Components Methods,"](#) provides a quick reference to the most common code that you will typically write, use, and override in your custom entity object and entity definition classes.

4.13.1 How to Generate Custom Classes

To enable the generation of custom Java classes for an entity object, use the Java page of the overview editor.

Before you begin:

It may be helpful to have an understanding of custom Java classes. For more information, see [Section 4.13, "Generating Custom Java Classes for an Entity Object."](#)

You may also find it helpful to understand additional functionality that can be added using other entity object features. For more information, see [Section 4.1.2, "Additional Functionality for Entity Objects."](#)

To generate a custom Java class for an entity object:

1. In the Application Navigator, double-click the entity.
2. In the overview editor, click the **Java** navigation tab, and then click the **Edit Java options** icon.
3. In the Select Java Options dialog, select the types of Java classes you want to generate.
 - Entity Object Class — the most frequently customized, it represents each row in the underlying database table.
 - Entity Collection Class — rarely customized.
 - Entity Definition Class — less frequently customized, it represents the related class that manages entity rows and defines their structure.
4. Click **OK**.

4.13.2 What Happens When You Generate Custom Classes

When you select one or more custom Java classes to generate, JDeveloper creates the Java file(s) you've indicated. For example, assuming an entity object named `fodemo.storefront.entities.OrderEO`, the default names for its custom Java files will be `OrderEOImpl.java` for the entity object class and `OrderEODefImpl.java` for the entity definition class. Both files are created in the same `./fodemo/storefront/entities` directory as the component's XML component definition file.

The Java generation options for the entity object continue to be reflected on subsequent visits to the Java page of the overview editor. Just as with the XML definition file, JDeveloper keeps the generated code in your custom Java classes up to date with any changes you make in the editor. If later you decide you didn't require a custom Java file for any reason, disabling the relevant options on the Java page causes the custom Java files to be removed.

4.13.3 What Happens When You Generate Entity Attribute Accessors

When you enable the generation of a custom entity object class, if you also enable the **Accessors** option, then JDeveloper generates getter and setter methods for each attribute in the entity object. For example, an `OrderEO` entity object that has the corresponding custom `OrderEOImpl.java` class might have methods (like those shown in [Example 4-17](#)) generated in it.

Example 4-17 Getter and Setter Methods from OrderEOImpl.java

```
public DBSequence getOrderId() { ... }
public void setOrderId(DBSequence value) { ... }

public Date getOrderDate() { ... }
public void setOrderDate(Date value) { ... }

public String getOrderStatusCode() { ... }
public void setOrderStatusCode(String value) { ... }

public Number getCustomerId() { ... }
```

```
public void setCustomerId(Number value) { ... }

public String getShipToName() { ... }
public void setShipToName(String value) { ... }
```

These methods allow you to work with the row data with compile-time checking of the correct data type usage. That is, instead of writing a line like this to get the value of the `CustomerId` attribute:

```
Number customerId = (Number)order.getAttribute("CustomerId");
```

you can write the code like:

```
Number customerId = order.getCustomerId();
```

You can see that with the latter approach, the Java compiler would catch a typographical error had you accidentally typed `CustomerCode` instead of `CustomerId`:

```
// spelling name wrong gives compile error
Number customerId = order.getCustomerCode();
```

Without the generated entity object accessor methods, an incorrect line of code like the following cannot be caught by the compiler:

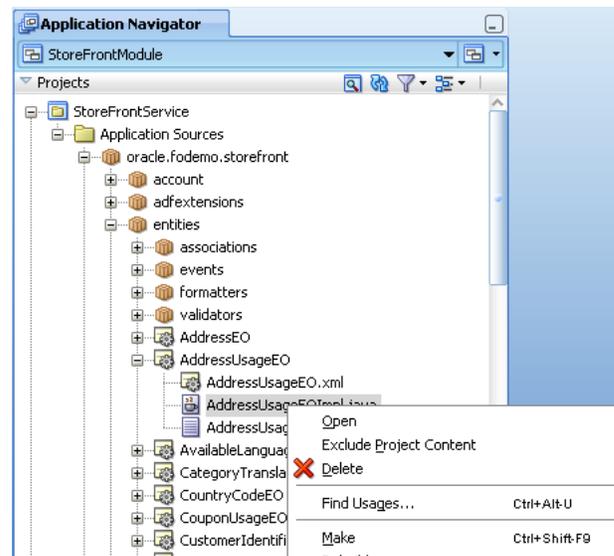

```
// Both attribute name and type cast are wrong, but compiler cannot catch it
String customerId = (String)order.getAttribute("CustomerCode");
```

It contains both an incorrectly spelled attribute name, as well as an incorrectly typed cast of the `getAttribute()` return value. When you use the generic APIs on the `Row` interface, which the base `EntityImpl` class implements, errors of this kind raise exceptions at runtime instead of being caught at compile time.

4.13.4 How to Navigate to Custom Java Files

As shown in [Figure 4-16](#), when you've enabled generation of custom Java classes, they also appear as child nodes under the **Application Sources** node for the entity object. As with all ADF components, when you select an entity object in the Application Navigator, the Structure window provides a structural view of the entity. When you need to see or work with the source code for a custom Java file, there are two ways to open the file in the source editor:

- You can right-click the Java file, and choose **Open**, as shown in [Figure 4-16](#).
- You can right-click an item in a node in the Structure window, and choose **Go To Source**.

Figure 4–16 Seeing and Navigating to Custom Java Classes for an Entity Object

4.13.5 What You May Need to Know About Custom Java Classes

The custom Java classes generated by JDeveloper extend the base classes for your entity object, and allow you the flexibility to implement custom code while maintaining the integrity of the generated code. The following sections provide additional information about custom Java classes.

4.13.5.1 Framework Base Classes for an Entity Object

When you use an XML-only entity object, at runtime its functionality is provided by the default ADF Business Components implementation classes. Each custom Java class that is generated extends the appropriate ADF Business Components base class so that your code inherits the default behavior and you can easily add to or customize it. An entity object class will extend `EntityImpl`, while the entity definition class will extend `EntityDefImpl` (both in the `oracle.jbo.server` package).

4.13.5.2 Safely Adding Code to the Custom Component File

Some developers are hesitant to add their own code to generated Java source files. Each custom Java source code file that JDeveloper creates and maintains for you includes the following comment at the top of the file to clarify that it is safe for you to add your own custom code to this file.

```
// -----
// --- File generated by Oracle ADF Business Components Design Time.
// --- Custom code may be added to this class.
// --- Warning: Do not modify method signatures of generated methods.
// -----
```

JDeveloper does not blindly regenerate the file when you click **OK** or **Apply** in an edit dialog. Instead, it performs a smart update to the methods that it needs to maintain, leaving your own custom code intact.

4.13.5.3 Configuring Default Java Generation Preferences

You can generate custom Java classes for your view objects when you need to customize their runtime behavior or when you simply prefer to have strongly typed access to bind variables or view row attributes.

To configure the default settings for ADF Business Components custom Java generation, you can choose **Preferences** from the **Tools** menu and open the Business Components page to set your preferences to be used for business components created in the future. Developers getting started with ADF Business Components should set their preference to generate no custom Java classes by default. As you run into a specific need for custom Java code, you can enable just the bit of custom Java you need for that one component. Over time, you'll discover which set of defaults works best for you.

4.13.5.4 Attribute Indexes and InvokeAccessor Generated Code

The entity object is designed to function based on XML only or as an XML component definition combined with a custom Java class. To support this design choice, attribute values are not stored in private member fields of an entity's class (a file that is not present in the XML-only situation). Instead, in addition to a name, attributes are also assigned a numerical index in the entity's XML component definition based on the zero-based, sequential order of the `<Attribute>` and association-related `<AccessorAttribute>` tags in that file. At runtime, attribute values in an entity row are stored in a sparse array structure managed by the base `EntityImpl` class, indexed by the attribute's numerical position in the entity's attribute list.

For the most part, this private implementation detail is unimportant, since as a developer using entity objects, you are shielded from having to understand this. However, when you enable a custom Java class for your entity object, this implementation detail relates to some of the generated code that JDeveloper maintains in your entity object class. It is sensible to understand what that code is used for. For example, in the custom Java class for a `OrderEO` entity object, each attribute or accessor attribute has a corresponding generated integer enum. JDeveloper ensures that the values of these enums correctly reflect the ordering of the attributes in the XML component definition.

You'll also notice that the automatically maintained, strongly typed getter and setter methods in the entity object class use these attribute enums, as shown in [Example 4-18](#).

Example 4-18 *Getter and Setter Methods Using Attribute Constants in the Custom Entity Java Class*

```
// In oracle.fodemo.storefront.entities.OrderEOImpl class
public Date getOrderDate() {
    return (Date)getAttributeInternal(ORDERDATE); // <-- Attribute enum
}
public void setOrderDate(Date value) {
    setAttributeInternal(ORDERDATE, value); // <-- Attribute enum
}
```

Another aspect of the maintained code related to entity attribute enums is the `getAttrInvokeAccessor()` and `setAttrInvokeAccessor()` methods. These methods optimize the performance of attribute access by numerical index, which is how generic code in the `EntityImpl` base class typically accesses attribute values when performing generic processing. An example of the `getAttrInvokeAccessor()` method is shown in [Example 4-19](#). The companion `setAttrInvokeAccessor()` method looks similar.

Example 4–19 `getAttrInvokeAccessor()` Method in the Custom Entity Java Class

```
// In oracle.fodemo.storefront.entities.OrderEOImpl class
/** getAttrInvokeAccessor: generated method. Do not modify. */
protected Object getAttrInvokeAccessor(int index, AttributeDefImpl attrDef)
    throws Exception {
    if ((index >= AttributesEnum.firstIndex()) && (index < AttributesEnum.count())) {
        return AttributesEnum.staticValues()[index - AttributesEnum.firstIndex()].get(this);
    }
    return super.getAttrInvokeAccessor(index, attrDef);
}
```

The rules of thumb to remember about this generated attribute index-related code are the following.

The Do's

- Add custom code if needed inside the strongly typed attribute getter and setter methods.
- Use the overview editor to change the order or type of entity object attributes.
JDeveloper changes the Java signature of getter and setter methods, as well as the related XML component definition for you.

The Don'ts

- Don't modify the `getAttrInvokeAccessor()` and `setAttrInvokeAccessor()` methods.
- Don't change the values of the attribute index numbers manually.

Note: If you need to manually edit the generated attribute enums because of source control merge conflicts or other reasons, you must ensure that the zero-based ordering reflects the sequential ordering of the `<Attribute>` and `<AccessorAttribute>` tags in the corresponding entity object XML component definition.

4.13.6 Programmatic Example for Comparison Using Custom Entity Classes

To better evaluate the difference between using custom generated entity classes and working with the generic `EntityImpl` class, [Example 4–20](#) shows a version of methods in a custom entity class (`StoreFrontServiceImpl.java`) from a custom application module class (`StoreFrontService2Impl.java`). Some important differences to notice are:

- Attribute access is performed using strongly typed attribute accessors.
- Association accessor attributes return the strongly typed entity class on the other side of the association.
- Using the `getDefinitionObject()` method in your custom entity class allows you to avoid working with fully qualified entity definition names as strings.
- The `createPrimaryKey()` method in your custom entity class simplifies creating the `Key` object for an entity.

Example 4–20 Programmatic Entity Examples Using Strongly Typed Custom Entity Object Classes

```
package devguide.examples.apmodules;

import oracle.fodemo.storefront.entities.OrderEOImpl;
```

```

import oracle.fodemo.storefront.entities.PersonEOImpl;
import oracle.fodemo.storefront.entities.ProductBaseEOImpl;

import oracle.jbo.ApplicationModule;
import oracle.jbo.JboException;
import oracle.jbo.Key;
import oracle.jbo.client.Configuration;
import oracle.jbo.domain.DBSequence;
import oracle.jbo.domain.Number;
import oracle.jbo.server.ApplicationModuleImpl;
import oracle.jbo.server.EntityDefImpl;

// -----
// ---      File generated by Oracle ADF Business Components Design Time.
// ---      Custom code may be added to this class.
// ---      Warning: Do not modify method signatures of generated methods.
// -----
/**
 * This custom application module class illustrates the same
 * example methods as StoreFrontServiceImpl.java, except that here
 * we're using the strongly typed custom Entity Java classes
 * OrderEOImpl, PersonsEOImpl, and ProductsBaseEOImpl instead of working
 * with all the entity objects using the base EntityImpl class.
 */

public class StoreFrontService2Impl extends ApplicationModuleImpl {
    /**This is the default constructor (do not remove).
    */
    public StoreFrontService2Impl() {
    }
    /**
    * Helper method to return an Order by Id
    */
    private OrderEOImpl retrieveOrderById(long orderId) {
        EntityDefImpl orderDef = OrderEOImpl.getDefinitionObject();
        Key orderKey = OrderEOImpl.createPrimaryKey(new DBSequence(orderId));
        return (OrderEOImpl)orderDef.findByPrimaryKey(getDBTransaction(),orderKey);
    }

    /**
    * Find an Order by Id
    */
    public String findOrderTotal(long orderId) {
        OrderEOImpl order = retrieveOrderById(orderId);
        if (order != null) {
            return order.getOrderTotal().toString();
        }
        return null;
    }

    /**
    * Create a new Product and Return its new id
    */
    public long createProduct(String name, String status, String shipCode) {
        EntityDefImpl productDef = ProductBaseEOImpl.getDefinitionObject();
        ProductBaseEOImpl newProduct =
        (ProductBaseEOImpl)productDef.createInstance2(getDBTransaction(),null);
        newProduct.setProductName(name);
        newProduct.setProductStatus(status);
    }
}

```

```

        newProduct.setShippingClassCode(shipCode);
        newProduct.setSupplierId(new Number(100));
        newProduct.setListPrice(new Number(499));
        newProduct.setMinPrice(new Number(479));
        newProduct.setCreatedBy("Test Client");
        newProduct.setLastUpdatedBy("Test Client");
        newProduct.setCategoryId(new Number(5));
    try {
        getDBTransaction().commit();
    }
    catch (JboException ex) {
        getDBTransaction().rollback();
        throw ex;
    }
    DBSequence newIdAssigned = newProduct.getProductId();
    return newIdAssigned.getSequenceNumber().longValue();
}
/*
 * Update the status of an existing order
 */
public void updateRequestStatus(long orderId, String newStatus) {
    OrderEOImpl order = retrieveOrderById(orderId);
    if (order != null) {
        order.setOrderStatusCode(newStatus);
        try {
            getDBTransaction().commit();
        }
        catch (JboException ex) {
            getDBTransaction().rollback();
            throw ex;
        }
    }
}

/*
 * Access an associated Customer entity from the Order entity
 */
public String findOrderCustomer(long orderId) {
    OrderEOImpl svcReq = retrieveOrderById(orderId);
    if (svcReq != null) {
        PersonEOImpl cust = (PersonEOImpl)svcReq.getPerson();
        if (cust != null) {
            return cust.getFirstName() + " " + cust.getLastName();
        }
        else {
            return "Unassigned";
        }
    }
    else {
        return null;
    }
}

/*
 * Testing method
 */
public static void main(String[] args) {
    String      amDef = "devguide.model.StoreFrontService";
    String      config = "StoreFrontServiceLocal";
    ApplicationModule am =

```

```

Configuration.createRootApplicationModule(amDef,config);
    /*
     * NOTE: This cast to use the StoreFrontServiceImpl class is OK since
     * this code is inside a business tier *Impl.java file and not in a
     * client class that is accessing the business tier from "outside".
     */
    StoreFrontServiceImpl service = (StoreFrontServiceImpl)am;
    String total = service.findOrderTotal(1011);
    System.out.println("Status of Order # 1011 = " + total);
    String customerName = service.findOrderCustomer(1011);
    System.out.println("Customer for Order # 1011 = " + customerName);
    try {
        service.updateOrderStatus(1011,"CANCEL");
    }
    catch (JboException ex) {
        System.out.println("ERROR: "+ex.getMessage());
    }
    long id = 0;
    try {
        id = service.createProduct(null, "NEW", "CLASS1");
    }
    catch (JboException ex) {
        System.out.println("ERROR: "+ex.getMessage());
    }
    id = service.createProduct("Canon PowerShot G9", "NEW", "CLASS1");
    System.out.println("New product created successfully with id = "+id);
    Configuration.releaseRootApplicationModule(am,true);
}
}

```

4.14 Working Programmatically with Entity Objects and Associations

You may not always need or want UI-based or programmatic clients to work directly with entity objects. Sometimes, you may just want to use an external client program to access an application module and work directly with the view objects in its data model. [Chapter 5, "Defining SQL Queries Using View Objects"](#) describes how to easily combine the flexible SQL-querying of view objects with the business logic enforcement and automatic database interaction of entity objects to build powerful applications. The combination enables a fully updatable application module data model, designed to meet the needs of the current end-user tasks at hand, that shares the centralized business logic in your reusable domain business object layer.

However, it is important first to understand how view objects and entity objects can be used on their own before learning to harness their combined power. By learning about these objects in greater detail, you will have a better understanding of when you should use them alone and when to combine them in your own applications.

Since clients don't work *directly* with entity objects, any code you write that works programmatically with entity objects will typically be custom code in a custom application module class or in the custom class of another entity object.

4.14.1 How to Find an Entity Object by Primary Key

To access an entity row, you use a related object called the *entity definition*. At runtime, each entity object has a corresponding entity definition object that describes the structure of the entity and manages the instances of the entity object it describes. After creating an application module and enabling a custom Java class for it, imagine you

wanted to write a method to return a specific order. It might look like the `retrieveOrderById()` method shown in [Example 4–21](#).

Before you begin:

It may be helpful to have an understanding of when to use a programmatic approach for working with entity objects and associations. For more information, see [Section 4.14, "Working Programmatically with Entity Objects and Associations."](#)

You may also find it helpful to understand additional functionality that can be added using other entity object features. For more information, see [Section 4.1.2, "Additional Functionality for Entity Objects."](#)

To find an entity object by primary key:

1. Find the entity definition.

You obtain the entity definition for an entity object (for example, `OrderEO`) by passing its fully qualified name to the static `getDefinitionObject()` method imported from the `EntityDefImpl` class. The `EntityDefImpl` class in the `oracle.jbo.server` package implements the entity definition for each entity object.

2. Construct a key.

You build a `Key` object containing the primary key attribute that you want to look up. For example, for the `OrderEO` entity object you create a key containing the single `orderId` value passed into the method as an argument.

3. Find the entity object using the key.

You use the entity definition's `findByPrimaryKey()` method to find the entity object by key, passing in the current transaction object, which you can obtain from the application module using its `getDBTransaction()` method. The concrete class that represents an entity object row is the `oracle.jbo.server.EntityImpl` class.

4. Return the object or some of its data to the caller.

[Example 4–21](#) show example code for a `retrieveOrderById()` method developed using this basic procedure.

Example 4–21 Retrieving an OrderEO Entity Object by Key

```
/* Helper method to return an Order by Id */
private OrderEOImpl retrieveOrderById(long orderId) {
    EntityDefImpl orderDef = OrderEOImpl.getDefinitionObject();
    Key orderKey = OrderEOImpl.createPrimaryKey(new DBSequence(orderId));
    return (OrderEOImpl)orderDef.findByPrimaryKey(getDBTransaction(), orderKey);
}
```

Note: The `oracle.jbo.Key` object constructor can also take an `Object` array to support creating multiattribute keys, in addition to the more typical single-attribute value keys.

4.14.2 How to Access an Associated Entity Using the Accessor Attribute

You can create a method to access an associated entity based on an accessor attribute that requires no SQL code. For example, the method `findOrderCustomer()` might find an order, then access the associated `PersonEO` entity object representing the customer assigned to the order. For an explanation of how associations enable easy

access from one entity object to another, see [Section 4.3, "Creating and Configuring Associations."](#)

To prevent a conflict with an existing method in the application module that finds the same associated entity using the same accessor attribute, you can refactor this functionality into a helper method that you can then reuse anywhere in the application module it is required. For example, the `retrieveOrderById()` method (shown in [Example 4–21](#)) refactors the functionality that finds an order.

Before you begin:

It may be helpful to have an understanding of when to use a programmatic approach for working with entity objects and associations. For more information, see [Section 4.14, "Working Programmatically with Entity Objects and Associations."](#)

You may also find it helpful to understand additional functionality that can be added using other entity object features. For more information, see [Section 4.1.2, "Additional Functionality for Entity Objects."](#)

To access an associated entity object using the accessor attribute:

1. Find the associated entity by the accessor attribute.

For example, the `findOrderCustomer()` method uses the `retrieveOrderById()` helper method to retrieve the `OrderEO` entity object by ID.

2. Access the associated entity using the accessor attribute.

Using the attribute getter method, you can pass in the name of an association accessor and get back the entity object on the other side of the relationship. (Note that [Section 4.3.3, "How to Change Entity Association Accessor Names,"](#) explains that renaming the association accessor allows it to have a more intuitive name.)

3. Return some of its data to the caller.

For example, the `findOrderCustomer()` method uses the getter methods on the returned `PersonEO` entity to return the assigned customer's name by concatenating their first and last names.

Notice that you did not need to write any SQL to access the related `PersonEO` entity. The relationship information captured in the ADF association between the `OrderEO` and `PersonEO` entity objects is enough to allow the common task of data navigation to be automated.

[Example 4–22](#) shows the code for `findOrderCustomer()` that uses the helper method.

Example 4–22 Accessing an Associated Entity Using the Accessor Attribute

```
/* Access an associated Customer entity from the Order entity */
public String findOrderCustomer(long orderId) {
    //1. Find the OrderEO object
    OrderEOImpl order = retrieveOrderById(orderId);
    if (order != null) {
        //2. Access the PersonEO object using the association accessor attribute
        PersonEOImpl cust = (PersonEOImpl)order.getPerson();
        if (cust != null) {
            //3. Return attribute values from the associated entity object
            return cust.getFirstName() + " " + cust.getLastName();
        }
    }
    else {
        return "Unassigned";
    }
}
```

```

    }
  }
  else {
    return null;
  }
}

```

4.14.3 How to Update or Remove an Existing Entity Row

Once you've got an entity row in hand, it's simple to update it or remove it. You could add a method like the `updateOrderStatus()` shown in [Example 4-23](#) to handle the job.

Before you begin:

It may be helpful to have an understanding of when to use a programmatic approach for working with entity objects and associations. For more information, see [Section 4.14, "Working Programmatically with Entity Objects and Associations."](#)

You may also find it helpful to understand additional functionality that can be added using other entity object features. For more information, see [Section 4.1.2, "Additional Functionality for Entity Objects."](#)

To update an entity row:

1. Find the Order by ID.

Using the `retrieveOrderById()` helper method, the `updateOrderStatus()` method retrieves the `OrderEO` entity object by ID.

2. Set one or more attributes to new values.

Using the `EntityImpl` class' `setAttribute()` method, the `updateOrderStatus()` method updates the value of the `Status` attribute to the new value passed in.

3. Commit the transaction.

Using the application module's `getDBTransaction()` method, the `updateOrderStatus()` method accesses the current transaction object and calls its `commit()` method to commit the transaction.

Example 4-23 Updating an Existing Entity Row

```

/* Update the status of an existing order */
public void updateOrderStatus(long orderId, String newStatus) {
    //1. Find the order
    OrderEOImpl order = retrieveOrderById(orderId);
    if (order != null) {
        //2. Set its Status attribute to a new value
        order.setOrderStatusCode(newStatus);
        //3. Commit the transaction
        try {
            getDBTransaction().commit();
        }
        catch (JboException ex) {
            getDBTransaction().rollback();
            throw ex;
        }
    }
}
}

```

The example for *removing* an entity row would be the same, except that after finding the existing entity, you would use the following line instead to remove the entity before committing the transaction:

```
// Remove the entity instead!  
order.remove();
```

4.14.4 How to Create a New Entity Row

In addition to using the entity definition to find existing entity rows, you can also use it to create new ones. In the case of product entities, you could write a `createProduct()` method like the one shown in [Example 4-24](#) to accept the name and description of a new product, and return the new product ID assigned to it. This example assumes that the `ProductId` attribute of the `ProductBaseEO` entity object has been updated to have the `DBSequence` type (see [Section 4.10.10, "How to Get Trigger-Assigned Primary Key Values from a Database Sequence"](#)). This setting ensures that the attribute value is refreshed to reflect the value of the trigger from the corresponding database table, assigned to it from the table's sequence in the application schema.

Before you begin:

It may be helpful to have an understanding of when to use a programmatic approach for working with entity objects and associations. For more information, see [Section 4.14, "Working Programmatically with Entity Objects and Associations."](#)

You may also find it helpful to understand additional functionality that can be added using other entity object features. For more information, see [Section 4.1.2, "Additional Functionality for Entity Objects."](#)

To create an entity row:

1. Find the entity definition.

Using the `getDefinitionObject()` method, the `createProduct()` method finds the entity definition for the `Product` entity.

2. Create a new instance.

Using the `createInstance2()` method on the entity definition, the `createProduct()` method creates a new instance of the entity object.

Note: The method name has a 2 at the end. The regular `createInstance()` method has protected access and is designed to be customized as described [Section D.3.4, "EntityImpl Class"](#) of [Appendix D, "Most Commonly Used ADF Business Components Methods."](#) The second argument of type `AttributeList` is used to supply attribute values that *must* be supplied at create time; it is *not* used to initialize the values of all attributes found in the list. For example, when creating a new instance of a composed child entity row using this API, you must supply the value of a composing parent entity's foreign key attribute in the `AttributeList` object passed as the second argument. Failure to do so results in an `InvalidOwnerException`.

3. Set attribute values.

Using the attribute setter methods on the entity object, the `createProduct()` method assigns values for the `Name`, `Status`, and other attributes in the new entity row.

4. Commit the transaction.

Calling `commit()` on the current transaction object, the `createProduct()` method commits the transaction.

5. Return the trigger-assigned product ID to the caller.

Using the attribute getter method to retrieve the value of the `ProductId` attribute as a `DBSequence`, and then calling `getSequenceNumber().longValue()`, the `createProduct()` method returns the sequence number as a long value to the caller.

Example 4–24 Creating a New Entity Row

```

/* Create a new Product and Return its new id */
public long createProduct(String name, String status, String shipCode) {
    //1. Find the entity definition for the Product entity
    EntityDefImpl productDef = ProductBaseEOImpl.getDefinitionObject();
    //2. Create a new instance of a Product entity
    ProductBaseEOImpl newProduct =
(ProductBaseEOImpl)productDef.createInstance2(getDBTransaction(),null);
    //3. Set attribute values
    newProduct.setProductName(name);
    newProduct.setProductStatus(status);
    newProduct.setShippingClassCode(shipCode);
    newProduct.setSupplierId(new Number(100));
    newProduct.setListPrice(new Number(499));
    newProduct.setMinPrice(new Number(479));
    newProduct.setCreatedBy("Test Client");
    newProduct.setLastUpdatedBy("Test Client");
    newProduct.setCategoryId(new Number(5));
    //4. Commit the transaction
    try {
        getDBTransaction().commit();
    }
    catch (JboException ex) {
        getDBTransaction().rollback();
        throw ex;
    }
    //5. Access the database-trigger-assigned ProductId value and return it
    DBSequence newIdAssigned = newProduct.getProductId();
    return newIdAssigned.getSequenceNumber().longValue();
}

```

4.14.5 Assigning the Primary Key Value Using an Oracle Sequence

As an alternative to using a trigger-assigned value (as described in [Section 4.10.10, "How to Get Trigger-Assigned Primary Key Values from a Database Sequence"](#)), you can assign the value to a primary key when creating a new row using an Oracle sequence. This metadata-driven approach allows you to centralize the code to retrieve the primary key into a single Java file that can be reused by multiple entity objects.

[Example 4–25](#) shows a simple `CustomEntityImpl` framework extension class on which the entity objects are based. Its overridden `create()` method tests for the presence of a custom attribute-level metadata property named `SequenceName` and if

detected, populates the attribute's default value from the next number in that sequence.

Example 4–25 CustomEntityImpl Framework Extension Class

```
package sample;

import oracle.jbo.AttributeDef;
import oracle.jbo.AttributeList;
import oracle.jbo.server.EntityImpl;
import oracle.jbo.server.SequenceImpl;

public class CustomEntityImpl extends EntityImpl {
    protected void create(AttributeList attributeList) {
        super.create(attributeList);
        for (AttributeDef def : getEntityDef().getAttributeDefs()) {
            String sequenceName = (String)def.getProperty("SequenceName");
            if (sequenceName != null) {
                SequenceImpl s = new SequenceImpl(sequenceName, getDBTransaction());
                setAttribute(def.getIndex(), s.getSequenceNumber());
            }
        }
    }
}
```

Before you begin:

It may be helpful to have an understanding of when to use a programmatic approach for working with entity objects and associations. For more information, see [Section 4.14, "Working Programmatically with Entity Objects and Associations."](#)

You may also find it helpful to understand additional functionality that can be added using other entity object features. For more information, see [Section 4.1.2, "Additional Functionality for Entity Objects."](#)

To assign the primary key value using an Oracle sequence:

1. Create the `CustomEntityImpl.java` file in your project, and insert the code shown in [Example 4–25](#).
2. In the Application Navigator, double-click the entity you want to edit.
3. In the overview editor, click the **Attributes** navigation tab, and select the attribute you want to edit.
4. Click the **Details** tab, and set the attribute **Type** to **Number**.
5. Click the **Custom Properties** tab, and click the **Add** icon.
6. Create a custom property with `SequenceName` for the name, and the name of the database sequence for the value.

For example, for a `Dept` entity, you could define the custom property `SequenceName` on its `Deptno` attribute with the value `DEPT_TABLE_SEQ`.

4.14.6 How to Update a Deleted Flag Instead of Deleting Rows

For auditing purposes, once a row is added to a table, sometimes your requirements may demand that rows never be physically deleted from the table. Instead, when the end user deletes the row in the user interface, the value of a `DELETED` column should be updated from "N" to "Y" to mark it as deleted. You can use two method overrides to alter an entity object's default behavior to achieve this effect.

To accomplish this, you need to perform the following tasks:

- Update a deleted flag when a row is removed, as described in [Section 4.14.6.1, "Updating a Deleted Flag When a Row Is Removed."](#)
- Force the entity object to be updated instead of deleted, as described in [Section 4.14.6.2, "Forcing an Update DML Operation Instead of a Delete."](#)

4.14.6.1 Updating a Deleted Flag When a Row Is Removed

To update a deleted flag when a row is removed, enable a custom Java class for your entity object and override the `remove()` method to set the deleted flag before calling the `super.remove()` method. [Example 4-26](#) shows what this would look like in the custom Java class of an entity object. It is important to set the attribute *before* calling `super.remove()` since an attempt to set the attribute of a deleted row will encounter the `DeadEntityAccessException`.

This example presumes that you've altered the table to have an additional `DELETED` column, and synchronized the entity object with the database to add the corresponding `Deleted` attribute.

Example 4-26 *Updating a Deleted Flag When an Entity Row Is Removed*

```
// In your custom Java entity class
public void remove() {
    setDeleted("Y");
    super.remove();
}
```

The row will still be removed from the row set, but it will have the value of its `Deleted` flag modified to "Y" in the entity cache. The second part of implementing this behavior involves forcing the entity to perform an `UPDATE` instead of an `DELETE` when it is asked to perform its DML operation. You need to implement both parts for a complete solution.

4.14.6.2 Forcing an Update DML Operation Instead of a Delete

To force an entity object to be updated instead of deleted, override the `doDML()` method and write code that conditionally changes the `operation` flag. When the operation flag equals `DML_DELETE`, your code will change it to `DML_UPDATE` instead. [Example 4-27](#) shows what this would look like in the custom Java class of an entity object.

This example presumes that you've altered the table to have an additional `DELETED` column, and synchronized the entity object with the database to add the corresponding `Deleted` attribute.

Example 4-27 *Forcing an Update DML Operation Instead of a Delete*

```
// In your custom Java entity class
protected void doDML(int operation, TransactionEvent e) {
    if (operation == DML_DELETE) {
        operation = DML_UPDATE;
    }
    super.doDML(operation, e);
}
```

With this overridden `doDML()` method in place to complement the overridden `remove()` method described in [Section 4.14.6.1](#), any attempt to remove an entity through any view object with a corresponding entity usage will update the `DELETED`

column instead of physically deleting the row. Of course, in order to prevent "deleted" products from appearing in your view object query results, you will need to appropriately modify their `WHERE` clauses to include only products `WHERE DELETED = 'N'`.

4.14.7 How to Control Entity Posting Order to Prevent Constraint Violations

Due to database constraints, when you perform DML operations to save changes to a number of related entity objects in the same transaction, the order in which the operations are performed can be significant. If you try to insert a new row containing foreign key references *before* inserting the row being referenced, the database can complain with a constraint violation. You must understand what the default order for the processing of entity objects is during commit time and how to programmatically influence that order when necessary.

Note: The example in this section refers to the `ControllingPostingOrder` project of the `AdvancedEntityExamples` application workspace in the `StandaloneExamples` module of the Fusion Order Demo application.

4.14.7.1 Default Post Processing Order

By default, when you commit the transaction the entity objects in the pending changes list are processed in chronological order, in other words, the order in which the entities were added to the list. This means that, for example, if you create a new `Product` and then a new `Supplier` related to that product, the new `Product` will be inserted first and the new `Supplier` second.

4.14.7.2 Compositions and Default Post Processing Order

When two entity objects are related by a *composition*, the strict chronological ordering is modified automatically to ensure that composed parent and child entity rows are saved in an order that prevents violating any constraints. This means, for example, that a new parent entity row is inserted before any new composed children entity rows.

4.14.7.3 Overriding `postChanges()` to Control Post Order

If your related entities are associated but *not* composed, then you need to write a bit of code to ensure that the related entities get saved in the appropriate order.

4.14.7.3.1 Observing the Post Ordering Problem First Hand Consider the `newProductForNewSupplier()` custom method from a `PostModule` application module in [Example 4-28](#). It accepts a set of parameters and:

1. Creates a new `Product`.
2. Creates a new `Supplier`.
3. Sets the product ID to which the server request pertains.
4. Commits the transaction.
5. Constructs a `Result` Java bean to hold new product ID and supplier ID.
6. Returns the result.

Note: The code makes the assumption that both `Products.ProductId` and `Suppliers.SupplierId` have been set to have `DBSequence` data type to populate their primary keys based on a sequence.

Example 4–28 *Creating a New Product, Then a New Supplier, and Returning the New IDs*

```
// In PostModuleImpl.java
public Result newProductForNewSupplier(String supplierName,
                                       String supplierStatus,
                                       String productName,
                                       String productStatus,
                                       Number listPrice,
                                       Number minPrice,
                                       String shipCode) {

    oracle.jbo.domain.Date today = new Date(Date.getCurrentDate());
    Number objectId = new Number(0);
    // 1. Create a new product
    ProductsBaseImpl newProduct = createNewProduct();
    // 2. Create a new supplier
    SuppliersImpl newSupplier = createNewSupplier();
    newSupplier.setSupplierName(supplierName);
    newSupplier.setSupplierStatus(supplierStatus);
    newSupplier.setCreatedBy("PostingModule");
    newSupplier.setCreationDate(today);
    newSupplier.setLastUpdatedBy("PostingModule");
    newSupplier.setLastUpdateDate(today);
    newSupplier.setObjectVersionId(objectId);
    // 3. Set the supplier id to which the product pertains
    newProduct.setSupplierId(newSupplier.getSupplierId().getSequenceNumber());
    newProduct.setProductName(productName);
    newProduct.setProductStatus(productStatus);
    newProduct.setListPrice(listPrice);
    newProduct.setMinPrice(minPrice);
    newProduct.setShippingClassCode(shipCode);
    newProduct.setCreatedBy("PostingModule");
    newProduct.setCreationDate(today);
    newProduct.setLastUpdatedBy("PostingModule");
    newProduct.setLastUpdateDate(today);
    newProduct.setObjectVersionId(objectId);
    // 4. Commit the transaction
    getDBTransaction().commit();
    // 5. Construct a bean to hold new supplier id and product id
    Result result = new Result();
    result.setProductId(newProduct.getProductId().getSequenceNumber());
    result.setSupplierId(newSupplier.getSupplierId().getSequenceNumber());
    // 6. Return the result
    return result;
}

private ProductsBaseImpl createNewProduct(){
    EntityDefImpl productDef = ProductsBaseImpl.getDefinitionObject();
    return (ProductsBaseImpl) productDef.createInstance2(getDBTransaction(), null);
}

private SuppliersImpl createNewSupplier(){
    EntityDefImpl supplierDef = SuppliersImpl.getDefinitionObject();
    return (SuppliersImpl) supplierDef.createInstance2(getDBTransaction(), null);
}
```

If you add this method to the application module's client interface and test it from a test client program, you get an error:

```
oracle.jbo.DMLConstraintException:
JBO-26048: Constraint "PRODUCT_SUPPLIER_FK" violated during post operation:
"Insert" using SQL Statement
"BEGIN
  INSERT INTO PRODUCTS(
    SUPPLIER_NAME,SUPPLIER_STATUS,PRODUCT_NAME,
    PRODUCT_STATUS,LIST_PRICE,MIN_PRICE, SHIPPING_CLASS_CODE)
  VALUES (?, ?, ?, ?, ?, ?, ?)
  RETURNING PRODUCT_ID INTO ?;
END;".
## Detail 0 ##
java.sql.SQLException:
ORA-02291: integrity constraint (FOD.PRODUCT_SUPPLIER_FK) violated
        - parent key not found
```

When the `PRODUCTS` row is inserted, the database complains that the value of its `SUPPLIER_ID` foreign key doesn't correspond to any row in the `SUPPLIERS` table. This occurred because:

- The code created the `Product` before the `Supplier`
- `Products` and `Suppliers` entity objects are associated but not composed
- The DML operations to save the new entity rows is done in chronological order, so the new `Product` gets inserted before the new `Supplier`.

4.14.7.3.2 Forcing the Supplier to Post Before the Product To remedy the problem of attempting to add a product with a not-yet-valid supplier ID, you could reorder the lines of code in the example to create the `Supplier` first, then the `Product`. While this would address the immediate problem, it still leaves the chance that another application developer could create things in an incorrect order.

The better solution is to make the entity objects *themselves* handle the posting order so the posting will work correctly regardless of the order of creation. To do this, you need to override the `postChanges()` method in the entity that contains the foreign key attribute referencing the associated entity object and write code as shown in [Example 4-29](#). In this example, since it is the `Product` that contains the foreign key to the `Supplier` entity, you need to update the `Product` to conditionally force a related, new `Supplier` to post before the service request posts itself.

The code tests whether the entity being posted is in the `STATUS_NEW` or `STATUS_MODIFIED` state. If it is, it retrieves the related product using the `getSupplier()` association accessor. If the related `Supplier` also has a post-state of `STATUS_NEW`, then *first* it calls `postChanges()` on the related parent row before calling `super.postChanges()` to perform its own DML.

Example 4-29 Overriding `postChanges()` in `ProductsBaseImpl` to Post `Supplier` First

```
// In ProductsBaseImpl.java
public void postChanges(TransactionEvent e) {
    /* If current entity is new or modified */
    if (getPostState() == STATUS_NEW ||
        getPostState() == STATUS_MODIFIED) {
        /* Get the associated supplier for the product */
        SuppliersImpl supplier = getSupplier();
        /* If there is an associated supplier */
        if (supplier != null) {
            /* And if its post-status is NEW */
```

```

    if (supplier.getPostState() == STATUS_NEW) {
        /*
         * Post the supplier first, before posting this
         * entity by calling super below
         */
        supplier.postChanges(e);
    }
}
super.postChanges(e);
}

```

If you were to re-run the example now, you would see that without changing the creation order in the `newProductForNewSupplier()` method's code, entities now post in the correct order — first new `Supplier`, then new `Product`. Yet, there is still a problem. The constraint violation still appears, but now for a different reason.

If the primary key for the `Suppliers` entity object were user-assigned, then the code in [Example 4-29](#) would be all that is required to address the constraint violation by correcting the post ordering.

Note: An alternative to the programmatic technique discussed here, which solves the problem at the Java EE application layer, is the use of deferrable constraints at the database layer. If you have control over your database schema, consider defining (or altering) your foreign key constraints to be `DEFERRABLE INITIALLY DEFERRED`. This database setting causes the database to defer checking the constraint until transaction commit time. When this is done, the application can perform DML operations in any order, provided that by `COMMIT` time all appropriate related rows have been saved and would alleviate the parent/child ordering. However, you would still need to write the code to cascade-update the foreign key values if the parent's primary key is assigned from a sequence, as described in [Section 4.14.7.3.3, "Associations Based on DBSequence-Valued Primary Keys,"](#) and [Section 4.14.7.3.4, "Refreshing References to DBSequence-Assigned Foreign Keys."](#)

In this example, however, the `Suppliers.SupplierId` is assigned from a database sequence, and not user-assigned. So when a new `Suppliers` entity row gets posted, its `SupplierId` attribute is refreshed to reflect the database-assigned sequence value. The foreign key value in the `Products.SupplierId` attribute referencing the new supplier is "orphaned" by this refreshing of the supplier's ID value. When the product's row is saved, its `SUPPLIER_ID` value still doesn't match a row in the `SUPPLIERS` table, and the constraint violation occurs again. The next two sections discuss the solution to address this "orphaning" problem.

4.14.7.3.3 Associations Based on DBSequence-Valued Primary Keys Recall from [Section 4.10.10, "How to Get Trigger-Assigned Primary Key Values from a Database Sequence,"](#) that when an entity object's primary key attribute is of `DBSequence` type, during the transaction in which it is created, its numerical value is a unique, temporary negative number. If you create a number of associated entities in the same transaction, the relationships between them are based on this temporary negative key value. When the entity objects with `DBSequence`-value primary keys are posted, their primary key is refreshed to reflect the correct database-assigned sequence number,

leaving the associated entities that are still holding onto the temporary negative foreign key value "orphaned."

For entity objects based on a *composition*, when the parent entity object's DBSequence-valued primary key is refreshed, the composed children entity rows automatically have their temporary negative foreign key value updated to reflect the owning parent's refreshed, database-assigned primary key. This means that for composed entities, the "orphaning" problem does not occur.

However, when entity objects are related by an association that is not a composition, you need to write a little code to insure that related entity rows referencing the temporary negative number get updated to have the refreshed, database-assigned primary key value. The next section outlines the code required.

4.14.7.3.4 Refreshing References to DBSequence-Assigned Foreign Keys When an entity like `Suppliers` in this example has a DBSequence-valued primary key, and it is referenced as a foreign key by other entities that are associated with (but not composed by) it, you need to override the `postChanges()` method as shown in [Example 4-30](#) to save a reference to the row set of entity rows that might be referencing this new `Suppliers` row. If the status of the current `Suppliers` row is `New`, then the code assigns the RowSet-valued return of the `getProduct()` association accessor to the `newProductsBeforePost` member field before calling `super.postChanges()`.

Example 4-30 Saving Reference to Entity Rows Referencing This New Supplier

```
// In SuppliersImpl.java
RowSet newProductsBeforePost = null;
public void postChanges(TransactionEvent TransactionEvent) {
    /* Only bother to update references if Product is a NEW one */
    if (getPostState() == STATUS_NEW) {
        /*
         * Get a rowset of products related
         * to this new supplier before calling super
         */
        newProductsBeforePost = (RowSet)getProductsBase();
    }
    super.postChanges(TransactionEvent);
}
```

This saved RowSet object is then used by the overridden `refreshFKInNewContainees()` method shown in [Example 4-31](#). It gets called to allow a new entity row to cascade-update its refreshed primary key value to any other entity rows that were referencing it before the call to `postChanges()`. It iterates over the `ProductsBaseImpl` rows in the `newProductsBaseBeforePost` row set (if non-null) and sets the new supplier ID value of each one to the new sequence-assigned supplier value of the newly posted `Suppliers` entity.

Example 4-31 Cascade-Updating Entity Rows with New SupplierId Value

```
// In SuppliersImpl.java
protected void refreshFKInNewContainees() {
    if (newProductsBeforePost != null) {
        Number newSupplierId = getSupplierId().getSequenceNumber();
        /*
         * Process the rowset of products that referenced
         * the new supplier prior to posting, and update their
         * SupplierId attribute to reflect the refreshed SupplierId value
         * that was assigned by a database sequence during posting.
         */
    }
}
```

```

*/
while (newProductsBeforePost.hasNext()) {
    ProductsBaseImpl svrReq =
        (ProductsBaseImpl)newProductsBeforePost.next();
    product.setSupplierId(newSupplierId);
}
closeNewProductRowSet();
}
}

```

After implementing this change, the code in [Example 4-28](#) runs without encountering any database constraint violations.

4.14.8 Advanced Entity Association Techniques

This section describes several advanced techniques for working with associations between entity objects.

4.14.8.1 Modifying Association SQL Clause to Implement Complex Associations

When you need to represent a more complex relationship between entities than one based only on the equality of matching attributes, you can modify the association's SQL clause to include more complex criteria. For example, sometimes the relationship between two entities depends on effective dates. A `Product` may be related to a `Supplier`, but if the name of the supplier changes over time, each row in the `SUPPLIERS` table might include additional `EFFECTIVE_FROM` and `EFFECTIVE_UNTIL` columns that track the range of dates in which that product row is (or was) in use. The relationship between a `Product` and the `Supplier` with which it is associated might then be described by a combination of the matching `SupplierId` attributes and a condition that the product's `RequestDate` lie between the supplier's `EffectiveFrom` and `EffectiveUntil` dates.

You can set up this more complex relationship in the overview editor for the association. First, add any additional necessary attribute pairs on the Relationship page, which in this example would include one (`EffectiveFrom`, `RequestDate`) pair and one (`EffectiveUntil`, `RequestDate`) pair. Then, on the Query page you can edit the **Where** field to change the `WHERE` clause to be:

```

(:Bind_SupplierId = Product.SUPPLIER_ID) AND
(Product.REQUEST_DATE BETWEEN :Bind_EffectiveFrom
                                AND :Bind_EffectiveUntil)

```

For more information about creating associations, see [Section 4.3, "Creating and Configuring Associations."](#)

4.14.8.2 Exposing View Link Accessor Attributes at the Entity Level

When you create a view link between two entity-based view objects, on the View Link Properties page, you have the option to expose view link accessor attributes both at the view object level as well as at the entity object level. By default, a view link accessor is exposed only at the view object level of the destination view object. By selecting the appropriate **In Entity Object: *SourceEntityName*** or **In Entity Object: *DestinationEntityName*** checkbox, you can opt to have JDeveloper include a view link attribute in either or both of the source or destination entity objects. This can provide a handy way for an entity object to access a set of related view rows, especially when the query to produce the rows depends only on attributes of the current row.

4.14.8.3 Optimizing Entity Accessor Access by Retaining the Row Set

Each time you retrieve an entity association accessor row set, by default the entity object creates a new `RowSet` object to allow you to work with the rows. This does *not* imply *re-executing* the query to produce the results each time, only creating a new instance of a `RowSet` object with its default iterator reset to the "slot" before the first row. To force the row set to refresh its rows from the database, you can call its `executeQuery()` method.

Since there is a small amount of overhead associated with creating the row set, if your code makes numerous calls to the same association accessor attributes, you can consider enabling the association accessor row set retention for the source entity object in the association. You can enable retention of the association accessor row set using the overview editor for the entity object that is the source for the association accessor. Select **Retain Association Accessor Rowset** in the **Tuning** section of the General page of the overview editor for the entity object.

Alternatively, you can enable a custom Java *entity collection* class for your entity object. As with other custom entity Java classes you've seen, you do this on the Select Java Options dialog that you open from the Java page of the overview editor for the entity object. In the dialog, select **Generate Entity Collection Class**. Then, in the `YourEntityCollImpl` class that JDeveloper creates for you, override the `init()` method, and add a line after `super.init()` that calls the `setAssociationAccessorRetained()` method passing `true` as the parameter. It affects all association accessor attributes for that entity object.

When this feature is enabled for an entity object, since the association accessor row set is not re-created each time, the current row of its default row set iterator is also retained as a side-effect. This means that your code will need to explicitly call the `reset()` method on the row set you retrieve from the association accessor to reset the current row in its default row set iterator back to the "slot" before the first row.

Note, however, that with accessor retention enabled, your failure to call `reset()` each time before you iterate through the rows in the accessor row set can result in a subtle, hard-to-detect error in your application. For example, say you iterate over the rows in an association accessor row set as shown in [Example 4-32](#) to calculate some aggregate total.

Example 4-32 Iterating Over a Row Set Incorrectly

```
// In your custom Java entity class
RowSet rs = (RowSet)getProducts();
while (rs.hasNext()) {
    ProductImpl r = (ProductImpl)rs.next();
    // Do something important with attributes in each row
}
```

The first time you work with the accessor row set, the code will work. However, since the row set (and its default row set iterator) are retained, the second and any subsequent time you access the row set, the current row will already be at the end of the row set and the while loop will be skipped because `rs.hasNext()` will be `false`. Instead, with this feature enabled, write your accessor iteration code as shown in [Example 4-33](#).

Example 4-33 Iterating Over a Row Set and Resetting to the First Row

```
// In your custom Java entity class
RowSet rs = (RowSet)getProducts();
rs.reset(); // Reset default row set iterator to slot before first row!
while (rs.hasNext()) {
```

```

ProductImpl r = (ProductImpl)rs.next();
// Do something important with attributes in each row
}

```

4.15 Creating Custom, Validated Data Types Using Domains

When you find yourself repeating the same sanity-checking validations on the values of similar attributes across multiple entity objects, you can save yourself time and effort by creating your own data types that encapsulate this validation. For example, imagine that across your business domain layer there are numerous entity object attributes that store strings that represent email addresses. One technique you could use to ensure that end users always enter a valid email address everywhere one appears in your business domain layer is to:

- Use a basic `String` data type for each of these attributes
- Add an attribute-level method validator with Java code that ensures that the `String` value has the format of a valid email address for each attribute

However, these approaches can become tedious quickly in a large application. Fortunately, ADF Business Components offers an alternative that allows you to create your own `EmailAddress` data type that represents an email address. After centralizing all of the sanity-checking regarding email address values into this new custom data type, you can use the `EmailAddress` as the type of every attribute in your application that represents an email address. By doing this, you make the intention of the attribute values more clear to other developers and simplify application maintenance by putting the validation in a single place. ADF Business Components calls these developer-created data types *domains*.

Domains are Java classes that extend the basic data types like `String`, `Number`, and `Date` to add constructor-time validation to ensure the candidate value passes relevant sanity checks. They offer you a way to define custom data types with cross-cutting behavior such as basic data type validation, formatting, and custom metadata properties in a way that is inherited by any entity objects or view objects that use the domain as the Java type of any of their attributes.

Note: The example in this section refers to the `SimpleDomains` project in the `AdvancedEntityExamples` application workspace in the `StandaloneExamples` module of the Fusion Order Demo application.

4.15.1 How to Create a Domain

To create a domain, use the Create Domain wizard. This wizard is available from the New Gallery in the **ADF Business Components** category.

Before you begin:

It may be helpful to have an understanding of using domains. For more information, see [Section 4.15, "Creating Custom, Validated Data Types Using Domains."](#)

You may also find it helpful to understand additional functionality that can be added using other entity object features. For more information, see [Section 4.1.2, "Additional Functionality for Entity Objects."](#)

To create a domain:

1. In the Application Navigator, right-click the project for which you want to create a domain and choose **New**.
2. In the New Gallery, expand **Business Tier**, select **ADF Business Components** and then **Domain**, and click **OK**.
3. In the Create Domain wizard, on the Name page, specify a name for the domain and a package in which it will reside. To create a domain based on a simple Java type, leave **Domain for an Oracle Object Type** unselected.
4. Click **Next**.
5. On the Settings page, indicate the base type for the domain and the database column type to which it will map.

For example, if you were creating a domain called `ShortEmailAddress` to hold eight-character short email addresses, you would set the base type to `String` and the **Database Column Type** to `VARCHAR2 (8)`. You can set other common attribute settings on this panel as well.

6. Click **Finish** to create your domain.

4.15.2 What Happens When You Create a Domain

When you create a domain, JDeveloper creates its XML component definition in the subdirectory of your project's source path that corresponds to the package name you chose. For example, if you created the `ShortEmailAddress` domain in the `devguide.advanced.domains` package, JDeveloper would create the `ShortEmailAddress.xml` file in the `./devguide/advanced/domains` subdirectory. A domain always has a corresponding Java class, which JDeveloper creates in the `common` subpackage of the package where the domain resides. This means it would create the `ShortEmailAddress.java` class in the `devguide.advanced.domains.common` package. The domain's Java class is automatically generated with the appropriate code to behave in a way that is identical to one of the built-in data types.

4.15.3 What You May Need to Know About Domains

Domains can be created as a variety of different types, and have different characteristics than standard attributes. The sections that follow describe some of the things you may need to know about when working with domains.

4.15.3.1 Domains as Entity and View Object Attributes

After you've created a domain in a project, it appears among the list of available data types in the **Attribute Type** dropdown list in the entity object and view object wizards and dialogs. To use the domain as the type of a given attribute, just pick it from the list.

Note: The entity-mapped attributes in an entity-based view object inherit their data type from their corresponding underlying entity object attribute. Therefore, if the entity attribute uses a domain type, the matching view object attribute will as well. For transient or SQL-derived view object attributes, you can directly set the type to use a domain since it is not inherited from any underlying entity.

4.15.3.2 DataCreationException in Custom validate() Method

Typically, the only coding task you need to do for a domain is to write custom code inside the generated `validate()` method. Your implementation of the `validate()` method should perform your sanity checks on the candidate value being constructed, and throw a `DataCreationException` in the `oracle.jbo` package if the validation fails.

In order to throw an exception message that is translatable, you can create a message bundle class similar to the one shown in [Example 4-34](#). Create it in the same `common` package as your domain classes themselves. The message bundle returns an array of `{MessageKeyString, TranslatableMessageString}` pairs.

Example 4-34 Custom Message Bundle Class for Domain Exception Messages

```
package devguide.advanced.simplesdomains.common;

import java.util.ListResourceBundle;

public class ErrorMessages extends ListResourceBundle {
    public static final String INVALID_SHORTEMAIL = "30002";
    public static final String INVALID_EVENNUMBER = "30003";
    private static final Object[][] sMessageStrings = new String[][] {
        { INVALID_SHORTEMAIL,
          "A valid short email address has no @-sign or dot."},
        { INVALID_EVENNUMBER,
          "Number must be even."}
    };

    /**
     * Return String Identifiers and corresponding Messages
     * in a two-dimensional array.
     */
    protected Object[][] getContents() {
        return sMessageStrings;
    }
}
```

4.15.3.3 String Domains and String Value Aggregation

Since `String` is a base JDK type, a domain based on a `String` aggregates a private `mData String` member field to hold the value that the domain represents. Then, the class implements the `DomainInterface` expected by the ADF runtime, as well as the `Serializable` interface, so the domain can be used in method arguments or return types of the custom client interfaces of Oracle ADF components.

[Example 4-35](#) shows the `validate()` method for a simple `ShortEmailAddress` domain class. It tests to make sure that the `mData` value does not contain an at-sign or a dot, and if it does, then the method throws `DataCreationException` referencing an appropriate message bundle and message key for the translatable error message.

Example 4-35 Simple ShortEmailAddress String-Based Domain Type with Custom Validation

```
public class ShortEmailAddress
    extends Object implements DomainInterface, Serializable {
    private String mData;
    // . . .
    /**Implements domain validation logic and throws a JboException on error. */
    protected void validate() {
        int atpos = mData.indexOf('@');
```

```

        int dotpos = mData.lastIndexOf('.');
        if (atpos > -1 || dotpos > -1) {
            throw new DataCreationException(ErrorMessages.class,
                ErrorMessages.INVALID_SHORTEMAIL,null,null);
        }
    }
    // . . .
}

```

4.15.3.4 Simple Domains and Built-In Types

Other simple domains based on a built-in type in the `oracle.jbo.domain` package extend the base type, as shown in [Example 4–36](#). It illustrates the `validate()` method for a simple Number-based domain called `EvenNumber` that represents even numbers.

Example 4–36 Simple EvenNumber Number-Based Domain Type with Custom Validation

```

public class EvenNumber extends Number {
    // . . .
    /**
     * Validates that value is an even number, or else
     * throws a DataCreationException with a custom
     * error message.
     */
    protected void validate() {
        if (getValue() % 2 == 1) {
            throw new DataCreationException(ErrorMessages.class,
                ErrorMessages.INVALID_EVENNUMBER,null,null);
        }
    }
    // . . .
}

```

4.15.3.5 Simple Domains As Immutable Java Classes

When you create a simple domain based on one of the basic data types, it is an *immutable* class. That means that once you've constructed a new instance of it like this:

```
ShortEmailAddress email = new ShortEmailAddress("emailaddress1");
```

You cannot change its value. If you want to reference a different short email address, you just construct another one:

```
ShortEmailAddress email = new ShortEmailAddress("emailaddress2");
```

This is not a new concept because it's the same way that `String`, `Number`, and `Date` classes behave, among others.

4.15.3.6 Creating Domains for Oracle Object Types When Useful

Oracle Database supports the ability to create user-defined types in the database. For example, you could create a type called `POINT_TYPE` using the following DDL statement:

```

create type point_type as object (
    x_coord number,
    y_coord number
);

```

If you use user-defined types like `POINT_TYPE`, you can create domains based on them, or you can reverse-engineer tables containing columns of object type to have JDeveloper create the domain for you. You can use the Create Domain wizard to create Oracle object type domains manually.

To manually create an Oracle object type domain:

1. In the Application Navigator, right-click the project for which you want to create a domain and choose **New**.
2. In the New Gallery, expand **Business Tier**, select **ADF Business Components** and then **Domain**, and click **OK**.
3. In the Create Domain wizard, on the Name page, select the **Domain for an Oracle Object Type** checkbox, then select the object type for which you want to create a domain from the **Available Types** list.
4. Click **Next**.
5. On the Settings page, use the **Attribute** dropdown list to switch between the multiple domain properties to adjust the settings as appropriate.
6. Click **Finish** to create the domain.

To reverse-engineer an Oracle object type domain:

In addition to manually creating object type domains, when you use the Business Components from Tables wizard and select a table containing columns of an Oracle object type, JDeveloper creates domains for those object types as part of the reverse-engineering process. For example, imagine you created a table like this with a column of type `POINT_TYPE`:

```
create table interesting_points(
  id number primary key,
  coordinates point_type,
  description varchar2(20)
);
```

If you create an entity object for the `INTERESTING_POINTS` table in the Business Components from Tables wizard, then you get both an `InterestingPoints` entity object and a `PointType` domain. The latter is generated, based on the `POINT_TYPE` object type, because it was required as the data type of the `Coordinates` attribute of the `InterestingPoints` entity object.

Unlike simple domains, object type domains are mutable. JDeveloper generates getter and setter methods into the domain class for each of the elements in the object type's structure. After changing any domain properties, when you set that domain as the value of a view object or entity object attribute, it is treated as a single unit. Oracle ADF does not track which domain properties have changed, only that a domain-valued attribute value has changed.

Note: Domains based on Oracle object types are useful for working programmatically with data whose underlying type is an Oracle object type. They can also simplify passing and receiving structure information to stored procedures. However, support for working with object type domains in the ADF binding layer is complete, so it's not straightforward to use object domain-valued attributes in declaratively databound user interfaces.

4.15.3.7 Quickly Navigating to the Domain Class

After selecting a domain in the Application Navigator, you can quickly navigate to its implementation class using one of the following methods:

- In the Application Navigator, right-click the domain and choose **Go to Domain Class**.
- In the Structure window, double-click the domain class.

4.15.3.8 Domains Packaged in the Common JAR

When you create a business components archive, as described in [Section 38.3.1, "How to Package a Component into an ADF Library JAR,"](#) the domain classes and message bundle files in the *.common subdirectories of your project's source path get packaged into the *CSCCommon.jar. They are classes that are common to both the middle-tier application server and to an eventual remote client you might need to support.

4.15.3.9 Custom Domain Properties and Attributes in Entity and View Objects

You can define custom metadata properties on a domain. Any entity object or view object attribute based on that domain inherits those custom properties as if they had been defined on the attribute itself. If the entity object or view object attribute defines the same custom property, its setting takes precedence over the value inherited from the domain.

4.15.3.10 Inherited Restrictive Properties of Domains in Entity and View Objects

JDeveloper enforces the declarative settings you impose at the domain definition level: they cannot be made *less* restrictive for the entity object or view object for an attribute based on the domain type. For example, if you define a domain to have its **Updatable** property set to **While New**, then when you use your domain as the Java type of an entity object attribute, you can set **Updatable** to be **Never** (more restrictive) but you cannot set it to be **Always**. Similarly, if you define a domain to be **Persistent**, you cannot make it transient later. When sensible for your application, set declarative properties for a domain to be as lenient as possible, so you can later make them more restrictive as needed.

4.16 Creating New History Types

History types are used to track data specific to a point in time. JDeveloper ships with a number of history types, but you can also create your own. For more information on the standard history types and how to use them, see [Section 4.10.12, "How to Track Created and Modified Dates Using the History Column."](#)

4.16.1 How to Create New History Types

You are not limited to the history types provided: you can add or remove custom history types using the History Types page in the Preferences dialog, and then write custom Java code to implement the desired behavior. The code to handle custom history types should be written in your application-wide entity base class for reuse.

[Figure 4–17](#) shows a custom type called `last_update_login` with type ID of 11. Assume that `last_update_login` is a foreign key in the `FND_LOGINS` table.

Figure 4–17 New History Types in the Overview Editor
Before you begin:

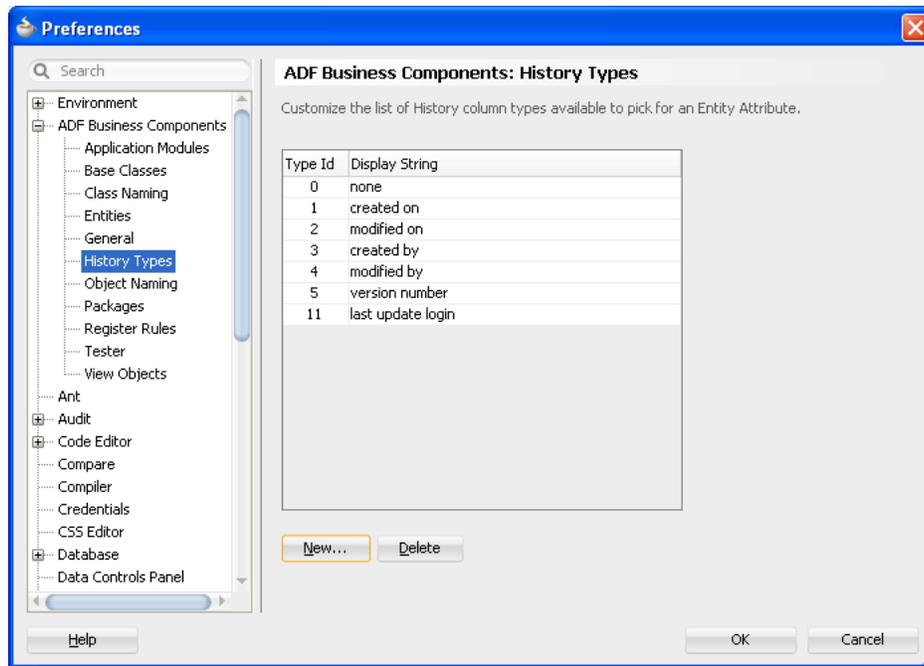

It may be helpful to have an understanding of history types. For more information, see [Section 4.16, "Creating New History Types."](#)

You may also find it helpful to understand additional functionality that can be added using other entity object features. For more information, see [Section 4.1.2, "Additional Functionality for Entity Objects."](#)

To create a custom history type:

1. From the **Tools** menu, choose **Preferences**.
2. In the Preferences dialog, expand **ADF Business Components** and click **History Types**.
3. On the History Types page, click **New**.
4. In the New History Type dialog, enter a string value for the name (spaces are allowed) and a numerical ID.

The **Type Id** must be an integer between 11 and 126. The numerical values 0-10 are reserved for internal use. The display string is displayed in the **Track Change History** dropdown list the next time you use the overview editor. [Figure 4–18](#) shows the new history type in the Preferences dialog.

Figure 4–18 Custom History Type in Preferences

5. Open the `EntityImpl.java` file and add a definition similar to the one in [Example 4–37](#).

Example 4–37 History Type Definition

```
private static final byte LASTUPDATELOGIN_HISTORY_TYPE = 11;
```

6. Override the `getHistoryContextForAttribute(AttributeDefImpl attr)` method in the `EntityImpl` base class with code similar to [Example 4–38](#).

Example 4–38 Overriding `getHistoryContextForAttribute()`

```
@Override
protected Object getHistoryContextForAttribute(AttributeDefImpl attr) {
    if (attr.getHistoryKind() == LASTUPDATELOGIN_HISTORY_TYPE) {
        // Custom History type logic goes here
    }
    else {
        return super.getHistoryContextForAttribute(attr);
    }
}
```

4.16.2 How to Remove a History Type

Because they are typically used for auditing values over the life of an application, it is rare that you would want to remove a history type. However, in the event that you need to do so, perform the following tasks:

1. Remove the history type from the JDeveloper history types list in the Preferences dialog.
2. Remove any custom code you implemented to support the history type in the base `EntityImpl.getHistoryContextForAttribute` method.

3. Remove all usages of the history type in the entity attribute metadata. Any attribute that you have defined to use this history type must be edited.

Before you begin:

It may be helpful to have an understanding of history types. For more information, see [Section 4.16, "Creating New History Types."](#)

You may also find it helpful to understand additional functionality that can be added using other entity object features. For more information, see [Section 4.1.2, "Additional Functionality for Entity Objects."](#)

To remove a history type from the JDeveloper history types list:

1. From the **Tools** menu, choose **Preferences**.
2. In the Preferences dialog, expand **ADF Business Components** and click **History Types**.
3. On the History Types page, select the history type that you want to remove and click **Delete**.

4.17 Basing an Entity Object on a PL/SQL Package API

If you have a PL/SQL package that encapsulates insert, update, and delete access to an underlying table, you can override the default DML processing event for the entity object that represents that table to invoke the procedures in your PL/SQL API instead. Often, such PL/SQL packages are used in combination with a companion database view. Client programs read data from the underlying table using the database view, and "write" data back to the table using the procedures in the PL/SQL package.

For example, say you want to create a `Product` entity object based on such a combination of a view and a package.

Given the `PRODUCTS` table in the Fusion Order Demo schema, consider a database view named `PRODUCTS_V`, created using the following DDL statement:

```
create or replace view products_v
as select product_id,name,image,description from products;
```

In addition, consider the simple `PRODUCTS_API` package shown in [Example 4-39](#) that encapsulates insert, update, and delete access to the underlying `PRODUCTS` table.

Example 4-39 Simple PL/SQL Package API for the PRODUCTS Table

```
create or replace package products_api is
  procedure insert_product(p_prod_id number,
                          p_name varchar2,
                          p_supplier_id number,
                          p_list_price number,
                          p_min_price number,
                          p_ship_code varchar2);
  procedure update_product(p_prod_id number,
                          p_name varchar2,
                          p_supplier_id number,
                          p_list_price number,
                          p_min_price number,
                          p_ship_code varchar2);
  procedure delete_product(p_prod_id number);
end products_api;
```

To create an entity object based on this combination of database view and PL/SQL package, you would perform the following tasks:

1. Create a view-based entity object, as described in [Section 4.17.1, "How to Create an Entity Object Based on a View."](#)
2. Create a base class for the entity object, as described in [Section 4.17.3, "How to Centralize Details for PL/SQL-Based Entities into a Base Class."](#)
3. Implement the appropriate stored procedure calls, as described in [Section 4.17.4, "How to Implement the Stored Procedure Calls for DML Operations."](#)
4. Handle selecting and locking functionality, if necessary, as described in [Section 4.17.5, "How to Add Select and Lock Handling."](#)

Note: The example in these sections refers to the `EntityWrappingPLSQLPackage` project of the `AdvancedEntityExamples` application workspace in the `StandaloneExamples` module of the Fusion Order Demo application.

4.17.1 How to Create an Entity Object Based on a View

To create an entity object based on a view, you use the Create Entity Object wizard.

Before you begin:

It may be helpful to have an understanding of how entity objects can use the PS/SQL API. For more information, see [Section 4.17, "Basing an Entity Object on a PL/SQL Package API."](#)

You may also find it helpful to understand additional functionality that can be added using other entity object features. For more information, see [Section 4.1.2, "Additional Functionality for Entity Objects."](#)

You will need to launch the Create Entity Object wizard as described in [Section 4.2.2, "How to Create Single Entity Objects Using the Create Entity Wizard,"](#) and proceed through the wizard with the exceptions noted in the following procedure.

To create an entity object based on a view:

1. On the Name page, give the entity a name like `Product`.
2. In the Select Schema Object dialog, select the **Views** checkbox in the **Object Type** section.

This enables the display of the available database views in the current schema in when you click **Query**.
3. Select the desired database view in the **Available Objects** list.
4. On the Attribute Settings page, use the **Select Attribute** dropdown list to choose the attribute that will act as the primary key, then select the **Primary Key** checkbox for that attribute.

Note: When defining the entity based on a view, JDeveloper cannot automatically determine the primary key attribute since database views do not have related constraints in the database data dictionary.

4.17.2 What Happens When You Create an Entity Object Based on a View

By default, an entity object based on a view performs all of the following directly against the underlying database view:

- SELECT statement (for `findByPrimaryKey()`)
- SELECT FOR UPDATE statement (for `lock()`), and
- INSERT, UPDATE, DELETE statements (for `doDML()`)

To use stored procedure calls, you will need to override the `doDML()` operations (as described in [Section 4.17.3, "How to Centralize Details for PL/SQL-Based Entities into a Base Class"](#)), and possibly override the `lock()` and `findByPrimaryKey()` handling (as described in [Section 4.17.4, "How to Implement the Stored Procedure Calls for DML Operations"](#)).

4.17.3 How to Centralize Details for PL/SQL-Based Entities into a Base Class

If you plan to have more than one entity object based on a PL/SQL API, it's a smart idea to abstract the generic details into a base framework extension class. In doing this, you'll be using several of the concepts described in [Chapter 12, "Extending Business Components Functionality."](#) Start by creating a `PLSQLEntityImpl` class that extends the base `EntityImpl` class that each one of your PL/SQL-based entities can use as their base class. As shown in [Example 4–40](#), you'll override the `doDML()` method of the base class to invoke a different helper method based on the operation.

Note: If you are already using an extended entity implementation class for your entity, you can extend it further with the `PLSQLEntityImpl` class. For example, if you have a framework extension class named `zzEntityImpl`, you would create a `PLSQLEntityImpl` class that extends the `zzEntityImpl` class.

Example 4–40 *Overriding `doDML()` to Call Different Procedures Based on the Operation*

```
// In PLSQLEntityImpl.java
protected void doDML(int operation, TransactionEvent e) {
    // super.doDML(operation, e);
    if (operation == DML_INSERT)
        callInsertProcedure(e);
    else if (operation == DML_UPDATE)
        callUpdateProcedure(e);
    else if (operation == DML_DELETE)
        callDeleteProcedure(e);
}
```

In the `PLSQLEntityImpl.java` base class, you can write the helper methods so that they perform the default processing like this:

```
// In PLSQLEntityImpl.java
/* Override in a subclass to perform non-default processing */
protected void callInsertProcedure(TransactionEvent e) {
    super.doDML(DML_INSERT, e);
}
/* Override in a subclass to perform non-default processing */
protected void callUpdateProcedure(TransactionEvent e) {
    super.doDML(DML_UPDATE, e);
}
/* Override in a subclass to perform non-default processing */
protected void callDeleteProcedure(TransactionEvent e) {
```

```
    super.doDML(DML_DELETE, e);  
}
```

After putting this infrastructure in place, when you base an entity object on the `PLSQLEntityImpl` class, you can use the **Source > Override Methods** menu item to override the `callInsertProcedure()`, `callUpdateProcedure()`, and `callDeleteProcedure()` helper methods and perform the appropriate stored procedure calls for that particular entity.

Note: If you do not override these helper methods in a subclass, they will perform the default processing as defined in the superclass. You only need to override the operations in the `doDML()` method that you want to provide alternative processing for.

To simplify the task of implementing these calls, you could add the `callStoredProcedure()` helper method (described in [Section 12.6, "Invoking Stored Procedures and Functions"](#)) to the `PLSQLEntityImpl` class as well. This way, any PL/SQL-based entity objects that extend this class can leverage the helper method.

4.17.4 How to Implement the Stored Procedure Calls for DML Operations

To implement the stored procedure calls for DML operations, you will need to create a custom Java class for the entity object and override the operations in it.

Before you begin:

It may be helpful to have an understanding of entity objects that are based on a PL/SQL package API. For more information, see [Section 4.17, "Basing an Entity Object on a PL/SQL Package API."](#)

You may also find it helpful to understand additional functionality that can be added using other entity object features. For more information, see [Section 4.1.2, "Additional Functionality for Entity Objects."](#)

To create the custom Java class with the override methods:

1. In the Application Navigator, double-click the entity object (for example, `Products`).
2. In the overview editor, click the **Java** navigation tab.
3. On the Java page of the overview editor, click the **Edit Java options** icon.
4. In the Select Java Options dialog, click **Classes Extend**.
5. In the Override Base Classes dialog, in the **Row** field, enter the package and class of the `PLSQLEntityImpl` class, or click **Browse** to search and select it.
6. Then select **Generate Entity Object Class**, and click **OK**.
7. In the Application Navigator, double-click the generated entity object class (for example, `ProductsImpl.java`).
8. From the **Source** menu, choose **Override Methods**.
9. In the Override Methods dialog, select the `callInsertProcedure()`, `callUpdateProcedure()`, and `callDeleteProcedure()` methods, and click **OK**.
10. Then enter the necessary code to override these procedures.

[Example 4–41](#) shows some sample code that you would write in these overridden helper methods.

Example 4–41 Leveraging a Helper Method to Invoke Insert, Update, and Delete Procedures

```
// In ProductsImpl.java
protected void callInsertProcedure(TransactionEvent e) {
    callStoredProcedure("products_api.insert_product(?,?,?,?,?)",
        new Object[] { getProductId(), getProductName(), getSupplierId(),
            getListPrice(), getMinPrice(), getShippingClassCode() });
}
protected void callUpdateProcedure(TransactionEvent e) {
    callStoredProcedure("products_api.update_product(?,?,?,?,?)",
        new Object[] { getProductId(), getProductName(), getSupplierId(),
            getListPrice(), getMinPrice(), getShippingClassCode() });
}
protected void callDeleteProcedure(TransactionEvent e) {
    callStoredProcedure("products_api.delete_product(?)",
        new Object[] { getProductId() });
}
```

At this point, if you create a default entity-based view object called `Products` for the `Products` entity object and add an instance of it to a `ProductsModule` application module you can quickly test inserting, updating, and deleting rows from the `Products` view object instance in the Oracle ADF Model Tester.

Often, overriding just the insert, update, and delete operations will be enough. The default behavior that performs the `SELECT` statement for `findByPrimaryKey()` and the `SELECT FOR UPDATE` statement for the `lock()` against the database view works for most basic kinds of views.

However, if the view is complex and does not support `SELECT FOR UPDATE` or if you need to perform the `findByPrimaryKey()` and `lock()` functionality using additional stored procedures APIs, then you can use the technique described in [Section 4.17.5, "How to Add Select and Lock Handling."](#)

4.17.5 How to Add Select and Lock Handling

You can handle the `lock()` and `findByPrimaryKey()` functionality of an entity object by invoking stored procedures if necessary. Imagine that the `PRODUCTS_API` package were updated to contain the two additional procedures shown in [Example 4–42](#). Both the `lock_product` and `select_product` procedures accept a primary key attribute as an `IN` parameter and return values for the remaining attributes using `OUT` parameters.

Example 4–42 Additional Locking and Select Procedures for the PRODUCTS Table

```
/* Added to PRODUCTS_API package */
procedure lock_product(p_prod_id number,
    p_name OUT varchar2,
    p_supplier_id OUT number,
    p_list_price OUT number,
    p_min_price OUT number,
    p_ship_code OUT varchar2);
procedure select_product(p_prod_id number,
    p_name OUT varchar2,
    p_supplier_id OUT number,
    p_list_price OUT number,
```

```
p_min_price OUT number,
p_ship_code OUT varchar2);
```

To add select and lock handling, you will need to perform the following tasks:

1. Update the base class to handle lock and select, as described in [Section 4.17.5.1, "Updating PLSQLEntityImpl Base Class to Handle Lock and Select."](#)
2. Update the entity object implementation class to implement the lock and select behaviors, as described in [Section 4.17.5.2, "Implementing Lock and Select for the Product Entity."](#)
3. Override the `lock()` method in the entity object implementation class to refresh the entity object after a `RowInconsistentException` has occurred, as described in [Section 4.17.5.3, "Refreshing the Entity Object After RowInconsistentException."](#)

4.17.5.1 Updating PLSQLEntityImpl Base Class to Handle Lock and Select

You can extend the `PLSQLEntityImpl` base class to handle the `lock()` and `findByPrimaryKey()` overrides using helper methods similar to the ones you added for insert, update, delete. At runtime, both the `lock()` and `findByPrimaryKey()` operations invoke the lower-level entity object method called `doSelect(boolean lock)`. The `lock()` operation calls `doSelect()` with a true value for the parameter, while the `findByPrimaryKey()` operation calls it passing false instead.

[Example 4-43](#) shows the overridden `doSelect()` method in `PLSQLEntityImpl` to delegate as appropriate to two helper methods that subclasses can override as necessary.

Example 4-43 *Overriding doSelect() to Call Different Procedures Based on the Lock Parameter*

```
// In PLSQLEntityImpl.java
protected void doSelect(boolean lock) {
    if (lock) {
        callLockProcedureAndCheckForRowInconsistency();
    } else {
        callSelectProcedure();
    }
}
```

The two helper methods are written to just perform the default functionality in the base `PLSQLEntityImpl` class:

```
// In PLSQLEntityImpl.java
/* Override in a subclass to perform non-default processing */
protected void callLockProcedureAndCheckForRowInconsistency() {
    super.doSelect(true);
}
/* Override in a subclass to perform non-default processing */
protected void callSelectProcedure() {
    super.doSelect(false);
}
```

Notice that the helper method that performs locking has the name `callLockProcedureAndCheckForRowInconsistency()`. This reminds you that you need to perform a check to detect at the time of locking the row whether the newly selected row values are the same as the ones the entity object in the entity cache believes are the current database values.

To assist subclasses in performing this old-value versus new-value attribute comparison, you can add one final helper method to the `PLSQLEntityImpl` class like this:

```
// In PLSQLEntityImpl
protected void compareOldAttrTo(int attrIndex, Object newVal) {
    if ((getPostedAttribute(attrIndex) == null && newVal != null) ||
        (getPostedAttribute(attrIndex) != null && newVal == null) ||
        (getPostedAttribute(attrIndex) != null && newVal != null &&
         !getPostedAttribute(attrIndex).equals(newVal))) {
        throw new RowInconsistentException(getKey());
    }
}
```

4.17.5.2 Implementing Lock and Select for the Product Entity

With the additional infrastructure in place in the base `PLSQLEntityImpl` class, you can override the `callSelectProcedure()` and `callLockProcedureAndCheckForRowInconsistency()` helper methods in the entity object implementation class (for example, `ProductsImpl`). Because the `select_product` and `lock_product` procedures have OUT arguments, as described in [Section 12.6.4, "How to Call Other Types of Stored Procedures,"](#) you need to use a JDBC `CallableStatement` object to perform these invocations.

[Example 4-44](#) shows the code you would use to invoke the `select_product` procedure for the `ProductsImpl` entity object implementation class. It's performing the following basic steps:

1. Creating a `CallableStatement` for the PLSQL block to invoke.
2. Registering the OUT parameters and types, by one-based bind variable position.
3. Setting the IN parameter value.
4. Executing the statement.
5. Retrieving the possibly updated column values.
6. Populating the possibly updated attribute values in the row.
7. Closing the statement.

Example 4-44 Invoking the Stored Procedure to Select a Row by Primary Key

```
// In ProductsImpl.java
protected void callSelectProcedure() {
    String stmt = "begin products_api.select_product(?,?,?,?);end;";
    // 1. Create a CallableStatement for the PLSQL block to invoke
    CallableStatement st =
        getDBTransaction().createCallableStatement(stmt, 0);
    try {
        // 2. Register the OUT parameters and types
        st.registerOutParameter(2, VARCHAR2);
        st.registerOutParameter(3, NUMBER);
        st.registerOutParameter(4, NUMBER);
        st.registerOutParameter(5, NUMBER);
        st.registerOutParameter(6, VARCHAR2);

        // 3. Set the IN parameter value
        st.setObject(1, getProductId());
        // 4. Execute the statement
        st.executeUpdate();
        // 5. Retrieve the possibly updated column values
    }
}
```

```

String possiblyUpdatedName = st.getString(2);
String possiblyUpdatedSupplierId = st.getString(3);
String possiblyUpdatedListPrice = st.getString(4);
String possiblyUpdatedMinPrice = st.getString(5);
String possiblyUpdatedShipCode = st.getString(6);

// 6. Populate the possibly updated attribute values in the row
populateAttribute(PRODUCTNAME, possiblyUpdatedName, true, false,
    false);
populateAttribute(SUPPLIERID, possiblyUpdatedSupplierId, true,
    false, false);
populateAttribute(LISTPRICE, possiblyUpdatedListPrice, true, false,
    false);
populateAttribute(MINPRICE, possiblyUpdatedMinPrice, true, false,
    false);
populateAttribute(SHIPPINGCLASSCODE, possiblyUpdatedShipCode, true,
    false, false);
} catch (SQLException e) {
    throw new JboException(e);
} finally {
    if (st != null) {
        try {
            // 7. Closing the statement
            st.close();
        } catch (SQLException e) {
        }
    }
}
}
}

```

[Example 4-45](#) shows the code to invoke the `lock_product` procedure. It's doing basically the same steps as those in [Example 4-44](#), with just the following two interesting differences:

- After retrieving the possibly updated column values from the OUT parameters, it uses the `compareOldAttrTo()` helper method inherited from the `PLSQLEntityImpl` to detect whether or not a `RowInconsistentException` should be thrown as a result of the row lock attempt.
- In the `catch (SQLException e)` block, it is testing to see whether the database has thrown the error:

```
ORA-00054: resource busy and acquire with NOWAIT specified
```

and if so, it again throws the ADF Business Components `AlreadyLockedException` just as the default entity object implementation of the `lock()` functionality would do in this situation.

Example 4-45 Invoking the Stored Procedure to Lock a Row by Primary Key

```

// In ProductsImpl.java
protected void callLockProcedureAndCheckForRowInconsistency() {
    String stmt = "begin products_api.lock_product(?,?,?,?);end;";
    CallableStatement st =
        getDBTransaction().createCallableStatement(stmt, 0);
    try {
        st.registerOutParameter(2, VARCHAR2);
        st.registerOutParameter(3, NUMBER);
        st.registerOutParameter(4, NUMBER);
        st.registerOutParameter(5, NUMBER);
        st.registerOutParameter(6, VARCHAR2);
    }
}

```

```

        st.setObject(1, getProductId());
        st.executeUpdate();
        String possiblyUpdatedName = st.getString(2);
        String possiblyUpdatedSupplierId = st.getString(3);
        String possiblyUpdatedListPrice = st.getString(4);
        String possiblyUpdatedMinPrice = st.getString(5);
        String possiblyUpdatedShipCode = st.getString(6);
        compareOldAttrTo(PRODUCTNAME, possiblyUpdatedName);
        compareOldAttrTo(SUPPLIERID, possiblyUpdatedSupplierId);
        compareOldAttrTo(LISTPRICE, possiblyUpdatedListPrice);
        compareOldAttrTo(MINPRICE, possiblyUpdatedMinPrice);
        compareOldAttrTo(SHIPPINGCLASSCODE, possiblyUpdatedShipCode);
    } catch (SQLException e) {
        if (Math.abs(e.getErrorCode()) == 54) {
            throw new AlreadyLockedException(e);
        } else {
            throw new JboException(e);
        }
    }
} finally {
    if (st != null) {
        try {
            st.close();
        } catch (SQLException e) {
        }
    }
}
}
}

```

With these methods in place, you have an entity object that wraps the PL/SQL package (in this case, a `Products` entity object with the `PRODUCTS_API` package) for all of its database operations. Due to the clean separation of the data querying functionality of view objects and the data validation and saving functionality of entity objects, you can now leverage this entity object in any way you would use a normal entity object. You can build as many different view objects as necessary that use this entity object as their entity usage.

4.17.5.3 Refreshing the Entity Object After `RowInconsistentException`

You can override the `lock()` method to refresh the entity object after a `RowInconsistentException` has occurred. [Example 4-46](#) shows code that can be added to the entity object implementation class to catch the `RowInconsistentException` and refresh the entity object.

Example 4-46 *Overridden `lock()` Method to Refresh Entity Object on `RowInconsistentException`*

```

// In the entity object implementation class
@Override
public void lock() {
    try {
        super.lock();
    }
    catch (RowInconsistentException ex) {
        this.refresh(REFRESH_UNDO_CHANGES);
        throw ex;
    }
}
}

```

4.18 Basing an Entity Object on a Join View or Remote DBLink

If you need to create an entity object based on either of the following:

- Synonym that resolves to a remote table over a DBLINK
- View with `INSTEAD OF` triggers

Then you will encounter the following error if any of its attributes are marked as **Refresh on Insert** or **Refresh on Update**:

```
JBO-26041: Failed to post data to database during "Update"
## Detail 0 ##
ORA-22816: unsupported feature with RETURNING clause
```

These types of schema objects do not support the `RETURNING` clause, which by default the entity object uses to more efficiently return the refreshed values in the same database roundtrip in which the `INSERT` or `UPDATE` operation was executed.

4.18.1 How to Disable the Use of the RETURNING Clause

Because some types of schema objects do not support the `RETURNING` clause, you might need to disable the `RETURNING` clause in your entity object. The following procedures explains how to do that.

Before you begin:

It may be helpful to have an understanding of the types of schema objects don't support the `RETURNING` clause. For more information, see [Section 4.18, "Basing an Entity Object on a Join View or Remote DBLink."](#)

You may also find it helpful to understand additional functionality that can be added using other entity object features. For more information, see [Section 4.1.2, "Additional Functionality for Entity Objects."](#)

To disable the use of the RETURNING clause for an entity object of this type:

1. Enable a custom entity definition class for the entity object.
2. In the custom entity definition class, override the `createDef()` method to call `setUseReturningClause(false)`.
3. If the **Refresh on Insert** attribute is the primary key of the entity object, you must specify some other attribute in the entity as an alternate unique key by setting the **Unique Key** property on it.

4.18.2 What Happens at Runtime: Disabling the RETURNING Clause

At runtime, when you have disabled the use of the `RETURNING` clause as described in [Section 4.18.1, "How to Disable the Use of the RETURNING Clause,"](#) the entity object implements the **Refresh on Insert** and **Refresh on Update** behavior using a separate `SELECT` statement to retrieve the values to refresh after insert or update as appropriate.

4.19 Using Inheritance in Your Business Domain Layer

Inheritance is a powerful feature of object-oriented development that can simplify development and maintenance when used appropriately. As shown in [Section 12.9, "Creating Extended Components Using Inheritance,"](#) ADF Business Components supports using inheritance to create new components that extend existing ones in

order to add additional properties or behavior or modify the behavior of the parent component. Inheritance can be useful in modeling the different kinds of entities in your reusable business domain layer.

Note: The example in this section refers to the `InheritanceAndPolymorphicQueries` project of the `AdvancedEntityExamples` application workspace in the `StandaloneExamples` module of the Fusion Order Demo application.

4.19.1 Understanding When Inheritance Can Be Useful

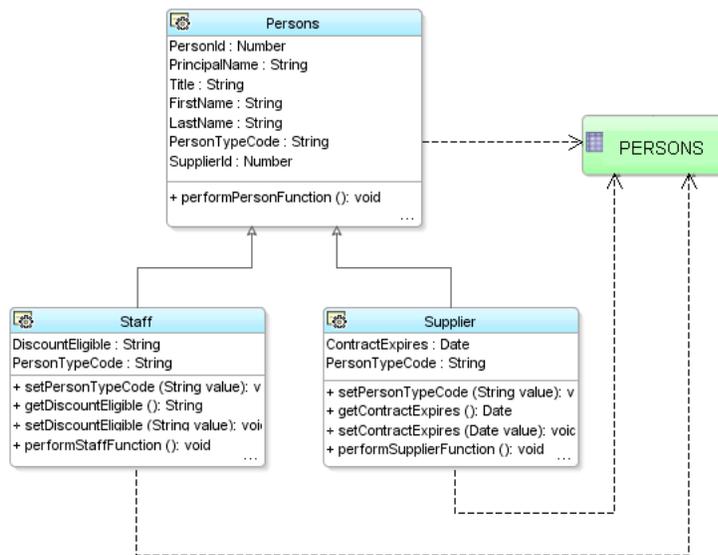

Your application's database schema might contain tables where different logical kinds of business information are stored in rows of the same table. These tables will typically have one column whose value determines the kind of information stored in each row. For example, the Fusion Order Demo application's `PERSONS` table stores information about customers, suppliers, and staff in the same table. It contains a `PERSON_TYPE_CODE` column whose value — `STAFF`, `CUST`, or `SUPP` — determines what kind of `PERSON` the row represents.

While the Fusion Order Demo implementation doesn't contain this differentiation, it's reasonable to assume that revisions of the application might require:

- Managing additional database-backed attributes that are specific to suppliers or specific to staff
- Implementing common behavior for all users that is different for suppliers or staff
- Implementing new functionality that is specific to only suppliers or only staff

[Figure 4-19](#) shows what the business domain layer would look like if you created distinct `Persons`, `Staff`, and `Supplier` entity objects to allow distinguishing the different kinds of business information in a more formal way inside your application. Since suppliers and staff are special *kinds* of persons, their corresponding entity objects would extend the base `Persons` entity object. This base `Persons` entity object would contain all of the attributes and methods common to all types of users. The `performPersonFunction()` method in the figure represents one of these common methods.

Then, for the `Supplier` and `Staff` entity objects you can add specific additional attributes and methods that are unique to that kind of user. For example, `Supplier` has an additional `ContractExpires` attribute of type `Date` to track when the supplier's current contract expires. There is also a `performSupplierFunction()` method that is specific to suppliers. Similarly, the `Staff` entity object has an additional `DiscountEligible` attribute to track whether the person qualifies for a staff discount. The `performStaffFunction()` is a method that is specific to staff.

Figure 4–19 Distinguishing Persons, Suppliers, and Staff Using Inheritance

By modeling these different kinds of persons as distinct entity objects in an inheritance hierarchy in your domain business layer, you can simplify having them share common data and behavior and implement the aspects of the application that make them distinct.

4.19.2 How to Create Entity Objects in an Inheritance Hierarchy

To create entity objects in an inheritance hierarchy, you use the Create Entity Object wizard to create each entity.

The example described here assumes that you've altered the FOD application's PERSONS table by executing the following DDL statement to add two new columns to it:

```
alter table persons add (
  discount_eligible varchar2(1),
  contract_expires date
);
```

To create entity objects in an inheritance hierarchy, you will perform the following tasks:

1. Identify the discriminator column and values, as described in [Section 4.19.2.1, "Identifying the Discriminator Column and Distinct Values."](#)
2. Identify the subset of attributes for each entity object, as described in [Section 4.19.2.2, "Identifying the Subset of Attributes Relevant to Each Kind of Entity."](#)
3. Create the base entity object, as described in [Section 4.19.2.3, "Creating the Base Entity Object in an Inheritance Hierarchy."](#)
4. Create the subtype entity objects, as described in [Section 4.19.2.4, "Creating a Subtype Entity Object in an Inheritance Hierarchy."](#)

4.19.2.1 Identifying the Discriminator Column and Distinct Values

Before creating entity objects in an inheritance hierarchy based on a table containing different kinds of information, you should first identify which column in the table is used to distinguish which kind of row it is.

For example, in the Fusion Order Demo application's `PERSONS` table, this is the `PERSON_TYPE_CODE` column. Since it helps partition or "discriminate" the rows in the table into separate groups, this column is known as the *discriminator column*.

Next, determine the valid values that the discriminator column takes on in your table. You might know this, or you could execute a simple SQL statement in the JDeveloper **SQL Worksheet** to determine the answer. To access the worksheet:

1. With the application open in JDeveloper, choose **Database Navigator** from the **View** menu.
2. Expand the workspace node, and select the connection.

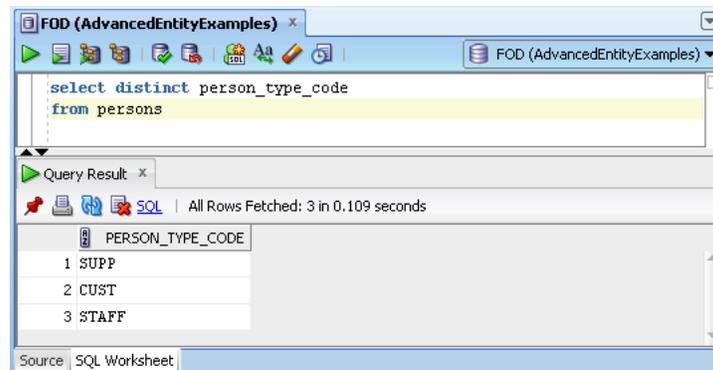

In this example, expand the **AdvancedEntityExamples** node and select the `FOD` connection.

3. Right-click the database connection, and choose **Open SQL Worksheet**.

In this example, the database connection is `FOD`.

Figure 4–20 shows the results of performing a `SELECT DISTINCT` query in the SQL Worksheet on the `PERSON_TYPE_CODE` column in the `PERSONS` table. It confirms that the rows are partitioned into three groups based on the `PERSON_TYPE_CODE` discriminator values: `SUPP`, `STAFF`, and `CUST`.

Figure 4–20 Using the SQL Worksheet to Find Distinct Discriminator Column Values

4.19.2.2 Identifying the Subset of Attributes Relevant to Each Kind of Entity

Once you know how many different kinds of business entities are stored in the table, you will also know how many entity objects to create to model these distinct items. You'll typically create one entity object per kind of item. Then, to help determine which entity should act as the base of the hierarchy, you need to determine which subset of attributes is relevant to each kind of item.

For example, assume you determine that all of the attributes except `ContractExpires` and `DiscountEligible` are relevant to all users, and that:

- `ContractExpires` is specific to suppliers
- `DiscountEligible` is specific to staff.

This information leads you to determine that the `Persons` entity object should be the base of the hierarchy, with the `Supplier` and `Staff` entity objects each extending `Persons` to add their specific attributes.

4.19.2.3 Creating the Base Entity Object in an Inheritance Hierarchy

To create the base entity object in an inheritance hierarchy, you use the Create Entity Object wizard.

Before you begin:

It may be helpful to have an understanding of entity objects in an inheritance hierarchy. For more information, see [Section 4.19, "Using Inheritance in Your Business Domain Layer."](#)

You may also find it helpful to understand additional functionality that can be added using other entity object features. For more information, see [Section 4.1.2, "Additional Functionality for Entity Objects."](#)

You will also need to determine the discriminator column and values, as described in [Section 4.19.2.1, "Identifying the Discriminator Column and Distinct Values,"](#) and determine the attributes for each entity object, as described in [Section 4.19.2.2, "Identifying the Subset of Attributes Relevant to Each Kind of Entity."](#)

To create the base entity object

1. In the Application Navigator, right-click the project you want to add the entity object to, and choose **New**.
2. In the New Gallery, expand **Business Tier**, select **ADF Business Components** and then **Entity Object**, and click **OK**.
3. In the Create Entity Object wizard, on the Name Page, provide a name and package for the entity, and select the schema object on which the entity will be based.

In this example, name the entity object `Persons` and base it on the `PERSONS` table.

4. On the Attributes page, select the attributes in the **Entity Attributes** list that are not relevant to the base entity object (if any) and click **Remove** to remove them.

In this example, you would remove the `DiscountEligible` and `ContractExpires` attributes from the list.

5. On the Attribute Settings page, use the **Select Attribute** dropdown list to choose the attribute that will act as the discriminator for the family of inherited entity objects and select the **Discriminator** checkbox to identify it as such. Importantly, you must also supply a **Default Value** for this discriminator attribute to identify rows of this base entity type.

In this example, you would select the `PersonTypeCode` attribute, mark it as a discriminator attribute, and set its **Default Value** to the value `"cust"`.

Note: Leaving the **Default Value** blank for a discriminator attribute is legal. A blank default value means that a row with the discriminator column value `IS NULL` will be treated as this base entity type.

6. Then click **Finish** to create the entity object.

4.19.2.4 Creating a Subtype Entity Object in an Inheritance Hierarchy

To create a subtype entity object in an inheritance hierarchy, you use the Create Entity Object wizard.

Before you begin:

It may be helpful to have an understanding of entity objects in an inheritance hierarchy. For more information, see [Section 4.19, "Using Inheritance in Your Business Domain Layer."](#)

You may also find it helpful to understand additional functionality that can be added using other entity object features. For more information, see [Section 4.1.2, "Additional Functionality for Entity Objects."](#)

You will also need to perform the following tasks:

1. Determine the discriminator column and values, as described in [Section 4.19.2.1, "Identifying the Discriminator Column and Distinct Values."](#)
2. Determine the attributes for each entity object, as described in [Section 4.19.2.2, "Identifying the Subset of Attributes Relevant to Each Kind of Entity."](#)
3. Create the parent entity object from which your new entity object will extend, as described in [Section 4.19.2.3, "Creating the Base Entity Object in an Inheritance Hierarchy."](#)
4. Make sure that the parent entity has a discriminator attribute already identified.
If it does not, use the overview editor to set the **Discriminator** property on the appropriate attribute of the parent entity before creating the inherited child.

To create the new subtype entity object in the hierarchy:

1. In the Application Navigator, right-click the project you want to add the entity object to, and choose **New**.
2. In the New Gallery, expand **Business Tier**, select **ADF Business Components** and then **Entity Object**, and click **OK**.
3. In the Create Entity Object wizard, on the Name Page, provide a name and package for the entity, and click the **Browse** button next to the **Extends** field to select the parent entity from which the entity being created will extend.

In this example, you would name the new entity `Staff` and select the `Persons` entity object in the **Extends** field.

4. On the Attributes page, the **Entity Attributes** list displays the attributes from the underlying table that are not included in the base entity object. Select the attributes you do not want to include in this entity object and click **Remove**.

In this example, because you are creating the `Staff` entity you would remove the `ContractExpires` attribute and leave the `DiscountEligible` attribute.

5. Click **Override** to select the discriminator attribute so that you can customize the attribute metadata to supply a distinct **Default Value** for the `Staff` subtype.

In this example, you would override the `PersonTypeCode` attribute.

6. On the Attribute Settings page, use the **Select Attribute** dropdown list to select the discriminator attribute. Change the **Default Value** field to supply a distinct default value for the discriminator attribute that defines the entity subtype being created.

In this example, you would select the `PersonTypeCode` attribute and change its **Default Value** to the value `"staff"`.

7. Click **Finish** to create the subtype entity object.

Note: You can repeat the same steps to define the `Supplier` entity object that extends `Persons` to add the additional `ContractExpires` attribute and overrides the **Default Value** of the `UserRole` discriminator attribute to have the value "supp".

4.19.3 How to Add Methods to Entity Objects in an Inheritance Hierarchy

To add methods to entity objects in an inheritance hierarchy, enable the custom Java class for the entity object and use the source editor to add the method. Methods that are common to all entity objects in the hierarchy are added to the base entity, while subtype-specific methods are added to the subtype. You can also override methods from the base entity object in the subtypes as necessary.

4.19.3.1 Adding Methods Common to All Entity Objects in the Hierarchy

To add a method that is common to all entity objects in the hierarchy, you add the method to the implementation class of the base entity object.

Before you begin:

It may be helpful to have an understanding of entity objects in an inheritance hierarchy. For more information, see [Section 4.19, "Using Inheritance in Your Business Domain Layer."](#)

You may also find it helpful to understand additional functionality that can be added using other entity object features. For more information, see [Section 4.1.2, "Additional Functionality for Entity Objects."](#)

You will also need to create the base entity object and subtypes in the hierarchy, as described in [Section 4.19.2, "How to Create Entity Objects in an Inheritance Hierarchy."](#)

To add a method common to all entity objects in a hierarchy:

1. In the Application Navigator, double-click the base entity object implementation class (for example, `PersonsImpl.java`).

If the base entity object doesn't have a custom Java implementation class, you'll need to create it.

- a. In the Application Navigator, double-click the entity object (for example, `Persons`).
 - b. In the overview editor, click the **Java** navigation tab.
 - c. On the Java page of the overview editor, click the **Edit Java options** icon.
 - d. Then select **Generate Entity Object Class**, and click **OK**.
2. In the source editor, add the method.

For example, you could add the following method to the `PersonsImpl` class for the base `Persons` entity object:

```
// In PersonsImpl.java
public void performPersonFunction() {
    System.out.println("## performPersonFunction as Customer");
}
```

Because this is the base entity object class, the methods you implement here are inherited by all subtype entity objects in the hierarchy.

4.19.3.2 Overriding Common Methods in a Subtype Entity Object

To override a method in a subtype entity object that is common to all entity objects in the hierarchy, you modify the common method inherited from the base entity object in the implementation class of the subtype entity object.

Before you begin:

It may be helpful to have an understanding of entity objects in an inheritance hierarchy. For more information, see [Section 4.19, "Using Inheritance in Your Business Domain Layer."](#)

You may also find it helpful to understand additional functionality that can be added using other entity object features. For more information, see [Section 4.1.2, "Additional Functionality for Entity Objects."](#)

You will also need to perform the following tasks:

1. Create the base entity object and subtypes in the hierarchy, as described in [Section 4.19.2, "How to Create Entity Objects in an Inheritance Hierarchy."](#)
2. Create the common method in the base entity object, which your subtype entity object will override, as described in [Section 4.19.3.1, "Adding Methods Common to All Entity Objects in the Hierarchy."](#)

Too override a method in a subtype entity object:

1. In the Application Navigator, double-click the subtype entity object implementation class (for example, `StaffImpl.java`).

If the subtype entity object doesn't have a custom Java implementation class, you'll need to create it.

- a. In the Application Navigator, double-click the entity object (for example, `Staff`).
 - b. In the overview editor, click the **Java** navigation tab.
 - c. On the Java page of the overview editor, click the **Edit Java options** icon.
 - d. Then select **Generate Entity Object Class**, and click **OK**.
2. With the subtype entity object implementation class open in the source editor, choose **Override Methods** from the **Source** menu.
 3. In the Override Methods dialog, select the method you want to override (for example, the `performPersonFunction()` method), and click **OK**.
 4. In the source editor, customize the overridden method's implementation.

For example, you could override the `performPersonFunction()` method in the `StaffImpl` class for the `Staff` subtype entity object and change the implementation to look like this:

```
// In StaffImpl.java
public void performPersonFunction() {
    System.out.println("## performPersonFunction as Staff");
}
```

When working with instances of entity objects in a subtype hierarchy, sometimes you will process instances of multiple different subtypes. Because the `Staff` and

Supplier entity objects are special kinds of Persons, you can write code that works with all of them using the more generic PersonsImpl type that they all have in common. When doing this generic kind of processing of classes that might be one of a *family* of subtypes in a hierarchy, Java will always invoke the most specific override of a method available.

This means that invoking the performPersonFunction() method on an instance of PersonsImpl that happens to really be the more specific StaffImpl subtype, will the result in printing out the following:

```
## performPersonFunction as Staff
```

instead of the default result that regular PersonsImpl instances would get:

```
## performPersonFunction as Customer
```

4.19.3.3 Adding Methods Specific to a Subtype Entity Object

To add a method that is specific to a subtype entity object in the hierarchy, you simply add the method in the implementation class of the subtype using the source editor.

Before you begin:

It may be helpful to have an understanding of entity objects in an inheritance hierarchy. For more information, see [Section 4.19, "Using Inheritance in Your Business Domain Layer."](#)

You may also find it helpful to understand additional functionality that can be added using other entity object features. For more information, see [Section 4.1.2, "Additional Functionality for Entity Objects."](#)

You will also need to create the base entity object and subtypes in the hierarchy, as described in [Section 4.19.2, "How to Create Entity Objects in an Inheritance Hierarchy."](#)

Too add a method specific to a subtype entity object:

1. In the Application Navigator, double-click the subtype entity object implementation class (for example, SupplierImpl.java).

If the base entity object doesn't have a custom Java implementation class, you'll need to create it.

- a. In the Application Navigator, double-click the entity object (for example, Supplier).
- b. In the overview editor, click the **Java** navigation tab.
- c. On the Java page of the overview editor, click the **Edit Java options** icon.
- d. Then select **Generate Entity Object Class**, and click **OK**.

2. In the source editor, add the method.

For example, you could add a performSupplierFunction() method to the SupplierImpl class for the base Supplier entity object:

```
// In SupplierImpl.java
public void performSupplierFunction() {
    System.out.println("## performSupplierFunction called");
}
```

4.19.4 What You May Need to Know About Using Inheritance

When using inheritance, you can also introduce a new base entity, find subtype entities using a primary key, and create view objects with polymorphic entity usages.

4.19.4.1 When to Introduce a New Base Entity

In the `InheritanceAndPolymorphicQueries` example project, the `Persons` entity object corresponds to a concrete kind of row in the `PERSONS` table and it also played the role of the base entity in the hierarchy. In other words, all of its attributes were common to all entity objects in the hierarchy.

A situation might arise, however, where the `Persons` entity object required a property that was specific to customers, but not common to staff or suppliers. Typically, for example, customers participate in customer satisfaction surveys, but staff and suppliers do not. The `Persons` entity would require a `LastSurveyDate` attribute to handle this requirement, but it wouldn't make sense to have `Staff` and `Supplier` entity objects inherit it.

In this case, you can introduce a new entity object (for example, `BasePersons`) to act as the base entity in the hierarchy. It would have all of the attributes common to all `Persons`, `Staff`, and `Supplier` entity objects. Then each of the three entities that correspond to concrete rows that appear in the table could have some attributes that are inherited from `BasePersons` and some that are specific to the individual subtype. In the `BasePersons` type, so long as you mark the `PersonTypeCode` attribute as a discriminator attribute, you can just leave the **Default Value** blank (or some other value that does *not* occur in the `PERSON_TYPE_CODE` column in the table). Because you will not use instances of the `BasePersons` entity in the application, it doesn't matter what its discriminator default value is.

4.19.4.2 Subtype Entity Objects and the `findByPrimaryKey()` Method

When you use the `findByPrimaryKey()` method on an entity definition, it only searches the entity cache for the entity object type on which you call it. In the `InheritanceAndPolymorphicQueries` example project, this means that if you call `PersonsImpl.getDefinitionObject()` to access the entity definition for the `Persons` entity object when you call `findByPrimaryKey()` on it, you will only find entities in the cache that happen to be customers. Sometimes this is exactly the behavior you want.

However, if you want to find an entity object by primary key allowing the possibility that it might be a subtype in an inheritance hierarchy, then you can use the `findByPKExtended()` method from the `EntityDefImpl` class instead.

For example, if you have created subtypes of the `Persons` entity object, this alternative finder method would find an entity object by primary key whether it is a customer, supplier, or staff. You can then use the Java `instanceof` operator to test which type you found, and then cast the `PersonsImpl` object to the more specific entity object type to work with features specific to that subtype.

4.19.4.3 View Objects with Polymorphic Entity Usages

When you create an entity-based view object with an entity usage corresponding to a base entity object in an inheritance hierarchy, you can configure the view object to query rows corresponding to multiple different subtypes in the base entity's subtype hierarchy. Each row in the view object will use the appropriate subtype entity object as the entity row part, based on matching the value of the discriminator attribute. See [Section 42.6.2, "How to Create a View Object with a Polymorphic Entity Usage,"](#) for specific instructions on setting up and using these view objects.

Defining SQL Queries Using View Objects

This chapter describes how to create view objects that join, filter, sort, and aggregate data for use in the application.

This chapter includes the following sections:

- [Section 5.1, "About View Objects"](#)
- [Section 5.2, "Populating View Object Rows from a Single Database Table"](#)
- [Section 5.3, "Populating View Object Rows with Static Data"](#)
- [Section 5.4, "Limiting View Object Rows Using Effective Date Ranges"](#)
- [Section 5.5, "Working with Multiple Tables in Join Query Results"](#)
- [Section 5.6, "Working with Multiple Tables in a Master-Detail Hierarchy"](#)
- [Section 5.7, "Working with a Single Table in a Recursive Master-Detail Hierarchy"](#)
- [Section 5.8, "Working with View Objects in Declarative SQL Mode"](#)
- [Section 5.9, "Working with View Objects in Expert Mode"](#)
- [Section 5.10, "Working with Bind Variables"](#)
- [Section 5.11, "Working with Named View Criteria"](#)
- [Section 5.12, "Working with List of Values \(LOV\) in View Object Attributes"](#)
- [Section 5.13, "Defining Attribute UI Hints for View Objects"](#)
- [Section 5.14, "Adding Calculated and Transient Attributes to a View Object"](#)

5.1 About View Objects

A *view object* is an Oracle Application Development Framework (Oracle ADF) component that encapsulates a SQL query and simplifies working with its results. There are several types of view objects that you can create in your data model project:

- Read-only view objects when updates to data are not necessary (can also be entity-based)
- Entity-based view objects when data updates will be performed
- Static data view objects for data defined by the view object itself
- Programmatically populated view objects (for more information, see [Chapter 42, "Advanced View Object Techniques"](#))

An *entity-based view object* can be configured to support updatable rows when you create view objects that map their attributes to the attributes of one or more existing

entity objects. The mapped entity object is saved as an entity usage in the view object definition. In this way, entity-based view objects cooperate automatically with entity objects to enable a fully updatable data model. The entity-based view object queries just the data needed for the client-facing task and relies on its mapped entity objects to automatically validate and save changes made to its view rows. Like the read-only view object, an entity-based view object encapsulates a SQL query, it can be linked into master-detail hierarchies, and it can be used in the data model of your application modules.

View objects with no entity usage definition are always read-only. They do not pick up entity-derived default values, they do not reflect pending changes, and they do not reflect updated reference information. In contrast to entity-based view objects, *read-only view objects* require you to write the query using the SQL query language. The Create View Object wizard and overview editor for entity-based view objects, on the other hand, simplify this task by helping you to construct the SQL query declaratively. For this reason, it is almost always preferable to create a non-updatable, entity-mapped view object, even when you want to create a view object just to read data. Additionally, as an alternative to creating view objects that specify a SQL statement at design time, you can create entity-mapped view objects that dynamically generate SQL statements at runtime.

There remain a few situations where it is still preferable to create a non-entity-mapped view object to read data, including SQL-based validation, Unions, and Group By queries.

When a view object has one or more underlying entity usages, you can create new rows, and modify or remove queried rows. The entity-based view object coordinates with underlying entity objects to enforce business rules and to permanently save the changes to the database. In addition, entity-based view objects provide these capabilities that do not exist with read-only view objects:

- Changes in cache (updates, inserts, deletes) managed by entities survive the view object's execution boundary.
- Changes made to relevant entity object attributes through other view objects in the same transaction are immediately reflected.
- Attribute values of new rows are initialized to the values from the underlying entity object attributes.
- Changes to foreign key attribute values cause reference information to get updated.
- Validation for row (entity) level is supported.
- Composition feature, including validation, locking, ordered-updates is supported.
- Support for effective dating, change indicator, and business events.

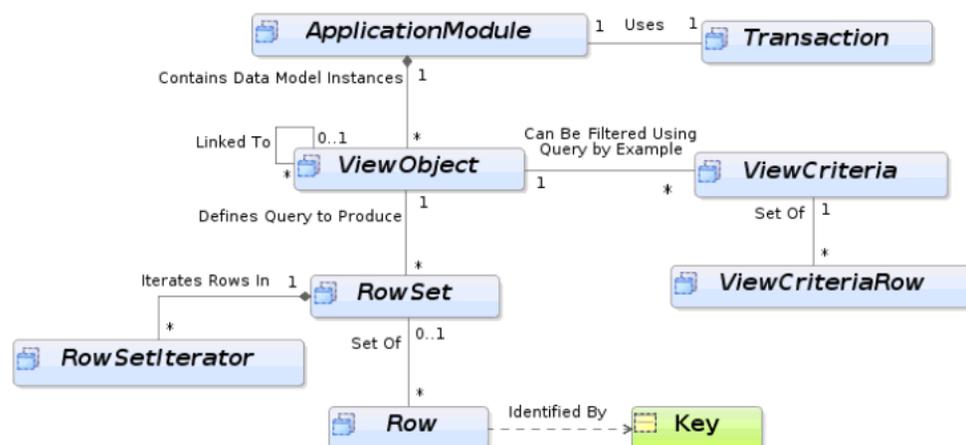

5.1.1 View Object Use Cases and Examples

This chapter helps you understand these view object concepts as illustrated in [Figure 5-1](#):

- You define a view object by providing a SQL query (either defined explicitly or declaratively).
- You use view object instances in the context of an application module that provides the database transaction for their queries.
- You can link a view object to one or more others to create master-detail hierarchies.

- At runtime, the view object executes your query and produces a set of rows (represented by a `RowSet` object).
- Each row is identified by a corresponding row key.
- You iterate through the rows in a row set using a row set iterator.
- You can filter the row set a view object produces by applying a set of Query-by-Example criteria rows.

Figure 5–1 A View Object Defines a Query and Produces a Row Set of Rows

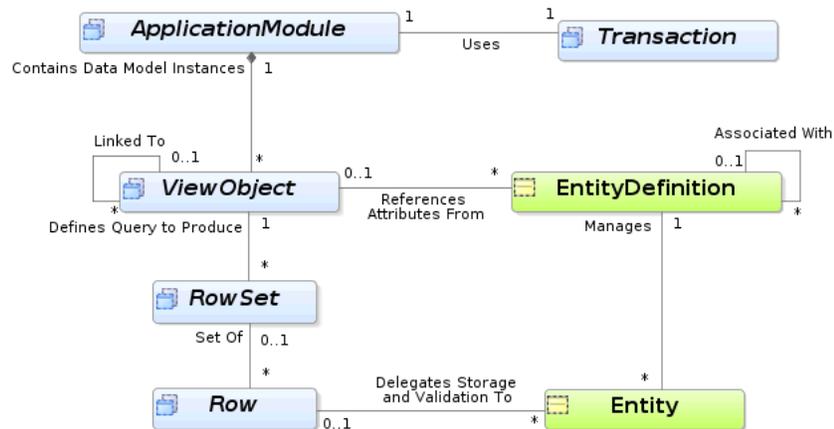

This chapter explains how instances of entity-based view objects contained in the data model of your application module enable clients to search for, update, insert, and delete business services layer information in a way that combines the full data shaping power of SQL with the clean, object-oriented encapsulation of reusable domain business objects. And all without requiring a line of code.

This chapter helps you to understand these entity-based view object concepts as illustrated in [Figure 5–2](#):

- You define an updatable view object by referencing attributes from one or more entity objects.
- You can use multiple, associated entity objects to simplify working with reference information.
- You can define view links based on underlying entity associations.
- You use your entity-based view objects in the context of an application module that provides the transaction.
- At runtime, the view row delegates the storage and validation of its attributes to underlying entity objects.

Figure 5–2 View Objects and Entity Objects Collaborate to Enable an Updatable Data Model

5.1.2 Additional Functionality for View Objects

You may find it helpful to understand other ADF features before you start working with view objects. Following are links to other functionality that may be of interest.

- For additional information about using Groovy script wherever expressions are supported in view object definitions, see [Section 3.6, "Overview of Groovy Scripting Language Support."](#)
- For details about using the interactive Oracle ADF Model Tester to validate view object query results, see [Chapter 6, "Testing View Instance Queries."](#)
- For details about creating a data model consisting of view object instances, see [Chapter 9, "Implementing Business Services with Application Modules."](#)
- For a quick reference to the most common code that you will typically write, use, and override in your custom view object classes, see [Appendix D, "Most Commonly Used ADF Business Components Methods."](#)
- For API documentation related to the `oracle.jbo` package, see the following Javadoc reference document:
 - *Oracle Fusion Middleware Java API Reference for Oracle ADF Model*

5.2 Populating View Object Rows from a Single Database Table

View objects provide the means to retrieve data from a data source. In the majority of cases, the data source will be a database and the mechanism to retrieve data is the SQL query. ADF Business Components can work with JDBC to pass this query to the database and retrieve the result.

When view objects use a SQL query, query columns map to view object attributes in the view object. The definition of these attributes, saved in the view object's XML definition file, reflect the properties of these columns, including data types and precision and scale specifications.

Performance Tip: If the query associated with the view object contains values that may change from execution to execution, use bind variables. Using bind variables in the query allows the query to reexecute without needing to reparse the query on the database. You can add bind variables to the view object in the Query page of the overview editor for the view object. For more information, see [Section 5.10, "Working with Bind Variables."](#)

Using the same Create View Object wizard, you can create view objects that either map to the attributes of existing entity objects or not. Only entity-based view objects automatically coordinate with mapped entity objects to enforce business rules and to permanently save data model changes. Additionally, you can disable the Updatable feature for entity-based view objects and work entirely declaratively to query read-only data. Alternatively, you can use the wizard or editor's expert mode to work directly with the SQL query language, but the view object you create will not support the transaction features of the entity-based view object.

While there is a small amount of runtime overhead associated with the coordination between view object rows and entity object rows, weigh this against the ability to keep the view object definition entirely declarative and maintain a customizable view object. Queries that cannot be expressed in entity objects, and that therefore require expert-mode query editing, include Unions and Group By queries. Expert mode-based view objects are also useful in SQL-based validation queries used by the view object-based Key Exists validator. Again, it is worth repeating that, by definition, using expert mode to define a SQL query means the view object must be read-only.

For more information about the differences between entity-based view objects and read-only view objects, see [Section 5.1, "About View Objects."](#)

5.2.1 How to Create an Entity-Based View Object

Creating an entity-based view object is the simplest way to create a view object. It is even easier than creating an expert-mode, read-only view object, since you don't have to type in the SQL statement yourself. An entity-based view object also offers significantly more runtime functionality than its expert-mode counterpart.

In an entity-based view object, the view object and entity object play cleanly separated roles:

- The view object is the data *source*: it retrieves the data using SQL.
- The entity object is the data *sink*: it handles validating and saving data changes.

Because view objects and entity objects have cleanly separated roles, you can build a hundred different view objects — projecting, filtering, joining, sorting the data in whatever way your user interfaces require, application after application — without any changes to the reusable entity object. In fact, it is possible that the development team responsible for the core business services layer of entity objects might be completely separate from another team responsible for the specific application modules and view objects needed to support the end-user environment. This relationship is enabled by metadata that the entity-based view object encapsulates. The metadata specifies how the `SELECT` list columns are related to the attributes of one or more underlying entity objects.

Your entity-based view object may be based on more than one database table. To use database joins to add multiple tables to the view object, see [Section 5.5, "Working with Multiple Tables in Join Query Results."](#)

5.2.1.1 Creating an Entity-Based View Object from a Single Table

To create an entity-based view object, use the Create View Object wizard, which is available from the New Gallery.

Before you begin:

It may be helpful to have an understanding of entity-based view objects. For more information, see [Section 5.2.1, "How to Create an Entity-Based View Object."](#)

You will need to complete this task:

Create the desired entity objects as described in [Section 4.2.1, "How to Create Multiple Entity Objects and Associations from Existing Tables."](#)

To create an entity-based view object from a single table:

1. In the Application Navigator, right-click the project in which you want to create the view object and choose **New**.
2. In the New Gallery, expand **Business Tier**, select **ADF Business Components** and then **View Object**, and click **OK**.

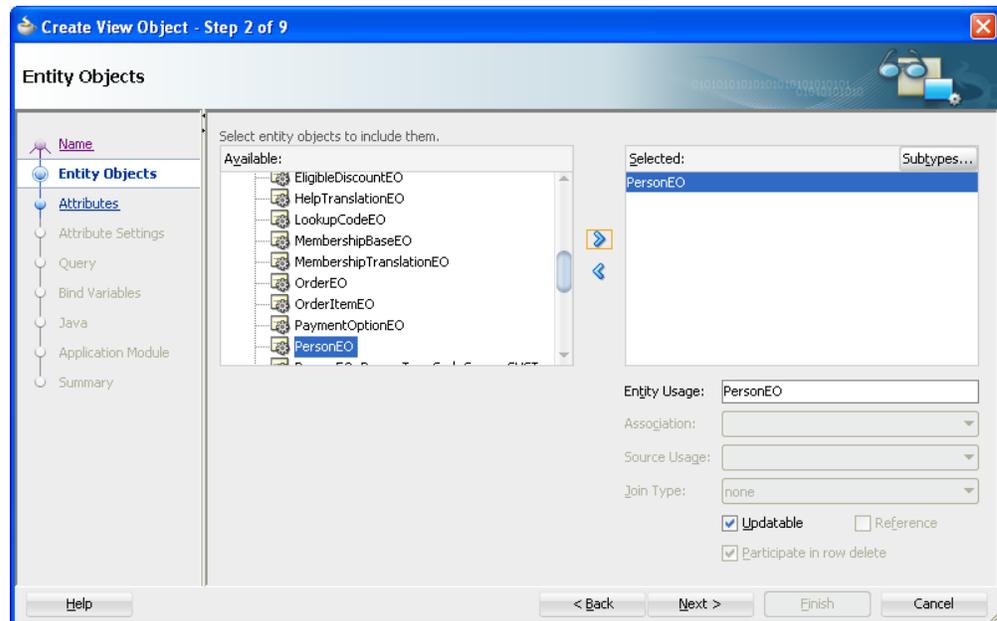

If this is the first component you're creating in the project, the Initialize Business Components Project dialog appears to allow you to select a database connection.

3. In the Initialize Business Components Project dialog, select the database connection or choose **New** to create a connection. Click **OK**.
4. In the Create View Object wizard, on the Name page, enter a package name and a view object name. Keep the default setting **Entity object** selected to indicate that you want this view object to manage data with its base entity object. Click **Next**.
5. On the Entity Objects page, select an entity object whose data you want to use in the view object. Click **Next**.

An entry in this list is known as an *entity usage*, since it records the entity objects that the view object will be using. Each entry could also be thought of as an *entity reference*, since the view object references attributes from that entity. For information about working table joins to create additional entity usages, see [Section 5.5, "Working with Multiple Tables in Join Query Results."](#)

For example, [Figure 5–3](#) shows the result after shuttling the `PersonEO` entity object into the **Selected** list.

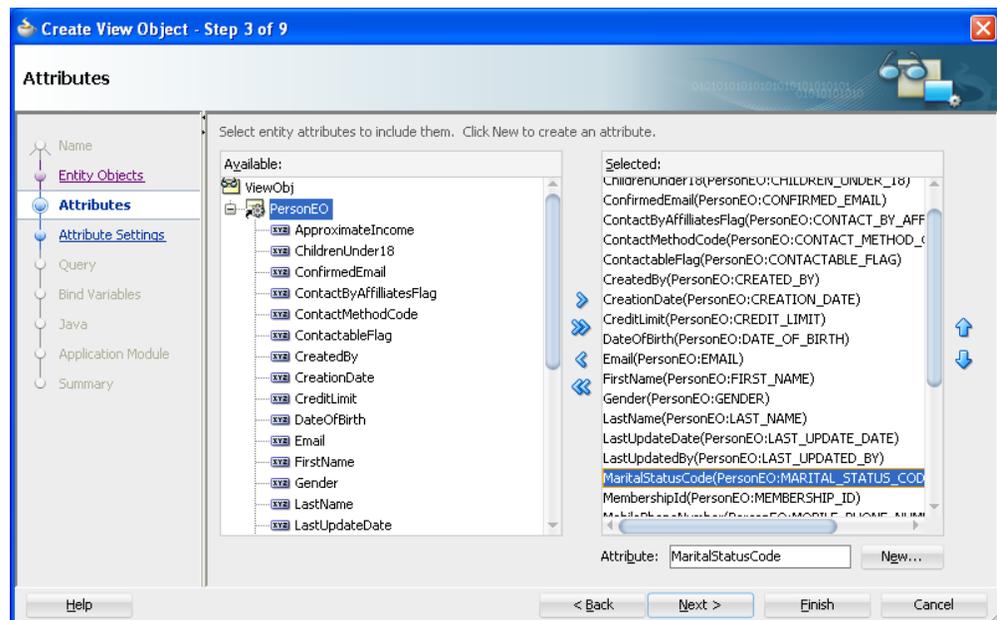

Figure 5–3 Create View Object Wizard, Entity Objects Page

- On the Attributes page, select the attributes you want to include from each entity usage in the **Available** list and shuttle them to the **Selected** list. Click **Next**.

For example, Figure 5–4 shows the attributes have been selected from the PersonEO.

Figure 5–4 Create View Object Wizard, Attributes Page

- On the Attribute Settings page, optionally, use the **Select Attribute** dropdown list to switch between the view object attributes in order to change their names or any of their initial settings.

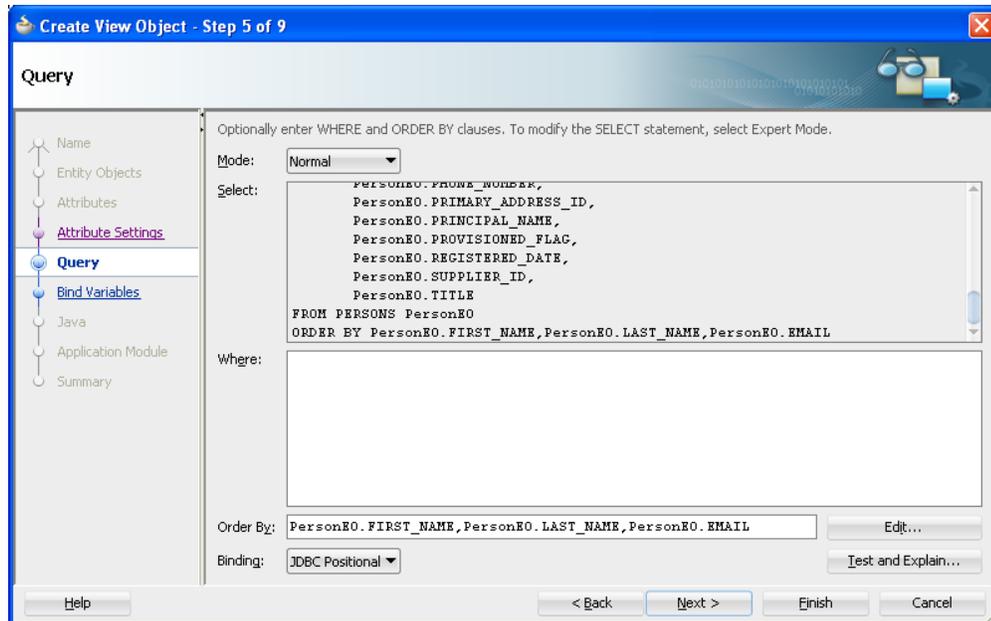

For more information about any of the attribute settings, press F1 or click **Help**.

- On the Query page, optionally, add a WHERE and ORDER BY clause to the query to filter and order the data as required. JDeveloper automatically generates the SELECT statement based on the entity attributes you've selected.

Do not include the WHERE or ORDER BY keywords in the **Where** and **Order By** field values. The view object adds those keywords at runtime when it executes the query.

For example, [Figure 5-5](#) shows the ORDER BY clause is specified to order the data by first name, last name, and email.

Figure 5-5 Create View Object Wizard, Query Page

- When you are satisfied with the view object, click **Finish**.

5.2.1.2 Creating a View Object with All the Attributes of an Entity Object

When you want to allow the client to work with *all* of the attributes of an underlying entity object, you can use the Create View Object wizard as described in [Section 5.2.1.1, "Creating an Entity-Based View Object from a Single Table."](#) After selecting the entity object, simply select *all* of its attributes on the Attributes page. However, for this frequent operation, there is an even quicker way to perform the same task in the Application Navigator.

Before you begin:

It may be helpful to have an understanding of entity-based view objects. For more information, see [Section 5.2.1, "How to Create an Entity-Based View Object."](#)

You will need to complete this task:

Create the desired entity objects as described in [Section 4.2.1, "How to Create Multiple Entity Objects and Associations from Existing Tables."](#)

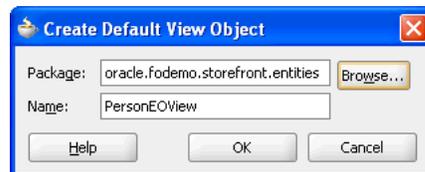

To create a default entity-based view object:

- In the Application Navigator, right-click the entity object and choose **New Default View Object**.

2. Provide a package and component name for the new view object in the Create Default View Object dialog.

In the Create Default View Object dialog you can click **Browse** to select the package name from the list of existing packages. For example, in [Figure 5–6](#), clicking Browse locates `oracle.fodemo.storefront.entities` package on the classpath for the `StoreFrontService` project in the `StoreFrontModule` application.

Figure 5–6 Shortcut to Creating a Default View Object for an Entity Object

The new entity-based view object created will be identical to one you could have created with the Create View Object wizard. By default, it will have a single entity usage referencing the entity object you selected in the Application Navigator, and will include all of its attributes. It will initially have neither a `WHERE` nor `ORDER BY` clause, and you may want to use the overview editor for the view object to:

- Remove unneeded attributes
- Refine its selection with a `WHERE` clause
- Order its results with an `ORDER BY` clause
- Customize any of the view object properties

5.2.2 What Happens When You Create an Entity-Based View Object

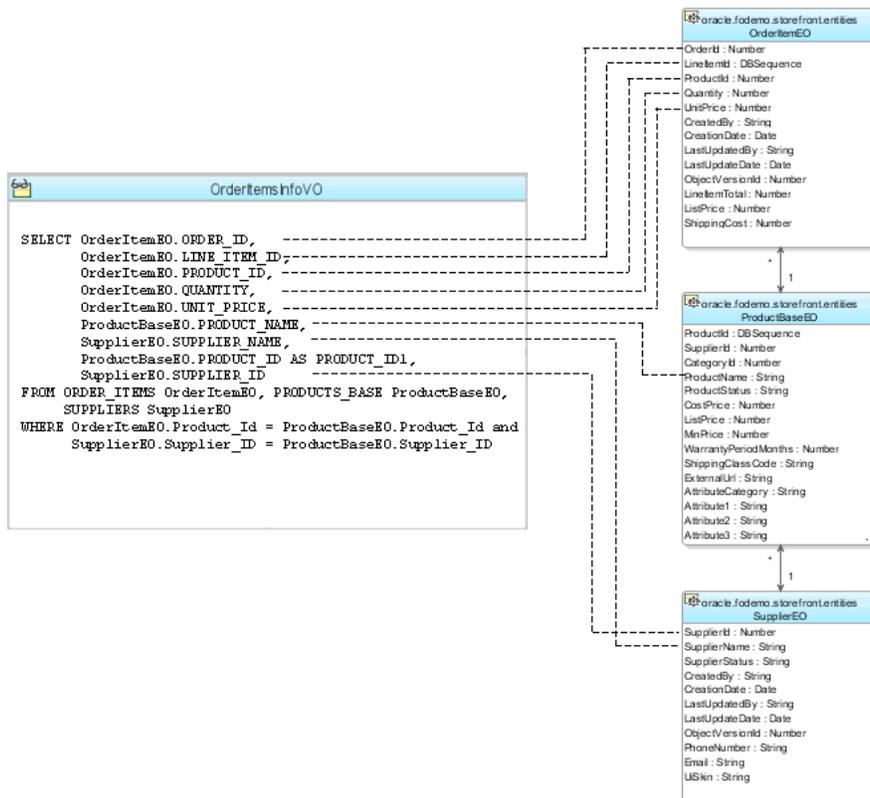

When you create a view object, JDeveloper creates the XML component definition file that represents the view object's declarative settings and saves it in the directory that corresponds to the name of its package. For example, the view object `Orders`, added to the `queries` package, will have the XML file `./queries/Orders.xml` created in the project's source path.

To view the view object settings, expand the desired view object in the Application Navigator, select the XML file under the expanded view object, and open the Structure window. The Structure window displays the list of definitions, including the SQL query, the name of the entity usage, and the properties of each attribute. To open the file in the editor, double-click the corresponding `.xml` node.

Note: If your IDE-level Business Components Java generation preferences so indicate, the wizard may also create an optional custom view object class `OrdersImpl.java` and/or a custom view row class `OrdersRowImpl.java` class.

[Figure 5–7](#) depicts the entity-based view object `OrderItemsInfoVO` and the three entity usages referenced in its query statement. The dotted lines represent the metadata captured in the entity-based view object's XML component definition that map `SELECT` list columns in the query to attributes of the entity objects used in the view object. The query of the entity-based view object joins data from a primary entity usage (`OrderItemEO`) with that from secondary reference entity usages (`ProductBaseEO` and `SupplierEO`).

Figure 5–7 View Object Encapsulates a SQL Query and Entity Attribute Mapping Metadata

5.2.3 How to Create an Expert Mode, Read-Only View Object

When you need full control over the SQL statement, the Create View Object wizard lets you specify that you want a view object to be read-only. In this case, you will not benefit from the declarative capabilities to define a non-updatable entity-based view object. However, there are a few situations where it is desirable to create read-only view objects using expert mode. Primarily, the read-only view object that you create will be useful when you need to write Unions or Group By queries. Additionally, you can use a read-only view object if you need to create SQL-based validation queries used by the view object-based Key Exists validator, provided that you have marked a key attribute.

For more information about the tradeoffs between working with entity-based view objects that you define as non-updatable and strictly read-only view objects, see [Section 42.2.2, "Consider Using Entity-Based View Objects for Read-Only Data."](#)

To create a read-only view object, use the Create View Object wizard, which is available from the New Gallery.

Before you begin:

It may be helpful to have an understanding of view objects. For more information, see [Section 5.2, "Populating View Object Rows from a Single Database Table."](#)

To create a read-only view object:

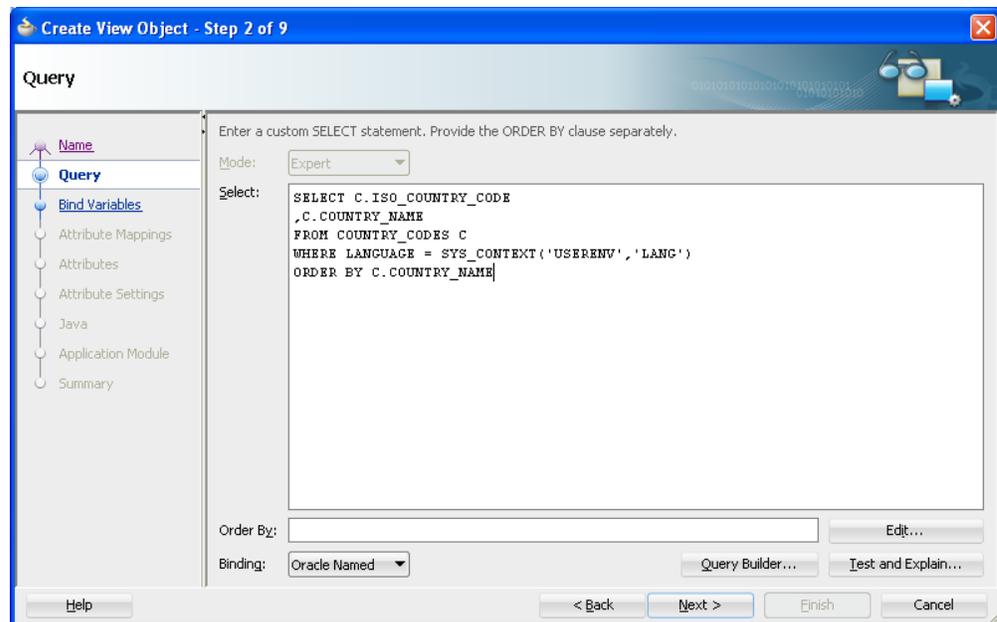

1. In the Application Navigator, right-click the project in which you want to create the view object and choose **New**.

2. In the New Gallery, expand **Business Tier**, select **ADF Business Components** and then **View Object**, and click **OK**.

If this is the first component you're creating in the project, the Initialize Business Components Project dialog appears to allow you to select a database connection.

3. In the Initialize Business Components Project dialog, select the database connection or choose **New** to create a connection. Click **OK**.
4. In the Create View Object wizard, on the Name page, enter a package name and a view object name. Select **SQL query** to indicate that you want this view object to manage data with read-only access. Click **Next**.
5. On the Query page, use one of the following techniques:
 - Paste any valid SQL statement into the **Query Statement** box. The query statement can use a `WHERE` clause and an `Order By` clause. For example, [Figure 5–8](#) shows a query statement that uses a `WHERE` clause and an `Order By` clause to query a list of country codes in the language used by the application.
 - Click **Query Builder** to open the SQL Statement dialog and use the interactive query builder.

Figure 5–8 Create View Object Wizard, Query Page

Note: If the Entity Objects page displays instead of the Query page, go back to Step 1 of the wizard and ensure that you've selected **Read-only Access**.

6. After entering or building the query statement, click **Next**.
7. On the Bind Variables page, do one of the following:
 - If the query does not reference any bind variables, click **Next** to skip Step 3.
 - To add a bind variable and work with it in the query, see [Section 5.10.1, "How to Add Bind Variables to a View Object Definition."](#)

8. On the Attribute Mappings page, click **Finish**.

Note: In the ADF Business Components wizards and editors, the default convention is to use camel-capped attribute names, beginning with a capital letter and using uppercase letters in the middle of the name to improve readability when the name comprises multiple words.

5.2.4 What Happens When You Create a Read-Only View Object

When you create a view object, JDeveloper first parses the query to infer the following from the columns in the SELECT list:

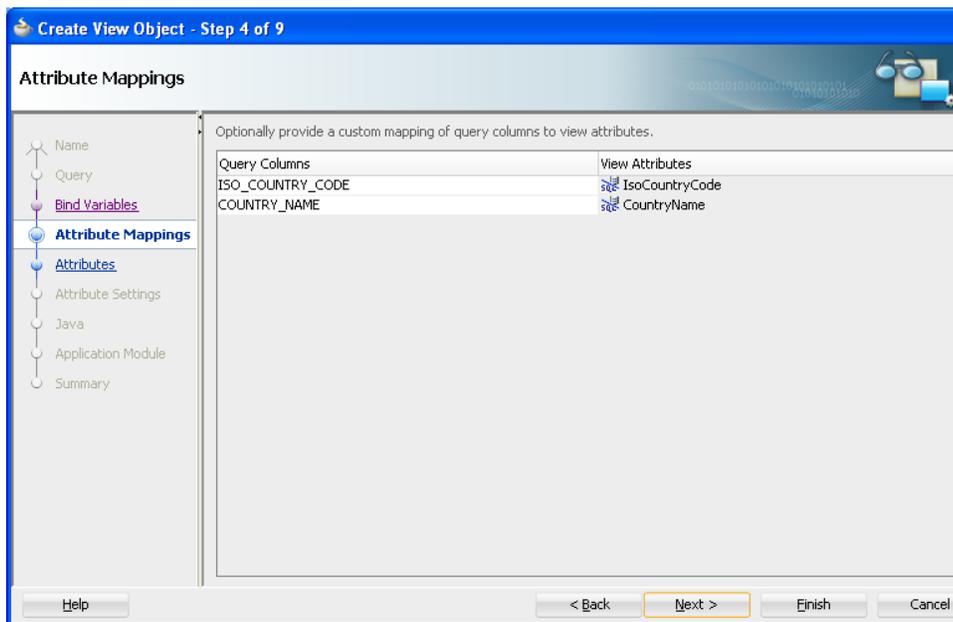

- The Java-friendly view attribute names (for example, `CountryName` instead of `COUNTRY_NAME`)

By default, the wizard creates Java-friendly view object attribute names that correspond to the SELECT list column names, as shown in [Figure 5–9](#).

For information about using view object attribute names to access the data from any row in the view object's result set by name, see [Section 6.4, "Testing View Object Instances Programmatically."](#)

- The SQL and Java data types of each attribute

Figure 5–9 Create View Object Wizard, Attribute Mappings Page

Each part of an underscore-separated column name like `SOME_COLUMN_NAME` is turned into a camel-capped word (like `SomeColumnName`) in the attribute name. While the view object attribute names correspond to the underlying query columns in the SELECT list, the attribute names at the view object level need not match necessarily.

Tip: You can rename the view object attributes to any names that might be more appropriate without changing the underlying query.

JDeveloper then creates the XML component definition file that represents the view object's declarative settings and saves it in the directory that corresponds to the name of its package. For example, the XML file created for a view object named `CountriesVO` in the `lookups` package is `./lookups/CountriesVO.xml` under the project's source path.

To view the view object settings, expand the desired view object in the Application Navigator, select the XML file under the expanded view object, and open the Structure window. The Structure window displays the list of definitions, including the SQL query, the name of the entity usage, and the properties of each attribute. To open the file in the editor, double-click the corresponding `.xml` node.

Note: If your IDE-level Business Components Java generation preferences so indicate, the wizard may also create an optional custom view object class `CountriesVOImpl.java` and/or a custom view row class `CountriesVORowImpl.java` class.

5.2.5 How to Edit a View Object

After you've created a view object, you can edit any of its settings in the overview editor for the view object.

Performance Tip: How you configure the view object to fetch data plays a large role in the runtime performance of the view object. For information about the tuning parameters that you can edit to optimize performance, see [Section 6.3.10, "What You May Need to Know About Optimizing View Object Runtime Performance."](#)

Before you begin:

It may be helpful to have an understanding of view objects. For more information, see [Section 5.2, "Populating View Object Rows from a Single Database Table."](#)

To edit a view object definition:

1. In the Application Navigator, double-click the view object to open the overview editor.
2. Click a navigation tab to open an editor page where you can adjust the SQL query, change the attribute names, add named bind variables, add UI controls hints, control Java generation options, and edit other settings.

5.2.5.1 Overriding the Inherit Properties from Underlying Entity Object Attributes

One interesting aspect of entity-based view objects is that each attribute that relates to an underlying entity object attribute inherits that attribute's properties. [Figure 5–10](#) shows the Details section of the view object editor's Attributes page with an inherited attribute selected. You can see that fields like the Java attribute type and the query column type are disabled and their values are inherited from the related attribute of the underlying entity object to which this view object is related. Some properties like the attribute's data type are inherited and cannot be changed at the view object level.

Other properties like `Queryable` and `Updatable` are inherited but can be overridden as long as their overridden settings are more restrictive than the inherited settings. For example, the attribute from underlying entity object might have an **Updatable** setting of **Always**. As shown [Figure 5–10](#), the Details section of the Attributes page of the view object overview editor allows you to set the corresponding view object attribute to a more restrictive setting like **While New** or **Never**. However, if the attribute in the

underlying entity object had instead an **Updatable** setting of **Never**, then the editor would not allow the view object's related attribute to have a less restrictive setting like **Always**.

Figure 5–10 View Object Attribute Properties Inherited from Underlying Entity Object

The screenshot shows the 'Entity Attribute' tab in the JDeveloper IDE. The attribute is named 'LastName' and is of type 'String'. The 'Updatable' property is set to 'Never'. The 'Type' property is set to 'VARCHAR2(30)'. The 'Service' section is checked for 'SDO Property'. Other properties include 'Persistent' (checked), 'Transient' (unchecked), 'Mandatory' (unchecked), 'Key Attribute' (unchecked), 'Selected in Query' (checked), 'Queryable' (checked), 'Passivate' (unchecked), 'Alias' (LAST_NAME), and 'XSD Type' (dropdown menu).

5.2.5.2 Controlling the Length, Precision, and Scale of View Object Attributes

When you display a particular attribute of the view object in the overview editor, you can see and change the values of the declarative settings that control its runtime behavior. One important property is the **Type** in the **Query Column** section, shown in [Figure 5–10](#). This property records the SQL type of the column, including the length information for VARCHAR2 columns and the precision and scale information for NUMBER columns.

JDeveloper tries to infer the type of the column automatically, but for some SQL expressions the inferred value might default to VARCHAR2 (255). You can update the **Type** value for this type of attribute to reflect the correct length if you know it. In the case of read-only view objects, this property is editable in the Details section that you display in the Attributes page of the overview editor for the view object. In the case of entity-based view objects, you must edit the **Type** property in the Details section of the Attributes page of the overview editor that you display for the entity object, as described in [Section 4.10.2, "How to Indicate Data Type Length, Precision, and Scale."](#)

For example, VARCHAR2 (30) which shows as the **Type** for the `FirstName` attribute in [Figure 5–11](#) means that it has a maximum length of 30 characters. For a NUMBER column, you would indicate a **Type** of NUMBER (7, 2) for an attribute that you want to have a precision of 7 digits and a scale of 2 digits after the decimal.

Performance Tip: Your SQL expression can control how long the describe from the database says the column is. Use the `SUBSTR()` function around the existing expression. For example, if you specify `SUBSTR(yourexpression, 1, 15)`, then the describe from the database will inform JDeveloper that the column has a maximum length of 15 characters.

Figure 5–11 Custom Attribute Settings in the Attribute Details Section

The screenshot shows the 'Attribute Details' configuration window. The 'Name' field contains 'FirstName' and 'Updateable' is set to 'Never'. The 'Display Name' is 'First Name'. The 'Type' is 'String'. The 'Property Set' is '<None>'. Under 'Default Value', 'Literal' is selected. The 'Service' section has 'SDO Property' checked. The 'Alias' is 'FIRST_NAME' and the 'Type' is 'VARCHAR2(30)'. Other options include 'Mandatory', 'Key Attribute', 'Passivate', 'Polymorphic Discriminator', 'View', 'Entity', 'Subtype Value', 'Effective Date', and 'XSD Type'.

5.2.5.3 Converting a Read-Only View Object to Allow Attribute Updates

When you use the Create View Object wizard to create a read-only view object, by default the attributes of the view object will not be updateable. Later you may decide to convert the view object to one that permits updates to its SQL-mapped table columns. However, this cannot be accomplished by merely changing the attribute's **Updateable** property. To convert a read-only view object to one that is updateable, you must add an entity usage that maps to the same table as the one used to create the read-only view object. Choosing an entity usage that defines the same table ensures that you can then remap the SQL-derived view attributes to entity usage attributes corresponding to the same table columns.

Before you begin:

It may be helpful to have an understanding of view objects. For more information, see [Section 5.2, "Populating View Object Rows from a Single Database Table."](#)

You may also find it helpful to have an understanding of entity-based view objects. For more information, see [Section 5.2.1, "How to Create an Entity-Based View Object."](#)

You will need to complete this task:

Create the desired entity objects as described in [Section 4.2.1, "How to Create Multiple Entity Objects and Associations from Existing Tables."](#)

To modify a read-only view object to allow updates:

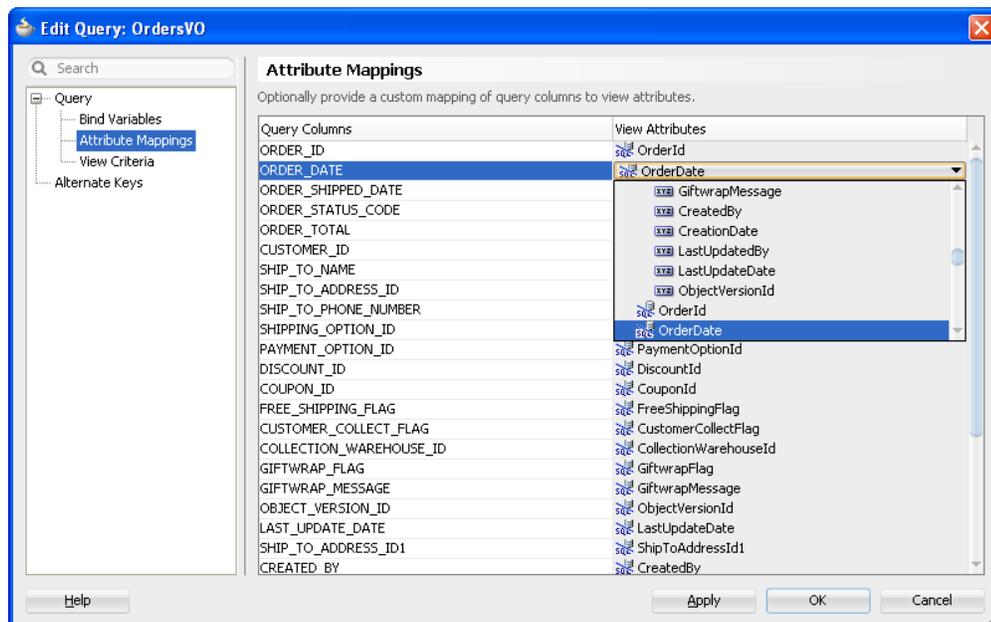

1. In the Application Navigator, double-click the read-only view object.
2. In the overview editor, click the **Entity Objects** navigation tab.
3. In the Entity Objects page, expand the **Available** list and double-click the entity object that describes the attributes of the read-only view object.

The entity object that you double-click will appear in the **Selected** list as an entity usage. You will need to remap the SQL-derived attributes to corresponding attributes defined by the entity usage.

4. Click the **Query** navigation tab, and in the Query page, click the **Edit SQL Query** button.
5. In the Edit Query dialog, click **Query** and then click **Attribute Mappings**.

6. In the Attribute Mappings page, perform the following steps to convert all SQL-derived attributes to their corresponding entity usage mapped attribute.
 - a. Click an attribute field in the **View Attributes** column and scroll to the top of the dropdown list to locate the entity usage attributes.
 - b. In the entity usage attribute list, select the attribute corresponding to the read-only attribute that you want to remap, as shown in [Figure 5–10](#).

Figure 5–12 Specifying an Entity-Derived Attribute in the Edit Query Dialog

7. Click **OK**.

5.2.5.4 Customizing View Object Attribute Display in the Overview Editor

When you edit view objects in the overview editor, you can customize the Attributes page of the overview editor to make better use of the attributes table displayed for the view object.

Customization choices that you make for the attributes table include the list of attribute properties to display as columns in the attributes table, the order that the columns appear (from left to right) in the attributes table, the sorting order of the columns, and the width of the columns. The full list of columns that you can choose to display correspond to the properties that you can edit for the attribute.

For example, you can add the **Updatable** property as a column to display in the attributes table when you want to quickly determine which attributes of your view object are updatable. Or, you can add the attributes' **Label** property as a column and see the same description as the end user. Or, you might want to view the list of attributes based on their entity usages. In this case, you can display the **Entity Usage** column and sort the entire attributes table on this column.

When you have set up the attributes table with the list of columns that you find most useful, you can apply the same set of columns to the attributes table displayed for other view objects by right-clicking the attributes table and choose **Apply to All View Objects**.

Before you begin:

It may be helpful to have an understanding of view objects. For more information, see [Section 5.2, "Populating View Object Rows from a Single Database Table."](#)

To customize the attributes table display:

1. In the Application Navigator, double-click the view object.
2. In the overview editor, click the **Attributes** navigation tab.
3. In the Attributes page, click the dropdown menu to the right of the attribute column headers (just below the attributes table's button bar) and choose **Select Columns**.
4. In the Select Columns dialog, perform any of the following actions.
 - a. Click the left/right shuttle buttons to change the list of visible columns in the attributes table of the overview editor. The overview editor displays only those columns corresponding to the attribute properties that appear the **Selected** list.
 - b. Click one of the **Move Selection** buttons to change the position of the columns in the attributes table of the overview editor. The overview editor displays the attribute properties arranged from left to right starting with the property at the top of the **Selected** list.
5. Click **OK**.
6. On the Attributes page of the overview editor, perform any of the following actions.
 - a. Click any column header to sort all columns in the attributes table by the selected column.

This feature is particularly useful when you want to focus on a particular column. For example, in the case of an entity-based view object, you can click the **Entity Usage** column header to group attributes in the attributes table by their underlying entity objects. To save this setting across all view objects that you display in the overview editor, click the dropdown menu to the right of the column headers and choose **Apply to All View Objects**.
 - b. Click any column header border and drag to adjust the width of the attributes table's column.
 - c. Click the dropdown list to the right of the column headers and select among the list of displayed columns to change the visibility of a column in the current attributes table display.

This feature lets you easily hide columns when you want to simplify the attributes table display in the current view object overview editor.
7. To extend the changes in the columns (including column list, column order, column sorting, and column width) to all other view object overview editors, click the dropdown menu to the right of the column headers and choose **Apply to All View Objects**.

This feature allows you to easily compare the same attributes across view objects. The overview editor will apply the column selections (and order) that you make in the Select Columns dialog and the current attributes table's column sorting and column widths to all view objects that you edit. View objects that are currently displayed in an open overview editor are not updated with these settings; you must close the open view object overview editor and then reopen the view object to see these settings applied.

5.2.5.5 Modifying the Order of Attributes in the View Object Source File

After you create a view object definition, you may decide to change the order of the attributes queried by the view object. This view object editing feature allows you to easily change the order that the attributes will appear in the attributes table displayed on the Attributes page of the view object overview editor. Because this feature acts on specific attributes and alters the XML definition of the current view object, it does not apply to other view objects that you may edit. Alternatively, you can sort the display of attributes on the Attribute page of the view object overview editor without affecting the source file by clicking any column header in the overview editor's attributes table.

Before you begin:

It may be helpful to have an understanding of view objects. For more information, see [Section 5.2, "Populating View Object Rows from a Single Database Table."](#)

To modify the order of attributes in the view object source file:

1. In the Application Navigator, double-click the view object.
2. In the overview editor, click the **Attributes** navigation tab and click **Set Source Order**.
3. In the Set Source Order dialog, select the attribute you want to reposition and click one of the **Move Selection** button.
4. Click **OK**.

This feature has no affect on other view objects that you may edit; it only affects the current view object.

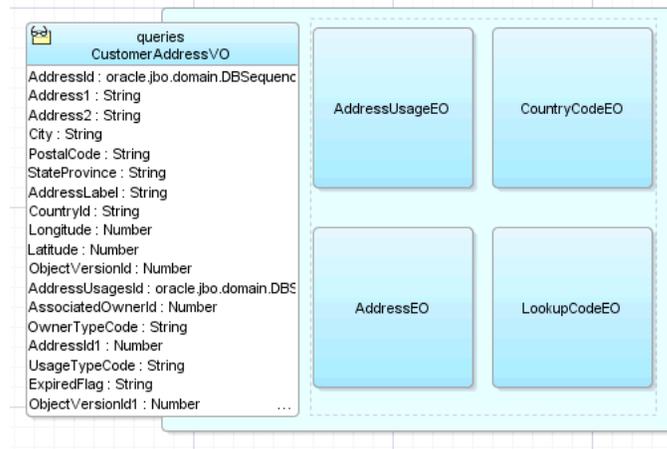

5.2.6 How to Show View Objects in a Business Components Diagram

JDeveloper's UML diagramming lets you create a Business Components diagram to visualize your business services layer. In addition to supporting entity objects, JDeveloper's UML diagramming allows you to drop view objects onto diagrams as well to visualize their structure and entity usages. For example, if you create a new Business Components Diagram named `StoreFrontService Data Model` in the `oracle.fodemo.storefront` package, and drag the `CustomerAddressVO` view object from the Application Navigator onto the diagram, its entity usages would display, as shown in [Figure 5-13](#). When viewed as an expanded node, the diagram shows a compartment containing the view objects entity usages.

Before you begin:

It may be helpful to have an understanding of view objects. For more information, see [Section 5.2, "Populating View Object Rows from a Single Database Table."](#)

You may also find it helpful to understand how to the diagram, see [Section 4.4, "Creating an Entity Diagram for Your Business Layer."](#)

Figure 5–13 View Object and Its Entity Usages in a Business Components Diagram

5.3 Populating View Object Rows with Static Data

ADF Business Components lets you create view objects in your data model project with rows that you populate at design time. Typically, you create view objects with static data when you have a small amount of data to maintain and you do not expect that data to change frequently. The decision whether to use a lookup table from the database or whether to use a static view object based on a list of hardcoded values depends on the size and nature of the data. The static view object is useful when you have no more than 100 entries to list. Any larger number of rows should be read from the database with a conventional table-based view object. The static view object has the advantage of being easily translatable. However, all of the rows of a static view object will be retrieved at once and therefore, using no more than 100 entries yields the best performance.

Best Practice: When you need to create a view object to access a small list of static data, you should use the static view object rather than query the database. The static view object is ideal for lists not exceeding 100 rows of data. Because the Create View Object wizard saves the data in a resource message file, these data are easily translatable.

Static list view objects are useful as an LOV data source when it is not desirable to query the database to supply the list of values. Suppose your order has the following statuses: open, closed, pending. You can create a static view object with these values and define an LOV on the static view object's status attribute. Because the wizard stores the values of the status view object in a translatable resource file, the UI will display the status values using the resource file corresponding to the application's current locale.

5.3.1 How to Create Static View Objects with Data You Enter

You use the Create View Object wizard to create static view objects. The wizard lets you define the desired attributes (columns) and enter as many rows of data as necessary. The wizard displays the static data table as you create it.

Note: Because the data in a static view object does not originate in database tables, the view object will be read-only.

You can also use the Create View Object wizard to create the attributes based on data from a comma-separated value (CSV) file format like a spreadsheet file. The wizard will attempt to create the attributes that you define in the wizard with data from the first row of the flat file.

Before you begin:

It may be helpful to have an understanding of static view objects. For more information, see [Section 5.3, "Populating View Object Rows with Static Data."](#)

To manually create attributes for a static view object:

1. In the Application Navigator, right-click the project in which you want to create the static list view object and choose **New**.
2. In the New Gallery, expand **Business Tier**, select **ADF Business Components** and then **View Object**, and click **OK**.

If this is the first component you're creating in the project, the Initialize Business Components Project dialog appears to allow you to select a database connection.
3. In the Initialize Business Components Project dialog, select the database connection or choose **New** to create a connection. Click **OK**.
4. In the Create View Object wizard, on the Name page, enter a package name and a view object name. Select **Static list** to indicate that you want to supply static list data for this view object. Click **Next**.
5. On the Attributes page, click **New** to add an attribute that corresponds to the columns in the static data table. In the New View Object Attribute dialog, enter a name and select the attribute type. Click **OK** to return to the wizard, and click **Next**.
6. On the Attribute Settings page, do nothing and click **Next**.
7. On the Static List page, click the **Add** icon to enter the data directly into the wizard page. The attributes you defined will appear as the columns for the static data table.
8. On the Application Module pages, do nothing and click **Next**.
9. On the Summary page, click **Finish**.

5.3.2 How to Create Static View Objects with Data You Import

Using the Import feature of the Create View Object wizard, you can create a static data view object with attributes based on data from a comma-separated value (CSV) file format like a spreadsheet file. The wizard will use the first row of a CSV flat file to identify the attributes and will use the subsequent rows of the CSV file for the data for each attribute. For example, if your application needs to display choices for international currency, you might define the columns Symbol, Country, and Description in the first row and then add rows to define the data for each currency type, as shown in [Figure 5-14](#).

Figure 5–14 Sample Data Ready to Import from CSV Flat File

	A	B	C
1	Symbol	Country	Description
2	USD	United States of America	Dollars
3	CNY	P.R. China	Yuan Renminbi
4	EUR	Europe	Euro
5	JPY	Japan	Yen

Before you begin:

It may be helpful to have an understanding of static view objects. For more information, see [Section 5.3, "Populating View Object Rows with Static Data."](#)

To create attributes of a static view object based on a flat file:

1. In the Application Navigator, right-click the project in which you want to create the static list view object and choose **New**.
2. In the New Gallery, expand **Business Tier**, select **ADF Business Components** and then **View Object**, and click **OK**.

If this is the first component you're creating in the project, the Initialize Business Components Project dialog appears to allow you to select a database connection.

3. In the Initialize Business Components Project dialog, select the database connection or choose **New** to create a connection. Click **OK**.
4. In the Create View Object wizard, on the Name page, enter a package name and a view object name. Select **Static list** to indicate that you want to supply static list data for this view object. Click **Next**.
5. On the Attributes page, optionally, click **New** to add an attribute that corresponds to the columns in the static data table. In the New View Object Attribute dialog, enter a name and select the attribute type. Click **OK** to return to the wizard, and click **Next**.

When the static data will be loaded from a CSV flat file, you can optionally skip this step. If you do not create the attributes yourself, the wizard will attempt to use the first row of the CSV file to create the attributes. However, if you create the attributes in the wizard, then the attributes you create must match the order of the columns defined by the flat file. If you have created fewer attributes than columns, the wizard will ignore extra columns during import. Conversely, if you create more attributes than columns, the wizard will define extra attributes with the value `NULL`.

6. On the Attribute Settings page, do nothing and click **Next**.
7. On the Static List page, click **Import** to locate the CSV file and display the data in the wizard. Verify the data and edit the values as needed.

To edit an attribute value, double-click in the value field.

8. Optionally, click the **Add** icon or **Remove** icon to change the number of rows of data. Click **Next**.

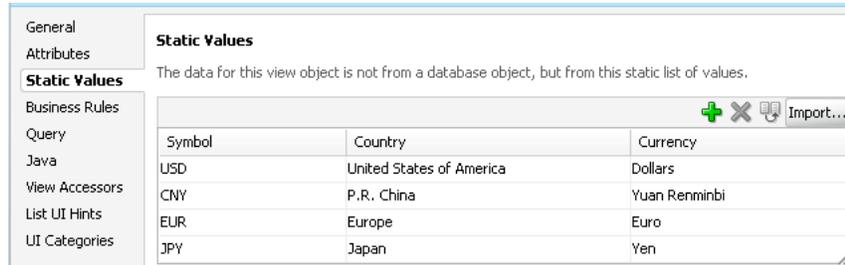

To enter values for the attributes of a new row, double-click in the value field.

9. On the Application Module page, do nothing and click **Next**.
10. On the Summary page, click **Finish**.

5.3.3 What Happens When You Create a Static List View Object

When you create a static view object, the overview editor for the view object displays the rows of data that you defined in the wizard. You can use the editor to define additional data, as shown in [Figure 5–15](#).

Figure 5–15 *Static Values Page Displays Data*

The generated XML definition for the static view object contains one transient attribute for each column of data. For example, if you import a CSV file with data that describes international currency, your static view object might contain a transient attribute for Symbol, Country, and Description, as shown in [Example 5–1](#).

Example 5–1 *XML Definition for Static View Object*

```
<ViewObject
...
// Transient attribute for first column
<ViewAttribute
  Name="Symbol"
  IsUpdateable="false"
  IsSelected="false"
  IsPersistent="false"
  PrecisionRule="true"
  Precision="255"
  Type="java.lang.String"
  ColumnType="VARCHAR2"
  AliasName="Symbol"
  SQLType="VARCHAR"/>
// Transient attribute for second column
<ViewAttribute
  Name="Country"
  IsUpdateable="false"
  IsPersistent="false"
  PrecisionRule="true"
  Precision="255"
  Type="java.lang.String"
  ColumnType="VARCHAR"
  AliasName="Country"
  SQLType="VARCHAR"/>
// Transient attribute for third column
<ViewAttribute
  Name="Description"
  IsUpdateable="false"
  IsPersistent="false"
  PrecisionRule="true"
  Precision="255"
  Type="java.lang.String"
  ColumnType="VARCHAR"
  AliasName="Description"
```

```

        SQLType="VARCHAR" />
    <StaticList
        Rows="4"
        Columns="3" />
    // Reference to file that contains static data
    <ResourceBundle>
        <PropertiesBundle
            PropertiesFile="model.ModelBundle" />
        </ResourceBundle>
    </ViewObject>

```

Because the data is static, the overview editor displays no Query page and the generated XML definition for the static view object contains no query statement. Instead, the `<ResourceBundle>` element in the XML definition references a resource bundle file. The resource bundle file describes the rows of data and also lets you localize the data. When the default resource bundle type is used, the file `ModelNameBundle.properties` appears in the data model project, as shown in [Example 5-2](#).

Example 5-2 Default Resource Bundle File for Static View Object

```

model.ViewObj.SL_0_0=USD
model.ViewObj.SL_0_1=United States of America
model.ViewObj.SL_0_2=Dollars
model.ViewObj.SL_1_0=CNY
model.ViewObj.SL_1_1=P.R. China
model.ViewObj.SL_1_2=Yuan Renminbi
model.ViewObj.SL_2_0=EUR
model.ViewObj.SL_2_1=Europe
model.ViewObj.SL_2_2=Euro
model.ViewObj.SL_3_0=JPY
model.ViewObj.SL_3_1=Japan
model.ViewObj.SL_3_2=Yen

```

5.3.4 How to Edit Static List View Objects

When you need to make changes to the static list table, double-click the view object in the Application Navigator to open the overview editor for the view object. You can add and delete attributes (columns in the static list table), add or delete rows (data in the static list table), sort individual rows, and modify individual attribute values. The editor will update the view object definition file and save the attribute names in the message bundle file.

5.3.5 What You May Need to Know About Static List View Objects

The static list view object has a limited purpose in the application module's data model. Unlike entity-based view objects, static list view objects will not be updatable. You use the static list view object when you want to display read-only data to the end user and you do not want to create a database table for the small amount of data the static list table contains.

5.4 Limiting View Object Rows Using Effective Date Ranges

Applications that need to query data over a specific date range can generate *date-effective row sets*. To define a date-effective view object you must create an entity-based view object that is based on a date-effective entity object. User control over the view object's effective date usage is supported by metadata on the view object

at design time. At runtime, ADF Business Components generates the query filter that will limit the view rows to an effective date.

5.4.1 How to Create an Date-Effective View Object

Whether or not the query filter for an effective date will be generated depends on the value of the **Effective Dated** property displayed in the Property Inspector for the view object (to view the property, click the **General** tab in the overview editor for the view object and expand the **Name** category in the Property Inspector).

Note: Because the date-effective view object must be based on an date-effective entity object, setting a view object's **Effective Dated** property to **True** without an underlying date-effective entity object, will result in a runtime exception.

The overview editor for the view object does not display the date-effective query clause in the `WHERE` clause. You can use the Explain Plan dialog or Test Query dialog to view the clause. A typical query filter for effective dates looks like this:

```
(:Bind_SysEffectiveDate BETWEEN Person.EFFECTIVE_START_DATE AND  
Person.EFFECTIVE_END_DATE)
```

At runtime, the bind value for the query is obtained from a property of the root application module. In order to set the effective date for a transaction, use code similar to the following snippet:

```
am.setProperty(ApplicationModule.EFF_DT_PROPERTY_STR, new  
Date("2008-10-01"));
```

If you do not set `EFF_DT_PROPERTY_STR` on the application module, the current date is used in the query filter, and the view object returns the effective rows filtered by the current date.

The view object has its own transient attribute, `SysEffectiveDate`, that you can use to set the effective date for view rows. Otherwise, the `SysEffectiveDate` attribute value for new rows and defaulted rows is derived from the application module. ADF Business Components propagates the effective date from the view row to the entity object during DML operations only.

Before you begin:

It may be helpful to have an understanding of data-effective row sets. For more information, see [Section 5.4, "Limiting View Object Rows Using Effective Date Ranges."](#)

You will need to complete these tasks:

1. Create an effective dated entity object as described in [Section 4.2.8, "How to Store Data Pertaining to a Specific Point in Time."](#)
2. Use the Create View Object wizard to create the entity-based view object as described in [Section 5.2.1, "How to Create an Entity-Based View Object."](#)

The view object you create should be based on the effective dated entity object you created. In the Attributes page of the wizard, be sure to add the date-effective attributes that specify the start date and end date on the entity object to the **Selected** list for the view object.

To enable effective dates for a view object using the SysEffectiveDate attribute:

1. In the Application Navigator, double-click the view object you created based on the effective dated entity object.
2. In the overview editor, click the **General** navigation tab.
3. In the Property Inspector, expand the **Name** category.
If the **Name** category is not displayed in the Property Inspector, click the **General** navigation tab in the overview editor to set the proper focus.
4. In the Name category, verify that the context menu for the **Effective Dated** property displays **True**.
5. In the overview editor, click the **Attributes** navigation tab and select the attribute for the start date, and then click the **Details** tab and verify that **Effective Date** is enabled and that **Start** is selected, as shown in [Figure 5–16](#).

Verify that the attribute for the end date is also enabled correctly, as shown in the figure. Note that these fields appear grayed out to indicate that they cannot be edited for the view object.

Figure 5–16 View Object Overview Editor Displays Effective Date Settings

No additional steps are required once you have confirmed that the view object has inherited the desired attributes from the date-effective entity object.

5.4.2 How to Create New View Rows Using Date-Effective View Objects

Creating (inserting) date-effective rows is similar to creating or inserting ordinary view rows. The start date and end date can be specified as follows:

- The user specifies the effective date on the application module. The start date is set to the effective date, and the end date is set to end of time.
- The user specifies values for the start date and the end date (advanced).

In either case, during entity validation, the new row is checked to ensure that it does not introduce any gaps or overlaps. During post time, ADF Business Components will acquire a lock on the previous row to ensure that the gap or overlaps are not created upon the row insert.

5.4.3 How to Update Date-Effective View Rows

You can update view rows by using API calls like `Row.setAttribute()`. ADF Business Components supports various modes to initiate the row update.

To set the update mode, invoke the `Row.setEffectiveDateMode(int mode)` method with one of the following mode constants.

- **CORRECTION** (Correction Mode)
The effective start date and effective end dates remain unchanged. The values of the other attributes may change. This is the standard row update behavior.
- **UPDATE** (Update Mode)
The effective end date of the row will be set to the effective date. All user modifications to the row values are reverted on this row. A new row with the

modified values is created. The effective start date of the new row is set to the effective date plus one day, and the effective end date is set to end of time. The new row will appear after the transaction is posted to the database.

- `UPDATE_OVERRIDE` (Update Override Mode)

The effective end date of the modified row will be set to the effective date. The effective start date of the next row is set to effective date plus one day.

- `UPDATE_CHANGE_INSERT` (Change Insert Mode)

The effective end date of the modified row should be set to the effective date. All user modifications to the row values are reverted on this row. A new row with the modified values will be created. The effective start date of the new row is set to effective date plus one day, and the effective end date is set to effective start date of the next row minus one day. The new row will appear after the transaction is posted to the database.

5.4.4 How to Delete Date-Effective View Rows

ADF Business Components supports various modes to initiate the row deletion. You can mark view rows for deletion by using API calls like `RowSet.removeCurrentRow()` or `Row.remove()`.

To set the deletion mode, invoke the `Row.setEffectiveDateMode(int mode)` method with one of the following mode constants.

- `DELETE` (Delete Mode)

The effective date of the row is set to the effective date. The operation for this row is changed from delete to update. All rows with the same noneffective date key values and with an effective start date greater than the effective date are deleted.

- `DELETE_NEXT_CHANGE` (Delete Next Change Mode)

The effective end date of the row is set to the effective end date of the next row with the same noneffective date key values. The operation for this row is changed from delete to update. The next row is deleted.

- `FUTURE_CHANGE` (Delete Future Change Mode)

The effective end date of the row is set to the end of time. The operation for this row is changed from delete to update. All future rows with the same noneffective date key values are deleted.

- `ZAP` (Zap Mode)

All rows with the same non-effective date key values are deleted.

The effective date mode constants are defined on the row interface as well.

5.4.5 What Happens When You Create a Date-Effective View Object

When you create an date-effective view object, the view object inherits the transient attribute `SysEffectiveDate` from the entity object to store the effective date for the row. Typically, the insert/update/delete operations modify the transient attribute while Oracle ADF decides the appropriate values for effective start date and effective end date.

The query displayed in the overview editor for the date-effective view object does not display the `WHERE` clause needed to filter the effective date range. To view the full query for the date-effective view object, including the `WHERE` clause, edit the query

and click **Explain Plan** in the Edit Query dialog. The following sample shows a typical query and query filter for effective dates:

```
SELECT OrdersVO.ORDER_ID,
       OrdersVO.CREATION_DATE,
       OrdersVO.LAST_UPDATE_DATE
FROM ORDERS OrdersVO
WHERE (:Bind_SysEffectiveDate BETWEEN OrdersVO.CREATION_DATE AND
       OrdersVO.LAST_UPDATE_DATE)
```

Example 5-3 shows sample XML entries that are generated when you create an date-effective view object.

Example 5-3 XML Definition for Date-Effective View Object

```
<ViewObject
...
// Property that enables date-effective view object.
  IsEffectiveDated="true">
  <EntityUsage
    Name="Orders1"
    Entity="model.OrdersDatedEO"
    JoinType="INNER JOIN"/>
  // Attribute identified as the start date
  <ViewAttribute
    Name="CreationDate"
    IsNotNull="true"
    PrecisionRule="true"
    IsEffectiveStartDate="true"
    EntityAttrName="CreationDate"
    EntityUsage="Orders1"
    AliasName="CREATION_DATE"/>
  // Attribute identified as the end date
  <ViewAttribute
    Name="LastUpdateDate"
    IsNotNull="true"
    PrecisionRule="true"
    IsEffectiveEndDate="true"
    EntityAttrName="LastUpdateDate"
    EntityUsage="Orders1"
    AliasName="LAST_UPDATE_DATE"/>
  // The SysEffectiveDate transient attribute
  <ViewAttribute
    Name="SysEffectiveDate"
    IsPersistent="false"
    PrecisionRule="true"
    Type="oracle.jbo.domain.Date"
    ColumnType="VARCHAR2"
    AliasName="SysEffectiveDate"
    Passivate="true"
    SQLType="DATE"/>
</ViewObject>
```

5.4.6 What You May Need to Know About Date-Effective View Objects and View Links

Effective dated associations and view links allow queries to be generated that take the effective date into account. The effective date of the driving row is passed in as a bind parameter during the query execution.

While it is possible to create a noneffective dated association between two entities when using the Create Association wizard or Create View Link wizard, JDeveloper will by default make the association or link effective dated if one of the ends is effective dated. However, when the association or view link exists between an effective dated and a noneffective dated object, then at runtime ADF Business Components will inspect the effective dated nature of the view object or entity object before generating the query clause and binding the effective date. The effective date is first obtained from the driving row. If it is not available, then it is obtained from the property `EFF_DT_PROPERTY_STR` of the root application module. If you do not set `EFF_DT_PROPERTY_STR` for the application module, the current date is used in the query filter on the driving row and applied to the other side of the association or view link.

5.5 Working with Multiple Tables in Join Query Results

Many queries you will work with will involve multiple tables that are related by foreign keys. In this scenario, you join the tables in a single view object query to show additional descriptive information in each row of the main query result. You use the Create View Object wizard to define the query using declarative options. Whether your view object is read-only or entity-based determines how you can define the join:

- When you work with entity-based view objects, the Create View Object wizard uses an existing association defined between the entities to automatically build the view object's join `WHERE` clause. You can declaratively specify the type of join you want to result from the entity objects. Inner join (equijoin) and outer joins are both supported.
- When you work with read-only view objects, you will use the SQL Builder dialog to build the view object's join `WHERE` clause. In this case, you must select the columns from the tables that you want to join.

Figure 5–17 illustrates the rows resulting from two tables queried by a view object that defines a join query. The join is a single flattened result.

Figure 5–17 Join Query Result

Join Query	101	Order	322	Pat	Fay
	212	Order	322	Pat	Fay
	222	Order	310	John	Chen
	123	Order	300	Steven	King

Persons
 Orders

5.5.1 How to Create Joins for Entity-Based View Objects

It is extremely common in business applications to supplement information from a *primary* business domain object with secondary reference information to help the end user understand what foreign key attributes represent. Take the example of the `OrderItems` entity object. It contains foreign key attribute of type `Number` like:

- `ProductId`, representing the product to which the order item pertains

From experience, you know that showing an end user exclusively these "raw" numerical values won't be very helpful. Ideally, reference information from the view object's related entity objects should be displayed to improve the application's usability. One typical solution involves performing a join query that retrieves the

combination of the primary and reference information. This is equivalent to populating "dummy" fields in each queried row with reference information based on extra queries against the lookup tables.

When the end user can *change* the foreign key values by editing the data, this presents an additional challenge. Luckily, entity-based view objects support easily including reference information that's always up to date. The key requirement to leverage this feature is the presence of associations between the entity object that act as the view object's primary entity usage and the entity objects that contribute reference information.

To include reference entities in a join view object, use the Create View Object wizard. The Create View Object wizard lets you specify the type of join:

- **Inner Join**

Select when you want the view object to return all rows between two or more entity objects, where each entity defines the same primary key column. The inner join view object will not return rows when a primary key value is missing from the joined entities.

- **Outer Join**

Select when you want the view object to return all rows that exist in one entity object, even though corresponding rows do not exist in the joined entity object. Both left and right outer join types are supported. The left and right designation refers to the source (left) and destination (right) entity object named in an association. For details about changing the default inner join to an outer join, see [Section 5.5.5, "How to Modify a Default Join Clause to Be an Outer Join When Appropriate."](#)

Both inner joins and outer joins are supported with the following options:

- **Reference**

Select when you want the data from the entity object to be treated as reference information for the view object. Automatic lookup of the data is supported and attribute values will be dynamically fetched from the entity cache when a controlling key attribute changes. For details about how this setting affects runtime behavior, see [Section 42.9.2, "What Happens at Runtime: View Row Creation."](#)

- **Updatable**

Deselect when you want to prevent the view object from modifying any entity attributes in the entity object. By default, the first entity object (primary) in the **Selected** list is updatable and subsequent entity objects (secondary) are not updatable. To understand how to create a join view object with *multiple* updatable entity usages, see [Section 42.9, "Creating a View Object with Multiple Updatable Entities."](#)

- **Participate in row delete**

Select when you have defined the entity as updatable and you want the action of removing rows in the UI to delete the participating reference entity object. This option is disabled for the primary entity. For example, while it may be possible to delete an order item, it should not be possible to delete the order when a remove row is called from the join view object.

Before you begin:

It may be helpful to have an understanding of how the type of view object effects joins. For more information, see [Section 5.5, "Working with Multiple Tables in Join Query Results."](#)

You will need to complete this task:

Create the desired entity objects as described in [Section 4.2.1, "How to Create Multiple Entity Objects and Associations from Existing Tables."](#)

To create a view object that joins entity objects:

1. In the Application Navigator, right-click the project in which you want to create the view object and choose **New**.

When you want to modify an existing view object that you created to include reference information from its related entity objects, double-click the view object and open the Entity Objects page in the overview editor for the view object.

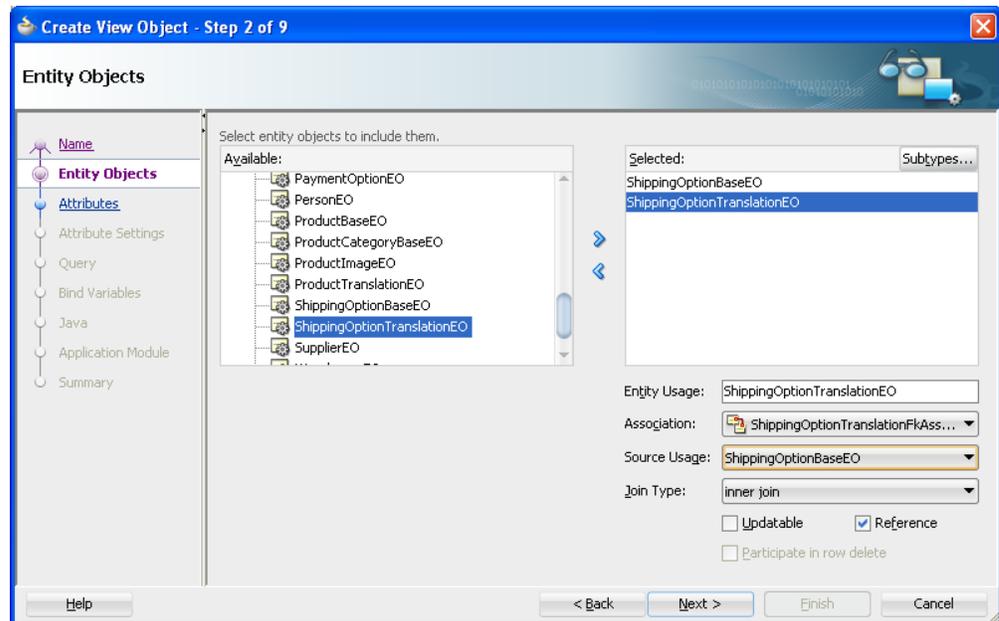

2. In the New Gallery, expand **Business Tier**, select **ADF Business Components** and then **View Object**, and click **OK**.
3. In the Create View Object wizard, on the Name page, enter a package name and a view object name. Keep the default setting **Entity object** enabled to indicate that you want this view object to manage data with its base entity object. Click **Next**.
4. In the Entity Objects page, the first entity usage in the **Selected** list is known as the *primary* entity usage for the view object. Select the primary entity object from the **Available** list and shuttle it to the **Selected** list.

The list is not limited to a single, primary entity usage.

5. To add additional, secondary entity objects to the view object, select them in the **Available** list and shuttle them to the **Selected** list.

The **Association** dropdown list shows you the name of the association that relates the selected secondary entity usage to the primary one. For example, [Figure 5–18](#) shows the result of adding one secondary reference entity usage, `ShippingOptionTranslationEO`, in addition to the primary `ShippingOptionBaseEO` entity usage. The association that relates to this secondary entity usage is `ShippingOptionTranslationFkAssociation`.

Figure 5–18 Create View Object Wizard, Entity Objects Page

6. Optionally, use the **Alias** field to give a more meaningful name to the entity usage when the default name is not clear.
7. If you add multiple entity usages for the same entity, use the **Association** dropdown list to select which association represents that usage's relationship to the primary entity usage. Click **Next**.

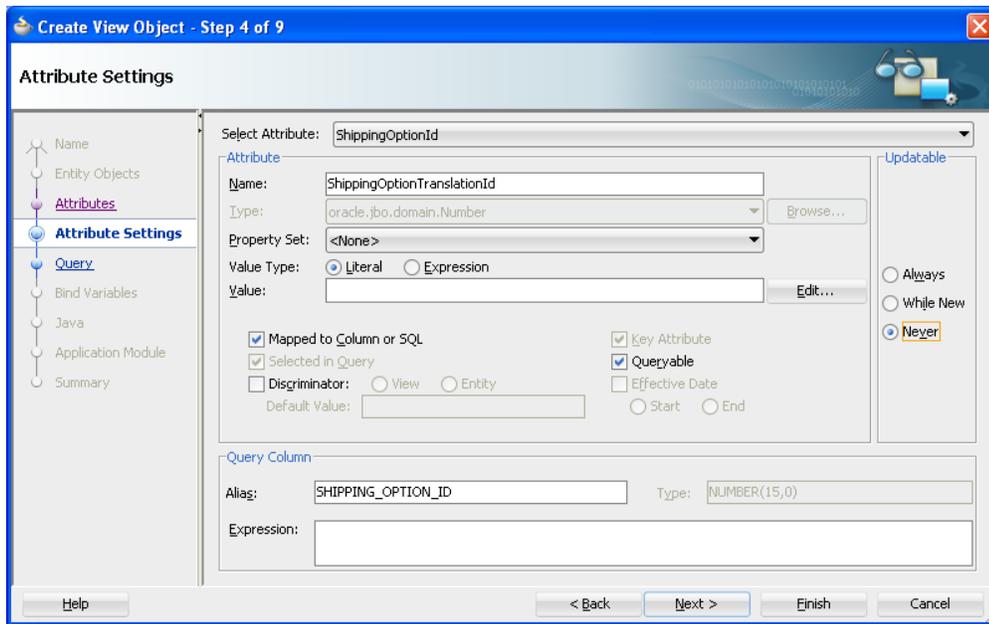

For each secondary entity usage, the **Reference** option is enabled to indicate that the entity provides reference information and that it is not the primary entity. The **Updatable** option is disabled. This combination represents the typical usage. However, when you want to create a join view object with multiple, updatable entity usages, see [Section 42.9, "Creating a View Object with Multiple Updatable Entities."](#)

Secondary entity usages that are updatable can also have the **Participate in row delete** option enabled. This will allow secondary entity attributes to appear NULL when the primary entity is displayed.

8. On the **Attributes** page, select the attributes you want each entity object usage to contribute to the view object. Click **Next**.
9. On the **Attribute Settings** page, you can rename an attribute when the names are not as clear as they ought to be.

The same attribute name often results when the reference and secondary entity objects derive from the same table. [Figure 5–19](#) shows the attribute `ShippingOptionId` in the **Select Attribute** dropdown list, which has been renamed to `ShippingOptionTranslationId` in the **Name** field.

Figure 5–19 Create View Object Wizard, Attribute Settings Page

10. Click **Finish**.

5.5.2 How to Select Additional Attributes from Reference Entity Usages

After adding secondary entity usages, you can use the overview editor for the view object to select the specific, additional *attributes* from these new usages that you want to include in the view object.

Tip: The overview editor lets you sort attributes displayed in the Attributes page by their entity usages. By default, the attributes table displays attributes in the order they appear in the underlying entity object. To sort the attributes by entity usage, click the header for the **Entity Usage** column of the attributes table. If the **Entity Usage** column does not appear in the attributes table, click the dropdown menu on the top-right corner of the table (below the button bar) and choose **Select Columns** to add the column to the **Selected** list.

Before you begin:

It may be helpful to have an understanding of how the type of view object effects joins. For more information, see [Section 5.5, "Working with Multiple Tables in Join Query Results."](#)

You will need to complete this task:

Create the desired entity objects as described in [Section 4.2.1, "How to Create Multiple Entity Objects and Associations from Existing Tables."](#)

To select attributes from a secondary entity usage:

1. In the Application Navigator, double-click the view object.
2. In the overview editor, click the **Attributes** navigation tab and click the dropdown menu on the **Create new attribute** icon and choose **Add Attribute from Entity** to view the list of available entity-derived attributes.
3. In the Attributes dialog, select the desired attribute and add it to the **Selected** list.

Note that even if you didn't intend to include them, JDeveloper automatically verifies that the primary key attribute from each entity usage is part of the **Selected** list. If it's not already present in the list, JDeveloper adds it for you. When you are finished, the overview editor Query page shows that JDeveloper has included the new columns in the `SELECT` statement.

4. Click OK.

5.5.3 How to Remove Unnecessary Key Attributes from Reference Entity Usages

The view object attribute corresponding to the primary key attribute of the primary entity usage acts as the primary key for identifying the view row. When you add secondary entity usages, JDeveloper marks the view object attributes corresponding to their primary key attributes as part of the view row key as well. When your view object consists of a single updatable primary entity usage and a number of reference entity usages, the primary key attribute from the primary entity usage is enough to uniquely identify the view row. Further key attributes contributed by secondary entity usages are not necessary and you should disable their **Key Attribute** settings.

For example, based on the view object with primary entity usage `ShippingOptionEO`, you could disable the **Key Attribute** property for the `ShippingOptionTranslationEO` entity usage so that this property is no longer selected for this additional key attribute: `ShippingTranslationsId`.

Before you begin:

It may be helpful to have an understanding of how the type of view object effects joins. For more information, see [Section 5.5, "Working with Multiple Tables in Join Query Results."](#)

You will need to complete this task:

Create the desired entity objects as described in [Section 4.2.1, "How to Create Multiple Entity Objects and Associations from Existing Tables."](#)

To remove unnecessary key attributes:

1. In the Application Navigator, double-click the view object.
2. In the overview editor, click the **Attributes** navigation tab.
3. In the Attributes page, in the attributes table, select the key attribute (identified by the key icon in the **Name** column), and then click the **Details** tab and deselect the **Key Attribute** property.

5.5.4 How to Hide the Primary Key Attributes from Reference Entity Usages

Since you generally won't want to display the primary key attributes that were automatically added to the view object, you can set the attribute's **Display Hint** property to **Hide**.

Before you begin:

It may be helpful to have an understanding of how the type of view object effects joins. For more information, see [Section 5.5, "Working with Multiple Tables in Join Query Results."](#)

You will need to complete this task:

Create the desired entity objects as described in [Section 4.2.1, "How to Create Multiple Entity Objects and Associations from Existing Tables."](#)

To hide the primary key attribute:

1. In the Application Navigator, double-click the view object.
2. In the overview editor, click the **Attributes** navigation tab.
3. In the Attributes page, select the primary key attribute (identified by the key icon in the **Name** column), and then click the **UI Hints** tab and select **Hide** in the **Display Hint** dropdown list.

5.5.5 How to Modify a Default Join Clause to Be an Outer Join When Appropriate

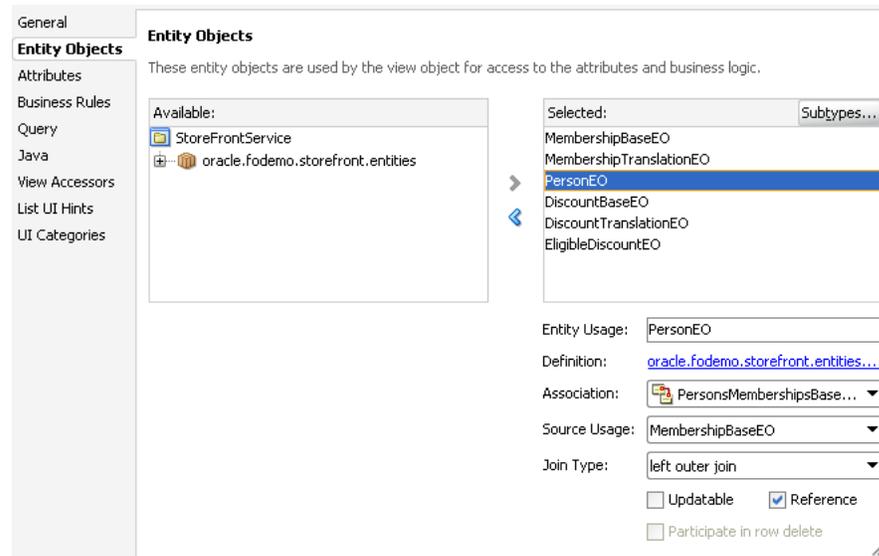

When you add a secondary entity usage to a view object, the entity usage is related to an entity usage that precedes it in the list of selected entities. This relationship is established by an entity association displayed in the **Association** dropdown list in the Entity Objects page of the overview editor for the view object. You use the **Association** dropdown list in the editor to select the entity association that relates the secondary entity usage to the desired preceding entity usage in the **Selected** list. The name of the preceding entity usage is identified in the **Source Usage** dropdown list.

When JDeveloper creates the `WHERE` clause for the join between the table for the primary entity usage and the tables for related secondary entity usages, by default it always creates inner joins. You can modify the default inner join clause to be a left or right outer join when appropriate. The left designation refers to the source entity object named in the selected association. This is the entity identified in the **Source Usage** dropdown list. The right designation refers to the current secondary entity usage that you have selected in the **Selected** list.

In the left outer join, you will include all rows from the left table (related to the entity object named in the **Source Usage** list) in the join, even if there is no matching row from the right table (related to the current secondary entity object selection). The right outer join specifies the reverse scenario: you will include all rows from the right table (related to the entity object named in the **Source Usage** list) in the join, even if there is no matching row from the left table (related to the current secondary entity object selection).

For example, assume that a person is not yet assigned a membership status. In this case, the `MembershipId` attribute will be `NULL`. The default inner join condition will not retrieve these persons from the `MEMBERSHIPS_BASE` table. Assuming that you want persons without membership status to be viewable and updatable through the `MembershipDiscountsVO` view object, you can use the Entity Objects page in the overview editor for the view object to change the query into an left outer join to the `MEMBERSHIPS_BASE` table for the possibly null `MEMBERSHIP_ID` column value.

When you add the person entity to the view object, you would select the **left outer join** as the join type. As shown in [Figure 5–20](#), the association `PersonsMembershipsBaseFkAssoc` identifies a source usage `MembershipBaseEO` on the left side of the join and the selected `PersonEO` entity usage on the right side. The view object `MembershipDiscountsVO` joins the rows related to both of these entity objects and defines a left outer join for `PersonEO` to allow the view object to return rows from the table related to `MembershipBaseEO` even if they do not have a match in the table related to `PersonEO`.

Figure 5–20 Setting an Outer Join to Return NULL Rows from Joined Entities

The view object's updated WHERE clause includes the addition (+) operator on the right side of the equals sign for the related table whose data is allowed to be missing in the left outer join:

```
PersonEO.MEMBERSHIP_ID = MembershipBaseEO.MEMBERSHIP_ID(+)
```

Before you begin:

It may be helpful to have an understanding of how the type of view object effects joins. For more information, see [Section 5.5, "Working with Multiple Tables in Join Query Results."](#)

You will need to complete this task:

Create the desired entity objects as described in [Section 4.2.1, "How to Create Multiple Entity Objects and Associations from Existing Tables."](#)

To change an inner join type to an outer join:

1. In the Application Navigator, double-click the view object.
2. In the overview editor, click the **Entity Objects** navigation tab.

The entity object you select represents the table on the right side of the join.

3. In the Entity Objects page, in the **Selected** list, select the entity object that you want to change the join type for.

The entity object you select represents the table on the right side of the join.

4. In the **Association** dropdown list, if only one association is defined, leave it selected; otherwise, select among the list of entity object associations that relate the secondary entity object to the desired entity object. The entity usage that represents the joined table will be displayed in the **Source Usage** dropdown list.

The entity object in the **Source Usage** dropdown list that you choose through the association selection represents the table on the left side of the join.

5. In the **Join Type** dropdown list, decide how you want the view object to return rows from the joined entity objects:

- **left outer join** will include rows from the left table in the join, even if there is no matching row from the right table.
- **right outer join** will include rows from the right table in the join, even if there is no matching row from the left table.

The **Source Usage** dropdown list is the left side of the join and the current entity usage in the **Selected** list is the right side.

5.5.6 What Happens When You Reference Entities in a View Object

When you create a join view object to include secondary entity usages by reference, JDeveloper updates the view object's XML component definition to include information about the additional entity usages. For example, the `ShippingOptionsVO.xml` file for the view object includes an additional reference entity usage. You will see this information recorded in the multiple `<EntityUsage>` elements. For example, [Example 5-4](#) shows an entity usage entry that defines the primary entity usage.

Example 5-4 Primary Entity Usage

```
<EntityUsage
  Name="ShippingOptionBaseEO"
  Entity="oracle.fodemo.storefront.entities.ShippingOptionBaseEO" />
```

The secondary reference entity usages will have a slightly different entry, including information about the association that relates it to the primary entity usage, like the entity usage shown in [Example 5-5](#).

Example 5-5 Secondary Reference Entity Usage

```
<EntityUsage
  Name="ShippingOptionTranslationEO"
  Entity="oracle.fodemo.storefront.entities.ShippingOptionTranslationEO"
  Association="oracle.fodemo.storefront.entities.associations.
    ShippingOptionTranslationFkAssoc"
  AssociationEnd="oracle.fodemo.storefront.entities.associations.
    ShippingOptionTranslationFkAssoc.ShippingOptionTranslation"
  SourceUsage="oracle.fodemo.storefront.store.queries.ShippingOptionsVO.
    ShippingOptionBaseEO"
  ReadOnly="true"
  Reference="true" />
```

Each attribute entry in the XML file indicates which entity usage it references. For example, the entry for the `ShippingOptionId` attribute in [Example 5-6](#) shows that it's related to the `ShippingOptionBaseEO` entity usage, while the `ShippingMethod` attribute is related to the `ShippingOptionTranslationEO` entity usage.

Example 5-6 Entity Usage Reference of View Object Attribute

```
<ViewAttribute
  Name="ShippingOptionId"
  IsNotNull="true"
  EntityAttrName="ShippingOptionId"
  EntityUsage="ShippingOptionBaseEO"
  AliasName="SHIPPING_OPTION_ID" >
</ViewAttribute>
...
<ViewAttribute
```

```

Name="ShippingMethod"
IsUpdatable="true"
IsNotNull="true"
EntityAttrName="ShippingMethod"
EntityUsage="ShippingOptionTranslationEO"
AliasName="SHIPPING_METHOD" >
</ViewAttribute>

```

The Create View Object wizard uses this association information at design time to automatically build the view object's join `WHERE` clause. It uses the information at runtime to enable keeping the reference information up to date when the end user changes foreign key attribute values.

5.5.7 How to Create Joins for Read-Only View Objects

To create a read-only view object joining two tables, use the Create View Object wizard.

Before you begin:

It may be helpful to have an understanding of how the type of view object effects joins. For more information, see [Section 5.5, "Working with Multiple Tables in Join Query Results."](#)

To create a read-only view object joining two tables:

1. In the Application Navigator, right-click the project in which you want to create the view object and choose **New**.
2. In the New Gallery, expand **Business Tier**, select **ADF Business Components** and then **View Object**, and click **OK**.
3. In the Initialize Business Components Project dialog, select the database connection or choose **New** to create a connection. Click **OK**.
4. In the Create View Object wizard, on the Name page, enter a package name and a view object name. Select **SQL query** to indicate that you want this view object to manage data with read-only access. Click **Next**.
5. On the Query page, use one of the following techniques to create the SQL query statement that joins the desired tables:
 - Paste any valid SQL statement into the **Query Statement** box.
 - Click **Query Builder** to open the SQL Statement dialog and use the interactive query builder, as described in [Section 5.5.9, "How to Use the Query Builder with Read-Only View Objects."](#)
6. After entering or building the query statement, click **Next**.
7. On the Bind Variables page, do one of the following:
 - If the query does not reference any bind variables, click **Next** to skip Step 3.
 - To add a bind variable and work with it in the query, see [Section 5.10.1, "How to Add Bind Variables to a View Object Definition."](#)
8. On the Attribute Mappings page, click **Finish**.

5.5.8 How to Test the Join View

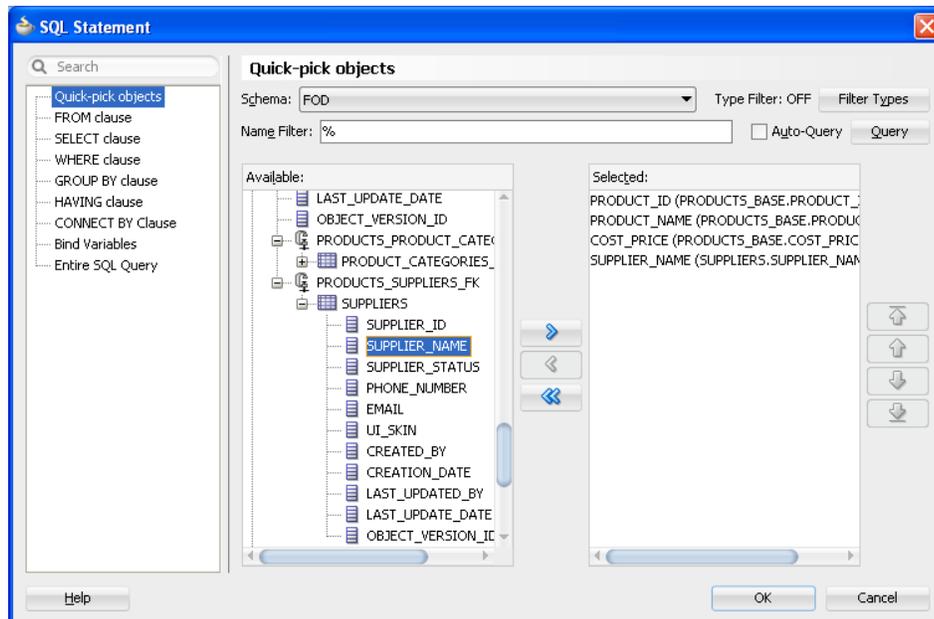

To test the new view object, edit the application module and on the Data Model page add an instance of the new view object to the data model. Then, use the Oracle ADF

Model Tester to verify that the join query is working as expected. For details about editing the data model and running the Oracle ADF Model Tester, see [Section 6.3, "Testing View Object Instances Using the Oracle ADF Model Tester."](#)

5.5.9 How to Use the Query Builder with Read-Only View Objects

The Quick-pick objects page of the SQL Statement dialog lets you view the tables in your schema, including the foreign keys that relate them to other tables. To include columns in the select list of the query, shuttle the desired columns from the **Available** list to the **Selected** list. For example, [Figure 5–21](#) shows the result of selecting the `PRODUCT_ID`, `PRODUCT_NAME`, and `COST_PRICE` columns from the `PRODUCTS` table, along with the `SUPPLIER_NAME` column from the `SUPPLIERS` table. The column from the second table appears, beneath the `PRODUCTS_SUPPLIERS_FK` foreign key in the **Available** list. When you select columns from tables joined by a foreign key, the query builder automatically determines the required join clause for you.

Figure 5–21 View Object Query Builder to Define a Join

Optionally, use the `WHERE` clause page of the SQL Statement dialog to define the expression. To finish creating the query, click **OK** in the SQL Statement dialog. The Edit Query dialog will show a query like the one shown in [Example 5–7](#).

Example 5–7 Creating a Query Using SQL Builder

```
SELECT
    PRODUCTS_BASE.PRODUCT_ID PRODUCT_ID,
    PRODUCTS_BASE.PRODUCT_NAME PRODUCT_NAME,
    PRODUCTS_BASE.COST_PRICE COST_PRICE,
    SUPPLIERS.SUPPLIER_NAME SUPPLIER_NAME
FROM
    PRODUCTS_BASE JOIN SUPPLIERS USING (SUPPLIER_ID)
```

You can use the Attributes page of the Create View Object wizard to rename the view object attribute directly as part of the creation process. Renaming the view object here saves you from having to edit the view object again, when you already know the attribute names that you'd like to use. As an alternative, you can also alter the default

Java-friendly name of the view object attributes by assigning a column alias, as described in [Section 5.9.2, "How to Name Attributes in Expert Mode."](#)

5.5.10 What You May Need to Know About Join View Objects

If your view objects reference multiple entity objects, they are displayed as separate entity usages on a business components diagram.

5.6 Working with Multiple Tables in a Master-Detail Hierarchy

Many queries you will work with will involve multiple tables that are related by foreign keys. In this scenario, you can create separate view objects that query the related information and then link a "source" view object to one or more "target" view objects to form a master-detail hierarchy.

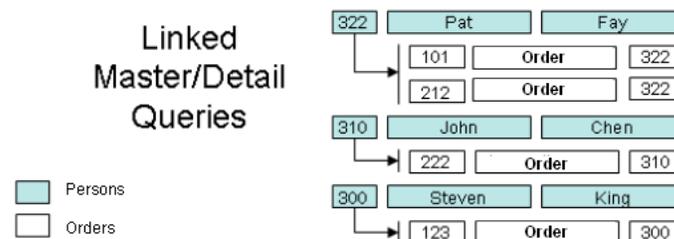

There are two ways you might handle this situation. You can either:

- Create a view link that defines how the source and target view objects relate.
- Create a view link based on an association between entity objects when the source and target view objects are based on the underlying entity objects' association.

In either case, you use the Create View Link wizard to define the relationship.

[Figure 5-22](#) illustrates the multilevel result that master-detail linked queries produce.

Figure 5-22 *Linked Master-Detail Queries*

5.6.1 How to Create a Master-Detail Hierarchy for Read-Only View Objects

When you want to show the user a set of master rows, and for each master row a set of coordinated detail rows, then you can create view links to define how you want the master and detail view objects to relate. For example, you could link the `Persons` view object to the `Orders` view object to create a master-detail hierarchy of customers and the related set of orders they have placed.

To create the view link, use the Create View Link wizard.

Before you begin:

It may be helpful to have an understanding of the ways to create a master-detail hierarchy. For more information, see [Section 5.6, "Working with Multiple Tables in a Master-Detail Hierarchy."](#)

You will need to complete this task:

- Create the desired read-only view objects as described in [Section 5.2.3, "How to Create an Expert Mode, Read-Only View Object."](#)

To create a view link between read-only view objects:

1. In the Application Navigator, right-click the project in which you want to create the view object and choose **New**.
2. In the New Gallery, expand **Business Tier**, select **ADF Business Components** and then **View Link**, and click **OK**.
3. In the Create View Link wizard, on the Name page, enter a package name and a view link name. For example, given the purpose of the view link, a name like `OrdersPlacedBy` is a valid name. Click **Next**.
4. On the View Objects page, select a "source" attribute from the view object that will act as the master.

For example, [Figure 5–23](#) shows the `PersonId` attribute selected from the `PersonsVO` view object to perform this role. Click **Next**.

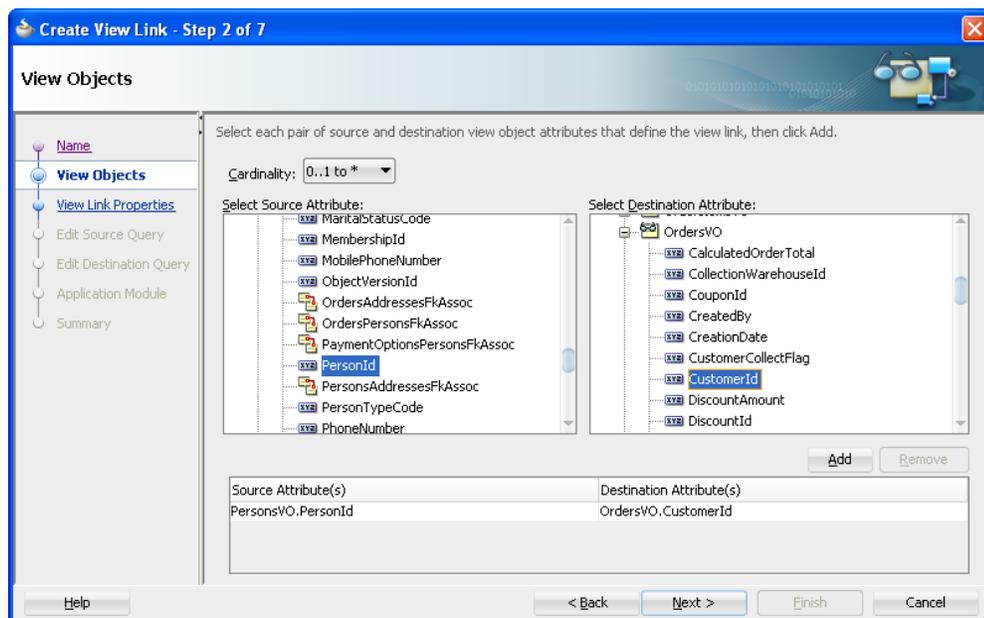

5. On the View Objects page, select a corresponding destination attribute from the view object that will act as the detail.

For example, if you want the detail query to show orders that were placed by the currently selected customer, select the `CustomerId` attribute in the `OrdersVO` to perform this role.

6. Click **Add** to add the matching attribute pair to the table of source and destination attribute pairs below. When you are finished defining master and detail link, click **Next**.

[Figure 5–23](#) shows just one (`PersonId`,`CustomerId`) pair. However, if you require multiple attribute pairs to define the link between master and detail, repeat the steps for the View Objects page to add additional source-target attribute pairs.

Figure 5–23 Defining Source/Target Attribute Pairs While Creating a View Link

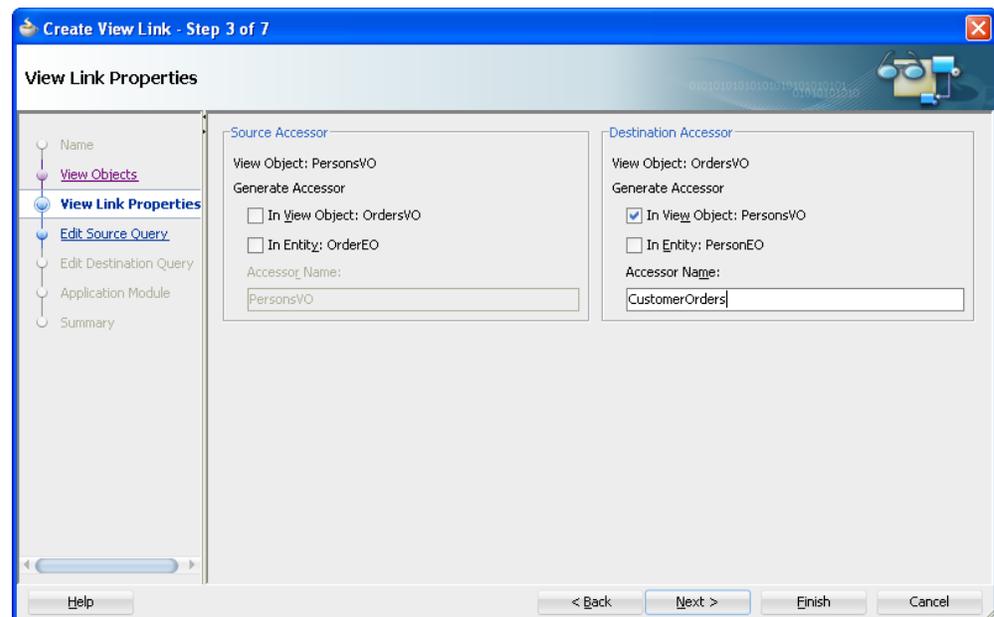

7. On the View Link Properties page, you can use the **Accessor Name** field to change the default name of the accessor that lets you programmatically access the destination view object.

By default, the accessor name will match the name of the destination view object. For example, you might change the default accessor name `OrdersVO` to `CustomerOrders` to better describe the master-detail relationship that the accessor defines.

8. Also on the View Link Properties page, you control whether the view link represents a one-way relationship or a bidirectional one.

By default, a view link is a one-way relationship that allows the current row of the source (master) to access a set of related rows in the destination (detail) view object. For example, in [Figure 5–24](#), the checkbox settings indicate that you'll be able to access a detail collection of rows from `OrdersVO` for the current row in `PersonsVO`, but not vice versa. In this case, this behavior is specified by the checkbox setting in the **Destination Accessor** group box for `OrdersVO` (the **Generate Accessor In View Object: PersonsVO** box is selected) and checkbox setting in the **Source Accessor** group box for `PersonsVO` (the **Generate Accessor In View Object: OrdersVO** box is not selected).

Figure 5–24 View Link Properties Control Name and Direction of Accessors

9. On the Edit Source Query page, preview the view link SQL predicate that will be used at runtime to access the master row in the source view object and click **Next**.
10. On the Edit Destination Query page, preview the view link SQL predicate that will be used at runtime to access the correlated detail rows from the destination view object for the current row in the source view object and click **Next**.
11. On the Application Module page, add the view link to the data model for the desired application module and click **Finish**.

By default the view link will not be added to the application module's data model. Later you can add the view link to the data model using the overview editor for the application module.

5.6.2 How to Create a Master-Detail Hierarchy for Entity-Based View Objects

Just as with read-only view objects, you can link entity-based view objects to other view objects to form master-detail hierarchies of any complexity. The only difference in the creation steps involves the case when both the master and detail view objects are entity-based view objects and their respective entity usages are related by an association. In this situation, since the association captures the set of source and destination attribute pairs that relate them, you create the view link just by indicating which association it should be based on.

To create an association-based view link, you use the Create View Link wizard.

Before you begin:

It may be helpful to have an understanding of the ways to create a master-detail hierarchy. For more information, see [Section 5.6, "Working with Multiple Tables in a Master-Detail Hierarchy."](#)

You will need to complete this task:

Create the desired entity-based view objects as described in [Section 5.2.1, "How to Create an Entity-Based View Object."](#)

To create an association-based view link

1. In the Application Navigator, right-click the project in which you want to create the view object and choose **New**.

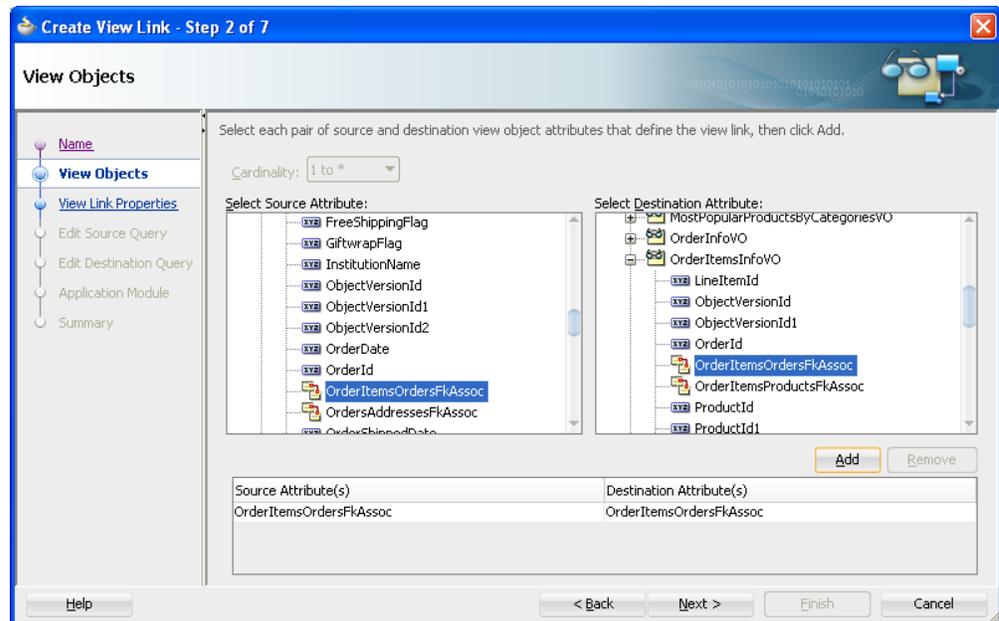

To avoid having to type in the package name in the Create View Link wizard, you can choose **New View Link** on the context menu of the **links** package node in the Application Navigator.

2. In the New Gallery, expand **Business Tier**, select **ADF Business Components** and then **View Link**, and click **OK**.
3. In the Create View Link wizard, on the Name page, supply a package and a component name.
4. On the View Objects page, in the **Select Source Attribute** tree expand the source view object in the desired package. In the **Select Destination Attribute** tree expand the destination view object.

For entity-based view objects, notice that in addition to the view object attributes, relevant associations also appear in the list.

5. Select the same association in both **Source** and **Destination** trees. Then click **Add** to add the association to the table below.

For example, [Figure 5–25](#) shows the same `OrderItemsOrdersFkAssoc` association in both **Source** and **Destination** trees selected.

Figure 5–25 Master and Detail Related by an Association Selection

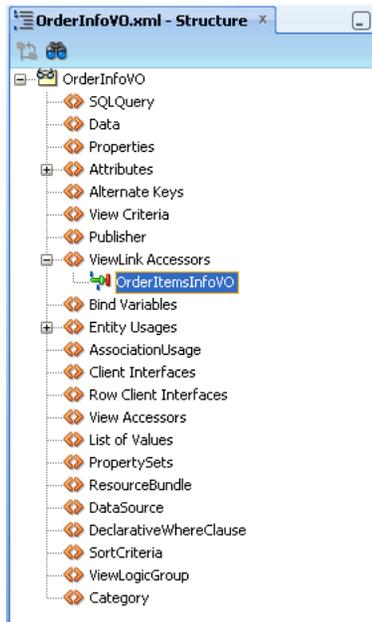

6. Click **Finish**.

5.6.3 What Happens When You Create Master-Detail Hierarchies Using View Links

When you create a view link or an association-based view link, JDeveloper creates the XML component definition file that represents its declarative settings and saves it in the directory that corresponds to the name of its package. For example, if the view link is named `OrderInfoToOrderItemsInfo` and it appears in the `queries.links` package, then the XML file created will be

`./queries/link/OrderInfoToOrderItemsInfo.xml` under the project's source path. This XML file contains the declarative information about the source and target attribute pairs you've specified and, in the case of an association-based view link, contains the declarative information about the association that relates the source and target view objects you've specified.

In addition to saving the view link component definition itself, JDeveloper also updates the XML definition of the *source* view object in the view link relationship to add information about the view link accessor you've defined. As a confirmation of this, you can select the source view object in the Application Navigator and inspect its details in the Structure window. As shown in [Figure 5–26](#), you can see the defined accessor under the **ViewLink Accessors** node for the `OrderItemsInfoVO` source view object of the `OrderInfoToOrderItemsInfo` view link.

Figure 5–26 View Object with View Link Accessor in the Structure Window

Note: A view link defines a basic master-detail relationship between two view objects. However, by creating more view links you can achieve master-detail hierarchies of any complexity, including:

- Multilevel master-detail-detail
- Master with multiple (peer) details
- Detail with multiple masters

The steps to define these more complex hierarchies are the same as the ones covered in [Section 5.6.2, "How to Create a Master-Detail Hierarchy for Entity-Based View Objects,"](#) you just need to create it one view link at a time.

5.6.4 How to Enable Active Master-Detail Coordination in the Data Model

When you enable programmatic navigation to a row set of correlated details by defining a view link as described in [Section 5.6.2, "How to Create a Master-Detail Hierarchy for Entity-Based View Objects,"](#) the view link plays a *passive* role, simply defining the information necessary to retrieve the coordinated detail row set when your code requests it. The view link accessor attribute is present and programmatically accessible in any result rows from any instance of the view link's source view object. In other words, programmatic access does not require modifying the application module's data model.

However, since master-detail user interfaces are such a frequent occurrence in enterprise applications, the view link can be also used in a more *active* fashion so you can avoid needing to coordinate master-detail screen programmatically. You opt to have this active master-detail coordination performed by *explicitly* adding an instance of a view-linked view object to your application module's data model.

To enable active master-detail coordination, open the application module in the overview editor and select the Data Model page.

Before you begin:

It may be helpful to have an understanding of the ways to create a master-detail hierarchy. For more information, see [Section 5.6, "Working with Multiple Tables in a Master-Detail Hierarchy."](#)

You will need to complete this task:

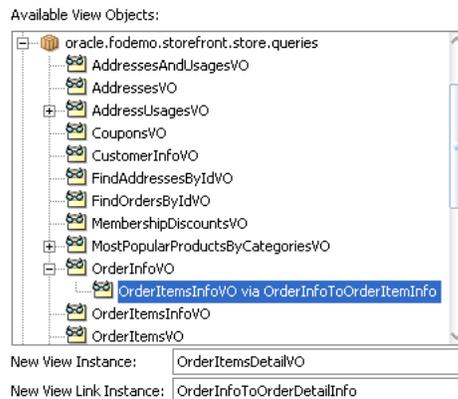

Create the desired view objects as described in [Section 5.2.1, "How to Create an Entity-Based View Object"](#) and [Section 5.2.3, "How to Create an Expert Mode, Read-Only View Object."](#)

To add a detail instance of a view object:

1. In the Application Navigator, double-click the application module.
2. In the overview editor, click the **Data Model** navigation tab.
3. In the Data Model page, expand the **View Object Instances** section and, in the **Available View Objects** list, select the detail view object node that is indented beneath the master view object.

Note that the list shows the detail view object *twice*: once on its own, and once as a detail view object via the view link. For example, in [Figure 5–27](#) you would select the detail view object `OrderItemsInfoVO` via `OrderInfoToOrderItemInfo` instead of the view object labeled as `OrderItemsInfoVO` (which, in this case, appears beneath the highlighted view object).

Figure 5–27 *Detail View Object Selection from Available View Objects*

4. Enter a name for the detail instance you're about to create in the **Name View Instance** field below the **Available View Objects** list.

For example, [Figure 5–27](#) shows the name `OrderItemsDetailVO` for the instance of the `OrderItemsInfoVO` view object that is a detail view.

5. In the **Data Model** list, select the instance of the view object that you want to be the actively-coordinating master.
6. Click **Add Instance** to add the detail instance to the currently selected master instance in the data model, with the name you've chosen.

For example, in [Figure 5–28](#), the **Data Model** list shows a master-detail hierarchy of view object instances with `OrderItemsDetailVO` as the detail view object.

Figure 5–28 Data Model with View Linked View Object

5.6.5 How to Test Master-Detail Coordination

To test active master-detail coordination, launch the Oracle ADF Model Tester on the application module by choosing **Run** from its context menu in the Application Navigator. The Oracle ADF Model Tester data model tree shows the view link instance that is actively coordinating the detail view object instance with the master view object instance. You can double-click the view link instance node in the tree to open a master-detail data view page in the Oracle ADF Model Tester. Then, when you use the toolbar buttons to navigate in the master view object — changing the view object's current row as a result — the coordinated set of details is automatically refreshed and the user interface stays in sync.

If you double-click another view object that is not defined as a master and detail, a second tab will open to show its data; in that case, since it is not actively coordinated by a view link, its query is not constrained by the current row in the master view object.

For information about editing the data model and running the Oracle ADF Model Tester, see [Section 6.3, "Testing View Object Instances Using the Oracle ADF Model Tester."](#)

5.6.6 How to Access the Detail Collection Using the View Link Accessor

To work with view links effectively, you should also understand that view link accessor attributes return a `RowSet` object and that you can access a detail collection using the view link accessor programmatically.

5.6.6.1 Accessing Attributes of Row by Name

At runtime, the `getAttribute()` method on a `Row` object allows you to access the value of any attribute of that row in the view object's result set by name. The view link accessor behaves like an additional attribute in the current row of the source view object, so you can use the same `getAttribute()` method to retrieve its value. The only practical difference between a regular view attribute and a view link accessor attribute is its data type. Whereas a regular view attribute typically has a scalar data type with a value like `303` or `ngreenbe`, the value of a view link accessor attribute is a row set of zero or more correlated detail rows. Assuming that `curUser` is a `Row` object from some instance of the `Orders` view object, you can write a line of code to retrieve the detail row set of order items:

```
RowSet items = (RowSet)curUser.getAttribute("OrderItems");
```

Note: If you generate the custom Java class for your view row, the type of the view link accessor will be `RowIterator`. Since at runtime the return value will always be a `RowSet` object, it is safe to cast the view link attribute value to `RowSet`.

5.6.6.2 Programmatically Accessing a Detail Collection Using the View Link Accessor

Once you've retrieved the `RowSet` object of detail rows using a view link accessor, you can loop over the rows it contains just as you would loop over a view object's row set of results, as shown in [Example 5-8](#).

Example 5-8 Programmatically Accessing a Detail Collection

```
while (items.hasNext()) {
    Row curItem = items.next();
    System.out.println("--> (" + curItem.getAttribute("LineItemId") + ") " +
        curItem.getAttribute("LineItemTotal"));
}
```

For information about creating a test client, see [Section 6.4.6, "How to Access a Detail Collection Using the View Link Accessor."](#)

5.6.7 How to Create a Master-Detail Hierarchy for Entity Objects with Transient-Only Attributes

When you link entity-based view objects to form master-detail hierarchies, the view objects and their respective entity usages are typically related by an association. At runtime, the association constructs an internal association view object that enables a query to be executed to enable the master-detail coordination. An exception to this scenario occurs when the entity object that participates in an association consists of all nonpersistent attributes. This may occur when you define an entity object with transient attributes that you wish to populate programmatically at runtime. In this case, you can use the association overview editor that links the nonpersistent entity object to select an association view object to perform the query.

Before you begin:

It may be helpful to have an understanding of associations. For more information, see [Section 4.2.3, "What Happens When You Create Entity Objects and Associations from Existing Tables."](#)

You will need to complete these tasks:

- Create the entity-based view object for the nonpersistent entity object, as described in [Section 5.2.1, "How to Create an Entity-Based View Object."](#)
- Use the Create Association wizard to create an association between the nonpersistent entity object and a database-derived entity object. For details about creating an association, see [Section 4.3, "Creating and Configuring Associations."](#)

To customize an association for nonpersistent entity objects:

1. In the Application Navigator, double-click the association.
2. In the overview editor, click the **Tuning** navigation tab and then click the **Edit accessors** button.

3. In the Custom Views dialog, select **Use Custom View Object** for the non-persistent entity object.
4. In the **Select View Object** list, select the view object that you created based on the non-persistent entity-object.
5. Click **OK** to save the definition.

5.7 Working with a Single Table in a Recursive Master-Detail Hierarchy

A recursive data model is one that utilizes a query that names source and destination attributes in a master-detail relationship based on a single table. In a typical master-detail relationship, the source attribute is supplied by the primary key attribute of the master view object and the destination attribute is supplied by foreign key attribute in the detail view object. For example, a typical master-detail relationship might relate the `DepartmentId` attribute on the `DEPARTMENT` table and the corresponding `DepartmentId` attribute on the `EMPLOYEE` table. However, in a recursive data model, the source attribute `EmployeeId` and the target attribute `ManagerId` both exist in the `EMPLOYEE` table. The query for this relationship therefore involves only a single view object. In this scenario, you create the view object for a single base entity object that specifies both attributes and then you define a self-referential view link to configure this view object as both the "source" and the "target" view object to form a master-detail hierarchy.

After you create the view link, there are two ways you can handle the recursive master-detail hierarchy in the data model project. You can either:

- Create a data model that exposes two instances of the same view object, one playing the role as master and the other playing the role as detail, actively coordinated by a view link instance. This can be useful when you anticipate needing to show a single level of master rows and detail rows at a time in two separate tables.
- Create a data model that exposes only a single instance of the view object, and use the view link accessor attribute in each row to access a row set of details. This is the more typical use case of the two because it allows you to display (or programmatically work with) the recursive master-detail hierarchy to any number of levels that exist in the data. For example, to show the recursive hierarchy in a `tree` or `treeTable` component, you would use this approach, as described in [Section 29.4.1, "How to Display Master-Detail Objects in Trees."](#)

5.7.1 How to Create a Recursive Master-Detail Hierarchy for an Entity-Based View Object

In a recursive master-detail hierarchy, the attributes of the view object that you select for the source and destination in the view link will typically be the same pair of attributes that define the self-referential association between the underlying entity object, if this association exists. While this underlying association is not required to create the view link, it does simplify the creation of the view link, so you will first create a foreign key association for the base entity object of the view object.

To create the recursive master-detail hierarchy:

1. Create the foreign key association for the base entity object of the view object.
2. Create the data model to expose the view object with a view criteria that will filter the view instance's results to include only those rows you want to see at the "root" of the hierarchy.

5.7.1.1 Creating an Association-Based, Self-Referential View Link

To create an association, you use the Create Association wizard. Then the association will appear as a selection choice when you use the Create View Link wizard. The view link will be self-referential because the association you select for the source and the destination view object names the *same* entity object, which is derived from a single database table.

Before you begin:

It may be helpful to have an understanding of the recursive data model. For more information, see [Section 5.7, "Working with a Single Table in a Recursive Master-Detail Hierarchy."](#)

You will need to complete this task:

- When you create the view link JDeveloper won't be able to infer the association between the source and destination attributes of the entity object. To support the recursive hierarchy, you can use the Create Association wizard to create an association between the source attribute and the destination attribute. On the Entity Objects page, select the same entity object to specify the source and destination attributes and leave all other default selections unchanged in the wizard. For details about creating an association, see [Section 4.3, "Creating and Configuring Associations."](#)

For example, assume the recursive master-detail hierarchy displays a list of employees based on their management hierarchy. In this scenario, you would create the association based on the `Employees` entity object. On the Entity Objects page of the Create Association wizard, you would select `Employees.EmployeeId` as the source attribute and `Employee.ManagerId` as the destination attribute. The entity object `Employees` supplies both attributes to ensure the association is self-referential.

To create an association-based, self-referential view link:

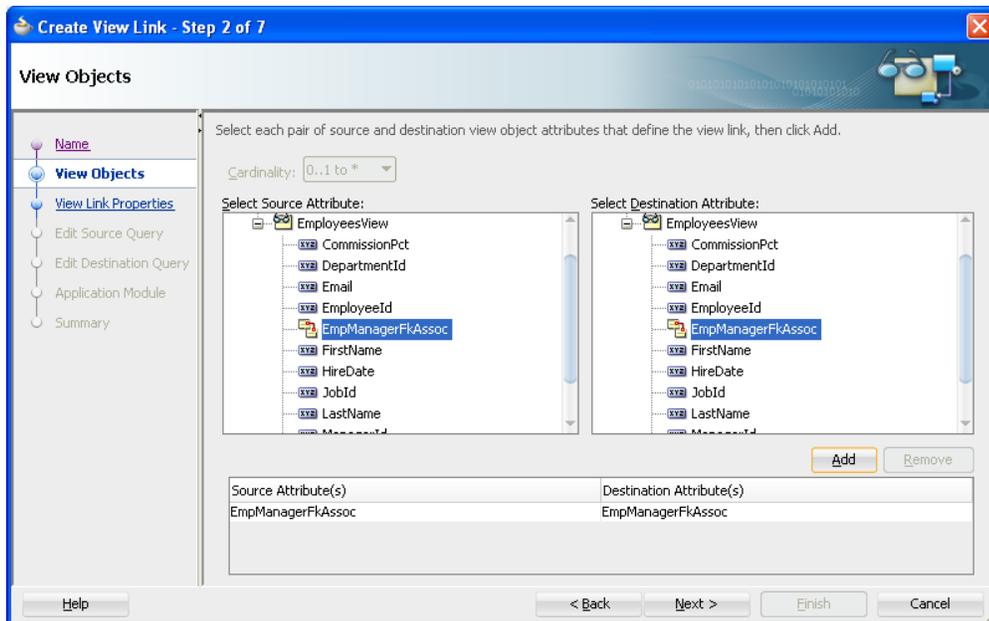

1. In the Application Navigator, right-click the project in which you want to create the view object and choose **New**.

To avoid having to type in the package name in the Create View Link wizard, you can choose **New View Link** on the context menu of the `links` package node in the Application Navigator.
2. In the New Gallery, expand **Business Tier**, select **ADF Business Components** and then **View Link**, and click **OK**.
3. In the Create View Link wizard, on the Name page, supply a package and a component name.
4. On the View Objects page, in the **Select Source Attribute** tree expand the source view object in the desired package. In the **Select Destination Attribute** tree expand the destination view object.

For entity-based view objects, notice that in addition to the view object attributes, relevant associations also appear in the list.

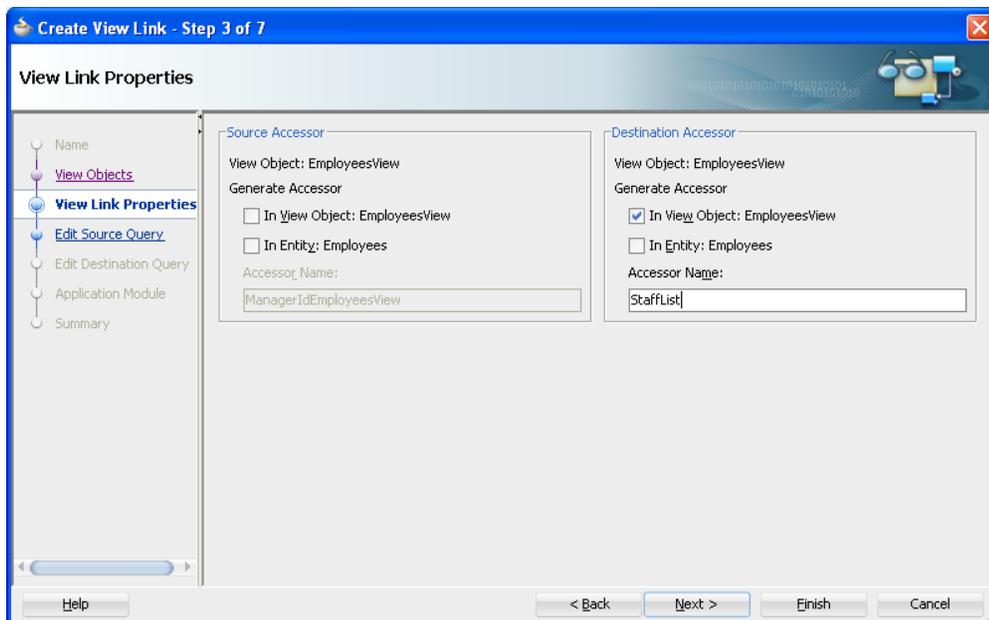

5. Select the same association in both **Source** and **Destination** trees. Then click **Add** to add the association to the table below.

For example, [Figure 5-29](#) shows the same `EmpManagersFkAssoc` association in both **Source** and **Destination** trees selected. The view link is self-referential because the definition of the association names the source and destination attribute on the *same* entity object (in this case, `Employees`).

Figure 5–29 Master and Detail Related by a Self-Referential Association Selection

- On the View Link Properties page, leave the default selections unchanged, but edit the accessor name of the destination accessor to provide a meaningful name.

For example, [Figure 5–30](#) shows the destination accessor has been renamed from `EmployeesView` to `StaffList`. This name will be exposed in the binding editor when the user interface developer populates the ADF Faces tree component by selecting this accessor. The name you provide will make clear to the UI developer the purpose of the accessor; in this case, to generate a list of employees associated with each manager.

Figure 5–30 Renamed Destination Accessor in View Link

- Click **Finish**.

5.7.1.2 Exposing the View Instance and Filter with a View Criteria

When you are ready to expose the view object in your project's data model, you will configure the view instance in the data model to use a view criteria to filter the initial value in the root of the tree. For example, assume the recursive master-detail hierarchy displays a list of employees based on their management hierarchy. In this scenario, you'll configure the view criteria's bind variable to specify the employee ID of the employee that you want to be the root value of the entire hierarchy. In this case, the root value of the recursive hierarchy of managers and employees would be the employee ID of the highest level manager in the organization.

Before you begin:

It may be helpful to have an understanding of the recursive data model. For more information, see [Section 5.7, "Working with a Single Table in a Recursive Master-Detail Hierarchy."](#)

You will need to complete this task:

- Create the entity-based view object and create a view criteria that will filter the view instance's results to include only those rows you want to see at the "root" of the hierarchy. To create a view criteria that uses a bind variable to filter the view object, see [Section 5.11, "Working with Named View Criteria."](#)

For example, in a recursive hierarchy of managers and employees, you would create the entity-based view object `EmployeesView`. After you create the view object in the Create View Object wizard, you can use the Query page of the overview editor to create a bind variable and view criteria which allow you to identify the employee or employees that will be seen at the top of the hierarchy. If only a single employee should appear at the root of the hierarchy, then the view criteria in this scenario will filter the employees using a bind variable for the employee ID (corresponding to the source attribute) and the WHERE clause shown in the Create View Criteria dialog would look like `((Employees.EMPLOYEE_ID = :TheEmployeeId))`, where `TheEmployeeId` is the bind variable name. For more information on creating a view criteria that uses a bind variable to filter the view object, see [Section 5.12.2.1, "Creating a Data Source View Object to Control the Cascading List."](#)

To define the view object instance in an existing application module:

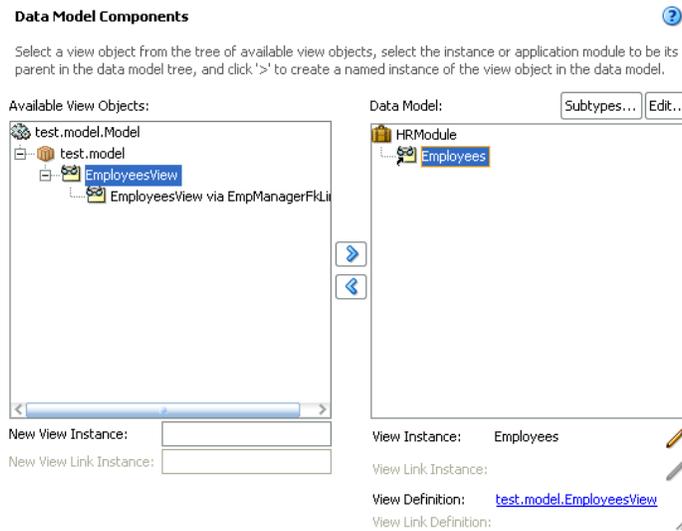

1. In the Application Navigator, double-click the application module.
2. In the overview editor, click the **Data Model** navigation tab.
3. In the Data Model page, expand the **View Object Instances** section and, in the **Available View Objects** list, select the view object definition that you defined the view criteria to filter.

The **New View Instance** field below the list shows the name that will be used to identify the next instance of that view object that you add to the data model.

4. To change the name before adding it, enter a different name in the **New View Instance** field.
5. With the desired view object selected, shuttle the view object to the **Data Model** list.

[Figure 5–31](#) shows the view object `EmployeesView` has been renamed to `Employees` before it was shuttled to the **Data Model** list.

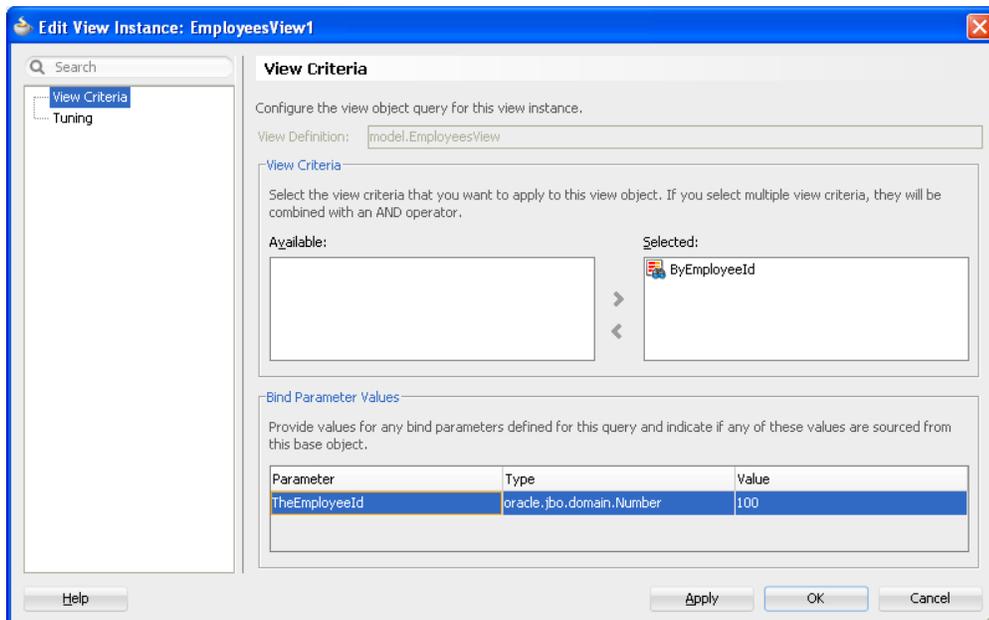

Figure 5–31 Data Model Displays Added View Object Instance

6. To filter the view object instance so that you specify the root value of the hierarchy, select the view object instance you added and click **Edit**.
7. In the Edit View Instance dialog, shuttle the view criteria you created to the **Selected** list and enter the bind parameter value that corresponds to the root of the hierarchy.

Figure 5–32 shows the view object ByEmployeeId view criteria with the bind parameter TheEmployeeId set to the value 100 corresponding to the employee that is at the highest level of the hierarchy.

Figure 5–32 View Criteria Filters View Instance

8. Click **OK**.

5.7.2 What Happens When You Create a Recursive Master-Detail Hierarchy

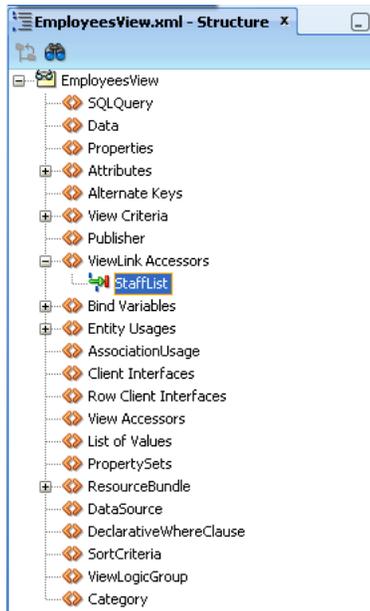

When you create a self-referential view link, JDeveloper creates the XML component definition file that represents its declarative settings and saves it in the directory that corresponds to the name of its package. This XML file contains the declarative information about the source and target attribute pairs that the association you selected specifies and contains the declarative information about the association that relates the source and target view object you selected.

[Example 5–9](#) shows how the `EmpManagerFkLink` defines the same view object `EmployeesView` for the source and destination in its XML component definition file.

Example 5–9 Self-Referential View Link Defined in XML

```
<ViewLink
  xmlns="http://xmlns.oracle.com/bc4j"
  Name="EmpManagerFkLink"
  EntityAssociation="test.model.EmpManagerFkAssoc">
  <ViewLinkDefEnd
    Name="EmployeesView1"
    Cardinality="1"
    Owner="test.model.EmployeesView"
    Source="true">
    <DesignTime>
      <Attr Name="_finderName" Value="ManagerIdEmployeesView"/>
      <Attr Name="_isUpdateable" Value="true"/>
    </DesignTime>
    <AttrArray Name="Attributes">
      <Item Value="test.model.EmployeesView.EmployeeId"/>
    </AttrArray>
  </ViewLinkDefEnd>
  <ViewLinkDefEnd
    Name="EmployeesView2"
    Cardinality="-1"
    Owner="test.model.EmployeesView">
    <DesignTime>
      <Attr Name="_finderName" Value="StaffList"/>
      <Attr Name="_isUpdateable" Value="true"/>
    </DesignTime>
    <AttrArray Name="Attributes">
      <Item Value="test.model.EmployeesView.ManagerId"/>
    </AttrArray>
  </ViewLinkDefEnd>
</ViewLink>
```

In addition to saving the view link component definition itself, JDeveloper also updates the XML definition of the view object to add information about the view link accessor you've defined. As a confirmation of this, you can select the view object in the Application Navigator and inspect its details in the Structure window. As shown in [Figure 5–33](#), you can see the defined accessor under the **ViewLink Accessors** node for the `EmployeesView` view object of the `EmpManagerFkLink` view link.

Figure 5–33 View Object with View Link Accessor in the Structure Window

5.8 Working with View Objects in Declarative SQL Mode

At runtime, when ADF Business Components works with JDBC to pass a query to the database and retrieve the result, the mechanism to retrieve the data is the SQL query. As an alternative to creating view objects that specify a SQL statement at design time, you can create entity-based view objects that contain no SQL statements. This capability of the ADF Business Components design time and runtime is known as *declarative SQL mode*. When the data model developer works with the wizard or editor for a view object in declarative SQL mode, they require no knowledge of SQL. In declarative SQL mode, the view object's metadata causes the ADF Business Components runtime to generate the SQL query statements as follows:

- Optionally, generates SELECT and FROM lists based on the rendered web page's databound UI components' usage of one or more entity objects' attributes

Specifying the runtime query statement based solely on databound UI component attribute usage is an optimization that you control at the level of each view object attribute by changing the attribute's `IsSelected` property setting. By default, the property setting is `IsSelected=true` for each attribute that you add to the view object in declarative SQL mode. The default setting specifies the added attribute will be selected in the SQL statement regardless of whether or not the attribute is exposed in the UI by a databound component. For details about changing the property setting to optimize the runtime query statement, see [Section 5.8.1, "How to Create SQL-Independent View Objects with Declarative SQL Mode."](#)

- Optionally, generates a WHERE clause based on a view criteria that you add to the view object definition
- Optionally, generates an ORDERBY clause based on a sort criteria that you add to the view object definition.
- Optionally, augments the WHERE clause to support table joins based on named view criteria that you add to the view object definition

- Optionally, augments the `WHERE` clause to support master-detail view filtering based on a view criteria that you add to either the source or destination of a view link definition

Additionally, the SQL statement that a declarative SQL mode view object generates at runtime will be determined by the SQL platform specified in the Business Components page of the Project Properties dialog.

Note: Currently, the supported platforms for runtime SQL generation are SQL92 (ANSI) style and Oracle style. For information about setting the SQL platform for your project, see [Section 3.3.1, "Choosing a Connection, SQL Platform, and Data Type Map."](#)

Declarative SQL mode selection is supported in JDeveloper as a setting that you can apply either to the entire data model project or to individual view objects that you create. The ADF Business Components design time also allows you to override the declarative SQL mode project-level setting for any view object you create.

The alternatives to declarative SQL mode are normal mode and expert mode. When you work in either of those modes, the view object definitions you create at design time always contain the entire SQL statement based on the SQL platform required by your application module's defined database connection. Thus the capability of SQL independence does not apply to view objects that you create in normal or expert mode. For information about using the wizard and editor to customize view objects when SQL is desired at design time, see [Section 5.2, "Populating View Object Rows from a Single Database Table."](#)

5.8.1 How to Create SQL-Independent View Objects with Declarative SQL Mode

All view objects that you create in JDeveloper rely on the same design time wizard and editor. However, when you enable declarative SQL mode, the wizard and editor change to support customizing the view object definition without requiring you to display or enter any SQL. For example, the Query page of the Create View Object wizard with declarative SQL mode enabled lacks the **Generated SQL** field present in normal mode.

Additionally, in declarative SQL mode, since the wizard and editor do not allow you to enter `WHERE` and `ORDERBY` clauses, you provide equivalent functionality by defining a view criteria and sort criteria respectively. In declarative SQL mode, these criteria appear in the view object metadata definition and will be converted at runtime to their corresponding SQL clause. When the databound UI component has no need to display filtered or sorted data, you may omit the view criteria or sort criteria from the view object definition.

Otherwise, after you enable declarative SQL mode, the basic procedure to create a view object with ensured SQL independence is the same as you would follow to create any entity-based view object. For example, you must still ensure that your view object encapsulates the desired entity object metadata to support the intended runtime query. As with any entity-based view object, the columns of the runtime-generated `FROM` list must relate to the attributes of one or more of the view object's underlying entity objects. In declarative SQL mode, you automatically fulfill this requirement when working with the wizard or editor when you add or remove the attributes of the entity objects on the view object definition.

If you prefer to optimize the declarative SQL query so that the `SELECT` and `FROM` clauses of the SQL query statement are based solely on whether or not the attributes

you add to the view object are rendered at runtime by a databound UI component, then you must disable the **Selected in Query** checkbox (sets `IsSelected=false` for the view object definition) for all added attributes. By default, the `IsSelected` property is `true` for any attribute that you add to the view object in declarative SQL mode. The default setting means the added attribute will be selected in the SQL statement regardless of whether or not the attribute is exposed by a databound UI component. When you create a new view object in declarative SQL mode, you can use the Attribute Settings page of the Create View Object wizard to change the setting for each attribute. If you need to alter this setting after you generate the view object, you can use the Property Inspector to change the **Selected in Query** property setting for one or more attributes that you select in the Attributes page of the view object editor.

Performance Tip: A view object instance configured to generate SQL statements dynamically will requery the database during page navigation if a subset of all attributes with the same list of key entity objects is used in the subsequent page navigation. Thus performance can be improved by activating a superset of all the required attributes to eliminate a subsequent query execution.

5.8.1.1 Enabling Declarative SQL Mode for All New View Objects

You can enable declarative SQL mode as a global preference so that it is the Create View Object wizard's default mode, or you can leave the setting disabled and select the desired mode directly in the wizard. The editor for a view object also lets you select and change the mode for an existing view object definition.

Before you begin:

It may be helpful to have an understanding of declarative SQL mode. For more information, see [Section 5.8.1, "How to Create SQL-Independent View Objects with Declarative SQL Mode."](#)

To enable declarative SQL mode for all new view objects:

1. From the main menu, choose **Tools > Preferences**.
2. In the Preferences dialog, expand the **ADF Business Components** node and choose **View Objects**.
3. On the ADF Business Components: View Object page, select **Enable Declarative SQL mode for new objects** and click **OK**.

To predetermine how the `FROM` list will be generated at runtime you can select **Include all attributes in runtime-generated query**, as described in [Section 5.8.4, "How to Support Programmatic Execution of Declarative SQL Mode View Objects."](#)

5.8.1.2 Enabling Declarative SQL Mode for Specific View Objects

There are no unique requirements for creating entity-based view objects in declarative SQL mode. The basic procedure to create a view object with ensured SQL independence is the same as you would follow to create any entity-based view object. To create an entity-based view object in declarative SQL mode, use the Create View Object wizard, which is available from the New Gallery. The editor for a view object lets you select and change the mode for an existing view object definition.

Before you begin:

It may be helpful to have an understanding of declarative SQL mode. For more information, see [Section 5.8.1, "How to Create SQL-Independent View Objects with Declarative SQL Mode."](#)

To create declarative SQL-based view objects:

1. In the Application Navigator, right-click the project in which you want to create the view objects and choose **New**.
2. In the New Gallery, expand **Business Tier**, select **ADF Business Components** and then **View Object**, and click **OK**.
3. On the Name page, enter a package name and a view object name. Keep the default setting **Entity object** selected to indicate that you want this view object to manage data with its base entity object. Click **Next**.

Any other choice for the data selection will disable declarative SQL mode in the Create View Object wizard.

4. On the Entity Objects page, select the entity object whose data you want to use in the view object. Click **Next**.

When you want to create a view object that joins entity objects, you can add secondary entity objects to the list. To create more complex entity-based view objects, see [Section 5.5.1, "How to Create Joins for Entity-Based View Objects."](#)

5. On the Attributes page, select at least one attribute from the entity usage in the **Available** list and shuttle it to the **Selected** list. Attributes you do not select will not be eligible for use in view criteria and sort criteria. Click **Next**.

You should select any attribute that you intend to customize (in the Attribute Settings page) or any attribute that you intend to use in a view criteria or sort criteria (in the Query page). Additionally, the tables that appear in the FROM list of the runtime-generated query will be limited to the tables corresponding to the attributes of the entity objects you select.

6. On the Attribute Settings page, optionally, use the **Select Attribute** dropdown list to switch between the view object attributes in order to change their names or any of their initial settings.
7. Use the **Select Attribute** dropdown list to switch between the previously selected view object attributes and deselect **Selected in Query** for each attribute that you want to be selected in the SQL statement based solely on whether or not the attribute is rendered by a databound UI component. Click **Next**.

By default, the **Selected in Query** checkbox is enabled for all view object attributes that you add in declarative SQL mode. This default setting will generate a SQL statement with all added attributes selected. When you deselect the checkbox for an attribute, the `isSelected` property is set to `false` and whether or not the attribute is selected will be determined at runtime by the databound UI component's usage of the attribute.

8. On the Query page, select **Declarative** in the **Query Mode** dropdown list if it is not already displayed. The wizard changes to declarative SQL mode.

If you did not select **Enable declarative SQL mode for new objects**, in the Preferences dialog, the wizard displays the default query mode, **Normal**. Changing the mode to **Declarative** in the wizard allows you to override the default mode for this single view object.

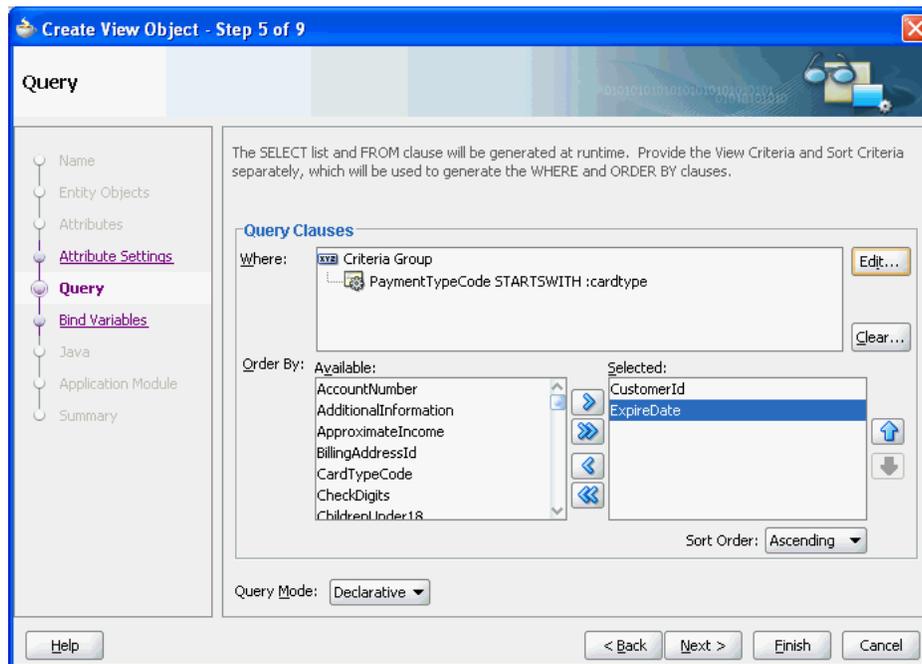

9. Optionally, define **Where** and **Order By** criteria to filter and order the data as required. At runtime, ADF Business Components automatically generates the corresponding SQL statements based on the criteria you create.

Click **Edit** next to the **Where** field to define the view criteria you will use to filter the data. The view criteria you enter will be converted at runtime to a WHERE clause that will be enforced on the query statement. For information about specifying view criteria, see [Section 5.11, "Working with Named View Criteria."](#)

In the **Order By** field select the desired attribute in the **Available** list and shuttle it to the **Selected** list. Attributes you do not select will not appear in the SQL ORDERBY clause generated at runtime. Add additional attributes to the **Selected** list when you want the results to be sorted by more than one column. Arrange the selected attributes in the list according to their sort precedence. Then for each sort attribute, assign whether the sort should be performed in ascending or descending order. Assigning the sort order to each attribute ensures that attributes ignored by the UI component still follow the intended sort order.

For example, as shown in [Figure 5-34](#), to limit the CustomerCardStatus view object to display only the rows in the CUSTOMERS table for customers with a specific credit card code, the view criteria in the **Where** field limits the CardTypeCode attribute to a runtime-determined value. To order the data by customer ID and the customer's card expiration date, the **Order By** field identifies those attributes in the **Selected** list.

Figure 5-34 *Creating View Object Wizard, Query Page with Declarative Mode Selected*

10. Click **Finish**.

5.8.2 How to Filter Declarative SQL-Based View Objects When Table Joins Apply

When you create an entity-based view object you can reference more than one entity object in the view object definition. In the case of view objects you create in declarative SQL mode, whether the base entity objects are activated from the view object definition will depend on the requirements of the databound UI component at

runtime. If the UI component displays attribute values from multiple entity objects, then the SQL generated at runtime will contain a `JOIN` operation to query the appropriate tables.

Just as with any view object that you create, it is possible to filter the results from table joins by applying named view criteria. In the case of normal mode view objects, all entity objects and their attributes will be referenced by the view object definition and therefore will be automatically included in the view object's SQL statement. However, by delaying the SQL generation until runtime with declarative SQL mode, there is no way to know whether the view criteria should be applied.

Note: In declarative SQL mode, you can define a view criteria to specify the `WHERE` clause (optional) when you create the view object definition. This type of view criteria when it exists will always be applied at runtime. For a description of this usage of the view criteria, see [Section 5.8.1, "How to Create SQL-Independent View Objects with Declarative SQL Mode."](#)

Because a SQL `JOIN` may not always result from a view object defined in declarative SQL mode with multiple entity objects, named view criteria that you define to filter query results should be applied conditionally at runtime. In other words, named view criteria that you create for declarative SQL-based view objects need not be applied as required, automatic filters. To support declarative SQL mode, named view criteria that you apply to a view object created in declarative SQL mode can be set to apply only on the condition that the UI component is bound to the attributes referenced by the view criteria. The named view criteria once applied will, however, support the UI component's need to display a filtered result set.

Before you begin:

It may be helpful to have an understanding of SQL independence at runtime. For more information, see [Section 5.8, "Working with View Objects in Declarative SQL Mode."](#)

You will need to complete these tasks:

- Create the view object with declarative SQL mode enabled as described in [Section 5.8.1, "How to Create SQL-Independent View Objects with Declarative SQL Mode."](#)
- Create a view criteria to filter the results from table joins as described in [Section 5.11.1, "How to Create Named View Criteria Declaratively."](#)

You will use the Edit View Criteria dialog to create the named view criteria. You then enable its conditional usage by setting the `appliedIfJoinSatisfied` property in the Property Inspector.

To define a view criteria to filter only when the join is satisfied:

1. In the Application Navigator, double-click the SQL-independent view object that supports table joins.
2. In the overview editor, click the **Query** navigation tab.
3. In Query page, expand the **View Criteria** section and select the view criteria you created to filter the SQL-independent view object.
4. With the view criteria selected, open the Property Inspector and set the `AppliedIfJoinSatisfied` property to **true**.

The property value **true** means you want the view criteria to be applied only on the condition that the UI component requires the attributes referenced by the view criteria. The default value **false** means that the view criteria will automatically be applied at runtime. In the case of declarative SQL mode-based view objects, the value **true** ensures that the query filter will be appropriate to needs of the view object's databound UI component.

5.8.3 How to Filter Master-Detail Related View Objects with Declarative SQL Mode

Just as with normal mode view objects, you can link view objects that you create in declarative SQL mode to other view objects to form master-detail hierarchies of any complexity. The steps to create the view links are the same as with any other entity-based view object, as described in [Section 5.6.2, "How to Create a Master-Detail Hierarchy for Entity-Based View Objects."](#) However, in the case of view objects that you create in declarative SQL mode, you can further refine the view object results in the Source SQL or Destination SQL dialog for the view link by selecting a previously defined view criteria in the Create View Link wizard or the overview editor for the view link.

Before you begin:

It may be helpful to have an understanding of SQL independence at runtime. For more information, see [Section 5.8, "Working with View Objects in Declarative SQL Mode."](#)

You will need to complete these tasks:

1. Create the master and detail view objects with declarative SQL mode enabled as described in [Section 5.8.1, "How to Create SQL-Independent View Objects with Declarative SQL Mode."](#)
2. Define the desired view criteria for either the source (master) view object or the destination (detail) view object as described in [Section 5.8.2, "How to Filter Declarative SQL-Based View Objects When Table Joins Apply."](#)
3. Create the view link as described in [Section 5.6.2, "How to Create a Master-Detail Hierarchy for Entity-Based View Objects."](#)

To filter a view link source or view link destination:

1. In the Application Navigator, double-click the view link you created to form the master-detail hierarchy:
2. In the overview editor navigation list, select **Query** and expand the **Source** or **Destination** sections.
3. In the **View Criteria** dropdown list, select the desired view criteria. The dropdown list will be empty if no view criteria exist for the view object.

If the overview editor does not display a dropdown list for view criteria selection, then the view objects you selected for the view link were not created in declarative SQL mode. For view objects created in normal or expert mode, you must edit the `WHERE` clause to filter the data as required.

5.8.4 How to Support Programmatic Execution of Declarative SQL Mode View Objects

Typically, when you define a declarative SQL mode view object, the attributes that get queried at runtime will be determined by the requirements of the databound UI component as it is rendered in the web page. This is the runtime-generation capability that makes view objects independent of the design time database's SQL platform. However, you may also need to execute the view object programmatically without

exposing it to an ADF data binding in the UI. In this case, you can enable the **Include all attributes in runtime-generated query** option to ensure that a programmatically executed view object has access to all of the entity attributes.

Note: Be careful to limit the use of the **Include all attributes in runtime-generated query** option to programmatically executed view objects. If you expose the view object with this setting enabled to a databound UI component, the runtime query will include all attributes.

The **Include all attributes in runtime-generated query** option can be specified as a global preference setting or as a setting on individual view objects. Both settings may be used in these combinations:

- Enable the global preference so that every view object you create includes all attributes in the runtime query statement.
- Enable the global preference, but disable the setting on view objects that will not be executed programmatically and therefore should not include all attributes in the runtime query statement.
- Disable the global preference (default), but enable the setting on view objects that will be executed programmatically and therefore should include all attributes in the runtime query statement.

5.8.4.1 Forcing Attribute Queries for All Declarative SQL Mode View Objects

You can enable the global preference to force attribute queries for all declarative SQL mode view objects as the default mode, or you can leave the option disabled and enable the option directly in the overview editor for a specific view object.

Before you begin:

It may be helpful to have an understanding of how the **Include all attributes in runtime-generated query** option supports programmatic execution of declarative SQL mode view objects. For more information, see [Section 5.8.4, "How to Support Programmatic Execution of Declarative SQL Mode View Objects."](#)

To set the global preference to include all attributes in the query:

1. From the main menu, choose **Tools > Preferences**.
2. In the Preferences dialog, expand **ADF Business Components** and select **View Objects**.
3. On the ADF Business Components: View Object page, select **Enable Declarative SQL mode for new objects**.
4. Select **Include all attributes in runtime-generated query** to force all attributes of the view object's underlying entity objects to participate in the query and click **OK**.

Enabling this option sets a flag in the view object definition but you will still need to add entity object selections and entity object attribute selections to the view object definition.

5.8.4.2 Forcing Attribute Queries for Specific Declarative SQL Mode View Objects

You can change the view object setting in the **Tuning** section of the overview editor's General page. The overview editor only displays the **Include all attributes in**

runtime-generated query option if you have created the view object in declarative SQL mode.

Before you begin:

It may be helpful to have an understanding of how the **Include all attributes in runtime-generated query** option supports programmatic execution of declarative SQL mode view objects. For more information, see [Section 5.8.4, "How to Support Programmatic Execution of Declarative SQL Mode View Objects."](#)

To set the view object-specific preference to include all attributes in the query:

1. When you want to force all attributes for specific view objects, create the view object in the Create View Object wizard and be sure that you have enabled declarative SQL mode.

You can verify this in the overview editor. In the overview editor, click the **Query** navigation tab and click the **Edit SQL Query** button along the top of the page. In the Edit Query dialog, verify that the **SQL Mode** dropdown list shows the selection **Declarative**.

2. In the overview editor, click the **General** navigation tab.
3. In the General page, expand the **Tuning** section and select **Include all attributes in runtime-generated query**.

Enabling this option forces all attributes of the view object's underlying entity objects to participate in the query. When enabled, it sets a flag in the view object definition but you will still need to add entity object selections and entity object attribute selections to the view object definition.

5.8.5 What Happens When You Create a View Object in Declarative SQL Mode

When you create the view object in declarative SQL mode, three properties get added to the view object's metadata: `SelectListFlags`, `FromListFlags`, and `WhereFlags`. Properties that are absent in declarative SQL mode are the normal mode view object's `SelectList`, `FromList`, and `Where` properties, which contain the actual SQL statement (or, for expert mode, the `SQLQuery` element). [Example 5-10](#) shows the three view object metadata flags that get enabled in declarative SQL mode to ensure that SQL will be generated at runtime instead of specified as metadata in the view object's definition.

Example 5-10 View Object Metadata with Declarative SQL Mode Enabled

```
<ViewObject
  xmlns="http://xmlns.oracle.com/bc4j"
  Name="CustomerCardStatus"
  SelectListFlags="1"
  FromListFlags="1"
  WhereFlags="1"
  ...
```

Similar to view objects that you create in either normal or expert mode, the view object metadata also includes a `ViewAttribute` element for each attribute that you select in the Attribute page of the Create View Object wizard. However, in declarative SQL mode, when you "select" attributes in the wizard (or add an attribute in the overview editor), you are not creating a `FROM` or `SELECT` list in the design time. The attribute definitions that appear in the view object metadata only determine the list of potential entities and attributes that will appear in the runtime-generated statements. For

information about how ADF Business Components generates these SQL lists, see [Section 5.8.6, "What Happens at Runtime: Declarative SQL Mode Queries."](#)

[Example 5–11](#) shows the additional features of declarative SQL mode view objects, including the optional declarative WHERE clause (`DeclarativeWhereClause` element) and the optional declarative ORDERBY clause (`SortCriteria` element).

Example 5–11 View Object Metadata: Declarative View Criteria and Sort Criteria

```
<DeclarativeWhereClause>
  <ViewCriteria
    Name="CustomerStatusWhereCriteria"
    ViewObjectName="oracle.fodemo.storefront.store.queries.CustomerCardStatus"
    Conjunction="AND"
    Mode="3"
    AppliedIfJoinSatisfied="false">
    <ViewCriteriaRow
      Name="vcrow60">
      <ViewCriteriaItem
        Name="CardTypeCode"
        ViewAttribute="CardTypeCode"
        Operator="STARTSWITH"
        Conjunction="AND"
        Required="Optional">
      <ViewCriteriaItemValue
        Value=":cardtype"
        IsBindVarValue="true"/>
      </ViewCriteriaItem>
    </ViewCriteriaRow>
  </ViewCriteria>
</DeclarativeWhereClause>
<SortCriteria>
  <Sort
    Attribute="CustomerId"/>
<Sort
  Attribute="CardTypeCode"/>
</SortCriteria>
```

5.8.6 What Happens at Runtime: Declarative SQL Mode Queries

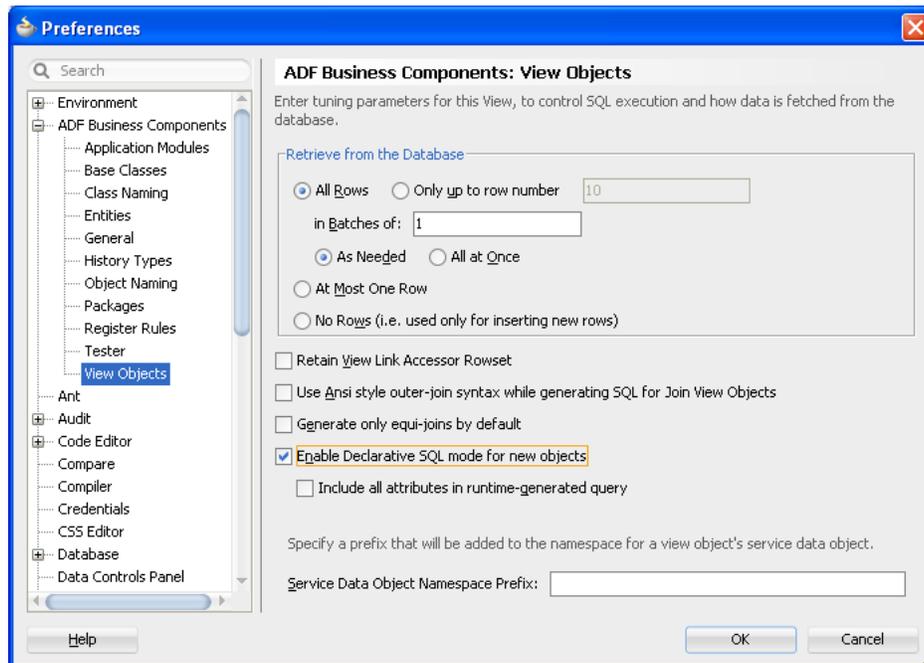

At runtime, when a declarative SQL mode query is generated, ADF Business Components determines which attributes were defined from the metadata `ViewCriteria` element and `SortCriteria` element. It then uses these attributes to generate the WHERE and ORDERBY clauses. Next, the runtime generates the FROM list based on the tables corresponding to the entity usages defined by the metadata `ViewAttribute` elements. Finally, the runtime builds the SELECT statement based on the attribute selection choices the end user makes in the UI. As a result, the view object in declarative SQL mode generates all SQL clauses entirely at runtime. The runtime-generated SQL statements will be based on the platform that appears in the project properties setting. Currently, the runtime supports SQL92 (ANSI) style and Oracle style platforms.

5.8.7 What You May Need to Know About Overriding Declarative SQL Mode Defaults

JDeveloper lets you control declarative SQL mode for all new view objects you add to your data model project or for individual view objects you create or edit. These settings may be used in these combinations:

- Enable the global preference in the Preferences dialog (select **Tools > Preferences**). Every view object you create will delay SQL generation until runtime. [Figure 5–35](#) shows the global preference **Enable declarative SQL for new objects** set to enabled.
- Enable the global preference in the Preferences dialog, but change the SQL mode for individual view objects. In this case, unless you change the SQL mode, the view objects you create will delay SQL generation until runtime.
- Disable the global preference (default) in the Preferences dialog, but select declarative SQL mode for individual view objects. In this case, unless you change the SQL mode, view objects you create will contain SQL statements.

Figure 5–35 Preferences Dialog with Declarative SQL Mode Enabled

To edit the SQL mode for a view object you have already created, open the Query page in the Edit Query dialog and select **Declarative** from the **SQL Mode** dropdown list. To display the Edit Query dialog, open the view object in the overview editor, select **Query** from the navigation list and click the **Edit SQL Query** button. The same option appears in the Query page of the Create View Object wizard.

5.8.8 What You May Need to Know About Working Programmatically with Declarative SQL Mode View Objects

As a convenience to developers, the view object implementation API allows individual attributes to be selected and deselected programmatically. This API may be useful in combination with the view objects you create in declarative SQL mode and intend to execute programmatically. [Example 5–12](#) shows how to call `selectAttributeDefs()` on the view object when you want to add a subset of attributes to those already configured with SQL mode enabled.

Example 5–12 ViewObjectImpl API with SQL Mode View Objects

```
ApplicationModule am = Configuration.createRootApplicationModule(amDef, config);
ViewObjectImpl vo = (ViewObjectImpl) am.findViewObject("CustomerVO");
```

```
vo.resetSelectedAttributeDefs(false);
vo.selectAttributeDefs(new String[] {"FirstName", "LastName"});
vo.executeQuery();
```

The call to `selectAttributeDefs()` adds the attributes in the array to a private member variable of `ViewObjectImpl`. A call to `executeQuery()` transfers the attributes in the private member variable to the actual select list. It is important to understand that these `ViewObjectImpl` attribute calls are not applicable to the client layer and are only accessible inside the `Impl` class of the view object on the middle tier.

Additionally, you might call `unselectAttributeDefs()` on the view object when you want to deselect a small subset of attributes after *enabling* the **Include all attributes in runtime-generated query** option. Alternatively, you can call `selectAttributeDefs()` on the view object to select a small subset of attributes after *disabling* the **Include all attributes in runtime-generated query** option.

Caution: Be careful not to expose a declarative SQL mode view object executed with this API to the UI since only the value of the **Include all attributes in runtime-generated query** option will be honored.

5.9 Working with View Objects in Expert Mode

When defining entity-based view objects, you can fully specify the `WHERE` and `ORDER BY` clauses, whereas, by default, the `FROM` clause and `SELECT` list are automatically derived. The names of the tables related to the participating entity usages determine the `FROM` clause, while the `SELECT` list is based on the:

- Underlying column names of participating entity-mapped attributes
- SQL expressions of SQL-calculated attributes

When you require full control over the `SELECT` or `FROM` clause in a query, you can enable expert mode.

Tips: The view object editors and wizard in the JDeveloper provide full support for generating SQL from choices that you make. For example, two such options allow you to declaratively define outer joins and work in declarative SQL mode (where no SQL is generated until runtime).

5.9.1 How to Customize SQL Statements in Expert Mode

To enable expert mode, select **Expert Mode** from the **SQL Mode** dropdown list on the Query panel of the Create View Object wizard. You can also modify the SQL statement of an existing entity-based view object in the view object overview editor. In the overview editor, navigate to the Query page and click the **Edit SQL Query** button. In the Edit Query dialog, select **Expert Mode** from the **SQL Mode** dropdown list.

5.9.2 How to Name Attributes in Expert Mode

If your SQL query includes a calculated expression, use a SQL alias to assist the Create View Object wizard in naming the column with a Java-friendly name. [Example 5-13](#) shows a SQL query that includes a calculated expression.

Example 5-13 SQL Query with Calculated Expression

```
select PERSON_ID, EMAIL,
       SUBSTR(FIRST_NAME,1,1)||'. '||LAST_NAME
from PERSONS
order by EMAIL
```

[Example 5-14](#) uses a SQL alias `USER_SHORT_NAME` to assist the Create View Object wizard in naming the column with a Java-friendly name. The wizard will display `UserShortName` as the name of the attribute derived from this calculated expression.

Example 5-14 SQL Query with SQL Alias

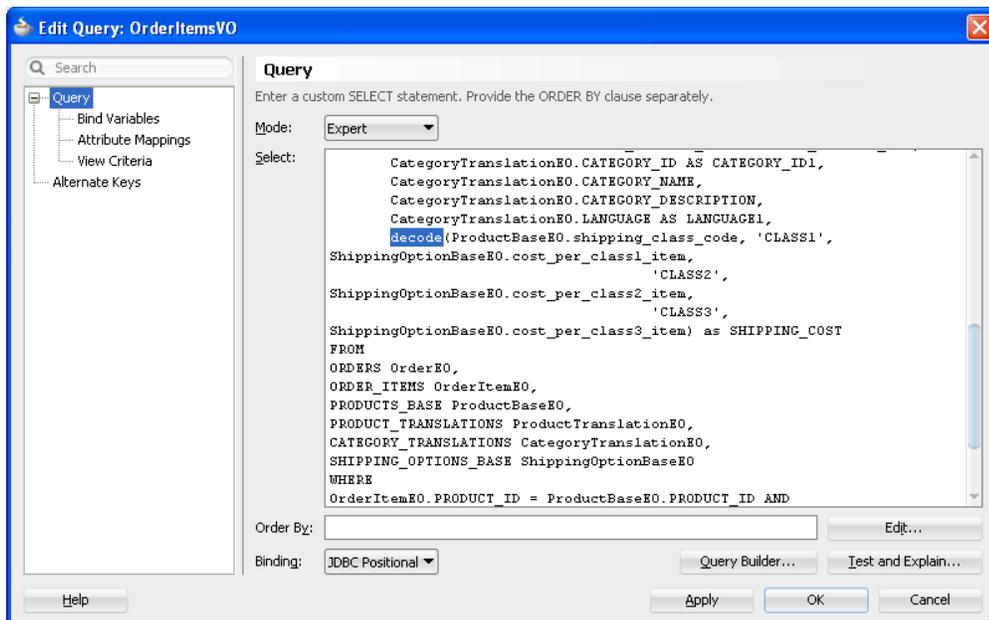

```
select PERSON_ID, EMAIL,
       SUBSTR(FIRST_NAME,1,1)||'. '||LAST_NAME AS USER_SHORT_NAME
from PERSONS
order by EMAIL
```

5.9.3 What Happens When You Enable Expert Mode

When you enable expert mode, the read-only **Generated Statement** section of the Query page becomes a fully editable **Query Statement** text box, displaying the full SQL statement. Using this text box, you can change every aspect of the SQL query.

For example, [Figure 5-36](#) shows the Query page of the Edit Query dialog for the `OrderItems` view object. It's an expert mode, entity-based view object that references a PL/SQL function `decode` that obtains its input values from an expression set on the `ShippingCost` attribute.

Figure 5-36 OrderItems Expert Mode View Object

5.9.4 What You May Need to Know About Expert Mode

When you define a SQL query using expert mode in the Edit Query dialog, you type a SQL language statement directly into the editor. Using this mode places some responsibility on the Business Components developer to understand how the view

object handles the metadata resulting from the query definition. Review the following information to familiarize yourself with the behavior of the Edit Query dialog that you use in expert mode.

5.9.4.1 Expert Mode Provides Limited Attribute Mapping Assistance

The automatic cooperation of a view object with its underlying entity objects depends on correct attribute-mapping metadata saved in the XML component definition. This information relates the view object attributes to corresponding attributes from participating entity usages. JDeveloper maintains this attribute mapping information in a fully automatic way for normal entity-based view objects. However, when you decide to use expert mode with a view object, you need to pay attention to the changes you make to the `SELECT` list. That is the part of the SQL query that directly relates to the attribute mapping. Even in expert mode, JDeveloper continues to offer some assistance in maintaining the attribute mapping metadata when you do the following to the `SELECT` list:

- Reorder an expression without changing its column alias
JDeveloper reorders the corresponding view object attribute and maintains the attribute mapping.
- Add a new expression
- JDeveloper adds a new SQL-calculated view object attribute with a corresponding camel-capped name based on the column alias of the new expression.
- Remove an expression
JDeveloper converts the corresponding SQL-calculated or entity-mapped attribute related to that expression to a transient attribute.

However, if you rename a column alias in the `SELECT` list, JDeveloper has no way to detect this, so it is treated as if you removed the old column expression and added a new one of a different name.

After making any changes to the `SELECT` list of the query, visit the Attribute Mappings page to ensure that the attribute-mapping metadata is correct. The table on this page, which is disabled for view objects in normal mode, becomes enabled for expert mode view objects. For each view object attribute, you will see its corresponding SQL column alias in the table. By clicking into a cell in the **View Attributes** column, you can use the dropdown list that appears to select the appropriate entity object attribute to which any entity-mapped view attributes should correspond.

Note: If the view attribute is SQL-calculated or transient, a corresponding attribute with a "SQL" icon appears in the **View Attributes** column to represent it. Since neither of these type of attributes are related to underlying entity objects, there is no entity attribute related information required for them.

5.9.4.2 Expert Mode Drops Custom Edits

When you disable expert mode for a view object, it will return to having its `SELECT` and `FROM` clause be derived again. JDeveloper warns you that doing this might cause your custom edits to the SQL statement to be lost. If this is what you want, after acknowledging the alert, your view object's SQL query reverts back to the default.

5.9.4.3 Expert Mode Ignores Changes to SQL Expressions

Consider a `Products` view object with a SQL-calculated attribute named `Shortens` whose SQL expression you defined as `SUBSTR (NAME, 1, 10)`. If you switch this view object to expert mode, the **Query Statement** box will show a SQL query similar to the one shown in [Example 5–15](#).

Example 5–15 SQL-Calculated Attribute Expression in Expert Mode

```
SELECT Products.PROD_ID,
       Products.NAME,
       Products.IMAGE,
       Products.DESCRPTION,
       SUBSTR(NAME,1,10) AS SHORT_NAME
FROM PRODUCTS Products
```

If you go back to the attribute definition for the `Shortens` attribute and change the **SQL Expression** field from `SUBSTR (NAME, 1, 10)` to `SUBSTR (NAME, 1, 15)`, then the change will be saved in the view object's XML component definition. Note, however, that the SQL query in the **Query Statement** box will remain as the original expression. This occurs because JDeveloper never tries to *modify* the text of an expert mode query. In expert mode, the developer is in full control. JDeveloper attempts to adjust metadata as a result of some kinds of changes you make yourself to the expert mode SQL statement, but it does not perform the reverse. Therefore, if you change view object metadata, the expert mode SQL statement is not updated to reflect it.

Therefore, you need to update the expression in the expert mode SQL statement itself. To be completely thorough, you should make the change *both* in the attribute metadata *and* in the expert mode SQL statement. This would ensure — if you (or another developer on your team) ever decides to toggle expert mode *off* at a later point in time — that the automatically derived `SELECT` list would contain the correct SQL-derived expression.

Note: If you find you had to make numerous changes to the view object metadata of an expert mode view object, you can avoid having to manually translate any effects to the SQL statement by copying the text of your customized query to a temporary backup file. Then, you can disable expert mode for the view object and acknowledge the warning that you will lose your changes. At this point JDeveloper will rederive the correct generated SQL statement based on all the new metadata changes you've made. Finally, you can enable expert mode once again and reapply your SQL customizations.

5.9.4.4 Expert Mode Returns Error for SQL Calculations that Change Entity Attributes

When changing the `SELECT` list expression that corresponds to *entity-mapped* attributes, don't introduce SQL calculations into SQL statements that change the value of the attribute when retrieving the data. To illustrate the problem that will occur if you do this, consider the query for a simple entity-based view object named `Products` shown in [Example 5–16](#).

Example 5–16 Query Statement Without SQL-Calculated Expression

```
SELECT Products.PROD_ID,
       Products.NAME,
       Products.IMAGE,
```

```

        Products.DESCRPTION
FROM PRODUCTS Products

```

Imagine that you wanted to limit the name column to display only the first ten characters of the name of a product query. The correct way to do that would be to introduce a new SQL-calculated field, such as `ShortName` with an expression like `SUBSTR(Products.NAME, 1, 10)`. One way you should *avoid* doing this is to switch the view object to expert mode and change the `SELECT` list expression for the entity-mapped `NAME` column to include the SQL-calculated expression, as shown in [Example 5-17](#).

Example 5-17 Query Statement with SQL-Calculated Expression

```

SELECT Products.PROD_ID,
       SUBSTR(Products.NAME, 1, 10) AS NAME,
       Products.IMAGE,
       Products.DESCRPTION
FROM PRODUCTS Products

```

This alternative strategy would initially appear to work. At runtime, you see the truncated value of the name as you are expecting. However, if you modify the row, when the underlying entity object attempts to lock the row it does the following:

- Issues a `SELECT FOR UPDATE` statement, retrieving all columns as it tries to lock the row.
- If the entity object successfully locks the row, it compares the original values of all the persistent attributes in the entity cache as they were last retrieved from the database with the values of those attributes just retrieved from the database during the lock operation.
- If any of the values differs, then the following error is thrown:

```

(oracle.jbo.RowInconsistentException)
JBO-25014: Another user has changed the row with primary key [...]

```

If you see an error like this at runtime even though you are the *only* user testing the system, it is most likely due to your inadvertently introducing a SQL function in your expert mode view object that changed the selected value of an entity-mapped attribute. In [Example 5-17](#), the `SUBSTR(Products.NAME, 1, 10)` function introduced causes the original selected value of the `Name` attribute to be truncated. When the row-lock SQL statement selects the value of the `NAME` column, it will select the entire value. This will cause the comparison shown in [Example 5-17](#) to fail, producing the "phantom" error that another user has changed the row.

The same thing would happen with `NUMBER`-valued or `DATE`-valued attributes if you inadvertently apply SQL functions in expert mode to truncate or alter their retrieved values for entity-mapped attributes.

Therefore, if you need to present altered versions of entity-mapped attribute data, introduce a new SQL-calculated attribute with the appropriate expression to handle the task.

5.9.4.5 Expert Mode Retains Formatting of SQL Statement

When you change a view object to expert mode, its XML component definition changes from storing parts of the query in separate XML attributes, to saving the entire query in a single `<SQLQuery>` element. The query is wrapped in an XML `CDATA` section to preserve the line formatting you may have done to make a complex query be easier to understand.

5.9.4.6 Expert Mode Wraps Queries as Inline Views

If your expert-mode view object:

- Contains a `ORDERBY` clause specified in the **Order By** field of the Query Clauses page at design time, or
- Has a dynamic `WHERE` clause or `ORDERBY` clause applied at runtime using `setWhereClause()` or `setOrderByClause()`

then its query gets nested into an inline view before applying these clauses. For example, suppose your expert mode query was defined like the one shown in [Example 5–18](#).

Example 5–18 Expert Mode Query Specified At Design Time

```
select PERSON_ID, EMAIL, FIRST_NAME, LAST_NAME
from PERSONS
union all
select PERSON_ID, EMAIL, FIRST_NAME, LAST_NAME
from INACTIVE_PERSONS
```

Then, at runtime, when you set an additional `WHERE` clause like `email = :TheUserEmail`, the view object nests its original query into an inline view like the one shown in [Example 5–19](#).

Example 5–19 Runtime-Generated Query with Inline Nested Query

```
SELECT * FROM(
select PERSON_ID, EMAIL, FIRST_NAME, LAST_NAME
from PERSONS
union all
select PERSON_ID, EMAIL, FIRST_NAME, LAST_NAME
from INACTIVE_PERSONS) QRSLT
```

And, the view object adds the dynamic `WHERE` clause predicate at the end, so that the final query the database sees looks like the one shown in [Example 5–20](#).

Example 5–20 Runtime-Generated Query with Dynamic WHERE Clause

```
SELECT * FROM(
select PERSON_ID, EMAIL, FIRST_NAME, LAST_NAME
from PERSONS
union all
select PERSON_ID, EMAIL, FIRST_NAME, LAST_NAME
from INACTIVE_PERSONS) QRSLT
WHERE email = :TheUserEmail
```

This query "wrapping" is necessary in general for expert mode queries, because the original query could be arbitrarily complex, including SQL `UNION`, `INTERSECT`, `MINUS`, or other operators that combine multiple queries into a single result. In those cases, simply "gluing" the additional runtime `WHERE` clause onto the end of the query text could produce unexpected results. For example, the clause might apply only to the *last* of several `UNION`'ed statements. By nesting the original query verbatim into an inline view, the view object guarantees that your additional `WHERE` clause is correctly used to filter the results of the original query, regardless of how complex it is.

5.9.4.7 Limitation of Inline View Wrapping at Runtime

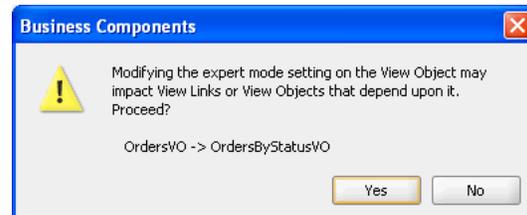

Inline view wrapping of expert mode view objects, limits a dynamically added `WHERE` clause to refer only to columns in the `SELECT` list of the original query. To avoid this

limitation, when necessary you can disable the use of the inline view wrapping by calling `setNestedSelectForFullSql (false)`.

5.9.4.8 Expert Mode Changes May Affect Dependent Objects

When you modify a view object query to be in expert mode after you have already created the view links that involve that view object or after you created other view objects that extend the view object, JDeveloper will warn you with the alert shown in [Figure 5-37](#). The alert reminds you that you should revisit these dependent components to ensure their SQL statements still reflect the correct query.

Figure 5-37 Proactive Reminder to Revisit Dependent Components

For example, if you were to modify the `OrdersVO` view object to use expert mode, because the `OrdersByStatusVO` view object extends it, you need to revisit the extended component to ensure that its query still logically reflects an extension of the modified parent component.

5.10 Working with Bind Variables

Bind variables provide you with the means to supply attribute values at runtime to the view object or view criteria. All bind variables are defined at the level of the view object and used in one of the following ways:

- You can type the bind variable directly into the `WHERE` clause of your view object's query to include values that might change from execution to execution. In this case, bind variables serve as placeholders in the SQL string whose value you can easily change at runtime without altering the text of the SQL string itself. Since the query doesn't change, the database can efficiently reuse the same parsed representation of the query across multiple executions, which leads to higher runtime performance of your application.
- You can select the bind variable from a selection list to define the attribute value for a view criteria in the Edit View Criteria dialog you open on the view object. In this case, the bind variables allow you to change the values for attributes you will use to filter the view object row set. For more information about filtering view object row sets, see [Section 5.11, "Working with Named View Criteria."](#)

If the view criteria is to be used in a seeded search, you have the option of making the bind variable updatable by the end user. With this updatable option, end users will be expected to enter the value in a search form corresponding to the view object query.

Bind variables that you add to a `WHERE` clause require a valid value at runtime, or a runtime exception error will be thrown. In contrast, view criteria execution need not require the bind variable value if the view criteria item for which the bind variable is assigned is not required. To enforce this desired behavior, the Bind Variable dialog lets you can specify whether a bind variable is required or not.

You can define a default value for the bind variable or write scripting expressions for the bind variable that includes dot notation access to attribute property values. Expressions are based on the Groovy scripting language, as described in [Section 3.6, "Overview of Groovy Scripting Language Support."](#)

5.10.1 How to Add Bind Variables to a View Object Definition

To add a named bind variable to a view object, use the Query page of the overview editor for the view object. You can define as many bind variables as you need.

Before you begin:

It may be helpful to have an understanding of the support for bind variables at the level of view objects. For more information, see [Section 5.10, "Working with Bind Variables."](#)

You will need to complete this task:

Create the desired view objects as described in [Section 5.2.1, "How to Create an Entity-Based View Object,"](#) and [Section 5.2.3, "How to Create an Expert Mode, Read-Only View Object."](#)

To define a named bind variable:

1. In the Application Navigator, double-click the view object.
2. In the overview editor, click the **Query** navigation tab.
3. In the Query page, expand the **Bind Variables** section and click the **Create new bind variable** button.
4. In the Bind Variable dialog, enter the name and data type for the new bind variable.

Because the bind variables share the same namespace as view object attributes, specify names that don't conflict with existing view object attribute names. As with view objects attributes, by convention bind variable names are created with an initial capital letter, but you can rename it as desired.

5. Optionally, specify a default value for the bind variable:
 - When you want the value to be determined at runtime using an expression, enter a Groovy scripting language expression, select the **Expression** value type and enter the expression in the **Value** field. Optionally, click **Edit** to open the Expression dialog. The Expression dialog gives you a larger text area to write the expression. For example, you might want to define a bind variable to filter view instances based on the current user, as described in [Section 5.10.2, "How to Reference the Current User in a Named Bind Variable Using Groovy."](#)
 - When you want to define a default value, select the **Literal** value type and enter the literal value in the **Value** field.
6. Decide on one of the following runtime usages for the bind variable:
 - When you want the value to be supplied to a SQL WHERE clause using a bind variable in the clause, select the **Required** checkbox. This ensures that a runtime exception will be thrown if the value is not supplied. For more information, see [Section 5.10.8.3, "Errors Related to Naming Bind Variables."](#)
 - When you want the value to be supplied to a view criteria using a bind variable in the view criteria, only select the **Required** checkbox when you need to reference the same bind variable in a SQL WHERE clause or when you want to use the bind variable as the assigned value of a view criteria item that

is specifically defined as required by a view criteria that is applied to a view object. When **Required** is unselected this ensures that the value is optional and that no runtime exception will be thrown if the bind variable is not resolved. For example, view criteria with bind variables defined can be used to create Query-by-Example search forms in the user interface. For more information, see [Section 5.11, "Working with Named View Criteria."](#)

7. In the Bind Variable dialog, click the **Control Hints** tab and specify hints like **Label Text**, **Format Type**, **Format** mask, and others.

The view layer will use bind variable control hints when you build user interfaces like search pages that allow the user to enter values for the named bind variables. The **Updatable** checkbox controls whether the end user will be allowed to change the bind variable value through the user interface. If a bind variable is not updatable, then its value can only be changed programmatically by the developer.

8. Click **OK**.

After defining the bind variables, the next step is to reference them in the SQL statement. While SQL syntax allows bind variables to appear both in the `SELECT` list and in the `WHERE` clause, you'll typically use them in the latter context, as part of your `WHERE` clause. For example, [Example 5-21](#) shows the bind variables `LowUserId` and `HighUserId` introduced into a SQL statement created using the Query page in the overview editor for the view object.

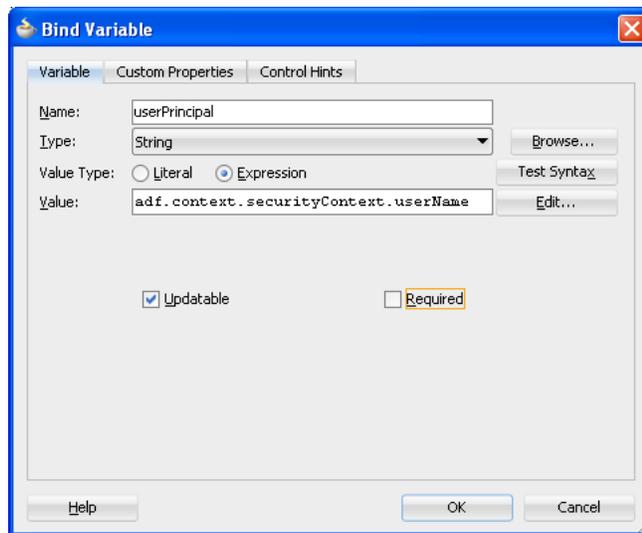

Example 5-21 Bind Variables in the WHERE Clause of View Object SQL Statement

```
select PERSON_ID, EMAIL, FIRST_NAME, LAST_NAME
from PERSONS
where (upper(FIRST_NAME) like upper(:TheName) || '%'
      or upper(LAST_NAME) like upper(:TheName) || '%')
      and PERSON_ID between :LowUserId and :HighUserId
order by EMAIL
```

Notice that you reference the bind variables in the SQL statement by prefixing their name with a colon like `:TheName` or `:LowUserId`. You can reference the bind variables in any order and repeat them as many times as needed within the SQL statement.

5.10.2 How to Reference the Current User in a Named Bind Variable Using Groovy

You can use the Groovy expression `adf.context.securityContext.userName` to set the default value for the named bind variable that you use to provide the current user in a view instance filter. Specifically, you can use the bind variable in a named view criteria that you define to filter a view object instance in the data model for the project. For example, in the `StoreFront` module of the Fusion Order Demo application, the named bind variable `userPrincipal` is defined for the `PersonsVO` view object, as shown in [Figure 5-38](#).

Figure 5–38 Groovy Expression Used to Set userPrincipal Bind Variable

The `PersonsVO` view object also defines the `AuthenticatedUserByPrincipalCriteria` view criteria. This view criteria defines a filter for the `PrincipalName` attribute of the `PersonsVO` with the bind variable `userPrincipal` providing the value. In this example, the bind variable `userPrincipal` is defined with **Updatable** enabled. This ensures that the view criteria is able to set the value obtained at runtime from the ADF security context. Since the bind variable is not used in the SQL `WHERE` clause for the `PersonsVO` view object, the **Required** field is unselected. This ensures that the value is optional and that no runtime exception will be thrown if the bind variable is not resolved.

Then in the data model for the `StoreFrontService` project, where the `PersonsVO` specifies the view definition for the usage `AuthenticatedUser`, the view criteria `AuthenticatedUserByPrincipalCriteria` with the named bind variable is defined as the view usage's runtime filter. For details about creating view instances for your project's data model, see [Section 9.2.3.3, "Customizing a View Object Instance that You Add to an Application Module."](#)

5.10.3 What Happens When You Add Named Bind Variables

Once you've added one or more named bind variables to a view object, you gain the ability to easily see and set the values of these variables at runtime. Information about the name, type, and default value of each bind variable is saved in the view object's XML component definition file. If you have defined UI hints for the bind variables, this information is saved in the view object's component message bundle file along with other UI hints for the view object.

5.10.4 How to Test Named Bind Variables

The Oracle ADF Model Tester allows you to interactively inspect and change the values of the named bind variables for any view object, which can really simplify experimenting with your application module's data model when named bind parameters are involved. For more information about editing the data model and running the Oracle ADF Model Tester, see [Section 6.3, "Testing View Object Instances Using the Oracle ADF Model Tester."](#)

The first time you execute a view object in the Oracle ADF Model Tester to display the results in the data view page, a Bind Variables dialog will appear, as shown in [Figure 5–39](#).

The Bind Variables dialog lets you:

- View the name, as well as the default and current values, of the particular bind variable you select from the list
- Change the value of any bind variable by updating its corresponding **Value** field before clicking **OK** to set the bind variable values and execute the query
- Inspect and set the bind variables for the view object in the current data view page, using the **Edit Bind Parameters** button in the toolbar — whose icon looks like " : id"
- Verify UI hints are correctly set up by showing the label text hint in the **Bind Variables** list and by formatting the **Value** attribute using the respective format mask

Figure 5–39 Setting Bind Variables in the Oracle ADF Model Tester

If you defined the bind variable in the Bind Variables dialog with the **Reference** checkbox deselected (the default), you will be able to test view criteria and supply the bind variable with values as needed. Otherwise, if you selected the **Reference** checkbox, then you must supply a value for the bind variable in the Oracle ADF Model Tester. The Oracle ADF Model Tester will throw the same exception seen at runtime for any view object whose SQL statement use bind variables that do not resolve with a supplied value.

5.10.5 How to Add a WHERE Clause with Named Bind Variables at Runtime

Using the view object's `setWhereClause()` method, you can add an additional filtering clause at runtime. This runtime-added `WHERE` clause predicate does *not* replace the design-time generated predicate, but rather further narrows the query result by adding to the existing design time `WHERE` clause. Whenever the dynamically added clause refers to a value that might change during the life of the application, you should use a named bind variable instead of concatenating the literal value into the `WHERE` clause predicate.

For example, assume you want to further filter the `PersonList` view object at runtime based on the value of the `PERSON_TYPE_CODE` column in the table. Also assume that you plan to search sometimes for rows where `PERSON_TYPE_CODE = 'CUST'` and other times for rows where `PERSON_TYPE_CODE = 'SUPP'`. While slightly fewer lines of code, [Example 5–22](#) is not desirable because it changes the

WHERE clause twice just to query two different *values* of the same PERSON_TYPE_CODE column.

Example 5–22 Incorrect Use of setWhereClause() Method

```
// Don't use literal strings if you plan to change the value!
vo.setWhereClause("person_type_code = 'CUST'");
// execute the query and process the results, and then later...
vo.setWhereClause("person_type_code = 'person'");
```

Instead, you should add a WHERE clause predicate that references named bind variables that you define at runtime as shown in [Example 5–23](#).

Example 5–23 Correct Use of setWhereClause() Method and Bind Variable

```
vo.setWhereClause("person_type_code = :ThePersonType");
vo.defineNamedWhereClauseParam("ThePersonType", null, null);
vo.setNamedWhereClauseParam("ThePersonType", "CUST");
// execute the query and process the results, and then later...
vo.setNamedWhereClauseParam("ThePersonType", "person");
```

This allows the text of the SQL statement to stay the same, regardless of the value of PERSON_TYPE_CODE you need to query on. When the query text stays the same across multiple executions, the database will return the results without having to reparse the query.

If you later need to remove the dynamically added WHERE clause and bind variable, you should do so the next time you need them to be different, just before executing the query. This will prevent the type of SQL execution error as described in [Section 5.10.8.1, "An Error Related to Clearing Bind Variables."](#) Avoid calling `removeNamedWhereClauseParam()` in your code immediately after setting the WHERE clause. For a useful helper method to assist with this removal, see [Section 5.10.8.2, "A Helper Method to Remove Named Bind Variables."](#)

An updated test client class illustrating these techniques would look like what you see in [Example 5–24](#). In this case, the functionality that loops over the results several times has been refactored into a separate `executeAndShowResults()` method. The program first adds an additional WHERE clause of `person_id = :ThePersonId` and then later replaces it with a second clause of `person_type_code = :ThePersonType`.

Example 5–24 TestClient Program Exercising Named Bind Variable Techniques

```
package devguide.examples.readonlyvo.client;

import oracle.jbo.ApplicationModule;
import oracle.jbo.Row;
import oracle.jbo.ViewObject;
import oracle.jbo.client.Configuration;
import oracle.jbo.domain.Number;

public class TestClientBindVars {
    public static void main(String[] args) {
        String      amDef = "devguide.examples.readonlyvo.PersonService";
        String      config = "PersonServiceLocal";
        ApplicationModule am =
            Configuration.createRootApplicationModule(amDef, config);
        ViewObject vo = am.findViewObject("PersonList");
        // Set the two design time named bind variables
        vo.setNamedWhereClauseParam("TheName", "shelli%");
```

```

        vo.setNamedWhereClauseParam("HighUserId", new Number(215));
        executeAndShowResults(vo);
        // Add an extra where clause with a new named bind variable
        vo.setWhereClause("person_type_code = :ThePersonId");
        vo.defineNamedWhereClauseParam("ThePersonId", null, null);
        vo.setNamedWhereClauseParam("ThePersonId", new Number(116));
        executeAndShowResults(vo);
        vo.removeNamedWhereClauseParam("ThePersonId");
        // Add an extra where clause with a new named bind variable
        vo.setWhereClause("person_type_code = :ThePersonType");
        vo.defineNamedWhereClauseParam("ThePersonType", null, null);
        vo.setNamedWhereClauseParam("ThePersonType", "SUPP");
        // Show results when :ThePersonType = 'SUPP'
        executeAndShowResults(vo);
        vo.setNamedWhereClauseParam("ThePersonType", "CUST");
        // Show results when :ThePersonType = 'CUST'
        executeAndShowResults(vo);
        Configuration.releaseRootApplicationModule(am, true);
    }
    private static void executeAndShowResults(ViewObject vo) {
        System.out.println("---");
        vo.executeQuery();
        while (vo.hasNext()) {
            Row curUser = vo.next();
            System.out.println(curUser.getAttribute("PersonId")+" "+
                curUser.getAttribute("ShortName"));
        }
    }
}

```

However, if you run this test program, you may actually get a runtime error like the one shown in [Example 5–25](#).

Example 5–25 Runtime Error Resulting From a SQL Parsing Error

```

oracle.jbo.SQLStmtException: JBO-27122: SQL error during statement preparation.
Statement:
SELECT * FROM (select PERSON_ID, EMAIL, FIRST_NAME, LAST_NAME
from PERSONS
where (upper(FIRST_NAME) like upper(:TheName)||'%'
      or upper(LAST_NAME) like upper(:TheName)||'%')
      and PERSON_ID between :LowUserId and :HighUserId
order by EMAIL) QRSLT WHERE (person_type_code = :ThePersonType)
## Detail 0 ##
java.sql.SQLException: ORA-00904: "PERSON_TYPE": invalid identifier

```

The root cause, which appears after the `## Detail 0 ##` in the stack trace, is a SQL parsing error from the database reporting that `PERSON_TYPE_CODE` column does not exist even though the `PERSONS` table definitely has a `PERSON_TYPE_CODE` column. The problem occurs due to the mechanism that view objects use by default to apply additional runtime `WHERE` clauses on top of read-only queries. [Section 5.10.7, "What Happens at Runtime: Dynamic Read-Only View Object WHERE Clause,"](#) explains a resolution for this issue.

5.10.6 How to Set Existing Bind Variable Values at Runtime

To set named bind variables at runtime, use the `setNamedWhereClauseParam()` method on the `ViewObject` interface. In JDeveloper, you can choose **Refactor > Duplicate** from the main menu to create a new `TestClientBindVars` class based on

the existing `TestClient.java` class as shown in [Section 6.4.2, "How to Create a Command-Line Java Test Client."](#) In the test client class, you can set the values of the bind variables using a few additional lines of code. For example, the `setNamedWhereClauseParam()` might take as arguments the bind variables `HighUserId` and `TheName` as shown in [Example 5-26](#).

Example 5-26 Setting the Value of Named Bind Variables Programmatically

```
// changed lines in TestClient class
ViewObject vo = am.findViewObject("PersonList");
vo.setNamedWhereClauseParam("TheName", "alex%");
vo.setNamedWhereClauseParam("HighUserId", new Number(315));
vo.executeQuery();
// etc.
```

Running the test client class shows that your bind variables are filtering the data. For example, the resulting rows for the `setNamedWhereClauseParam()` method shown in [Example 5-26](#) may show only two matches based on the name `alex` as shown in [Example 5-27](#).

Example 5-27 Result of Bind Variables Filtering the Data in TestClient Class

```
303 ahunold
315 akhoo
```

Whenever a view object's query is executed, you can view the actual bind variable values in the runtime debug diagnostics like the sample shown in [Example 5-28](#).

Example 5-28 Debug Diagnostic Sample with Bind Variable Values

```
[256] Bind params for ViewObject: PersonList
[257] Binding param "LowUserId": 0
[258] Binding param "HighUserId": 315
[259] Binding param "TheName": alex%
```

This information that can be invaluable when debugging your applications. Notice that since the code did not set the value of the `LowUserId` bind variable, it took on the default value of 0 (zero) specified at design time. Also notice that the use of the `UPPER()` function in the `WHERE` clause and around the bind variable ensured that the match using the bind variable value for `TheName` was performed case-insensitively. The sample code set the bind variable value to `"alex%"` with a lowercase "a", and the results show that it matched `Alexander`.

5.10.7 What Happens at Runtime: Dynamic Read-Only View Object WHERE Clause

If you dynamically add an additional `WHERE` clause at runtime to a read-only view object, its query gets nested into an inline view before applying the additional `WHERE` clause.

For example, suppose your query was defined as shown in [Example 5-29](#).

Example 5-29 Query Specified At Design Time

```
select PERSON_ID, EMAIL, FIRST_NAME, LAST_NAME
from PERSONS
where (upper(FIRST_NAME) like upper(:TheName)||'%'
      or upper(LAST_NAME) like upper(:TheName)||'%')
      and PERSON_ID between :LowUserId and :HighUserId
order by EMAIL
```

At runtime, when you set an additional `WHERE` clause like `person_type_code = :ThePersonType` as the test program did in [Example 5-24](#), the framework nests the original query into an inline view like the sample shown in [Example 5-30](#).

Example 5-30 Runtime-Generated Query with Inline Nested Query

```
SELECT * FROM(
select PERSON_ID, EMAIL, FIRST_NAME, LAST_NAME
from PERSONS
where (upper(FIRST_NAME) like upper(:TheName)||'%'
      or upper(LAST_NAME) like upper(:TheName)||'%'
      and PERSON_ID between :LowUserId and :HighUserId
order by EMAIL) QRSLT
```

Then the framework adds the dynamic `WHERE` clause predicate at the end, so that the final query the database sees is like the sample shown in [Example 5-31](#).

Example 5-31 Runtime-Generated Query with Dynamic WHERE Clause

```
SELECT * FROM(
select PERSON_ID, EMAIL, FIRST_NAME, LAST_NAME
from PERSONS
where (upper(FIRST_NAME) like upper(:TheName)||'%'
      or upper(LAST_NAME) like upper(:TheName)||'%'
      and PERSON_ID between :LowUserId and :HighUserId
order by EMAIL) QRSLT
WHERE person_type_code = :ThePersonType
```

This query "wrapping" is necessary in the general case since the original query could be arbitrarily complex, including `SQL UNION`, `INTERSECT`, `MINUS`, or other operators that combine multiple queries into a single result. In those cases, simply "gluing" the additional runtime `WHERE` clause onto the end of the query text could produce unexpected results because, for example, it might apply only to the *last* of several `UNION`'ed statements. By nesting the original query verbatim into an inline view, the view object guarantees that your additional `WHERE` clause is correctly used to filter the results of the original query, regardless of how complex it is. The consequence (that results in an `ORA-00904` error) is that the dynamically added `WHERE` clause can refer only to columns that have been selected in the original query.

The simplest solution is to add the dynamic query column names to the end of the query's `SELECT` list on the Edit Query dialog (click the **Edit SQL Query** button on the Query page of the overview editor for the view object). Just adding the new column name at the end of the existing `SELECT` list — of course, preceded by a comma — is enough to prevent the `ORA-00904` error: JDeveloper will automatically keep your view object's attribute list synchronized with the query statement. Alternatively, [Section 5.9.4.7, "Limitation of Inline View Wrapping at Runtime"](#) explains how to disable this query nesting when you don't require it.

The test client program in [Example 5-24](#) now produces the results shown in [Example 5-32](#).

Example 5-32 Named Bind Variables Resulting From Corrected TestClient

5.10.8 What You May Need to Know About Named Bind Variables

There are several things you may need to know about named bind variables, including the runtime errors that are displayed when bind variables have mismatched names and the default value for bind variables.

5.10.8.1 An Error Related to Clearing Bind Variables

You need to ensure that your application handles changing the value of bind variables properly for use with activation and passivation of the view object instance settings at runtime. For example, before you deploy the application, you will want to stress-test your application in JDeveloper by disabling application module pooling, as described in [Section 43.10, "Testing to Ensure Your Application Module is Activation-Safe."](#) Following the instructions in that section effectively simulates the way your application will manage the passivation store when you eventually deploy the application.

When the application reactivates the pending state from the passivation store upon subsequent requests during the same user session, the application will attempt to set the values of any dynamically added named `WHERE` clause bind variables. Changing the values to null before passivation take places will prevent the bind variable values from matching the last time the view object was executed and the following error will occur during activation:

```
(oracle.jbo.SQLStmtException) JBO-27122: SQL error during statement preparation.
(java.sql.SQLException) Attempt to set a parameter name that does not occur in
SQL: 1
```

Do not change the value of the bind variables (or other view object instance settings) just after executing the view object. Rather, if you will not be re-executing the view object again during the same block of code (and therefore during the same HTTP request), you should defer changing the bind variable values for the view object instance until the next time you need them to change, just before executing the query. To accomplish this, use the following pattern:

1. (Request begins and application module is acquired)
2. Call `setWhereClause(null)` to clear `WHERE` clause
3. Call `setWhereClauseParam(null)` to clear the `WHERE` clause bind variables
4. Call `setWhereClause()` that references `n` bind variables
5. Calling `setWhereClauseParam()` to set the `n` values for those `n` bind variables
6. Calling `executeQuery()`
7. (Application module is released)

5.10.8.2 A Helper Method to Remove Named Bind Variables

The helper method `clearWhereState()` that you can add to your `ViewObjectImpl` framework ensures that declaratively defined bind variables are not removed. [Example 5-33](#) shows the use of `clearWhereState()` to safely remove named bind variables that have been added to the view instance at runtime.

Example 5-33 Helper Method to Clear Named Bind Variables Values Programmatically

```
protected void clearWhereState() {
```

```

ViewDefImpl viewDef = getViewDef();
Variable[] viewInstanceVars = null;
VariableManager viewInstanceVarMgr = ensureVariableManager();
if (viewInstanceVarMgr != null) {
viewInstanceVars = viewInstanceVarMgr.getVariablesOfKind
    (Variable.VAR_KIND_WHERE_CLAUSE_PARAM);

if (viewInstanceVars != null) {
    for (Variable v: viewInstanceVars) {
        // only remove the variable if its not on the view def.
        if (!hasViewDefVariableNamed(v.getName())) {
            removeNamedWhereClauseParam(v.getName());
        }
    }
}
}
getDefaultRowSet().setExecuteParameters(null, null, true);
setWhereClause(null);
getDefaultRowSet().setWhereClauseParams(null);
}

private boolean hasViewDefVariableNamed(String name) {
    boolean ret = false;
    VariableManager viewDefVarMgr = getViewDef().ensureVariableManager();
    if (viewDefVarMgr != null) {
        try {
            ret = viewDefVarMgr.findVariable(name) != null;
        }
        catch (NoDefException ex) {
            // ignore
        }
    }
    return ret;
}
}

```

5.10.8.3 Errors Related to Naming Bind Variables

You need to ensure that the list of named bind variables that you reference in your SQL statement matches the list of named bind variables that you've defined in the **Bind Variables** section of the overview editor's Query page for the view object. Failure to have these two agree correctly can result in one of the following two errors at runtime.

If you use a named bind variable in your SQL statement but have not defined it, you'll receive an error like this:

```

(oracle.jbo.SQLStmtException) JBO-27122: SQL error during statement preparation.
## Detail 0 ##
(java.sql.SQLException) Missing IN or OUT parameter at index:: 1

```

On the other hand, if you have defined a named bind variable, but then forgotten to reference it or mistyped its name in the SQL, then you will see an error like this:

```

oracle.jbo.SQLStmtException: JBO-27122: SQL error during statement preparation.
## Detail 0 ##
java.sql.SQLException: Attempt to set a parameter name that does not occur in the
SQL: LowUserId

```

To resolve either of these errors, double-check that the list of named bind variables in the SQL matches the list of named bind variables in the **Bind Variables** section of the overview editor's Query page for the view object. Additionally, open the Bind Variables dialog for the bind variable and verify that the **Reference** checkbox is not

still deselected (the default). To use the bind variable in a SQL statement, you must select the **Reference** checkbox.

5.10.8.4 Default Value of NULL for Bind Variables

If you do not supply a default value for your named bind variable, it defaults to the NULL value at runtime. This means that if you have a WHERE clause like:

```
PERSON_ID = :ThePersonId
```

and you do not provide a default value for the `ThePersonId` bind variable, it will default to having a NULL value and cause the query to return no rows. Where it makes sense for your application, you can leverage SQL functions like `NVL()`, `CASE`, `DECODE()`, or others to handle the situation as you require. For example, the following WHERE clause fragment allows the view object query to match any name if the value of `:TheName` is null.

```
upper(FIRST_NAME) like upper(:TheName) || '%'
```

5.11 Working with Named View Criteria

A view criteria you define lets you specify filter information for the rows of a view object collection. The view criteria object is a row set of one or more view criteria rows, whose attributes mirror those in the view object. The view criteria definition comprises query conditions that augment the WHERE clause of the target view object. Query conditions that you specify apply to the individual attributes of the target view object.

The key difference between a view object row of query results and a view criteria row is that the data type of each attribute in the view criteria row is `String`. This key difference supports Query-by-Example operators and therefore allows the user to enter conditions such as "OrderId > 304", for example.

The Edit View Criteria dialog lets you create view criteria and save them as part of the view object's definition, where they appear as named view criteria. You use the Query page of the overview editor to define view criteria for specific view objects. View criteria that you define at design time can participate in these scenarios where filtering results is desired at runtime:

- Supporting Query-by-Example search forms that allow the end user to supply values for attributes of the target view object.
For example, the end user might input the value of a customer name and the date to filter the results in a web page that displays the rows of the `CustomerOrders` view object. The web page designer will see the named view criteria in the JDeveloper Data Controls panel and, from them, easily create a search form. For more information about the utilizing the named view criteria in the Data Controls panel, see [Section 31.2, "Creating Query Search Forms."](#)
- Filtering the list of values (LOV) components that allow the end user may select from one attribute list (displayed in the UI as an LOV component).
The web page designer will see the attributes of the view object in the JDeveloper Data Controls panel and, from them, easily create LOV controls. For more information about utilizing LOV-enabled attributes in the Data Controls panel, see [Section 30.3, "Creating a Selection List."](#)
- Validating attribute values using a view accessor with a view criteria applied to filter the view accessor results.

For more information about create view accessor validators, see [Section 10.4.2, "How to Validate Against the Attribute Values Specified by a View Accessor."](#)

- Creating the application module's data model from a single view object definition with a unique view criteria applied for each view instance.

The single view object query modified by view criteria is useful with look up data that must be shared across the application. In this case, a base view object definition queries the lookup table in the database and the view criteria set the lookup table's `TYPE` column to define application-specific views. To define view instances in the data model using the view criteria you create for a base view object definition, see [Section 10.3.3, "How to Define the WHERE Clause of the Lookup View Object Using View Criteria."](#)

Additionally, view criteria have full API support, and it is therefore possible to create and apply view criteria to view objects programmatically.

5.11.1 How to Create Named View Criteria Declaratively

View criteria have a number of uses in addition to applying them to declarative queries at runtime. In all usages, the named view criteria definition consists of a set of attribute requirements that you specify to filter individual view object results. The features of the view criteria definition that you can use will depend on its intended usage.

To define view criteria for the view object you wish to filter, you open the view object in the overview editor and use the **View Criteria** section of the Query page. A dedicated editor (the Create View Criteria dialog) that you open from the **View Criteria** section helps you to build a `WHERE` clause using attribute names instead of the target view object's corresponding SQL column names. You may define multiple named view criteria for each view object.

Before you work with the Create View Criteria dialog to create named view criteria, familiarize yourself with the usages described in [Section 5.11, "Working with Named View Criteria."](#) The chapter references provide additional details that will help you to anticipate using the appropriate features of the Create View Criteria dialog. For example, when you create a view criteria to specify the searchable attributes of a search form, the view criteria condition defines a simple list of attributes (a subset of the view object's attributes) to be presented to the user, but then the view criteria definition requires that you specify UI hints (model-level properties) to control the behavior of those attributes in the search form. The Create View Criteria dialog displays all the UI hints in a separate tabbed page that you select for the view criteria you are defining. Whereas, when your view criteria is intended to specify view instances in the data model, you can define arbitrarily complex query filter conditions, but you can ignore the UI hints features displayed by the Create View Criteria dialog.

Each view criteria definition consists of the following elements:

- One or more view criteria rows consisting of an arbitrary number of view criteria groups or an arbitrary number of references to another named view criteria already defined for the current view object.
- Optional view criteria groups consisting of an arbitrary number of view criteria items.
- View criteria items consisting of an attribute name, an attribute-appropriate operator, and an operand. Operands can be a literal value when the filter value is defined or a bind variable that can optionally utilize a scripting expression that includes dot notation access to attribute property values.

Expressions are based on the Groovy scripting language, as described in [Section 3.6, "Overview of Groovy Scripting Language Support."](#)

When you define a view criteria, you control the source of the filtered results. You can limit the results of the filtered view object to:

- Just the database table specified by the view object
- Just the in-memory results of the view object query
- Both the database and the in-memory results of the view object query.

Filtering on both database tables and the view object's in-memory results allows you to filter rows that were created in the transaction but not yet committed to the database.

View criteria expressions you construct in the Edit View Criteria dialog use logical conjunctions to specify how to join the selected criteria item or criteria group with the previous item or group in the expression:

- AND conjunctions specify that the query results meet both joined conditions. This is the default for each view criteria item you add.
- OR conjunctions specify that the query results meet either or both joined conditions. This is the default for view criteria groups.

Additionally, you may create nested view criteria when you want to filter rows in the current view object based on criteria applied to view-linked detail views. A nested view criteria group consists of an arbitrary number of nested view criteria items. You can use nested view criteria when you want to have more controls over the logical conjunctions among the various view criteria items. The nested criteria place restrictions on the rows that satisfy the criteria under the nested criteria's parent view criteria group. For example, you might want to query both a list of employees with (`Salary > 3000`) and belonging to (`DeptNo = 10` or `DeptNo = 20`). You can define a view criteria with the first group with one item for (`Salary > 3000`) and a nested view criteria with the second group with two items `DeptNo = 10` and `DeptNo = 20`.

Before you begin:

It may be helpful to have an understanding of the ways you can use view criteria. The usage you intend will affect the best practices for creating named view criteria. For more information about the supported usages, see [Section 5.11, "Working with Named View Criteria."](#)

You will need to complete these tasks:

- Create the desired view objects as described in [Section 5.2.1, "How to Create an Entity-Based View Object,"](#) and [Section 5.2.3, "How to Create an Expert Mode, Read-Only View Object."](#)
- If the view criteria will use a bind variable in the operand, create the bind variable as described in [Section 5.10.1, "How to Add Bind Variables to a View Object Definition."](#)

To define a named view criteria:

1. In the Application Navigator, double-click the view object for which you want to create the named view criteria.
2. In the overview editor, click the **Query** navigation tab.
3. In the Query page, expand the **View Criteria** section and click the **Create new view criteria** button.

4. In the Create View Criteria dialog, enter the name of the view criteria to identify its usage in your application.
5. In the **Query Execution Mode** dropdown list, decide how you want the view criteria to filter the view object query results.

You can limit the view criteria to filter the database table specified by the view object query, the in memory row set produced by the query, or both the database table and the in-memory results.

Choosing **Both** may be appropriate for situations where you want to include rows created as a result of enforced association consistency. In this case, in-memory filtering is performed after the initial fetch.

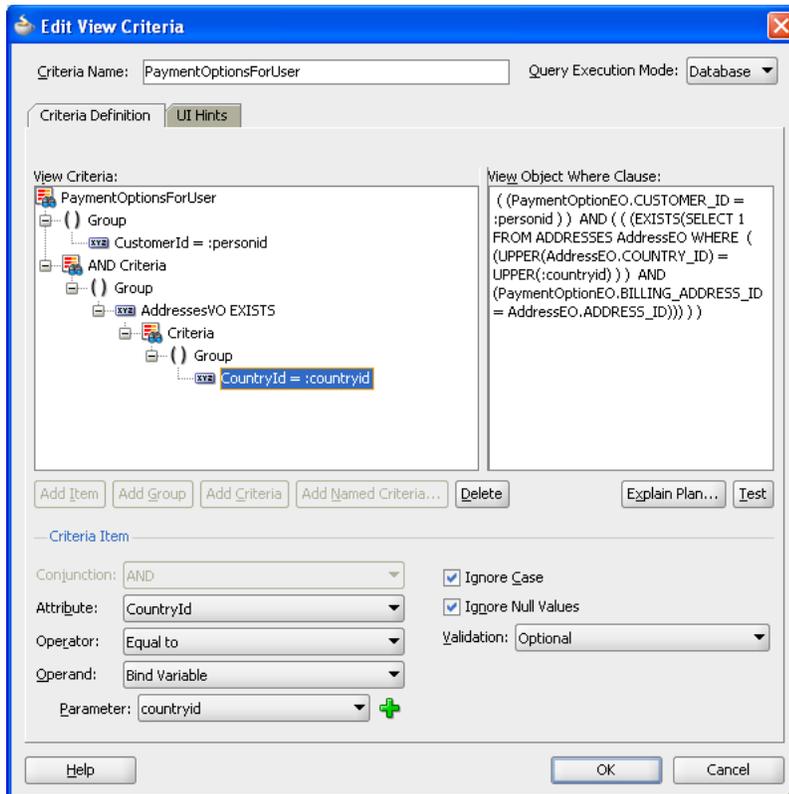

6. Click one of these **Add** buttons to define the view criteria.
 - **Add Item** to add a single criteria item. The editor will add the item to the hierarchy beneath the current group or view criteria selection. By default each time you add an item, the editor will choose the next attribute to define the criteria item. You can change the attribute to any attribute that the view object query defines.
 - **Add Group** to add a new group that will compose criteria items that you intend to add to it. When you add a new group, the editor inserts the OR conjunction into the hierarchy. You can change the conjunction as desired.
 - **Add Criteria** to add a view criteria that you intend to define. This selection is an alternative to adding a named criteria that already exists in the view object definition. When you add a new view criteria, the editor inserts the AND conjunction into the hierarchy. You can change the conjunction as desired. Each time you add another view criteria, the editor nests the new view criteria beneath the current view criteria selection in the hierarchy. The root node of the hierarchy defines the named view criteria that you are currently editing.

Search forms that the UI designer will create from view criteria are not able to use directly nested view criteria. For more information about defining nested expressions for use with search forms, see [Section 5.11.4, "What You May Need to Know About Nested Expressions."](#)

- **Add Named Criteria** to add a view criteria that the view object defines. The named criteria must appear in the overview editor for the view object you are defining the view criteria.
7. Select a view criteria item node in the view criteria hierarchy and define the added node in the **Criteria Item** section.
 - Choose the desired **Attribute** for the criteria item. By default the editor adds the first one in the list.

Optionally, you can add a nested view criteria inline when a view link exists for the current view object you are editing. The destination view object name will appear in the **Attribute** dropdown list. Selecting a view object lets you filter the view criteria based on view criteria items for the nested view criteria based on a view link relationship. For example, `AddressVO` is linked to the `PaymentOptionsVO` and a view criteria definition for `PaymentOptionsVO` will display the destination view object `AddressVO`. You could define the nested view criteria to filter payment options based on the `CountryId` attribute of the current customer, as specified by the `CustomerId` criteria item, as shown in [Figure 5-40](#).

Figure 5–40 Edit View Criteria Dialog with Nested View Criteria Specified

- Choose the desired **Operator**.

The list displays only the operators that are appropriate for the selected attribute or view object. In the case of a view object selection, the **exists** operator applies to a view criteria that you will define (or reference) as an operand. In the case of String and Date type attributes, the **Between** and **Not between** operators require you to supply two operand values to define the range. In the case of Date type attributes, you can select operators that test for a date or date range (with date values entered in the format YYYY-MM-DD). For example, for December 16th, 2010, enter 2010-12-16.

JDeveloper does not support the **IN** operator. However, you can create a view criteria with the **IN** operator using the API, as described in [Section 5.11.7, "How to Create View Criteria Programmatically."](#)

8. Choose the desired **Operand** for the view criteria item selection.
 - Select **Literal** when you want to supply a value for the attribute or when you want to define a default value for a user-specified search field for a Query-by-Example search form. When the view criteria defines a query search form for the user interface, you may leave the **Value** field empty. In this case, the user will supply the value. You may also provide a value that will act as a search field default value that the user will be able to override. The value you supply in the **Value** field can include wildcard characters * or %.
 - Select **Bind Variable** when you want the value to be determined at runtime using a bind variable. If the variable was already defined for the view object, select it from the **Parameters** dropdown list. Otherwise, click **New** to display the Bind Variable dialog that lets you create a new bind variable on the view

object. For more information about creating bind variables, see [Section 5.10.1, "How to Add Bind Variables to a View Object Definition."](#)

When you define bind variables on the view object for use by the view criteria, you must specify that the variable is not required by the SQL query that the view object defines. To do this, deselect the **Required** checkbox in the Bind Variables dialog, as explained in [Section 5.10.1, "How to Add Bind Variables to a View Object Definition."](#)

For further discussion about view criteria use cases for bind variables and literals, see [Section 5.11.3, "What You May Need to Know About Bind Variable Options."](#)

9. For each item, group, or nested view criteria that you define, optionally change the default conjunction to specify how the selection should be joined.
 - **AND** conjunction specifies that the query results meet both joined conditions. This is the default for each view criteria item or view nested view criteria that you add.
 - **OR** conjunction specifies that the query results meet either or both joined conditions. This is the default for view criteria groups.
10. Verify that the view criteria definition is valid by doing one of the following:
 - Click **Explain Plan** to visually inspect the view criteria's generated `WHERE` clause.
 - Click **Test** to allow JDeveloper to verify that the `WHERE` clause is valid.
11. To prevent the attribute to be filtered based on the case of the runtime-supplied value, leave **Ignore Case** selected.

The criteria item can be a literal value that you define or a runtime parameter that the end user supplies. This option is supported for attributes of type String only. The default disables case sensitive searches.
12. In the **Validation** dropdown list, decide whether the view criteria item is a required or an optional part of the attribute value comparison in the generated `WHERE` clause.
 - **Selectively Required** means that the `WHERE` clause will ignore the view criteria item at runtime if no value is supplied and there exists at least one criteria item at the same level that has a criteria value. Otherwise, an exception is thrown.
 - **Optional** means the view criteria is added to the `WHERE` clause only if the value is non-NULL. The default **Optional** for each new view criteria item means no exception will be generated for null values.
 - **Required** means that the `WHERE` clause will fail to execute and an exception will be thrown when no value is supplied for the criteria item.
13. If the view criteria uses a bind variable as the operand, decide whether the `IS NULL` condition is the generated in the `WHERE` clause. This field is enabled only if you have selected **Optional** for the validation of the bind variable.
 - Leave **Ignore Null Values** selected (default) when you want to permit the view criteria to return a result even when the bind variable value is not supplied at runtime. For example, suppose you define a view criteria to allow users to display a cascading list of countries and states (or provinces) through a bind variable that takes the `countryID` as the child list's controlling attribute. In this case, the default behavior for the view criteria execution

returns the list of *all* states if the user makes no selection in the parent LOV (an empty `countryId` field). The generated `WHERE` clause would look similar to `((CountryEO.COUNTRY_ID = :bvCountryId) OR (:bvCountryId IS NULL))`, where the test for a null value guarantees that the child list displays a result even when the bind variable is not set. When validation is set to **Required** or **Optionally Required**, the view criteria expects to receive a value and thus this option to ignore null values is disabled.

- **Deselect Ignore Null Values** when you expect the view criteria to return a null result when the bind variable value is not supplied at runtime. In the example of the cascading lists, the view criteria execution returns *no* states if the user makes no selection with an empty `countryID` field. In this case, the generated `WHERE` clause would look similar to `(CountryEO.COUNTRY_ID = :bvCountryId)`, where the test for null is not performed, which means the query is expected to function correctly with a null value bind variable.

Note that the validation settings **Required** or **Optionally Required** also remove the null value condition but support a different use case. They should be used in combination with **Ignore Null Values** feature to achieve the desired runtime behavior. For more details about the interaction of these features, see [Section 5.11.3, "What You May Need to Know About Bind Variable Options."](#)

14. Click OK.

5.11.2 What Happens When You Create a Named View Criteria

The Create View Criteria dialog in JDeveloper lets you easily create view criteria and save them as named definitions. These named view criteria definitions add metadata to the XML component definition file that represents the target view object's declarative settings. Once defined, named view criteria appear by name in the Query page of the overview editor for the view object.

To view the view criteria, expand the desired view object in the Application Navigator, select the XML under the expanded view object, open the Structure window, and expand the View Criteria node. Each view criteria definition for a view object contains one or more `<ViewCriteriaRow>` elements corresponding to the number of groups that you define in the Create View Criteria dialog. [Example 5–34](#) shows the `ProductsVO.xml` file with the `<ViewCriteria>` definition `FindByProductNameCriteria` and a single `<ViewCriteriaRow>` that defines a developer-seeded search for products using the bind variable `:bvProductName`. Any UI hints that you selected to customize the behavior of a developer-seeded search will appear in the `<ViewCriteria>` definition as attributes of the `<CustomProperties>` element. For details about specific UI hints for view criteria, see [Section 5.11.5, "How to Set User Interface Hints on View Criteria to Support Search Forms."](#)

Example 5–34 *FindByProductNameCriteria View Criteria in the ProductsVO View Object Definition*

```
<ViewObject
  xmlns="http://xmlns.oracle.com/bc4j"
  Name="ProductsVO"
  ... >
<SQLQuery>
  ...
</SQLQuery>
...
```

```

<ViewCriteria
  Name="FindByProductNameCriteria"
  ViewObjectName="oracle.fodemo.storefront.store.queries.ProductsVO"
  Conjunction="AND">
  <Properties>
    <CustomProperties>
      <Property
        Name="mode"
        Value="Basic" />
      <Property
        Name="autoExecute"
        Value="false" />
      <Property
        Name="showInList"
        Value="true" />
      <Property
        Name="displayName"
        Value="Find Products By Name" />
      <Property
        Name="displayOperators"
        Value="InAdvancedMode" />
      <Property
        Name="allowConjunctionOverride"
        Value="true" />
    </CustomProperties>
  </Properties>
  <ViewCriteriaRow
    Name="vcrow87">
    <ViewCriteriaItem
      Name="ProductName"
      ViewAttribute="ProductName"
      Operator="CONTAINS"
      Conjunction="AND"
      Value=":bvProductName"
      UpperColumns="1"
      IsBindVarValue="true"
      Required="Optional" />
    </ViewCriteriaRow>
  </ViewCriteria>
  ...
</ViewObject>

```

Additionally, when you create view objects and specify them as instances in an application module, JDeveloper automatically creates a data control to encapsulate the collections (view instances) that the application module contains. JDeveloper then populates the Data Controls panel with these collections and any view criteria that you have defined, as shown in [Section 13.3.1.3, "How View Objects Appear in the Data Controls Panel."](#)

5.11.3 What You May Need to Know About Bind Variable Options

The view criteria filter that you define using a bind variable expects to obtain its value at runtime. This can be helpful in a variety of user interface scenarios. To support a particular use case, familiarize yourself with the combination of the **Validation** and **Ignore Null Values** settings shown in [Table 5-1](#).

Table 5–1 Use Cases for Bind Variable Options in View Criteria

Validation	Ignore Null Values	Use Cases	Notes
Optional	True (Default)	Configure cascading List of Values (LOV) where the parent LOV value is optional. Generate an optional search field in a search form.	This combination generates the SQL query <code>(ProductName = :bind) OR (:bind IS NULL)</code> . When used for cascading LOVs, no selection in the parent LOV returns all rows in the child LOV. Note that the preferred implementation for an optional search field is a view criteria item with a literal operand type.
Optional	False	Configure cascading LOVs where the parent LOV value is required.	This combination generates the SQL query <code>(ProductName = :bind)</code> . When used for cascading LOVs, no selection in the parent LOV returns no rows in the child LOV. Avoid this combination for search forms, because when the user leaves the search field blank the search will attempt to find rows where this field is explicitly NULL. A better way to achieve this is for the user to explicitly select the "IS NULL" operator in advanced search mode.
Required	False (default)	Generate a required search field in a search form.	This combination generates the SQL query <code>ProductName = :bind</code> . Avoid this setting for cascading LOVs, because no selection in the parent LOV will cause a validation error. Note that the preferred implementation for a required search field is a view criteria item with a literal operand (not a bind variable) type.

5.11.4 What You May Need to Know About Nested Expressions

Search forms that the UI designer will create from view criteria are not able to work with all types of nested expressions. Specifically, search forms do not support expressions with directly nested view criteria. This type of nested expression defines one view criteria as a direct child of another view criteria. Query search forms do support nested expressions where you nest the view criteria as a child of a criteria item which is itself a child of a view criteria. For more information about using view criteria to create search forms, see [Section 31.1.1, "Implicit and Named View Criteria."](#)

5.11.5 How to Set User Interface Hints on View Criteria to Support Search Forms

Named view criteria that you create for view object collections can be used by the web page designer to create Query-by-Example search forms. Web page designers select your named view criteria from the JDeveloper Data Controls panel to create search forms for the Fusion web application. In the web page, the search form utilizes an ADF Faces query search component that will be bound initially to the named view criteria selected in the Data Controls panel. At runtime, the end user may select among all other named view criteria that appear in the Data Controls panel. Named view criteria that the end user can select in a search form are known as *developer-seeded searches*. The

query component automatically displays these seeded searches in its **Saved Search** dropdown list. For more information about creating search forms and using the ADF query search component, see [Section 31.2, "Creating Query Search Forms."](#)

Note: By default, any named view criteria you create in the Edit View Criteria dialog will appear in the Data Controls panel. As long as the **Show In List** option appears selected in the UI Hints page of the Edit View Criteria dialog, JDeveloper assumes that the named view criteria should be available as a developer-seeded search. When you want to create a named view criteria that you do not want the end user to see in search forms, deselect the **Show In List** option in the dialog. For example, you might create a named view criteria only for an LOV-enabled attribute and so you would need to deselect **Show In List**.

Because developer-seeded searches are created in the data model project, the UI Hints page of the Edit View Criteria dialog lets you specify the default properties for the query component's runtime usage of individual named view criteria. At runtime, the query component's behavior will conform to the selections you make for the following seeded search properties:

Search Region Mode: Select the mode that you want the query component to display the seeded search as. The **Basic** mode has all features of **Advanced** mode, except that it does not allow the end user to dynamically modify the displayed search criteria fields. The default is **Basic** mode for a view criteria you define in the Edit View Criteria dialog.

Query Automatically: Select when you want the query associated with the named view criteria to be executed and the results displayed in the web page. Any developer-seeded search with this option enabled will automatically be executed when the end user selects it from the query component's **Saved Search** list. Deselect when the web page designer prefers not to update the previously displayed results until the end user submits the search criteria values on the form. Additionally, when a search form is invoked from a task flow, the search form will appear empty when this option is deselected and populated when enabled. By default, this option is disabled for a view criteria you define in the Edit View Criteria dialog.

Show Operators: Determine how you want the query component to display the operator selection field for the view criteria items to the end user. For example, select **Always** when you want to allow the end user to customize the operators for criteria items (in either basic or advanced modes) or select **Never** when you want the view criteria to be executed using the operators it defines. Note that the end user cannot change the operator for criteria items that you specify with a bind variable because bind variables may be used in more than one criteria item.

Show Match All and Match Any: Select to allow the query component to display the **Match All** and **Match Any** radio selection buttons to the end user. When these buttons are present, the end user can use them to modify the search to return matches for all view criteria items or any one view criteria item. This is equivalent to enforcing **AND** (match all) or **OR** (match any) conjunctions between view criteria items. Deselect when you want the view criteria to be executed using the view criteria item conjunctions it defines. In this case, the query component will not display the radio selection buttons.

Rendered Mode: Select individual view criteria items from the view criteria tree component and choose whether you want the selected item to appear in the search form when the end user toggles the query component between basic mode and

advanced mode. The default for every view criteria item is **All**. The default mode permits the query component to render an item in either basic or advanced mode. By changing the **Rendered Mode** setting for individual view criteria items, you can customize the search form's appearance at runtime. For example, you may want basic mode to display a simplified search form to the end user, reserving advanced mode for displaying a search form with the full set of view criteria items. In this case, you would select **Advanced** for the view criteria item that you do not want displayed in the query component's basic mode. In contrast, when you want the selected view criteria item to be rendered only in basic mode, select **Basic**. Set any item that you do not want the search form to render in either basic or advanced mode to **Never**.

Note: When your view criteria includes an item that should not be exposed to the user, use the **Rendered Mode** setting **Never** to prevent it from appearing in the search form. For example, a view criteria may be created to search for products in the logged-in customer's cart; however, you may want to prevent the user from changing the customer ID to display another customer's cart contents. In this scenario, the view criteria item corresponding to the customer ID would be set to the current customer ID using a named bind variable. Although the bind variable definition might specify the variable as not required and not updatable, with the UI hint property **Display** set to **Hide**, only the **Rendered Mode** setting determines whether or not the search form displays the value.

Support Multiple Value Selection: Select when you want to allow the end user to make multiple selections for an individual criteria item that the query component displays. This option is only enabled when the view object attribute specified by the view criteria item has a List of Values (LOV) defined. Additionally, multiple selections will only be supported by the query component when the end user selects the operator **equal to** or **not equal to**. For example, if the criteria item names an attribute `CountryId` and this attribute derives its values from a list of country IDs accessed by the attribute's associated LOV, then selecting this option would allow the end user to submit the query with multiple country selections. At runtime, the query component will generate the appropriate query clause based on the end user's operator selection.

Display Width: Enter the character width to be used by the control that displays this criteria item in the query component. The value you enter will override the display width control hint defined for the criteria item's corresponding view object attribute. For example, in an edit form the attribute control hint may allow text of 1024 length, but in the search form you might want to limit the field for the criteria item to 20 character length.

Show In List: Select to ensure that the view criteria is defined as a developer-seeded query. Deselect when the named view criteria you are defining is not to be used by the query search component to display a search form. Your selection determines whether the named view criteria will appear in the query search component's **Saved Search** dropdown list of available seeded searches. By default, this option is enabled for a view criteria you define in the Edit View Criteria dialog.

Display Name: Enter the name of the seeded search that you want to appear in the query component's **Saved Search** dropdown list or click the ... button (to the right of the edit field) to select a message string from the resource bundle associated with the view object. The display name will be the name by which the end user identifies the seeded search. When you select a message string from the resource bundle, JDeveloper saves the string's corresponding message key in the view object definition file. At

runtime, the UI locates the string to display based on the end user's locale setting and the message key in the localized resource bundle. When you do not specify a display name, the view criteria name displayed in the Edit View Criteria dialog will be used by default.

To create a seeded search for use by the ADF query search component, you select **Show In List** in the UI Hints page of the Edit View Criteria dialog. You deselect **Show In List** when you do not want the end user to see the view criteria in their search form.

Before you begin:

It may be helpful to have an understanding of view criteria. For more information, see [Section 5.11, "Working with Named View Criteria."](#)

You will need to complete these tasks:

- Create the desired view objects as described in [Section 5.2.1, "How to Create an Entity-Based View Object,"](#) and [Section 5.2.3, "How to Create an Expert Mode, Read-Only View Object."](#)
- Create the view criteria as described in [Section 5.11.1, "How to Create Named View Criteria Declaratively."](#)

To customize a named view criteria for the user interface:

1. In the Application Navigator, double-click the view object that defines the named view criteria you want to use as a seeded search.
2. In the overview editor, click the **Query** navigation tab.
3. In the Query page, expand the **View Criteria** section and double-click the named view criteria that you want to allow in seeded searches.
4. In Edit View Criteria dialog, click the **UI Hints** tab and ensure that **Show In List** is selected.

This selection determines whether or not the query component will display the seeded search in its **Saved Search** dropdown list.

5. Enter a user-friendly display name for the seeded search to be added to the query component **Saved Search** dropdown list.

When left empty, the view criteria name displayed in the Edit View Criteria dialog will be used by the query component.

6. Optionally, enable **Query Automatically** when you want the query component to automatically display the search results whenever the end user selects the seeded search from the **Saved Search** dropdown list.

By default, no search results will be displayed.

7. Optionally, apply **Criteria Item UI Hints** to customize whether the query component renders individual criteria items when the end user toggles the search from between basic and advanced mode.

By default, all view criteria items defined by the seeded search will be displayed in either mode.

If a rendered criteria item is of type `Date`, you must also define UI hints for the corresponding view object attribute. Set the view object attribute's Format Type hint to **Simple Date** and set the Format Mask to an appropriate value, as described in [Section 5.13.1, "How to Add Attribute UI Hints."](#) This will allow the search form to accept date values.

8. Click **OK**.

5.11.6 How to Test View Criteria Using the Oracle ADF Model Tester

To test the view criteria you added to a view object, use the Oracle ADF Model Tester, which is accessible from the Application Navigator.

The Oracle ADF Model Tester, for any view object instance that you browse, lets you bring up the View Criteria dialog, as shown in [Figure 5-41](#). The dialog allows you to create a view criteria comprising one or more view criteria rows.

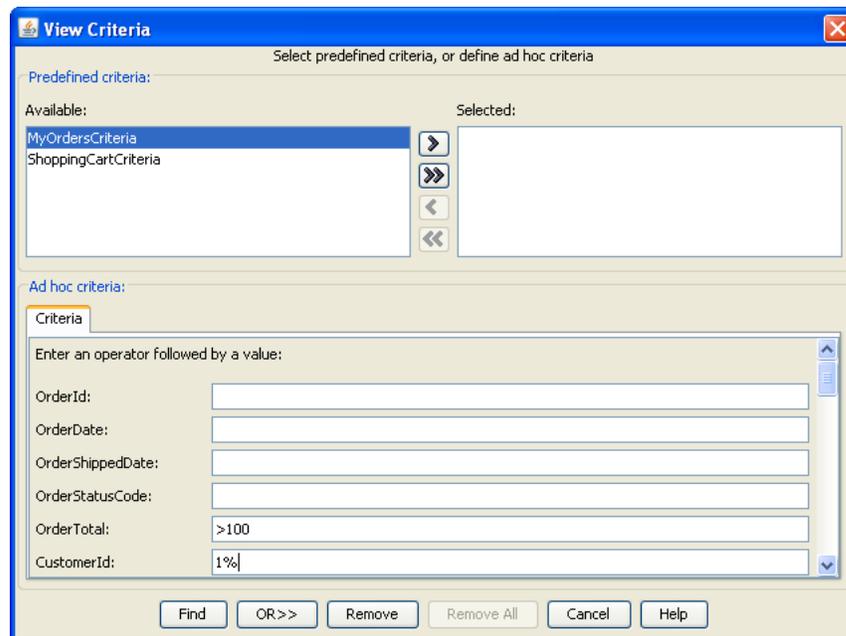

To apply criteria attributes from a single view criteria row, click the **Specify View Criteria** toolbar button in the browser and enter Query-by-Example criteria in the desired fields, then click **Find**.

To test view criteria using the Oracle ADF Model Tester:

1. In the Application Navigator, expand the project containing the desired application module and view objects.
2. Right-click the application module and choose **Run**.
3. In the Oracle ADF Model Tester, double-click the view instance you want to filter to open it in the tester, and then right-click the view instance and choose **Find**.

Alternatively, after you double-click a view instance, you can click the **Specify View Criteria** toolbar button to test the view criteria.

4. In the View Criteria dialog, perform one of the following tasks:
 - To test a view criteria that you added to the view object in your project, select from the list and click **Find**. Any additional criteria that you enter in the ad hoc Criteria panel will be added to the filter.
 - To test ad hoc criteria attributes from a single view criteria row, enter the desired values for the view criteria and click **Find**. For example, [Figure 5-41](#) shows the filter to return all customers who possess a customer ID that begins with the number "1" and placed an order in the amount greater than 100.
 - To test additional ad hoc view criteria rows, click the **OR** tab and use the additional tabs that appear to switch between pages, each representing a distinct view criteria row. When you click **Find**, the Oracle ADF Model Tester will create and apply the view criteria to filter the result.

Figure 5–41 View Criteria Dialog in Oracle ADF Model Tester

5.11.7 How to Create View Criteria Programmatically

[Example 5–35](#) shows the `main()` method finds the `PersonList` view object instance to be filtered, creates a view criteria for the attributes of this view object, and applies the view criteria to the view object.

To create a view criteria programmatically, follow these basic steps (as illustrated in [Example 5–35](#)):

1. Find the view object instance to be filtered.
2. Create a view criteria row set for the view object.
3. Use the view criteria to create one or more empty view criteria rows
4. Set attribute values to filter on the appropriate view criteria rows.

You can use the single method `setAttribute()` on the view criteria rows to set attribute name, comparison operator, and value to filter on. Alternatively, use `ensureCriteriaItem()`, `setOperator()`, and `setValue()` on the view criteria rows to set attribute name, comparison operator, and value to filter on individually.

5. Add the view criteria rows to the view criteria row set.
6. Apply the view criteria to the view object.
7. Execute the query.

The last step to execute the query is important, since a newly applied view criteria is applied to the view object's SQL query only at its next execution.

Example 5–35 Creating and Applying a View Criteria

```
package devguide.examples.readonlyvo.client;

import oracle.jbo.ApplicationModule;
import oracle.jbo.Row;
```

```

import oracle.jbo.ViewCriteria;
import oracle.jbo.ViewCriteriaRow;
import oracle.jbo.ViewObject;
import oracle.jbo.client.Configuration;

public class TestClientViewCriteria {
    public static void main(String[] args) {
        String amDef = "devguide.examples.readonlyvo.PersonService";
        String config = "PersonServiceLocal";
        ApplicationModule am =
            Configuration.createRootApplicationModule(amDef, config);
        // 1. Find the view object to filter
        ViewObject vo = am.findViewObject("PersonList");
        // Work with your appmodule and view object here
        Configuration.releaseRootApplicationModule(am, true);
        // 2. Create a view criteria row set for this view object
        ViewCriteria vc = vo.createViewCriteria();
        // 3. Use the view criteria to create one or more view criteria rows
        ViewCriteriaRow vcr1 = vc.createViewCriteriaRow();
        ViewCriteriaRow vcr2 = vc.createViewCriteriaRow();
        // 4. Set attribute values to filter on in appropriate view criteria rows
        vcr1.setAttribute("PersonId", "> 200");
        vcr1.setAttribute("Email", "d%");
        vcr1.setAttribute("PersonTypeCode", "STAFF");
        vcr2.setAttribute("PersonId", "IN (204,206)");
        vcr2.setAttribute("LastName", "Hemant");
        // 5. Add the view criteria rows to the view criteria row set
        vc.add(vcr1);
        vc.add(vcr2);
        // 6. Apply the view criteria to the view object
        vo.applyViewCriteria(vc);
        // 7. Execute the query
        vo.executeQuery();
        while (vo.hasNext()) {
            Row curPerson = vo.next();
            System.out.println(curPerson.getAttribute("PersonId") + " " +
                curPerson.getAttribute("Email"));
        }
    }
}

```

Running the `TestClientViewCriteria` example produces the results shown in [Example 5–35](#):

206 SHEMANT

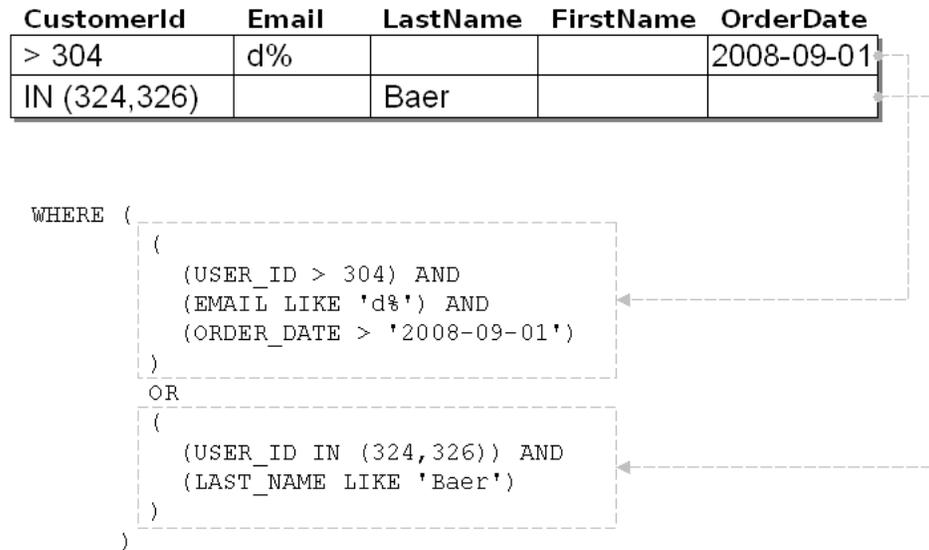

5.11.8 What Happens at Runtime: How the View Criteria Is Applied to a View Object

When you apply a view criteria containing one or more view criteria rows to a view object, the next time it is executed it augments its SQL query with an additional `WHERE` clause predicate corresponding to the Query-by-Example criteria that you've populated in the view criteria rows. As shown in [Figure 5–42](#), when you apply a view criteria containing multiple view criteria rows, the view object augments its design time `WHERE` clause by adding an additional runtime `WHERE` clause based on the non-null example criteria attributes in each view criteria row.

A corollary of the view criteria feature is that each time you apply a new view criteria (or remove an existing one), the text of the view object's SQL query is effectively changed. Changing the SQL query causes the database to reparse the statement the next time it is executed. You can eliminate the reparsing and improve the performance

of a view criteria as described in [Section 5.11.10, "What You May Need to Know About Query-by-Example Criteria."](#)

Figure 5–42 View Object Automatically Translates View Criteria Rows into Additional Runtime WHERE Filter

5.11.9 What You May Need to Know About the View Criteria API

When you need to perform tasks that the Edit View Criteria dialog does not support, review the View Criteria API. For example, programmatically, you can alter compound search conditions using multiple view criteria rows, search for a row whose attribute value is NULL, search case insensitively, and clear view criteria in effect.

5.11.9.1 Referencing Attribute Names in View Criteria

The `setWhereClause()` method allows you to add a dynamic WHERE clause to a view object, as described in [Section 6.4.1, "ViewObject Interface Methods for Working with the View Object's Default RowSet."](#) You can also use `setWhereClause()` to pass a string that contains literal database column names like this:

```
vo.setWhereClause("LAST_NAME LIKE UPPER(:NameToFind)");
```

In contrast, when you use the view criteria mechanism, shown in [Example 5–35](#), you must reference the view object attribute name instead, like this:

```
ViewCriteriaItem vc_item1 = vc_row1.ensureCriteriaItem("UserId");
vc_item1.setOperator(">");
vc_item1.setValue("304");
```

The view criteria rows are then translated by the view object into corresponding WHERE clause predicates that reference the corresponding column names. The programmatically set WHERE clause is AND-ed with the WHERE clauses of any view criteria that have been defined for the view object at design time.

5.11.9.2 Referencing Bind Variables in View Criteria

When you want to set the value of a view criteria item to a bind variable, use `setIsBindVarValue(true)`, like this:

```
ViewCriteriaItem vc_item1 = vc_row1.ensureCriteriaItem("UserId");
vc_item1.setIsBindVarValue(true);
vc_item1.setValue(":VariableName");
```

5.11.9.3 Altering Compound Search Conditions Using Multiple View Criteria

When you add multiple view criteria, you can call the `setConjunction()` method on a view criteria to alter the conjunction used between the predicate corresponding to that view criteria and the one for the previous view criteria. The legal constants to pass as an argument are:

- `ViewCriteriaComponent.VC_CONJ_AND`
- `ViewCriteriaComponent.VC_CONJ_NOT`
- `ViewCriteriaComponent.VC_CONJ_UNION`
- `ViewCriteriaComponent.VC_CONJ_OR` (*default*)

The NOT value can be combined with AND or OR to create filter criteria like:

```
( PredicateForViewCriteria1 ) AND ( NOT ( PredicateForViewCriteria2 ) )
```

or

```
( PredicateForViewCriteria1 ) OR ( NOT ( PredicateForViewCriteria2 ) )
```

The syntax to achieve compound search conditions requires using Java's bitwise OR operator like this:

```
vc2.setConjunction(ViewCriteriaComponent.VC_CONJ_AND | ViewCriteriaComponent.VC_CONJ_NOT);
```

Performance Tip: Use the UNION value instead of an OR clause when the UNION query can make use of indices. For example, if the view criteria searches for `sal > 2000 or job = 'CLERK'` this query may turn into a full table scan. Whereas if you specify the query as the union of two inner view criteria, and the database table has an index on `sal` and an index on `job`, then the query can take advantage of these indices and the query performance will be significantly better for a large data set.

The limitation for the UNION clause is that it must be defined over one view object. This means that the SELECT and the FROM list will be the same for inner queries of the UNION clause. To specify a UNION query, call `setConjunction()` on the outer view criteria like this:

```
vc.setConjunction(ViewCriteriaComponent.VC_CONJ_UNION);
```

The outer view criteria should contain inner queries whose results will be the union. For example, suppose you want to specify the union of these two view criteria:

- A view criteria named `MyEmpJob`, which searches for `Job = 'SALESMAN'`.
- A view criteria named `MyEmpSalary`, which searches for `Sal = 1500`.

To create the UNION query for these two view criteria, you would make the calls shown in [Example 5-36](#).

Example 5–36 Applying the Union of Two View Criteria

```
vcu = voEmp.createViewCriteria();
vcm = voEmp.getViewCriteriaManager();

vcu.setConjunction(ViewCriteria.VC_CONJ_UNION);
vcu.add(vcm.getViewCriteria("MyEmpJob"));
vcu.add(vcm.getViewCriteria("MyEmpSal"));

voEmp.applyViewCriteria(vcu);
```

When this view criteria is applied, it will return rows where Job is SALESMAN or Sal is greater than 1500.

When you use a UNION view criteria, be sure that only one of the applied view criteria has the UNION conjunction. Other view criteria that you apply will be applied to each inner query of the UNION query.

5.11.9.4 Searching for a Row Whose Attribute Value Is NULL Value

To search for a row containing a NULL value in a column, populate a corresponding view criteria row attribute with the value "IS NULL" or use `ViewCriteriaItem.setOperator("ISBLANK")`.

5.11.9.5 Searching for Rows Whose Attribute Value Matches a Value in a List

To search for all rows with a value in a column that matches any value in a list of values that you specify, populate a corresponding view criteria row attribute with the comma-separated list of values and use the IN operator. For example, to filter the list of persons by IDs that match 204 and 206, set:

```
vcr.setAttribute("PersonId", "IN (204,206)");
```

Note that there must be a space between the IN operator and the brace:

- IN (204,206) is correct.
- IN(204,206) throws a `SQLSyntaxErrorException` error.

5.11.9.6 Searching Case-Insensitively

To search case-insensitively, call `setUpperColumns(true)` on the view criteria row to which you want the case-insensitivity to apply. This affects the WHERE clause predicate generated for String-valued attributes in the view object to use `UPPER(COLUMN_NAME)` instead of `COLUMN_NAME` in the predicate. Note that the value of the supplied view criteria row attributes for these String-valued attributes must be uppercase or the predicate won't match. In addition to the predicate, it also possible to use `UPPER()` on the value. For example, you can set `UPPER(ename) = UPPER("scott")`.

5.11.9.7 Clearing View Criteria in Effect

To clear any view criteria in effect, you can call `getViewCriteria()` on a view object and then delete all the view criteria rows from it using the `remove()` method, passing the zero-based index of the criteria row you want to remove. If you don't plan to add back other view criteria rows, you can also clear all the view criteria in effect by simply calling `applyViewCriteria(null)` on the view object.

5.11.10 What You May Need to Know About Query-by-Example Criteria

For performance reasons, you want to avoid setting a bind variable as the value of a view criteria item in these two cases:

- In the specialized case where the value of a view criteria item is defined as selectively required and the value changes from non-NULL to NULL.
In this case, the SQL statement for the view criteria will be regenerated each time the value changes from non-NULL to NULL.
- In the case where the value of the view criteria item is optional and that item references an attribute for an indexed column.
In the case of optional view criteria items, an additional SQL clause OR (:Variable IS NULL) is generated, and the clause does not support using column indices.

In either of the following cases, you will get better performance by using a view object whose WHERE clause contains the named bind variables, as described in [Section 5.10.1, "How to Add Bind Variables to a View Object Definition."](#) In contrast to the view criteria filtering feature, when you use named bind variables, you can change the *values* of the search criteria without changing the *text* of the view object's SQL statement each time those values change.

5.12 Working with List of Values (LOV) in View Object Attributes

Edit forms displayed in the user interface portion of your application can utilize LOV-enabled attributes that you define in the data model project to predetermine a list of values for individual input fields. When the user submits the form with their selected values, ADF data bindings in the ADF Model layer update the value on the view object attributes corresponding to the databound fields. To facilitate this common design task, ADF Business Components provides declarative support to specify the LOV usage in the user interface.

Defining an LOV for attributes of a view object in the data model project greatly simplifies the task of working with list controls in the user interface. Because you define the LOV on the individual attributes of the view object, you can customize the LOV usage for an attribute once and expect to see the list component in the form wherever the attribute appears.

Note: In order for the LOV to appear in the UI, the LOV usage must exist before the user interface designer creates the databound form. Defining an LOV usage for an attribute referenced by an existing form will not change the component that the form displays to an LOV.

You can define an LOV for any view object attribute that you anticipate the user interface will display as a selection list. The characteristics of the attribute's LOV definition depend on the requirements of the user interface. The information you gather from the user interface designer will determine the best solution. For example, you might define LOV attributes in the following cases:

- When you need to display attribute values resulting from a view object query against a business domain object.

For example, define LOV attributes to display the list of suppliers in a purchase order form.

- When you want to display attribute values resulting from a view object query that you wish to filter using a parameter value from any attribute of the LOV attribute's current row.

For example, define LOV attributes to display the list of supplier addresses in a purchase order form but limit the addresses list based on the current supplier.

If you wish, you can enable a second LOV to drive the value of the parameter based on a user selection. For example, you can let the user select the current supplier to drive the supplier addresses list. In this case, the two LOVs are known as a *cascading list*.

Before you can define the LOV attribute, you must create a data source view object in your data model project that queries the eligible rows for the attribute value you want the LOV to display. After this, you work entirely on the base view object to define the LOV. The base view object is the one that contains the primary data for display in the user interface. The LOV usage will define the following additional view object metadata:

- A view accessor to access the data source for the LOV attribute. The view accessor is the ADF Business Components mechanism that lets you obtain the full list of possible values from the row set of the data source view object.
- Optionally, supplemental values that the data source may return to attributes of the base view object other than the data source attribute for which the list is defined.
- User interface hints, including the type of list component to display, attributes to display from the current row when multiple display attributes are desirable, and a few options specific to the choice list component.

The general process for defining the LOV-enabled attribute relies on the Create List of Values dialog that you display for the base view object attribute.

To define the LOV-enabled attribute, follow this general process:

1. Open the Create List of Values dialog for the base attribute.
2. Create a new view accessor definition to point to the data source view object or select an existing view accessor that the base view object already defines.

Optionally, you can filter the view accessor by creating a view criteria using a bind variable that obtains its value from any attribute of base view object's current row.
3. Select the list attribute from the view accessor's data source view object.

This maps the attribute you select to the current attribute of the base view object.
4. Optionally, select list return values to map any supplemental values that your list returns to the base view object.
5. Select user interface hints to specify the list's display features.
6. Save the attribute changes.

Note: If you create a view criteria to filter the data source view object, you may also set an LOV on the attribute of the base view object that you use to supply the value for the view criteria bind variable. You set cascading LOV lists when you want the user's selection of one attribute to drive the options displayed in a second attribute's list.

Once you create the LOV-enabled attribute, the user interface designer can create the list component in the web page by dragging the LOV-enabled attribute's collection from the Data Controls panel. For further information about creating a web page that display the list, see [Chapter 30, "Creating Databound Selection Lists and Shuttles."](#) Specifically, for more information about working with LOV-enabled attributes in the web page, see [Section 30.3.1, "How to Create a Model-Driven List."](#)

5.12.1 How to Define a Single LOV-Enabled View Object Attribute

When an edit form needs to display a list values that is not dependent on another selection in the edit form, you can define a view accessor to point to the list data source. For example, assume that a purchase order form contains a field that requires the user to select the order item's supplier. In this example, you would first create a view accessor that points to the data source view object (`SuppliersView`). You would then set the LOV on the `SupplierDesc` attribute of the base view object (`PurchaseOrdersView`). Finally, you would reference that view accessor from the LOV-enabled attribute (`SupplierDesc`) of the base view object and select the data source attribute (`SupplierDesc`).

You will use the Create List of Values dialog to define an LOV-enabled attribute for the base view object. The dialog lets you select an existing view accessor or create a new one to save with the LOV-attribute definition.

Before you begin:

It may be helpful to have an understanding of LOV-enabled attributes. For more information, see [Section 5.12, "Working with List of Values \(LOV\) in View Object Attributes."](#)

You will need to complete this task:

Create the desired view objects as described in [Section 5.2.1, "How to Create an Entity-Based View Object,"](#) and [Section 5.2.3, "How to Create an Expert Mode, Read-Only View Object."](#)

To define an LOV that displays values from a view object attribute:

1. In the Application Navigator, double-click the view object that contains the attribute you wish to enable as an LOV.
2. In the overview editor, click the **Attributes** navigation tab.
3. In the Attributes page, select the attribute that is to display the LOV, and then click the **List of Values** tab and click the **Add list of values** button.

Use the Create List of Values dialog to create the LOV on the attribute you have currently selected in the attribute list of the overview editor. JDeveloper assigns a unique name to identify the LOV usage. For example, the metadata for the attribute `SupplierDesc` will specify the name `SupplierDescLOV` to indicate that the attribute is LOV enabled.

4. In the Create List of Values dialog, click the **Create new view accessor** button to add a view accessor to the view object you are currently editing.

Alternatively, you can expand **List Data Source** and select among the existing view accessors. The dropdown list displays all view accessors that you have added to the view object you are editing.

5. In the View Accessors dialog, select the view object definition or shared view instance that defines the data source for the attribute and shuttle it to the view accessors list.

By default, the view accessor you create will display the same name as the view object. You can edit the accessor name to supply a unique name. For example, assign the name `SuppliersViewAccessor` for the `SuppliersView` view object.

The view instance is a view object usage that you have defined in the data model of a shared application module. For more information about using shared view instances in an LOV, see [Section 10.4.5, "How to Create an LOV Based on a Lookup Table."](#)

6. Click **OK** to save the view accessor definition for the view object.
7. In the Create List of Values dialog, expand **List Data Source** and select the view accessor you created for the base view object to use as the data source. Then select the same attribute from this view accessor that will provide the list data for the LOV-enabled attribute.

The editor creates a default mapping between the list data source attribute and the LOV-enabled attribute. For example, the attribute `SuppliersDesc` from the `PurchaseOrdersView` view object would map to the attribute `SuppliersDesc` from the `SuppliersViewAccessor` view accessor.

The editor does not allow you to remove the default attribute mapping for the attribute for which the list is defined.

8. Optionally, when you want to specify supplemental values that your list returns to the base view object, click the **Create return attribute map** button in the **List Return Values** section and map the desired base view object attributes with attributes accessed by the view accessor.

Supplemental attribute return values are useful when you do not require the user to make a list selection for the attributes, yet you want those values, as determined by the current row, to participate in the update. For example, to map the attribute `SupplierAddress` from the `PurchaseOrdersView` view object, you would choose the attribute `SupplierAddress` from the `SuppliersViewAccessor` view accessor.

9. Click **OK**.

5.12.2 How to Define Cascading Lists for LOV-Enabled View Object Attributes

When the application user interface requires a list of values in one input field to be dependent on the user's entry in another field, you can create attributes that will display as cascading lists in the user interface. In this case, the list of possible values for the LOV-enabled attributes might be different for each row. As the user changes the current row, the LOV values vary based on the value of one or more controlling attribute values in the LOV-enabled attribute's view row. To apply the controlling attribute to the LOV-enabled attribute, you will create a view accessor to access the data source view object with the additional requirement that the accessor filters the list of possible values based on the current value of the controlling attribute. To filter the LOV-enabled attribute, you can edit the view accessor to add a named view criteria with a bind variable to obtain the user's selection.

For example, assume that a purchase order form contains a field that requires the user to select the supplier's specific site and that the available sites will depend on the order's already specified supplier. To implement this requirement, you would first create a view accessor that points to the data source view object. The data source view object will be specific to the LOV usage, because it must perform a query that filters the available supplier sites based on the user's supplier selection. You might name this data source view object definition `SupplierIdsForCurrentSupplierSite` to help

distinguish it from the `SupplierSitesView` view object that the data model already contains. The data source view object will use a named view criteria (`SupplierCriteria`) with a single view criteria item set by a bind variable (`TheSupplierId`) to obtain the user's selection for the controlling attribute (`SupplierId`).

You would then set the LOV on the `SupplierSiteId` attribute of the base view object (`PurchaseOrdersView`). You can then reference the view accessor that points to the data source view object from the LOV-enabled attribute (`PurchaseOrdersView.SupplierSiteId`) of the base view object. Finally, you must edit the LOV-enabled attribute's view accessor definition to specify the corresponding attribute (`SupplierIdsForCurrentSupplierSite.SupplierSiteId`) from the view object as the data source and, importantly, source the value of the bind variable from the view row's result using the attribute `SupplierId`.

To define cascading lists for LOV-enabled view object attributes:

1. Create a data source view object to control the cascading list.
2. Create a view accessor to filter the cascading list.

5.12.2.1 Creating a Data Source View Object to Control the Cascading List

The data source view object defines the controlling attribute for the LOV-enabled attribute. To make the controlling attribute accessible to the LOV-enabled attribute of the base view object, you must define a named view criteria to filter the data source attribute based on the value of another attribute. Because the value of the controlling attribute is expected to change at runtime, the view criteria uses a bind variable to set the controlling attribute.

Before you begin:

It may be helpful to have an understanding of cascading LOV-enabled attributes. For more information, see [Section 5.12.2, "How to Define Cascading Lists for LOV-Enabled View Object Attributes."](#)

To define the view criteria for the data source to be referenced by the LOV-enabled attribute:

1. In the Application Navigator, double-click the view object that you created to query the list of all possible values for the controlling attribute.

For example, if the LOV-enabled attribute `SupplierSiteId` depends on the controlling attribute `SupplierId` value, you might have created the data source view object `SupplierIdsForCurrentSupplierSite` to query the list of all supplier sites.

2. In the overview editor, click the **Query** navigation tab.
3. In the Query page, expand the **Bind Variables** section and click the **Create new bind variable** button to add a bind variable to the data source view object.

For example, for a data source view object `SupplierIdsForCurrentSupplierSite` used to query the list of all supplier sites, you would create the bind variable `TheSupplierId`, since it will be the controlling attribute for the LOV-enabled attribute.

4. In the Bind Variable dialog, enter the name and type of the bind variable. Leave all other options unchanged and click **OK**.

By default, the view accessor you create will display the same name as the view object instance. You can edit the accessor name to supply a unique name. For example, assign the name `CurrencyLookupViewAccessor` for the `CurrencyLookupView` view object instance.

5. In Query page of the overview editor, expand the **View Criteria** section and click the **Create new view criteria** button to add the view criteria to the data source view object you are currently editing.
6. In the Create View Criteria dialog, click **Add Group** and define a single **Criteria Item** for the group as follows:
 - Enter a **Criteria Name** to identify the view criteria. For example, you might enter the name `SupplierCriteria` for the `SupplierIdsForCurrentSupplierSite`.
 - Select the controlling attribute from the **Attributes** list. For example, you would select the `SupplierSiteId` attribute from the `SupplierIdsForCurrentSupplierSite`.
 - Select **equal to** from the view criteria **Operator** list.
 - Select **Bind Variable** from the view criteria **Operand** list.
 - Select the name of the previously defined bind variable from the **Parameter** list.
 - Select among the following bind variable configuration options to determine whether or not the value is required by the parent LOV:

Optional from the **Validation** menu and deselect **Ignore Null Values** when you want to configure cascading LOVs where the parent LOV value is required. This combination supports the cascading LOV use case where no selection in the parent LOV returns *no* rows in the child LOV. The `WHERE` clause shown in the Edit View Criteria dialog should look similar to `((SupplierIdsForCurrentSupplierSite.SUPPLIER_ID = :TheSupplierId))`.

Optional from the **Validation** menu and leave **Ignore Null Values** selected (default) when you want to configure cascading LOVs where the parent LOV value is optional. This combination supports the cascading LOV use case where no selection in the parent LOV returns *all* rows in the child LOV. The `WHERE` clause shown in the Edit View Criteria dialog should look similar to `((SupplierIdsForCurrentSupplierSite.SUPPLIER_ID = :TheSupplierId) OR (:TheSupplierId IS NULL))`.

For more details about these settings, see [Section 5.11.3, "What You May Need to Know About Bind Variable Options."](#) Do not select **Required** for the Validation option for cascading LOVs, because no selection in the parent LOV will cause a validation error.

7. Click **OK**.

5.12.2.2 Creating a View Accessor to Filter the Cascading List

To populate the cascading LOV-enabled attribute, you must first set up a named view criteria on a data source view object. To make the LOV-enabled attribute of the base view object dependent on the controlling attribute of the data source view object, you then add a view accessor to the LOV-enabled attribute of the base view object and reference the previously defined data source view object's named view criteria.

Before you begin:

It may be helpful to have an understanding of cascading LOV-enabled attributes. For more information, see [Section 5.12.2, "How to Define Cascading Lists for LOV-Enabled View Object Attributes."](#)

You will need to complete this task:

Create the data source view object and named view criteria as described in [Section 5.12.2.1, "Creating a Data Source View Object to Control the Cascading List."](#)

To create a view accessor that filters display values for an LOV-enabled attribute based on the value of another attribute in the same view row:

1. In the Application Navigator, double-click the base view object that contains the attribute you want to use the filtered view accessor as the list data source.

For example, the base view object `PurchaseOrdersView` might contain the attribute `SupplierSiteId` that will depend on the value of the controlling attribute `SupplierId`.

2. In the overview editor, click the **Attributes** navigation tab.
3. In the Attributes page, select the attribute that is to filter the cascading LOV, and then click the **List of Values** tab and click the **Add list of values** button.
4. In the Create List of Values dialog, click the **Create new view accessor** button to add a view accessor to the view object you are currently editing.

Alternatively, you can expand **List Data Source** and select among the existing view accessors. The dropdown list displays all view accessors that you have added to the view object you are editing.

5. In the View Accessors dialog, select the view object instance name you created for data source view object and shuttle it to the view accessors list.
6. With the new view accessor selected in the dialog, click **Edit**.
7. In the Edit View Accessor dialog, apply the previously defined view criteria to the view accessor and provide a value for the bind variable as follows:
 - Click the data source view object's view criteria in the **Available** list and add it to the Selected list. For example, you would select `SupplierCriteria` from the `SupplierIdsForCurrentSupplierSite` view object definition.
 - Set the value for the bind variable to the name of the controlling attribute. The attribute name must be identical to the base view object's controlling attribute. For example, if the base view object `PurchaseOrdersView` contains the LOV-enabled attribute `SupplierSiteId` that depends on the value of the controlling attribute `SupplierId`, you would enter `SupplierId` for the bind variable value.
 - Select the name of the previously defined bind variable from the **Parameter** list.
 - Select **Required** from the **Usage** dropdown list.
8. Click **OK** to save the view accessor definition for the base view object.
9. In the Attributes page of the overview editor, select the attribute that is to display the LOV, and then click the **List of Values** tab and click the **Add list of values** button.

10. In the Create List of Values dialog, expand **List Data Source** and select the view accessor you created for the data source view object instance to use as the data source. Then select the controlling attribute from this view accessor that will serve to filter the attribute you are currently editing.

The editor creates a default mapping between the view object attribute and the LOV-enabled attribute. You use separate attributes in order to allow the bind variable (set by the user's controlling attribute selection) to filter the LOV-enabled attribute. For example, the LOV-enabled attribute `SupplierId` from the `PurchaseOrdersView` view object would map to the controlling attribute `SupplierSiteId` for the `SupplierIdsForCurrentSupplierSiteViewAccessor`. The runtime automatically supports these two cascading LOVs where the row set and the base row attribute differ.

11. Click OK.

5.12.3 How to Specify Multiple LOVs for an LOV-Enabled View Object Attribute

Another way to vary the list of values that your application user interface can display is to define multiple list of values for a single LOV-enabled view object attribute. In contrast to a cascading list, which varies the list contents based on a dependent LOV list selection, an LOV-enabled switcher attribute with multiple LOVs lets you vary the entire LOV itself. The LOV choice to display is controlled at runtime by the value of an attribute that you have defined specifically to resolve to the name of the LOV to apply.

For example, you might want to define one LOV to apply in a create or edit form and another LOV to apply for a search component. In the first case, the LOV-enabled attribute that the form can use is likely to be an entity-based view accessor that is shared across all the view objects that reference the entity. The entity-based view accessor is useful for user interface forms because a single accessor definition can apply to each instance of the LOV in the forms. However, in the case of the search component, LOV definitions based on view accessors derived from an underlying entity will not work. The LOV definitions for search components must be based on view accessors defined in the view object. Note that when the user initiates a search, the values in the criteria row will be converted into `WHERE` clause parameters. Unlike a regular view row displayed in create or edit type forms, the criteria row is not backed by an entity. In this scenario, one LOV uses the entity-based accessor as a data source and a second LOV uses the view object-based accessor as a data source.

To address this requirement to define multiple LOV lists that access the same attribute, you add a switcher attribute to the base view object. For example, you might add a `ShipperLOVSwitcher` attribute for the `Orders` view object that resolves through an expression to the name of the LOV to display. Such an expression can specify two LOVs that may apply to the `ShipperID` attribute:

```
(adf.isCriteriaRow) ? "LOV_ShipperID_ForSearch" : "LOV_ShipperID"
```

This expression would appear in the **Value** field of the switcher attribute. At runtime, in the case of the search component, the expression resolves to the value that identifies the view object-based accessor LOV. In the case of the create or edit form, the expression resolves to the value that identifies the entity-based accessor LOV.

You will use the Create List of Values dialog to add multiple LOV lists to an attribute of the base view object. You will also use the List of Values section in the Attributes page of the overview editor for the base view object to define the default LOV to display and the switcher attribute to apply.

Before you begin:

It may be helpful to have an understanding of LOV-enabled attributes. For more information, see [Section 5.12, "Working with List of Values \(LOV\) in View Object Attributes."](#)

You will need to complete this task:

Create the first LOV list for the attribute as described in [Section 5.12.1, "How to Define a Single LOV-Enabled View Object Attribute."](#)

To specify additional LOV lists for a view object attribute with an existing LOV:

1. In the Application Navigator, double-click the view object that contains the attribute for which you want to specify multiple LOV lists.
2. In the overview editor, click the **Attributes** navigation tab.
3. In the Attributes page, select the desired attribute, and then click the **List of Values** tab and click the **Add list of values** button.
4. In the Create List of Values dialog, define the first LOV as described in [Section 5.12.1, "How to Define a Single LOV-Enabled View Object Attribute."](#)

When you define the LOV, change the name of the LOV to match the value returned by the attribute that you will use to determine which LOV your application applies to the LOV-enabled attribute.

5. After you define the first LOV, return to the **List of Values** section of the Attributes page of the overview editor and, with the original attribute selected, click the **Add List of Values** button.

If you have selected the correct attribute from the Attributes page of the overview editor, the **List of Values** section should display your previously defined LOV.

6. In the Create List of Values dialog, repeat the procedure described in [Section 5.12.1, "How to Define a Single LOV-Enabled View Object Attribute"](#) to define each subsequent LOV.

The name of each LOV must correspond to a unique value returned by the attribute that determines which LOV to apply to the LOV-enabled attribute.

You can define the LOV using any accessor and any attribute. There are no restrictions on the type of LOV lists that you can add to an attribute with multiple LOV lists specified.

After you finish defining the second LOV, the **List of Values** section in the view object overview editor changes to display additional features that you will use to control the selection of the LOV.

7. In the Attributes page of the overview editor, click the **List of Values** tab and use the **List of Values Switcher** dropdown list to select the attribute that will return the name of the List of Value to use.

The dropdown list displays the attributes of the base view object. If you want your application to dynamically apply the LOV from the LOVs you have defined, your view object must define an attribute whose values resolve to the names of the LOVs you defined. If you have not added this attribute to the view object, be sure that the dropdown list displays **<None Specified>**. In this case, at runtime your application will display the LOV-enabled attribute with the default LOV and it will not be possible to apply a different LOV.

8. To change the default LOV to apply at runtime, choose the **Default** radio button corresponding to the desired LOV definition.

The default LOV selection determines which list of values your application will display when the **List of Values Switcher** dropdown list displays **<None Specified>**. Initially, the first LOV in the overview editor **List of Values** section is the default.

9. To change the component that your application will use to display the various LOV lists, select from desired component from the **List Type UI Hint** dropdown list.

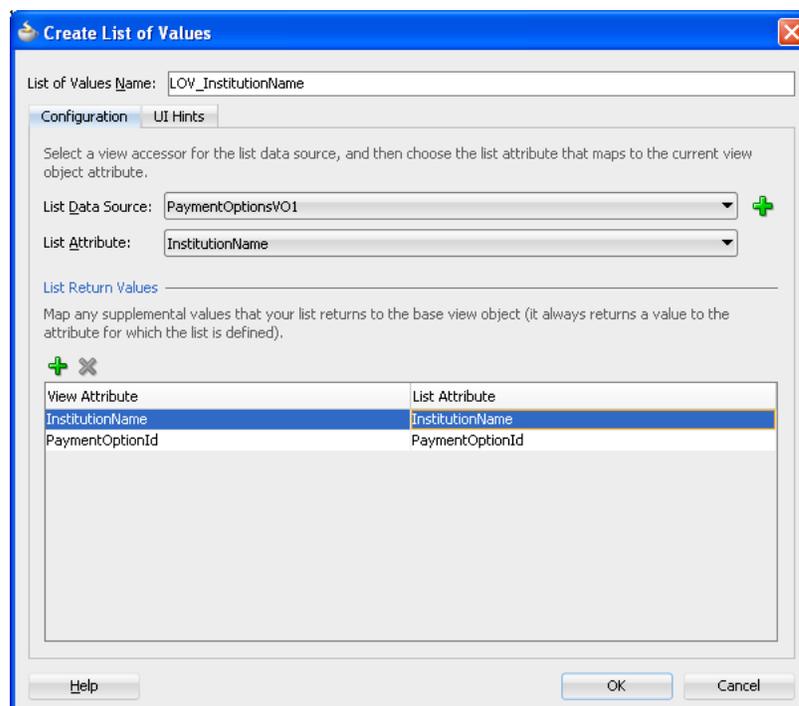

The component you select will apply to all LOV lists. For a description of the available components, see [Table 5-2](#).

5.12.4 How to Define an LOV to Display a Reference Attribute

Reference attributes that your view objects define are often desirable attributes to use as the source for LOV lists. Reference attributes belong to secondary entity usages that you have added to the view object to provide meaningful information beyond the entity usage's primary key attribute. For example, when you create an `OrderInfo` view object, the view object may define a secondary entity usage for `PaymentOptionsEO` to include billing information for the order, including the list of credit cards the end user has added to their account.

An LOV that you define for the secondary entity object needs to be able to update the primary attribute value, but to be meaningful to the end user, you typically hide the primary attribute in the list and display one or more reference attributes instead. In this case, your LOV might display the list of credit cards by institution name, but hide the payment option ID value that gets updated by the end user's selection. [Figure 5-43](#) shows the LOV defined on the reference attribute `InstitutionName`. The **List Return Values** section of the Create List of Values dialog lists the reference attribute and then lists the primary key attribute `PaymentOptionId` to provide supplemental values.

Figure 5-43 Create View Criteria Dialog with Reference Attribute Specified

Before you begin:

It may be helpful to have an understanding of reference attributes in secondary entity usages. For more information, see [Section 5.12, "Working with List of Values \(LOV\) in View Object Attributes."](#)

You will need to complete this task:

Create the entity-based view object and add a secondary entity usage that defines the desired LOV attributes, as described in [Section 5.12.1, "How to Define a Single LOV-Enabled View Object Attribute."](#) By default, the secondary entity usage will include the primary key attribute that you want the LOV to update.

To define reference attributes for an LOV:

1. In the Application Navigator, double-click the view object that contains the secondary entity usage attribute you wish to enable as an LOV.
2. In the overview editor, click the **Attributes** navigation tab.
3. In the Attributes page, select the desired reference attribute that is to display the LOV, click the **List of Values** tab, and then click the **Add list of values** button.

Use the Create List of Values dialog to create the LOV on the attribute you have currently selected in the attribute list of the overview editor. JDeveloper assigns a unique name to identify the LOV usage. For example, the metadata for the attribute `SupplierDesc` will specify the name `SupplierDescLOV` to indicate that the attribute is LOV-enabled.

4. In the Create List of Values dialog, click the **Create new view accessor** button to add a view accessor to the view object you are currently editing.

Alternatively, you can expand **List Data Source** and select among the existing view accessors. The dropdown list displays all the view accessors that you have added to the view object you are editing.

5. In the View Accessors dialog, select the view object definition or shared view instance that defines the data source for the attribute and shuttle it to the view accessors list.

By default, the view accessor you create will display the same name as the view object. You can edit the accessor name to supply a unique name. For example, assign the name `SuppliersViewAccessor` for the `SuppliersView` view object.

6. Click **OK** to save the view accessor definition for the view object.
7. In the Create List of Values dialog, expand **List Data Source** and select the view accessor you created for the base view object to use as the data source. Then select the same attribute from this view accessor that will provide the list data for the LOV-enabled attribute.

The editor creates a default mapping between the list data source attribute and the LOV-enabled attribute. For example, the attribute `SuppliersDesc` from the `PurchaseOrdersView` view object would map to the attribute `SuppliersDesc` from the `SuppliersViewAccessor` view accessor.

The editor does not allow you to remove the default attribute mapping for the attribute for which the list is defined.

8. Optionally, when you want to specify supplemental values that your list returns to the base view object, click the **Create return attribute map** button in the **List Return Values** section and map the desired base view object attributes with attributes accessed by the view accessor.

Supplemental attribute return values are useful when you do not require the user to make a list selection for the attributes, yet you want those values, as determined by the current row, to participate in the update. For example, to map the attribute `SupplierAddress` from the `PurchaseOrdersView` view object, you would choose the attribute `SupplierAddress` from the `SuppliersViewAccessor` view accessor.

9. Click OK.

5.12.5 How to Set User Interface Hints on a View Object LOV-Enabled Attribute

When you know how the view object attribute that you define as an LOV should appear in the user interface, you can specify additional properties of the LOV to determine its display characteristics. These properties, or *UI hints*, augment the attribute hint properties that ADF Business Components lets you set on any view object attribute. Among the LOV UI hints for the LOV-enabled attribute is the type of component the user interface will use to display the list. For a description of the available components, see [Table 5-2](#). (Not all ADF Faces components support the default list types, as noted in the [Table 5-2](#).)

Table 5-2 List Component Types for List Type UI Hint

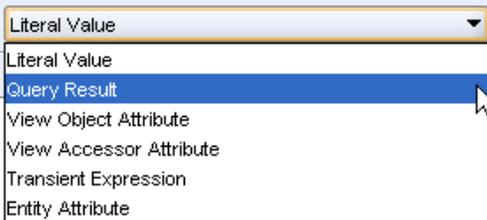

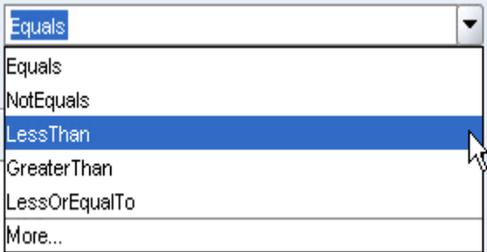

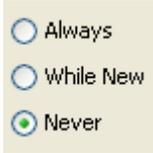

LOV List Component Type	Usage
<p>Choice List</p> 	<p>This component does not allow the user to type in text, only select from the dropdown list.</p>
<p>Combo Box</p> 	<p>This component allows the user to type text or select from the dropdown list. This component sometimes supports auto-complete as the user types.</p> <p>This component is <i>not</i> supported for ADF Faces.</p>
<p>Combo Box with List of Values</p> 	<p>This component is the same as the combo box, except that the last entry (More...) opens a List of Values lookup dialog that supports query with filtering when enabled for the LOV attribute in its UI hints. The default UI hint enables queries on all attributes.</p> <p>Note that when the LOV attribute appears in a table component, the list type changes to an Input Text with List of Values component.</p>

Table 5–2 (Cont.) List Component Types for List Type UI Hint

LOV List Component Type	Usage
<p>Input Text with List of Values</p> 	<p>This component displays an input text field with an LOV button next to it. The List of Values lookup dialog opens when the user clicks the button or enters an invalid value into the text field. The List of Values lookup dialog for this component supports query with filtering when enabled in the UI hints for the LOV attribute. The default UI hint enables queries on all attributes.</p> <p>This component may also support auto-complete when a unique match exists.</p>
<p>List Box</p> 	<p>This component takes up a fixed amount of real estate on the screen and is scrollable (as opposed to the choice list, which takes up a single line until the user clicks on it).</p>
<p>Radio Group</p> 	<p>This component displays a radio button group with the selection choices determined by the LOV attribute values. This component is most useful for very short, fixed lists.</p>

Before you begin:

It may be helpful to have an understanding of LOV-enabled attributes. For more information, see [Section 5.12, "Working with List of Values \(LOV\) in View Object Attributes."](#)

You will need to complete this task:

Create the LOV list for the attribute as described in [Section 5.12.1, "How to Define a Single LOV-Enabled View Object Attribute."](#)

To set view object attribute UI hints for an LOV-enabled attribute:

1. In the Application Navigator, double-click the view object that contains the attribute that you want to customize.
2. In the overview editor, click the **Attributes** navigation tab.
3. In the Attributes page, select the desired attribute and then click the **List of Values** tab.
4. In the List of Values section, select the LOV list that you want to customize and click the **Edit list of values** button.
5. In the Edit List of Values dialog, click the **UI Hints** tab.

6. In the UI Hints page, select a default list type as the type of component to display the list.

For a description of the available components, see [Table 5-2](#).

The list component displayed by the web page and the view object's default list type must match at runtime or a method-not-found runtime exception results. To avoid this error, confirm the desired list component with the user interface designer. You can also edit the default list type to match, so that, should the user interface designer subsequently change the component used in the web page, the two stay in sync.

7. Optionally, select additional display attributes to add values to the display.

The list of additional attributes is derived from the LOV-enabled attribute's view row. The additional attribute values can help the end user select an item from the list.

8. If you selected the **Combo Box with List of Values** type component, by default, the dropdown list for the component will display the first 10 records from the data source. This limit also serves to keep the view object fetch size small. To change the number of records the dropdown list of a Combo Box with List of Values component can display, enter the number of records for **Query Limit**.

Because **Query Limit** also controls the number of rows the view object will fetch (its sets the view object definition `ListRangeSize` property), specifying a large value for **Query Limit** is not recommended. The end user can open the component's LOV lookup dialog to access the full set of records (by clicking the component's lookup icon). **Query Limit** is disabled for all other component types and those components place no restriction on the number of rows that the LOV will access.

For details about the `ListRangeSize` property, see [Section 5.12.10, "What Happens at Runtime: How an LOV Queries the List Data Source."](#)

9. If you selected a component type that allows the user to open a List of Values lookup dialog to select a list value (this includes either the **Combo Box with List of Values** type component or **Input Text with List of Values** type component), by default, the lookup dialog will display a search form that will allow the user to search on all queryable attributes of the data source view object (the one defined by the LOV-enabled attribute's view accessor). Decide how you want to customize these components.
 - a. When you select the **Combo Box with List of Values** type component and you have added a large number of attributes to the **Selected** list, use **Show in Combo Box** to improve the readability of the dropdown list portion of the component. To limit the attribute columns to display in the dropdown list that the Combo Box with List of Values component displays, choose **First** from **Show in Combo Box** and enter a number corresponding to the number of attributes from the top of the **Selected** list that you want the dropdown list to display (this combination means you are specifying the "first" x number of attributes to display from the Create List of Values dialog's **Selected** list). Limiting the number of attribute columns to display in the dropdown list ensures that the user does not have to horizontally scroll to view the full list, but it does not limit the number of attribute columns to display in the List of Values lookup dialog. This option is disabled for all list component types except Combo Box with List of Values.
 - b. You can limit the attributes to display in the List of Values lookup dialog by selecting a view criteria from the **Include Search Region** dropdown list. To

appear in the dropdown list, the view criteria must already have been defined on the data source view object (the one that the LOV-enabled attribute's view accessor defines). Click the **Edit View Criteria** button to set search form properties for the selected view criteria. For more information about customizing view criteria for search forms, see [Section 5.11.5, "How to Set User Interface Hints on View Criteria to Support Search Forms."](#)

- c. You can prepopulate the results table of the List of Values lookup dialog by selecting **Query List Automatically**. The List of Values lookup dialog will display the results of the query when the user opens the dialog. If you leave this option deselected, no results will be displayed until the user submits the search form.
10. Alternatively, if you prefer not to display a search region in the List of Values lookup dialog, select **<No Search>** from the **Include Search Region** dropdown list. In this case, the List of Values lookup dialog will display only attributes you add to the **Display Attributes** list.
11. If you selected a choice type component to display the list, you can specify a **Most Recently Used Count** as an alternative to displaying all possible values.

For example, your form might display a choice list of `SupplierId` values to drive a purchase order form. In this case, you can allow the user to select from a list of their most recently viewed suppliers, where the number of supplier choices is determined by the count you enter. The default count 0 (zero) for the choice list displays all values for the attribute.
12. If you selected a **Combo Box with List of Values** type component to display the list, you can select a view criteria from the **Filter Combo Box Using** dropdown list to limit the list of valid values the LOV will display.

When you enable **Filter Combo Box Using**, the dropdown list displays the existing view criteria from the view object definition related to the LOV's view accessor. If the dropdown list displays no view criteria, then the data source view object defines no view criteria. When you do not enable this feature, the Combo Box with List of Values component derives its values from the full row set returned by the view accessor. The filtered Combo Box with List of Values is a useful feature when you want to support the use of an LOV with popup search dialog or LOV with a dropdown list that has a limited set of valid choices. For details about using the Combo Box with List of Values component in user interfaces, see [Section 31.1.2, "List of Values \(LOV\) Input Fields."](#)
13. Decide how you want the list component to handle a `NULL` value choice to display in the list component. This option is not enabled for every list component type that you can select.

If you enable **Include "No Selection" Item**, you can also determine how the `NULL` value selection should appear in the list by making a selection from the dropdown list. For example, when you select **Labeled Item**, you can enter the desired label in the edit field to the right of the dropdown list or you can click the **...** button (to the right of the edit field) to select a message string from the resource bundle associated with the view object. When you select a message string from the resource bundle, JDeveloper saves the string's corresponding message key in the view object definition file. At runtime, the UI locates the string to display based on the current user's locale setting and the message key in the localized resource bundle.
14. Click **OK**.

5.12.6 How to Handle Date Conversion for List Type UI Components

When the LOV-enabled attribute of the view object is bound to date information (such as the attribute `OrderShippedDate`), by default Oracle ADF assumes a format for the field like `yyyy-MM-dd hh:mm:ss`, which combines date and time. This combined date-time format is specified by the ADF Business Components Date domain class (`jbo.domain.Date`) and creates a conversion issue for the ADF Faces component when the user selects a date supplied by the LOV-enabled attribute. When the ADF Faces component is unable to convert the domain type to the Date type, the user interface invalidates the input field and displays the message `Error: The date is not in the correct format.`

To avoid this potential conversion error, configure a UI hint setting for the date value attribute of the view object that you want to enable for an LOV. The UI hint you specify will define a date-only mask, such as `yyyy-MM-dd`. Subsequently, any ADF Faces component that references the attribute will perform the conversion based on a pattern specified by its EL value-binding expression (such as `{bindings.Hiredate.format}`) and will reference the UI hint format instead of the ADF Business Components domain date-time. The conversion error results when the EL expression evaluates to null because no format mask has been specified.

Before you begin:

It may be helpful to have an understanding of LOV-enabled attributes. For more information, see [Section 5.12, "Working with List of Values \(LOV\) in View Object Attributes."](#)

You may also find it helpful to understand support for UI hints at the level of view objects. For more information about UI hints, see [Section 5.13, "Defining Attribute UI Hints for View Objects."](#)

You will need to complete this task:

Create the LOV list for the attribute as described in [Section 5.12.1, "How to Define a Single LOV-Enabled View Object Attribute."](#)

To set a UI hint to match the date format for the LOV-enabled attribute:

1. In the Application Navigator, double-click the view object.
2. In the overview editor, click the **Attributes** navigation tab.

Alternatively, display the Property Inspector for the selected attribute and click the **UI Hints** navigation tab. The Property Inspector provides a way to customize the attribute's UI hints without using the overview editor.

3. In the Attributes page, select the date-value attribute that you want to customize with UI hints, and then click the **UI Hints** tab.
4. In the UI Hints section, select **Simple Date** for the **Format Type** and choose the format with the date only mask.

Mapping of the ADF Business Components domain type to its available formatters is provided in the `formatinfo.xml` file in the BC4J subdirectory of the JDeveloper system directory (for example, `C:\Documents and Settings\\Application Data\JDeveloper\system<version#>\o.BC4J.\formatinfo.xml`).

5.12.7 How to Automatically Refresh the View Object of the View Accessor

If you need to ensure that your view accessor always queries the latest data from the database table, you may be able to set the **Auto Refresh** property on the data source

view object. This property allows the view object instance to refresh itself after a change in the database. You can enable this feature for any view instance that your application modules define. Once you enable this property on a view object, it ensures that changes a user commits to a database table will become available to any other user working with the same database table. A typical use case is to enable auto refresh for the data source view object when you define a view accessor for a LOV-enabled view object attribute.

Because the auto-refresh feature relies on the database change notification feature, observe these restrictions when enabling auto-refresh for your view object:

- The view objects should query as few read-only tables as possible. This will ensure the best performance and prevent the database invalidation queue from becoming too large.
- The application module that contains updateable, auto-refresh view instances must be configured to lock rows during updates.
- The database user must have database notification privileges. For example, to accomplish this with a SQL*Plus command use `grant change notification to <user name>`.

When you enable auto refresh for the view object, at runtime, prior to executing the view object query, the framework will use the JDBC API to register the view object query to receive Oracle database change notifications for underlying data changes. When the view object receives a notification (because its underlying data has changed), the row sets of the view object are marked as dirty and the framework will refresh the row set on the next server trip from the client to the middle tier. At that point, the dirty collections will be discarded and the request for the updated data will trigger a new query execution by the view object. For example, assume that a user can create or edit a calendar entry but cannot edit calendar entries added by other users. When the user creates a new entry, then in the same server trip the calendar entries that other users modified or entered will be updated. But when another user creates a calendar entry, the view object receives a notification and waits for the next server trip before it refreshes itself; the delay to perform the update prevents contention among various users to read the same data.

Best Practice: Use optimistic row locking for web applications. Optimistic locking, the default configuration setting, assumes that multiple transactions can complete without affecting each other. Optimistic locking therefore allows auto-refresh to proceed without locking the rows being refreshed. Pessimistic row locking, prevents the row set refresh and causes the framework to throw an exception anytime the row set has a transaction pending (for example, a user may be in the process of adding a new row). To ensure that the application module configuration uses optimistic row locking, open the **Properties** tab of the Business Components Configuration dialog and confirm the property `jbo.locking.mode` is set to `optimistic`.

Before you begin:

It may be helpful to have an understanding of LOV-enabled attributes. For more information, see [Section 5.12, "Working with List of Values \(LOV\) in View Object Attributes."](#)

To register a view object to receive data change notifications:

1. In the Application Navigator, double-click the view object that you want to receive database change notifications.
2. In the Property Inspector expand the **Tuning Database Retrieve** section, and select **True** for the **Auto Refresh** property.

5.12.8 How to Test LOV-Enabled Attributes Using the Oracle ADF Model Tester

To test the LOV you created for a view object attribute, use the Oracle ADF Model Tester, which is accessible from the Application Navigator.

The Oracle ADF Model Tester, for any view object instance that you browse, will display any LOV-enabled attributes using one of two component types you can select in the UI Hints page of the List of Values dialog. Currently, only a Choice List component type and Input Text with List of Values component type are supported. Otherwise, the Oracle ADF Model Tester uses the default choice list type to display the LOV-enabled attribute.

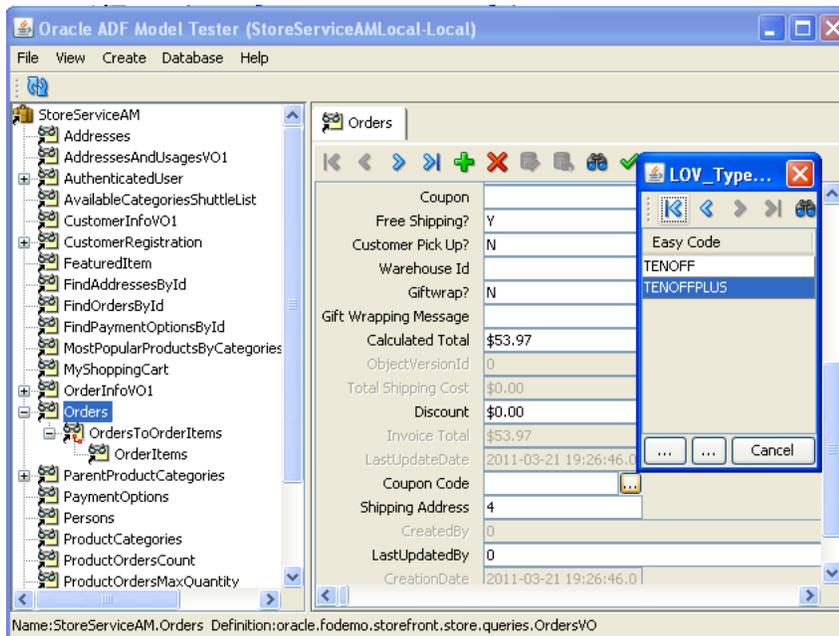

Before you begin:

It may be helpful to have an understanding of LOV-enabled attributes. For more information, see [Section 5.12, "Working with List of Values \(LOV\) in View Object Attributes."](#)

To test an LOV using the Oracle ADF Model Tester:

1. In the Application Navigator, expand the project containing the desired application module and view objects.
2. Right-click the application module and choose **Run**.
3. In the Select Business Components Configuration dialog, select the desired application module configuration from the **Configuration Name** list to run the Oracle ADF Model Tester.
4. Click **Connect** to start the application module using the selected configuration.
5. In the Oracle ADF Model Tester, select the desired view object from the section on the left. The Oracle ADF Model Tester displays the LOV-enabled attribute values in a dropdown list unless you specified the component type as an Input Text with List of Value, UI hint.

[Figure 5–44](#) shows an LOV-enabled attribute, `TypeCouponCode` for the `OrdersVO`, that specifies an input text field and List of Values dialog as the UI hint list type. The Input Text with List of Values component is useful when you want to display the choices in a separate LOV dialog. Other list types are not supported by the Oracle ADF Model Tester.

Figure 5–44 Displaying LOV-Enabled Attributes in the Oracle ADF Model Tester

5.12.9 What Happens When You Define an LOV for a View Object Attribute

When you define an LOV for a view object attribute, the view object metadata defines the following additional information, as shown in [Example 5–37](#) for the `OrdersVO`. `TypedCouponCode` attribute in the Fusion Order Demo application.

- The `<ViewAttribute>` element names the attribute, points to the list binding element that defines the LOV behavior, and specifies the component type to display in the web page. For example, the LOV-enabled attribute `TypedCouponCode` points to the list binding named `LOV_TypedCouponCode` and defines the `CONTROLTYPE` input text field with list (`input_text_lov`) to display the LOV data.

When the user interface designer creates the web page using the Data Controls panel, the `<CONTROLTYPE Value="namedType" />` definition determines the component that JDeveloper will add to the web page. When the component type definition in the data model project does not match the component type displayed in the web page, a runtime exception will result. For more information, see [Section 5.12.10, "What Happens at Runtime: How an LOV Queries the List Data Source."](#)

- The `<ListBinding>` element defines the behavior of the LOV. It also identifies a view accessor to access the data source for the LOV-enabled attribute. The view accessor is the ADF Business Components mechanism that lets you obtain the full list of possible values from the row set of the data source view object. For example, `ListVOName="Coupon"` points to the `Coupons` view accessor, which accesses the view object `CouponsVO`.
- The `<ListBinding>` element maps the list data source attribute to the LOV-enabled attribute. For example, the `ListAttrNames` item `EasyCode` is mapped to the LOV-enabled attribute `TypedCouponCode`.
- Optionally, the `<ListBinding>` element defines supplemental values that the data source may return to attributes of the base view object other than the data source attribute for which the list is defined. For example, `DerivedAttrNames`

item `CouponId` is a supplemental value set by the `ListAttrNames` item `DiscountId`.

- The `<ListBinding>` element also identifies one or more attributes to display from the current row and provides a few options that are specific to the choice list type component. For example, the `ListDisplayAttrNames` item `EasyCode` is the only attribute displayed by the LOV-enabled attribute `TypedCouponCode`. In this example, the value `none` for `NullValueFlag` means the user cannot select a blank item from the list.

Example 5-37 View Object MetaData For LOV-Attribute Usage

```
<ViewAttribute
  Name="TypedCouponCode"
  LOVName="LOV_TypedCouponCode"
  . . .
  <Properties>
    <SchemaBasedProperties>
      <CONTROLTYPE Value="input_text_lov"/>
    </SchemaBasedProperties>
  </Properties>
</ViewAttribute>
. . .
<ListBinding
  Name="LOV_TypedCouponCode"
  ListVOName="Coupons"
  ListRangeSize="-1"
  NullValueFlag="none"
  NullValueId="LOV_TypedCouponCode_NullValueId"
  MRUCount="0">
  <AttrArray Name="AttrNames">
    <Item Value="TypedCouponCode"/>
  </AttrArray>
  <AttrArray Name="DerivedAttrNames">
    <Item Value="CouponId"/>
  </AttrArray>
  <AttrArray Name="ListAttrNames">
    <Item Value="EasyCode"/>
    <Item Value="DiscountId"/>
  </AttrArray>
  <AttrArray Name="ListDisplayAttrNames">
    <Item Value="EasyCode"/>
  </AttrArray>
</ListBinding>

. . .
<ViewAccessor
  Name="Coupons"
  ViewObjectName="oracle.fodemo.storefront.store.queries.CouponsVO"/>
```

5.12.10 What Happens at Runtime: How an LOV Queries the List Data Source

The ADF Business Components runtime adds view accessors in the attribute setters of the view row and entity object to facilitate the LOV-enabled attribute behavior. In order to display the LOV-enabled attribute values in the user interface, the LOV facility fetches the data source, and finds the relevant row attributes and mapped target attributes.

The number of data objects that the LOV facility fetches is determined in part by the `ListRangeSize` setting in the LOV-enabled attribute's list binding definition which

is specified in the Edit List of Values dialog that you display on the attribute from the view object overview editor. If the number of records fetched is very large, the default value for `ListRangeSize` may truncate the values available to the dropdown list component used to display the records. The default number of fetched records for LOV queries depends on the type of list component used to display the records. In the case of the Combo Box with List of Values component and the Input Text with List of Values component, the default value for `ListRangeSize` is 10. In the case of all other types of list components that you can select (including choice list, combo box, list box, and radio button group), the default value for `ListRangeSize` is set to -1. The value -1 means that the user will be able to view all the data objects from the data source. The `ListRangeSize` value has no effect on the records that the end user can search on in the lookup dialog displayed for the two List of Values type components. For more information about how each list component displays values, see [Section 5.12.5, "How to Set User Interface Hints on a View Object LOV-Enabled Attribute."](#)

Note that although you can alter the `ListRangeSize` value in the metadata definition for the `<ListBinding>` element, setting the value to a discrete number of records (for example, `ListRangeSize="5"`) most likely will not provide the user with the desired selection choices. Instead, if the value is -1 (default for simple list components without a LOV dialog), then no restrictions are made to the number of records the list component will display, and the user will have access to the full set of values.

Performance Tip: To limit the set of values a LOV displays, use a view accessor to filter the LOV binding, as described in [Section 5.12.1, "How to Define a Single LOV-Enabled View Object Attribute."](#) Additionally, in the case of component types that display a choice list, you can change the **Most Recently Used Count** setting to limit the list to display the user's previous selections, as described in [Section 5.12.5, "How to Set User Interface Hints on a View Object LOV-Enabled Attribute."](#)

Note, a runtime exception will occur when a web page displays a UI component for an LOV-enabled attribute that does not match the view object's `CONTROLTYPE` definition. When the user interface designer creates the page in JDeveloper using the Data Controls panel, JDeveloper automatically inserts the list component identified by the **Default List Type** selection you made for the view object's LOV-enabled attribute in the List UI Hint dialog. However, if the user interface designer changes the list type subsequent to creating the web page, you will need to edit the selection in the List UI Hint dialog to match.

5.12.11 What You May Need to Know About Lists

There are several things you may need to know about LOVs that you define for attributes of view objects, including how to propagate LOV-enabled attributes from parent view objects to child view objects (by extending an existing view object) and when to use validators instead of an LOV to manage a list of values.

5.12.11.1 Inheritance of AttributeDef Properties from Parent View Object Attributes

When a view object extends another view object, you can create the LOV-enabled attribute on the base object. Then when you define the child view object in the overview editor, the LOV definition will be visible on the corresponding view object attribute. This inheritance mechanism allows you to define an LOV-enabled attribute once and later apply it across multiple view objects instances for the same attribute.

You can also use the overview editor to extend the inherited LOV definition. For example, you may add extra attributes already defined by the base view object's query to display in selection list. Alternatively, you can define a view object that uses a custom WHERE clause to query the supplemental attributes not already queried by the based view object. For information about customizing entity-based view objects, see [Section 5.10, "Working with Bind Variables."](#)

5.12.11.2 Using Validators to Validate Attribute Values

If you have created an LOV-enabled attribute for a view object, there is no need to validate the attribute using a List Validator. You only use an attribute validator when you do not want the list to display in the user interface, but still need to restrict the list of valid values. List validation may be a simple static list or it may be a list of possible values obtained through a view accessor you define. Alternatively, you might prefer to use Key Exists validation when the attribute displayed in the UI is one that references a key value (such as a primary, foreign, or alternate key). For information about declarative validation in ADF Business Components, see [Chapter 7, "Defining Validation and Business Rules Declaratively."](#)

5.13 Defining Attribute UI Hints for View Objects

One of the built-in features of ADF Business Components is the ability to define control hints on attributes. Control hints are additional attribute settings that the view layer can use to automatically display the queried information to the user in a consistent, locale-sensitive way. JDeveloper stores the hints in resource bundle files that you can easily localize for multilingual applications.

5.13.1 How to Add Attribute UI Hints

To create UI hints for attributes of a view object, use the overview editor for the view object, which is accessible from the Application Navigator. You can also display and edit UI hints using the Property Inspector that you display for an attribute.

Before you begin:

It may be helpful to have an understanding of attribute UI hints. For more information, see [Section 5.13, "Defining Attribute UI Hints for View Objects."](#)

You will need to complete this task:

Create the desired view objects as described in [Section 5.2.1, "How to Create an Entity-Based View Object,"](#) and [Section 5.2.3, "How to Create an Expert Mode, Read-Only View Object."](#)

To customize view object attribute with UI hints:

1. In the Application Navigator, double-click the view object.
2. In the overview editor, click the **Attributes** navigation tab.

Alternatively, display the Property Inspector for the selected attribute and click the **UI Hints** navigation tab. The Property Inspector provides a way to customize the attribute's control hints without using the overview editor.

3. In the Attributes page, select the attribute that you want to customize with UI hints, and then click the **UI Hints** tab and define the desired hints.

For example, for an attribute `USERID`, you might enter a value for its **Label Text** hint like "Id" or set the **Format Type** to Number, and enter a **Format** mask of 00000.

Note: Java defines a standard set of format masks for numbers and dates that are different from those used by the Oracle database's SQL and PL/SQL languages. For reference, see the Javadoc for the `java.text.DecimalFormat` and `java.text.SimpleDateFormat` classes.

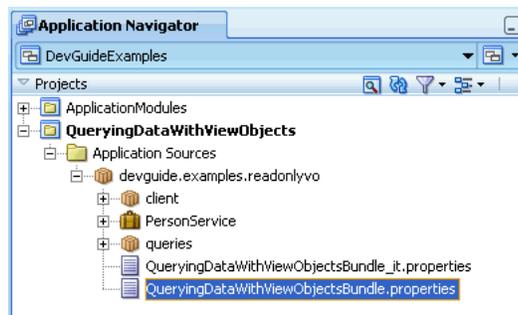

5.13.2 What Happens When You Add Attribute UI Hints

When you define attribute UI hints for a view object, by default JDeveloper creates a project-level resource bundle file in which to store them. For example, when you define control hints for a view object in the `StoreFront` project, JDeveloper creates the message bundle file named `StoreFrontBundle.xxx` for the package. The hints that you define can be used by generated forms and tables in associated view clients.

The type of resource bundle file that JDeveloper uses and the granularity of the file are determined by settings on the Resource Bundle page of the Project Properties dialog. By default, JDeveloper sets the option to **Properties Bundle** and generates one `.properties` file for the entire data model project.

Alternatively, if you select the option in the Project Properties dialog to generate one resource bundle per file, you can inspect the message bundle file for any view object by selecting the object in the Application Navigator and looking under the corresponding **Sources** node in the Structure window. The Structure window shows the implementation files for the component you select in the Application Navigator. You can inspect the resource bundle file for the view object by expanding the parent package of the view object in the Application Navigator, as shown in [Figure 5–45](#).

Figure 5–45 Resource Bundle File in Application Navigator

For more information on the resource bundle options you can select, see [Section 4.7.1, "How to Set Message Bundle Options."](#)

[Example 5–38](#) shows a sample message bundle file where the UI hint information appears. The first entry in each `String` array is a message key; the second entry is the locale-specific `String` value corresponding to that key.

Example 5–38 Resource File with Locale-Sensitive UI Hints

```
devguide.examples.readonlyvo.queries.Persons.PersonId_FMT_FORMATTER=
    oracle.jbo.format.DefaultNumberFormatter
devguide.examples.readonlyvo.queries.Persons.PersonId_FMT_FORMAT=00000
devguide.examples.readonlyvo.queries.Persons.PersonId_LABEL=Id
devguide.examples.readonlyvo.queries.Persons.Email_LABEL=Email Address
devguide.examples.readonlyvo.queries.Persons.LastName_LABEL=Surname
devguide.examples.readonlyvo.queries.Persons.FirstName_LABEL=Given Name
```

5.13.3 How to Define UI Category Hints

UI categories provide the means to group attributes that a view object defines. The category names that you create are identifiers to be used by the dynamic rendering user interface to group attributes for display. The user interface will render the attribute with other attributes of the same category. You can use the category hint to aid the user interface to separate a large list of view object attributes into smaller groups related by categories.

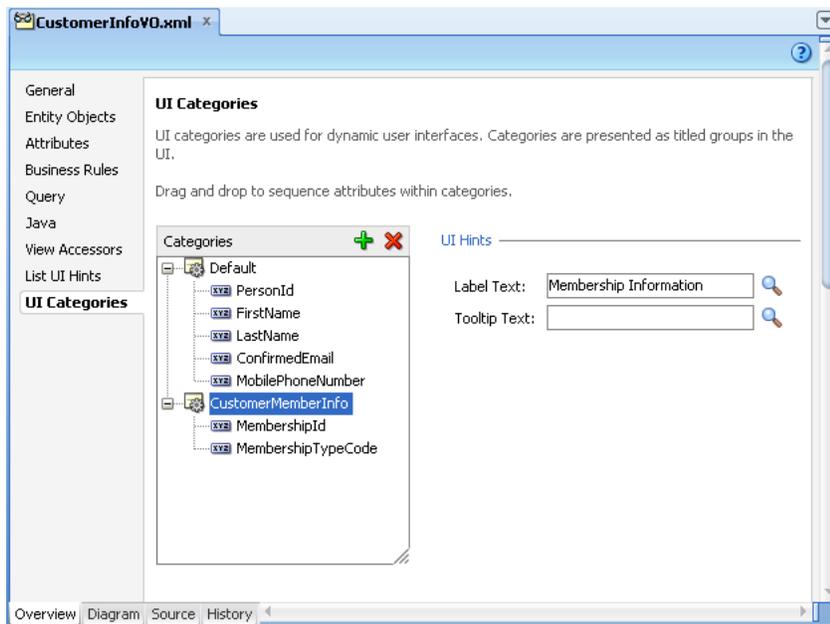

Additionally, you can specify the field order hint to reorder how the user interface will render the attribute values within its category. For example, if a view object defines four attributes `attributeA`, `attributeB`, `attributeC`, and `attributeD` and you specify the field order 4, 3, 2, and 1 respectively for each attribute, then wherever the user interface renders the category, the attributes of that category will appear in the order `attributeD`, `attributeC`, `attributeB`, and `attributeA`.

Note: Use the UI Categories page in the overview editor for the view object to change the order of the attributes listed within a category you've created. JDeveloper automatically assigns and maintains the field order values of the attributes based on their order in the list, and you do not need to edit numeric values to define the field order hint.

The category and field order hints will be utilized by any dynamic rendering user interface that displays the attribute, including dynamic forms and search forms:

- In the case of dynamic forms, the attributes from each category will appear in a separate tab.
- In the case of search forms, the order of the form's individual view criteria is determined by the field order assigned to the attribute upon which the view criteria items are based.

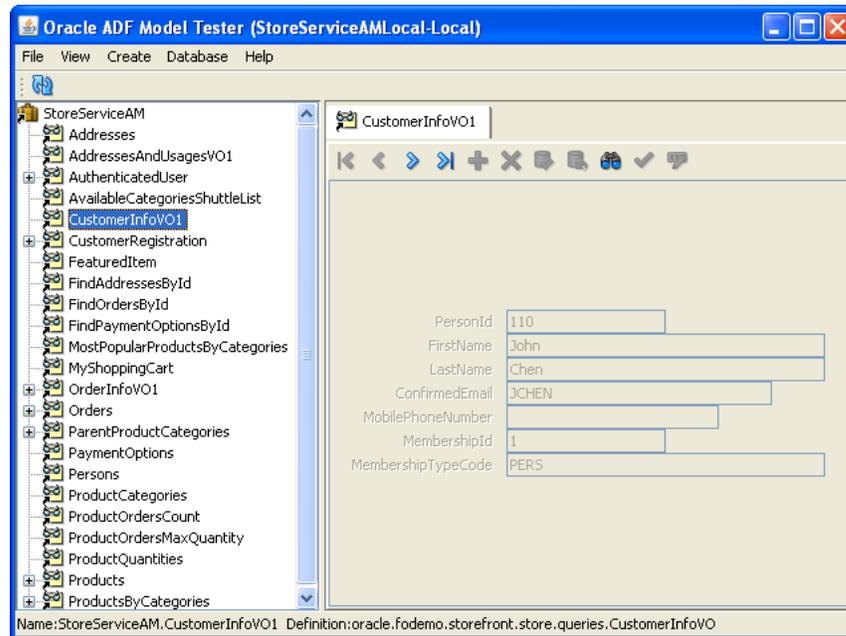

To create UI categories for attributes of a view object, use the overview editor for the view object, which is accessible from the Application Navigator. You can create and edit categories for the entire view object using the UI Categories page, as shown in [Figure 5-46](#).

Figure 5–46 Attribute UI Categories in View Object Overview Editor

When you assign a view object attribute to a category that you create in the UI Categories page, the order of the attributes displayed in the category list determines its numeric field order. The UI Categories page lets you change the field order of the attributes you've assigned to a category by dragging and dropping attributes within the list. When you drag and drop the attributes into the list, JDeveloper automatically maintains the correct sequence of the field order hints within the category. In the editor for the view object, you can view the assigned category name and field order value of individual attributes in the **UI Hints** tab of the Attributes page. JDeveloper synchronizes the **UI Hints** tab definitions with the changes you make in the UI Categories page.

Each category can have a label and tooltip text string resource to be utilized by the user interface when the category is rendered. You can localize these resource strings in the resource bundle file that you select to store the entries. For example, [Figure 5–47](#) shows the attributes `MembershipId` and `MembershipTypeCode` with labels **Membership ID** and **Membership Type Code** in a category with the label **Membership Information**.

Figure 5–47 UI Categories Displayed in Oracle ADF Model Tester

**Before you begin:**

It may be helpful to have an understanding of attribute UI hints. For more information, see [Section 5.13, "Defining Attribute UI Hints for View Objects."](#)

You will need to complete this task:

Create the desired view objects, as described in [Section 5.2.1, "How to Create an Entity-Based View Object,"](#) and [Section 5.2.3, "How to Create an Expert Mode, Read-Only View Object."](#)

To create user interface categories and reorder the attributes for display:

1. In the Application Navigator, double-click the view object.
2. In the overview editor, click the **UI Categories** navigation tab.
3. In the UI Categories page, click the **Create New Category** button to create the category and then right-click the new category and choose **Rename**.
4. In the Rename dialog, enter the name of the category.
5. In the overview editor, in the **UI Hints** section, enter the user interface **Label Text** and **Tooltip Text** for the category.

The text that you enter will be added to the default resource bundle file for the project, as described in [Section 5.13.2, "What Happens When You Add Attribute UI Hints."](#) To select a different resource bundle file to store the label and tooltip strings, click the browse (. . .) button beside the text field.

6. In the **Categories** list, expand the **Default** category and scroll the list of attributes to locate the attribute you want to add to a category.

The **Default** category displays all the attributes that the view object you are editing defines. This category is displayed only by the overview editor as a selection list for the creation of UI Category hints and is not used as a category to render attributes in the user interface.

7. Select the desired attribute and drag it into the new category you created. If the category contains more than one attribute, the position of the attribute that you drop into the list will determine its field order value.

JDeveloper automatically assigns a numeric value to the field order hint based on the sequence of the attributes that appear within a UI Category list. The attribute you place at the top of a category list will be rendered by the user interface first, the attribute second in the list will be rendered second, and so on.

8. To view the field order hint for the attribute, in the overview editor, click the **Attributes** navigation tab, select the attribute in the page, and then click the **UI Hints** tab.

Tip: Do not edit the field order hint in the **UI Hints** tab; instead, use the UI Categories page of the view object editor to reorder the attributes in the list by dragging and dropping them. You can also right-click an attribute within a category list and choose **Move Up**, **Move Down**, or **Move to Category** to change the field order within the categories.

The field order hint does not appear in the overview editor UI Categories page. The hint value is visible in the source for the view object definition or in the **UI Hints** tab that you display in the view object editor for a specific attribute.

5.13.4 What Happens When You Assign Attributes to UI Categories

When you define attribute UI categories for a view object, JDeveloper updates the view object's XML component definition file. JDeveloper adds the `CATEGORY` and the `FIELDORDER` UI hints in the `<SchemaBasedProperties>` element of the `<ViewAttribute>` element. The definition of the categories appears in a new `<Category>` element.

The metadata in [Example 5–39](#) shows that the `PersonId` attribute's `CATEGORY` hint refers to the `AccountInformation` category and the `FirstName` attribute's `CATEGORY` hint refers to the `UserInformation` category. The definition for both categories appears in `<Category>` elements. The `FIELDORDER` hint for each attribute specifies a numeric value, which JDeveloper assigns and maintains based on the order of the attributes in the UI categories lists you create in the overview editor. As shown in [Example 5–39](#), the `FIELDORDER` hint is a decimal value. A decimal value is used by JDeveloper to allow you to insert new attributes into a category without requiring JDeveloper to change all the existing attribute values and still be able to maintain the correct order.

Note that the default field order value for the first attribute in a category is assigned by JDeveloper as `0.0`. The field order value can be changed to any number to sort the category list, and it is not an index. The field order numeric values do not need to be contiguous.

Example 5–39 View Object MetaData for Attribute UI Category Hints

```
<Category
  Name="AccountInformation">
  <Properties>
    <SchemaBasedProperties>
      <LABEL
        ResId="CUSTOMER_DETAILS" />
      <TOOLTIP
        ResId="AccountInformation_TOOLTIP" />
```

```

        </SchemaBasedProperties>
    </Properties>
</Category>
<Category
    Name="UserInformation">
    <Properties>
        <SchemaBasedProperties>
            <TOOLTIP
                ResId="UserInformation_TOOLTIP" />
            <LABEL
                ResId="CUSTOMER_DETAILS" />
        </SchemaBasedProperties>
    </Properties>
</Category>
...
<ViewAttribute
    Name="PersonId"
    IsNotNull="true"
    PrecisionRule="true"
    EntityAttrName="PersonId"
    EntityUsage="Person"
    AliasName="PERSON_ID">
    <Data>
        <Property
            Name="OWNER_SCOPE"
            Value="INSTANCE" />
        ...
    </Data>
    <Properties>
        <SchemaBasedProperties>
            <CATEGORY
                Value="AccountInformation" />
            <FIELDORDER
                Value="0.0" />
        </SchemaBasedProperties>
    </Properties>
</ViewAttribute>
...
<ViewAttribute
    Name="FirstName"
    PrecisionRule="true"
    EntityAttrName="FirstName"
    EntityUsage="Person"
    AliasName="FIRST_NAME">
    <Data>
        <Property
            Name="OWNER_SCOPE"
            Value="INSTANCE" />
        ...
    <Properties>
        <SchemaBasedProperties>
            <CATEGORY
                Value="UserInformation" />
            <FIELDORDER
                Value="0.0" />
        </SchemaBasedProperties>
    </Properties>
</ViewAttribute>

```

5.13.5 What You May Need to Know About Resource Bundles

Internationalizing the model layer of an application built using ADF Business Components entails producing translated versions of each component's resource bundle file. For example, the Italian version of the `QueryDataWithViewObjectsBundle.properties` file would be a file named `QueryDataWithViewObjectsBundle_it.properties`, and a more specific *Swiss* Italian version would have the name `QueryDataWithViewObjectsBundle_it_ch.properties`.

Resource bundle files contain entries for the message keys that need to be localized, together with their localized translation. For example, assuming you didn't want to translate the number format mask for the Italian locale, the Italian version of the `QueryDataWithViewObjects` view object message keys would look like what you see in [Example 5–40](#). At runtime, the resource bundles are used automatically, based on the current user's locale settings.

Example 5–40 Localized View Object Component Resource Bundle for Italian

```
devguide.examples.readonlyvo.queries.Persons.PersonId_FMT_FORMATTER=
                                oracle.jbo.format.DefaultNumberFormatter
devguide.examples.readonlyvo.queries.Persons.PersonId_FMT_FORMAT=00000
devguide.examples.readonlyvo.queries.Persons.PersonId_LABEL=Codice Utente
devguide.examples.readonlyvo.queries.Persons.Email_LABEL=Indirizzo Email
devguide.examples.readonlyvo.queries.Persons.LastName_LABEL=Cognome
devguide.examples.readonlyvo.queries.Persons.FirstName_LABEL=Nome
```

5.14 Adding Calculated and Transient Attributes to a View Object

In addition to having attributes that map to underlying entity objects, your view objects can include calculated attributes that don't map to any entity object attribute value. The two kinds of calculated attributes are known as:

- *SQL-calculated attributes*, when their value is retrieved as an expression in the SQL query's SELECT list
- *Transient attributes*, when their value is not retrieved as part of the query

A view object can include an entity-mapped attribute which itself is a transient attribute at the entity object level.

5.14.1 How to Add a SQL-Calculated Attribute

You use the overview editor for the view object to add a SQL-calculated attribute.

Before you begin:

It may be helpful to have an understanding of calculated attributes. For more information, see [Section 5.14, "Adding Calculated and Transient Attributes to a View Object."](#)

You will need to complete this task:

Create the desired view objects as described in [Section 5.2.1, "How to Create an Entity-Based View Object,"](#) and [Section 5.2.3, "How to Create an Expert Mode, Read-Only View Object."](#)

To add a SQL-calculated attribute to a view object:

1. In the Application Navigator, double-click the view object for which you want to define a SQL-calculated attribute.

2. In the overview editor, click the **Attributes** navigation tab and click the **Create new attribute** button.
3. In the New View Object Attribute dialog, enter a name for the attribute.
4. Set the Java attribute type to an appropriate value.
5. Select the **Mapped to Column or SQL** checkbox.
6. Provide a SQL expression in the **Expression** field.

For example, to change the order of first name and last name, you could write the expression `LAST_NAME || ' , ' || FIRST_NAME`, as shown in [Figure 5–48](#).

Figure 5–48 *New SQL-Calculated Attribute*

7. Consider changing the SQL column alias to match the name of the attribute.
8. Verify the database query column type and adjust the length (or precision/scale) as appropriate.
9. Click **OK**.

5.14.2 What Happens When You Add a SQL-Calculated Attribute

When you add a SQL-calculated attribute in the overview editor for the view object, JDeveloper updates the XML component definition for the view object to reflect the new attribute. The entity-mapped attribute's `<ViewAttribute>` tag looks like the sample shown in [Example 5–41](#). The entity-mapped attribute inherits most of its properties from the underlying entity attribute to which it is mapped.

Example 5–41 *Metadata For Entity-Mapped Attribute*

```
<ViewAttribute
  Name="LastName"
  IsNotNull="true"
  EntityAttrName="LastName"
  EntityUsage="User1"
  AliasName="LAST_NAME" >
</ViewAttribute>
```

Whereas, in contrast, a SQL-calculated attribute's `<ViewAttribute>` tag looks like sample shown in [Example 5–42](#). As expected, the tag has no `EntityUsage` or `EntityAttrName` property, and includes datatype information along with the SQL expression.

Example 5–42 Metadata For SQL-Calculated Attribute

```
<ViewAttribute
  Name="LastCommaFirst"
  IsUpdatable="false"
  IsPersistent="false"
  Precision="62"
  Type="java.lang.String"
  ColumnType="VARCHAR2"
  AliasName="FULL_NAME"
  Expression="LAST_NAME || '&#39;;, &#39; || FIRST_NAME"
  SQLType="VARCHAR" >
</ViewAttribute>
```

Note: The `'` is the XML character reference for the apostrophe. You reference it by its numerical ASCII code of 39 (decimal). Other characters in literal text that require similar construction in XML are the less-than, greater-than, and ampersand characters.

5.14.3 How to Add a Transient Attribute

Transient attributes are often used to provide subtotals or other calculated expressions that are not stored in the database.

Before you begin:

It may be helpful to have an understanding of transient attributes. For more information, see [Section 5.14, "Adding Calculated and Transient Attributes to a View Object."](#)

You will need to complete this task:

Create the desired view objects as described in [Section 5.2.1, "How to Create an Entity-Based View Object,"](#) and [Section 5.2.3, "How to Create an Expert Mode, Read-Only View Object."](#)

To add a transient attribute to a view object:

1. In the Application Navigator, double-click the view object for which you want to define a transient attribute.
2. In the overview editor, click the **Attributes** navigation tab and click the **Create new attribute** button.
3. In the New View Object Attribute dialog, enter a name for the attribute and click **OK**.
4. In the Attributes page of the overview editor, select the new attribute, and then click the **Details** tab and verify that **Transient** appears selected.
5. In the Details section, change **Type** to an appropriate Java type.

For example, a calculated attribute that concatenates a first name and a last name would have the type `String`, as shown in [Figure 5–49](#).

Figure 5–49 New Transient Attribute

To create a transient attribute based on an expression:

1. In the Application Navigator, double-click the view object for which you want to define a transient attribute.
2. In the overview editor, click the **Attributes** navigation tab and click the **Create new attribute** icon.
3. In the New View Object Attribute dialog, enter a name for the attribute and click **OK**.
4. In the Attributes page of the overview editor, select the new attribute, and then click the **Details** tab and verify that **Transient** appears selected.
5. In the Details section, change **Type** to an appropriate Java type.
6. For the **Default Value**, select **Expression** and click **Edit value** to define an expression that calculates the value of the attribute.

Expressions you define will be evaluated using the Groovy Expression Language. Groovy lets you insert expressions and variables into strings. The expression will be saved as part of the view object definition. For more information about Groovy, see [Section 3.6, "Overview of Groovy Scripting Language Support."](#)

7. In the Edit Expression dialog, enter an expression in the field provided.

Attributes that you reference can include any attribute that the base entity objects define. Do not reference attributes in the expression that are not defined by the view object's underlying entity objects.

8. Select the appropriate recalculate setting.

If you select **Always** (default), the expression is evaluated each time any attribute in the row changes. If you select **Never**, the expression is evaluated only when the row is created.

9. You can optionally provide a condition for when to recalculate the expression.

For example, the following expression in the **Based on the following expression** field causes the attribute to be recalculated when either the `Quantity` attribute or the `UnitPrice` attribute are changed:

```
return (adf.object.isAttributeChanged("Quantity") ||
adf.object.isAttributeChanged("UnitPrice"));
```

10. When either the value expression or the optional recalculate expression that you define references an attribute from the base entity object, you must define this as a dependency in the Edit Expression dialog. Locate each attribute in the **Available** list and shuttle it to the **Selected** list.
11. Click **OK**.

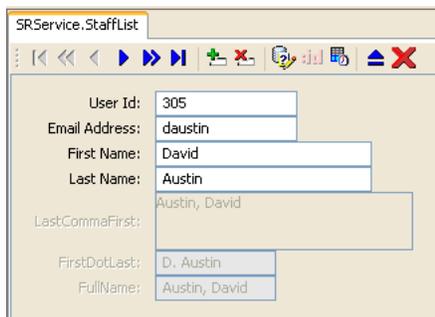

A view object can include an entity-mapped attribute which itself is a transient attribute at the entity object level.

To add a transient attribute from an entity object to an entity-based view object:

1. In the Application Navigator, double-click the view object for which you want to add a transient attribute based on an entity usage.
2. In the overview editor, click the **Attributes** navigation tab and click the dropdown menu on the **Create new attribute** icon and choose **Add Attribute from Entity** to view the list of available entity-derived attributes.
3. In the Attributes dialog, move the desired transient attribute from the **Available** list into the **Selected** list.
4. Click **OK**.

If you use the Oracle ADF Model Tester to test the data model, you can see the usage of your transient attributes. [Figure 5-50](#) shows three attributes that were created using a SQL-calculated attribute (`LastCommaFirst`), a transient attribute (`FirstDotLast`) and an entity-derived transient attribute (`FullName`).

Figure 5-50 View Object with Three Kinds of Calculated Attributes

5.14.4 How to Add a Validation Rule to a Transient Attribute

Attribute-level validation rules are triggered for a particular view object transient attribute when either the end user or the program code attempts to modify the attribute's value. Since you cannot determine the order in which attributes will be set, attribute-level validation rules should be used only when the success or failure of the rule depends exclusively on the candidate value of that single attribute.

The process for adding a validation rule to an view object transient attribute is similar to the way you create any declarative validation rule, and is done using the Add Validation Rule dialog. You can open this dialog from the overview editor for the view object by clicking the **Add Validation Rule** icon in the Validation Rules section of the Attributes page. You must first select the transient attribute from the attributes list and the transient attribute must be defined as updatable. Validation rules cannot be defined for read-only transient attributes.

Before you begin:

It may be helpful to have an understanding of attribute UI hints. For more information, see [Section 5.13, "Defining Attribute UI Hints for View Objects."](#)

You may also find it helpful to understand the different types of validation rules you can define. For more information, see [Section 7.4, "Using the Built-in Declarative Validation Rules."](#)

You will need to complete this task:

Create the desired view objects as described in [Section 5.2.1, "How to Create an Entity-Based View Object,"](#) and [Section 5.2.3, "How to Create an Expert Mode, Read-Only View Object."](#)

To add a validation rule for a transient attribute:

1. In the Application Navigator, double-click the desired view object.
2. Click the **Attributes** navigation tab on the overview editor.
3. In the Attributes page of the overview editor, select the transient attribute, and then click the **Details** tab and verify that **Updatable** displays either **While New** or **Always**.

Validation rules for transient attributes must be updatable. The value **Never** specifies a read-only attribute.

4. In the Attributes page, click the **Validation Rules** tab and then click the **Add Validation Rule** icon.
5. In the Add Validation Rule dialog, select the type of validation rule desired from the **Rule Type** dropdown list.
6. Use the dialog settings to configure the new rule.

The controls will change depending on the kind of validation rule you select. For more information about the different validation rules, see [Section 7.4, "Using the Built-in Declarative Validation Rules."](#)
7. Optionally, click the **Validation Execution** tab and enter criteria for the execution of the rule, such as dependent attributes and a precondition expression. For more information, see [Section 7.6, "Triggering Validation Execution."](#)
8. Click the **Failure Handling** tab and enter or select the error message that will be shown to the user if the validation rule fails. For more information, see [Section 7.7, "Creating Validation Error Messages."](#)
9. Click **OK**.

5.14.5 What Happens When You Add a Transient Attribute

When you add a transient attribute in the overview editor for a view object, JDeveloper updates the XML component definition for the view object to reflect the new attribute. A transient attribute's `<ViewAttribute>` tag in the XML is similar to the SQL-calculated one, but it lacks an `Expression` property.

When you base a transient attribute on a Groovy expression, a `<TransientExpression>` tag is created within the appropriate attribute, as shown in [Example 5-43](#).

Example 5-43 Calculating a Transient Attribute Using a Groovy Expression

```
<TransientExpression>
```

```
<![CDATA[
    ((Quantity == null) ? 0 : Quantity) * ((UnitPrice == null) ? 0 : UnitPrice)
]]>
</TransientExpression>
```

5.14.6 Adding Java Code in the View Row Class to Perform Calculation

A transient attribute is a placeholder for a data value. If you change the **Updatable** property of the transient attribute to **While New** or **Always**, the end user can enter a value for the attribute. If you want the transient attribute to display a calculated value, then you'll typically leave the **Updatable** property set to **Never** and write custom Java code that calculates the value.

After adding a transient attribute to the view object, to make it a *calculated* transient attribute you need to enable a custom view row class and choose to generate accessor methods, in the Java dialog that you open clicking the **Edit** icon on the Java page of the overview editor for the view object. Then you would write Java code inside the accessor method for the transient attribute to return the calculated value.

[Example 5-43](#) shows the `StaffListRowImpl.java` view row class contains the Java code to return a calculated value in the `getLastCommaFirst()` method.

```
// In StaffListRowImpl.java
public String getFirstDotLast() {
    // Commented out this original line since we're not storing the value
    // return (String) getAttributeInternal(FIRSTDOTLAST);
    return getFirstName().substring(0,1)+" ". +getLastName();
}
```

5.14.7 What You May Need to Know About Transient Attributes

The view object includes the SQL expression for your SQL-calculated attribute in the `SELECT` list of its query at runtime. The database is the one that evaluates the expression, and it returns the result as the value of that column in the query. The value is reevaluated each time you execute the query.

Testing View Instance Queries

This chapter describes how to interactively test view instance query results using the Oracle ADF Model Tester provided in JDeveloper. This chapter also explains how to use the Business Components API to access view object instances in a test client outside of JDeveloper.

This chapter includes the following sections:

- [Section 6.1, "About View Instance Queries"](#)
- [Section 6.2, "Creating an Application Module to Test View Instances"](#)
- [Section 6.3, "Testing View Object Instances Using the Oracle ADF Model Tester"](#)
- [Section 6.4, "Testing View Object Instances Programmatically"](#)

6.1 About View Instance Queries

JDeveloper includes an interactive application module testing tool that you can use to test all aspects of its data model without having to use your application user interface or write a test client program. Running the Oracle ADF Model Tester can often be the quickest way of exercising the data functionality of your business service during development.

Note: When you want to test an application module programmatically, you can write a test client. For more information, see [Section 6.4.2, "How to Create a Command-Line Java Test Client."](#)

6.1.1 View Instance Use Cases and Examples

Using the Oracle ADF Model Tester, you can simulate an end user interacting with your application module data model before you have started to build any custom user interface of your own. Even *after* you have your UI pages constructed, you will come to appreciate using the Oracle ADF Model Tester to assist in diagnosing problems when they arise. You can reproduce the issues in the Oracle ADF Model Tester to discover if the issue lies in the view or controller layers of the application, or is instead a problem in the business service layer application module itself.

6.1.2 Additional Functionality for View Instances

You may find it helpful to understand other ADF features before you start working with view instances. Following are links to other functionality that may be of interest.

- For details about creating a data model consisting of view object instances, see [Chapter 9, "Implementing Business Services with Application Modules."](#)

- For a quick reference to the most common code that you will typically write, use, and override in your custom ADF Business Components classes, see [Appendix D, "Most Commonly Used ADF Business Components Methods."](#)
- For API documentation related to the `oracle.jbo` package, see the following Javadoc reference document:
 - *Oracle Fusion Middleware Java API Reference for Oracle ADF Model*

6.2 Creating an Application Module to Test View Instances

Before you can test view objects that you create in your data model project, you must create an application module where you will define instances of the view objects you want to test. The application module is the transactional component that the Oracle ADF Model Tester (or UI client) will use to work with application data. The set of view objects used by an application module defines its *data model*, in other words, the set of data that a client can display and manipulate through a user interface.

To test the view objects you added to an application module, use the Oracle ADF Model Tester, which is accessible from the Application Navigator. For details about using the Oracle ADF Model Tester, see [Section 6.3, "Testing View Object Instances Using the Oracle ADF Model Tester."](#)

6.2.1 How to Create the Application Module with Individual View Object Instances

To create an application module that will define instances of individual view objects, use the Create Application Module wizard, which is available in the New Gallery.

Before you begin:

It may be helpful to have an understanding of application modules. For more information, see [Section 6.2, "Creating an Application Module to Test View Instances."](#)

You will need to complete this task:

Create the desired view objects, as described in [Section 5.2.1, "How to Create an Entity-Based View Object"](#) and [Section 5.2.3, "How to Create an Expert Mode, Read-Only View Object."](#)

To create an application module to test individual view object instances:

1. In the Application Navigator, right-click the project in which you want to create the application module and choose **New**.
2. In the New Gallery, expand **Business Tier**, select **ADF Business Components** and then **Application Module**, and click **OK**.
3. In the Items list, select **Application Module** to launch the Create Application Module wizard.
4. In the Create Application Module wizard, in the Name page, provide a package name and an application module name. Click **Next**.
5. On the Data Model page, include instances of the view objects you have previously defined and edit the view object instance names to be exactly what you want clients to see. Then click **Finish**.

Instead of accepting the default instance name shown in the Data Model page, you can change the instance name to something more meaningful (for example, instead of the default name `OrderItems1` you can rename it to `AllOrderItems`).

6.2.2 How to Create the Application Module with Master-Detail View Object Instances

You can also use the Create Application Module wizard to create a hierarchy of view objects for an application module, based on master-detail relationships that the view objects represent.

Before you begin:

It may be helpful to have an understanding of application modules. For more information, see [Section 6.2, "Creating an Application Module to Test View Instances."](#)

You will need to complete this task:

Create hierarchical relationships between view objects, as described in [Section 5.6, "Working with Multiple Tables in a Master-Detail Hierarchy."](#)

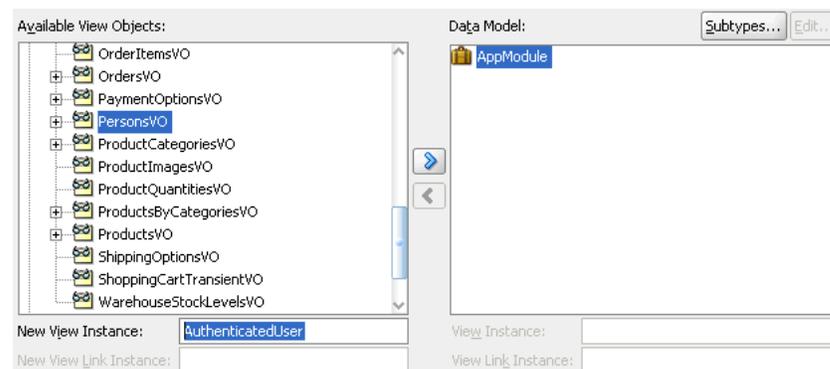

To create an application module based on view object relationships:

1. In the Application Navigator, right-click the project in which you want to create the application module and choose **New**.
2. In the New Gallery, expand **Business Tier**, select **ADF Business Components** and then **Application Module**, and click **OK**.
3. In the Items list, select **Application Module** to launch the Create Application Module wizard.
4. In the Create Application Module wizard, select the **Data Model** node.
5. In the **Available View Objects** list on the left, select the instance of the view object that you want to be the actively coordinating master.

The master view object will appear with a plus sign in the list indicating the available view links for this view object. The view link must exist to define a master-detail hierarchy.

For example, [Figure 6–1](#) shows `PersonsVO` selected and renamed `AuthenticatedUser` in the **New View Instance** field.

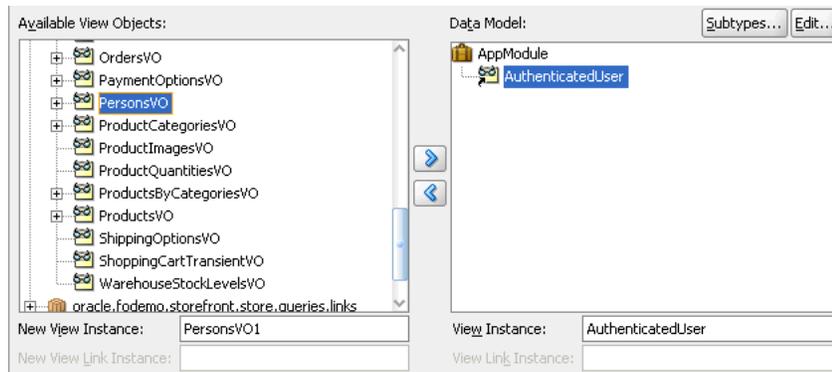

Figure 6–1 Master View Object Selected

6. Shuttle the selected master view object to the **Data Model** list

For example, [Figure 6–2](#) shows the newly created master view instance `AuthenticatedUser` in the **Data Model** list after you add it to the list.

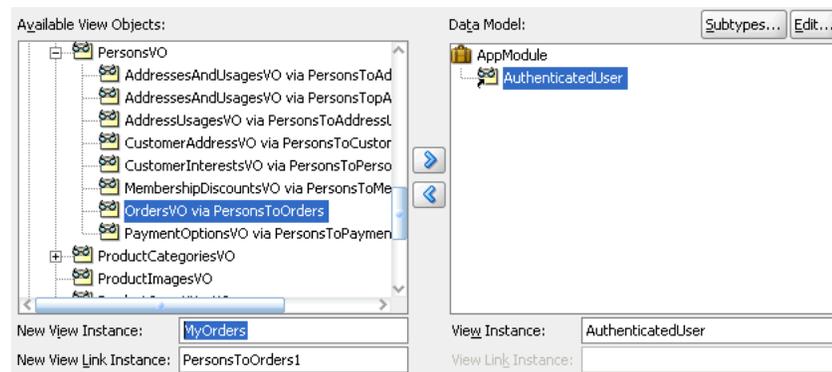

Figure 6–2 Master View Instance Created

7. In the **Data Model** list, leave the newly created master view instance selected, so that it appears highlighted. This will be the target of the detail view instance you will add. Then locate and select the detail view object beneath the master view object in the **Available View Objects** list.

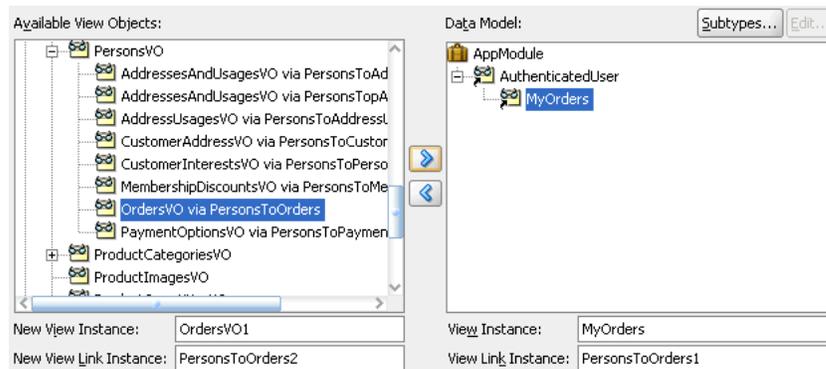

For example, [Figure 6–3](#) shows the detail `OrdersVO` indented beneath master `PersonsVO` with the name `OrdersVO via PersonsToOrders`. The name identifies the view link `PersonsToOrders`, which defines the master-detail hierarchy between `PersonsVO` and `OrdersVO`. The detail view instance is renamed to `MyOrders`.

Figure 6–3 Detail View Object Selected

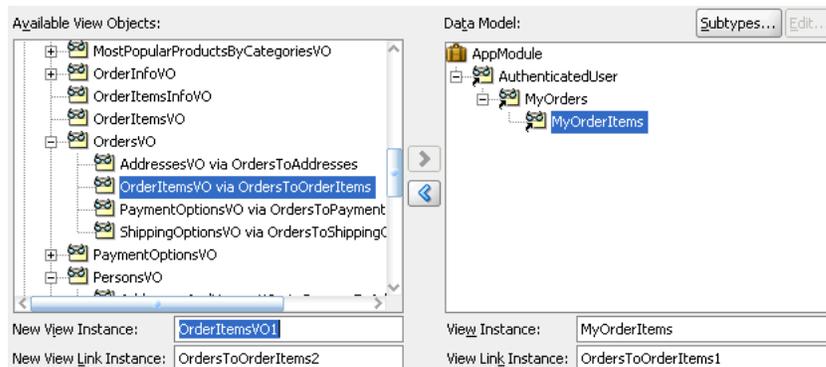

8. To add the detail instance to the previously added master instance, shuttle the detail view object to the **Data Model** list below the selected master view instance.

[Figure 6–4](#) shows the newly created detail view instance `MyOrders` is a detail of the `AuthenticatedUser` in the data model.

Figure 6–4 Master View Instance Created

9. To add another level of hierarchy, select the newly added detail in the **Data Model** list, then shuttle over the new detail which itself has a master-detail relationship with the previously added detail instance.

Your data model can contain as many levels of hierarchy as your view object relationships support. For example, [Figure 6–5](#) shows the **Data Model** list with instance `AuthenticatedUser` (renamed for `PersonsVO`) as the master of `MyOrders` (renamed for `OrdersVO via PersonsToOrders`), which in turn is a master for `MyOrderItems` (renamed from `OrderItemsVO via OrdersToOrderItems`). The detail view object `MyOrderItems` is the last level of the hierarchy possible because this view object is itself not a master for another view object.

Figure 6–5 Master-Detail-Detail Hierarchy Created

6.3 Testing View Object Instances Using the Oracle ADF Model Tester

Using the Oracle ADF Model Tester, you can simulate an end user interacting with your application module data model before you have started to build any custom user interface of your own. Even *after* you have your UI pages constructed, you will come to appreciate using the Oracle ADF Model Tester to assist in diagnosing problems when they arise. You can reproduce the issues in the Oracle ADF Model Tester to discover whether the problem lies in the view or controller layers of the application, or whether there is instead a problem in the business service layer application module itself.

6.3.1 How to Run the Oracle ADF Model Tester

To test the view objects you added to an application module, use the Oracle ADF Model Tester, which is accessible from the Application Navigator.

Before you begin:

It may be helpful to have an understanding of the Oracle ADF Model Tester. For more information, see [Section 6.3, "Testing View Object Instances Using the Oracle ADF Model Tester."](#)

To test view objects in an application module configuration:

1. In the Application Navigator, expand the project containing the desired application module and view objects.
2. Right-click the application module and choose **Run**.

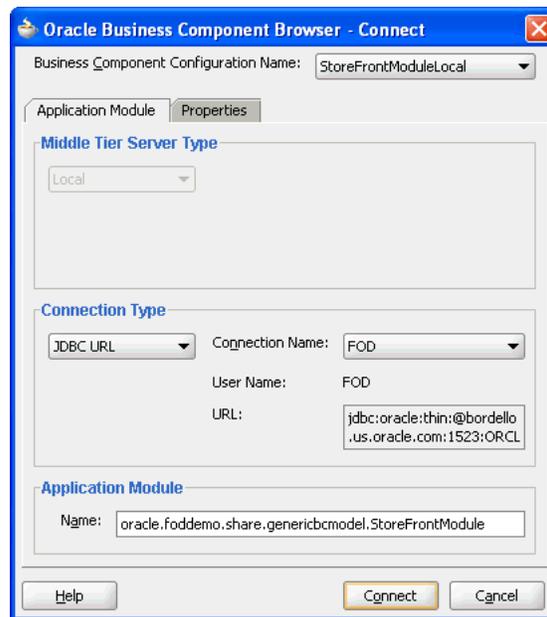

Alternatively, choose **Debug** when you want to run the application in the Oracle ADF Model Tester with debugging enabled. JDeveloper opens the debugger process panel in the Log window and the various debugger windows. For example, when debugging using the Oracle ADF Model Tester, you can view status message and exceptions, step in and out of source code, and manage breakpoints.

For information about receiving diagnostic messages specific to ADF Business Component debugging, see [Section 6.3.8, "How to Enable ADF Business Components Debug Diagnostics"](#).

3. In the Select Business Components Configuration dialog, choose the desired application module configuration from the **Business Component Configuration Name** list to run the Oracle ADF Model Tester.

By default, an application module has only its default configurations, named *AppModuleNameLocal* and *AppModuleNameShared*. For example, [Figure 6-6](#) shows the *StoreFrontModuleLocal* configuration used by the application module to connect to the database.

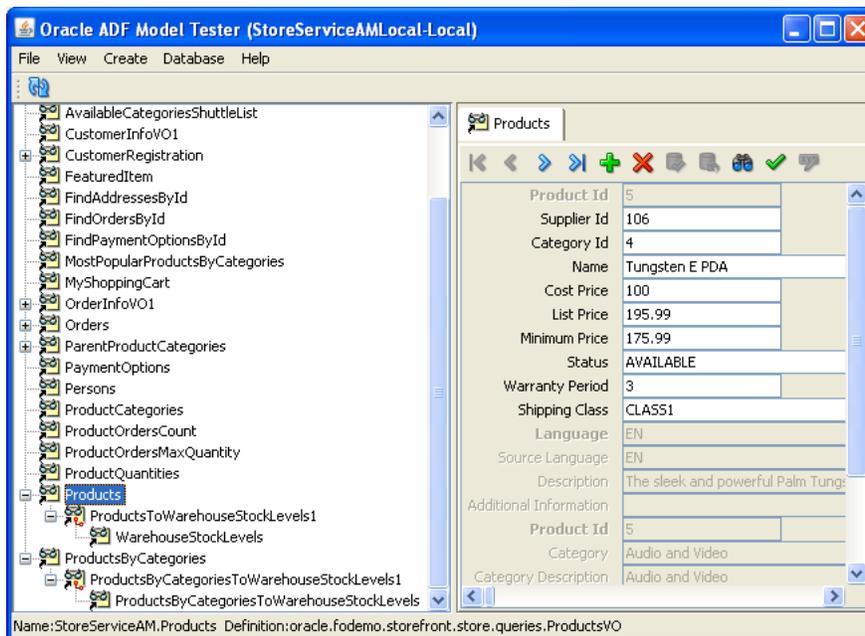

If you have created additional configurations for your application module and want to test it using one of those instead, just select the desired configuration from the **Business Component Configuration Name** dropdown list on the Configuration dialog before clicking **Connect**.

Figure 6–6 Configuration Selection in Configuration Dialog

4. Click **Connect** to start the application module using the selected configuration.
5. To execute a view object in the Oracle ADF Model Tester, expand the data model tree and double-click the desired view object node.

Note that the view object instance may already appear executed in the testing session. In this case, the Oracle ADF Model Tester data view page on the right already displays query results for the view object instance. The fields in the Oracle ADF Model Tester data view page of a read-only view object will always appear disabled since the data it represents is not editable. For example, in [Figure 6–7](#), data for the view instance `Products` appears in the tester. Fields like **Product Id**, **Language**, and **Category** appear disabled because the attributes themselves are not editable.

Figure 6–7 Testing the Data Model in the Oracle ADF Model Tester

6. Right-click a node in the data model tree at the left of the Oracle ADF Model Tester to display the context menu for that node. For example, on a view object node you can reexecute the query if needed, to remove the view object from the data model tree, and perform other tasks.
7. Right-click the tab of an open data viewer to display the context menu for that tab, as shown in Figure 6–8. For example, you can close the data viewer or open it in a separate window.

Figure 6–8 Context Menu for Data Viewer Tabs in the Oracle ADF Model Tester

6.3.2 How to Test Entity-Based View Objects Interactively

You test entity-based view objects interactively in the same way as read-only ones. Just add instances of the desired view objects to the data model of some application module, and then test that application module using the Oracle ADF Model Tester.

You'll find the Oracle ADF Model Tester invaluable for quickly testing and debugging your application modules. Table 6–1 gives an overview of the operations that the Oracle ADF Model Tester toolbar buttons perform when you display an entity-based view object.

Table 6–1 Oracle ADF Model Tester Toolbar Buttons

Button	Operation	Usage
	Move to ... row	Changes the current row displayed by the Oracle ADF Model Tester. Moves to the first, previous, next, or last row.

Table 6–1 (Cont.) Oracle ADF Model Tester Toolbar Buttons

Button	Operation	Usage
	Insert a new row	Creates and inserts a new row.
	Delete the current row	Deletes the current row.
	Save changes to the database	Posts and commits changes that you made in the ADF Business Components cache.
	Discard all changes since last save	Discards changes that you made in the ADF Business Components cache and restores the original values, rolling back any changes posted to the database.
	Specify view criteria	Displays the View Criteria dialog that you can use to create and apply view criteria to the master view object instance.
	Validate row	Validates the current row by applying validation rules defined for all entity object instances. Disabled unless at least one field is editable.
	Edit bind variables	Displays the Bind Variable dialog that you can use to enter values for bind parameters used in the view object query. Disabled unless the view object query uses bind parameters in the query statement.

To test the entity-based view objects you added to an application module, use the Oracle ADF Model Tester, which is accessible from the Application Navigator.

Before you begin:

It may be helpful to have an understanding of the Oracle ADF Model Tester. For more information, see [Section 6.3, "Testing View Object Instances Using the Oracle ADF Model Tester."](#)

To test entity-based view objects using an application module configuration:

1. Select the application module in the Application Navigator and choose **Run** from the context menu.
2. Click **Connect** on the Select Oracle ADF Model Tester Configuration dialog and use the desired configuration for testing.
3. To execute an entity-based view object in the Oracle ADF Model Tester, expand the data model tree and double-click the desired view object node.

Unlike the fields of a read-only view object, the fields displayed in the data view page will appear enabled, because the data it represents is editable.

4. You can use the editable fields to update individual values and perform validation checks on the entered data.

In the case of a view instance with referenced entities, you can change the foreign key value and observe that the referenced part changes.

5. You can use the toolbar buttons to perform row-level operations, such as navigate rows, create row, remove row, and validate the current row.

For further discussion about simulating end-user interaction in the data view page, see [Section 6.3.5, "How to Simulate End-User Interaction in the Oracle ADF Model Tester"](#).

6.3.3 How to Update the Oracle ADF Model Tester to Display Project Changes

Normally, changes that you make to the data model project will not be picked up automatically by running the Oracle ADF Model Tester. You can, however, force the Oracle ADF Model Tester to reload metadata from the data model project any time you want to synchronize the displayed data model and the data model project. This option is an alternative to quitting the Oracle ADF Model Tester, editing your project, and rerunning the Oracle ADF Model Tester to view the latest changes.

Using the **Reload Application** option saves time, especially as you work iteratively between the Oracle ADF Model Tester and JDeveloper. For example, while running the Oracle ADF Model Tester you might determine the need to modify the data model with a new view instance or you might find that a view instance is missing an LOV attribute definition. You can return to JDeveloper and use the Business Components overview editors to make the changes that alter the data model metadata. Then, after you recompile the project (a necessary step), you can return to the Oracle ADF Model Tester to reload the updated metadata from the project's class path.

Before you begin:

It may be helpful to have an understanding of the Oracle ADF Model Tester. For more information, see [Section 6.3, "Testing View Object Instances Using the Oracle ADF Model Tester."](#)

To reload the data model metadata in the running Oracle ADF Model Tester:

1. In the Application Navigator, right-click the application module and choose **Run**.
2. Test the data model and determine any changes you want to make. Do not exit the Oracle ADF Model Tester.
3. In JDeveloper, make the desired changes and recompile the data model project. (For example, you can right-click the data model project in the Application Navigator and choose **Make** to complete the recompile step.)

Although the metadata changes that you make are not involved in compiling the project, the compile step is necessary to copy the metadata to the class path and to allow the Oracle ADF Model Tester to reload it.

4. Return to the Oracle ADF Model Tester and click the **Reload the Application Metadata** button above the data model tree. The Oracle ADF Model Tester closes all open windows.

Alternatively, you can choose **Reload Application** from the **File** menu of the Oracle ADF Model Tester.

5. Reopen the desired windows and view your changes.

6.3.4 What Happens When You Use the Oracle ADF Model Tester

When you launch the Oracle ADF Model Tester, JDeveloper starts the tool in a separate process and the Oracle ADF Model Tester appears. The tree at the left of the dialog displays all of the view object instances in your application module's data model. After you double-click the desired view object instance, the Oracle ADF Model Tester will display a data view page to inspect the query results. For example, [Figure 6-7](#) shows the view instance `Products` that has been double-clicked in the

expanded tree to display the data for this view instance in the data view page on the right.

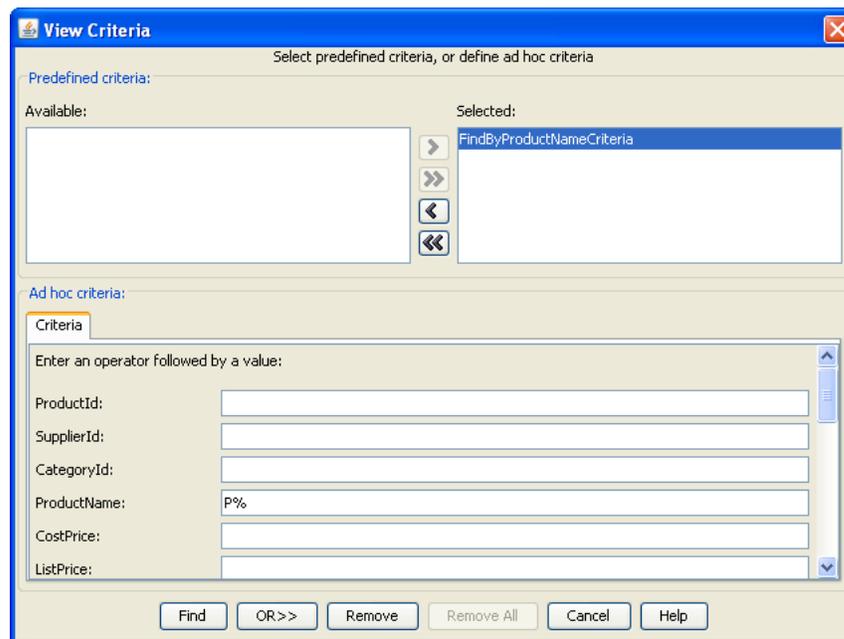

The data view page will appear disabled for any read-only view objects you display because the data is not editable. But even for a read-only view object, the tool affords some useful features:

- You can validate that the UI hints based on the Label Text hint and format masks are defined correctly.
- You can also scroll through the data using the toolbar buttons.
- You can enter Query-by-Example criteria to find a particular row whose data you want to inspect. By clicking the **Specify View Criteria** button in the toolbar, the View Criteria dialog displays the list of available Query-by-Example criteria.

For example, as shown in [Figure 6–9](#), you can select a view criteria like `FindByProductNameCriteria` and enter a query criteria like "P%" for a `ProductName` attribute and click **Find** to narrow the search to only those products with a name that begins with the letter P.

The Oracle ADF Model Tester becomes even more useful when you create entity-based view objects that allow you to simulate inserting, updating, and deleting rows, as described in [Section 6.3.2, "How to Test Entity-Based View Objects Interactively."](#)

Figure 6–9 Built-in Query-by-Example Functionality

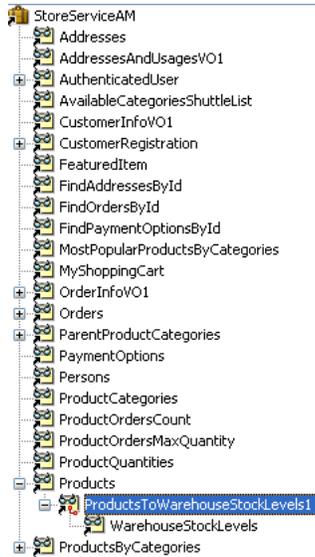

6.3.5 How to Simulate End-User Interaction in the Oracle ADF Model Tester

When you launch the Oracle ADF Model Tester, the tree at the left of the display shows the hierarchy of the view object instances that the data model of your application module defines. If the data model defines master-detail view instance relationships, the tree will display them as parent and child nodes. A node between the master-detail view instances represents the view link instance that performs the active master-detail coordination as the current row changes in the master. For example, in [Figure 6–10](#) the tree is expanded to show the master-detail relationship

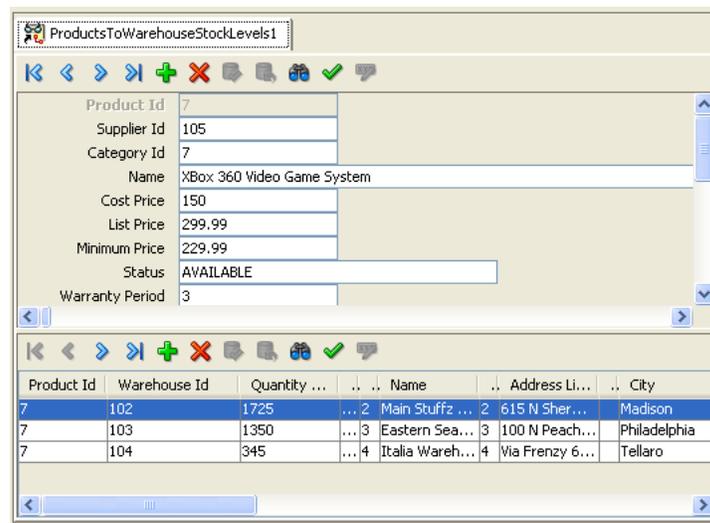

between the master `Products` view instance and the detail `WarehouseStockLevels` view instance. The selected node, `ProductsToWarehouseStockLevels1`, is the view link instance that defines the master-detail relationship.

Figure 6–10 Application Module Data Model in the Oracle ADF Model Tester

Double-clicking the view link instance executes the master object and displays the master-detail data in the data view page. For example, in [Figure 6–11](#), double-clicking the `ProductsToWarehouseStockLevels1` view link instance in the tree executes the `Products` master view instance in the top portion of the data view page and the `WarehouseStockLevels` view instance in the bottom portion of the data view page. Additional context menu items on the view object node allow you to reexecute the query if needed, remove the view object from the data model panel, and perform other tasks.

In the master-detail data view page, you can scroll through the query results. Additionally, because instance of entity-based view objects are fully editable, instead of displaying *disabled* UI controls showing read-only data for a read-only view object, the data view page displays editable fields. You are free to experiment with creating, inserting, updating, validating, committing, and rolling back.

Figure 6–11 Master-Detail Data View Page in the Oracle ADF Model Tester

For example, you can view multiple levels of master-detail hierarchies, opening multiple data view pages at the same time. Use the **Detach** context menu item to open any tab into a separate window and visualize multiple view object's data at the same time.

Using just the master-detail data view page, you can test several functional areas of your application.

6.3.5.1 Testing Master-Detail Coordination

When you click the navigation buttons on the Oracle ADF Model Tester toolbar, you can see that the rows for the current master view object are correctly coordinated. For example, [Figure 6–11](#) shows a master-detail hierarchy with products and warehouses. If you click the **Next Row** button in the master panel, the master panel will display the next product (identified by a product ID) and the detail panel will update to display the list of warehouses and quantities available for the product.

6.3.5.2 Testing UI Hints

The entity-based view object attributes inherit their UI hints from those on the underlying entity object attribute. The prompts displayed in the data view page help you see whether you have correctly defined a user-friendly label text UI hint for each attribute. For details on setting up the hint on your entity object, see [Section 5.13, "Defining Attribute UI Hints for View Objects."](#)

6.3.5.3 Testing Business Domain Layer Validation

Depending on the validation rules you have defined, you can try entering invalid values to trigger and verify validation exceptions. For example, when you have defined a range validation rule, enter a value outside the range and see an error similar to:

```
(oracle.jbo.AttrSetValException) Valid product codes are between 100 and 999
```

Click the rollback button in the toolbar to revert data to the previous state.

6.3.5.4 Testing Alternate Language Message Bundles and UI Hints

When your application defines alternative languages in your resource message bundles, you can configure the Oracle ADF Model Tester to recognize these languages. In the Oracle ADF Model Tester, you can then display the **Locale** menu and select among the available language choices.

To specify a default language for the Oracle ADF Model Tester:

1. Choose **Preferences** from the JDeveloper **Tools** menu.
2. Expand **ADF Business Components** in the selection panel, and select **Tester**.
3. To execute an entity-based view object in the Oracle ADF Model Tester, expand the data model tree and double-click the desired view object node.
4. In the Oracle ADF Model Tester page, add any locale for which you have created a resource message bundle to the **Selected** list.

Alternatively, you can configure the default language choice by setting ADF Business Components runtime configuration properties. These runtime properties also determine which language the Oracle ADF Model Tester will display as the default. In the Select Oracle ADF Model Tester Configuration dialog, select the **Properties** tab and enter the desired country code for the country and language. For example, to specify the Italian language, you would enter `IT` and `it` for these two properties:

- `jbo.default.country = IT`
- `jbo.default.language = it`

Testing the language message bundles in the Oracle ADF Model Tester lets you verify that the translations of the entity object UI hints are correctly located. Or, if the message bundle defines date formats for specific attributes, the tool lets you verify that date formats change (like `04/12/2007` to `12/04/2007`).

6.3.5.5 Testing View Objects That Reference Entity Usages

By scrolling through the data — or using the **Specify View Criteria** button in the Oracle ADF Model Tester toolbar to search — you can verify whether you have correctly altered the `WHERE` clause in an entity-based view object's query to use an outer join. The rows should appear as expected.

You also can try changing a primary key attribute of a master view object. This will allow you to verify that the corresponding reference information is automatically updated to reflect the new primary key value.

Use the Oracle ADF Model Tester to verify that UI hints defined at the view object level override the ones it would normally inherit from the underlying entity object. If you notice that several attributes share the same label text, you can edit the UI hint for the desired attributes at the view object level. For example, you can set the **Label Text** hint to **Member Since** for the `RegisteredDate` attribute and **Provisioned?** for the `ProvisionedFlag` attribute.

6.3.5.6 Testing Row Creation and Default Value Generation

When displaying an entity-based view object, click the **Create Row** button in the Oracle ADF Model Tester toolbar for the view object instance to create a new blank row. Any fields that have a declarative default value will appear with that value in the blank row. If the a `DBSequence`-valued attribute is used, a temporary value will appear in the new row. After entering all the required fields, click the **Commit** button to commit the transaction. The actual, trigger-assigned primary key should appear in the field after successful commit.

6.3.5.7 Testing That New Detail Rows Have Correct Foreign Keys

If you click **Create Row** in the Oracle ADF Model Tester toolbar to try adding a new row to an existing detail entity-based view object instance, you'll notice that the view link automatically ensures that the foreign key attribute value in the new row is set to the value of the current master view instance row.

6.3.6 How to Test Multiuser Scenarios in the Oracle ADF Model Tester

When view objects and entity objects cooperate at runtime, two exceptions can occur when you run the application in a multiuser environment. To anticipate these exceptions, you can simulate a multiuser environment for testing purposes using the Oracle ADF Model Tester. For example, when the application displays edit forms for view object queries, what is the expected behavior when two users attempt to modify the same attribute in their forms?

To understand the expected behavior, open two instances of the Oracle ADF Model Tester on the application module to simulate two users editing the same view object attribute. Keep both instances open and perform the following two tests to demonstrate how multiuser exceptions can arise:

- In one instance of the Oracle ADF Model Tester, modify an attribute of an existing view object and tab out of the field. Then, in the other tester instance, try to modify the same view object attribute in some way. You'll see that the second user gets the `oracle.jbo.AlreadyLockedException`.

You can then change the value of `jbo.locking.mode` to be `pessimistic` on the Properties page of the Oracle ADF Model Tester Connect dialog and try repeating the test (the default mode is set to `pessimistic`). You'll see the error occurs for the second user immediately after changing the value instead of after committing the change.

- In one instance of the Oracle ADF Model Tester, modify an attribute of an existing view object and tab out of the field. Then, in the other tester instance, retrieve (but don't modify) the same view object attribute. Back in the first window, commit the change. If the second user then tries to modify that same attribute, you'll see that the second user gets the `oracle.jbo.RowInconsistentException`. The row has been modified and committed by another user since the second user retrieved the row into the entity cache.

6.3.7 How to Customize Configuration Options Before Running the Tester

Using the Select Business Components Configuration dialog, you can select a predefined configuration to run the tool using that named set of runtime configuration properties. The Select Configuration dialog also features a **Properties** tab that allows you to see the selected configurations settings and to override any of the configuration's settings for the current run of the tester. For example, you could alter the default language for the UI hints for a single instance of the Oracle ADF Model Tester by opening the **Properties** tab and setting the following two properties with the desired country code (in this case, `IT` for Italy):

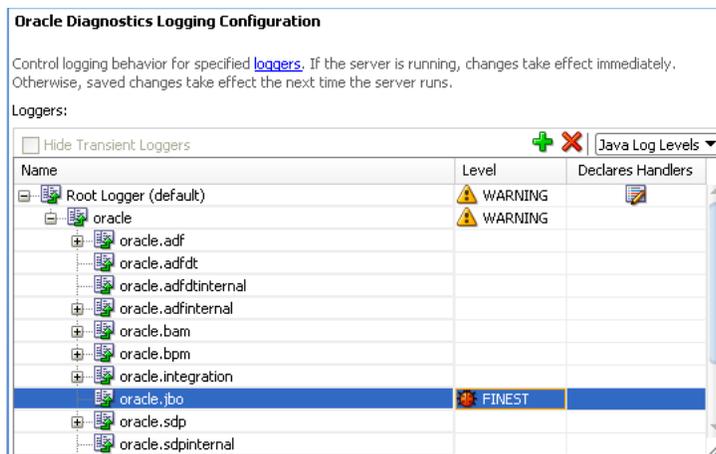

- `jbo.default.country = IT`
- `jbo.default.language = it`

Tip: If you wanted to make the changes to your configuration permanent, you could use the Configuration Manager to copy the current configuration and create a new configuration in which you set the desired properties set. For example, anytime you wanted to test in Italian you could simply choose to use the `UserServiceLocalItalian` configuration, instead of the default `UserServiceLocal`.

6.3.8 How to Enable ADF Business Components Debug Diagnostics

When launching the Oracle ADF Model Tester, if you have configured diagnostic logging for the `oracle.jbo` logger, JDeveloper will direct ADF Business Components debug diagnostics messages to the JDeveloper Log window. [Figure 6–12](#) shows the `oracle.jbo` logger set to a log level of `FINEST` to enable ADF Business Components debug diagnostics.

Figure 6–12 Configuring a Logger for ADF Business Components Debugging

The `oracle.jbo` logger can be configured either before running the application or while the application is running in Integrated WebLogic Server. The logging will begin without the need to restart the server. You do not need to run the application in debug mode to log diagnostic messages.

With the `oracle.jbo` logger configured, the next time you run the Oracle ADF Model Tester and double-click the view object, you'll see detailed diagnostic output in the Log window, as shown in [Example 6–1](#). Configuring the `oracle.jbo` logger with a log level `FINEST` will allow you to visualize everything the ADF Business Components framework components are doing for your application.

Example 6–1 Diagnostic Output of Oracle ADF Model Tester

```

:
[355] Oracle SQLBuilder: Registered driver: oracle.jdbc.OracleDriver
[356] Creating a new pool resource
[357] **** DBTransactionImpl establishNewConnection
[358] Successfully logged in
[359] JDBCDriverVersion: 11.1.0.7.0-Production
[360] DatabaseProductName: Oracle
[361] DBTransactionImpl initTransaction
[362] Replacing: null with: StoreServiceAM_AddressesPageDef
[363] Replacing: null with: StoreServiceAM_MostPopularProductsByCategoriesPageDef
...

```

```

[537] Orders ViewRowSetImpl.execute caused params to be "un"changed
[538] Column count: 41
[539] ViewObject: Orders Created new QUERY statement
[540] Orders>#q computed SQLStmtBufLen: 952, actual=865, storing=895
[541] SELECT OrderEO.ORDER_ID, OrderEO.ORDER_DATE, OrderEO.ORDER_SHIPPED_DATE,
      FROM ORDERS OrderEO ORDER BY OrderEO.ORDER_DATE desc
[542] Bind params for ViewObject: Orders

```

For backward compatibility, it remains possible to enable ADF Business Components debug diagnostics on the data model project using the Java system property `jbo.debugoutput=console`. To set the property, open the Run/Debug/Profile page in the Project Properties dialog for your data model project. Click **Edit** to edit the chosen run configuration, and add `-Djbo.debugoutput=console` to the **Java Options** field in the page. Other legal values for this property are `silent` (the default, if not specified) and `file`. If you choose the file option, diagnostics are written to the system `temp` directory.

Other legal values for the `-Djbo.debugoutput` system property are `silent` (the default, if not specified) and `file`. If you enter the `file` option, diagnostics are written to the system `temp` directory.

6.3.9 What Happens at Runtime: How View Objects and Entity Objects Cooperate

On their own, view objects and entity objects simplify two important jobs that every enterprise application developer needs to do:

- Work with SQL query results
- Modify and validate rows in database tables

Entity-based view objects can query any selection of data that you want the end user to be able to view and modify. Any data the end user is allowed to change will be validated and saved by your reusable business domain layer. The key ingredients you provide as the developer are the ones that only *you* can know:

- You decide what business logic should be enforced in your business domain layer
- You decide what queries describe the data you need to put on the screen

These are the things that make *your* application unique. The built-in functionality of your entity-based view objects handles the rest of the implementation details.

Note: Understanding row keys and what role the entity cache plays in the transaction are important concepts that help to clarify the nature of the entity-based view objects. These two concepts are addressed in [Section 6.4.1, "ViewObject Interface Methods for Working with the View Object's Default RowSet."](#)

6.3.9.1 What Happens at Runtime: After a View Object Executes Its Query

After adding an instance of an entity-based view object to the application module's data model, you can see what happens at runtime when you execute the query. Like a read-only view object, an entity-based view object sends its SQL query straight to the database using the standard Java Database Connectivity (JDBC) API, and the database produces a result set. In contrast to its read-only counterpart, however, as the entity-based view object retrieves each row of the database result set, it partitions the row attributes based on which entity usage they relate to. This partitioning occurs by creating an entity object row of the appropriate type for each of the view object's entity usages, populating them with the relevant attributes retrieved by the query, and

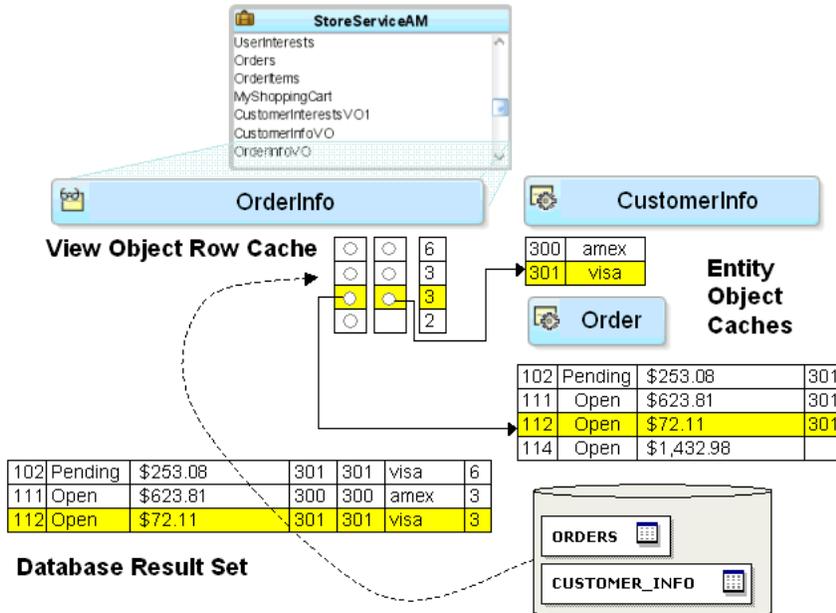

storing each of these entity rows in its respective entity cache. Then, rather than storing duplicate copies of the data, the view row simply *points* at the entity row parts that comprise it.

Figure 6–13 illustrates how the entity cache partitions the result set attributes of two entity-based view objects. In this example, the highlighted row in the database result set is partitioned into an *Order* entity row with primary key 112 and a *CustomerInfo* entity row with primary key 301.

As described in Section 6.4.1.2, "The Role of the Entity Cache in the Transaction," the entity row that is brought into the cache using `findByPrimaryKey()` contains *all* attributes of the entity object. In contrast, an entity row created by partitioning rows from the entity-based view object's query result contains values only for attributes that appear in the query. It does *not* include the complete set of attributes. This partially populated entity row represents an important runtime performance optimization.

Since the ratio of rows retrieved to rows modified in a typical enterprise application is very high, you can save memory by bringing only the attributes into memory that you need to display instead of bringing all attributes into memory all the time.

Figure 6–13 Entity Cache Partitions View Rows into Entity Rows

By partitioning queried data this way into its underlying entity row constituent parts, the first benefit you gain is that all of the rows that include some data queried will display a consistent result when changes are made in the current transaction. In other words, if one view object allows the `PaymentType` attribute of customer 301 to be modified, then all rows in any entity-based view object showing the `PaymentType` attribute for customer 301 will update instantly to reflect the change. Since the data related to customer 301 is stored exactly once in the *CustomerInfo* entity cache in the entity row with primary key 301, any view row that has queried the order's `PaymentType` attribute is just pointing at this single entity row.

Luckily, these implementation details are completely hidden from a client working with the rows in a view object's row set. The client works with a view row, getting and setting the attributes, and is unaware of how those attributes might be related to entity rows behind the scenes.

6.3.9.2 What Happens at Runtime: After a View Row Attribute Is Modified

When a user attempts to update the attribute of a view row, a series of steps occur to automatically coordinate this view row attribute modification with the underlying entity row. These steps ensure that a validation rule defined on the entity-mapped attribute will be triggered before the value is changed.

Figure 6–14 illustrates the basic steps that occur at runtime when the user attempts to update an entity-mapped attribute. In this example, the modified attribute `Status` is mapped to an entity usage where a validation rule is defined.

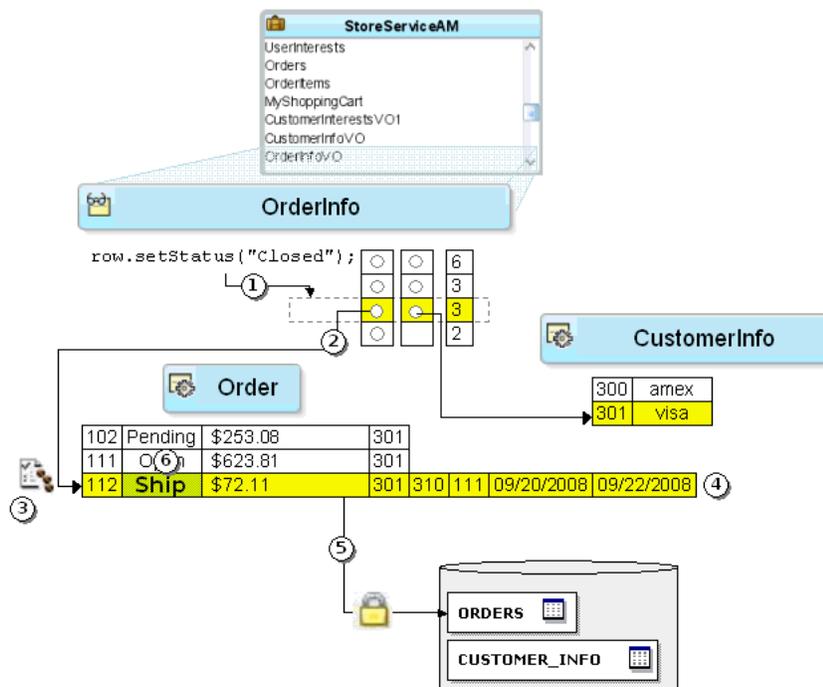

1. The user attempts to set the `Status` attribute to the value `Ship`.
2. Since `Status` is an entity-mapped attribute from the `Order` entity usage, the view row delegates the attribute set to the appropriate underlying entity row in the `Order` entity cache having primary key 112.
3. Any attribute-level validation rules on the `Status` attribute of the `Order` entity object are evaluated and the modification attempt will fail if any rule does not succeed.

Assume that some validation rule for the `Status` attribute programmatically references the `ShipDate` attribute (for example, to enforce a business rule that an `Order` cannot be shipped the same day it is placed). The `ShipDate` was not one of the `Order` attributes retrieved by the query, so it is not present in the partially populated entity row in the `Order` entity cache.

4. To ensure that business rules can always reference all attributes of the entity object, the entity object detects this situation and "faults-in" the entire set of `Order` entity object attributes for the entity row being modified using the primary key (which must be present for each entity usage that participates in the view object).
5. After the attribute-level validations all succeed, the entity object attempts to acquire a lock on the row in the `ORDERS` table before allowing the first attribute to be modified.
6. If the row can be locked, the attempt to set the `Status` attribute in the row succeeds and the value is changed in the entity row.

Note: The `jbo.locking.mode` configuration property controls how rows are locked. The default value is `optimistic`. Typically, Fusion web applications will use the default setting `optimistic`, so that rows aren't locked until transaction commit time. In `pessimistic` locking mode, the row must be lockable before any change is allowed to it in the entity cache.

Figure 6–14 View Row Attribute Updates Delegate to the Entity

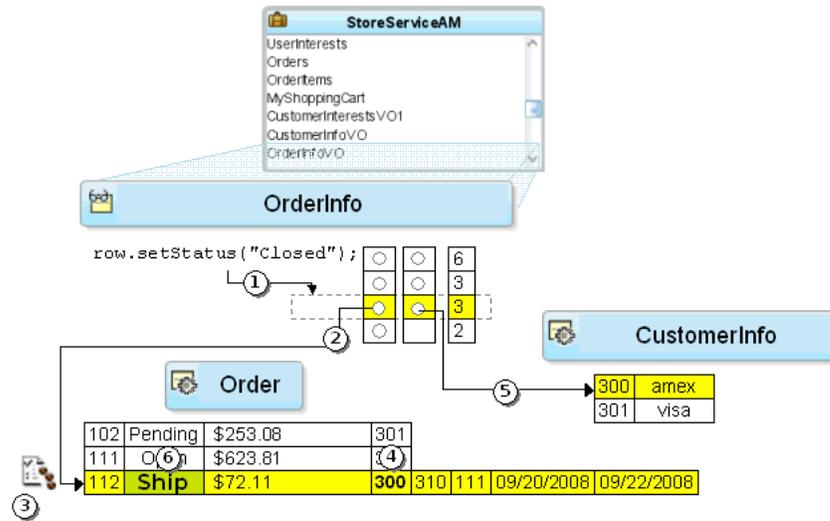

6.3.9.3 What Happens at Runtime: After a Foreign Key Attribute is Changed

When a user attempts to update a foreign key attribute, a series of steps occur to automatically coordinate this view row attribute modification with the underlying entity row. These steps ensure that a validation rule defined on the foreign key, entity-mapped attribute will be triggered before the value is changed. They also ensure that the view row for the changed foreign key attribute reflects the correct attributes of all referenced entity objects.

Figure 6–15 illustrates the basic steps that occur at runtime when the user attempts to update a foreign key, entity-mapped attribute. In this example, the modified attribute `CustomerInfoId` is mapped to an entity usage `Order` where the attribute is associated with another entity object `CustomerInfo`.

1. The user attempts to set the `CustomerInfoId` attribute to the value 300.
2. Since `CustomerInfoId` is an entity-mapped attribute from the `Order` entity usage, the view row delegates the attribute set to the appropriate underlying entity row in the `Order` entity cache, which has primary key 112.
3. Any attribute-level validation rules on the `CustomerInfoId` attribute of the `Order` entity object are evaluated and the modification attempt will fail if any rule does not succeed.
4. The row is already locked, so the attempt to set the `CustomerInfoId` attribute in the row succeeds and the value is changed in the entity row.
5. Since the `CustomerInfoId` attribute on the `Order` entity usage is associated with the `CustomerInfo` entity object, this change of foreign key value causes the view row to replace its current entity row part for customer 301 with the entity row corresponding to the new `CustomerInfoId = 300`. This effectively makes the view row for order 112 point to the entity row for 300, so the value of the `PaymentType` in the view row updates to reflect the correct reference information for this newly assigned customer.

Figure 6–15 After Updating a Foreign Key, View Row Points to a New Entity

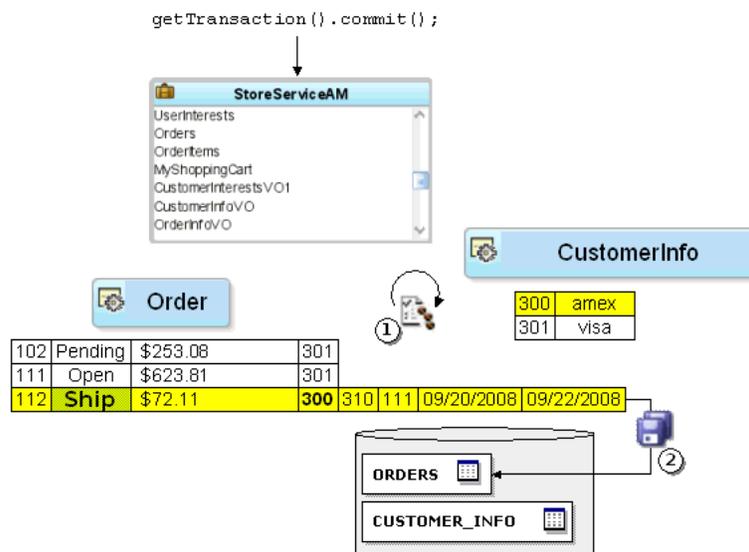

6.3.9.4 What Happens at Runtime: After a Transaction is Committed

Suppose the user is satisfied with the changes, and commits the transaction. As shown in Figure 6–16, there are two basic steps:

1. The Transaction object validates any invalid entity rows in its pending changes list.
2. The entity rows in the pending changes list are saved to the database.

The figure depicts a loop in Step 1 before the act of validating one modified entity object might programmatically affect changes to other entity objects. Once the transaction has processed its list of invalid entities on the pending changes list, if the list has entities, the transaction will complete another pass. It will attempt up to ten passes through the list. If by that point there are still invalid entity rows, it will throw an exception because this typically means you have an error in your business logic that needs to be investigated.

Figure 6–16 Committing the Transaction Validates Invalid Entities, Then Saves Them

6.3.9.5 What Happens at Runtime: After a View Object Requeries Data

When you reexecute a view object's query, by default the view rows in its current row set are "forgotten" in preparation for reading in a fresh result set. This view object operation does not directly affect the entity cache, however. The view object then sends the SQL to the database and the process begins again to retrieve the database result set rows and partition them into entity row parts.

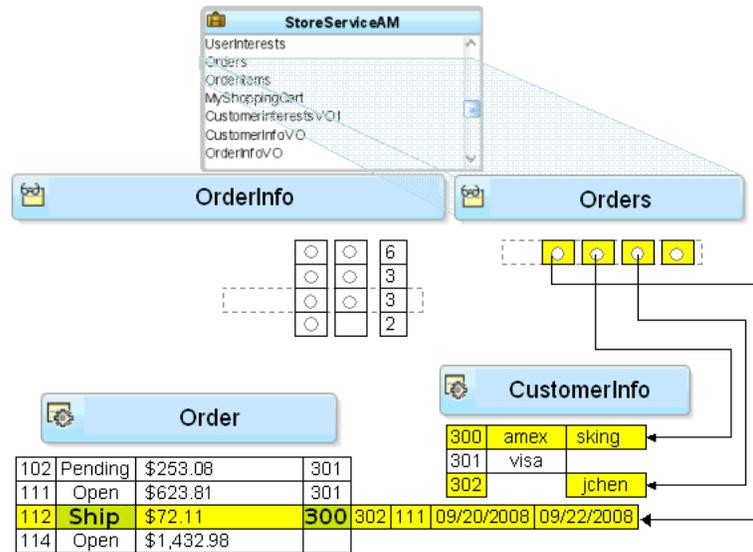

Note: Typically when the view object requeries data, you expect it to retrieve the latest database information. If instead you want to avoid a database roundtrip by restricting your view object to querying only over existing entity rows in the cache, or over existing rows already in the view object's row set, see [Section 42.5, "Performing In-Memory Sorting and Filtering of Row Sets."](#)

6.3.9.5.1 How Unmodified Attributes are Handled During Requery As part of the entity row partitioning process during a requery, if an attribute on the entity row is unmodified, then its value in the entity cache is updated to reflect the newly queried value.

6.3.9.5.2 How Modified Attributes are Handled During Requery However, if the value of an entity row attribute has been *modified* in the current transaction, then during a requery the entity row partitioning process does not refresh its value. Uncommitted changes in the current transaction are left intact so the end-user's logical unit of work is preserved. As with any entity attribute value, these pending modifications continue to be consistently displayed in any entity-based view object rows that reference the modified entity rows.

Note: End-user row inserts and deletes are also managed by the entity cache, which permits new rows to appear and deleted rows to be skipped during requerying. For more information about new row behavior, see [Section 42.1.2, "Maintaining New Row Consistency in View Objects Based on the Same Entity."](#)

For example, [Figure 6-17](#) illustrates the scenario where a user "drills down" to a different page that uses the `Orders` view object instance to retrieve all details about order 112 and that this happens in the context of the current transaction's pending changes. That view object has two entity usages: a primary `Orders` usage and a reference usage for `CustomerInfo`. When its query result is partitioned into entity rows, it ends up pointing at the same `Order` entity row that the previous `OrderInfo` view row had modified. This means the end user will correctly see the pending change, that the order is assigned to `sking` in this transaction.

Figure 6–17 Entity Cache Merges Sets of Entity Attributes from Different View Objects

6.3.9.5.3 How Overlapping Subsets of Attributes are Handled During Requery Two different view objects can retrieve two *different* subsets of reference information and the results are merged whether or not they have matching sets of attributes. For example, [Figure 6–17](#) also illustrates the situation, where the Orders view object queries the user's Email, while the OrderInfo view object queried the user's PaymentOption. The figure shows what happens at runtime: if while partitioning the retrieved row, the entity row part contains a different set of attributes than does the partially populated entity row that is already in the cache, the attributes get "merged". The result is a partially populated entity row in the cache with the *union* of the overlapping subsets of user attributes. In contrast, for jchen (user 302), who wasn't in the cache already, the resulting new entity row contains only the Email attribute, but not the PaymentOption.

6.3.10 What You May Need to Know About Optimizing View Object Runtime Performance

The view object provides tuning parameters that let you control how SQL is executed and how data is fetched from the database. These tuning parameters play a significant role in the runtime performance of the view object. If the fetch options are not tuned correctly for the application, then your view object may fetch an excessive amount of data and may make too many roundtrips to the database.

You can use the **Tuning** section of the General page of the overview editor to configure the fetch options shown in [Table 6–2](#).

Table 6–2 Parameters to Tune View Object Performance

Fetch Tuning Parameters	Usage
Fetch Mode	<p>The default fetch option is the All Rows option, which will be retrieved As Needed (<code>FetchMode="FETCH_AS_NEEDED"</code>) or All at Once (<code>FetchMode="FETCH_ALL"</code>), depending on which option is desired. The As Needed option ensures that an <code>executeQuery()</code> operation on the view object initially retrieves only as many rows as necessary to fill the first page of a display, whose number of rows is set based on the view object's range size.</p>
Fetch Size	<p>In conjunction with the Fetch Mode option, the in Batches of field controls the number of records fetched at one time from the database (<code>FetchSize</code> in the view object XML). The default value is 1, which will give poor performance unless only one row will be fetched. The suggested configuration is to set this value to $n+1$ where n is the number of rows to be displayed in the user interface.</p>
Max Fetch Size	<p>The default max fetch size for a view object is -1, which means that there is no limit to the number of rows the view object can fetch. In cases where the result set should contain only n rows of data, the option Only up to row number should be selected and set to n. The developer can alternatively call <code>setMaxFetchSize(n)</code> to set this programmatically or manually add the parameter <code>MaxFetchSize</code> to the view object XML.</p> <p>For view objects whose <code>WHERE</code> clause expects to retrieve a single row, set the option At Most One Row. This way the view object knows you don't expect any more rows and it will skip its normal test for that situation.</p> <p>As mentioned earlier, setting a maximum fetch size of 0 (zero) makes the view object insert-only. In this case, no select query will be issued, so no rows will be fetched.</p> <p>When you want to specify a global threshold for all view object queries in the application, you can configure the Row Fetch Limit property in the <code>adf-config.xml</code> file. Setting this property means you can avoid changing the Max Fetch Size for individual query operations. If you do specify a fetch limit for individual view objects, the Row Fetch Limit setting will be ignored in those cases. For more details about Row Fetch Limit, see Section 42.1.1, "Limiting the View Object Max Fetch Size to Fetch the First n Rows."</p>

Table 6–2 (Cont.) Parameters to Tune View Object Performance

Fetch Tuning Parameters	Usage
Forward-only Mode	If a data set will only be traversed going forward, then forward-only mode can help performance when iterating through the data set. This can be configured by programmatically calling <code>setForwardOnly(true)</code> on the view object. Setting forward-only will also prevent caching previous sets of rows as the data set is traversed.

When you tune view objects, you should also consider these issues:

- **Large data sets:** View objects provide a mechanism to page through large data sets such that a user can jump to a specific page in the results. This is configured by calling `setRangeSize(n)` followed by `setAccessMode(RowSet.RANGE_PAGING)` on the view object where *n* is the number of rows contained within one page. When the user navigates to a specific page in the data set, the application can call `scrollToRangePage(P)` on the view object to navigate to page *P*. Range paging fetches and caches only the current page of rows in the view object row cache at the cost of another query execution to retrieve each page of data. Range paging is not appropriate where it is beneficial to have all fetched rows in the view object row cache (for example, when the application needs to read all rows in a dataset for an LOV or page back and forth in records of a small data set).
- **Spillover:** There is a facility to use the data source as "virtual memory" when the JVM container runs out of memory. By default, this is disabled and can be turned on as a last resort by setting `jbo.use.pers.coll=true`. Enabling spillover can have a large performance impact.
- **SQL platform:** If the generic SQL92 SQL platform is used to connect to generic SQL92-compliant databases, then some view object tuning options will not function correctly. The parameter that choosing the generic SQL92 SQL platform affects the most is the fetch size. When SQL92 SQL platform is used, the fetch size defaults to 10 rows regardless of what is configured for the view object. You can set the SQL platform when you define the database connection or you can define it as global project setting in the `adf-config.xml` file. By default, the SQL platform will be `Oracle`. To manually override the SQL platform, you can also pass the parameter `-Djbo.SQLBuilder="SQL92"` to the JVM upon startup.

Additionally, you have some options to tune the view objects' associated SQL for better database performance:

- **Bind variables:** If the query associated with the view object contains values that may change from execution to execution, use bind variables. Using bind variables in the query allows the query to reexecute without needing to reparse the query on the database. You can add bind variables to the view object in the Query page of the overview editor for the view object. For more information, see [Section 5.10, "Working with Bind Variables."](#)
- **Query optimizer hints:** The view object can pass hints to the database to influence which execution plan to use for the associated query. The optimizer hints can be specified in the **Retrieve from the Database** group box in the Tuning section of the overview editor for the view object. For information about optimizer hints, see [Section 42.2.4.3, "Specify a Query Optimizer Hint if Necessary."](#)

6.4 Testing View Object Instances Programmatically

When you are ready to test a working application module containing at least one view object instance, you can build a simple test client program to illustrate the basics of working programmatically with the data in the contained view object instances.

From the point of view of a client accessing your application module's data model, the API's to work with a read-only view object and an entity-based view object are identical. The key functional difference is that entity-based view objects allow the data in a view object to be fully updatable. The application module that contains the entity-based view objects defines the unit of work and manages the transaction. This section presents four simple test client programs that work with the `StoreFrontAM` application module in the Fusion Order Demo to illustrate:

- Iterating master-detail-detail hierarchy
- Finding a row and updating a foreign key value
- Creating a new order
- Retrieving the row key identifying a row

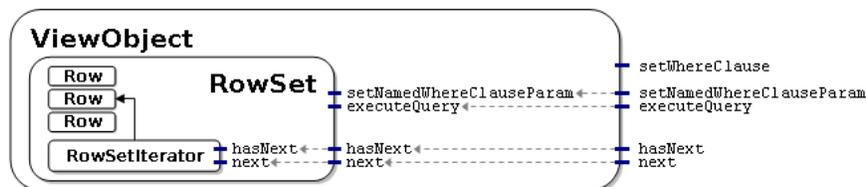

6.4.1 ViewObject Interface Methods for Working with the View Object's Default RowSet

The `ViewObject` interface in the `oracle.jbo` package provides the methods to easily perform any data-retrieval task. Some of these methods used in the example include:

- `executeQuery()`, to execute the view object's query and populate its row set of results
- `setWhereClause()`, to add a dynamic predicate at runtime to narrow a search
- `setNamedWhereClauseParam()`, to set the value of a named bind variable
- `hasNext()`, to test whether the row set iterator has reached the last row of results
- `next()`, to advance the row set iterator to the next row in the row set
- `getEstimatedRowCount()`, to count the number of rows a view object's query would return

Typically, when you work with a view object, you will work with only a single row set of results at a time. To simplify this overwhelmingly common use case, as shown in [Figure 6–18](#), the view object contains a default `RowSet`, which, in turn, contains a default `RowSetIterator`. The default `RowSetIterator` allows you to call all of the data-retrieval methods directly on the `ViewObject` component itself, knowing that they will apply automatically to its default row set.

Figure 6–18 *ViewObject Contains a Default RowSet and RowSetIterator*

Note: Chapter 42, "Advanced View Object Techniques" presents situations when you might want a single view object to produce *multiple* distinct row sets of results. You can also find scenarios for creating *multiple* distinct row set iterators for a row set. Most of the time, however, you'll need only a single iterator.

The phrase "working with the rows in a view object," when used in this guide more precisely means working with the rows in the view object's default row set. Similarly, the phrase "iterate over the rows in a view object," more precisely means you will use the default row set iterator of the view object's default row set to loop over its rows.

6.4.1.1 The Role of the Key Object in a View Row or Entity Row

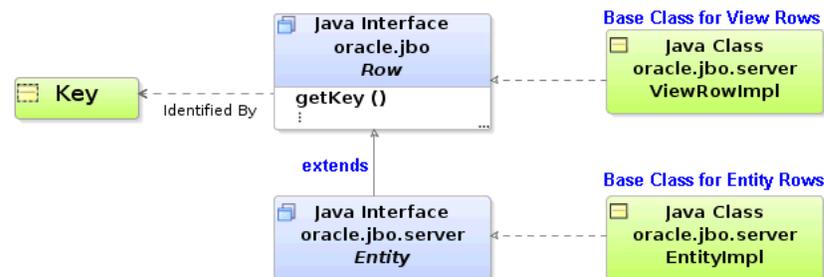

When you work with view rows you use the Row interface in the `oracle.jbo` package. As shown in Figure 6–19, the interface contains a method called `getKey()` that you can use to access the Key object that identifies any row. Notice that the Entity interface in the `oracle.jbo.server` package extends the Row interface. This relationship provides a concrete explanation of why the term *entity row* is so appropriate. Even though an entity row supports additional features for encapsulating business logic and handling database access, you can still treat any entity row as a Row.

An entity-based view object delegates the task of finding rows by key to its underlying entity row parts.

Recall that both view rows and entity rows support either single-attribute or multiattribute keys, so the Key object related to any given Row will encapsulate all of the attributes that comprise its key. Once you have a Key object, you can use the `findByKey()` method on any row set to find a row based on its Key object. When you use the `findByKey()` method to find a view row by key, the view row proceeds to use the entity definition's `findByPrimaryKey()` method to find each entity row contributing attributes to the view row key.

In the case of a read-only view object with no underlying entity row to which to delegate this task, the view object implementation automatically enables the `manageRowsByKey` flag when at least one primary key attribute is detected. This ensures that the `findByKey()` method is successful in the case of read-only view objects. If the `manageRowsByKey` flag is not enabled, then UI operations like setting the current row with the key, which depend on the `findByKey()` method, would not work.

Figure 6–19 Any View Row or Entity Row Supports Retrieving Its Identifying Key

Note: When you define an entity-based view object, by default the primary key attributes for all of its entity usages are marked with their **Key Attribute** property set to `true`. In any *nonupdatable* reference entity usages, you should disable the **Key Attribute** property for the key attributes. Since view object attributes related to the primary keys of *updatable* entity usages must be part of the composite view row key, their **Key Attribute** property cannot be disabled.

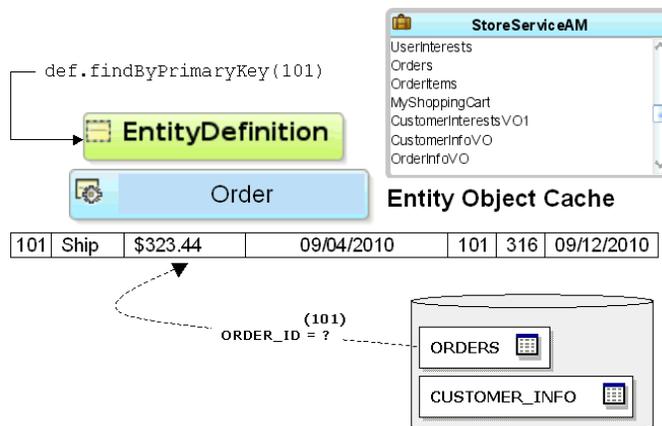

6.4.1.2 The Role of the Entity Cache in the Transaction

An application module is a transactional container for a logical unit of work. At runtime, it acquires a database connection using information from the named configuration you supply, and it delegates transaction management to a companion `Transaction` object. Since a logical unit of work may involve finding and modifying multiple entity rows of different types, the `Transaction` object provides an entity cache as a "work area" to hold entity rows involved in the current user's transaction. Each entity cache contains rows of a single entity type, so a transaction involving two or more entity objects holds the working copies of those entity rows in separate caches.

By using an entity object's related entity definition, you can write code in an application module to find and modify existing entity rows. As shown in [Figure 6–20](#), by calling `findByPrimaryKey()` on the entity definition for the `Order` entity object, you can retrieve the row with that key. If it is not already in the entity cache, the entity object executes a query to retrieve it from the database. This query selects all of the entity object's persistent attributes from its underlying table, and finds the row using an appropriate `WHERE` clause against the column corresponding to the entity object's primary key attribute. Subsequent attempts to find the same entity row by key during the same transaction will find it in the cache, preventing the need for a trip to the database. In a given entity cache, entity rows are indexed by their primary key. This makes finding an entity row in the cache a fast operation.

When you access related entity rows using association accessor methods, they are also retrieved from the entity cache. If related entity rows are not in the cache, then they are retrieved from the database. Finally, the entity cache is also the place where new entity rows wait to be saved. In other words, when you use the `createInstance2()` method on the entity definition to create a new entity row, it is added to the entity cache.

Figure 6–20 Entity Cache Stores Entity Rows During the Transaction

When an entity row is created, modified, or removed, it is automatically enrolled in the transaction's list of pending changes. When you call `commit()` on the `Transaction` object, it processes its pending changes list, validating new or modified entity rows that might still be invalid. When the entity rows in the pending list are all valid, the `Transaction` issues a database `SAVEPOINT` and coordinates saving the entity rows to the database. If all goes successfully, it issues the final database `COMMIT` statement. If anything fails, the `Transaction` performs a `ROLLBACK TO SAVEPOINT` to allow the user to fix the error and try again.

The `Transaction` object used by an application module represents the working set of entity rows for a single end-user transaction. By design, it is *not* a shared, global cache. The database engine itself is an extremely efficient shared, global cache for multiple, simultaneous users. Rather than attempting to duplicate all the work of fine-tuning that has gone into the database's shared, global cache functionality, ADF Business Components consciously embraces it. To refresh a single entity object's data from the database at any time, you can call its `refresh()` method. You can `setClearCacheOnCommit()` or `setClearCacheOnRollback()` on the `Transaction` object to control whether entity caches are cleared at commit or rollback. The defaults are `false` and `true`, respectively. The `Transaction` object also provides a `clearEntityCache()` method you can use to programmatically clear entity rows of a given entity type (or all types). When you clear an entity cache, you allow entity rows of that type to be retrieved from the database fresh the next time they are either found by primary key or retrieved by an entity-based view object.

6.4.2 How to Create a Command-Line Java Test Client

To create a test client program, use the Create Java Class wizard, which is accessible from the New Gallery.

6.4.2.1 Generating a Test Client with Skeleton Code

When you use the Create Java Class wizard to create the test client program, JDeveloper will open your program file in the source editor and allow you to add code from a predefined code template to complete the test client.

To generate a skeleton Java test client:

1. In the Application Navigator, right-click the project in which you want to create the test client and choose **New**.
2. In the New Gallery, expand **General**, select **Java** and then **Java Class**, and click **OK**.
3. In the Create Java Class dialog, enter a class name, like `TestClient`, a package name, like `oracle.fodemo.storefront.client`, and ensure that the **Extends** field shows `java.lang.Object`.
4. In **Optional Attributes**, deselect **Constructors from Superclass** and select **Main Method**.
5. Click **OK**.

The `.java` file opens in the source editor to show the skeleton code, as shown in [Example 6-2](#).

Example 6-2 Skeleton Code for `TestClient.java`

```
package oracle.fodemo.storefront.client;
public class TestClient {
    public static void main(String[] args) {
```

```

    }
}

```

6.4.2.2 Modifying the Skeleton Code to Create the Test Client

After you generate skeleton code for the test client, you can proceed to edit the file using the predefined `bc4jclient` code template available from JDeveloper.

To insert the `bc4jclient` code template:

1. Place the cursor on a blank line inside the body of the `main()` method and use the `bc4jclient` code template to create the few lines of necessary code.
2. Type the characters `bc4jclient` followed `Ctrl + Enter`.

JDeveloper will expand the class file with the template as shown in [Example 6–3](#).

3. Adjust the values of the `amDef` and `config` variables to reflect the names of the application module definition and the configuration that you want to use, respectively.

For the [Example 6–3](#), the changed lines look like this:

```
String amDef = "oracle.fodemo.storefront.store.service.StoreServiceAM";
String config = "StoreServiceAMLocal";
```

4. Finally, change the view object instance name in the call to `findViewObject()` to the one you want to work with. Specify the name exactly as it appears in the **Data Model** tree on the Data Model page of the overview editor for the application module.

For the [Example 6–3](#), the changed line looks like this:

```
ViewObject vo = am.findViewObject("Persons");
```

Example 6–3 Expanded Skeleton Code for `TestClient.java`

```
package oracle.fodemo.storefront.client;
import oracle.jbo.client.Configuration;
import oracle.jbo.*;
import oracle.jbo.domain.Number;
import oracle.jbo.domain.*;
public class TestClient {
    public static void main(String[] args) {
        String      amDef = "test.TestModule";
        String      config = "TestModuleLocal";
        ApplicationModule am =
            Configuration.createRootApplicationModule(amDef,config);
        ViewObject vo = am.findViewObject("TestView");
        // Work with your appmodule and view object here
        Configuration.releaseRootApplicationModule(am,true);
    }
}

```

Your skeleton test client for your application module should contain source code like what you see in [Example 6–4](#).

Note: The examples throughout [Section 9.10, "Working Programmatically with an Application Module's Client Interface"](#) expand this test client sample code to illustrate calling custom application module service methods, too.

Example 6–4 Working Skeleton Code for an Application Module Test Client Program

```
package oracle.fodemo.storefront.client;
import oracle.jbo.ApplicationModule;
import oracle.jbo.Row;
import oracle.jbo.RowSet;
import oracle.jbo.ViewObject;
import oracle.jbo.client.Configuration;

public class TestClient {

    public static void main(String[] args) {
        String amDef = "oracle.fodemo.storefront.store.service.StoreServiceAM";
        String config = "StoreServiceAMLocal";
        ApplicationModule am =
            Configuration.createRootApplicationModule(amDef, config);
        // 1. Find the Persons view object instance.
        ViewObject personList = am.findViewObject("Persons");
        // Work with your appmodule and view object here
        Configuration.releaseRootApplicationModule(am, true);
    }
}
```

Replace `// Work with your appmodule and view object here`, with code that will execute the view objects you want to test. For example, to execute the view object's query, display the number of rows it will return, and loop over the result to fetch the data and print it out to the console, you can adapt the code shown in [Example 6–5](#) for your data model project components.

Example 6–5 Looping Over Master-Detail View Objects and Printing the Results to the Console

```
// 2. Execute the query
personList.executeQuery();
// 3. Iterate over the resulting rows
while (personList.hasNext()) {
    Row person = personList.next();
    // 4. Print the person's email
    System.out.println("Person: " + person.getAttribute("Email"));
    // 5. Get related rowset of Orders using view link accessor attribute
    RowSet orders = (RowSet)person.getAttribute("Orders");
    // 6. Iterate over the Orders rows
    while (orders.hasNext()) {
        Row order = orders.next();
        // 7. Print out some order attribute values
        System.out.println(" ["+order.getAttribute("OrderStatusCode")+"] "+
            order.getAttribute("OrderId")+": "+
            order.getAttribute("OrderTotal"));
        if(!order.getAttribute("OrderStatusCode").equals("COMPLETE")) {
            // 8. Get related rowset of OrderItems
            RowSet items = (RowSet)order.getAttribute("OrderItems");
            // 9. Iterate over the OrderItems rows
            while (items.hasNext()) {
```

```

        Row item = items.next();
        // 10. Print out some order items attributes
        System.out.println("  "+item.getAttribute("LineItemId")+": "+
                           item.getAttribute("LineItemTotal"));
    }
}
}
}

```

The first line calls the `executeQuery()` method to execute the view object's query. This produces a row set of zero or more rows that you can loop over using a `while` statement that iterates until the view object's `hasNext()` method returns `false`. Inside the loop, the code puts the current `Row` in a variable named `person`, then invokes the `getAttribute()` method twice on that current `Row` object to get the value of the `Email` and `Orders` attributes to print order information to the console. A second `while` statement performs the same task for the line items of the order.

6.4.3 What Happens When You Run a Test Client Program

The call to `createRootApplicationModule()` on the `Configuration` object returns an instance of the application module to work with. As you might have noticed in the debug diagnostic output, the ADF Business Components runtime classes load XML component definitions as necessary to instantiate the application module and the instance of the view object component that you've defined in its data model at design time. The `findViewObject()` method on the application module finds a view object instance by name from the application module's data model. After the loop shown in [Example 6-5](#), the test client executes `releaseRootApplicationModule()` on the `Configuration` object. This signals that you're done using the application module and it allows the framework to clean up resources, like the database connection that was used by the application module.

6.4.4 What You May Need to Know About Running a Test Client

The `createRootApplicationModule()` and `releaseRootApplicationModule()` methods are very useful for command-line access to application module components. However, you typically won't need to write these two lines of code in the context of an ADF-based web or Swing application. The ADF Model data binding layer cooperates automatically with the ADF business services layer to acquire and release ADF application module components for you in those scenarios.

6.4.5 How to Count the Number of Rows in a Row Set

The `getEstimatedRowCount()` method is used on a `RowSet` to determine how many rows it contains:

```
long numReqs = reqs.getEstimatedRowCount();
```

The implementation of the `getEstimatedRowCount()` initially issues a `SELECT COUNT(*)` query to calculate the number of rows that the query will return. The query is formulated by "wrapping" your view object's entire query in a statement like:

```
SELECT COUNT(*) FROM ( ... your view object's SQL query here ... )
```

The `SELECT COUNT(*)` query allows you to access the count of rows for a view object without necessarily retrieving all the rows themselves. This approach permits an important optimization for working with queries that return a large number of

rows, or for testing how many rows a query *would* return before proceeding to work with the results of the query.

Once the estimated row count is calculated, subsequent calls to the method do not reexecute the `COUNT (*)` query. The value is cached until the next time the view object's query is executed, since the fresh query result set returned from the database could potentially contain more, fewer, or different rows compared with the last time the query was run. The estimated row count is automatically adjusted to account for pending changes in the current transaction, adding the number of relevant new rows and subtracting the number of removed rows from the count returned.

You can also override `getEstimatedRowCount()` to perform a custom count query that suits your application's needs.

6.4.6 How to Access a Detail Collection Using the View Link Accessor

Once you've retrieved the `RowSet` of detail rows using a view link accessor, as described in [Section 5.6.6.2, "Programmatically Accessing a Detail Collection Using the View Link Accessor,"](#) you can loop over the rows it contains using the same pattern used by the view object's row set of results, as shown in [Example 6-6](#).

Example 6-6 Pattern Used to Access a Detail Collection

```
while (reqs.hasNext()) {
    Row curReq = reqs.next();
    System.out.println("--> (" + curReq.getAttribute("OrderId") + ") " +
        curReq.getAttribute("OrderTotal"));
}
```

[Example 6-7](#) shows the `main()` method sets a dynamic `WHERE` clause to restrict the `PersonList` view object instance to show only persons whose `person_type_code` has the value `CUST`. Additionally, the `executeAndShowResults()` method accesses the view link accessor attribute and prints out the request number (`PersonId`) and `Email` attribute for each one.

To access the a detail collection using a view link accessor, follow these basic steps (as illustrated in [Example 6-7](#)):

1. Find the master view object instance.
2. Execute the query.
3. Iterate over the master view object rows.
4. Get the related row set of the detail view object using the view link accessor attribute.
5. Iterate over the detail view object rows.
6. Optionally, do something with the detail row set attributes.

Performance Tip: If the code you write to loop over the rows does not need to display them, then you can call the `closeRowSet()` method on the row set when you're done. This technique will make memory use more efficient. The next time you access the row set, its query will be reexecuted.

Example 6-7 Programmatically Accessing Detail Rows Using the View Link Accessor

```
package devguide.examples.readonlyvo.client;

import oracle.jbo.ApplicationModule;
```

```

import oracle.jbo.Row;
import oracle.jbo.RowSet;
import oracle.jbo.ViewObject;
import oracle.jbo.client.Configuration;

public class TestClient2 {
    public static void main(String[] args) {
        String amDef = "devguide.examples.readonlyvo.PersonService";
        String config = "PersonServiceLocal";
        ApplicationModule am =
            Configuration.createRootApplicationModule(amDef, config);
        // 1. Find the Persons view object instance.
        ViewObject vo = am.findViewObject("PersonList");
        // Add an extra where clause with a new named bind variable
        vo.setWhereClause("person_type_code = :ThePersonType");
        vo.defineNamedWhereClauseParam("ThePersonType", null, null);
        vo.setNamedWhereClauseParam("ThePersonType", "CUST");
        // Show results when :ThePersonType = 'CUST'
        executeAndShowResults(vo);
        Configuration.releaseRootApplicationModule(am, true);
    }
    private static void executeAndShowResults(ViewObject vo) {
        System.out.println("---");
        // 2. Execute the query
        vo.executeQuery();
        // 3. Iterate over the resulting rows of the Persons view object
        while (vo.hasNext()) {
            Row curPerson = vo.next();
            // 4. Access the row set of Orders using the view link accessor attribute
            RowSet orders = (RowSet)curPerson.getAttribute("OrdersShippedToPurchaser");
            long numOrders = orders.getEstimatedRowCount();
            System.out.println(curPerson.getAttribute("PersonId") + " " +
                curPerson.getAttribute("Email")+" ["+
                    numOrders+" orders]");
            // 5. Iterate over the resulting detail rows
            while (orders.hasNext()) {
                Row curOrder = orders.next();
                // 6. Print out some Order attribute values
                System.out.println("--> (" + curOrder.getAttribute("OrderId") + ") " +
                    curOrder.getAttribute("OrderTotal"));
            }
        }
    }
}

```

Running `TestClient2.java` produces output in the Log window, as shown in [Example 6-8](#). Each customer is listed, and for each customer that has some orders, the order total appears beneath their name.

Example 6-8 Results of Running `TestClient.java`

```

---
121 AFRIPP [0 orders]

If you run `TestClient2.java` with debug diagnostics enabled, you will see the SQL queries that the view object performed. The view link `WHERE` clause predicate is used to automatically perform the filtering of the detail service request rows for the current row in the `PersonList` view object.

6.4.7 How to Iterate Over a Master-Detail-Detail Hierarchy

To iterate over a master-detail with an additional level of nesting, follow these basic steps (as illustrated in [Example 6-9](#)):

1. Find the master view object instance.
2. Executes the query.
3. Iterate over the resulting rows.
4. Optionally, do something with the attributes of the master row set.
5. Get the related row set of the detail view object using the view link accessor attribute.
6. Iterate over the detail row set rows.
7. Optionally, do something with the attributes of the detail row set.
8. Get the related row set of the second detail view object using the view link accessor attribute.
9. Iterates over the second detail row set rows.
10. Optionally, do something with the second detail row set attributes.

Other than having one additional level of nesting, [Example 6-9](#) uses the same API's used in the `TestClient` program that was iterating over master-detail read-only view objects in [Section 6.4.6, "How to Access a Detail Collection Using the View Link Accessor."](#)

If you use JDeveloper's **Refactor > Duplicate** functionality on an existing `TestClient.java` class, you can quickly "clone" it to create a `TestClient2.java` class. For example, the `TestClient.java` class in [Example 6-8](#) is suited to this technique.

Example 6-9 Iterating Master/Detail/Detail Hierarchy

```
package oracle.fodemo.storefront.client;
```

```

import oracle.jbo.ApplicationModule;
import oracle.jbo.Row;
import oracle.jbo.RowSet;
import oracle.jbo.ViewObject;
import oracle.jbo.client.Configuration;

public class TestClient2 {

    public static void main(String[] args) {
        String    amDef =
            "oracle.fodemo.storefront.store.service.StoreServiceAM";
        String    config = "StoreServiceAMLocal";
        ApplicationModule am =
            Configuration.createRootApplicationModule(amDef, config);
        // 1. Find the Persons view object instance.
        ViewObject personList = am.findViewObject("Persons");
        // 2. Execute the query
        personList.executeQuery();
        // 3. Iterate over the resulting rows
        while (personList.hasNext()) {
            Row person = personList.next();
            // 4. Print the person's email
            System.out.println("Person: " + person.getAttribute("Email"));
            // 5. Get related rowset of Orders using view link accessor attribute
            RowSet orders = (RowSet)person.getAttribute("Orders");
            // 6. Iterate over the Orders rows
            while (orders.hasNext()) {
                Row order = orders.next();
                // 7. Print out some order attribute values
                System.out.println(" ["+order.getAttribute("OrderStatusCode")+"] "+
                    order.getAttribute("OrderId")+": "+
                    order.getAttribute("OrderTotal"));
                if(!order.getAttribute("OrderStatusCode").equals("COMPLETE")) {
                    // 8. Get related rowset of OrderItems using view link accessor attribute
                    RowSet items = (RowSet)order.getAttribute("OrderItems");
                    // 9. Iterate over the OrderItems rows
                    while (items.hasNext()) {
                        Row item = items.next();
                        // 10. Print out some order items attributes
                        System.out.println("   "+item.getAttribute("LineItemId")+": "+
                            item.getAttribute("LineItemTotal"));
                    }
                }
            }
        }
        Configuration.releaseRootApplicationModule(am, true);
    }
}

```

Running the program produces the output shown in [Example 6–10](#).

6.4.8 How to Find a Row and Update a Foreign Key Value

To find a row and update a foreign key value, follow these basic steps (as illustrated in [Example 6–11](#)):

1. Find the view object instance.
2. Construct a `Key` object to look up the row for the view instance.
3. Use `findByKey()` to find the row.
4. Optionally, do something with the row's attribute.

[Example 6–11](#) shows the `main()` method finds and updates a foreign key value to find a row of the `Orders` view object instance. The sample then prints out the existing value of the `OrderStatusCode` attribute before changing the value on the row.

Example 6–11 Finding and Updating a Foreign Key Value

```

package oracle.fodemo.storefront.client;

import oracle.jbo.ApplicationModule;
import oracle.jbo.JboException;
import oracle.jbo.Key;
import oracle.jbo.Row;
import oracle.jbo.ViewObject;
import oracle.jbo.client.Configuration;

public class TestFindAndUpdate {
    public static void main(String[] args) {
        String amDef =
            "oracle.fodemo.storefront.store.service.StoreServiceAM";
        String config = "StoreServiceAMLocal";
        ApplicationModule am =
            Configuration.createRootApplicationModule(amDef, config);
        // 1. Find the Orders view object instance
        ViewObject vo = am.findViewObject("Orders");
        // 2. Construct a new Key to find Order # 1011
        Key orderKey = new Key(new Object[]{1011});
        // 3. Find the row matching this key
        Row[] ordersFound = vo.findByKey(orderKey, 1);
        if (ordersFound != null && ordersFound.length > 0) {
            Row order = ordersFound[0];
            // 4. Print some order information
            String orderStatus = (String)order.getAttribute("OrderStatusCode");
            System.out.println("Current status is: " + orderStatus);
            try {
                // 5. Try setting the status to an illegal value
                order.setAttribute("OrderStatusCode", "REOPENED");
            }
            catch (JboException ex) {
                System.out.println("ERROR: " + ex.getMessage());
            }
            // 6. Set the status to a legal value

```

```

        order.setAttribute("OrderStatusCode", "PENDING");
        // 7. Show the value of the status was updated successfully
        System.out.println("Current status is: " +
            order.getAttribute("OrderStatusCode"));
        // 8. Show the current value of the customer for this order
        System.out.println("Customer: " + order.getAttribute("CustomerId"));
        // 9. Reassign the order to customer # 113
        order.setAttribute("CustomerId", 113); // Luis Popp
        // 10. Show the value of the reference information now
        System.out.println("Customer: "+order.getAttribute("CustomerId"));
        // 11. Rollback the transaction
        am.getTransaction().rollback();
        System.out.println("Transaction canceled");
    }
    Configuration.releaseRootApplicationModule(am, true);
}
}
}

```

Running this example produces the output shown in [Example 6–12](#).

Example 6–12 Results of Running TestFindAndUpdate.java

```

Current status is: Closed
ERROR: The status must be Open, Pending, or Closed
Current status is: Open
Assigned: bernst
Assigned: Luis Popp
Transaction canceled

```

6.4.9 How to Create a New Row for a View Object Instance

To create a new view row instance, follow these basic steps (as illustrated in [Example 6–13](#)):

1. Find the view object instance.
2. Create a new row and insert it into the row set.
3. Set the values of the required attributes in the new row.
4. Commit the transaction.

[Example 6–13](#) shows the `main()` method finds the `Orders` view object instance and inserts a new row into the row set. Because the `Orders` view object is entity-based, the `CreatedBy` attribute derives its value from the mapped entity object attribute. The sample then sets values for the remaining attributes before committing the transaction.

Example 6–13 Creating a New Order

```

package oracle.fodemo.storefront.client;
import oracle.jbo.ApplicationModule;
import oracle.jbo.Row;
import oracle.jbo.ViewObject;
import oracle.jbo.client.Configuration;
import oracle.jbo.domain.DBSequence;
import oracle.jbo.domain.Date;
import oracle.jbo.domain.Timestamp;

public class TestCreateOrder {
    public static void main(String[] args) throws Throwable {
        String amDef = "oracle.fodemo.storefront.store.service.StoreServiceAM";
        String config = "StoreServiceAMLocal";
    }
}

```

```

ApplicationModule am =
    Configuration.createRootApplicationModule(amDef, config);
// 1. Find the Orders view object instance.
ViewObject orders = am.findViewObject("Orders");
// 2. Create a new row and insert it into the row set
Row newOrder = orders.createRow();
orders.insertRow(newOrder);
// Show the entity object-related defaulting for CreatedBy attribute
System.out.println("CreatedBy defaults to: " +
    newOrder.getAttribute("CreatedBy"));
// 3. Set values for some of the required attributes
Date now = new Date(new Timestamp(System.currentTimeMillis()));
newOrder.setAttribute("OrderDate", now);
newOrder.setAttribute("OrderStatusCode", "PENDING");
newOrder.setAttribute("OrderTotal", 500);
newOrder.setAttribute("CustomerId", 110);
newOrder.setAttribute("ShipToAddressId", 2);
newOrder.setAttribute("ShippingOptionId", 2);
newOrder.setAttribute("FreeShippingFlag", "N");
newOrder.setAttribute("GiftwrapFlag", "N");
// 4. Commit the transaction
am.getTransaction().commit();
// 5. Retrieve and display the trigger-assigned order id
DBSequence id = (DBSequence)newOrder.getAttribute("OrderId");
System.out.println("Thanks, reference number is " +
    id.getSequenceNumber());
Configuration.releaseRootApplicationModule(am, true);
}
}

```

Running this example produces the results shown in [Example 6–14](#).

Example 6–14 Results of Running TestCreateOrder.java

```

CreatedBy defaults to: Luis Popp
Thanks, reference number is 200

```

6.4.10 How to Retrieve the Row Key Identifying a Row

To retrieve a row key to identify a row, follow these basic steps (as illustrated in [Example 6–15](#)):

1. Find the view object instance.
2. Construct a key using a supplied value.
3. Find the row with this key.
4. Optionally, do something with the key of the row.

[Example 6–15](#) shows the `main()` method finds the `Orders` view object instance and constructs a row key to find an order number. The `findByKey()` method find the `Orders` rows with the specified key. The sample then displays the key of the row, accesses the row set using the `OrderItems` view link accessor, and iterates over the rows to display the key of each `OrderItems` row.

Example 6–15 Retrieving the Row Key Identifying a Row

```

package oracle.fodemo.storefront.client;
import oracle.jbo.ApplicationModule;
import oracle.jbo.Key;
import oracle.jbo.Row;

```

```

import oracle.jbo.RowSet;
import oracle.jbo.ViewObject;
import oracle.jbo.client.Configuration;

public class TestFindAndShowKeys {
    public static void main(String[] args) {
        String amDef = "oracle.fodemo.storefront.store.service.StoreServiceAM";
        String config = "StoreServiceAMLocal";
        ApplicationModule am =
            Configuration.createRootApplicationModule(amDef, config);
        // 1. Find the Orders view object instance
        ViewObject vo = am.findViewObject("Orders");
        // 2. Construct a key to find order number 1011
        Key orderKey = new Key(new Object[] { 1011 });
        // 3. Find the Orders row with the key
        Row[] ordersFound = vo.findByKey(orderKey, 1);
        if (ordersFound != null && ordersFound.length > 0) {
            Row order = ordersFound[0];
            // 4. Displays the key of the Orders row
            showKeyFor(order);
            // 5. Accesses row set of Orders using OrderItems view link accessor
            RowSet items = (RowSet)order.getAttribute("OrderItems");
            // 6. Iterates over the OrderItems row
            while (items.hasNext()) {
                Row itemRow = items.next();
                // 4. Displays the key of each OrderItems row
                showKeyFor(itemRow);
            }
        }
        Configuration.releaseRootApplicationModule(am, true);
    }

    private static void showKeyFor(Row r) {
        // get the key for the row passed in
        Key k = r.getKey();
        // format the key as "(val1,val2)"
        String keyAttrs = formatKeyAttributeNamesAndValues(k);
        // get the serialized string format of the key, too
        String keyStringFmt = r.getKey().toStringFormat(false);
        System.out.println("Key " + keyAttrs + " has string format " +
            keyStringFmt);
    }
    // Build up "(val1,val2)" string for key attributes

    private static String formatKeyAttributeNamesAndValues(Key k) {
        StringBuffer sb = new StringBuffer("");
        int attrsInKey = k.getAttributeCount();
        for (int i = 0; i < attrsInKey; i++) {
            if (i > 0)
                sb.append(",");
            sb.append(k.getAttributeValues()[i]);
        }
        sb.append(")");
        return sb.toString();
    }
}

```

Running the example produces the results shown in [Example 6-16](#). Notice that the serialized string format of a key is a hexadecimal number that includes information in a single string that represents all the attributes in a key.

Example 6–16 Results of Running TestFindAndShowKeys.java

```
Key (1011) has string format 000100000003313031
Key (1011,1) has string format 000200000003C2020200000002C102
Key (1011,2) has string format 000200000003C2020200000002C103
```

6.4.11 How to Authenticate Test Users in the Test Client

If you have enabled ADF Security for your application and provisioned the `jazn-data.xml` file with test users, you will need to include method calls to authenticate a user before you run the test client. To authenticate a user in the test client, follow these basic steps (as illustrated in [Example 6–17](#)):

1. Create the authentication service.
2. Pass in the login credentials for a test user defined in the `jazn-data.xml` file.
3. If authentication succeeds, then test the application module.
4. Log the user out.

For details about how to run the Configure ADF Security wizard to enable ADF Security and how to create test users in JDeveloper’s identity store, see [Section 35.2, "ADF Security Process Overview."](#)

Example 6–17 Passing Login Credentials in the Test Client

```
package oracle.fodemo.storefront.client;
import oracle.jbo.ApplicationModule;
import oracle.jbo.Key;
import oracle.jbo.Row;
import oracle.jbo.RowSet;
import oracle.jbo.ViewObject;
import oracle.jbo.client.Configuration;

import oracle.adf.share.ADFContext;
import oracle.adf.share.security.SecurityContext;
import oracle.adf.share.security.SecurityEnv;
import oracle.adf.share.security.authentication.JAASAuthenticationService;

import javax.security.auth.Subject;
import javax.security.jacc.PolicyContext;

public class TestAuthenticationClient {
    public static void main(String[] args) {
        String amDef = "test.TestAuthModule";
        String config = "TestAuthModuleLocal";

        // 1. Create authentication service.
        JAASAuthenticationService authService = new JAASAuthenticationService();
        try
        {
            // 2. Pass in user id and password defined in local identity store.
            authService.login("tester1", "welcome1");
        }
        catch (Exception e)
        {
        }

        // Uncomment to output authentication status
        // String userName =
```

```
        ADFContext.getCurrent().getSecurityContext().getUserName();

// System.out.println("*** userName : " + userName);
// Subject subject =
        ADFContext.getCurrent().getSecurityContext().getSubject();
// System.out.println("Subject : " + subject);

// 3. Test application module if authentication succeeds.
if (ADFContext.getCurrent().getSecurityContext().isAuthenticated() {
    ApplicationModule am =
        Configuration.createRootApplicationModule(amDef,config);
    ViewObject vo = am.findViewObject("TestView");
    // Work with your appmodule and view object here
    Configuration.releaseRootApplicationModule(am,true);

// 4. Log out test user.
    authService.logout();

// Uncomment to report logout success
// boolean isAuthenticated =
        ADFContext.getCurrent().getSecurityContext().isAuthenticated();
// System.out.println("*** isAuthenticated : " + isAuthenticated);
}
}
}
```

Defining Validation and Business Rules Declaratively

This chapter explains the key entity object features for implementing the most common kinds of validation rules.

This chapter includes the following sections:

- [Section 7.1, "About Declarative Validation"](#)
- [Section 7.2, "Understanding the Validation Cycle"](#)
- [Section 7.3, "Adding Validation Rules to Entity Objects and Attributes"](#)
- [Section 7.4, "Using the Built-in Declarative Validation Rules"](#)
- [Section 7.5, "Using Groovy Expressions For Validation and Business Rules"](#)
- [Section 7.6, "Triggering Validation Execution"](#)
- [Section 7.7, "Creating Validation Error Messages"](#)
- [Section 7.8, "Setting the Severity Level for Validation Exceptions"](#)
- [Section 7.9, "Bulk Validation in SQL"](#)

7.1 About Declarative Validation

The easiest way to create and manage validation rules is through *declarative validation rules*. Declarative validation rules are defined using the overview editor, and once created, are stored in the entity object's XML file. Declarative validation is different from programmatic validation (covered in [Chapter 8, "Implementing Validation and Business Rules Programmatically"](#)), which is stored in an entity object's Java file.

Oracle ADF provides built-in declarative validation rules that satisfy many of your business needs. If you have custom validation rules you want to reuse, you can code them and add them to the IDE, so that the rules are available directly from JDeveloper. Custom validation rules are an advanced topic and covered in [Section 8.14, "Implementing Custom Validation Rules."](#) You can also base validation on a Groovy expression, as described in [Section 7.5, "Using Groovy Expressions For Validation and Business Rules."](#)

When you add a validation rule, you supply an appropriate error message and can later translate it easily into other languages if needed. You can also define how validation is triggered and set the severity level.

7.1.1 Declarative Validation Use Cases and Examples

In an ADF Business Components application, most of your validation code is defined in your entity objects. Encapsulating the business logic in these shared, reusable components ensures that your business information is validated consistently in every view object or client that accesses it, and it simplifies maintenance by centralizing where the validation is stored.

Another benefit of using declarative validation (versus writing your own validation) is that the validation framework takes care of the complexities of batching validation exceptions, which frees you to concentrate on your application's specific validation rule logic.

In the model layer, ADF Model validation rules can be set for the attributes of a collection. Many of the declarative validation features available for entity objects are also available at the model layer, should your application warrant the use of model-layer validation in addition to business-layer validation. For more information, see [Chapter 16, "Using Validation in the ADF Model Layer."](#)

When you use the ADF Business Components application module data control, you do not need to use model-layer validation. Consider defining all or most of your validation rules in the centralized, reusable, and easier to maintain entity objects of your business layer. With other types of data controls, model-layer validation can be more useful.

7.1.2 Additional Functionality for Declarative Validation

You may find it helpful to understand other ADF features before you start using declarative validation. It is possible to go beyond the declarative behavior to implement more complex validation rules for your business domain layer when needed. Following are links to other functionality that may be of interest.

- [Section 8.2, "Using Method Validators"](#) explains how to use the Method validator to invoke custom validation code.
- [Section 8.14, "Implementing Custom Validation Rules"](#) details how to extend the basic set of declarative rules with custom rules of your own.

7.2 Understanding the Validation Cycle

Each entity row tracks whether or not its data is valid. When an existing entity row is retrieved from the database, the entity is assumed to be valid. When the first persistent attribute of an existing entity row is modified, or when a new entity row is created, the entity is marked invalid.

When an entity is in an invalid state, the declarative validation you have configured and the programmatic validation rules you have implemented are evaluated again before the entity can be considered valid again. You can determine whether a given entity row is valid at runtime by calling the `isValid()` method on it.

Note: Because attributes can (by default) be left blank, validations are not triggered if the attribute contains no value. For example, if a user creates a new entity row and does not enter a value for a given attribute, the validation on that attribute is not run. To force the validation to execute in this situation, set the Mandatory flag on the attribute.

7.2.1 Types of Entity Object Validation Rules

Entity object validation rules fall into two basic categories: *attribute-level* and *entity-level*.

7.2.1.1 Attribute-Level Validation Rules

Attribute-level validation rules are triggered for a particular entity object attribute when either the end user or the program code attempts to modify the attribute's value. Since you cannot determine the order in which attributes will be set, attribute-level validation rules should be used only when the success or failure of the rule depends exclusively on the candidate value of that single attribute.

The following examples are attribute-level validations:

- The value of the `OrderDate` of an order should not be a date in the past.
- The `ProductId` attribute of a product should represent an existing product.

7.2.1.2 Entity-Level Validation Rules

All other kinds of validation rules are entity-level validation rules. These are rules whose implementation requires considering two or more entity attributes, or possibly composed children entity rows, in order to determine the success or failure of the rule.

The following examples are entity-level validations:

- The value of the `OrderShippedDate` should be a date that comes after the `OrderDate`.
- The `ProductId` attribute of an order should represent an existing product.

Entity-level validation rules are triggered by calling the `validate()` method on a `Row`. This occurs when:

- You call the method explicitly on the entity object
- You call the method explicitly on a view row with an entity row part that is invalid
- A view object's iterator calls the method on the current row in the view object before allowing the current row to change
- During transaction commit, processing validates an invalid entity (in the list of pending changes) before proceeding with posting the changes to the database

As part of transaction commit processing, entity-level validation rules can fire multiple times (up to a specified limit). For more information, see [Section 7.2.4, "Avoiding Infinite Validation Cycles."](#)

7.2.2 Understanding Commit Processing and Validation

Transaction commit processing happens in three basic phases:

1. Ensure that any invalid entity rows on the pending changes list are valid.
2. Post the pending changes to the database by performing appropriate DML operations.
3. Commit the transaction.

If you have business validation logic in your entity objects that executes queries or stored procedures that depend on seeing the posted changes in the `SELECT` statements they execute, they should be coded in the `beforeCommit()` method described in [Section 8.5.3, "What You May Need to Know About Row Set Access with View Accessors."](#) This method fires after all DML statements have been applied so queries or

stored procedures invoked from that method can "see" all of the pending changes that have been saved, but not yet committed.

Caution: don't use the transaction-level `postChanges()` method in web applications unless you can guarantee that the transaction will definitely be committed or rolled-back during the same HTTP request. This method exists to force the transaction to post unvalidated changes without committing them. Failure to heed this advice can lead to strange results in an environment where both application modules and database connections can be pooled and shared serially by multiple different clients.

7.2.3 Understanding the Impact of Composition on Validation Order

Because a composed child entity row is considered an integral part of its composing parent entity object, any change to composed child entity rows causes the parent entity to be marked invalid. For example, if a line item on an order were to change, the entire order would now be considered to be changed, or invalid.

Therefore, when the composing entity is validated, it causes any currently invalid composed children entities to be validated first. This behavior is recursive, drilling into deeper levels of invalid composed children if they exist.

7.2.4 Avoiding Infinite Validation Cycles

If your validation rules contain code that updates attributes of the current entity or other entities, then the act of validating the entity can cause that or other entities to become invalid. As part of the transaction commit processing phase that attempts to validate all invalid entities in the pending changes list, the transaction performs multiple passes (up to a specified limit) on the pending changes list in an attempt to reach a state where all pending entity rows are valid.

The maximum number of validation passes is specified by the transaction-level validation threshold setting. The default value of this setting is 10. You can increase the threshold count to greater than one if the entities involved contain the appropriate logic to validate themselves in the subsequent passes.

If after 10 passes, there are still invalid entities in the list, you will see the following exception:

```
JBO-28200: Validation threshold limit reached. Invalid Entities still in cache
```

This is a sign that you need to debug your validation rule code to avoid inadvertently invalidating entities in a cyclic fashion.

To change the validation threshold, use the `SetValidationThreshold()` method as shown in [Example 7-1](#). In this example, the new threshold is 12.

Example 7-1 Changing the Validation Threshold

```
oracle.jbo.server.DBTransaction::setValidationThreshold(12)
```

7.2.5 What Happens When Validations Fail

When an entity object's validation rules throw exceptions, the exceptions are bundled and returned to the client. If the validation failures are thrown by methods you've overridden to handle events during the transaction `postChanges` processing, then

the validation failures cause the transaction to roll back any database INSERT, UPDATE, or DELETE statements that might have been performed already during the current `postChanges` cycle.

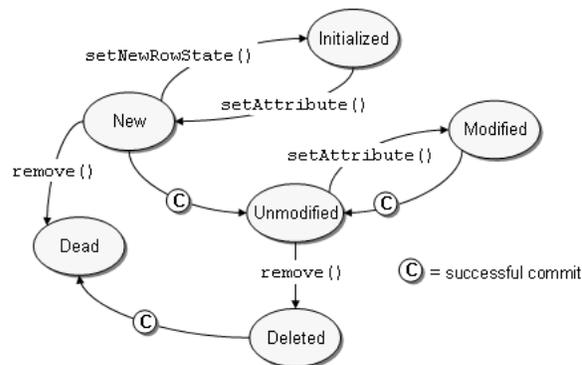

Note: The bundling of exceptions is the default behavior for ADF Model-based web applications, but not for Oracle ADF Model Tester or Swing bindings. Additional configuration is required to bundle exceptions for the Oracle ADF Model Tester or Swing clients.

7.2.6 Understanding Entity Objects Row States

When an entity row is in memory, it has an entity state that reflects the logical state of the row. [Figure 7-1](#) illustrates the different entity row states and how an entity row can transition from one state to another. When an entity row is first created, its status is `New`. You can use the `setNewRowState()` method to mark the entity as being `Initialized`, which removes it from the transaction's list of pending changes until the user sets at least one of its attributes, at which time it returns to the `New` state. This allows you to create more than one initialized row and post only those that the user modifies.

The `Unmodified` state reflects an entity that has been retrieved from the database and has not yet been modified. It is also the state that a `New` or `Modified` entity transitions to after the transaction successfully commits. During the transaction in which it is pending to be deleted, an `Unmodified` entity row transitions to the `Deleted` state. Finally, if a row that was `New` and then was removed before the transaction commits, or `Unmodified` and then successfully deleted, the row transitions to the `Dead` state.

Figure 7-1 Diagram of Entity Row States and Transitions

You can use the `getEntityState()` and `getPostState()` methods to access the current state of an entity row in your business logic code. The `getEntityState()` method returns the current state of an entity row with regard to the transaction, while the `getPostState()` method returns the current state of an entity row with regard to the database after using the `postChanges()` method to post pending changes without committing the transaction.

For example, if you start with a new row, both `getEntityState()` and `getPostState()` return `STATUS_NEW`. Then when you post the row (before commit or rollback), the row will have an entity state of `STATUS_NEW` and a post state of `STATUS_UNMODIFIED`. If you subsequently remove that row, the entity state will remain `STATUS_NEW` because for the transaction the row is still new. But the post state will be `STATUS_DEAD`.

7.2.7 Understanding Bundled Exception Mode

An application module provides a feature called bundled exception mode which allows web applications to easily present a maximal set of failed validation exceptions to the end user, instead of presenting only the *first* error that gets raised. By default, the ADF Business Components application module pool enables bundled exception mode for web applications.

You typically will not need to change this default setting. However it is important to understand that it is enabled by default since it effects how validation exceptions are thrown. Since the Java language and runtime only support throwing a single exception object, the way that bundled validation exceptions are implemented is by wrapping a set of exceptions as details of a new "parent" exception that contains them. For example, if multiple attributes in a single entity object fail attribute-level validation, then these multiple `ValidationException` objects will be wrapped in a `RowValException`. This wrapping exception contains the row key of the row that has failed validation. At transaction commit time, if multiple rows do not successfully pass the validation during commit, then all of the `RowValException` objects will get wrapped in an enclosing `TxnValException` object.

When writing custom error processing code, you can use the `getDetails()` method of the `JboException` base exception class to recursively process the bundled exceptions contained inside it.

Note: All the exception classes mentioned here are in the `oracle.jbo` package.

7.3 Adding Validation Rules to Entity Objects and Attributes

The process for adding a validation rule to an entity object is similar for most of the validation rules, and is done using the Add Validation Rule dialog. You can open this dialog from the overview editor by clicking the **Add** icon on the Business Rules page.

It is important to note that when you define a rule declaratively using the Add Validation Rule dialog, the rule definition you provide specifies the *valid* condition for the attribute or entity object. At runtime, the entry provided by the user is evaluated against the rule definition and an error or warning is raised if the entry fails to satisfy the specified criteria. For example, if you specify a Length validator on an attribute that requires it to be `Less Than or Equal To 12`, the validation fails if the entry is more than 12 characters, and the error or warning is raised.

7.3.1 How to Add a Validation Rule to an Entity or Attribute

To add a declarative validation rule to an entity object, use the Business Rules page of the overview editor.

Before you begin:

It may be helpful to have an understanding of the use of validation rules in entity objects and attributes. For more information, see [Section 7.3, "Adding Validation Rules to Entity Objects and Attributes."](#)

You may also find it helpful to understand additional functionality that can be added using other validation features. For more information, see [Section 7.1.2, "Additional Functionality for Declarative Validation."](#)

To add a validation rule:

1. In the Application Navigator, double-click the desired entity object.
2. In the overview editor, click the **Business Rules** navigation tab, select the object for which you want to add a validation rule, and then click the **Add** icon.
 - To add a validation rule at the entity object level, select **Entity**.
 - To add a validation rule for an attribute, expand **Attributes** and select the desired attribute.

When you add a new validation rule, the Add Validation Rule dialog appears.

3. From the **Rule Type** dropdown list, select the desired type of validation rule.
4. Use the dialog settings to configure the new rule.

The controls will change depending on the kind of validation rule you select.

For more information about the different validation rules, see [Section 7.4, "Using the Built-in Declarative Validation Rules."](#)

5. You can optionally click the **Validation Execution** tab and enter criteria for the execution of the rule, such as dependent attributes and a precondition expression.

For more information, see [Section 7.6, "Triggering Validation Execution."](#)

Note: For Key Exists and Method entity validators, you can also use the **Validation Execution** tab to specify the validation level.

6. Click the **Failure Handling** tab and enter or select the error message that will be shown to the user if the validation rule fails.

For more information, see [Section 7.7, "Creating Validation Error Messages."](#)
7. Click **OK**.

7.3.2 How to View and Edit a Validation Rule on an Entity Object or Attribute

The Business Rules page of the overview editor for entity objects displays the validation rules for an entity and its attributes in a tree control. To see the validation rules that apply to the entity as a whole, expand in the **Entity** node. To see the validation rules that apply to an attribute, expand the **Attributes** node and then expand the attribute.

The validation rules that are shown on the Business Rules page of the overview editor include those that you have defined as well as database constraints, such as mandatory or precision. To open a validation rule for editing, double-click the rule or select the rule and click the **Edit** icon.

7.3.3 What Happens When You Add a Validation Rule

When you add a validation rule to an entity object, JDeveloper updates its XML component definition to include an entry describing what rule you've used and what rule properties you've entered. For example, if you add a range validation rule to the `DiscountAmount` attribute, this results in a `RangeValidationBean` entry in the XML file, as shown in [Example 7-2](#).

Example 7-2 Range Validation Bean

```
<Attribute
```

```
Name="DiscountAmount"  
IsNotNull="true"  
ColumnName="DISCOUNT_AMOUNT"  
. . .  
<validation:RangeValidationBean  
  xmlns="http://xmlns.oracle.com/adfm/validation"  
  Name="DiscountAmount_Rule_0"  
  ResId="DiscountAmount_RangeError_0"  
  OnAttribute="DiscountAmount"  
  OperandType="LITERAL"  
  Inverse="false"  
  MinValue="0"  
  MaxValue="40"/>  
. . .  
</Attribute>
```

At runtime, the rule is enforced by the entity object based on this declarative information.

7.3.4 What You May Need to Know About Entity and Attribute Validation Rules

Declarative validation enforces both entity-level and attribute-level validation, depending on where you place the rules. Entity-level validation rules are enforced when a user tries to commit pending changes or navigates between rows. Attribute-level validation rules are enforced when the user changes the value of the related attribute.

The Unique Key validator (described in [Section 7.4.1, "How to Ensure That Key Values Are Unique"](#)) can be used only at the entity level. Internally the Unique Key validator behaves like an attribute-level validator. This means that users see the validation error when they tab out of the key attribute for the key that the validator is validating. This is done because the internal cache of entities can never contain a duplicate, so it is not allowed for an attribute value to be set that would violate that. This check needs to be performed when the attribute value is being set because the cache consistency check is done during the setting of the attribute value.

Best Practice: If the validity of one attribute is dependent on one or more other attributes, enforce this rule using entity validation, not attribute validation. Examples of when you would want to do this include the following:

- You have a Compare validator that compares one attribute to another.
- You have an attribute with an expression validator that examines the value in another attribute to control branching in the expression to validate the attribute differently depending on the value in this other attribute.
- You make use of conditional execution, and your precondition expression involves an attribute other than the one that you are validating.

Entity object validators are triggered whenever the entity, as a whole, is dirty. To improve performance, you can indicate which attributes play a role in your rule and thus the rule should be triggered only if one or more of these attributes are dirty. For more information on triggering attributes, see, [Section 7.6, "Triggering Validation Execution."](#)

7.4 Using the Built-in Declarative Validation Rules

The built-in declarative validation rules can satisfy many, if not all, of your business needs. These rules are easy to implement because you don't write any code. You use the user-interface tools to choose the type of validation and how it is used.

Built-in declarative validation rules can be used to:

- Ensure that key values are unique (primary key or other unique keys)
- Determine the existence of a key value
- Make a comparison between an attribute and anything from a literal value to a SQL query
- Validate against a list of values that might be a literal list, a SQL query, or a view attribute
- Make sure that a value falls within a certain range, or that it is limited by a certain number of bytes or characters
- Validate using a regular expression or evaluate a Groovy expression
- Make sure that a value satisfies a relationship defined by an aggregate on a child entity available through an accessor
- Validate using a validation condition defined in a Java method on the entity

7.4.1 How to Ensure That Key Values Are Unique

The Unique Key validator ensures that primary key values for an entity object are always unique. The Unique Key validator can also be used for a non-primary-key attribute, as long as the attribute is defined as an alternate key. For information on how to define alternate keys, see [Section 4.10.15, "How to Define Alternate Key Values."](#)

Whenever any of the key attribute values change, this rule validates that the new key does not belong to any other entity object instance of this entity object class. (It is the business-logic tier equivalent of a unique constraint in the database.) If the key is found in one of the entity objects, a `TooManyObjectsException` is thrown. The validation check is done both in the entity cache and in the database.

There is a slight possibility that unique key validation might not be sufficient to prevent duplicate rows in the database. It is possible for two application module sessions to simultaneously attempt to create records with the same key. To prevent this from happening, create a unique index in the database for any unique constraint that you want to enforce.

Before you begin:

It may be helpful to have a general understanding of the built-in validation rules. For more information, see [Section 7.4, "Using the Built-in Declarative Validation Rules."](#)

You may also find it helpful to understand additional functionality that can be added using other validation features. For more information, see [Section 7.1.2, "Additional Functionality for Declarative Validation."](#)

To ensure that a key value is unique:

1. In the Application Navigator, double-click the desired entity object.
2. In the overview editor, click the **Business Rules** navigation tab, select the **Entity** node, and click the **Add** icon.

3. In the Add Validation Rule dialog, in the **Rule Type** dropdown list, select **UniqueKey**.
4. In the **Keys** box, select the primary or alternate key.
5. You can optionally click the **Validation Execution** tab and enter criteria for the execution of the rule, such as dependent attributes and a precondition expression.
For more information, see [Section 7.6, "Triggering Validation Execution."](#)

Best Practice: While it is possible to add a precondition for a Unique Key validator, it is not a best practice. If a Unique Key validator fails to fire, for whatever reason, the cache consistency check is still performed and an error will be returned. It is generally better to add the validator and a meaningful error message.

6. Click the **Failure Handling** tab and enter or select the error message that will be shown to the user if the validation rule fails.
For more information, see [Section 7.7, "Creating Validation Error Messages."](#)
7. Click **OK**.

7.4.2 What Happens When You Use a Unique Key Validator

When you use a Unique Key validator, a `<UniqueKeyValidationBean>` tag is added to the entity object's XML file. [Example 7-3](#) shows the XML for a Unique Key validator.

Example 7-3 Unique Key Validator XML Code

```
<validation:UniqueKeyValidationBean
  Name="PersonEO_Rule_1"
  KeyName="AltKey"
  ResId="PersonEO_Rule_1">
  <validation:OnAttributes>
    <validation:Item
      Value="Email" />
  </validation:OnAttributes>
</validation:UniqueKeyValidationBean>
```

7.4.3 How to Validate Based on a Comparison

The Compare validator performs a logical comparison between an entity attribute and a value. When you add a Compare validator, you specify an operator and something to compare with. You can compare the following:

- Literal value

When you use a Compare validator with a literal value, the value in the attribute is compared against the specified literal value. When using this kind of comparison, it is important to consider data types and formats. The literal value must conform to the format specified by the data type of the entity attribute to which you are applying the rule. In all cases, the type corresponds to the type mapping for the entity attribute.

For example, an attribute of column type DATE maps to the `oracle.jbo.domain.Date` class, which accepts dates and times in the same format accepted by `java.sql.TimeStamp` and `java.sql.Date`. You can use format masks to ensure that the format of the value in the attribute matches that of

the specified literal. For information about entity object attribute type mappings, see [Section 4.10.1, "How to Set Database and Java Data Types for an Entity Object Attribute."](#) For information about the expected format for a particular type, refer to the Javadoc for the type class.

- Query result

When you use this type of validator, the SQL query is executed each time the validator is executed. The validator retrieves the first row from the query result, and it uses the value of the first column in the query (of that first row) as the value to compare. Because this query cannot have any bind variables in it, this feature should be used only when selecting one column of one row of data that does not depend on the values in the current row.

- View object attribute

When you use this type of validator, the view object's SQL query is executed each time the validator is executed. The validator retrieves the first row from the query result, and it uses the value of the selected view object attribute from that row as the value to compare. Because you cannot associate values with the view object's named bind variables, those variables can only take on their default values. Therefore this feature should be used only for selecting an attribute of one row of data that does not depend on the values in the current row.

- View accessor attribute

When defining the view accessor, you can assign row-specific values to the validation view object's bind variables.

- Expression

For information on the expression option, see [Section 7.5, "Using Groovy Expressions For Validation and Business Rules."](#)

- Entity attribute

The entity attribute option is available only for entity-level Compare validators.

Before you begin:

It may be helpful to have a general understanding of the built-in validation rules. For more information, see [Section 7.4, "Using the Built-in Declarative Validation Rules."](#)

You may also find it helpful to understand additional functionality that can be added using other validation features. For more information, see [Section 7.1.2, "Additional Functionality for Declarative Validation."](#)

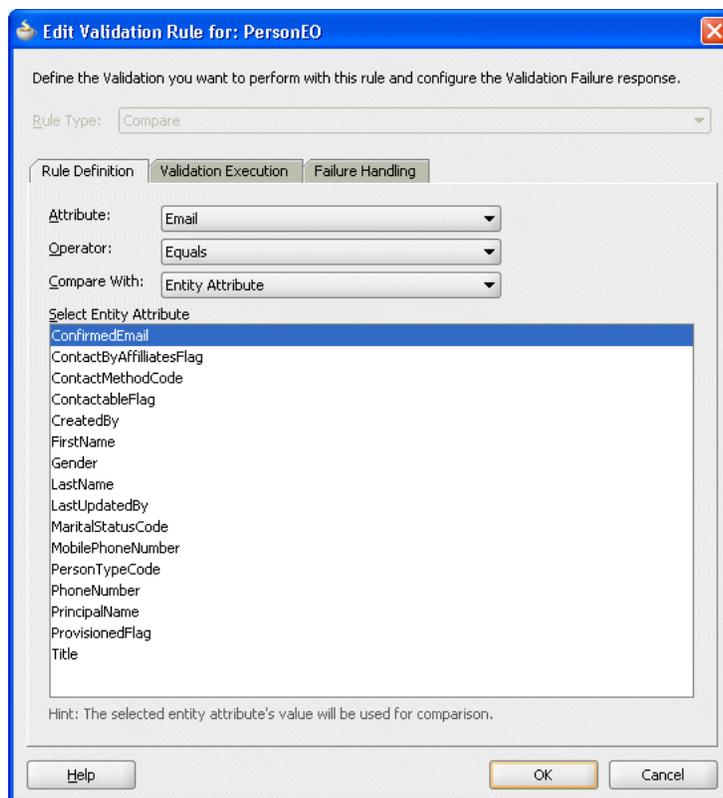

To validate based on a comparison:

1. In the Application Navigator, double-click the desired entity object.
2. In the overview editor, click the **Business Rules** navigation tab, select where you want to add the validator, and click the **Add** icon.
 - To add an entity-level validator, select the **Entity** node.
 - To add an attribute-level validator, expand the **Attributes** node and select the appropriate attribute.
3. In the Add Validation Rule dialog, in the **Rule Type** dropdown list, select **Compare**. Note that the subordinate fields change depending on your choices.
4. Select the appropriate operator.

5. Select an item in the **Compare With** list, and based on your selection provide the appropriate comparison value.
6. You can optionally click the **Validation Execution** tab and enter criteria for the execution of the rule, such as dependent attributes and a precondition expression.
For more information, see [Section 7.6, "Triggering Validation Execution."](#)
7. Click the **Failure Handling** tab and enter or select the error message that will be shown to the user if the validation rule fails.
For more information, see [Section 7.7, "Creating Validation Error Messages."](#)
8. Click **OK**.

[Figure 7-2](#) shows what the dialog looks like when you use an entity-level Compare validator with an entity object attribute.

Figure 7-2 Compare Validator Using an Entity Object Attribute

7.4.4 What Happens When You Validate Based on a Comparison

When you use a Compare validator, a `<CompareValidationBean>` tag is added to an entity object's XML file. [Example 7-4](#) shows the XML code for the Email attribute in the PersonEO entity object.

Example 7-4 Compare Validator XML Code

```
<validation:CompareValidationBean
  xmlns="http://xmlns.oracle.com/adfm/validation"
  Name="PersonEO_Rule_0"
  ResId="PersonEO_Rule_0"
  OnAttribute="Email"
```

```

OperandType="ATTR"
Inverse="false"
CompareType="EQUALTO"
CompareValue="ConfirmedEmail"/>

```

7.4.5 How to Validate Using a List of Values

The List validator compares an attribute against a list of values (LOV). When you add a List validator, you specify the type of list to choose from:

- **Literal values** - The validator ensures that the entity attribute is in (or not in, if specified) the list of values.
- **Query result** - The validator ensures that the entity attribute is in (or not in, if specified) the first column of the query's result set. The SQL query validator cannot use a bind variable, so it should be used only on a fixed, small list that you have to query from a table. All rows of the query are retrieved into memory.
- **View object attribute** - The validator ensures that the entity attribute is in (or not in, if specified) the view attribute. The View attribute validator cannot use a bind variable, so it should be used only on a fixed, small list that you have to query from a table. All rows of the query are retrieved into memory.
- **View accessor attribute** - The validator ensures that the entity attribute is in (or not in) the view accessor attribute. The view accessor is probably the most useful option, because it can take bind variables and after you've created the LOV on the user interface, a view accessor is required.

Best Practice: When using a List validator, the view accessor is typically the most useful choice because you can define a view criteria on the view accessor to filter the view data when applicable; and when defining an LOV on a view attribute, you typically use a view accessor with a view criteria.

Before you begin:

It may be helpful to have a general understanding of the built-in validation rules. For more information, see [Section 7.4, "Using the Built-in Declarative Validation Rules."](#)

You may also find it helpful to understand additional functionality that can be added using other validation features. For more information, see [Section 7.1.2, "Additional Functionality for Declarative Validation."](#)

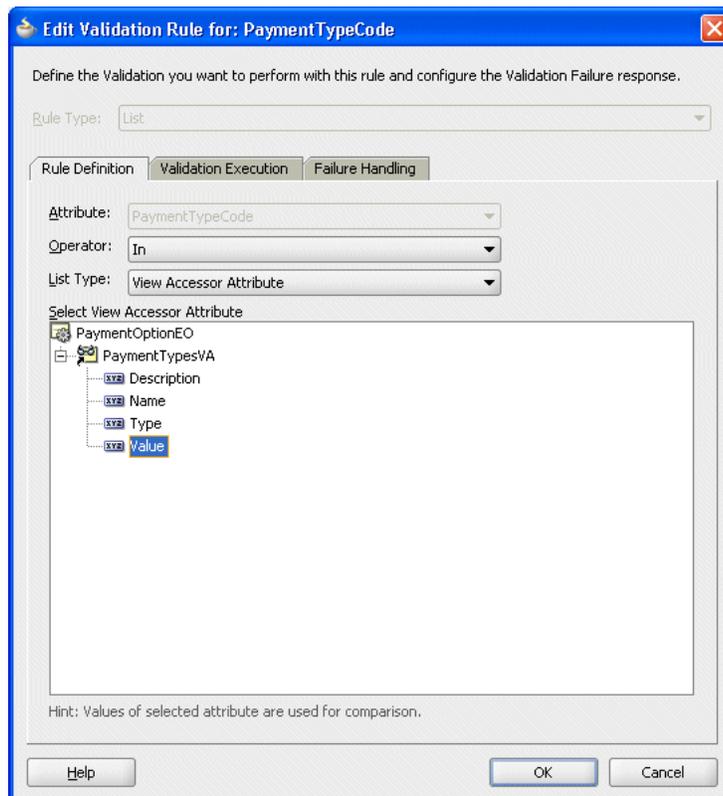

To validate using a list of values:

1. In the Application Navigator, double-click the desired entity object.
2. In the overview editor, click the **Business Rules** navigation tab, select where you want to add the validator, and click the **Add** icon.
 - To add an entity-level validator, select the **Entity** node.
 - To add an attribute-level validator, expand the **Attributes** node and select the appropriate attribute.
3. In the Add Validation Rule dialog, in the **Rule Type** dropdown list, select **List**.
4. In the **Attribute** list, choose the appropriate attribute.
5. In the **Operator** field, select **In** or **NotIn**, depending on whether you want an inclusive list or exclusive.

6. In the **List Type** field, select the appropriate type of list.
7. Depending on the type of list you selected, you can either enter a list of values (each value on a new line) or an SQL query, or select a view object attribute or view accessor attribute.
8. You can optionally click the **Validation Execution** tab and enter criteria for the execution of the rule, such as dependent attributes and a precondition expression.
For more information, see [Section 7.6, "Triggering Validation Execution."](#)
9. Click the **Failure Handling** tab and enter or select the error message that will be shown to the user if the validation rule fails.
For more information, see [Section 7.7, "Creating Validation Error Messages."](#)
10. Click **OK**.

Figure 7–3 shows what the dialog looks like when you use a List validator with a view accessor attribute.

Figure 7–3 List Validator Using a View Accessor Attribute

7.4.6 What Happens When You Validate Using a List of Values

When you validate using a list of values, a `<ListValidationBean>` tag is added to an entity object's XML file. [Example 7–5](#) shows the `PaymentOptionEO.PaymentTypeCode` attribute, which uses a view accessor attribute for the List validator.

Example 7–5 List Validator XML Code

```
<validation:ListValidationBean
```

```

xmlns="http://xmlns.oracle.com/adfm/validation"
Name="PaymentTypeCode_Rule_0"
ResId="PaymentTypeCode_Rule_0"
OnAttribute="PaymentTypeCode"
OperandType="VO_USAGE"
Inverse="false"
ViewAccAttrName="Value"
ViewAccName="PaymentTypesVA"/>

```

7.4.7 What You May Need to Know About the List Validator

The List validator is designed for validating an attribute against a relatively small set of values. If you select the **Query Result** or **View Object Attribute** type of list validation, keep in mind that the validator retrieves all of the rows from the query before performing an in-memory scan to validate whether the attribute value in question matches an attribute in the list. The query performed by the validator's SQL or view object query does not reference the value being validated in the WHERE clause of the query.

It is inefficient to use a validation rule when you need to determine whether a user-entered product code exists in a table of a large number of products. Instead, [Section 8.5, "Using View Objects for Validation"](#) explains the technique you can use to efficiently perform SQL-based validations by using a view object to perform a targeted validation query against the database. See also [Section 5.12.11.2, "Using Validators to Validate Attribute Values."](#)

Also, if the attribute you're comparing to is a key, the Key Exists validator is more efficient than validating a list of values; and if these choices need to be translatable, you should use a static view object instead of the literal choice.

7.4.8 How to Make Sure a Value Falls Within a Certain Range

The Range validator performs a logical comparison between an entity attribute and a range of values. When you add a Range validator, you specify minimum and maximum literal values. The Range validator verifies that the value of the entity attribute falls within the range (or outside the range, if specified).

If you need to dynamically calculate the minimum and maximum values, or need to reference other attributes on the entity, use the Script Expression validator and provide a Groovy expression. For more information, see [Section 3.6.1, "Referencing Business Components Objects in Groovy Expressions"](#) and [Section 3.6.3, "Manipulating Business Component Attribute Values in Groovy Expressions."](#)

Before you begin:

It may be helpful to have a general understanding of the built-in validation rules. For more information, see [Section 7.4, "Using the Built-in Declarative Validation Rules."](#)

You may also find it useful to understand additional functionality that can be added using other validation features. For more information, see [Section 7.1.2, "Additional Functionality for Declarative Validation."](#)

To validate within a certain range:

1. In the Application Navigator, double-click the desired entity object.
2. In the overview editor, click the **Business Rules** navigation tab, select where you want to add the validator, and click the **Add** icon.

- To add an entity-level validator, select the **Entity** node.
 - To add an attribute-level validator, expand the **Attributes** node and select the appropriate attribute.
3. In the Add Validation Rule dialog, in the **Rule Type** dropdown list, select **Range**.
 4. In the **Attribute** list, select the appropriate attribute.
 5. In the **Operator** field, select **Between** or **NotBetween**.
 6. In the **Minimum** and **Maximum** fields, enter appropriate values.
 7. You can optionally click the **Validation Execution** tab and enter criteria for the execution of the rule, such as dependent attributes and a precondition expression.
For more information, see [Section 7.6, "Triggering Validation Execution."](#)
 8. Click the **Failure Handling** tab and enter or select the error message that will be shown to the user if the validation rule fails.
For more information, see [Section 7.7, "Creating Validation Error Messages."](#)
 9. Click **OK**.

7.4.9 What Happens When You Use a Range Validator

When you validate against a range, a `<RangeValidationBean>` tag is added to the entity object's XML file. [Example 7-6](#) shows the `PersonEO.CreditLimit` attribute with a minimum credit limit of zero and a maximum of 10,000.

Example 7-6 Range Validator XML Code

```
<validation:RangeValidationBean
  Name="CreditLimit_Rule_0"
  ResId="CreditLimit_Rule_0"
  OnAttribute="CreditLimit"
  OperandType="LITERAL"
  Inverse="false"
  MinValue="0"
  MaxValue="10000"/>
```

7.4.10 How to Validate Against a Number of Bytes or Characters

The Length validator validates whether the string length (in characters or bytes) of an attribute's value is less than, equal to, or greater than a specified number, or whether it lies between a pair of numbers.

Before you begin:

It may be helpful to have a general understanding of the built-in validation rules. For more information, see [Section 7.4, "Using the Built-in Declarative Validation Rules."](#)

You may also find it helpful to understand additional functionality that can be added using other validation features. For more information, see [Section 7.1.2, "Additional Functionality for Declarative Validation."](#)

To validate against a number of bytes or characters:

1. In the Application Navigator, double-click the desired entity object.
2. In the overview editor, click the **Business Rules** navigation tab, select where you want to add the validator, and click the **Add** icon.

- To add an entity-level validator, select the **Entity** node.
 - To add an attribute-level validator, expand the **Attributes** node and select the appropriate attribute.
3. In the Add Validation Rule dialog, in the **Rule Type** dropdown list, select **Length**.
 4. In the **Attribute** list, select the appropriate attribute.
 5. In the **Operator** field, select how to evaluate the value.
 6. In the **Comparison Type** field, select **Byte** or **Character** and enter a length.
 7. You can optionally click the **Validation Execution** tab and enter criteria for the execution of the rule, such as dependent attributes and a precondition expression. For more information, see [Section 7.6, "Triggering Validation Execution."](#)
 8. Click the **Failure Handling** tab and enter or select the error message that will be shown to the user if the validation rule fails. For more information, see [Section 7.7, "Creating Validation Error Messages."](#)
 9. Click OK.

7.4.11 What Happens When You Validate Against a Number of Bytes or Characters

When you validate using length, a `<LengthValidationBean>` tag is added to the entity object's XML file, as shown in [Example 7-7](#). For example, you might have a field where the user enters a password or PIN and the application wants to validate that it is at least 6 characters long, but not longer than 10. You would use the Length validator with the Between operator and set the minimum and maximum values accordingly.

Example 7-7 Validating the Length Between Two Values

```
<validation:LengthValidationBean
  OnAttribute="pin"
  CompareType="BETWEEN"
  DataType="CHARACTER"
  MinValue="6"
  MaxValue="10"
  Inverse="false"/>
```

7.4.12 How to Validate Using a Regular Expression

The Regular Expression validator compares attribute values against a mask specified by a Java regular expression.

If you want to create expressions that can be personalized in metadata, you can use the Script Expression validator. For more information, see [Section 7.5, "Using Groovy Expressions For Validation and Business Rules."](#)

Before you begin:

It may be helpful to have a general understanding of the built-in validation rules. For more information, see [Section 7.4, "Using the Built-in Declarative Validation Rules."](#)

You may also find it useful to understand additional functionality that can be added using other validation features. For more information, see [Section 7.1.2, "Additional Functionality for Declarative Validation."](#)

To validate using a regular expression

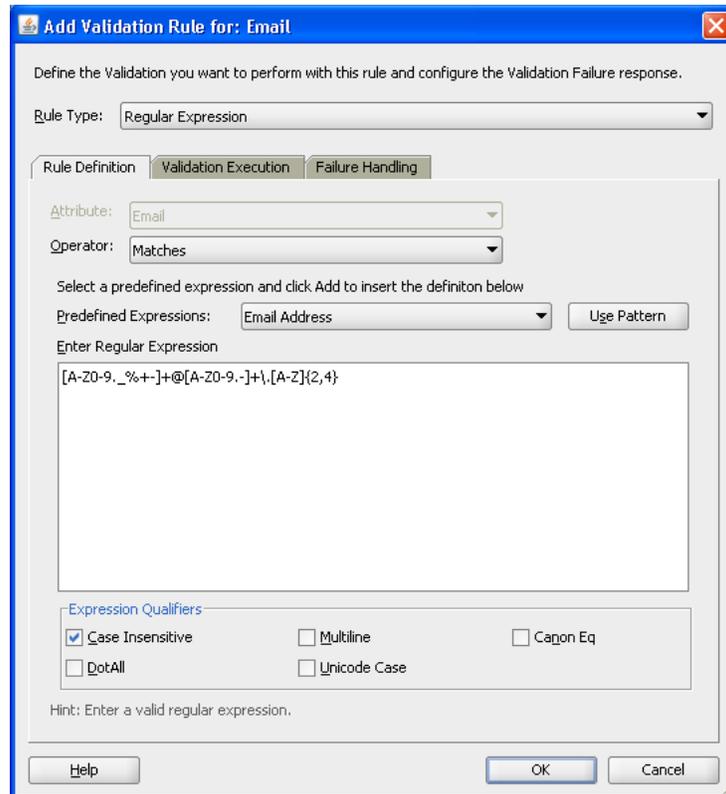

1. In the Application Navigator, double-click the desired entity object.

2. In the overview editor, click the **Business Rules** navigation tab, select where you want to add the validator, and click the **Add** icon.
 - To add an entity-level validator, select the **Entity** node.
 - To add an attribute-level validator, expand the **Attributes** node and select the appropriate attribute.
3. In the Add Validation Rule dialog, in the **Rule Type** dropdown list, select **Regular Expression**.
4. In the **Operator** field, you can select **Matches** or **Not Matches**.
5. To use a predefined expression (if available), you can select one from the dropdown list and click **Use Pattern**. Otherwise, write your own regular expression in the field provided.

Note: You can add your own expressions to the list of predefined expressions. To add a predefined expression, add an entry in the `PredefinedRegExp.properties` file in the BC4J subdirectory of the JDeveloper system directory (for example, `C:\Documents and Settings\username\Application Data\JDeveloper\system##\o.BC4J\PredefinedRegExp.properties`).

6. You can optionally click the **Validation Execution** tab and enter criteria for the execution of the rule, such as dependent attributes and a precondition expression. For more information, see [Section 7.6, "Triggering Validation Execution."](#)
7. Click the **Failure Handling** tab and enter or select the error message that will be shown to the user if the validation rule fails. For more information, see [Section 7.7, "Creating Validation Error Messages."](#)
8. Click **OK**.

[Figure 7-4](#) shows what the dialog looks like when you select a Regular Expression validator and validate that the `Email` attribute matches a predefined **Email Address** expression.

Figure 7-4 Regular Expression Validator Matching Email Address

7.4.13 What Happens When You Validate Using a Regular Expression

When you validate using a regular expression, a `<RegExpValidationBean>` tag is added to the entity object's XML file. [Example 7-8](#) shows an `Email` attribute that must match a regular expression.

Example 7-8 Regular Expression Validator XML Code

```
<validation:RegExpValidationBean
  Name="Email_Rule_0"
  OnAttribute="Email"
  Pattern="[A-Z0-9._%+-]+@[A-Z0-9.-]+\.[A-Z]{2,4}"
  Flags="CaseInsensitive"
  Inverse="false"/>
```

7.4.14 How to Use the Average, Count, or Sum to Validate a Collection

You can use collection validation on the average, count, sum, min, or max of a collection. This validator is available only at the entity level. It is useful for validating the aggregate calculation over a collection of associated entities by way of an entity accessor to a child entity (on the many end of the association). You must select the association accessor to define the Collection validator.

Before you begin:

It may be helpful to have a general understanding of the built-in validation rules. For more information, see [Section 7.4, "Using the Built-in Declarative Validation Rules."](#)

You may also find it helpful to understand additional functionality that can be added using other validation features. For more information, see [Section 7.1.2, "Additional Functionality for Declarative Validation."](#)

To validate using an aggregate calculation:

1. In the Application Navigator, double-click the desired entity object.
2. In the overview editor, click the **Business Rules** navigation tab, select the **Entity** node and click the **Add** icon.
3. In the Add Validation Rule dialog, in the **Rule Type** dropdown list, select **Collection**.
4. In the **Operation** field, specify the operation (sum, average, count, min, or max) to perform on the collection for comparison.
5. Select the appropriate accessor and attribute for the validation.
The accessor you choose must be a composition association accessor. Only accessors of this type are displayed in the dropdown list.
6. Specify the operator and the comparison type and value.
7. You can optionally click the **Validation Execution** tab and enter criteria for the execution of the rule, such as dependent attributes and a precondition expression. For more information, see [Section 7.6, "Triggering Validation Execution."](#)
8. Click the **Failure Handling** tab and enter or select the error message that will be shown to the user if the validation rule fails. For more information, see [Section 7.7, "Creating Validation Error Messages."](#)
9. Click **OK**.

7.4.15 What Happens When You Use Collection Validation

When you validate using a Collection validator, a `<CollectionValidationBean>` tag is added to the entity object's XML file, as in [Example 7-9](#).

Example 7-9 Collection Validator XML Code

```
<validation:CollectionValidationBean
  Name="OrderEO_Rule_0"
  OnAttribute="OrderTotal"
  OperandType="LITERAL"
  Inverse="false"
  CompareType="LESSTHAN"
  CompareValue="5"
  Operation="sum" />
```

7.4.16 How to Determine Whether a Key Exists

The Key Exists validator is used to determine whether a key value (primary, foreign, or alternate key) exists.

There are a couple of benefits to using the Key Exists validator:

- The Key Exists validator has better performance because it first checks the cache and only goes to the database if necessary.
- Since the Key Exists validator uses the cache, it will find a key value that has been added in the current transaction, but not yet committed to the database. For

example, you add a new Department and then you want to link an Employee to that new department.

Before you begin:

It may be helpful to have a general understanding of the built-in validation rules. For more information, see [Section 7.4, "Using the Built-in Declarative Validation Rules."](#)

You may also find it useful to understand additional functionality that can be added using other validation features. For more information, see [Section 7.1.2, "Additional Functionality for Declarative Validation."](#)

To determine whether a value exists:

1. In the Application Navigator, double-click the desired entity object.
2. In the overview editor, click the **Business Rules** navigation tab, select where you want to add the validator, and click the **Add** icon.
 - To add an entity-level validator, select the **Entity** node.
 - To add an attribute-level validator, expand the **Attributes** node and select the appropriate attribute.
3. In the Add Validation Rule dialog, select **Key Exists** from the **Rule Type** list.
4. Select the type of validation target (**Entity Object**, **View Object**, or **View Accessor**).

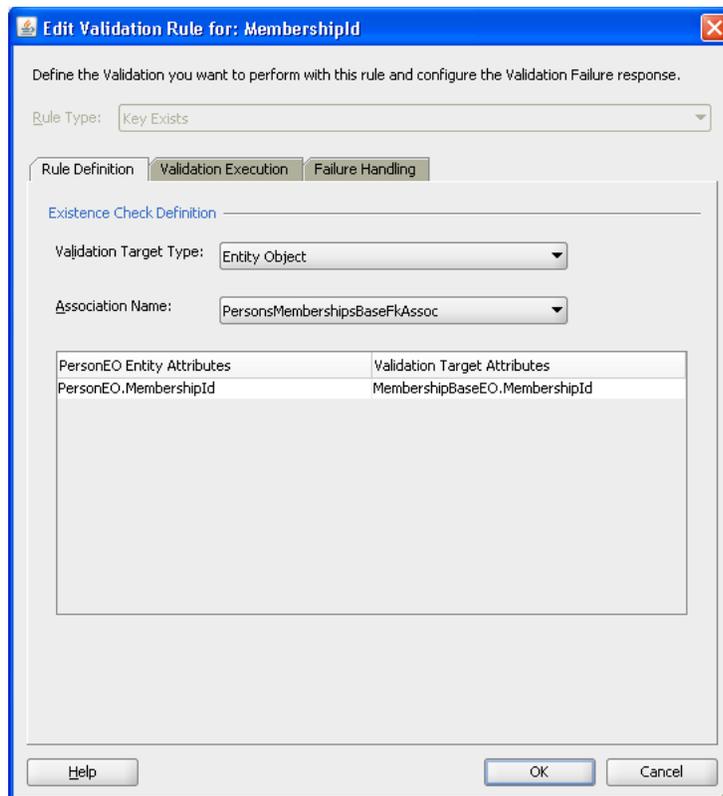

If you want the Key Exists validator to be used for all view objects that use this entity attribute, select **Entity Object**.

5. Depending on the validation target, you can choose either an association or a key value.

If you are searching for an attribute that does not exist in the **Validation Target Attributes** list, it is probably not defined as a key value. To create alternate keys, see [Section 4.10.15, "How to Define Alternate Key Values."](#)

6. You can optionally click the **Validation Execution** tab and enter criteria for the execution of the rule, such as dependent attributes and the validation level (entity or transaction). For more information, see [Section 7.6, "Triggering Validation Execution."](#)
7. Click the **Failure Handling** tab and enter or select the error message that will be shown to the user if the validation rule fails. For more information, see [Section 7.7, "Creating Validation Error Messages."](#)
8. Click **OK**.

[Figure 7–5](#) shows a Key Exists validator that validates whether the `MembershipId` entered in the `PersonEO` entity object exists in the `MembershipBaseEO` entity object.

Figure 7-5 Key Exists Validator on an Entity Attribute

7.4.17 What Happens When You Use a Key Exists Validator

When you use a Key Exists validator, an `<ExistsValidationBean>` tag is created in the XML file for the entity object, as in [Example 7-10](#).

Example 7-10 Using the Key Exists Validator With an Association

```
<validation:ExistsValidationBean
  Name="MembershipId_Rule_0"
  ResId="MembershipId_Rule_0"
  OperandType="EO"
  AssocName=
"oracle.fodemo.storefront.entities.associations.PersonsMembershipsBaseFkAssoc"/>
```

7.4.18 What You May Need to Know About Declarative Validators and View Accessors

When using declarative validators you must consider how your validation will interact with expected input. The combination of declarative validators and view accessors provides a simple yet powerful alternative to coding. But, as powerful as the combination is, you still need to consider how data composition can impact performance.

Consider a scenario where you have the following:

- A `ServiceRequestEO` entity object with `Product` and `RequestType` attributes, and a view accessor that allows it to access the `RequestTypeVO` view object
- A `RequestTypeVO` view object with a query specifying the `Product` attribute as a bind parameter

The valid list of `RequestTypes` varies by `Product`. So, to validate the `RequestType` attribute, you use a List validator using the view accessor.

Now lets add a set of new service requests. For the first service request (row), the List validator binds the value of the `Product` attribute to the view accessor and executes it. For each subsequent service request the List validator compares the new value of the `Product` attribute to the currently bound value.

- If the value of `Product` matches, the current `RowSet` object is retained.
- If the value of `Product` has changed, the new value is bound and the view accessor re-executed.

Now consider the expected composition of input data. For example, the same products could appear in the input multiple times. If you simply validate the data in the order received, you might end up with the following:

1. Dryer (initial query)
2. Washing Machine (re-execute view accessor)
3. Dish Washer (re-execute view accessor)
4. Washing Machine (re-execute view accessor)
5. Dryer (re-execute view accessor)

In this case, the validator will execute 5 queries to get 3 distinct row sets. As an alternative, you can add an `ORDER BY` clause to the `RequestTypeVO` to sort it by `Product`. In this case, the validator would execute the query only once each for Washing Machine and Dryer.

1. Dish Washer (initial query)
2. Dryer (re-execute view accessor)
3. Dryer
4. Washing Machine (re-execute view accessor)
5. Washing Machine

A small difference on a data set this size, but multiplied over larger data sets and many users this could easily become an issue. An `ORDER BY` clause is not a solution to every issue, but this example illustrates how data composition can impact performance.

7.5 Using Groovy Expressions For Validation and Business Rules

Groovy expressions are Java-like scripting code stored in the XML definition of an entity object. Because Groovy expressions are stored in XML, you can change the expression values even if you don't have access to the entity object's Java file. You can even change or specify values at runtime.

For more information about using Groovy script in your entity object business logic, see [Section 3.6, "Overview of Groovy Scripting Language Support."](#)

7.5.1 How to Reference Entity Object Methods in Groovy Validation Expressions

You can call methods on the current entity instance using the `source` property of the current object. The `source` property allows you to access to the entity instance being validated.

If the method is a non-boolean type and the method name is `getXyzABC()` with no arguments, then you access its value as if it were a property named `XyzABC`. For a boolean-valued property, the same holds true but the JavaBean naming pattern for the getter method changes to recognize `isXyzABC()` instead of `getXyzABC()`. If the method on your entity object does not match the JavaBean getter method naming pattern, or if it takes one or more arguments, then you must call it like a method using its complete name.

For example, say you have an entity object with the four methods shown in [Example 7–11](#).

Example 7–11 Sample Entity Object Methods

```
public boolean isNewRow() {
    System.out.println("## isNewRow() accessed ##");
    return true;
}

public boolean isNewRow(int n) {
    System.out.println("## isNewRow(int n) accessed ##");
    return true;
}

public boolean testWhetherRowIsNew() {
    System.out.println("## testWhetherRowIsNew() accessed ##");
    return true;
}

public boolean testWhetherRowIsNew(int n) {
    System.out.println("## testWhetherRowIsNew(int n) accessed ##");
    return true;
}
```

Then the following Groovy validation condition would trigger them all, one of them being triggered twice, as shown in [Example 7–12](#).

Example 7–12 Groovy Script Calling Sample Methods

```
newRow && source.newRow && source.isNewRow(5) && source.testWhetherRowIsNew() &&
source.testWhetherRowIsNew(5)
```

By running this example and forcing entity validation to occur, you would see the diagnostic output shown in [Example 7–13](#) in the log window:

Example 7–13 Output From Sample Groovy Script

```
## isNewRow() accessed ##
## isNewRow() accessed ##
## isNewRow(int n) accessed ##
## testWhetherRowIsNew() accessed ##
## testWhetherRowIsNew(int n) accessed ##
```

Notice the slightly different syntax for the reference to a method whose name matches the JavaBeans property getter method naming pattern. Both `newRow` and `source.newRow` work to access the boolean-valued, JavaBeans getter-style method that has no arguments. But because the `testWhetherRowIsNew` method does not match the JavaBeans getter method naming pattern, and the second `isRowNew` method takes an argument, then you must call them like methods using their complete name.

7.5.2 How to Validate Using a True/False Expression

You can use a Groovy expression to return a true/false statement. The Script Expression validator *requires* that the expression either return `true` or `false`, or that it calls the `adf.error.raise/warn()` method. A common use of this feature would be to validate an attribute value, for example, to make sure that an account number is valid.

Note: Using the `adf.error.raise/warn()` method (rather than simply returning `true` or `false`) allows you to define the message text to show to the user, and to associate an entity-level validator with a specific attribute. For more information, see [Section 7.7.3, "How to Conditionally Raise Error Messages Using Groovy."](#)

Before you begin:

It may be helpful to have an understanding of the use of Groovy in validation rules. For more information, see [Section 7.5, "Using Groovy Expressions For Validation and Business Rules."](#)

You may also find it useful to understand additional functionality that can be added using other validation features. For more information, see [Section 7.1.2, "Additional Functionality for Declarative Validation."](#)

To validate using a true/false expression:

1. In the Application Navigator, double-click the desired entity object.
2. In the overview editor, click the **Business Rules** navigation tab, select where you want to add the validator, and click the **Add** icon.
 - To add an entity-level validator, select the **Entity** node.
 - To add an attribute-level validator, expand the **Attributes** node and select the appropriate attribute.
3. In the Add Validation Rule dialog, in the **Rule Type** dropdown list, select **Script Expression**.
4. Enter a validation expression in the field provided.
5. You can optionally click the **Validation Execution** tab and enter criteria for the execution of the rule, such as dependent attributes and a precondition expression. For more information, see [Section 7.6, "Triggering Validation Execution."](#)
6. Click the **Failure Handling** tab and enter or select the error message that will be shown to the user if the validation rule fails. For more information, see [Section 7.7, "Creating Validation Error Messages."](#)
7. Click **OK**.

The sample code in [Example 7-14](#) comes from the `PaymentOptionEO` entity object. The code validates account numbers based on the Luhn algorithm, a checksum formula in widespread use.

Example 7-14 Validating an Account Number Using an Expression

```
<validation:ExpressionValidationBean
  Name="AccountNumber_Rule_0"
  OperandType="EXPR"
  Inverse="false">
  <OnCondition>
```

```

    <![CDATA[PaymentTypeCode=='CC']]>
</OnCondition>
<MsgIds>
  <Item
    Value="PaymentOption_AccountNumber"/>
</MsgIds>
<TransientExpression>
<![CDATA[
String acctnumber = newValue;
sumofdigits = 0;
digit = 0;
addend = 0;
timesTwo = false;
range = acctnumber.length()-1..0
range.each { i ->
digit = Integer.parseInt (acctnumber.substring (i, i + 1));
if (timesTwo) {
  addend = digit * 2;
  if (addend > 9) {
    addend -= 9;
  }
}
else {
  addend = digit;
}
sumofdigits += addend;
timesTwo = !timesTwo;
}
modulus = sumofdigits % 10;
return modulus == 0;
]]>
</TransientExpression>
</ExpressionValidationBean>

```

7.5.3 What Happens When You Add a Groovy Expression

When you create a Groovy expression, it is saved in the entity object's XML component. [Example 7-15](#) shows the `RegisteredDate` attribute in the `PersonEO.xml` file. The Groovy expression is wrapped by a `<TransientExpression>` tag.

Example 7-15 XML Code for RegisteredDate Attribute on the PersonEO Entity Object

```

<Attribute
  Name="RegisteredDate"
  IsUpdateable="true"
  ColumnName="REGISTERED_DATE"
  Type="oracle.jbo.domain.Date"
  ColumnType="DATE"
  SQLType="DATE"
  TableName="PERSONS">
  <DesignTime>
    <Attr Name="_DisplaySize" Value="7"/>
  </DesignTime>
  <validation:ExpressionValidationBean
    Name="RegisteredDate_Rule_0"
    OperandType="EXPR"
    Inverse="false">
  <MsgIds>

```

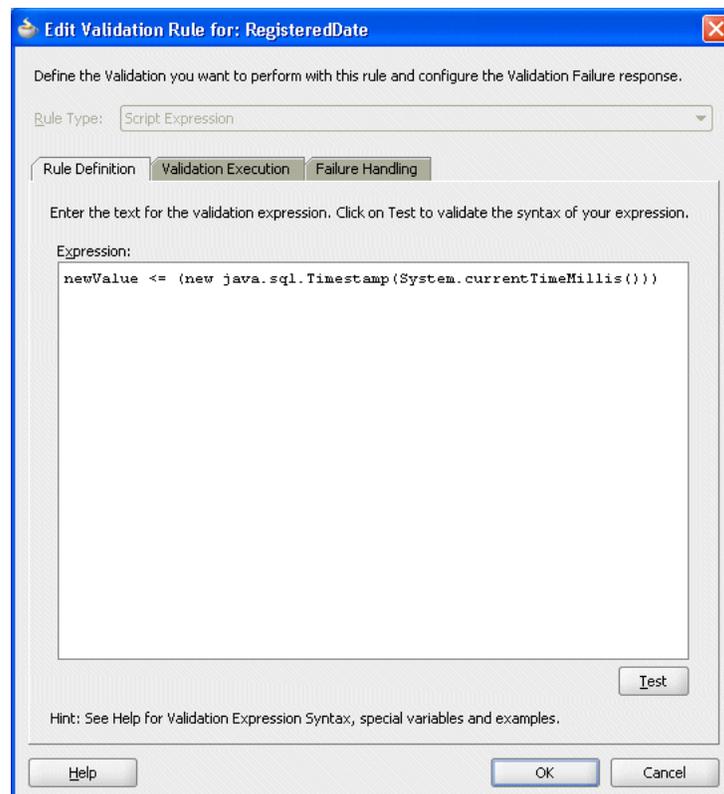

```

    <Item
      Value="RegisteredDate_Rule_0"/>
    </MsgIds>
    <TransientExpression>
      <![CDATA[
newValue <= (new java.sql.Timestamp(System.currentTimeMillis()))
]]>
    </TransientExpression>
  </ExpressionValidationBean>
</Attribute>

```

This tag can take one of several forms. For some Groovy expressions, the `<TransientExpression>` tag is wrapped by an `<ExpressionValidationBean>` tag as well. [Figure 7-6](#) shows the validation expression in the Edit Validation Rule dialog.

Figure 7-6 Validation Expression for RegisteredDate Attribute on the PersonEO Entity Object

7.6 Triggering Validation Execution

JDeveloper allows you to select the attributes that trigger validation, so that validation execution happens only when one of the triggering attributes is dirty. In previous releases of JDeveloper, an entity-level validator would fire on an attribute whenever the entity as a whole was dirty. This feature is described in [Section 7.6.1, "How to Specify Which Attributes Fire Validation."](#)

JDeveloper also allows you to specify a precondition for the execution of a validator (as described in [Section 7.6.3, "How to Set Preconditions for Validation"](#)) and set

transaction-level validation (described in [Section 7.6.4, "How to Set Transaction-Level Validation"](#)).

7.6.1 How to Specify Which Attributes Fire Validation

When defining a validator at the entity level, you have the option of selecting one or more attributes of the entity object that, when changed, trigger execution of the validator.

Note: When the validity of one attribute is dependent on the value in another attribute, the validation should be performed as entity validation, not attribute validation. You can set validation execution order on the entity level or attribute level.

If you do not specify one or more dependent attributes, the validator will fire whenever the entity is dirty. Firing execution only when required makes your application more performant.

Before you begin:

It may be helpful to have an understanding of how validation rules are triggered. For more information, see [Section 7.6, "Triggering Validation Execution."](#)

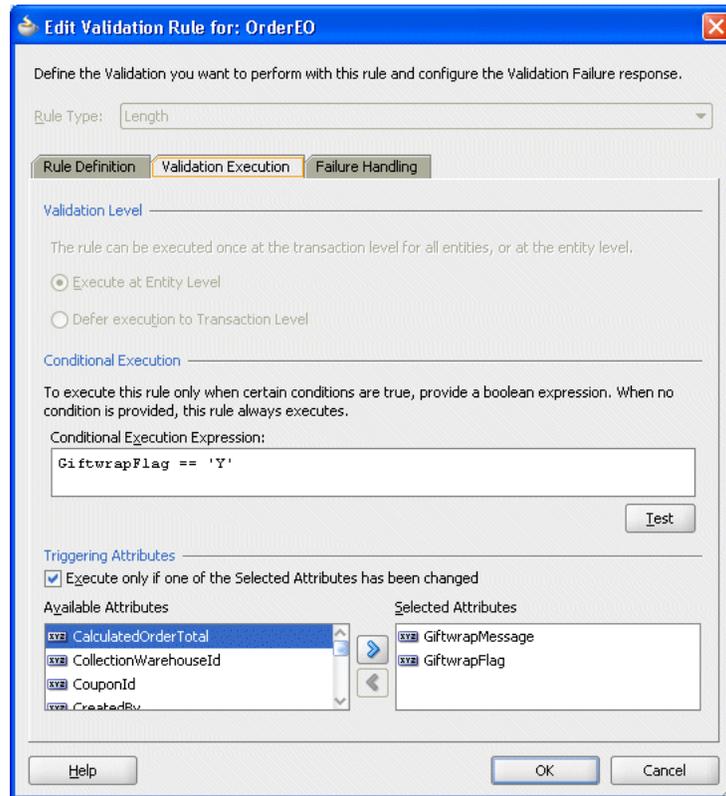

You may also find it useful to understand additional functionality that can be added using other validation features. For more information, see [Section 7.1.2, "Additional Functionality for Declarative Validation."](#)

To specify which attributes fire validation:

1. In the Application Navigator, double-click the desired entity object.
2. In the overview editor, click the **Business Rules** navigation tab, select the **Entity** node and click the **Edit** icon.
3. In the Edit Validation Rule dialog, click the **Validation Execution** tab.
4. Select the attributes that will fire validation.
5. Click **OK**.

For example, in the StoreFront module of the Fusion Order Demo application, the OrderEO entity object has an entity-level validator that constrains the length of the GiftwrapMessage attribute. As shown in [Figure 7-7](#), this validator is set to be executed on the entity object only when either the GiftwrapMessage attribute or the GiftwrapFlag attribute has been changed.

Figure 7–7 Triggering attributes on the Validation Execution tab of the Edit Validation Rule dialog

7.6.2 What Happens When You Constrain Validation Execution with Triggering Attributes

When you specify triggering attributes on the **Validation Execution** tab of the Edit Validation Rule dialog, JDeveloper adds an `<OnAttributes>` tag to the validator definition in the entity object's XML file. [Example 7–16](#) shows the XML code for the entity-level validator for the `OrderEO` entity object in the StoreFront module of the Fusion Order Demo application.

Example 7–16 `OnAttributes` element in XML validation code

```
<LengthValidationBean
  xmlns="http://xmlns.oracle.com/adfm/validation"
  Name="OrderEO_Rule_0"
  OnAttribute="GiftwrapMessage"
  CompareType="GREATERTHANEQUALTO"
  DataType="CHARACTER"
  CompareLength="1"
  Inverse="false"
  ResId="GiftMessage_Required_Error_0">
  <OnAttributes>
    <Item Value="GiftwrapMessage"/>
    <Item Value="GiftwrapFlag"/>
  </OnAttributes>
  <OnCondition>
    <![CDATA[GiftwrapFlag == 'Y']]>
  </OnCondition>
</LengthValidationBean>
```

7.6.3 How to Set Preconditions for Validation

The **Validation Execution** tab (on the Add/Edit Validation Rule dialog) allows you to add a Groovy expression that serves as a precondition. If you enter an expression in the **Conditional Execution Expression** box, the validator is executed only if the condition evaluates `True`.

Best Practice: While it is possible to add a precondition for a Unique Key validator, it is not a best practice. If a Unique Key validator fails to fire, for whatever reason, the cache consistency check is still performed and an error will be returned. It is generally better to add the validator and a meaningful error message.

7.6.4 How to Set Transaction-Level Validation

Performing a validation during the transaction level (rather than entity level) means that the validation will be performed after all entity-level validation is performed. For this reason, it may be useful if you want to ensure that a validator is performed at the end of the process.

In addition, the Key Exists validator is more performant with bulk transactions if it is run as a transaction level validator since it will be run only once for all entities in the transaction (of the same type), rather than once per entity. This will result in improved performance if the validator has to go to the database.

Note: Transaction-level validation is only applicable to Key Exists and Method entity validators.

Before you begin:

It may be helpful to have an understanding of how validation rules are triggered. For more information, see [Section 7.6, "Triggering Validation Execution."](#)

You may also find it useful to understand additional functionality that can be added using other validation features. For more information, see [Section 7.1.2, "Additional Functionality for Declarative Validation."](#)

To specify entity-level or transaction-level validation:

1. In the Application Navigator, double-click the desired entity object.
2. In the overview editor, click the **Business Rules** navigation tab, select an entity-level validation rule and click the **Edit** icon.
3. In the Edit Validation Rule dialog, click the **Validation Execution** tab.
4. Select **Execute at Entity Level** or **Defer Execution to Transaction Level**.
5. Click **OK**.

7.6.5 What You May Need to Know About the Order of Validation Execution

You cannot control the order in which attributes are validated – they are always validated in the order they appear in the entity definition. You can order validations for a given attribute (or for the entity), but you cannot reorder the attributes themselves.

7.7 Creating Validation Error Messages

Validation error messages provide important information for the user: the message should convey what went wrong and how to fix it.

7.7.1 How to Create Validation Error Messages

When you create or edit a validation rule, enter text to help the user determine what caused the error.

Before you begin:

It may be helpful to have an understanding of error messages in validation rules. For more information, see [Section 7.7, "Creating Validation Error Messages."](#)

You may also find it useful to understand additional functionality that can be added using other validation features. For more information, see [Section 7.1.2, "Additional Functionality for Declarative Validation."](#)

To create validation error messages:

1. In the Application Navigator, double-click the desired entity object.
2. In the overview editor, click the **Business Rules** navigation tab, select a validation rule and click the **Edit** icon.
3. In the Edit Validation Rule dialog, click the **Failure Handling** tab.
4. In the **Message Text** field, enter your error message.

You can also define error messages in a message bundle file. To select a previously defined error message or to define a new one in a message bundle file, click the **Select Message** icon.

Note: The Script Expression validator allows you to enter more than one error message. This is useful if the validation script conditionally returns different error or warning messages. For more information, see [Section 7.7.3, "How to Conditionally Raise Error Messages Using Groovy."](#)

5. You can optionally include message tokens in the body of the message, and define them in the **Token Message Expressions** list.

[Figure 7–8](#) shows the failure message for a validation rule in the `PaymentOptionEO` entity object that contains message tokens. For more information on this feature, see [Section 7.7.4, "How to Embed a Groovy Expression in an Error Message."](#)

6. Click **OK**.

7.7.2 How to Localize Validation Messages

The error message is a translatable string and is managed in the same way as translatable UI control hints in an entity object message bundle class. To view the error message for the defined rule in the message bundle class, locate the `String` key in the message bundle that corresponds to the `ResId` property in the XML component definition entry for the validator. For example, [Example 7–17](#) shows a message bundle where the `NAME_CANNOT_BEGIN_WITH_U` key appears with the error message for the default locale.

Example 7-17 Message Bundle Contains Validation Error Messages

```

package devguide.advanced.customerrors;
import java.util.ListResourceBundle;

public class CustomMessageBundle extends ListResourceBundle {
    private static final Object[][] sMessageStrings = new String[][] {
        // other strings here
        {"NAME_CANNOT_BEGIN_WITH_U", "The name cannot begin with the letter u!"},
        // other strings here
    };
    // etc.
}

```

Resource bundles can be created for your applications as a list resource bundle (as shown in [Example 7-17](#)), as a properties bundle, or as an XLIFF resource bundle. For more information about using translatable strings in a resource bundle, see [Section 4.7, "Working with Resource Bundles."](#)

7.7.3 How to Conditionally Raise Error Messages Using Groovy

You can use the `adf.error.raise()` and `adf.error.warn()` methods to conditionally raise one error message or another depending upon branching in the Groovy expression. For example, if an attribute value is *x*, then validate as follows, and if the validation fails, raise error messageA; whereas if the attribute value is *y*, then instead validate a different way and if validation fails, raise error messageB.

If the expression returns `false` (versus raising a specific error message using the `raise()` method), the validator calls the first error message associated with the validator.

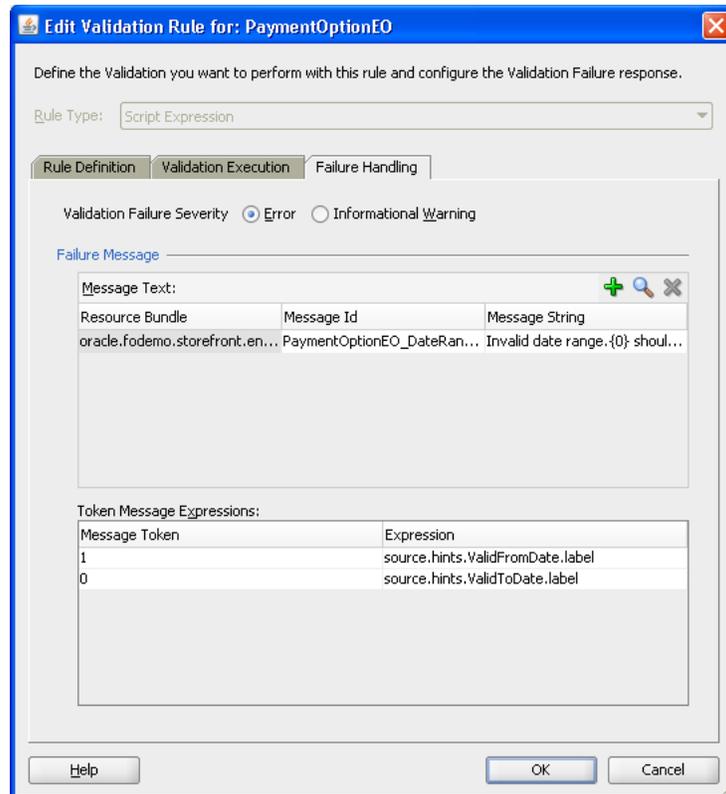

The syntax of the `raise()` method takes one required parameter (the `msgId` to use from the message bundle), and optionally can take the `attrName` parameter. If you pass in the `AttrName`, the error is associated with that attribute even if the validation is assigned to the entity.

You can use either `adf.error.raise()` or `adf.error.warn()` methods, depending on whether you want to throw an exception, or whether you want processing to continue, as described in [Section 7.8, "Setting the Severity Level for Validation Exceptions."](#)

7.7.4 How to Embed a Groovy Expression in an Error Message

A validator's error message can contain embedded expressions that are resolved by the server at runtime. To access this feature, simply enter a named token delimited by curly braces (for example, `{2}` or `{errorParam}`) in the error message text where you want the result of the Groovy expression to appear.

After entering the token into the text of the error message (on the **Failure Handling** tab of the Edit Validation Rule dialog), the **Token Message Expressions** table at the bottom of the dialog displays a row that allows you to enter a Groovy expression for the token. [Figure 7-8](#) shows the failure message for a validation rule in the `PaymentOptionEO` entity object that contains message tokens.

Figure 7–8 Using Message Tokens in a Failure Message

The expressions shown in [Figure 7–8](#) are Groovy expressions that return the labels of the specified fields. You can also use Groovy expressions to access attribute values and other business components objects. You can use the Groovy expression `newValue` to return the entered value, as shown in the Rule validator for the `RoutingIdentifier` attribute of the `PaymentOptionEO` entity object in the StoreFront module of the Fusion Order Demo application.

The Groovy syntax to retrieve a value from a view accessor is `accessorName.currentRow.AttributeName`. For example, the Groovy expression `MyEmpAccessor.currentRow.Job` returns the value of the `Job` attribute in the current row of the `MyEmpAccessor` view accessor.

The Groovy expression can also be more complex, as in [Example 7–18](#), which shows an expression in the error message for the List validation rule for the `OwnerTypeCode` attribute in the `AddressUsageEO` entity object.

Example 7–18 Groovy Script in the OwnerTypeCode Validation Error Message

```
def ownertypevalue = []
while ( AddressOwnerTypesVA.hasNext() ) {
    AddressOwnerTypesVA.next()
    ownertypevalue.add(AddressOwnerTypesVA.currentRow.Value)
}
return ownertypevalue
```

For more information about accessing business components objects using Groovy, see [Section 3.6, "Overview of Groovy Scripting Language Support."](#)

7.8 Setting the Severity Level for Validation Exceptions

You can set the severity level for validation exceptions to two levels, Informational Warning and Error. If you set the severity level to Informational Warning, an error message will display, but processing will continue. If you set the validation level to Error, the user will not be able to proceed until you have fixed the error.

Under most circumstances you will use the Error level for validation exceptions, so this is the default setting. However, you might want to implement a Informational Warning message if the user has a certain security clearance. For example, a store manager may want to be able to make changes that would surface as an error if a clerk tried to do the same thing.

To set the severity level for validation exceptions, use the **Failure Handling** tab of the Add Validation Rule dialog.

To set the severity level of a validation exception:

1. In the Application Navigator, double-click the desired entity object.
2. On the Business Rules page, select an existing validation rule and click the **Edit** icon, or click the **Add** icon to create a new rule.
3. In the Edit/Add Validation Rule dialog, click the **Failure Handling** tab and select the option for either **Error** or **Informational Warning**.
4. Click **OK**.

7.9 Bulk Validation in SQL

To improve the performance of batch-load applications, such as data synchronization programs, the ADF framework employs bulk validation for primary keys (including alternate keys) and foreign keys.

When the Key Exists validator is configured to defer validation until the transaction commits, or when the rows are being updated or inserted through the `processXXX` methods of the ADF business components service layer, the validation cache is preloaded. This behavior uses the normal row-by-row derivation and validation logic, but uses validation logic that checks a memory cache before making queries to the database. Performance is improved by preloading the memory cache using bulk SQL operations based on the inbound data.

Implementing Validation and Business Rules Programmatically

This chapter explains the key entity object events and features for implementing the most common kinds of business rules.

This chapter includes the following sections:

- Section 8.1, "About Programmatic Business Rules"
- Section 8.2, "Using Method Validators"
- Section 8.3, "Assigning Programmatically Derived Attribute Values"
- Section 8.4, "Undoing Pending Changes to an Entity Using the Refresh Method"
- Section 8.5, "Using View Objects for Validation"
- Section 8.6, "Accessing Related Entity Rows Using Association Accessors"
- Section 8.7, "Referencing Information About the Authenticated User"
- Section 8.8, "Accessing Original Attribute Values"
- Section 8.9, "Storing Information About the Current User Session"
- Section 8.10, "Accessing the Current Date and Time"
- Section 8.11, "Sending Notifications Upon a Successful Commit"
- Section 8.12, "Conditionally Preventing an Entity Row from Being Removed"
- Section 8.13, "Determining Conditional Updatability for Attributes"
- Section 8.14, "Implementing Custom Validation Rules"

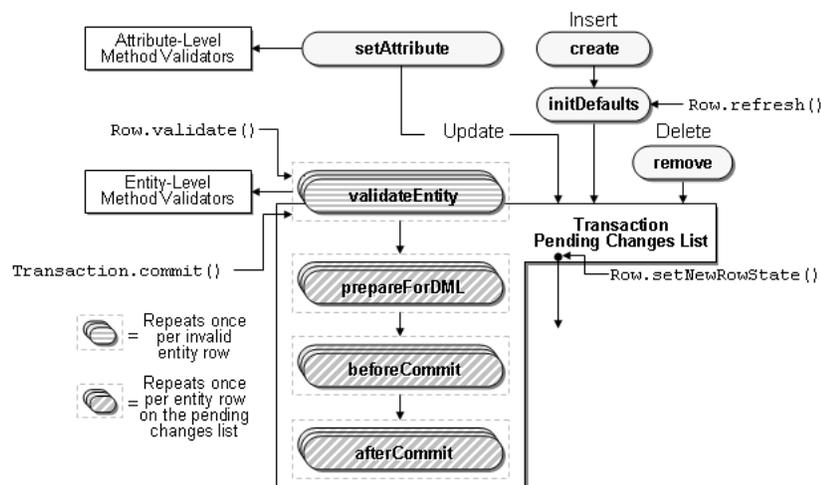

8.1 About Programmatic Business Rules

Complementing the built-in *declarative* validation features, entity objects and view objects have method validators and several events you can handle to *programmatically* implement encapsulated business logic using Java code. These concepts are illustrated in [Figure 8-1](#).

- Attribute-level method validators trigger validation code when an attribute value changes.
- Entity-level method validators trigger validation code when an entity row is validated.
- You can override the following key methods in a custom Java class for an entity:
 - `create()`, to assign default values when a row is created

- `initDefaultExpressionAttributes()`, to assign defaults either when a row is created or when a new row is refreshed
- `remove()`, to conditionally disallow deleting
- `isAttributeUpdateable()`, to make attributes conditionally updatable
- `setAttribute()`, to trigger attribute-level method validators
- `validateEntity()`, to trigger entity-level method validators
- `prepareForDML()`, to assign attribute values before an entity row is saved
- `beforeCommit()`, to enforce rules that must consider all entity rows of a given type
- `afterCommit()`, to send notifications about a change to an entity object's state

Figure 8–1 Key Entity Objects Features and Events for Programmatic Business Logic

Note: When coding programmatic business rules, it's important to have a firm grasp of the validation cycle. For more information, see [Section 7.2, "Understanding the Validation Cycle."](#)

8.1.1 Programmatic Business Rules Use Cases and Examples

While much of your validation can be implemented using basic declarative behavior, you can implement more complex business rules for your business domain layer when needed, using the Method validator to invoke custom validation code.

Some examples of when you might want to use programmatic business rules include:

- Eagerly defaulting an attribute value from a database sequence
- Assigning values derived from complex calculations
- Undoing pending changes to an entity object
- Accessing and storing information about the current user session
- Determining conditional updatability for attributes

8.1.2 Additional Functionality for Programmatic Business Rules

You may find it helpful to understand other ADF features before you start using programmatic validation. Following are links to other functionality that may be of interest.

- Before implementing business rules programmatically, you should see if the declarative validation can handle the needs of your application. For more information, see [Chapter 7, "Defining Validation and Business Rules Declaratively."](#)
- You can use resource bundles to provide localizable validation error messages, as described in [Section 4.7, "Working with Resource Bundles."](#)
- [Section 4.10.9, "How to Synchronize with Trigger-Assigned Values,"](#) explains how to use the `DBSequence` type for primary key attributes whose values need to be populated by a database sequence at *commit* time.
- For information about security features in Oracle Fusion Web Applications, including how to access information about the authenticated user, see [Chapter 35, "Enabling ADF Security in a Fusion Web Application."](#)
- For information about using Groovy script in your entity object business logic, see [Section 3.6, "Overview of Groovy Scripting Language Support."](#)

8.2 Using Method Validators

Method validators are the primary way of supplementing declarative validation rules and Groovy-scripted expressions using your own Java code. Method validators trigger Java code that you write in your own validation methods at the appropriate time during the entity object validation cycle. There are many types of validation you can code with a method validator, either on an attribute or on an entity as a whole.

You can add any number of attribute-level or entity-level method validators, provided they each trigger a distinct method name in your code. All validation method names must begin with the word `validate`; however, following that rule you are free to name them in any way that most clearly identifies the functionality. For an attribute-level validator, the method must take a single argument of the same type as the entity attribute. For an entity-level validator, the method takes no arguments. The method must also be public, and must return a boolean value. Validation will fail if the method returns `false`.

Note: Although it is important to be aware of these rules, when you use JDeveloper to create method validators, JDeveloper creates the correct interface for the class.

At runtime, the Method validator passes an entity attribute to a method implemented in your entity object class.

In [Example 8–1](#), the method accepts strings that start with a capital letter and throws an exception on null values, empty strings, and strings that do not start with a capital letter.

Example 8–1 Method That Validates If the First Letter Is a Capital

```
public boolean validateIsCapped(String text)
{
    if (text != null &&
```

```
        text.length() != 0 &&
        text[0] >= 'A' &&
        text[0] <= 'Z')
    {
        return true;
    }
}
```

8.2.1 How to Create an Attribute-Level Method Validator

The use of method validators is a programmatic approach that supplements your declarative validation rules.

Before you begin:

It may be helpful to have an understanding of what method validators are. For more information, see [Section 8.2, "Using Method Validators."](#)

You may also find it helpful to understand additional functionality that can be added using other validation features. For more information, see [Section 8.1.2, "Additional Functionality for Programmatic Business Rules."](#)

To create an attribute-level Method validator:

1. In the Application Navigator, double-click the desired entity object.
2. In the overview editor, click the **Java** navigation tab.

The Java page shows the Java generation options that are currently enabled for the entity object. If your entity object does not yet have a custom entity object class, then you must generate one before you can add a Method validator. To generate the custom Java class, click the **Edit** icon, then select **Generate Entity Object Class**, and click **OK** to generate the *.java file.

3. Click the **Business Rules** navigation tab, and then expand the **Attributes** node, and select the attribute that you want to validate.
4. Click the **New** icon to add a validation rule.
5. Select **Method** from the **Rule Type** dropdown list.

The Add Validation Rule dialog displays the expected method signature for an attribute-level validation method. You have two choices:

- If you already have a method in your entity object's custom Java class of the appropriate signature, it will appear in the list and you can select it after deselecting the **Create and Select Method** checkbox.
 - If you leave the **Create and Select Method** checkbox selected (see [Figure 8-2](#)), you can enter any method name in the **Method Name** box that begins with the word `validate`. When you click **OK**, JDeveloper adds the method to your entity object's custom Java class with the appropriate signature.
6. Finally, supply the text of the error message for the default locale that the end user should see if this validation rule fails.

Figure 8–2 Adding an Attribute-Level Method Validator

8.2.2 What Happens When You Create an Attribute-Level Method Validator

When you add a new method validator, JDeveloper updates the XML component definition to reflect the new validation rule. If you asked to have the method created, the method is added to the entity object's custom Java class. [Example 8–2](#) illustrates a simple attribute-level validation rule that ensures that the `OrderShippedDate` of an order is a date in the current month. Notice that the method accepts an argument of the same type as the corresponding attribute, and that its conditional logic is based on the value of this incoming parameter. When the attribute validator fires, the attribute value has not yet been set to the new value in question, so calling the `getOrderShippedDate()` method inside the attribute validator for the `OrderShippedDate` attribute would return the attribute's *current* value, rather than the *candidate* value that the client is attempting to set.

Example 8–2 Simple Attribute-Level Method Validator

```
public boolean validateOrderShippedDate(Date data) {
    if (data != null && data.compareTo(getFirstDayOfCurrentMonth()) <= 0) {
        return false;
    }
    return true;
}
```

Note: The return value of the `compareTo()` method is zero (0) if the two dates are equal, negative one (-1) if the first date is less than the second, or positive one (1) if the first date is greater than the second.

8.2.3 How to Create an Entity-Level Method Validator

Entity-level method validators are similar to attribute-level method validators, except that they have a broader scope: the entire entity rather than a single attribute.

Before you begin:

It may be helpful to have an understanding of what method validators are. For more information, see [Section 8.2, "Using Method Validators."](#)

You may also find it helpful to understand additional functionality that can be added using other validation features. For more information, see [Section 8.1.2, "Additional Functionality for Programmatic Business Rules."](#)

To create an entity-level method validator:

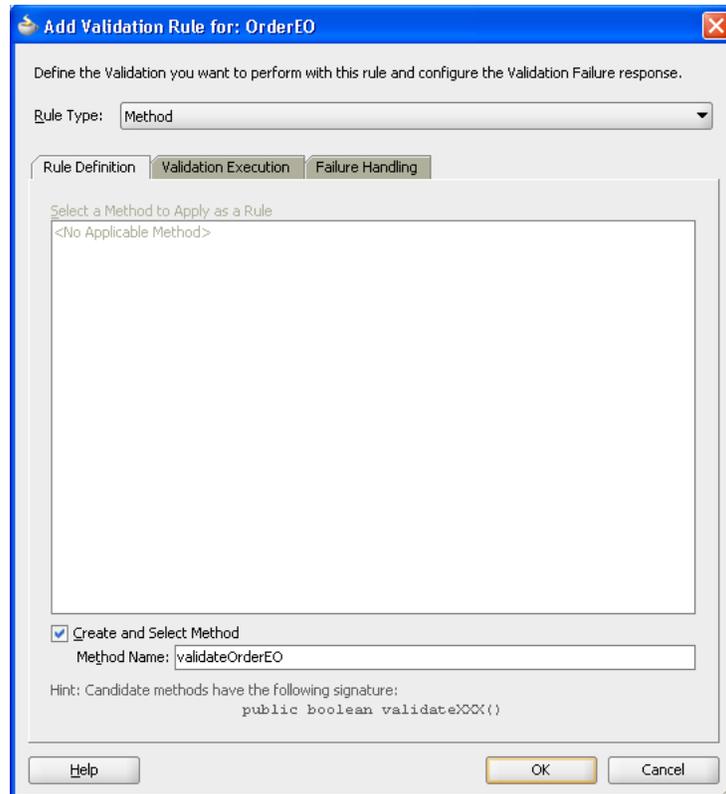

1. In the Application Navigator, double-click the desired entity object.
2. In the overview editor, click the **Java** navigation tab.

The Java page shows the Java generation options that are currently enabled for the entity object. If your entity object does not yet have a custom entity object class, then you must generate one before you can add a Method validator. To generate the custom Java class, click the **Edit** icon, then select **Generate Entity Object Class**, and click **OK** to generate the *.java file.

3. Click the **Business Rules** navigation tab, and then select the **Entity** node.
4. Click the **New** icon to add a validation rule.
5. Select **Method** from the **Rule Type** dropdown list.

The Add Validation Rule dialog displays the expected method signature for an entity-level validation method. You have two choices:

- If you already have a method in your entity object's custom Java class of the appropriate signature, it will appear in the list and you can select it after deselecting the **Create and Select Method** checkbox.
 - If you leave the **Create and Select Method** checkbox selected (see [Figure 8-3](#)), you can enter any method name in the **Method Name** box that begins with the word `validate`. When you click **OK**, JDeveloper adds the method to your entity object's custom Java class with the appropriate signature.
6. Finally, supply the text of the error message for the default locale that the end user should see if this validation rule fails.

Figure 8–3 Adding an Entity-Level Method Validator

8.2.4 What Happens When You Create an Entity-Level Method Validator

When you add a new method validator, JDeveloper updates the XML component definition to reflect the new validation rule. If you asked to have the method created, the method is added to the entity object's custom Java class. [Example 8–3](#) illustrates a simple entity-level validation rule that ensures that the `OrderShippedDate` of an order comes after the `OrderDate`.

Example 8–3 Simple Entity-Level Method Validator

```
public boolean validateOrderShippedDateAfterOrderDate() {
    Date orderShippedDate = getOrderShippedDate();
    Date orderDate = getOrderDate();
    if (orderShippedDate != null && orderShippedDate.compareTo(orderDate) < 0) {
        return false;
    }
    return true;
}
```

8.2.5 What You May Need to Know About Translating Validation Rule Error Messages

Like the locale-specific UI control hints for entity object attributes, the validation rule error messages are added to the entity object's component message bundle file. These entries in the message bundle represent the strings for the default locale for your application. To provide translated versions of the validation error messages, follow the same steps as for translating the UI control hints, as described in [Section 4.7, "Working with Resource Bundles."](#)

8.3 Assigning Programmatically Derived Attribute Values

When declarative defaulting falls short of your needs, you can perform programmatic defaulting in your entity object:

- When an entity row is first created
- When the entity row is first created or when refreshed to null values
- When the entity row is saved to the database
- When an entity attribute value is set

8.3.1 How to Provide Default Values for New Rows at Create Time

The `create()` method provides the entity object event you can handle to initialize default values the first time an entity row is created. [Example 8-4](#) shows the overridden create method of the `OrderEO` entity object in the `StoreFront` module of the Fusion Order Demo. It calls an attribute setter methods to populate the `OrderDate` attribute in a new order entity row.

You can also define default values using a Groovy expression. For more information, see [Section 4.10.6, "How to Define a Static Default Value."](#)

Example 8-4 Programmatically Defaulting Attribute Values for New Rows

```
// In OrderEOImpl.java in Fusion Order Demo
protected void create(AttributeList nameValuePair) {
    super.create(nameValuePair);
    this.setOrderDate(new Date());
}
```

Note: Calling the `setAttribute()` method inside the overridden `create()` method does not mark the new row as being changed by the user. These programmatically assigned defaults behave like declaratively assigned defaults.

8.3.1.1 Choosing Between `create()` and `initDefaultExpressionAttributes()` Methods

You should override the `initDefaultExpressionAttributes()` method for programmatic defaulting logic that you want to fire both when the row is first created, and when it might be refreshed back to initialized status.

If an entity row has `New` status and you call the `refresh()` method on it, then the entity row is returned to an `Initialized` status if you do not supply either the `REFRESH_REMOVE_NEW_ROWS` or `REFRESH_FORGET_NEW_ROWS` flag. As part of this process, the entity object's `initDefaultExpressionAttributes()` method is invoked, but not its `create()` method again.

8.3.1.2 Eagerly Defaulting an Attribute Value from a Database Sequence

[Section 4.10.9, "How to Synchronize with Trigger-Assigned Values,"](#) explains how to use the `DBSequence` type for primary key attributes whose values need to be populated by a database sequence at `commit` time. Sometimes you may want to eagerly allocate a sequence number at entity row creation time so that the user can see its value and so that this value does not change when the data is saved. To accomplish this, use the `SequenceImpl` helper class in the `oracle.jbo.server` package in an overridden `create()` method as shown in [Example 8-5](#). It shows code from the

custom Java class of the WarehouseEO entity object in the StoreFront module of the Fusion Order Demo. After calling `super.create()`, it creates a new instance of the `SequenceImpl` object, passing the sequence name and the current transaction object. Then it calls the `setWarehouseId()` attribute setter method with the return value from `SequenceImpl`'s `getSequenceNumber()` method.

Note: For a metadata-driven alternative to this approach, see [Section 4.14.5, "Assigning the Primary Key Value Using an Oracle Sequence."](#)

Example 8-5 Eagerly Defaulting an Attribute's Value from a Sequence at Create Time

```
// In WarehouseEOImpl.java
import oracle.jbo.server.SequenceImpl;
// Default WarehouseId value from WAREHOUSE_SEQ sequence at entity row create time
protected void create(AttributeList attributeList) {
    super.create(attributeList);
    SequenceImpl sequence = new SequenceImpl("WAREHOUSE_SEQ",getDBTransaction());
    setWarehouseId(sequence.getSequenceNumber());
}
```

8.3.2 How to Assign Derived Values Before Saving

If you want to assign programmatic defaults for entity object attribute values before a row is saved, override the `prepareForDML()` method and call the appropriate attribute setter methods to populate the derived attribute values. To perform the assignment only during INSERT, UPDATE, or DELETE, you can compare the value of the `operation` parameter passed to this method against the integer constants `DML_INSERT`, `DML_UPDATE`, `DML_DELETE` respectively.

[Example 8-6](#) shows an overridden `prepareForDML()` method that assigns derived values.

Example 8-6 Assigning Derived Values Before Saving Using PrepareForDML

```
protected void prepareForDML(int operation, TransactionEvent e) {
    super.prepareForDML(operation, e);
    //Populate GL Date
    if (operation == DML_INSERT) {
        if (this.getGlDate() == null) {
            String glDateDefaultOption =
                (String)this.getInvoiceOption().getAttribute("DefaultGlDateBasis");
            if ("I".equals(glDateDefaultOption)) {
                setAttribute(GLDATE, this.getInvoiceDate());
            } else {
                setAttribute(GLDATE, this.getCurrentDBDate());
            }
        }
    }
}

//Populate Exchange Rate and Base Amount if null
if ((operation == DML_INSERT) || (operation == DML_UPDATE)) {
    BigDecimal defaultExchangeRate = new BigDecimal(1.5);
    if ("Y".equals(this.getInvoiceOption().getAttribute("UseForeignCurTrx"))) {
        if (!(this.getInvoiceCurrencyCode().equals(
            this.getLedger().getAttribute("CurrencyCode")))) {
            if (this.getExchangeDate() == null) {
```

- `REFRESH_WITH_DB_FORGET_CHANGES` forgets modifications made to the row in the current transaction, and the row's data is refreshed from the database. The latest data from the database replaces data in the row regardless of whether the row was modified or not.
- `REFRESH_WITH_DB_ONLY_IF_UNCHANGED` works just like `REFRESH_WITH_DB_FORGET_CHANGES`, but for *unmodified* rows. If a row was already modified by this transaction, the row is not refreshed.
- `REFRESH_UNDO_CHANGES` works the same as `REFRESH_WITH_DB_FORGET_CHANGES` for *unmodified* rows. For a modified row, this mode refreshes the row with attribute values at the beginning of this transaction. The row remains in a modified state if it had been previously posted but not committed in the current transaction prior to performing the refresh operation.

8.4.1 How to Control What Happens to New Rows During a Refresh

By default, any entity rows with `New` status that you `refresh()` are reverted back to blank rows in the `Initialized` state. Declarative defaults are reset, as well as programmatic defaults coded in the `initDefaultExpressionAttributes()` method, but the entity object's `create()` method is not invoked during this blanking-out process.

You can change this default behavior by combining one of the flags in [Section 8.4](#) with one of the following two flags (using the bitwise-OR operator):

- `REFRESH_REMOVE_NEW_ROWS`, new rows are removed during refresh.
- `REFRESH_FORGET_NEW_ROWS`, new rows are marked `Dead`.

8.4.2 How to Cascade Refresh to Composed Children Entity Rows

You can cause a `refresh()` operation to cascade to composed child entity rows by combining the `REFRESH_CONTAINEES` flag (using the bitwise-OR operator) with any of the valid flag combinations described in [Section 8.4](#) and [Section 8.4.1](#). This causes the entity to invoke `refresh()` using the same mode on any composed child entities it contains.

8.5 Using View Objects for Validation

When your business logic requires performing SQL queries, the natural choice is to use a view object to perform that task. Keep in mind that the SQL statements you execute for validation will "see" pending changes in the entity cache only if they are entity-based view objects. Read-only view objects will only retrieve data that has been posted to the database.

8.5.1 How to Use View Accessors for Validation Against View Objects

Since entity objects are designed to be reused in any application scenario, they should not depend *directly* on a view object instance in any specific application module's data model. Doing so would prevent them from being reused in other application modules, which is highly undesirable.

Instead, you should use a view accessor to validate against a view object. For more information, see [Section 10.4.1, "How to Create a View Accessor for an Entity Object or View Object."](#)

Using a view accessor, your validation code can access the view object and set bind variables, as shown in [Example 8–8](#).

Example 8–8 Using a Validation View Object in a Method Validator

```
// Sample entity-level validation method
public boolean validateSomethingUsingViewAccessor() {
    RowSet rs = getMyValidationVO();
    rs.setNamedBindParameter("Name1", value1);
    rs.setNamedBindParameter("Name2", value2);
    rs.executeQuery();
    if ( /* some condition */ ) {
        /*
         * code here returns true if the validation succeeds
         */
    }
    return false;
}
```

Best Practice: Any time you access a row set programmatically, you should consider creating a secondary iterator for the row set. This ensures that you will not disturb the current row set of the default row set iterator that may be utilized when you expose your view objects as data controls to the user interface project. You can call `createRowSetIterator()` on the row set you are working with to create a secondary named row set iterator. When you are through with programmatic iteration, your code should call `closeRowSetIterator()` on the row set to remove the secondary iterator from memory.

As the sample code suggests, view objects used for validation typically have one or more named bind variables in them. In this example, the bind variables are set using the `setNamedBindParameter()` method. However, you can also set these variables declaratively in JDeveloper using Groovy expressions in the view accessor definition page.

Depending on the kind of data your view object retrieves, the `/* some condition */` expression in the example will look different. For example, if your view object's SQL query is selecting a `COUNT()` or some other aggregate, the condition will typically use the `rs.first()` method to access the first row, then use the `getAttribute()` method to access the attribute value to see what the database returned for the count.

If the validation succeeds or fails based on whether the query has returned zero or one row, the condition might simply test whether `rs.first()` returns `null` or not. If `rs.first()` returns `null`, there is no "first" row. In other words, the query retrieved no rows. In other cases, you may be iterating over one or more query results retrieved by the view object to determine whether the validation succeeds or fails.

8.5.2 How to Validate Conditions Related to All Entities of a Given Type

The `beforeCommit()` method is invoked on *each* entity row in the pending changes list after the changes have been posted to the database, but before they are committed. This can be a useful method in which to execute view object-based validations that must assert some rule over all entity rows of a given type.

Note: You can also do this declaratively using a transaction-level validator (see [Section 7.6.4, "How to Set Transaction-Level Validation"](#)).

If your `beforeCommit()` logic can throw a `ValidationException`, you must set the `jbo.txn.handleafterpostexc` property to `true` in your configuration to have the framework automatically handle rolling back the in-memory state of the other entity objects that may have already successfully posted to the database (but not yet been committed) during the current commit cycle.

Note: The example in this section refers to the `ViewObjectValidations` project of the `AdvancedViewObjectExamples` application workspace in the `StandaloneExamples` module of the Fusion Order Demo application.

For example, consider the overridden `beforeCommit()` shown in [Example 8–9](#). In this example, there are three view objects based on polymorphic entity objects (`Persons`, `Staff`, and `Supplier`), with the `PersonTypeCode` attribute as the discriminator. The `PersonsImpl.java` file has an overridden `beforeCommit()` method that calls a validation method. The validation method uses the fourth view object, `PersonsValidator`, to make sure that the principal name is unique across each person type. For example, there is a `PrincipalName` of `SKING` for the `Staff` view object, but there cannot be another `SKING` in this or the other person types.

Example 8–9 Overriding `beforeCommit()` to Validate All Entities of a Given Type

```
// from the PersonsImpl.java file
...
@Override
public void beforeCommit(TransactionEvent transactionEvent) throws
ValidationException {
    String principalName = getPrincipalName();
    if (!validatePrincipalNameIsUniqueUsingViewAccessor(principalName)) {
        throw new ValidationException("Principal Name must be unique across person
types");
    }
    super.beforeCommit(transactionEvent);
}

public boolean validatePrincipalNameIsUniqueUsingViewAccessor(String
principalName) {
    RowSet rs = getPersonsValidatorVO();
    rs.setNamedWhereClauseParam("principalName", principalName);
    rs.setRangeSize(-1);
    rs.executeQuery();
    Row[] validatorRows = rs.getAllRowsInRange();
    if (validatorRows.length > 1)
        // more than one row has the same principalName
    {
        return false;
    }
    rs.closeRowSetIterator();
    return true;
}
```

8.5.3 What You May Need to Know About Row Set Access with View Accessors

If your entity object or view object business logic iterates over its own view accessor row set, and that view accessor is not also used by a model-defined List of Values, then there is no need to use a secondary row set iterator. For example, if an entity object has a view accessor named `AirportValidationVA` for a view object that takes one named bind parameter, it can iterate its own view accessor row set using either Groovy script or Java. [Example 8–10](#) show a Groovy script that iterates over a view accessor row set.

Example 8–10 Using a View Accessor in Groovy Script

```
AirportValidationVA.setNamedWhereClauseParam("VarTla",newValue)
AirportValidationVA.executeQuery();
return AirportValidationVA.first() != null;
```

[Example 8–11](#) shows a Java method validator that iterates over a view accessor row set.

Example 8–11 Using a View Accessor in a Method Validator

```
public boolean validateJob(String job) {
    getAirportValidationVA().setNamedWhereClauseParam("VarTla",job);
    getAirportValidationVA().executeQuery();
    return getAirportValidationVA().first() != null;
}
```

8.6 Accessing Related Entity Rows Using Association Accessors

To access information from related entity objects, you use an association accessor method in your entity object's custom Java class. By calling the accessor method, you can easily access any related entity row — or set of entity rows — depending on the cardinality of the association.

8.6.1 How to Access Related Entity Rows

You can use an association accessor to access related entity rows. [Example 8–12](#) shows code from the `ControllingPostingOrder` project in the `AdvancedEntityExamples` module of the Fusion Order Demo that shows the overridden `postChanges()` method in the `ProductsBase` entity object's custom Java class. It uses the `getSupplier()` association accessor to retrieve the related supplier for the product.

Example 8–12 Accessing a Parent Entity Row In a Create Method

```
// In ProductstBaseImpl.java in the ControllingPostingOrder project
// of the Fusion Order Demo Advanced Entity Examples
@Override
public void postChanges(TransactionEvent transactionEvent) {
    /* If current entity is new or modified */
    if (getPostState() == STATUS_NEW || getPostState() == STATUS_MODIFIED) {
        /* Get the associated supplier for the product */
        SuppliersImpl supplier = getSupplier();
        /* If there is an associated product */
        if (supplier != null) {
            /* And if its post-status is NEW */
```

```

        if (supplier.getPostState() == STATUS_NEW) {
            /* Post the supplier first, before posting this entity */
            supplier.postChanges(transactionEvent);
        }
    }
    super.postChanges(transactionEvent);
}

```

8.6.2 How to Access Related Entity Row Sets

If the cardinality of the association is such that multiple rows are returned, you can use the association accessor to return sets of entity rows.

[Example 8-13](#) illustrates the code for the overridden `postChanges()` method in the `Suppliers` entity object's custom Java class. It shows the use of the `getProductsBase()` association accessor to retrieve the `RowSet` object of `ProductsBase` rows in order to update the `SupplierId` attribute in each row using the `setSupplierId()` association accessor.

Example 8-13 Accessing a Related Entity Row Set Using an Association Accessor

```

// In SuppliersImpl.java in the ControllingPostingOrder project
// of the Fusion Order Demo Advanced Entity Examples
RowSet newProductsBeforePost = null;
@Override
public void postChanges(TransactionEvent transactionEvent) {
    /* Only update references if Supplier is new */
    if (getPostState() == STATUS_NEW) {
        /*
         * Get a rowset of products related to this new supplier before calling super
         */
        newProductsBeforePost = (RowSet) getProductsBase();
    }
    super.postChanges(transactionEvent);
}

...

protected void refreshFKInNewContainees() {
    if (newProductsBeforePost != null) {
        Number newSupplierId = getSupplierId().getSequenceNumber();
        /*
         * Process the rowset of suppliers that referenced the new product prior
         * to posting, and update their ProdId attribute to reflect the refreshed
         * ProdId value that was assigned by a database sequence during posting.
         */
        while (newProductsBeforePost.hasNext()){
            ProductsBaseImpl product = (ProductsBaseImpl) newProductsBeforePost.next();
            product.setSupplierId(newSupplierId);
        }
        closeNewProductRowSet();
    }
}

```

8.7 Referencing Information About the Authenticated User

If you have run the Configure ADF Security wizard on your application to enable the ADF authentication servlet to support user login and logout, the `oracle.jbo.server.SessionImpl` object provides methods you can use to get information about the name of the authenticated user and about the roles of which they are a member. This is the implementation class for the `oracle.jbo.Session` interface that clients can access.

For information about how to access information about the authenticated user, see [Section 35.11.3.3, "How to Determine the Current User Name, Enterprise Name, or Enterprise ID"](#) and [Section 35.11.3.4, "How to Determine Membership of a Java EE Security Role"](#).

For more information about security features in Oracle Fusion Web Applications, read [Chapter 35, "Enabling ADF Security in a Fusion Web Application."](#)

8.8 Accessing Original Attribute Values

If an entity attribute's value has been changed in the current transaction, when you call the attribute getter method for it you will get the pending changed value. Sometimes you want to get the original value before it was changed. Using the `getPostedAttribute()` method, your entity object business logic can consult the original value for any attribute as it was read from the database before the entity row was modified. This method takes the attribute *index* as an argument, so pass the appropriate generated attribute index enums that JDeveloper maintains for you.

8.9 Storing Information About the Current User Session

If you need to store information related to the current user session in a way that entity object business logic can reference, you can use the user data hash table provided by the `Session` object.

8.9.1 How to Store Information About the Current User Session

When a new user accesses an application module for the first time, the `prepareSession()` method is called. As shown in [Example 8-14](#), the application module overrides `prepareSession()` to retrieve information about the authenticated user by calling a `retrieveUserInfoForAuthenticatedUser()` method on the view object instance. Then, it calls the `setUserIdIntoUserDataHashtable()` helper method to save the user's numerical ID into the user data hash table.

Example 8-14 *Overriding `prepareSession()` to Query User Information*

```
// In the application module
protected void prepareSession(Session session) {
    super.prepareSession(session);
    /*
     * Query the correct row in the VO based on the currently logged-in
     * user, using a custom method on the view object component
     */
    getLoggedInUser().retrieveUserInfoForAuthenticatedUser();
    setUserIdIntoUserDataHashtable();
}
```

[Example 8-15](#) shows the code for the view object's `retrieveUserInfoForAuthenticatedUser()` method. It sets its own `EmailAddress` bind variable to the name of the authenticated user from the session and then calls `executeQuery()` to retrieve the additional user information from the `USERS` table.

Example 8-15 Accessing Authenticated User Name to Retrieve Additional User Details

```
// In the view object's custom Java class
public void retrieveUserInfoForAuthenticatedUser() {
    SessionImpl session = (SessionImpl) getDBTransaction().getSession();
    setEmailAddress(session.getUserPrincipalName());
    executeQuery();
    first();
}
```

One of the pieces of information about the authenticated user that the view object retrieves is the user's numerical ID number, which that method returns as its result. For example, the user `sking` has the numeric `UserId` of 300.

[Example 8-16](#) shows the `setUserIdIntoUserDataHashtable()` helper method — used by the `prepareSession()` code in [Example 8-14](#) — that stores this numerical user ID in the user data hash table, using the key provided by the string constant `CURRENT_USER_ID`.

Example 8-16 Setting Information into the UserData Hashtable for Access By Entity Objects

```
// In the application module
private void setUserIdIntoUserDataHashtable() {
    Integer userid = getUserIdForLoggedInUser();
    Hashtable userdata = getDBTransaction().getSession().getUserData();
    userdata.put(CURRENT_USER_ID, userid);
}
```

The corresponding entity objects in this example can have an overridden `create()` method that references this numerical user ID using a helper method like the one in [Example 8-17](#) to set the `CreatedBy` attribute programmatically to the value of the currently authenticated user's numerical user ID.

Example 8-17 Referencing the Current User ID in a Helper Method

```
protected Number getCurrentUserId() {
    Hashtable userdata = getDBTransaction().getSession().getUserData();
    Integer userId = (Integer) userdata.get(CURRENT_USER_ID);
    return userdata != null ? Utils.intToNumber(userId) : null;
}
```

8.9.2 How to Use Groovy to Access Information About the Current User Session

The top-level `adf` object allows you access to objects that the framework makes available to Groovy script. The `adf.userSession` object returns a reference to the ADF Business Components user session, which you can use to reference values in the `userData` hash map that is part of the session.

[Example 8-18](#) shows the Groovy script you would use to reference a `userData` hash map key named `MyKey`.

Example 8–18 Accessing the Current User Session Using Groovy Script

```
adf.userSession.userData.MyKey
```

8.10 Accessing the Current Date and Time

You might find it useful to reference the current date and time in your entity object business logic. You can reference the current date or current date and time using the following Groovy script expressions:

- `adf.currentDate` — returns the current date (time truncated)
- `adf.currentDateTime` — returns the current date and time

For more information about using Groovy script in your entity object business logic, see [Section 3.6, "Overview of Groovy Scripting Language Support."](#)

8.11 Sending Notifications Upon a Successful Commit

The `afterCommit()` method is invoked on *each* entity row that was in the pending changes list and got successfully saved to the database. You can use this method to send a notification on a commit.

A better way to send notifications upon a successful commit is by declaring a business event. For more information on how to create a business event, see [Section 4.12, "Creating Business Events."](#)

8.12 Conditionally Preventing an Entity Row from Being Removed

Before an entity row is removed, the `remove()` method is invoked on an entity row. You can throw a `JobException` in the `remove()` method to prevent a row from being removed if the appropriate conditions are not met.

For example, you can add a test in the `remove()` method that determines the state of the entity object and allows the removal only if it is a new record. [Example 8–19](#) demonstrates this technique.

Note: This example is in the `AddressesImpl.java` file in the `ConditionalDelete` project of the `DevGuideExamples` workspace in the `StandaloneExamples` module of the Fusion Order Demo application.

Example 8–19 Overriding the `remove()` Method to Verify Entity Status Before Removal

```
// In the Addresses entity object custom Java class
private boolean isDeleteAllowed() {
    byte s = this.getEntityState();
    return s==STATUS_NEW;
}

/**
 * Add entity remove logic in this method.
 */
public void remove() {
    if (isDeleteAllowed())
        super.remove();
    else
```

```

        throw new JboException("Delete not allowed in this view");
    }

```

Note: The entity object offers declarative prevention of deleting a master entity row that has existing, composed children rows. You configure this option on the Relationship page of the overview editor for the association.

8.13 Determining Conditional Updatability for Attributes

You can override the `isAttributeUpdateable()` method in your entity object class to programmatically determine whether a given attribute is updatable or not at runtime based on appropriate conditions.

[Example 8–20](#) shows how an entity object can override the `isAttributeUpdateable()` method to enforce that its `PersonTypeCode` attribute is updatable only if the current authenticated user is a staff member. Notice that when the entity object fires this method, it passes in the integer attribute index whose updatability is being considered.

You can implement conditional updatability logic for a particular attribute inside an `if` or `switch` statement based on the attribute index. Here `PERSONTYPECODE` is referencing the integer attribute index enums that JDeveloper maintains in your entity object custom Java class.

Example 8–20 Conditionally Determining an Attribute's Updatability at Runtime

```

// In the entity object custom Java class
public boolean isAttributeUpdateable(int index) {
    if (index == PERSONTYPECODE) {
        if (!currentUserIsStaffMember()) {
            return super.isAttributeUpdateable(index);
        }
        return CUSTOMER_TYPE.equals(getPersonTypeCode()) ? false : true;
    }
    return super.isAttributeUpdateable(index);
}

```

Note: Entity-based view objects inherit this conditional updatability as they do everything else encapsulated in your entity objects. Should you need to implement this type of conditional updatability logic in a way that is specific to a transient view object attribute, or to enforce some condition that involves data from multiple entity objects participating in the view object, you can override this same method in a view object's view row class to achieve the desired result.

8.14 Implementing Custom Validation Rules

ADF Business Components comes with a base set of built-in declarative validation rules that you can use. However, a powerful feature of the validator architecture for entity objects is that you can create your own custom validation rules. When you notice that you or your team are writing the same kind of validation code over and over, you can build a custom validation rule class that captures this common validation "pattern" in a parameterized way.

After you've defined a custom validation rule class, you can register it in JDeveloper so that it is as simple to use as any of the built-in rules. In fact, you can even bundle your custom validation rule with a custom UI panel that JDeveloper leverages to facilitate developers' using and configuring the parameters your validation rule might require.

8.14.1 How to Create a Custom Validation Rule

To write a custom validation rule for entity objects, you need a Java class that implements the `JboValidatorInterface` in the `oracle.jbo.rules` package. You can create a skeleton class from the New Gallery.

Before you begin:

It may be helpful to have an understanding of custom validation rules. For more information, see [Section 8.14, "Implementing Custom Validation Rules."](#)

You may also find it helpful to understand additional functionality that can be added using other validation features. For more information, see [Section 8.1.2, "Additional Functionality for Programmatic Business Rules."](#)

To create a custom validator:

1. In the Application Navigator, right-click the project where you want to create the validator, and choose **New** from the context menu.
2. In the New Gallery, expand **Business Tier**, click **ADF Business Components**, select **Validation Rule** and click **OK**.

As shown in [Example 8–21](#), `JboValidatorInterface` contains one main `validate()` method, and a getter and setter method for a `Description` property.

Example 8–21 All Validation Rules Must Implement the JboValidatorInterface

```
package oracle.jbo.rules;
public interface JboValidatorInterface {
    void validate(JboValidatorContext valCtx) { }
    java.lang.String getDescription() { }
    void setDescription(String description) { }
}
```

If the behavior of your validation rule will be parameterized to make it more flexible, then add additional bean properties to your validator class for each parameter. For example, the code in [Example 8–22](#) implements a custom validation rule called `DateMustComeAfterRule` which validates that one date attribute must come after another date attribute. To allow the developer using the rule to configure the names of the date attributes to use as the initial and later dates for validation, this class defines two properties `initialDateAttrName` and `laterDateAttrName`.

[Example 8–22](#) shows the code that implements the custom validation rule. It extends the `AbstractValidator` to inherit support for working with the entity object's custom message bundle, where JDeveloper saves the validation error message when a developer uses the rule in an entity object.

The `validate()` method of the validation rule gets invoked at runtime whenever the rule class should perform its functionality. The code performs the following basic steps:

1. Ensures validator is correctly attached at the entity level.
2. Gets the entity row being validated.

3. Gets the values of the initial and later date attributes.
4. Validate that initial date is before later date.
5. Throws an exception if the validation fails.

Example 8–22 Custom DateMustComeAfterRule

```
// NOTE: package and imports omitted
public class DateMustComeAfterRule extends AbstractValidator
    implements JboValidatorInterface {
    /**
     * This method is invoked by the framework when the validator should do its job
     */
    public void validate(JboValidatorContext valCtx) {
        // 1. If validator is correctly attached at the entity level...
        if (validatorAttachedAtEntityLevel(valCtx)) {
            // 2. Get the entity row being validated
            EntityImpl eo = (EntityImpl)valCtx.getSource();
            // 3. Get the values of the initial and later date attributes
            Date initialDate = (Date) eo.getAttribute(getInitialDateAttrName());
            Date laterDate = (Date) eo.getAttribute(getLaterDateAttrName());
            // 4. Validate that initial date is before later date
            if (!validateValue(initialDate, laterDate)) {
                // 5. Throw the validation exception
                RulesBeanUtils.raiseException(getErrorMessageClass(),
                    getErrorMsgId(),
                    valCtx.getSource(),
                    valCtx.getSourceType(),
                    valCtx.getSourceFullName(),
                    valCtx.getAttributeDef(),
                    valCtx.getNewValue(),
                    null, null);
            }
        }
        else {
            throw new RuntimeException("Rule must be at entity level");
        }
    }
    /**
     * Validate that the initialDate comes before the laterDate.
     */
    private boolean validateValue(Date initialDate, Date laterDate) {
        return (initialDate == null) || (laterDate == null) ||
            (initialDate.compareTo(laterDate) < 0);
    }
    /**
     * Return true if validator is attached to entity object
     * level at runtime.
     */
    private boolean validatorAttachedAtEntityLevel(JboValidatorContext ctx) {
        return ctx.getOldValue() instanceof EntityImpl;
    }
    // NOTE: Getter/Setter Methods omitted
    private String description;
    private String initialDateAttrName;
    private String laterDateAttrName;
}
```

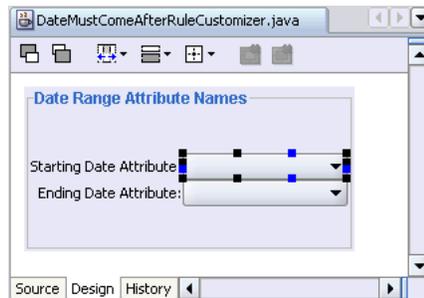

For easier reuse of your custom validation rules, you would typically package them into a JAR file for reference by applications that make use of the rules.

8.14.2 Adding a Design Time Bean Customizer for Your Rule

Since a validation rule class is a bean, you can implement a standard JavaBean customizer class to improve the design time experience of setting the bean properties. In the example of the `DateMustComeAfter` rule (in [Example 8-22](#)), the two properties that the developers must configure are the `initialDateAttrName` and `laterDateAttrName` properties.

[Figure 8-4](#) illustrates using JDeveloper's visual designer for Swing to create a `DateMustComeAfterRuleCustomizer` using a `JPanel` with a titled border containing two `JLabel` prompts and two `JComboBox` controls for the dropdown lists. The code in the class populates the dropdown lists with the names of the `Date`-valued attributes of the current entity object being edited in the IDE. This will allow a developer who adds a `DateMustComeAfterRule` validation to their entity object to easily pick which date attributes should be used for the starting and ending dates for validation.

Figure 8-4 Using JDeveloper's Swing Visual Designer to Create a Validation Rule Customizer

To associate a customizer with your `DateMustComeAfterRule` Java Bean, you follow the standard practice of creating a `BeanInfo` class. As shown in [Example 8-23](#), the `DateMustComeAfterRuleBeanInfo` returns a `BeanDescriptor` that associates the customizer class with the `DateMustComeAfter` bean class.

You would typically package your customizer class and this bean info in a separate JAR file for design-time-only use.

Example 8-23 BeanInfo to Associate a Customizer with a Custom Validation Rule

```
package oracle.fodemo...frameworkExt.rules;
import java.beans.BeanDescriptor;
import java.beans.SimpleBeanInfo;
public class DateMustComeAfterRuleBeanInfo extends SimpleBeanInfo {
    public BeanDescriptor getBeanDescriptor() {
        return new BeanDescriptor(DateMustComeAfterRule.class,
            DateMustComeAfterRuleCustomizer.class);
    }
}
```

8.14.3 How to Register and Using a Custom Rule in JDeveloper

After you've created a custom validation rule, you can add it to the project or application level in the JDeveloper IDE so that other developers can use the rule declaratively.

8.14.3.1 Registering a Custom Validator at the Project Level

When you register a custom validation rule at the project level, you can use it within the project.

Before you begin:

It may be helpful to have an understanding of custom validation rules. For more information, see [Section 8.14, "Implementing Custom Validation Rules."](#)

You may also find it helpful to understand additional functionality that can be added using other validation features. For more information, see [Section 8.1.2, "Additional Functionality for Programmatic Business Rules."](#)

To register a custom validation rule, you must have already created it, as described in [Section 8.14.1, "How to Create a Custom Validation Rule."](#)

To register a custom validation rule in a project containing entity objects:

1. In the Application Navigator, right-click the desired project, and choose **Project Properties** from the context menu.
2. In the Project Properties dialog, expand **Business Components**, and select **Registered Rules**.
3. On the Registered Rules page, click **Add**.
4. In the Register Validation Rule dialog, browse to find the validation rule you have created (such as the one created in [Section 8.14.1, "How to Create a Custom Validation Rule"](#)), and click **OK**.

8.14.3.2 Registering a Custom Validator at the IDE Level

When you register a custom validation rule at the IDE level for JDeveloper, you can use it in other projects as well as your current project.

Before you begin:

It may be helpful to have an understanding of custom validation rules. For more information, see [Section 8.14, "Implementing Custom Validation Rules."](#)

You may also find it helpful to understand additional functionality that can be added using other validation features. For more information, see [Section 8.1.2, "Additional Functionality for Programmatic Business Rules."](#)

To register a custom validation rule, you must have already created it, as described in [Section 8.14.1, "How to Create a Custom Validation Rule."](#)

To register a custom validator at the IDE level:

1. From the **Tools** menu, choose **Preferences**.
2. In the Preferences dialog, expand **Business Components**, and select **Register Rules**.
3. From the Register Rules page, you can add a one or more validation rules.

When adding a validation rule, provide the fully-qualified name of the validation rule class, and supply a validation rule name that will appear in JDeveloper's list of available validators.

Implementing Business Services with Application Modules

This chapter describes how to create application modules to encapsulate a data model using view objects. This chapter also describes how to combine business service methods with that data model to implement a complete business service.

This chapter includes the following sections:

- [Section 9.1, "About Application Modules"](#)
- [Section 9.2, "Creating and Modifying an Application Module"](#)
- [Section 9.3, "Configuring Your Application Module Database Connection"](#)
- [Section 9.4, "Defining Nested Application Modules"](#)
- [Section 9.5, "Creating an Application Module Diagram for Your Business Service"](#)
- [Section 9.6, "Supporting Multipage Units of Work"](#)
- [Section 9.7, "Customizing an Application Module with Service Methods"](#)
- [Section 9.8, "Customizing Application Module Message Strings"](#)
- [Section 9.9, "Publishing Custom Service Methods to UI Clients"](#)
- [Section 9.10, "Working Programmatically with an Application Module's Client Interface"](#)
- [Section 9.11, "Overriding Built-in Framework Methods"](#)
- [Section 9.12, "Calling a Web Service from an Application Module"](#)

9.1 About Application Modules

An *application module* is an ADF Business Components component that encapsulates the business service methods and data model for a logical unit of work related to an end-user task.

In the early phases of application development, architects and designers often use UML use case techniques to create a high-level description of the application's planned end-user functionalities. Each high-level, end-user use case identified during the design phase typically depends on:

- The domain business objects involved. To answer the question, "What core business data is relevant to the use case?"

- The user-oriented view of business data required. To answer the questions, "What subset of columns, what filtered set of rows, sorted in what way, grouped in what way, is needed to support the use case?"

The identified domain objects involved in each use case help you identify the required entity objects from your business domain layer. The user-oriented view of the required business data helps to define the right SQL queries captured as view objects and to retrieve the data in the exact way needed by the end user. For best performance, this includes retrieving the minimum required details necessary to support the use case. In addition to leveraging view object queries to shape the data, you've learned how to use view links to set up natural master-detail hierarchies in your data model to match exactly the kind of end-user experience you want to offer the user to accomplish the use case.

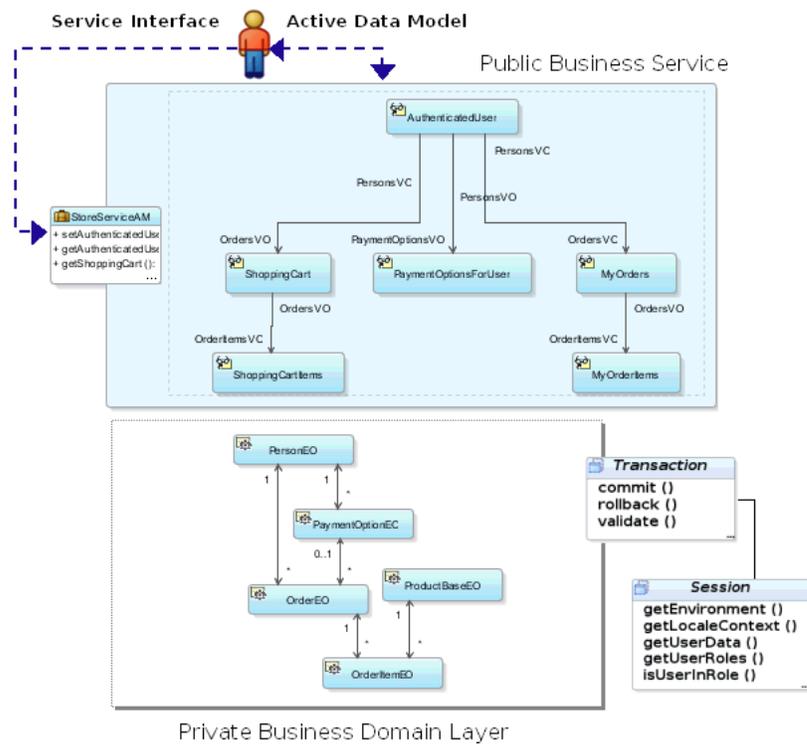

The application module is the "work unit" container that includes instances of the reusable view objects required for the use case in question, related through metadata to the underlying entity objects in your reusable business domain layer whose information the use case is presenting or modifying.

9.1.1 Application Module Use Cases and Examples

This chapter illustrates the following concepts illustrated in [Figure 9-1](#), and more:

- You use instances of view objects in an application module to define its data model.
- You write service methods to encapsulate task-level business logic.
- You expose selected methods on the client interface for UI clients to call.
- You expose selected methods on the service interface for programmatic use in application integration scenarios.
- You use application modules from a pool during a logical transaction that can span multiple web pages.
- Your application module works with a `Transaction` object that acquires a database connection and coordinates saving or rolling back changes made to entity objects.
- The related `Session` object provides runtime information about the current application user.

Figure 9–1 Application Module Is a Business Service Component Encapsulating a Unit of Work

9.1.2 Additional Functionality for Application Modules

You may find it helpful to understand other ADF features before you start working with application modules. Following are links to other functionality that may be of interest.

- For details about creating shared application modules, see [Chapter 10, "Sharing Application Module View Instances."](#)
- For details about reusing ADF Business Components using external services, see [Chapter 11, "Integrating Service-Enabled Application Modules."](#)
- For details about how the Data Controls panel exposes the application module to UI developers, see [Chapter 13, "Using ADF Model in a Fusion Web Application."](#)
- For details about configuring application module instances to improve runtime performance, see [Chapter 43, "Application State Management"](#) and [Chapter 44, "Tuning Application Module Pools and Connection Pools."](#)
- For a quick reference to the most common code that you will typically write, use, and override in your custom application module classes, see [Appendix D, "Most Commonly Used ADF Business Components Methods."](#)
- For API documentation related to the `oracle.jbo` package, see the following Javadoc reference document:
 - *Oracle Fusion Middleware Java API Reference for Oracle ADF Model*

9.2 Creating and Modifying an Application Module

In a large application, you typically create one application module to support each coarse-grained end-user task. In a smaller-sized application, you may decide that

creating a single application module is adequate to handle the needs of the complete set of application functionality. [Section 9.4, "Defining Nested Application Modules"](#) provides additional guidance on this subject.

9.2.1 How to Create an Application Module

Any view object you create is a reusable component that can be used in the context of one or more application modules to perform the query it encapsulates in the context of that application module's transaction. The set of view objects used by an application module defines its *data model*, in other words, the set of data that a client can display and manipulate through a user interface.

To create an application module, use the Create Application Module wizard, which is available in the New Gallery.

Before you begin:

It may be helpful to have an understanding of application modules. For more information, see [Section 9.2, "Creating and Modifying an Application Module."](#)

Complete this task:

Create the desired view objects as described in [Section 5.2.1, "How to Create an Entity-Based View Object,"](#) and [Section 5.2.3, "How to Create an Expert Mode, Read-Only View Object."](#)

To create an application module:

1. In the Application Navigator, right-click the project node in which you want to create the application module and choose **New**.
2. In the New Gallery, expand **Business Tier**, select **ADF Business Components** and then **Application Module**, and click **OK**.
3. In the Create Application Module wizard, on the Name page, provide a package name and an application module name. Click **Next**.

Note: In Fusion web applications, the reserved words *data*, *bindings*, *security*, and *adfContext* must not be used to name your application module. Also, avoid using the "_" (underscore) at the beginning of the name. For more information, see [Section 9.2.5, "How to Edit an Existing Application Module."](#)

4. On the Data Model page, include instances of the view objects you have previously defined and edit the view object instance names to be exactly what you want clients to see. Then click **Next**.
5. On the Java page, you can optionally generate the Java files that allow you to programmatically customize the behavior of the application module or to expose methods on the application module's client interface that can be called by clients. To generate an XML-only application module component, leave the fields unselected and click **Finish**.

Initially, you may want to generate only the application module XML definition component. After you complete the wizard, you can subsequently use the overview editor to generate the application module class files when you require programmatic access. For details about the programmatic use of the application module, see [Section 9.7, "Customizing an Application Module with Service Methods."](#)

For more step by step details, see [Section 9.2.3.2, "Adding Master-Detail View Object Instances to an Application Module."](#)

9.2.2 What Happens When You Create an Application Module

When you create an application module, JDeveloper creates the XML component definition file that represents its declarative settings and saves it in the directory that corresponds to the name of its package. For example, given an application module named `StoreServiceAM` in the `storefront.model` package, the XML file created will be `./storefront/model/StoreServiceAM.xml` under the project's source path. This XML file contains the information needed at runtime to re-create the view object instances in the application module's data model.

If you are curious to view its contents, you can see the XML file for the application module by double-clicking the **StoreServiceAM** node in the Application Navigator to open the overview editor. In the editor window, click the **Source** tab to view the XML so that you can inspect it. The Structure window shows the structure of the XML file.

When you create business components, JDeveloper automatically creates a data control that contains all the functionality of the application module. Data controls are an ADF Model abstraction layer that provides supplemental metadata to describe the application module's operations and data collections (row sets of view object instances), including information about the attributes, methods, and types involved. Developers can then use the representation of the data control displayed in JDeveloper's Data Controls panel to create UI components that are automatically bound to the application module. At runtime, the ADF Model layer reads the metadata describing the data controls and bindings from appropriate XML files and implements the two-way connection between the user interface and the business service.

For example, the `StoreServiceAMDataControl` application module implements the business service layer of the StoreFront module application. Its data model contains numerous view object instances, including several master-detail hierarchies. The view layer of the Fusion Order Demo application consists of JSF pages whose UI components are bound to data from the view object instances in the `StoreServiceAMDataControl`'s data model, and to built-in operations and service methods on its client interface. For details about how the Data Controls panel exposes the application module to UI developers, see [Section 13.3, "Exposing Application Modules with Oracle ADF Data Controls."](#)

9.2.3 How to Add a View Object to an Application Module

You can add a view object to an application module as you are creating the application module with the Create Application Module wizard, or you can add it later.

For information about using the Create Application Module wizard, see [Section 9.2.1, "How to Create an Application Module."](#)

9.2.3.1 Adding a View Object Instance to an Existing Application Module

You can add a view object to an application module that you have already created. To add a view object to an existing application module, and optionally, customize the view object instance, use the Data Model Components page of the overview editor for the application module.

Before you begin:

It may be helpful to have an understanding of application modules. For more information, see [Section 9.2, "Creating and Modifying an Application Module."](#)

Complete this task:

Create the desired view objects as described in [Section 5.2.1, "How to Create an Entity-Based View Object,"](#) and [Section 5.2.3, "How to Create an Expert Mode, Read-Only View Object."](#)

To add a view object instance to an existing application module:

1. In the Application Navigator, double-click the application module.
2. In the overview editor, click the **Data Model** navigation tab.
3. On the Data Model Components page, expand the **View Object Instances** section and, in the **Available View Objects** list, select the view instance you want to add.

The **New View Instance** field below the list shows the name that will be used to identify the next instance of that view object that you add to the data model.

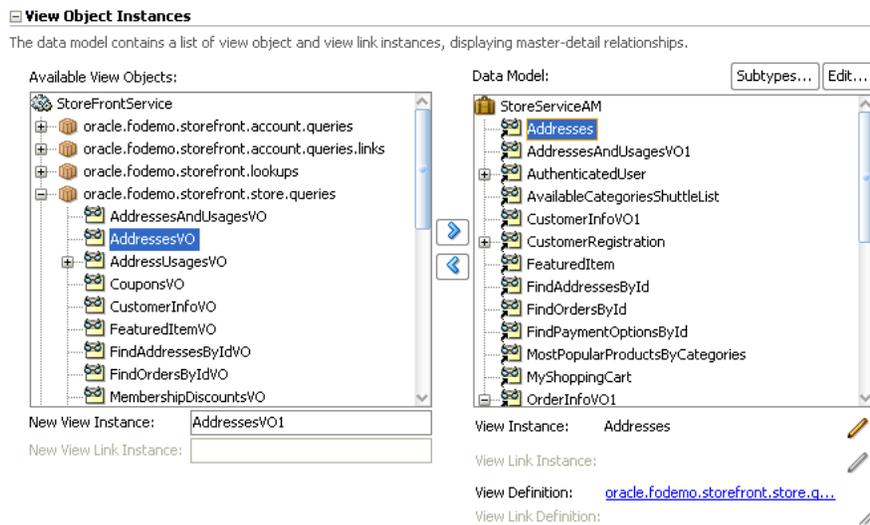

4. To change the name before adding it, enter a different name in the **New View Instance** field.
5. With the desired view object selected, shuttle the view object to the **Data Model** list.

[Figure 9–2](#) shows the view object AddressVO has been renamed to Address before it was shuttled to the **Data Model** list.

Figure 9–2 Data Model Displays Added View Object Instances

Data Model Components

Select a view object from the tree of available view objects, select the instance or application module to be its parent in the data model tree, and click '>' to create a named instance of the view object in the data model.

9.2.3.2 Adding Master-Detail View Object Instances to an Application Module

You can use the data model that the application module overview editor displays to create a hierarchy of view instances, based on existing view links that your project defines. If you have defined view links that establish more than one level of

master-detail hierarchy, then you can proceed to create as many levels of master-detail view instances as your application supports.

Before you begin:

It may be helpful to have an understanding of application modules. For more information, see [Section 9.2, "Creating and Modifying an Application Module."](#)

Complete this task:

Create hierarchical relationships between view objects as described in [Section 5.6, "Working with Multiple Tables in a Master-Detail Hierarchy."](#)

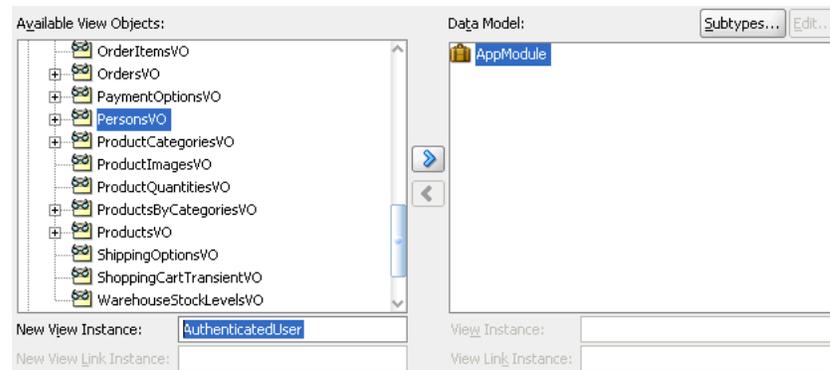

To add master-detail view object instances to a data model:

1. In the Application Navigator, double-click the application module.
2. In the overview editor, click the **Data Model** navigation tab.
3. On the Data Model Components page, expand the **View Object Instances** section and, in the **Data Model** list, select the instance of the view object that you want to be the actively coordinating master.

The master view object will appear with a plus sign in the list indicating the available view links for this view object. The view link must exist to define a master-detail hierarchy.

[Figure 9–3](#) shows `PersonsVO` selected and renamed `AuthenticatedUser` in the **New View Instance** field.

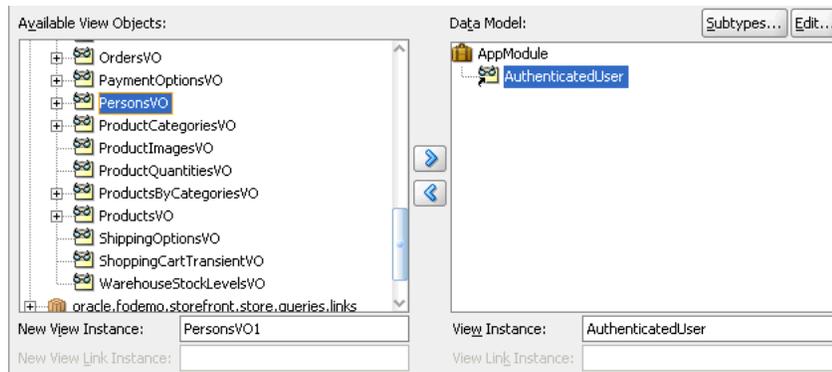

Figure 9–3 Master View Object Selected

4. Shuttle the selected master view object to the **Data Model** list.

[Figure 9–4](#) shows the newly created master view instance `AuthenticatedUser` in the **Data Model** list.

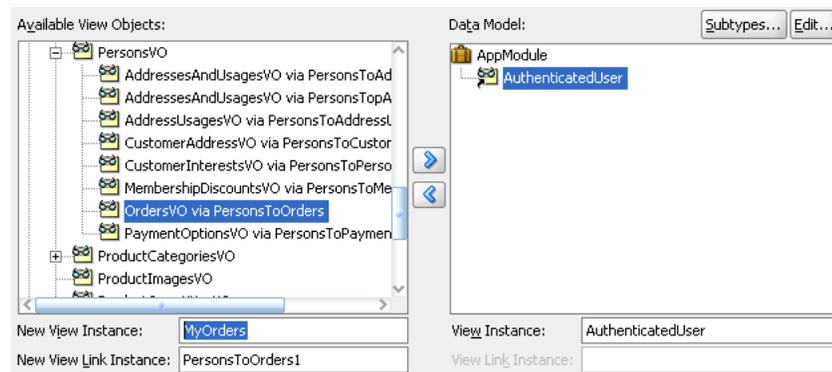

Figure 9–4 Master View Instance Created

5. In the **Data Model** list, leave the newly created master view instance selected so that it appears highlighted. This will be the target of the detail view instance you will add. Then locate and select the detail view object beneath the master view object in the **Available View Objects** list.

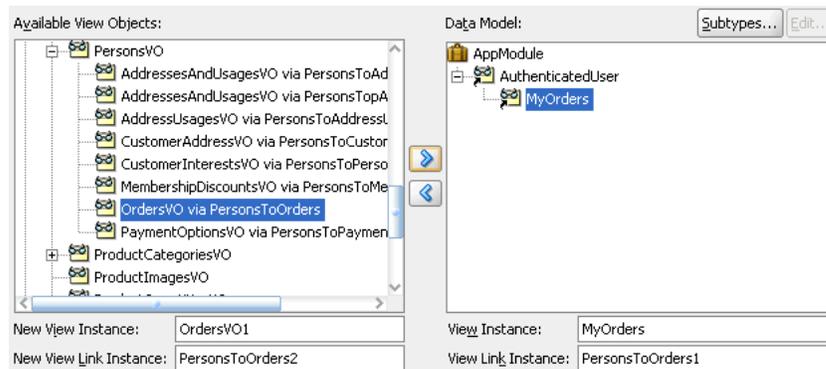

Figure 9–5 shows the detail `OrdersVO` indented beneath master `PersonsVO` with the name `OrdersVO via PersonsToOrders`. The name identifies the view link `PersonsToOrders`, which defines the master-detail hierarchy between `PersonsVO` and `OrdersVO`. Notice also that the `OrdersVO` will have the view instance name `MyOrders` when added to the data model.

Figure 9–5 Detail View Object Selected

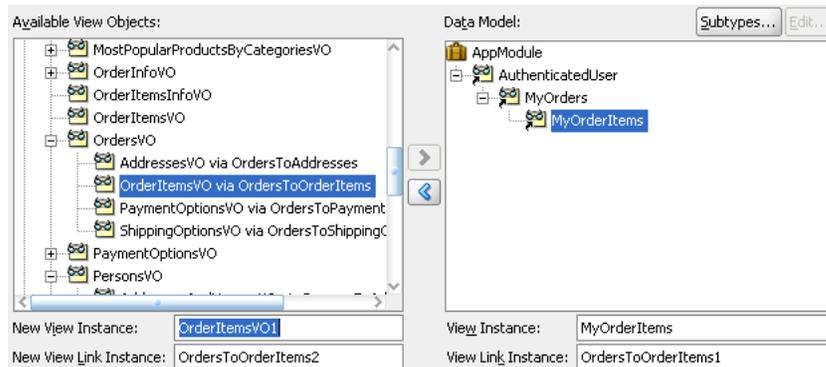

6. To add the detail instance to the previously added master instance, shuttle the detail view object to the **Data Model** list below the selected master view instance.

Figure 9–6 shows the newly created detail view instance `MyOrders` as a detail of the `AuthenticatedUser` in the data model.

Figure 9–6 Master View Instance Created

- To add another level of hierarchy, repeat Step 3 through Step 6, but select the newly added detail in the **Data Model** list, then shuttle over the new detail, which itself has a master-detail relationship with the previously added detail instance.

[Figure 9–7](#) shows the **Data Model** list with instance `AuthenticatedUser` (renamed from `PersonsVO`) as the master of `MyOrders` (renamed from `OrdersVO via PersonsToOrders`), which is, in turn, a master for `MyOrderItems` (renamed from `OrderItemsVO via OrdersToOrderItems`).

Figure 9–7 Master-Detail-Detail Hierarchy Created

9.2.3.3 Customizing a View Object Instance that You Add to an Application Module

You can optionally customize the view object instance by using the Data Model Components page of the overview editor for the application module. For example, you might want to apply a filter to set the controlling attribute for a master-detail view object relationship.

Before you begin:

It may be helpful to have an understanding of application modules. For more information, see [Section 9.2, "Creating and Modifying an Application Module."](#)

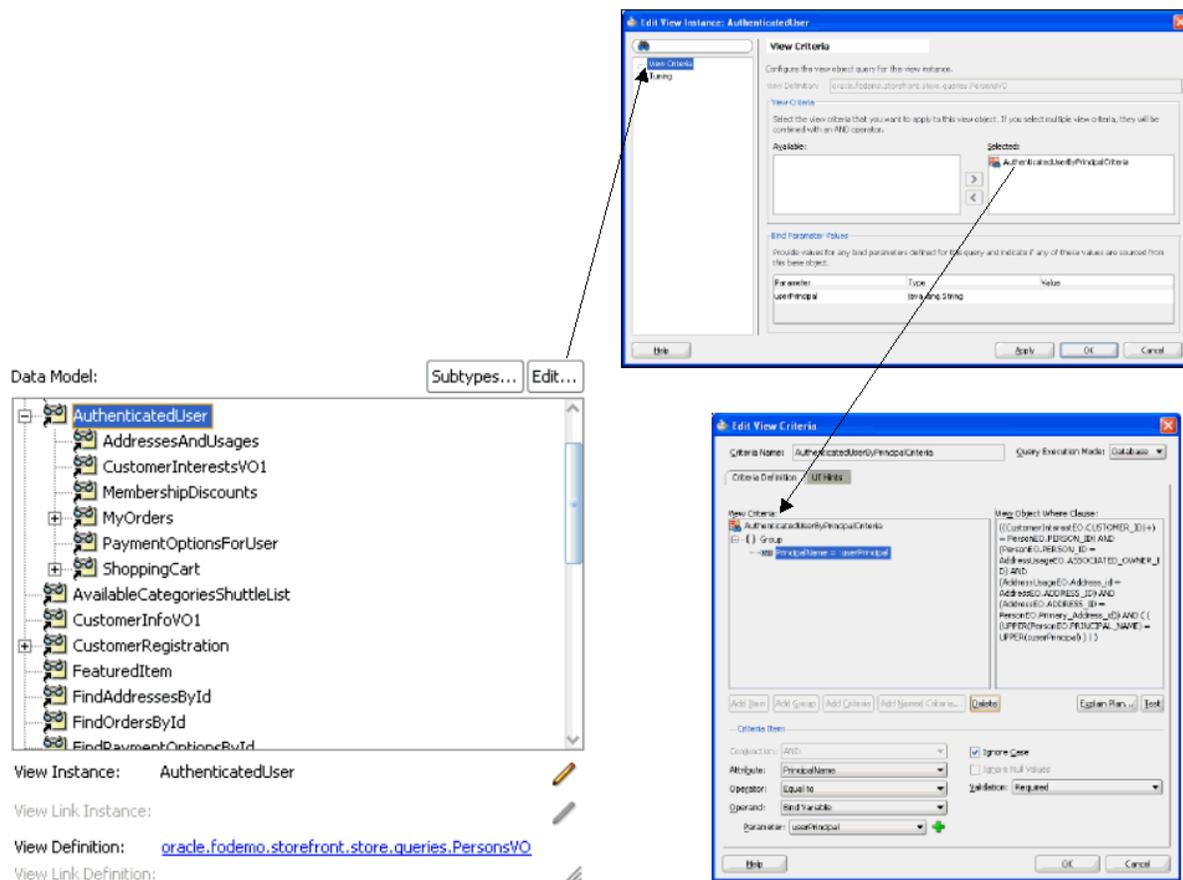

To customize a view object instance that you add to an existing application module:

- In the Application Navigator, double-click the application module.
- In the overview editor, click the **Data Model** navigation tab.

3. On the Data Model Components page, expand the **View Object Instances** section and, in the **Data Model** list, select the view object instance you want to customize and click the **Edit** button.
4. In the Edit View Instance dialog, perform any of the following steps, and then click **OK**.
 - In the **View Criteria** group box, select one or more view criteria that you want to apply to the view object instance. The view criteria will be appended as a **WHERE** clause to the instance query. For details about defining view criteria, see [Section 5.11, "Working with Named View Criteria."](#)
 - In the **Bind Parameters Values** group box, enter any values that you wish the instance to use when applying the defined view criteria. For more information about defining bind variables, see [Section 5.10, "Working with Bind Variables."](#)

Figure 9–8 shows the Edit View Instance dialog opened for the `AuthenticatedUser` view usage with the `AuthenticatedUserByPrincipalCriteria` selected. No default value is supplied for the bind variable `userPrincipal` since the value will be provided at runtime through the evaluation of a Groovy expression that obtains the current user from the ADF security context. The data model for the project defines a master-detail relationship with the `PrincipalName` attribute as the controlling attribute for `AuthenticatedUser` view usage. The controlling attribute, when set by the view criteria filter, provides a way to retrieve only the view rows for the current user.

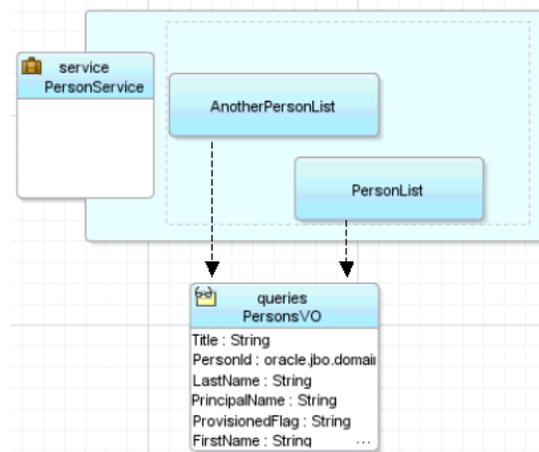

Figure 9–8 Customized View Object Instance Using a View Criteria Filter

9.2.4 What Happens When You Add a View Object to an Application Module

While adding a view object to an application module, you use instances of a view object component to define its data model. [Figure 9–9](#) shows a JDeveloper business components diagram of a `PersonService` application module.

Figure 9–9 Application Module Containing Two Instances of a View Object Component

The sample application module contains two instances of the `Persons` view object component, with member names of `PersonList` and `AnotherPersonList` to distinguish them. At runtime, both instances share the same `PersonsVO` view object component definition—ensure that they have the same attribute structure and view object behavior—however, each might be used independently to retrieve data about different users. For example, some of the runtime properties, like an additional filtering `WHERE` clause or the value of a bind variable, might be different on the two distinct instances.

[Example 9–1](#) shows how the `PersonService` application module defines its member view object instances in its XML component definition file.

Example 9–1 Member View Object Instances Defined in XML

```

<AppModule Name="PersonService">
  <ViewUsage
    Name="PersonList"
    ViewObjectName="oracle.fodemo.storefront.store.queries.PersonsVO" />
  <ViewUsage
    Name="AnotherPersonList"
    ViewObjectName="oracle.fodemo.storefront.store.queries.PersonsVO" />
</AppModule>
  
```

9.2.5 How to Edit an Existing Application Module

After you've created a new application module, you can edit any of its settings by using the Edit Application Module dialog. To launch the editor, in the Application Navigator, right-click the application module node and choose **Open**, or double-click the application module. By visiting the different pages of the editor, you can adjust the data model to determine whether or not to reference nested application modules, specify Java generation settings, client interface methods, remote deployment options, runtime instantiation behavior, and custom properties.

If you edit the name of your application module, choose a name that is not among the reserved words that Oracle Application Development Framework (Oracle ADF) defines. In particular, reserved words are not valid for a data control usage name which JDeveloper automatically assigns based on your application module's name. In Fusion web applications, these reserved words consist of `data`, `bindings`, `security`, and `adfContext`. For example, you should not name an application module `data`. If JDeveloper creates a data control usage with an ID that collides with a reserved word, your application may not reliably access your data control objects at runtime and may fail with a runtime `ClassCastException`.

Do not name the application module with an initial underscore (`_`) character to prevent a potential name collision with a wider list of reserved words that begin with the underscore.

Application module names that incorporate a reserved word into their name (or that change the case of the reserved word) will not conflict. For example, `Product_Data`, `Product_data`, or just `Data` are all valid application module names since the whole name does not match the reserved word `data`.

9.2.6 How to Change the Data Control Name Before You Begin Building Pages

By default, an application module will appear in the Data Controls panel as a data control named `AppModuleNameDataControl`. The user interface designer uses the Data Controls panel to bind data from the application module to the application's web pages. For example, if the application module is named `StoreServiceAM`, the Data Controls panel will display the data control with the name `StoreServiceAMDataControl`. You can change the default data control name to make it shorter or to supply a more preferable name.

When the user interface designer works with the data control, they will see the data control name for your application module in the `DataBindings.cpx` file in the user interface project and in each data binding page definition XML file. In addition, you might refer to the data control name in code when needing to work programmatically with the application module service interface. For this reason, if you plan to change the name of your application module, do this change before you begin building your view layer.

For complete information about the application module data control, see [Chapter 13, "Using ADF Model in a Fusion Web Application."](#)

Note: If you decide to change the application module's data control name after you have already referenced it in one or more pages, you will need to open the page definition files and `DataBindings.cpx` file where it is referenced and update the old name to the new name manually.

To change the application module data control name:

1. In the Application Navigator, double-click the application module.
2. Open the Property Inspector and expand the **Other** section.
3. Enter your preferred data control name in the **Data Control Name** field.

9.2.7 What You May Need to Know About Application Module Granularity

A common question related to application modules is, "How big should my application module be?" In other words, "Should I build one big application module to

contain the entire data model for my enterprise application, or many smaller application modules?" The answer depends on your situation.

In general, application modules should be as big as necessary to support the specific use case you have in mind for them to accomplish. They can be assembled from finer-grained application module components using a nesting feature, as described in [Section 9.4, "Defining Nested Application Modules."](#) Since a complex business application is not really a single use case, a complex business application implemented using Oracle ADF will typically not be just a single application module.

In actual practice, you may choose any granularity you wish. For example, in a small application with one main use case and a "backend" supporting use case, you could create two application modules. However, for the sake of simplicity you can combine both use cases, rather than create a second application module that contains just a couple of view objects.

9.2.8 What You May Need to Know About View Object Components and View Object Instances

While designing an application module, you use instances of a view object component to define its data model. Just as the user interface may contain two instances of a `Button` component with member names of `myButton` and `anotherButton` to distinguish them, your application module contains two instances of the `Persons` view object component, with member names of `PersonList` and `AnotherPersonList` to distinguish them.

9.3 Configuring Your Application Module Database Connection

When you initialize your data model project to use ADF Business Components, JDeveloper prompts you to supply database connection details. You must specify a database connection before you can run ADF Business Components wizards and work with the database's tables and views to create business components. After you specify the connection details, JDeveloper also creates a Java Database Connectivity (JDBC) data source that will be used as the default runtime connection for all application modules created in the current project. You can use the Edit Business Components Configuration dialog to change the JDBC data source definition for each application module individually. In cases, where you do not want to use a data source, you also use the dialog to replace the connection type for individual application modules with a JDBC URL connection type.

You can use either the JDBC data source or the JDBC URL connection type to run the application module in any context where Java can run. Your application is not restricted to running inside a Java Enterprise Edition (Java EE) application server. For example, although the Oracle ADF Model Tester is a standalone Java tool and does not run within the context of a Java EE application server, you can use either connection type to test your business components in the Oracle ADF Model Tester. You can use the Edit Business Components Configuration dialog to select among both connection types for the existing application resource connections that appear in the Database Navigator

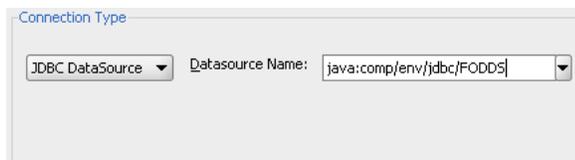

When you make no connection type selection, JDeveloper configures the application module by default to use the data source connection type. A JDBC data source is a vendor-independent encapsulation of a database server connection. The JDBC data source offers advantages that the JDBC URL connection type does not. When you define a connection type based on a data source, you reconfigure the data source without changing the deployed application. The data source is also centrally defined at the application server level, whereas JDBC URL connections are not. In cases, where

a JDBC data source is not viable, at runtime, ADF Business Components will construct a default JDBC URL based on the data source connection information.

9.3.1 How to Use a JDBC Data Source Connection Type

The type of connection all default application module configurations use is a JDBC data source. You define a JDBC data source as part of your application server configuration information, and then the application module looks up the resource at runtime using a logical name. When you use the JDBC data source as the connection type, your application resource connection details may change, and you will not need to change the deployed application module configuration. For this reason the JDBC data source is the recommended choice for all application module configurations. [Figure 9–10](#) shows how the default selection appears in the Edit Business Components Configuration dialog.

Figure 9–10 JDBC DataSource Connection Type Setting in Edit Business Components Configuration Dialog

[Example 9–2](#) shows the `<resource-ref>` tags in the `web.xml` file of a Fusion web application. These define two logical data sources named `jdbc/FODemoDS` and `jdbc/FODemoCoreDS`. The Edit Business Components Configuration dialog references this logical connection name after the prefix `java:comp/env` in the **JDBC Datasource Name** field. For example, the JDBC data source name for the same Fusion web application would display the value `java:comp/env/jdbc/FODemoDS` that you can select. Therefore the **Datasource Name** field is prepopulated with the JNDI name for all available application resources connection names.

Example 9–2 Logical Data Source Resource Names Defined in web.xml

```
<!-- In web.xml -->
<resource-ref>
  <res-ref-name>jdbc/FODemoDS</res-ref-name>
  <res-type>javax.sql.DataSource</res-type>
  <res-auth>Container</res-auth>
</resource-ref>
<resource-ref>
  <res-ref-name>jdbc/FODemoCoreDS</res-ref-name>
  <res-type>javax.sql.DataSource</res-type>
  <res-auth>Container</res-auth>
</resource-ref>
```

You can directly edit the **Datasource Name** field when you want to specify a connection name for a global data source that is required to run the application on a target standalone application server. When you deploy to Oracle WebLogic Server, by default, the application-specific data source is not packaged with the application and Oracle WebLogic Server is configured to find a global data source named `jdbc/applicationConnectNameDS` using the look up `java:comp/env/jdbc/applicationConnectNameDS`. Therefore, by following this naming convention, you enable a single data source connection name to work correctly when running the application in JDeveloper using an application-specific

data source or when running on the deployed standalone server using a global data source.

Note: When configuring the ADF application module to access a highly available database system, such as redundant databases or Oracle Real Application Clusters (Oracle RAC) as the backend, the data source must be container-defined. In this scenario, the application module will use a multi data source; however, from the standpoint of the application module configuration, the naming convention for the multi data source is the same as it is for a non-multi data source. This ensures that the correct data source will be used at runtime. For details about configuring multi data sources for high availability applications, see the *Oracle Fusion Middleware High Availability Guide*.

9.3.2 How to Use a JDBC URL Connection Type

The other type of connection type you can use for an application module configuration is a JDBC URL connection. It is based on the named connection definition set on the Business Components page of the Project Properties dialog for the project containing your application module. [Figure 9–11](#) shows what this section would look like in a configuration using a JDBC URL connection.

Note: If you are using a non-Oracle JDBC driver, make sure that you set the appropriate properties for the driver on the **Properties** page of the Edit Business Components Configuration dialog to avoid runtime exceptions.

For example, if you are using a Sybase JDBC driver, you must set the `jbo.sql92.LockTrailer` property (which is set to `FOR UPDATE` by default) to a value appropriate for the Sybase database. Not setting this property would generate a `SySQLException` runtime exception.

Figure 9–11 JDBC URL Connection Type Setting in Edit Business Components Configuration Dialog

The screenshot shows a dialog box titled "Connection Type". It has a dropdown menu for "Connection Type" set to "JDBC URL". To its right is a "Connection Name:" label followed by a dropdown menu set to "FOD". Below these are two text input fields: "User Name:" with the value "fod" and "URL:" with the value "jdbc:oracle:thin:@localhost:1521:XE".

Note: See [Section 44.1.1.2, "Database Connection Pools,"](#) and [Section 44.2.9, "What You May Need to Know About Database Connection Pool Parameters"](#) for more information on how database connection pools are used and how you can tune them.

9.3.3 What Happens When You Create an Application Module Database Connection

When you select connection type in the Edit Business Components Configuration dialog, JDeveloper updates the application module configuration file, `bc4j.xcfg` in

the `./common` subdirectory relative to the application module's XML component definition. The file defines configurations for all of the application modules in a single Java package. For example, if you look at the `bc4j.xcfg` file in the `./classes/oracle/fodemo/storefront/store/service/common` directory of the Fusion Order Demo application's `StoreFront` project, you will see the three named configurations for its `StoreServiceAM` application module.

The configurations defined by the `bc4j.xcfg` file allow the Fusion web application to interact with specific, deployed application modules. In addition to the connection type for the application module, the `bc4j.xcfg` file contains metadata information about application module names and it contains the runtime parameters that are configured for the application module. The application resource database connection details for the named connection type are defined in the `Connections` folder of the Application Navigator and saved in the application's `connection.xml` file.

Example 9–3 displays a sample `bc4j.xcfg` file from the Fusion Order Demo application. The configurations `StoreServiceAMLocal` and `StoreServiceAMLocalWeb` both reference a data source (named `FODDS`) in the `JDBCDataSource` attribute. The configuration `StoreFrontService` references a data source that will eventually be defined on the target application server. The `JDBCDataSource` attribute in each configuration specifies the JNDI name for the application resources connection name in the form of `java:comp/env/jdbc/applicationConnectNameDS`, where `applicationConnectName` is the name of the application resources database connection defined in JDeveloper (in this case, `FOD`). This JNDI naming convention (with the application-specific name space `java:comp/env/jdbc/` and `DS` appended to the application resources database connection name) ensures that a deployed Fusion web application will run on Oracle WebLogic Server using the application's global data source and no changes will be required. The global data source is typically defined by the application server administrator using the Oracle WebLogic Server Administration Console.

Example 9–3 Application Module Database Configurations in the `bc4j.xcfg` File

```
<BC4JConfig version="11.1" xmlns="http://xmlns.oracle.com/bc4j/configuration">
  <AppModuleConfigBag ApplicationName="oracle.fodemo.storefront.store.service.StoreServiceAM">
    <AppModuleConfig
      DeployPlatform="LOCAL"
      jbo.project="StoreFrontService"
      name="StoreServiceAMLocal"
      ApplicationName="oracle.fodemo.storefront.store.service.StoreServiceAM">
      <Database jbo.locking.mode="optimistic"/>
      <Security AppModuleJndiName="oracle.fodemo.storefront.store.service.StoreServiceAM"/>
      <Custom JDBCDataSource="java:comp/env/jdbc/FODDS"/>
    </AppModuleConfig>
    <AppModuleConfig
      DeployPlatform="LOCAL"
      jbo.project="StoreFrontService"
      name="StoreServiceAMLocalWeb"
      ApplicationName="oracle.fodemo.storefront.store.service.StoreServiceAM">
      <AM-Pooling jbo.ampool.initpoolsize="1"/>
      <Database jbo.locking.mode="optimistic"/>
      <Security AppModuleJndiName="oracle.fodemo.storefront.store.service.StoreServiceAM"/>
      <Custom JDBCDataSource="java:comp/env/jdbc/FODDS" fod.application.isssoenabled="false"/>
    </AppModuleConfig>
    <AppModuleConfig
      DeployPlatform="SI"
      jbo.project="StoreFrontService"
      name="StoreFrontService"
    </AppModuleConfig>
  </AppModuleConfigBag>
</BC4JConfig>
```

```

    ApplicationName="oracle.fodemo.storefront.store.service.StoreServiceAM">
  <Database jbo.TypeMapEntries="Java" jbo.locking.mode="optimistic"/>
  <Security AppModuleJndiName="oracle.fodemo.storefront.store.service.StoreServiceAM"/>
  <Custom JDBCDataSource="java:comp/env/jdbc/FODDS"/>
</AppModuleConfig>
</AppModuleConfigBag>
</BC4JConfig>

```

9.3.4 How to Change Your Application Module's Runtime Configuration

In addition to creating the application module XML component definition, JDeveloper also adds a default configuration named `appModuleNameLocal` to the `bc4j.xcfg` file in the subdirectory named `common`, relative to the directory containing the application module XML component definition file. The `bc4j.xcfg` file does not appear in the Application Navigator. To view the default settings or to change the application module's runtime configuration settings, you can use the Edit Business Components Configuration dialog shown in [Figure 9–12](#).

Figure 9–12 *bc4j.xcfg File Configurations Displayed by Edit Business Components Configuration Dialog*

Before you begin:

It may be helpful to have an understanding of application module database connections. For more information, see [Section 9.3, "Configuring Your Application Module Database Connection."](#)

To manage your application module's configuration:

1. In the Application Navigator, double-click the application module.
2. In the overview editor, click the **Configurations** navigation tab.
3. In the Configurations page, double-click the configuration you want to edit. JDeveloper may display these three default configurations:

- *appModuleNameLocal*: One local configuration is automatically defined when you create the application module. Create a new local configuration, for example, when you want to change the runtime properties for the application module for testing purposes.
 - *appModuleNameShared*: The shared application module configuration is present only when a named instance of a shared application module has been defined in the Project Properties dialog for the data model project. A shared application module is one that groups view instances when you want to reuse lists of static data across the application. For example, you can define a shared application module to group view instances that access lookup data, such as a list of countries.
 - *appModuleNameService* (type SI for service interface): The service interface configuration is present only when the service interface (web service implementation wrapper) has been defined in the Service Interface page of the overview editor for the application module. An application module exposed as a web service allows your application module to participate in a composite application to provide data access and method calls to web service clients. The same application module can support interactive web user interfaces using ADF data controls and web service clients.
4. In the Edit Business Components Configuration dialog, edit the desired runtime properties and click **OK** to save the changes for your configuration.

9.3.5 How to Change the Database Connection for Your Project

When you are developing applications, you may have a number of different users or schemas that you want to switch between. You can do this by changing the database connection properties of the project that contains the business components. The selection you make will automatically update the connection string for each configuration in your project's `bc4j.xcfg` file that specifies a JDBC URL type connection.

Before you begin:

It may be helpful to have an understanding of application module database connections. For more information, see [Section 9.3, "Configuring Your Application Module Database Connection."](#)

To change the connection used by your application module's configuration:

1. In the Application Navigator, right-click the project that contains the application module and choose **Project Properties**.
2. In the Project Properties dialog, select **Business Components** to display the Business Components page, which shows details of the current database connection.
3. Click **Edit**, and in the Edit Database Connection dialog, make the appropriate changes.
4. Click **OK**.

9.4 Defining Nested Application Modules

Application modules support the ability to create software components that mimic the modularity of your use cases, for which your higher-level functions might reuse a "subfunction" that is common to several business work flows. You can implement this

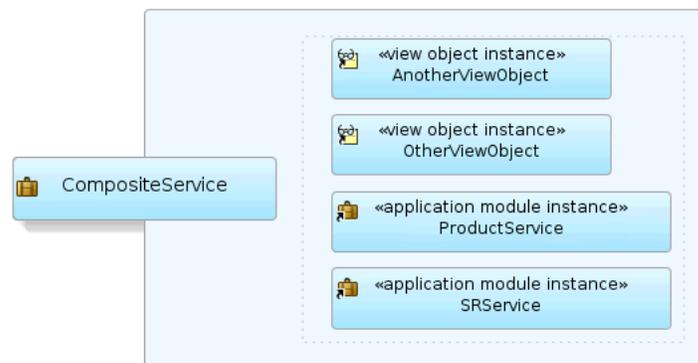

modularity by defining composite application modules that you assemble using instances of other application modules. This task is referred to as *application module nesting*. That is, an application module can contain (logically) one or more other application modules, as well as view objects. The outermost containing application module is referred to as the *root application module*.

Declarative support for defining nested application modules is available through the overview editor for the application module, as shown in [Figure 9–14](#). The API for application modules also supports nesting of application modules at runtime.

When you nest an instance of one application module inside another, you aggregate not only the view objects in its data model, but also any custom service methods it defines. This feature of "nesting," or reusing, an instance of one application module inside of another is one of the most powerful design aspects of ADF Business Components for implementing larger-scale, real-world application systems.

Using the basic logic that an application module represents an end-user use case or work flow, you can build application modules that cater to the data required by some shared, modular use case, and then reuse those application modules inside of other more complicated application modules that are designed to support a more complex use case. For example, imagine that after creating the application modules `StoreServiceAM` and `ProductService`, you later need to build an application that uses both of these services as an integral part of a new `CompositeService` application module. [Figure 9–13](#) illustrates what this `CompositeService` would look like in a JDeveloper business components diagram. Notice that an application module like `CompositeService` can contain a combination of view object instances and application module instances.

Figure 9–13 *Application Module Instances Can Be Reused to Assemble Composite Services*

9.4.1 How to Define a Nested Application Module

To specify a composite root application module that nests an instance of an existing application module, use the overview editor for the application module. All of the nested component instances (contained by the application module instance) share the same transaction and entity object caches as the root application module that reuses an instance of them.

Tip: If you leverage nested application modules in your application, be sure to read [Section 13.3.1.4, "How Nested Application Modules Appear in the Data Controls Panel"](#) to avoid common pitfalls when performing data binding involving them.

Before you begin:

It may be helpful to have an understanding of nested application modules. For more information, see [Section 9.4, "Defining Nested Application Modules."](#)

Complete this task:

Create the desired application modules as described in [Section 9.2.1, "How to Create an Application Module."](#)

To define a nested application module:

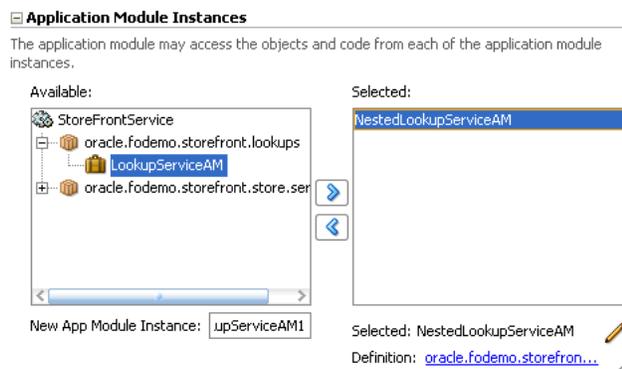

1. In the Application Navigator, double-click the root application module.
2. In overview editor, click the **Data Model** navigation tab.
3. In the Data Model Components page, expand the **Application Module Instances** section and, in the **Available** list, select the application module that you want to add to the data model.

The **New App Module Instance** field below the list shows the name that will be used to identify the nested application module that you add to the data model.

4. To change the name before adding it, type a different name in the **New App Module Instance** field.
5. With the desired application module selected, shuttle the application module to the **Selected** list.

[Figure 9–14](#) shows the application module `LookupServiceAM` has been renamed to `NestedLookupServiceAM` before it was shuttled to the **Selected** list.

Figure 9–14 Data Model Displays Added Application Module Instances

9.4.2 What You May Need to Know About Root Application Modules Versus Nested Application Module Usages

At runtime, your application works with a *main* — or what's known as a *root* — application module. Any application module can be used as a root application module; however, in practice the application modules that are used as root application modules are the ones that map to more complex end-user use cases, assuming you're not just building a straightforward CRUD application. When a root application module contains other nested application modules, they all participate in the root application module's transaction and share the same database connection and a single set of entity caches. This sharing is handled for you automatically by the root application module and its `Transaction` object.

Additionally, when you construct an application using an ADF bounded task flow, to declaratively manage the transactional boundaries, Oracle ADF will automatically nest application modules used by the task flow at runtime. For details about bounded task flows and transactions, see [Section 22.2, "Managing Transactions in Task Flows."](#)

9.5 Creating an Application Module Diagram for Your Business Service

As you develop the business service's data model, it is often convenient to be able to visualize it using a UML model. JDeveloper supports easily creating a diagram for your application module that other developers can use for reference.

You can perform a number of tasks directly on the diagram, such as editing the application module, controlling display options, filtering methods names, showing related objects and files, publishing the application, and launching the Oracle ADF Model Tester.

9.5.1 How to Create an Application Module Diagram

To create an application module diagram, use the Create Business Components Diagram dialog, which is available in the New Gallery.

To create a diagram of your application module:

1. In the Application Navigator, right-click the project in which you want to create the diagram and choose **New**.
2. In the New Gallery, expand **Business Tier**, select **ADF Business Components** and then **Business Components Diagram**, and click **OK**.
3. In the Create Business Components dialog, enter a diagram name and a package name in which the diagram will be created.
4. Click **OK** to create the empty diagram and open the diagrammer.
5. To add your existing application module to the open diagram, select the desired application module in the Application Navigator and drop it onto the diagram surface.
6. Use the Property Inspector to:
 - Hide the package name
 - Change the font
 - Turn off the grid and page breaks
 - Turn off the display of the end names on the view link connectors ("Master"/"Detail")

After completing these steps, the diagram looks similar to the diagram shown in [Figure 9–15](#).

Figure 9–15 Partial UML Diagram of Application Module

9.5.2 What Happens When You Create an Application Module Diagram

When you create a business components diagram, JDeveloper creates a `.adfbcdiagram` file to represent the diagram in a subdirectory of the project's model path that matches the package name in which the diagram resides.

By default, the Application Navigator unifies the display of the project content's paths so that ADF components and Java files in the source path appear in the same package tree as the UML model artifacts in the project model path. You can use the **Navigator Display Options > Show Directories** toolbar option in the Application Navigator to switch between the unified directory view and a more distinct directory path view of the project content.

9.5.3 How to Use the Diagram to Edit the Application Module

The UML diagram of business components is not just a static picture that reflects the point in time when you dropped the application module onto the diagram. Rather, it is a UML-based rendering of the current component definitions, so it will always reflect the current state of affairs. The UML diagram is both a visualization aid and a visual navigation and editing tool.

You can bring up the overview editor for any application module in a diagram by choosing **Properties** from the context menu (or by double-clicking the application module).

You can also perform some application module editing tasks directly on the diagram, tasks such as renaming view object instances, dropping view object definitions from the Application Navigator onto the data model to create a new view object instance, and removing view object instances by pressing the Delete key.

Note: Deleting components from the diagram only removes their visual representation on the diagram surface. The components and classes remain on the file system and in the Application Navigator.

9.5.4 How to Control Diagram Display Options

After you display the application module in the diagram, you can use the Property Inspector to control its display options.

In the **Display Options** category, toggle properties like the following:

- **Show Methods** — to display service methods
- **Show Package** — to display the package name
- **Show Stereotype** — to display the type of object (for example "`<<application module>>`")
- **Show Usages** — to display all usages by other application modules in the current project

Note: The term *operation* is a more generic, UML name for methods.

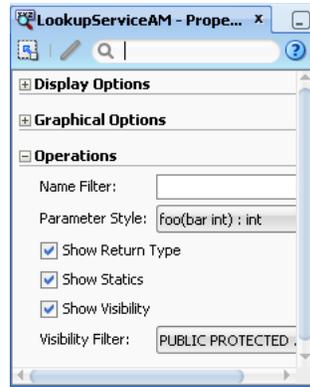

In the **Operations** category, consider changing the following properties depending on the amount of detail you want to provide in the diagram:

- **Parameter Style**
- **Show Return Type**

- **Show Visibility** (public, private, etc.)

By default, all operations of the application module are fully displayed, as shown by the Property Inspector settings in [Figure 9–16](#).

Figure 9–16 *Property Inspector with Default Diagrammer Options*

On the context menu of the diagram, you can also select to **View As**:

- **Compact** — to show only the icon and the name
- **Symbolic** — to show service operations
- **Expanded** — to show operations and data model (*default*)

9.5.5 How to Filtering Method Names Displayed in the Diagram

Initially, if you show the operations for the application module, the diagram displays all the methods. Any method it recognizes as an overridden framework method displays in the `<<Framework>>` operations category. The rest display in the `<<Business>>` methods category.

The **Name Filter** property in the **Operations** category of the Property Inspector is a regular expression that you can use to filter out methods you don't want to display on the diagram. For example, by setting the **Name Filter** property to:

```
findLoggedInUser.*|retrieveOrder.*|get.*
```

you can filter out all of the following application module methods:

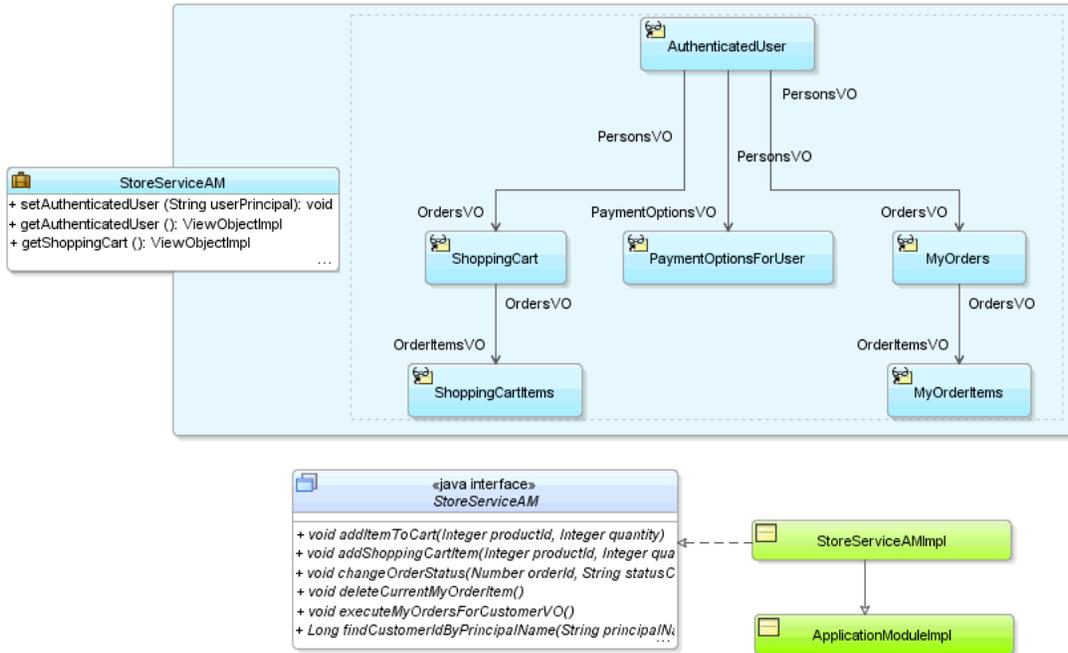

- `findLoggedInUserByEmail`
- `retrieveOrderById`
- All the generated view object getter methods

9.5.6 How to Show Related Objects and Implementation Files in the Diagram

After selecting the application module on the diagram — or any set of individual view object instances in its data model — you can choose **Show > Related Elements** from the context menu to display related component definitions on the diagram. In a similar fashion, choosing **Show > Implementation Files** will include the files that implement the application module on the diagram. You can repeat these options on the additional diagram elements that appear until the diagram includes the level of detail you want to convey.

Figure 9–17 illustrates how the diagram displays the implementation files for an application module. You will see the related elements for the application module's implementation class (`StoreServiceAMImpl`). The diagram also draws an additional dependency line between the application module and the implementation class. If you have cast the application module instance to a specific custom interface, the diagram will also show that.

Figure 9–17 Adding Detail to a Diagram Using Show Related Elements and Show Implementation Files

9.5.7 How to Publish the Application Module Diagram

To publish the diagram to PNG, JPG, SVG, or compressed SVG format, choose **Publish Diagram** from the context menu on the diagram surface.

9.5.8 How to Test the Application Module from the Diagram

To launch the Oracle ADF Model Tester for an application module in the diagram, choose **Run** from the context menu.

9.6 Supporting Multipage Units of Work

While interacting with your Fusion web application, end users might:

- Visit the same pages multiple times, expecting fast response times
- Perform a logical unit of work that requires visiting many different pages to complete
- Need to perform a partial "rollback" of a pending set of changes they've made but haven't saved yet.
- Unwittingly be the victim of an application server failure in a server farm before saving pending changes

The application module pooling and state management features simplify implementing scalable, well-performing applications to address these requirements.

Note: ADF bounded task flows can represent a transactional unit of work. You can specify options on the task flow to determine how to handle the transaction. For details about the declarative capabilities of ADF bounded task flows, see [Section 22.2, "Managing Transactions in Task Flows."](#)

9.6.1 How to Simulate State Management in the Oracle ADF Model Tester

To simulate what the state management functionality does, you can launch two instances of Oracle ADF Model Tester on an application module in the Application Navigator.

Before you begin:

It may be helpful to have an understanding of state management. For more information, see [Section 9.6, "Supporting Multipage Units of Work."](#)

To simulate transaction state passivation using the Oracle ADF Model Tester:

1. Run the Oracle ADF Model Tester and double-click a view object instance to query its data.
2. Make a note of the current values of a several attributes for a few rows.
3. Update those rows to have a different value those attributes, but do not commit the changes.
4. Choose **File > Save Transaction State** from the Oracle ADF Model Tester main menu.

A Passivated Transaction State dialog appears, indicating a numerical transaction ID number. Make a note of this number.

5. Exit out of the Oracle ADF Model Tester completely.
6. Restart the Oracle ADF Model Tester and double-click the same view object instance to query its data.
7. Notice that the data is *not* changed. The queried data from the data reflects the current state of the database without your changes.
8. Choose **File > Restore Transaction State** from the Oracle ADF Model Tester main menu, and enter the transaction ID you noted in Step 4.

At this point, you'll see that your pending changes are reflected again in the rows you modified. If you commit the transaction now, your changes are permanently saved to the database.

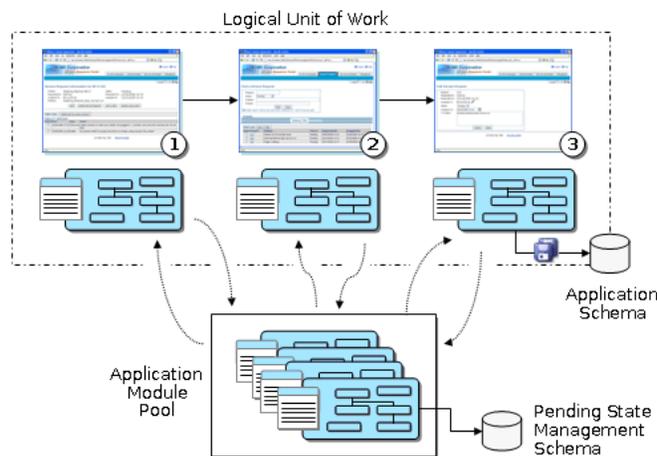

9.6.2 What Happens at Runtime: How the Application Uses Application Module Pooling and State Management

Applications you build that leverage an application module as their business service take advantage of an automatic application module pooling feature. This facility manages a configurable set of application module instances that grows and shrinks as the end-user load on your application changes during the day. Due to the natural "think time" inherent in the end user's interaction with your application user interface,

the number of application module instances in the pool can be smaller than the overall number of active users using the system.

As shown in [Figure 9–18](#), as a given end user visits multiple pages in your application to accomplish a logical task, with each page request an application module instance in the pool is acquired automatically from the pool for the lifetime of that one request. At the end of the request, the instance is automatically returned to the pool for use by another user session. In order to protect the end user's work against application server failure, the application module supports the ability to freeze the set of pending changes in its entity caches to a persistent store by saving an XML snapshot describing the change set. For scalability reasons, this state snapshot is typically saved in a state management schema that is a different database schema than the one containing the application data.

Figure 9–18 Using Pooled Application Modules Throughout a Multipage, Logical Unit of Work

The pooling algorithm affords a tunable optimization whereby a certain number of application module instances will attempt to stay "sticky" to the last user session that returned them to the pool. The optimization is not a guarantee, but when a user can benefit from the optimization, they continue to work with the same application module instance from the pool as long as system load allows. When load is too high, the pooling algorithm uses any available instance in the pool to service the user's request and the frozen snapshot of their logical unit of work is reconstituted from the persistent store to allow the new instance of the application module to continue where the last one left off. The end user continues to work in this way until they commit or roll back their changes.

Using these facilities, the application module delivers the productivity of a stateful development paradigm that can easily handle multipage work flows, in an architecture that delivers the runtime performance near that of a completely stateless application. You will learn more about these application module features in [Chapter 43, "Application State Management"](#) and about how to tune them in [Chapter 44, "Tuning Application Module Pools and Connection Pools."](#)

Note: This application module pooling and state management is also available for thin-client, desktop-fidelity Swing applications and web-style user interfaces.

9.7 Customizing an Application Module with Service Methods

An application module can expose its data model of view objects to clients without requiring any custom Java code. This allows client code to use the `ApplicationModule`, `ViewObject`, `RowSet`, and `Row` interfaces in the `oracle.jbo` package to work directly with any view object in the data model. However, just because you *can* programmatically manipulate view objects any way you want to in client code doesn't mean that doing so is always a best practice.

Whenever the programmatic code that manipulates view objects is a logical aspect of implementing your complete business service functionality, you should encapsulate the details by writing a custom method in your application module's Java class. This includes code that:

- Configures view object properties to query the correct data to display
- Iterates over view object rows to return an aggregate calculation
- Performs any kind of multistep procedural logic with one or more view objects

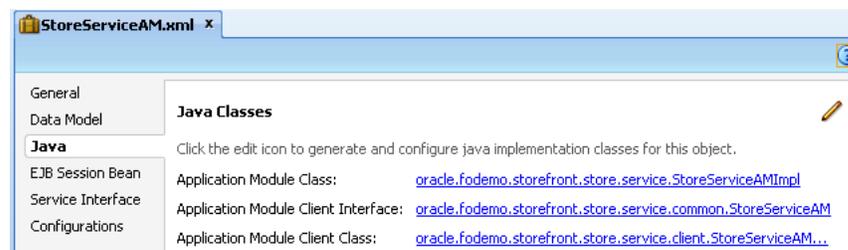

By centralizing these implementation details in your application module, you gain the following benefits:

- You make the intent of your code more clear to clients.
- You allow multiple client pages to easily call the same code if needed.
- You simplify regression-testing of your complete business service functionality.
- You keep the option open to improve your implementation without affecting clients.
- You enable *declarative* invocation of logical business functionality in your pages.

9.7.1 How to Generate a Custom Class for an Application Module

To add a custom service method to your application module, you must first enable a custom Java class for it. If you have configured your IDE-level Business Components Java generation preferences to automatically generate an application module class, a custom class will be present. As [Figure 9–19](#) shows, if you're not sure whether your application module has a custom Java class, open the overview editor for the application module node in the Application Navigator. The Java Classes page of the editor displays the complete list of classes generated for the application module in the project. If the file exists because someone created it already, then the Java Classes page will display a linked file name identified as the **Application Module Class**. To open an existing file in the source editor, click the corresponding file name link.

Figure 9–19 Application Module's Custom Java Class in Overview Editor

If no Java class exists in your project, you can generate one using the Java Classes page of the overview editor for the application module.

Before you begin:

It may be helpful to have an understanding of application module service methods. For more information, see [Section 9.7, "Customizing an Application Module with Service Methods."](#)

Complete this task:

Create the desired application modules as described in [Section 9.2.1, "How to Create an Application Module."](#)

To generate a Java file for your application module class:

1. In the Application Navigator, double-click the application module.
2. In the overview editor, click the **Java** navigation tab and click the **Edit java options** button.
3. In the Select Java Options dialog, select **Generate Application Module Class**.
4. Click **OK**.

The new .java file will appear in the Java Classes page.

9.7.2 What Happens When You Generate a Custom Class for an Application Module

When you generate a custom class for an application module, JDeveloper creates the file in the same directory as the component's XML component definition file. The default name for its custom Java file will be `AppModuleNameImpl.java`.

The Java generation option choices you made for the application module persist on the Java Classes page on subsequent visits to the overview editor for the application module. Just as with the XML definition file, JDeveloper keeps the generated code in your custom Java classes up to date with any changes you make in the editor. If later you decide you do not require a custom Java file, from the Java Classes page open the Select Java Options dialog and deselect **Generate Application Module Class** to remove the custom Java file from the project.

9.7.3 What You May Need to Know About Default Code Generation

By default, the application module Java class will look similar to what you see in [Example 9-4](#) when you've first enabled it. Of interest, it contains:

- Getter methods for each view object instance in the data model
- A `main()` method allowing you to debug the application module using the Oracle ADF Model Tester

Example 9-4 Default Application Module Generated Code

```
package devguide.model;
import devguide.model.common.StoreServiceAM;
import oracle.jbo.server.ApplicationModuleImpl;
import oracle.jbo.server.ViewLinkImpl;
import oracle.jbo.server.ViewObjectImpl;
// -----
// ---   File generated by Oracle ADF Business Components Design Time.
// ---   Custom code may be added to this class.
// ---   Warning: Do not modify method signatures of generated methods.
// -----
public class StoreServiceAMImpl extends ApplicationModuleImpl {
    /** This is the default constructor (do not remove) */
    public StoreServiceImpl() { }
```

```

/** Container's getter for YourViewObjectInstance1 */
public ViewObjectImpl getYourViewObjectInstance1() {
    return (ViewObjectImpl)findViewObject("YourViewObjectInstance1");
}

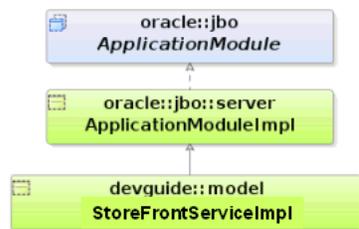

// ... Additional ViewObjectImpl getters for each view object instance

// ... ViewLink getters for view link instances here
}

```

As shown in [Figure 9–20](#), your application module class extends the base ADF `ApplicationModuleImpl` class to inherit all the default behavior before adding your custom code.

Figure 9–20 Your Custom Application Module Class Extends `ApplicationModuleImpl`

9.7.4 How to Add a Custom Service Method to an Application Module

To add a custom service method to an application module, simply navigate to the application module's custom class and enter the Java code for a new method into the application module's Java implementation class. Use the following guidelines to decide on the appropriate visibility for the method:

- If you will use the method only inside this component's implementation as a helper method, make the method `private`.
- If you want to allow eventual subclasses of your application module to be able to invoke or override the method, make it `protected`.
- If you need clients to be able to invoke it, it must be `public`.

Note: The `StoreServiceAM` application module examples in this chapter use the strongly typed, custom entity object classes that you saw illustrated in the `StoreServiceAMImpl2.java` example at the end of [Chapter 4, "Creating a Business Domain Layer Using Entity Objects."](#)

[Example 9–5](#) shows a private `retrieveOrderByid()` helper method in the `StoreServiceAMImpl.java` class for the `StoreServiceAM` application module. It uses the static `getDefinition()` method of the `OrderseOImpl` entity object class to access its related entity definition, it uses the `createPrimaryKey()` method on the entity object class to create an appropriate `Key` object to look up the order, and then it uses the `findByPrimaryKey()` method on the entity definition to find the entity row in the entity cache. It returns an instance of the strongly typed `OrderseOImpl` class, the custom Java class for the `OrderEO` entity object.

Example 9–5 Private Helper Method in Custom Application Module Class

```
// In devguide.model.StoreServiceAMImpl class
/*
 * Helper method to return a Order by Id
 */
private OrdersEOImpl retrieveOrderById(long orderId) {
    EntityDefImpl orderDef = OrdersEOImpl.getDefinitionObject();
    Key orderKey =
        OrdersEOImpl.createPrimaryKey(new DBSequence(orderId));
    return (OrdersEOImpl)orderDef.findByPrimaryKey(getDBTransaction(),
                                                orderKey);
}
```

[Example 9–6](#) shows a public `createProduct()` method that allows the caller to pass in a name and description of a product to be created. It uses the `getDefinition()` method of the `ProductImpl` entity object class to access its related entity definition, and it uses the `createInstance2()` method to create a new `ProductImpl` entity row, whose `Name` and `Description` attributes it populates with the parameter values passed in before committing the transaction.

Example 9–6 Public Method in Custom Application Module Class

```
/*
 * Create a new Product and Return its new id
 */
public long createProduct(String name, String description) {
    EntityDefImpl productDef = ProductImpl.getDefinitionObject();
    ProductImpl newProduct =
        (ProductImpl)productDef.createInstance2(getDBTransaction(), null);
    newProduct.setName(name);
    newProduct.setDescription(description);
    try {
        getDBTransaction().commit();
    }
    catch (JboException ex) {
        getDBTransaction().rollback();
        throw ex;
    }
    DBSequence newIdAssigned = newProduct.getProdId();
    return newIdAssigned.getSequenceNumber().longValue();
}
```

9.7.5 How to Test the Custom Application Module Using a Static Main Method

When you are ready to test the methods of your custom application module, you can use JDeveloper to generate JUnit test cases. With JUnit, you can use any of the programmatic APIs available in the `oracle.jbo` package to work with the application module and invoke the custom methods. For details about using JUnit with ADF Business Components, see [Section 36.11, "Regression Testing with JUnit."](#)

As an alternative to JUnit test cases, a common technique to test your custom application module methods is to write a simple test case. For example, you could build the testing code into an object and include that code in the `static main()` method. [Example 9–7](#) shows a sample `main()` method you could add to your custom application module class to test the sample methods you will write. You'll make use of a Configuration object (see [Section 6.4.2, "How to Create a Command-Line Java Test Client"](#)) to instantiate and work with the application module for testing.

Note: The fact that this `Configuration` object resides in the `oracle.jbo.client` package suggests that it is used for accessing an application module as an application *client*. Because a `main()` method is a kind of programmatic, command-line client, so this is an acceptable practice. Furthermore, even though you typically would not cast the return value of `createRootApplicationModule()` directly to an application module's implementation class, it is legal to do so in this one situation since despite being a client to the application module, the `main()` method's code resides right inside the application module implementation class itself.

A glance through the code in [Example 9-7](#) shows that it exercises the four methods created in the previous examples to:

1. Retrieve the total for order 1011.
2. Retrieve the name of the customer for order 1011.
3. Set the status of order 1011 to the value "CANCEL".
4. Create a new product supplying a null product name.
5. Create a new product with a product name and display its newly assigned product ID.

Example 9-7 Sample Main Method to Test a Custom Application Module from the Inside

```
// Main method in StoreServiceAMImpl.java
public static void main(String[] args) {
    String      amDef = "devguide.model.StoreFrontService";
    String      config = "StoreServiceLocal";
    /*
     * This is the correct way to use application custom methods
     * from the client, by using the application module's automatically-
     * maintained custom service interface.
     */
    // 1. Acquire instance of application module, cast to client interface
    ApplicationModule am =
        Configuration.createRootApplicationModule(amDef,config);
    /*
     * NOTE: This cast to use the StoreFrontServiceImpl class is OK since this
     * code is inside a business tier *Impl.java file and not in a
     * client class that is accessing the business tier from "outside".
     */
    StoreFrontServiceImpl service = (StoreFrontServiceImpl)am;
    String total = service.findOrderTotal(1011);
    System.out.println("Total for Order # 1011 = " + total);
    String customerName = service.findOrderCustomer(1011);
    System.out.println("Customer for Order # 1011 = " + customerName);
    try {
        service.updateOrderStatus(1011,"CANCEL");
    }
    catch (JboException ex) {
        System.out.println("ERROR: "+ex.getMessage());
    }
    long id = 0;
    try {
        id = service.createProduct(null, "NEW", "CLASS1");
    }
}
```

```

catch (JboException ex) {
    System.out.println("ERROR: "+ex.getMessage());
}
id = service.createProduct("Canon PowerShot G9", "NEW", "CLASS1");
System.out.println("New product created successfully with id = "+id);
Configuration.releaseRootApplicationModule(am,true);
}

```

Running the custom application module class calls the `main()` method in [Example 9-7](#), and shows the following output:

```

Total for Order # 1011 = 99.99
Customer for Order # 1011 = John Chen
ERROR: JBO-27014: Attribute ProductName in ProductsBaseEO is required.
New product created successfully with id = 133

```

Notice that the first attempt to call `createProduct()` with a null for the product name raises an exception due to the built-in mandatory validation on the Name attribute of the `Product` entity object.

Note: For an explanation of how you can use the client application to invoke the custom service methods that you create in your custom application module, see [Section 9.9, "Publishing Custom Service Methods to UI Clients."](#)

9.7.6 What You May Need to Know About Programmatic Row Set Iteration

Any time your application logic accesses a row set to perform programmatic iteration, you should use a secondary row set iterator when working with view object instances in an application module's data model, or view link accessor row sets of these view object instances, since they may be bound to user interface components. To create a secondary iterator, use the `createRowSetIterator()` method on the row set you are working with. When you are done using it, call the `closeRowSetIterator()` method on the row set to remove the secondary iterator from memory. [Example 9-8](#) shows a typical application module custom method that correctly uses a secondary row set iterator for programmatic iteration, because the `EmpView1` view object instance in its data model may be bound to a user interface (either now or at a later time).

Example 9-8 Using a Secondary Row Set Iterator in an Application Module Custom Method

```

// Custom method in an application module implementation class
public void doSomeCustomProcessing() {
    ViewObject vo = getEmpView1();
    // create secondary row set iterator with system-assigned name
    RowSetIterator iter = vo.createRowSetIterator(null);
    while (iter.hasNext()) {
        Row r = iter.next();
        // Do something with the current row.
    }
    // close secondary row set iterator
    iter.closeRowSetIterator();
}

```

Note: The same recommendation holds for custom code in a view object's implementation class that iterates its own default row set using that row set's default row set iterator.

There are two important reasons to follow this recommendation. Failing to do so can lead to confusion for the end user when the current row unexpectedly changes or it can introduce subtle business logic errors because the first or last row, or both rows get skipped.

- Confusing the end user by changing the current row unexpectedly

The iterator bindings determine what row the end-user sees as the current row in the row set. If your own programmatic logic iterates through the row set using the same default row set iterator that the iterator binding uses, you may inadvertently change the current row the user has selected, leaving the user confused.

- Introducing subtle business logic errors by inadvertently skipping the first or last row

Iterator bindings force their row set iterator to be on a valid row to guarantee that UI components display data when the row set is not empty. This has the side-effect of preventing your custom logic from navigating to the slot either before the first row or to the slot after the last row (when it is using the same row set iterator as an iterator binding). In concrete terms, this means that a typical `while (rowset.hasNext())` iteration loop will either be skipped or start by processing the second row instead of the first as shown in [Example 9-9](#).

Example 9-9 Consequences of Using the Default Row Set Iterator

```
// Reset the default row set iterator to the slot before the first row
rowset.reset();
// If an iterator binding is bound to the same default row set iterator,
// then it has already forced it to navigate to the first row here instead
// of being on the slot before the first row.
//
// If the row set has only one row, the following will then return false
while (rowset.hasNext()) {
    // If the row set has more than one row, the first time through the loop
    // this call to next() will return the second row rather than the first
    // row as expected.
    Row curRow = rowset.next();
    // Do something with current row
}
```

9.8 Customizing Application Module Message Strings

The ADF application module does not have a resource bundle of its own and there is no design time in JDeveloper to associate one with the application module. However, if you do want to register a `.properties` file that contains your custom message strings, you can set a resource bundle definition in the definition class file that you generate for the application module.

9.8.1 How to Add a Resource Bundle to an Application Module

To generate the custom definition class file for the application module, use the Select Java Options dialog, which you open for the application module on the Java Classes

page of the application module overview editor. You can use this file to override the built-in framework method `finishedLoading()`.

Before you begin:

1. Create the desired application module, as described in [Section 9.2.1, "How to Create an Application Module."](#)
2. Create the `.properties` file and add the message key and message, as described in [Section 4.7, "Working with Resource Bundles."](#)

The `.properties` file you create can reference attribute properties by their fully-qualified package name and custom method exception messages. For example, you might define message keys and strings as follows:

```
test.Order.Orderno_LABEL=Order Number
INVALID=You have called the method foo in an invalid way.
```

3. If your resource bundle defines a message for a method exception message, the custom method should appear in the application module client interface, as described in [Section 9.9.1, "How to Publish a Custom Method on the Application Module's Client Interface."](#)

For example, if you defined a message for the method `foo()` that to replace the exception message `INVALID`, your interface might define this method to invoke the message from the resource bundle as:

```
public void foo() {
    ResourceBundle r = getResourceBundleDef();
    throw new JboException(r, "INVALID", null);
}
```

To generate the definition class and override the finishedLoading method:

1. In the Application Navigator, double-click the application module.
2. In the overview editor, click the **Java** navigation tab.
3. On the Java Classes page, click the **Edit java options** button.
4. In the Select Java Options dialog, select **Generate Application Module Definition Class** and click **OK**.
5. In the overview editor, on the Java Classes page, click the linked file name of the application module definition class that you want to customize. JDeveloper opens the class file in the source editor.
6. From the main menu, choose **Source > Override Methods**.
If the Source menu is not displayed in the main menu, be sure the definition class file is open and the source editor is visible.
7. In the Override Methods dialog, scroll the list to locate the `finishedLoading()` methods, select it, and click **OK**.
8. In the source editor for the definition class file, add the code to invoke your message bundle `.properties` file.

For example, if your file is `MyAMBundLe` in the `test` package, your code would look like:

```
@Override
protected void finishedLoading() {
    super.finishedLoading();
    PropertiesBundleDef pbd = new PropertiesBundleDef(this);
```

```
        pbd.setPropertiesFile("test.MyAMBundle");
        setResourceBundleDef(pbd);
    }
```

In this example, the `finishedLoading()` method creates a message bundle definition and then sets the custom message bundle on the definition.

9. Save the file.

9.8.2 What Happens When You Add a Resource Bundle to an Application Module

When you generate a custom definition class for an application module, JDeveloper creates the file in the same directory as the component's XML component definition file. The default name for its custom Java file will be

AppModuleNameDefImpl.java.

Because you override the built-in `finishedLoading()` method in the definition class file, after the application is loaded at runtime, the framework will invoke the method and automatically load the named `.properties` file.

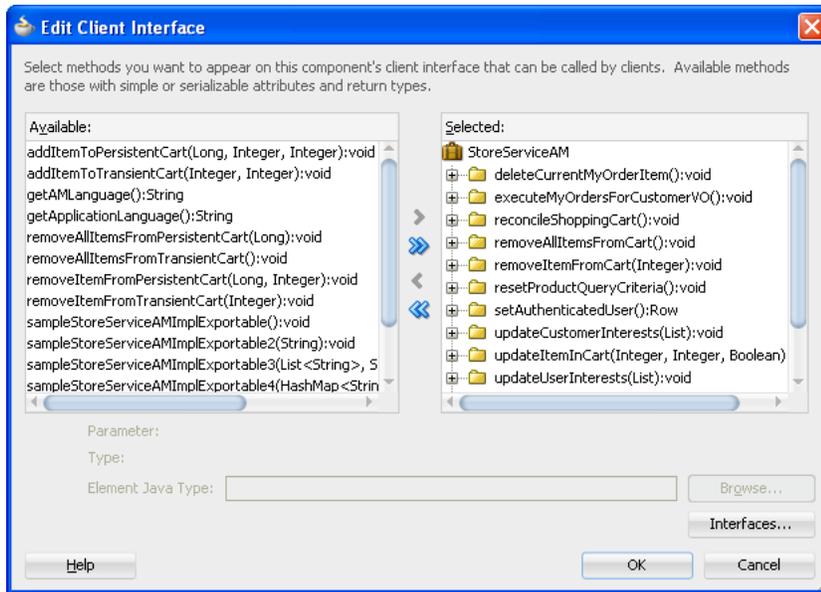

9.9 Publishing Custom Service Methods to UI Clients

When you add a `public` custom method to your application module class, if you want your application's UI to be able to invoke it, you need to include the method on the application module's UI client interface.

9.9.1 How to Publish a Custom Method on the Application Module's Client Interface

To include a public method from your application module's custom Java class on the client interface, use the Java Classes page of the overview editor for the application module, and then click the **Edit** icon in the **Client Interface** section of the page to display the Edit Client Interface dialog. Select one or more desired methods from the **Available** list and click the **Add** button to shuttle them into the **Selected** list. Then click **OK** to close the editor. [Figure 9-21](#) shows multiple public methods added to the client interface.

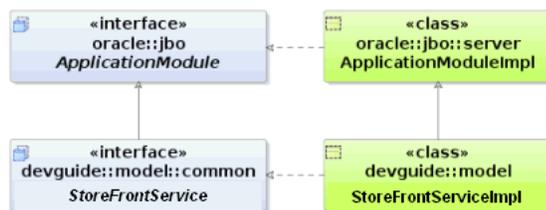

Figure 9–21 Public Methods Added to an Application Module's Client Interface

9.9.2 What Happens When You Publish Custom Service Methods

When you publish custom service methods on the client interface, as shown in [Figure 9–22](#), JDeveloper creates a Java interface with the same name as the application module in the common subpackage of the package in which your application module resides. For an application module named `StoreServiceAM` in the `fodemo.model` package, this interface will be named `StoreServiceAM` and reside in the `fodemo.model.common` package. The interface extends the base `ApplicationModule` interface in the `oracle.jbo` package, reflecting that a client can access all of the base functionality that your application module inherits from the `ApplicationModuleImpl` class.

Figure 9–22 Custom Client Interface Extends the Base ApplicationModule Interface

As shown in [Example 9–10](#), the `StoreServiceAM` interface includes the method signatures of all of the methods you've selected to be on the client interface of your application module.

Example 9–10 Custom Client Interface Based on Methods Selected in the Client Interface Panel

```
package fodemo.model.common;
import oracle.jbo.ApplicationModule;
// -----
// ---   File generated by Oracle ADF Business Components Design Time.
// -----
public interface StoreServiceAM extends ApplicationModule {
```

```

void deleteCurrentMyOrderItem();
void executeMyOrdersForCustomerVO();
void userRegistrationCreate(String userType);
void updateUserInterests(List pCategoryIds);
void userRegistrationCreateAddress();
}

```

Each time you add or remove methods in the **Client Interface** section, the corresponding client interface file is updated automatically. JDeveloper also generates a companion client proxy class that is used when you deploy your application module for access by a remote client. For the `StoreServiceAM` application module in this example, the client proxy file is called `StoreServiceAMClient` and it is created in the `devguide.model.client` subpackage.

Note: After adding new custom methods to the client interface, if your new custom methods do not appear to be available when you use JDeveloper's code insight context-sensitive statement completion, try recompiling the generated client interface. To do this, select the application module in the Application Navigator, select the source file for the interface of the same name in the Structure window, and choose **Rebuild** from the context menu. Consider this tip for new custom methods added to view objects and view rows as well.

9.9.3 How to Generate Client Interfaces for View Objects and View Rows

In addition to generating a client interface for your application module, it is also possible to generate strongly typed client interfaces for working with the other key client objects that you can customize. For example, you can open Java page in the overview editor for a view object, you can then expand the **Client Interface** section and the **Client Row Interface** section and add custom methods to the view object client interface and the view row client interface, respectively.

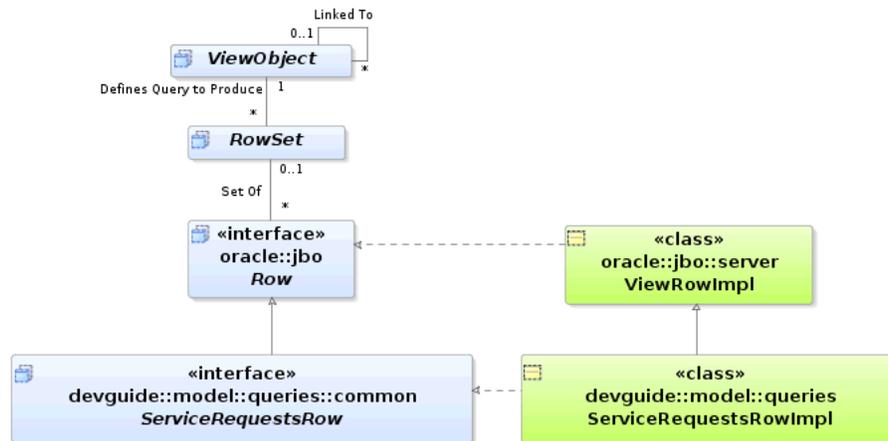

If for the `Products` view object in the `devguide.model.queries` package you were to enable the generation of a custom view object Java class and add one or more custom methods to the view object client interface, JDeveloper would generate the `ProductsImpl` class and `Products` interface, as shown in [Figure 9-23](#). As with the application module custom interface, notice that it gets generated in the `common` subpackage.

Figure 9-23 Custom View Object Interface Extends the Base ViewObject Interface

Likewise, if for the same view object you were to enable the generation of a custom view row Java class and add one or more custom methods to the view row client interface, JDeveloper would generate the `ProductsRowImpl` class and `ProductsRow` interface, as shown in [Figure 9-24](#).

Figure 9–24 Custom View Row Interface Extends the Base Row Interface

9.9.4 How to Test Custom Service Methods Using the Oracle ADF Model Tester

You can test the methods of your custom application module in the Oracle ADF Model Tester after you have published them on the client interface, as described in [Section 9.9, "Publishing Custom Service Methods to UI Clients."](#)

To test the service methods that you have published:

1. In the Application Navigator, expand the project containing the desired application module and view objects.
2. Right-click the application module and choose **Run**.

Alternatively, choose **Debug** when you want to run the application in the Oracle ADF Model Tester with debugging enabled. JDeveloper opens the debugger process panel in the Log window and the various debugger windows. When debugging using the Oracle ADF Model Tester, you can use these windows to view status message and exceptions, step in and out of source code, and manage breakpoints.

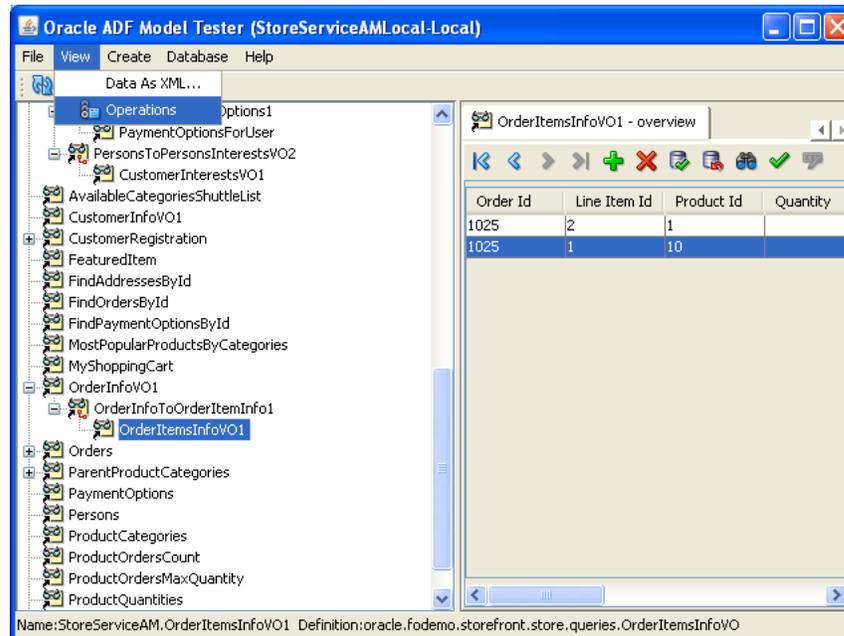

For information about receiving diagnostic messages specific to ADF Business Component debugging, see [Section 6.3.8, "How to Enable ADF Business Components Debug Diagnostics."](#)

3. To open the method testing panel for a method defined by a client interface, do one of the following:
 - In the data model tree, select the application module node and from the main menu choose **View - Operations** when you want to execute a method you published for the application module client interface. You can also double-click the application module node to display the method testing panel.
 - In the data model tree, select the desired view object node and from the main menu choose **View - Operations** when you want to execute a method you published on the client interface for a view object. You can also right-click the view object node and choose **Operations**.
4. To open the method testing panel for a method defined by a client row interface for a view object row, expand the data model tree, right-click the desired view object node and choose **Show Table**. Then in the overview panel for the view instance, select the desired row, and from the main menu, choose **View - Operations**.

Do not select a master view instance in the data model tree since view row operations are not permitted on master view objects. Always select a detail view instance or a view instance that is not specified in a master-detail hierarchy, as shown in [Figure 9–25](#).

Tip: In the case of a detail view instance, you can open the master view instance to navigate to the detail with the desired row. The Oracle ADF Model Tester automatically synchronizes the data displayed in the open overview panel with the master view instance that you navigate to.

Figure 9–25 Menu Selection for View Row Operations in the Oracle ADF Model Tester

5. In the method panel, select the desired service method from the dropdown list, enter values to pass as method parameters, and click **Execute**.

Notice that the method testing panel displays the parameter names to help you identify where to enter the values to pass. This is particularly useful when the method signature defines multiple parameters of the same data type.

You can view the return value (if any) and test result. The result displayed in the Oracle ADF Model Tester will indicate whether or not the method executed successfully.

9.9.5 What You May Need to Know About Method Signatures on the Client Interface

You can include any custom method in the client interface that obeys these implementation rules:

- If the method has a non-void return type, the type must be serializable.
- If the method accepts any parameters, all their types must be serializable.
- If the method signature includes a throws clause, the exception must be an instance of `JboException` in the `oracle.jbo` package.

In other words, all the types in its method signature must implement the `java.io.Serializable` interface, and any checked exceptions must be

`JboException` or its subclass. Your method can throw any unchecked exception — `java.lang.RuntimeException` or a subclass of it — without disqualifying the method from appearing on the application module's client interface.

Note that method signatures of type `java.util.List` are allowed as long as the implementing class for the interface is serializable. For example, `java.util.ArrayList` and `java.util.LinkedList` are both serializable implementing classes. The same requirement applies to element types within the collection. The ADF Business Components runtime will produce an error if you instantiate a class that implements the interface yet does not implement the `java.io.Serializable` interface.

Note: If the method you've added to the application module class doesn't appear in the **Available** list, first verify that it doesn't violate any of the method implementation rules. If it seems like it should be a legal method, try recompiling the application module class before visiting the overview editor for the application module again.

9.9.6 What You May Need to Know About Passing Information from the Data Model

The private implementation of an application module custom method can easily refer to any view object instance in the data model using the generated accessor methods. By calling the `getCurrentRow()` method on any view object, it can access the same current row for any view object that the client user interface sees as the current row. As a result, while writing application module business service methods, you may not need to pass in parameters from the client. This is true if you would be passing in values only from the current rows of other view object instances in the same application module's data model.

For example, the custom application module method in [Example 9–11](#) accepts no parameters. Internally, the `createOrderItem()` method calls `getGlobals().getCurrentRow()` to access the current row of the `Globals` view object instance. Then it uses the strongly typed accessor methods on the row to access the values of the `Description` and `LineItemId` attributes to set them as the values of corresponding attributes in a newly created `OrderItem` entity object row.

Example 9–11 Using View Object Accessor Methods to Access a Current Row

```
// In StoreServiceAMImpl.java, createOrderItem() method
GlobalsRowImpl globalsRow = (GlobalsRowImpl)getGlobals().getCurrentRow();
newReq.setDescription(globalsRow.getDescription());
newReq.setLineItemId(globalsRow.getLineItemId());
```

9.10 Working Programmatically with an Application Module's Client Interface

After publishing methods on your application module's client interface, you can invoke those methods from a client.

9.10.1 How to Work Programmatically with an Application Module's Client Interface

To work programmatically with an application module's client interface, do the following:

- Cast `ApplicationModule` to the more specific client interface.

- Call any method on the interface.

Note: For simplicity, this section focuses on working only with the custom application module interface; however, the same downcasting approach works on the client to use a `ViewObject` interface as a view object interface like `Orders` or a `Row` interface as a custom view row interface like `OrdersRow`.

[Example 9–12](#) illustrates a `TestClientCustomInterface` class that puts these two steps into practice. You could also use the `main()` method of this class to test application module methods, as described in [Section 9.7.5, "How to Test the Custom Application Module Using a Static Main Method."](#) Here you use it to call all of the same methods from the client using the `StoreFrontService` client interface.

Note: If you work with your application module using the default `ApplicationModule` interface in the `oracle.jbo` package, you won't have access to your custom methods. Make sure to cast the application module instance to your more specific custom interface like the `StoreFrontService` interface in this example.

The basic logic of [Example 9–12](#) follows these steps:

1. Retrieve the total for order 1011.
2. Retrieve the name of the customer for order 1011.
3. Set the status of order 1011 to the value "CANCEL".
4. Create a new product supplying a null product name.
5. Create a new product with a product name and display its newly assigned product ID.

Example 9–12 Using the Custom Interface of an Application Module from the Client

```
package devguide.examples.appmodules;

import devguide.examples.appmodules.common.StoreFrontService;
import devguide.examples.entities.PersonsEOImpl;
import devguide.examples.entities.ProductsBaseEOImpl;

import oracle.jbo.ApplicationModule;
import oracle.jbo.JboException;
import oracle.jbo.Key;
import oracle.jbo.client.Configuration;
import oracle.jbo.domain.DBSequence;
import oracle.jbo.domain.Number;
import oracle.jbo.server.ApplicationModuleImpl;
import oracle.jbo.server.EntityDefImpl;

public class TestClientCustomInterface {
    public static void main(String[] args) {
        String      amDef = "devguide.model.StoreFrontService";
        String      config = "StoreFrontServiceLocal";
        /*
         * This is the correct way to use application custom methods
         * from the client, by using the application module's automatically-
         * maintained custom service interface.
        */
    }
}
```

```

    */
    // Acquire instance of application module, cast to client interface
StoreFrontService service =
    (StoreFrontService)Configuration.createRootApplicationModule(amDef,config);
String total = service.findOrderTotal(1011);
System.out.println("Status of Order # 1011 = " + total);
String customerName = service.findOrderCustomer(1011);
System.out.println("Customer for Order # 1011 = " + customerName);
try {
    service.updateOrderStatus(1011,"CANCEL");
}
catch (JboException ex) {
    System.out.println("ERROR: "+ex.getMessage());
}
long id = 0;
try {
    id = service.createProduct(null, "NEW", "CLASS1");
}
catch (JboException ex) {
    System.out.println("ERROR: "+ex.getMessage());
}
id = service.createProduct("Canon PowerShot G9", "NEW", "CLASS1");
System.out.println("New product created successfully with id = "+id);
Configuration.releaseRootApplicationModule(am,true);
}
}

```

Running the test client in [Example 9–12](#) calls the custom methods of the client interface, and shows the following output:

```

Total for Order # 1011 = 99.99
Customer for Order # 1011 = John Chen
ERROR: JBO-27014: Attribute ProductName in ProductsBaseEO is required.
New product created successfully with id = 133

```

Notice that the first attempt to call `createProduct()` with a null for the product name raises an exception due to the built-in mandatory validation on the `Name` attribute of the `Product` entity object

9.10.2 What Happens at Runtime: How the Application Module's Client Interface is Accessed

If the client layer accessing your application module will be located in the same tier of the Java EE architecture, the application module will be deployed in what is known as *local mode*. In local mode, the client interface is implemented directly by your custom application module Java class. Typically, you access an application module in local mode when you need to:

- Access the application module in the web tier of a JavaServer Faces application
- Access the application module in the web tier of a JSP/Struts application
- Access the application module in the client tier (two-tier client-server style) for a Swing application

In contrast, when the client layer accessing your application module is located in a *different* tier of the Java EE architecture, the application module will be deployed in what is known as *remote mode*. In remote mode, the generated client proxy class implements your application module client interface on the client side, and the class handles all of the communications details of working with the remotely deployed application module service. You typically access the application module in remote

mode only when a thin-client Swing application needs to access the application module on a remote application server.

A unique feature of ADF Business Components is that by adhering to the interface-only approach for working with client service methods, you can be sure your client code works unchanged regardless of your chosen deployment mode. Even if you plan to work only in local mode, the Java EE development community favors the interface-based approach to working with services. Using application modules, it's extremely easy to follow this approach in your applications.

Note: Whether you plan to deploy your application modules in local mode or remote mode, as described in [Section 9.9.5, "What You May Need to Know About Method Signatures on the Client Interface,"](#) the JDeveloper design time ensures that your custom interface methods will use serializable types. This allows you to switch at any time between local mode or remote mode, or to support both at the same time, with no code changes.

9.10.3 How to Access an Application Module Client Interface in a Fusion Web Application

The `Configuration` class in the `oracle.jbo.client` package makes it very easy to get an instance of an application module for *testing*. This eases writing test client programs like the test client program described in [Section 36.11, "Regression Testing with JUnit"](#) as part of the JUnit regression testing fixture.

Because it is easy, it is tempting for developers to use the class `createRootApplicationModule()` and `releaseApplicationModule()` methods *anywhere* to access an application module. However, for Fusion web applications you should resist this temptation because there is an even easier way.

When working with Fusion web applications using the ADF Model layer for data binding, JDeveloper configures a servlet filter in your user interface project called the `ADFBindingFilter`. It orchestrates the automatic acquisition and release of an appropriate application module instance based on declarative binding metadata, and ensures that the service is available to be looked up as a data control using a known action binding or iterator binding, specified by any page definition file in the user interface project. You may eventually want to read about the ADF binding container, data controls, page definition files, and bindings, as described in [Chapter 13, "Using ADF Model in a Fusion Web Application."](#) For now, it is enough to realize that you can access the application module's client interface from this `DCBindingContainer` by naming an ADF action binding or an ADF iterator binding. You can reference the binding context and call methods on the custom client interface in a JSF managed bean, as shown in [Example 9-13](#) for an action binding and [Example 9-14](#) for an iterator binding.

To access the custom interface of your application module using an action binding, follow these basic steps (as illustrated in [Example 9-13](#)):

1. Access the ADF binding container.
2. Find a named action binding. (Use the name of any available action binding in the page definition files of the user interface project.)
3. Get the data control by name from the action binding.
4. Access the application module data provider from the data control.
5. Cast the application module to its client interface.

6. Call any method on the client interface.

Example 9–13 Accessing the Application Module Client Interface in a JSF Backing Bean Using a Named Action Binding

```
package demo.view;
import oracle.fodemo.storefront.store.service.common.StoreServiceAM;
import oracle.adf.model.binding.DCBindingContainer;
import oracle.adf.model.binding.DCDataControl;
import oracle.jbo.ApplicationModule;
import oracle.jbo.uicli.binding.JUCtrlActionBinding;
public class YourBackingBean {
    public String commandButton_action() {
        // Example using an action binding to get the data control
        public String commandButton_action() {
            // 1. Access the binding container
            DCBindingContainer bc = (DCBindingContainer)getBindings();
            // 2. Find a named action binding
            JUCtrlActionBinding action =
                (JUCtrlActionBinding)bc.findCtrlBinding("SomeActionBinding");
            // 3. Get the data control from the iterator binding (or method binding)
            DCDataControl dc = action.getDataControl();
            // 4. Access the data control's application module data provider
            ApplicationModule am = (ApplicationModule)dc.getDataProvider();
            // 5. Cast the AM to call methods on the custom client interface
            StoreServiceAM service = (StoreServiceAM)am;
            // 6. Call a method on the client interface
            service.doSomethingInteresting();
            return "SomeNavigationRule";
        }
    }
}
```

To access the custom interface of your application module using an iterator binding, follow these basic steps (as illustrated in [Example 9–14](#)):

1. Access the ADF binding container.
2. Find a named iterator binding. (Use the name of any iterator binding in the page definition files of the user interface project.)
3. Get the data control by name from the iterator binding.
4. Access the application module data provider from the data control.
5. Cast the application module to its client interface.
6. Call any method on the client interface.

Example 9–14 Accessing the Application Module Client Interface in a JSF Backing Bean Using a Named Iterator Binding

```
package demo.view;
import oracle.fodemo.storefront.store.service.common.StoreServiceAM;
import oracle.adf.model.binding.DCBindingContainer;
import oracle.adf.model.binding.DCDataControl;
import oracle.adf.model.binding.DCIteratorBinding;
import oracle.jbo.ApplicationModule;
public class YourBackingBean {
    public String commandButton_action() {
        // Example using an iterator binding to get the data control
        public String commandButton_action() {
            // 1. Access the binding container
            DCBindingContainer bc = (DCBindingContainer)getBindings();
```

```

// 2. Find a named iterator binding
DCIteratorBinding iter = bc.findIteratorBinding("SomeIteratorBinding");
// 3. Get the data control from the iterator binding
DCDataControl dc = iter.getDataControl();
// 4. Access the data control's application module data provider
ApplicationModule am = (ApplicationModule)dc.getDataProvider();
// 5. Cast the AM to call methods on the custom client interface
StoreServiceAM service = (StoreServiceAM)am;
// 6. Call a method on the client interface
service.doSomethingInteresting();
return "SomeNavigationRule";
}
}

```

These backing bean examples depend on the helper method shown in [Example 9–15](#).

Example 9–15 Helper Method for Backing Bean Class

```

public BindingContainer getBindings() {
    if (this.bindings == null) {
        FacesContext fc = FacesContext.getCurrentInstance();
        this.bindings =
            (BindingContainer)fc.getApplication().evaluateExpressionGet(fc,
                "#{bindings}", BindingContainer.class);
    }
    return this.bindings;
}

```

If you create the backing bean class by overriding a button that is declaratively bound to an ADF action, then JDeveloper will automatically generate this method in your class. Otherwise, you will need to add the helper method to your class yourself.

9.11 Overriding Built-in Framework Methods

The `ApplicationModuleImpl` base class provides a number of built-in methods that implement its functionality. While [Appendix D, "Most Commonly Used ADF Business Components Methods"](#) provides a quick reference to the most common code that you will typically write, use, and override in your custom application module classes, this section focuses on helping you understand the basic steps to override one of these built-in framework methods to augment the default behavior.

9.11.1 How to Override a Built-in Framework Method

To override a built-in framework method for an application module, use the Override Methods dialog, which you select for the application module Java class from the main menu.

Before you begin:

It may be helpful to have an understanding of the application module base class. For more information, see [Section 9.11, "Overriding Built-in Framework Methods."](#)

Complete this task:

Create the desired application modules as described in [Section 9.2.1, "How to Create an Application Module."](#)

To override an application module framework method:

1. In the Application Navigator, double-click the application module.

2. In the overview editor, click the **Java** navigation tab.
3. On the Java Classes page, click the linked file name of the application module Java class that you want to customize.

JDeveloper opens the class file in the source editor.

4. From the main menu, choose **Source > Override Methods**.

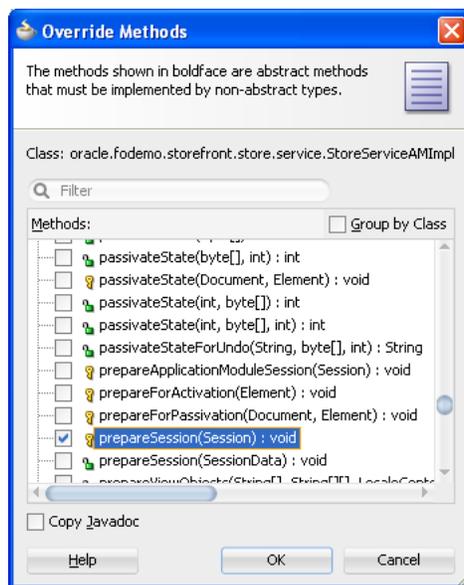

If the **Source** menu is not displayed, be sure that the desired Java class file is open and that the source editor is visible.

5. In the Override Methods dialog, scroll the list to locate the desired methods or type the first few letters of the method name to perform an incremental search.
6. Select one or more methods.

The Override Methods dialog allows you to select any number of methods to override simultaneously.

For example, if you wanted to override the application module's `prepareSession()` method to augment the default functionality when a new user session begins working with an application module service component for the first time, you would select the checkbox next to the `prepareSession(Session)` method, as shown in [Figure 9–26](#).

Figure 9–26 Overriding a Built-in Framework Method

7. Click **OK**.

9.11.2 What Happens When You Override a Built-in Framework Method

When you dismiss the Override Methods dialog, you return to the source editor with the cursor focus on the overridden method, as shown in [Figure 9–27](#). Notice that the method appears with a single line that calls `super.prepareSession()`. This is the syntax in Java for invoking the default behavior that the base class would have normally performed for this method. By adding code before or after this line in the custom application module class, you can augment the default behavior before or after the default functionality.

Figure 9–27 Source Editor Margin Gives Visual Feedback About Overridden Methods

```

316     @Override
317     protected void prepareSession(Session session) {
318         super.prepareSession(session);
319     }

```

Also notice that when you override a method using the Override Methods dialog, the source editor inserts the JDK `@Override` annotation just before the overridden method. This causes the compiler to generate a compile-time error if the method in the application module class does not match the signature of any method in the superclass.

Be careful when you add method names to your class to override a method in the superclass; you must have the signature *exactly* the same as the base class method you want to override. Be sure to add the `@Override` annotation just before the method. This way, if your method does not match the signature of any method in the superclass, the compiler will generate a compile-time error. Also, when you write code for a method instead of calling the superclass implementation, you should have a thorough understanding of what built-in code you are suppressing or replacing.

9.11.3 How to Override `prepareSession()` to Set Up an Application Module for a New User Session

Since the `prepareSession()` method is invoked by the application module when it is used for the first time by a new user session, it's a useful method to override in your custom application module class to perform setup tasks that are specific to each new user that uses your application module. [Example 9–16](#) illustrates an overridden `prepareSession()` method in the `oracle.fodemo.storefront.adfextensions.FODApplicationModuleImpl` class that invokes a `setCurrentUserLanguage()` helper method to initialize the language used by the application.

Example 9–16 Initializing the Language to Use for Current User Session

```

public class FODApplicationModuleImpl extends ApplicationModuleImpl {

    public static String preferredLanguage;
    public static boolean isWebUser=false;
    private String[] supportedLanguages = {"EN", "JA", "EL", "FR", "DE"};

    /**
     * @param session
     */
    @Override
    protected void prepareSession(Session session) {
        super.prepareSession(session);
        setCurrentUserLanguage();
    }

    private void setCurrentUserLanguage() {
        DBTransactionImpl dbti = (DBTransactionImpl) getDBTransaction();
        CallableStatement statement =
            dbti.createCallableStatement(("BEGIN " +
                "user_context_pkg.set_app_user_lang(?); " +
                "END;"), 0);
        try {
            statement.setString(1, getApplicationLanguage());
            statement.execute();
        }
    }
}

```

```

    } catch (SQLException sqlerr) {
        throw new JboException(sqlerr);
    } finally {
        try {
            if (statement != null) {
                statement.close();
            }
        } catch (SQLException closeerr) {
            throw new JboException(closeerr);
        }
    }
}

/**
 * @return
 */
public String getApplicationLanguage(){
    String appLanguage = "EN";
    if (isWebUser){
        for (int index=0; index<supportedLanguages.length; index++){
            if (preferredLanguage.equals(supportedLanguages[index])){
                appLanguage = preferredLanguage;
                break;
            }
        }
    } else{
        appLanguage = getAMLanguage();
    }
    return appLanguage;
}

/**
 * @return
 */
public String getAMLanguage(){
    PropertyMetadata langProperty =
        PropertyMetadata.findProperty("jbo.default.language");
    String amLanguage = langProperty.getProperty();
    return amLanguage.toUpperCase();
}
}

```

9.12 Calling a Web Service from an Application Module

In a service-oriented architecture, your Oracle ADF application module may need to take advantage of functionality offered by a web service that is not based on an application module. A web service can be implemented in any programming language and can reside on any server on the network. Each web service identifies the methods in its API by describing them in a standard, language-neutral XML format. This XML document, whose syntax adheres to the Web Services Description Language (WSDL), enables JDeveloper to understand the names of the web service's methods, as well as the data types of the parameters they might expect and their eventual return value.

Note: Application modules can also be exposed as web services so that they can be consumed across modules of the deployed Fusion web application. For details about reusing ADF Business Components using external services, see [Chapter 11, "Integrating Service-Enabled Application Modules."](#)

JDeveloper's built-in web services wizards make this an easy task. Create a web service proxy class using the wizard, then call the service using method calls you add to a local Java object.

9.12.1 How to Call an External Service Programmatically

To call a web service from an application module, you create a web service proxy class for the service you want to invoke. A web service proxy is a generated Java class that represents the web service inside your application. It encapsulates the service URL of the web service and handles the lower-level details of making the call.

To work with a web service, you need to know the URL that identifies its WSDL document. If you have received the WSDL document as an email attachment, for example, and saved it to your local hard drive, the URL could be similar to:

```
file:///D:/temp/SomeService.wsdl
```

Alternatively, the URL could be an HTTP-based URL like:

```
http://someserver.somecompany.com/SomeService/SomeService.wsdl
```

Some web services make their WSDL document available by using a special parameter to modify the service URL. For example, a web service that expects to receive requests at the HTTP address of `http://someserver.somecompany.com/SomeService` might publish the corresponding WSDL document using the same URL with an additional parameter on the end, like this:

```
http://someserver.somecompany.com/SomeService?WSDL
```

Since there is no established standard, you will just need to know what the correct URL to the WSDL document is. With the URL information, you can then create a web service proxy class to call the service.

ADF Business Components services have URLs to the service of the following formats:

- On Integrated WebLogic Server, the URL has the format
`http://host:port/EJB-context-root/@WebService-name?WSDL`,
for example:
`http://localhost:8888/EJB-StoreFrontService/StoreFrontService?WSDL`
- On Oracle Application Server, the URL has the format
`http://host:port/context-root/@WebService-name?WSDL`,
for example:
`http://localhost:8888/StoreFrontService/StoreFrontService?WSDL`

The web service proxy class presents a set of Java methods that correspond to the web service's public API. By using the web service proxy class, you can call any method in the web service in the same way as you work with the methods of any other local Java class.

To call a web service from an application module using a proxy class, you perform the following tasks:

1. Create a web service proxy class for the web service. To create a web service proxy class for a web service that you need to call, use the Create Web Service Proxy wizard.
2. Implement the methods in the proxy class to access the desired web services.
3. Create an instance of the web service proxy class in your application module and invoke one or more methods on the web service proxy object.

9.12.1.1 Creating a Web Service Proxy Class to Programmatically Access the Service

To create a web service proxy class for a web service you need to call, use the Create Web Service Proxy wizard.

To create a web service proxy class to programmatically access the service:

1. In the Application Navigator, right-click the project in which you want to create the web service proxy, and choose **New**.
2. In the New Gallery, expand **Business Tier**, select **Web Services** and then **Web Service Proxy Client**, and click **OK**.
3. On the Select Web Service Description page of the wizard, enter or choose a Java package name for the generated web service proxy class.
4. Enter the URL for the WSDL of the service you want to call in your application, and then tab out of the field.

If the **Next** button does not enable, click **Why Not?** to understand what problem JDeveloper encountered when trying to read the WSDL document. If necessary, fix the problem after verifying the URL and repeat this step.

5. When the wizard displays **Next** enabled, then JDeveloper has recognized and validated the WSDL document. You can click **Next** and continue.
6. Continue through the pages of the wizard to specify details about the web service proxy. For more information about each page of the wizard, press F1 or click **Help**.
7. Click **Finish**.

9.12.1.2 Calling the Web Service Proxy Template to Invoke the Service

After you create the web service proxy, you must implement the methods in the proxy class to access the desired web services.

To call the web service proxy template to invoke the service:

1. Open the proxy client class, called `port_nameClient.java`, in the source editor, and locate the comment `// Add your own code to call the desired methods, which is in the main method.`
2. Add the appropriate code to invoke the web service.
3. Deploy the full set of client module classes that JDeveloper has generated, and reference this class in your application.

9.12.1.3 Calling a Web Service Method Using the Proxy Class in an Application Module

After you've generated the web service proxy class, you can use it inside a custom method of your application module, as shown in [Example 9-17](#). The method creates an instance of the web service proxy class and calls the web service method from the web service proxy class for the result.

Example 9-17 Web Service Proxy Class Calls Web Service Method

```
// In YourModuleImpl.java
public void performSomeApplicationTask(String symbol) throws Exception {
    // application-specific code here
    :
    // Create an instance of the web service proxy class
    StockQuoteServiceSoapHttpClient svc =
        new StockQuoteServiceSoapHttpClient();
    // Call a method on the web service proxy class and get the result
    QuoteInfo quote = svc.quoteForSymbol(symbol);
    float currentPrice = quote.getPrice();
    // more application-specific code here
}
```

9.12.2 What Happens When You Create the Web Service Proxy

JDeveloper generates the web service proxy class in the package you've indicated with a name that reflects the name of the web service port it discovered in the WSDL document. The web service port name might be a human-readable name like `StockQuoteService`, or could be a less-friendly name like `StockQuoteServiceSoapHttpPort`. The port name is decided by the developer that published the web service you are using. If the port name of the service were `StockQuoteServiceSoapHttpPort`, for example, JDeveloper would generate a web proxy class named `StockQuoteServiceSoapHttpClient`.

The web service proxy displays in the Application Navigator as a single, logical node called *WebServiceNameProxy*. For example, the node for the `StockQuoteService` web service would appear in the navigator with the name `StockQuoteServiceProxy`. As part of generating the proxy class, in addition to the main web service proxy class that you use to invoke the server, JDeveloper generates a number of auxiliary classes and interfaces. You can see these files in the Application Navigator under the *WebServiceNameProxy* node. The generated files are used as part of the lower-level implementation of invoking the web service.

The only auxiliary generated classes you need to reference are those created to hold structured web service parameters or return types. For example, imagine that the `StockQuoteService` web service has a `quoteForSymbol()` method that accepts one `String` parameter and returns a floating-point value indicating the current price of the stock. If the designer of the web service chose to return a simple floating-point number, then the web service proxy class would have a corresponding method like this:

```
public float quoteForSymbol(String symbol)
```

If instead the designer of the web service thought it useful to return multiple pieces of information as the result, then the service's WSDL file would include a named structure definition describing the multiple elements it contains. For example, assume that the service returns both the symbol name and the current price as a result. To contain these two data elements, the WSDL file might define a structure named `QuoteInfo` with an element named `symbol` of string type and an element named

price of floating-point type. In this situation, when JDeveloper generates the web service proxy class, the Java method signature would instead look like this:

```
public QuoteInfo quoteForSymbol(String symbol)
```

The `QuoteInfo` return type references one of the auxiliary classes that comprises the web service proxy implementation. It is a simple bean whose properties reflect the names and types of the structure defined in the WSDL document. In a similar way, if the web service accepts parameters whose values are structures or arrays of structures, then you will work with these structures in your Java code using the corresponding generated beans.

9.12.3 What Happens at Runtime: When You Call a Web Service Using a Web Service Proxy Class

When you invoke a web service from an application module, the web service proxy class handles the lower-level details of using the XML-based web services protocol described in SOAP. In particular, it does the following:

- Creates an XML document to represent the method invocation
- Packages any method arguments in XML
- Sends the XML document to the service URL using an HTTP POST request
- Unpackages the XML-encoded response from the web service

If the method you invoke has a return value, your code receives it as an appropriately typed object to work with in your application module code.

9.12.4 What You May Need to Know About Web Service Proxies

When you are implementing web service proxies in an application, you might want to use a try-catch block to handle web service exceptions or invoke an application module with a web service proxy class. The following sections contain additional information you might need to know about these and other features with regard to web service proxies.

9.12.4.1 Using a Try-Catch Block to Handle Web Service Exceptions

By using the generated web service proxy class, invoking a remote web service becomes as easy as calling a method in a local Java class. The only distinction to be aware of is that the web service method call could fail if there is a problem with the HTTP request involved. The method calls that you perform against a web service proxy should anticipate the possibility that the request might fail by wrapping the call with an appropriate `try...catch` block. [Example 9–18](#) improves on the simpler example (shown in [Section 9.12.1.3, "Calling a Web Service Method Using the Proxy Class in an Application Module"](#)) by catching the web service exception. In this case, it simply rethrows the error as a `JboException`, but you could implement more appropriate error handling in your own application.

Example 9–18 Wrapping Web Service Method Calls with a Try-Catch Block

```
// In YourModuleImpl.java
public void performSomeApplicationTask(String symbol) {
    // application-specific code here
    // :
    QuoteInfo quote = null;
    try {
        // Create an instance of the web service proxy class
```

```

    StockQuoteServiceSoapHttpClient svc =
        new StockQuoteServiceSoapHttpClient();
    // Call a method on the web service proxy class and get the result
    quote = svc.quoteForSymbol(symbol);
}
catch (Exception ex) {
    throw new JboException(ex);
}
float currentPrice = quote.getPrice();
// more application-specific code here
}

```

9.12.4.2 Separating Application Module and Web Services Transactions

You will use some web services to access reference information. However, other services you call may modify data. This data modification might be in your own company's database if the service was written by a member of your own team or another team in your company. If the web service is outside your firewall, of course the database being modified will be managed by another company.

In either of these situations, it is important to understand that any data modifications performed by a web service you invoke will occur in their own distinct transaction, unrelated to the application module's current unit of work. For example, if you have invoked a web service that modifies data and then you later call `rollback()` to cancel the pending changes in the application module's current unit of work, this has no effect on the changes performed by the web service you called in the process. You may need to invoke a corresponding web service method to perform a compensating change to account for your rollback of the application module's transaction.

9.12.4.3 Setting Browser Proxy Information

If the web service you need to call resides outside your corporate firewall, you need to ensure that you have set the appropriate Java system properties to configure the use of an HTTP proxy server. The Java system properties to configure are:

- `http.proxyHost` — Set this to the name of the proxy server.
- `http.proxyPort` — Set this to the HTTP port number of the proxy server (often 80).
- `http.nonProxyHosts` — Optionally set this to a vertical-bar-separated list of servers not requiring the user of a proxy server (for example, `localhost|127.0.0.1|*.yourcompany.com`).

Within JDeveloper, you can configure an HTTP proxy server on the Web Browser and Proxy page of the Preferences dialog. When you run your application, JDeveloper includes appropriate `-D` command-line options to set these three system properties based on the settings you've indicated in this dialog.

9.12.4.4 Invoking Application Modules with a Web Service Proxy Class

If you use a web service proxy class to invoke an Oracle ADF service-based application module, you lose the ability to optimize the call when the calling component and the service you are calling are colocated. As an alternative, you can use the service interface approach described in [Chapter 11, "Integrating Service-Enabled Application Modules."](#)

Sharing Application Module View Instances

This chapter describes how to organize your data model project to most efficiently utilize read-only data accessed from lookup tables or other static data source, such as a flat file.

This chapter includes the following sections:

- [Section 10.1, "About Shared Application Modules"](#)
- [Section 10.2, "Sharing an Application Module Instance"](#)
- [Section 10.3, "Defining a Base View Object for Use with Lookup Tables"](#)
- [Section 10.4, "Accessing View Instances of the Shared Service"](#)
- [Section 10.5, "Testing View Object Instances in a Shared Application Module"](#)

10.1 About Shared Application Modules

Web applications often utilize data that is required across sessions and does not change very frequently. An example of this type of *static data* might be displayed in the application user interface in a lookup list. Each time your application accesses the static data, you could incur an unnecessary overhead when the static data caches are repopulated from the database for each application session on every request. In order to optimize performance, a common practice when working with ADF Business Components is to cache the shared static data for reuse across sessions and requests.

10.1.1 Shared Application Module Use Cases and Examples

View accessors in ADF Business Components are value accessor objects that point from an entity object attribute (or view object) to a destination view object or shared view instance in the same application workspace.

This ability to access view objects in different application modules makes view accessors particularly useful for:

- Validation rules that you set on the attributes of an entity object. For example, when the end user fills out a registration form, individual validation rules can verify the title, marital status, and contact code against lookup table data queried by view instances of the shared application module.
- List of Value (LOV) that you enable for the attribute of any view object. For example, to display a list of values to the end user at runtime.

10.1.2 Additional Functionality for Shared Application Modules

You may find it helpful to understand other ADF features before you start working with shared application modules. Following are links to other functionality that may be of interest.

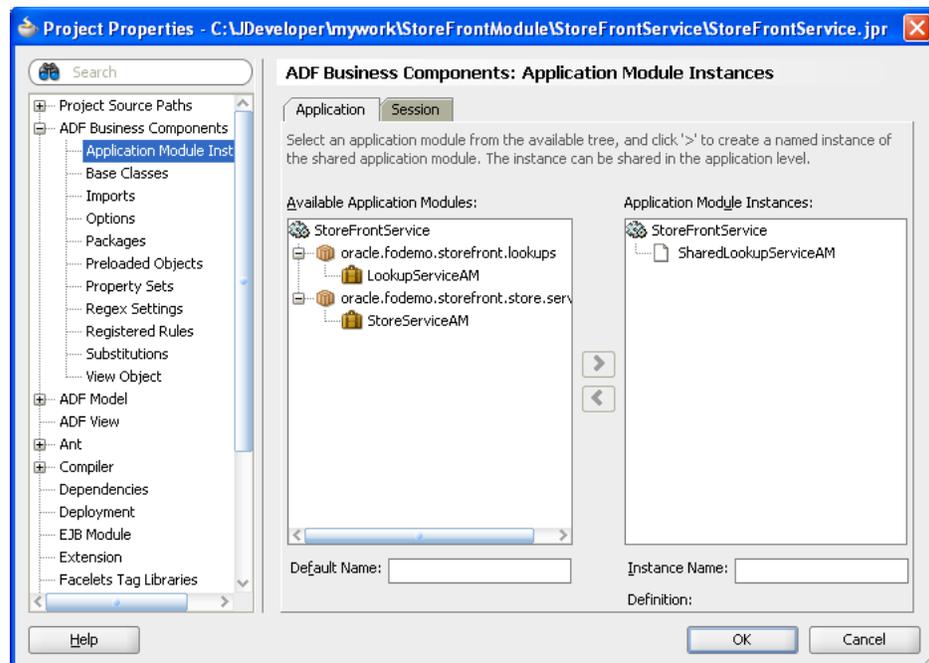

- For details about configuring application module instances to improve runtime performance, see [Chapter 43, "Application State Management"](#) and [Chapter 44, "Tuning Application Module Pools and Connection Pools."](#)
- For a quick reference to the most common code that you will typically write, use, and override in your custom application module classes, see [Appendix D, "Most Commonly Used ADF Business Components Methods."](#)
- For API documentation related to the `oracle.jbo` package, see the following Javadoc reference document:
 - *Oracle Fusion Middleware Java API Reference for Oracle ADF Model*

10.2 Sharing an Application Module Instance

Declarative support for shared data caches is available in JDeveloper through the Project Properties dialog. Creating a shared application module allows requests from multiple sessions to share a single application module instance which is managed by an application pool for the lifetime of the web server virtual machine.

Best Practice: Use a shared application module to group view instances when you want to reuse lists of static data across the application. The shared application module can be configured to allow any user session to access the data or it can be configured to restrict access to just the UI components of a single user session. For example, you can use a shared application module to group view instances that access lookup data, such as a list of countries. The use of a shared application module allows all shared resources to be managed in a single place and does not require a scoped managed bean for this purpose.

As shown in [Figure 10–1](#), the Project Properties dialog lets you specify application-level or session-level sharing of the application module's data model. In the case of *application-level sharing*, any HTTP user session will be able to access the same view instances contained in the shared application module. In contrast, the lifecycle of the *session-level shared* application module extends to an application module session (`SessionImpl`) that is in use by a single HTTP user session and applies to a single root application module. In this case, each distinct *root* application module used by a given HTTP user session will get its own distinct instance of a session-scoped shared application module. In other words, distinct root application modules used by the same HTTP session do not share data in a session-scoped shared application module.

Figure 10–1 Project Properties Dialog Defines Shared Application Module Instance

When you create the data model for the application module that you intend to share, be sure that the data in cached row sets will not need to be changed either at the application level or session level. For example, in the application-level shared application module, view instances should query only static data such as state codes or currency types. If a view object instance queries data that depends on the current user, then the query can be cached at the session level and shared by all components that reference the row-set cache. For example, the session-level shared application module might contain a view instance with data security that takes a manager as the current user to return the list of direct reports. In this case, the cache of direct reports would exist for the duration of the manager's HTTP user session. The ADF Business Components application module pool will recreate the session-scoped application module should an HTTP user session be assigned a recycled application module from the pool. This ensures that the duration of the session-scoped application module is tied to the HTTP session for as long as the HTTP session is able to continue to use the same root application module instance. Note that the cache of direct reports of the session-level shared application module cannot be accessed across distinct root application modules.

10.2.1 How to Create a Shared Application Module Instance

To create a shared application module instance, use the Project Properties dialog. You define a logical name for a distinct, separate root application module that will hold your application's read-only data.

Before you begin:

Create the application module that you will share as described in [Section 9.2.1, "How to Create an Application Module."](#)

To create a shared application module instance:

1. In the Application Navigator, right-click the project in which you want to create the shared application module and choose **Project Properties**.

2. In the Project Properties dialog, expand **ADF Business Components** and select **Application Module Instances**.
3. On the ADF Business Components: Application Module Instances page, select one of these tabs:
 - When you want to define the shared application module for the context of the application, select the **Application** tab.
 - When you want to define the shared application module for the context of the current user session, select the **Session** tab
4. In the **Available Application Modules** list, select the desired application module and shuttle it to the **Application Module Instances** list.
5. Assign the application module a unique instance name.
The shared application module instance (of either scope) must have a unique instance name. Supplying a meaningful name will also help to clarify which shared application module instance a given usage is referencing.
6. Click **OK**.

10.2.2 What Happens When You Define a Shared Application Module

JDeveloper automatically creates the `AppModuleNamedShared` configuration when you create an application module. The presence of this configuration in the `bc4j.xcfg` file informs JDeveloper that the application module is a candidate to be shared, and allows JDeveloper to display the application module in the **Available Application Modules** list of the Project Properties dialog's Application Module Usage page.

The `AppModuleNamedShared` configuration sets these properties on the application module to enable sharing and help to maintain efficient use of the shared resource at runtime:

- `jbo.ampool.isuseexclusive` is set to `false` to specify that requests from multiple sessions can share a single instance of the application module, which is managed by the application pool for the lifetime of the web server virtual machine. When you do not enable application module sharing, JDeveloper sets the value `true` to repopulate the data caches from the database for each application session on every request.
- `jbo.ampool.maxpoolsize` is set to 1 (one) to specify that only a single application module instance will be created for the ADF Business Components application module pool. This setting enforces the efficient use of the shared application module resource and prevents unneeded multiple instances of the shared application module from being created at runtime.

You can view the shared application module's configuration by choosing **Configurations** from the context menu on the application module in the Application Navigator. JDeveloper saves the `bc4j.xcfg` file in the `./common` subdirectory relative to the application module's XML component definition. If you remove the configuration or modify the values of the `jbo.ampool` runtime properties (`isuseexclusive`, `maxpoolsize`), the application module will not be available to use as a shared application module instance.

For example, if you look at the `bc4j.xcfg` file in the `./src/oracle/fodemo/storefront/lookups/common` directory of the Fusion Order Demo application's `StoreFrontService` project, you will see the two named configurations for the `LookupServiceAM` application module, as shown in

Example 10–1. Specifically, the `LookupServiceAMShared` configuration sets the `jbo.ampool` runtime properties on the shared application module instance. For more information about the ADF Business Components application module pooling and runtime configuration of application modules, see [Chapter 44, "Tuning Application Module Pools and Connection Pools."](#)

Example 10–1 LookupServiceAMShared Configuration in the `bc4j.xcfg` File

```
<BC4JConfig version="11.1" xmlns="http://xmlns.oracle.com/bc4j/configuration">
  <AppModuleConfigBag
    ApplicationName="oracle.fodemo.storefront.lookups.LookupServiceAM">
    <AppModuleConfig DeployPlatform="LOCAL"
      JDBCName="FOD"
      jbo.project="StoreFrontService"
      name="LookupServiceAMLocal"
      ApplicationName="oracle.fodemo.storefront.lookups.LookupServiceAM">
    <Database jbo.locking.mode="optimistic"/>
    <Security
      AppModuleJndiName="oracle.fodemo.storefront.lookups.LookupServiceAM"/>
    </AppModuleConfig>
    <AppModuleConfig DeployPlatform="LOCAL"
      JDBCName="FOD"
      jbo.project="StoreFrontService"
      name="LookupServiceAMShared"
      ApplicationName="oracle.fodemo.storefront.lookups.LookupServiceAM">
    <AM-Pooling jbo.ampool.dynamicjdbccredentials="false"
      jbo.ampool.isuseexclusive="false"
      jbo.ampool.maxpoolsize="1"
      jbo.ampool.resetnontransactionalstate="false"/>
    <Database jbo.locking.mode="optimistic"/>
    <Security
      AppModuleJndiName="oracle.fodemo.storefront.lookups.LookupServiceAM"/>
    </AppModuleConfig>
  </AppModuleConfigBag>
</BC4JConfig>
```

Because the shared application module can be accessed by any data model project (based on ADF Business Components) in the same application workspace, JDeveloper maintains the scope of the shared application module in the ADF Business Components project configuration file (`.jspx`). This file is saved in the `src` directory of the project. For example, if you look at the `StoreFrontServicejspx` file in the `./src` directory of the Fusion Order Demo application's `StoreFrontService` project, you will see that the `SharedLookupService` application module's usage definition specifies `SharedScope = 2`, corresponding to application-level sharing, as shown in [Example 10–2](#). An application module that you set to session-level sharing will show `SharedScope = 1`.

Example 10–2 Application Module Usage Configuration in the `.jspx` File

```
<JboProject
  xmlns="http://xmlns.oracle.com/bc4j"
  Name="StoreFrontService"
  SeparateXMLFiles="true"
  PackageName="">
  . . .
  <AppModuleUsage
    Name="SharedLookupService"
    FullName="oracle.fodemo.storefront.lookups.LookupServiceAM"
    ConfigurationName="oracle.fodemo.storefront.lookups.LookupServiceAMShared"
```

```
    SharedScope="2" />  
</JboProject>
```

10.2.3 What You May Need to Know About Design Time Scope of the Shared Application Module

Defining the shared application module in the Project Properties dialog makes the application module's data model available to other data model projects of the same application workspace only. When you want to make the data model available beyond the application workspace, you can publish the data model as an ADF Library, as described in [Chapter 38, "Reusing Application Components."](#)

When viewing a data control usage from the `DataBindings.cpx` file in the Structure window, do not set the **Configuration** property to a shared application module configuration. By default, for an application module named `AppModuleName`, the Property Inspector will list the configurations named `AppModuleNameShared` and `AppModuleNameLocal`. At runtime, Oracle Application Development Framework (Oracle ADF) uses the shared configuration automatically when you configure an application as a shared application module, but the configuration is not designed to be used by an application module data control usage. For more information about data control usage, see [Section 13.5, "Working with the DataBindings.cpx File."](#)

10.2.4 What You May Need to Know About the Design Time Scope of View Instances of the Shared Application Module

You define view accessors on the business component definition for the data model project that will permit access to view instances of the shared application module. The view accessor lets you point from an entity object or view object definition in one data model project to a view object definition or view instance in a shared application module. For details about creating view accessors for this purpose, see [Section 10.4, "Accessing View Instances of the Shared Service."](#)

10.2.5 What You May Need to Know About Managing the Number of Shared Query Collections

Similar to the way application module pooling works in ADF Business Components, shared query collections are stored in a query collection pool. To manage the query collection pool, the ADF Business Components framework removes query collections based on a maximum idle time setting. This behavior limits the growth of the cache and prevents rarely-used query collections from occupying memory space.

As in application module and connection pooling, a query collection pool monitor wakes up after a user-specified sleep interval and then initiates the cleanup operation. Any query collection that exceeds the maximum idle time (length of time since it was last used), will be removed from the pool.

You can change the default values for the maximum idle time for the shared query collection (default is 900000 ms/15 min) and the sleep period for its pool monitor (default is 1800000 ms/30 min). To configure these values, open the Edit Business Components Configuration dialog, select the `AppModuleNameShared` configuration, and set these properties in the Properties page of the editor:

- `jbo.qcpool.monitorsleepinterval` the time (ms) that the shared query collection pool monitor should sleep between pool checks.

- `jbo.qcpool.maxinactiveage` the maximum amount of time (ms) that a shared query collection may remain unused before it is removed from the pool.

10.2.6 What You May Need to Know About Shared Application Modules and Connection Pooling

The default connection behavior for all application modules is to allow each root application module to have its own database connection. When your application defines more than one shared application module, you can change the default to optimize database connection usage by defining a named transaction for each root application module to use. The transaction name is an arbitrary string that you set on the `jbo.shared.txn` property in the Properties page of the editor for the `bc4j.xcfg` file of the root application module. At runtime, the root application modules with the same `jbo.shared.txn` property setting (identified by the string you supply) will share the same database connection and entity cache. This optimization can reduce the database resources that the application uses and is particularly useful in shared application modules cases because they are read only and have longer life than transactional application modules.

Currently, the application module configuration parameter `jbo.doconnectionpooling=true` is not supported for use with shared application modules. This feature is available to configure non-shared application modules when it is desirable to release JDBC connection objects to the database connection pool.

This feature is intentionally not supported for shared application modules to prevent decreases in performance that would result from managing state for shared access. Instead, the default use of `jbo.doconnectionpooling=false` is enforced.

The default connection pooling configuration ensures that each shared application module instance holds onto the JDBC connection object that it acquires from the pool until the application module instance is removed from the application module pool. For more information about the `jbo.doconnectionpooling` parameter and connection pool behavior, see [Section 44.2.6, "What You May Need to Know About How Database and Application Module Pools Cooperate."](#)

10.3 Defining a Base View Object for Use with Lookup Tables

When your application needs to display static data, you can define a shared application module with view instances that most likely will access lookup tables. A lookup table is a static, translated list of data to which the application refers. Lookup table data can be organized in the database in various ways. While it is possible to store related lookup data in separate tables, it is often convenient to combine all of the lookup information for your application within a single table. For example, a column `LOOKUP_TYPE` created for the `ORDERS_LOOKUPS` table would serve to partition one table that might contain diverse codes such as `FWK_TBX_YES_NO` for the values yes and no, `FWK_TBX_COUNTRY` for country names, and `FWK_TBK_CURRENCY` for the names of national currencies.

When your database schema organizes lookup data in a single database table, you want to avoid creating individual queries for each set of data. Instead, you will use the overview editor to define a single, base view object that maps the desired columns of the lookup table to the view object attributes you define. Since only the value of the `LOOKUP_TYPE` column will need to change in the query statement, you can add view criteria on the view object definition to specify a `WHERE` clause that will set the `LOOKUP_TYPE` value. In this way, your application encapsulates access to the lookup table data in a single view object definition that will be easy to maintain when a

LOOKUP_TYPE value changes or your application needs to query additional lookup types.

10.3.1 How to Create a Base View Object Definition for a Lookup Table

The base view object that queries columns of the lookup table will be a read-only view object, since you do not need to handle updating data or require any of the benefits provided by entity-based view objects. (For a description of those benefits, see [Section 5.1, "About View Objects."](#))

Note: While read-only view objects you create to access lookup tables are ideal for inclusion in a shared application module, if you intend to share the view object in a shared application module instance, you must create the view object in the same package as the shared application module.

To create a read-only view object, use the Create View Object wizard, which is available from the New Gallery.

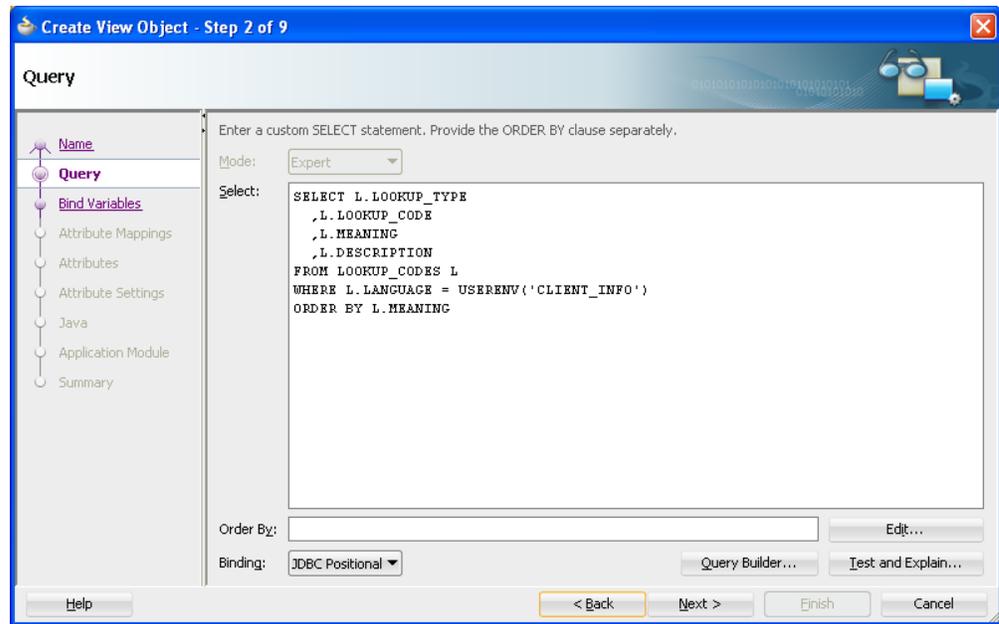

To create a base view object for a lookup table:

1. In the Application Navigator, locate the shared application module you created in which you want to create the view object, right-click its package node, and choose **New**.
2. In the New Gallery, expand **Business Tier**, select **ADF Business Components** and then select **View Object**, and click **OK**.
3. In the Create View Object wizard, on the Name page, enter a package name and a view object name.

When naming the package, consider creating a separate package for the lookup.

4. Select **SQL query** to indicate that you want this view object to manage data with read-only access and click **Next**.
5. On the Query page, enter your SQL statement directly into the **Query Statement** box.

Your query names the columns of the lookup table, similar to the SQL statement shown in [Figure 10-2](#) to query the LOOKUP_CODE, MEANING, and DESCRIPTION columns in the LOOKUP_CODES table.

Figure 10–2 Create View Object Wizard, SQL Query for Lookup Table

6. After entering the query statement, no other changes are required. Click **Next**.

7. On the Bind Variables page, click **Next**.

8. On the Attribute Mappings page, note the mapped view object attribute names displayed and click **Next**.

By default, the wizard creates Java-friendly view object attribute names that correspond to the `SELECT` list column names.

9. On the Attribute Settings page, you can optionally rename the attributes to use any names that might be more appropriate. Choose the attribute to rename from the **Select Attributes** dropdown list. When you are finished, click **Next**.

For example, the Fusion Order Demo application renames the default attributes `LookupType` and `LookupCode` to `Type` and `Value` respectively. Changes you make to the view object definition will not change the underlying query.

10. On the Java page, click **Next**.

11. On the Application Module page, do not add an instance of the view object to the application module data model. Click **Finish**.

The shared application module data model will include view instances based on view criteria that you add to the base view object definition. In this way, you do not need to create an individual view object to query each `LOOKUP_TYPE` value. For details about adding the view object instances to the data model, see [Section 9.2.3.2, "Adding Master-Detail View Object Instances to an Application Module."](#)

10.3.2 What Happens When You Create a Base View Object

When you create the view object definition for the lookup table, JDeveloper first describes the query to infer the following from the columns in the `SELECT` list:

- The Java-friendly view attribute names (for example, `LookupType` instead of `LOOKUP_TYPE`)

By default, the wizard creates Java-friendly view object attribute names that correspond to the `SELECT` list column names.

- The SQL and Java data types of each attribute

JDeveloper then creates the XML component definition file that represents the view object's declarative settings and saves it in the directory that corresponds to the name of its package. For example, the XML file created for a view object named `LookupsBaseVO` in the `lookups` package is `./lookups/LookupsBaseVO.xml` under the project's source path.

To view the view object settings, expand the desired view object in the Application Navigator, select the XML file under the expanded view object, and open the Structure Window. The Structure window displays the list of definitions, including the SQL query and the properties of each attribute. To open the file in the editor, double-click the corresponding `.xml` node. As shown in [Example 10-3](#), the `LookupsBaseVO.xml` file defines one `<SQLQuery>` definition and one `<ViewAttribute>` definition for each mapped column. Without a view criteria to filter the query results, the view object query returns the `LOOKUP_CODE`, `LOOKUP_MEANING`, and `LOOKUP_DESCRIPTION` and maps them to view instance attribute values for `Value`, `Name`, and `Description` respectively.

Example 10-3 *LookupsBaseVO SQL Query and Attribute Mapping Definition*

```
<ViewObject
  xmlns="http://xmlns.oracle.com/bc4j"
  Name="LookupsBaseVO"
  BindingStyle="OracleName"
  CustomQuery="true"
  PageIterMode="Full"
  UseGlueCode="false"
  FetchMode="FETCH_AS_NEEDED"
  FetchSize="500">
  <SQLQuery>
    <![CDATA[SELECT L.LOOKUP_TYPE
      ,L.LOOKUP_CODE
      ,L.MEANING
      ,L.DESCRPTION
    FROM LOOKUP_CODES L
    WHERE L.LANGUAGE = USERENV('CLIENT_INFO')
    ORDER BY L.MEANING]]>
  </SQLQuery>
  <DesignTime>
    <Attr Name="_codeGenFlag2" Value="Access|VarAccess"/>
    <Attr Name="_isExpertMode" Value="true"/>
  </DesignTime>
  <ViewAttribute
    Name="Type"
    IsUpdateable="false"
    IsPersistent="false"
    IsNotNull="true"
    PrecisionRule="true"
    Precision="255"
    Type="java.lang.String"
    ColumnType="VARCHAR2"
    AliasName="LOOKUP_TYPE"
    Expression="LOOKUP_TYPE"
    SQLType="VARCHAR">
    <DesignTime>
      <Attr Name="_DisplaySize" Value="30"/>
    </DesignTime>
  </ViewAttribute>
</ViewObject>
```

```

    </DesignTime>
    ...
</ViewAttribute>

  Passivate="true"
  Expression="DESCRIPTION"
  SQLType="VARCHAR">
  <DesignTime>
    <Attr Name="_DisplaySize" Value="240"/>
  </DesignTime>
  ...
</ViewAttribute>
...
</ViewObject>

```

10.3.3 How to Define the WHERE Clause of the Lookup View Object Using View Criteria

You create named view criteria definitions in the data model project when you need to filter view object results. View criteria that you define at design time can participate in UI scenarios that require filtering of data.

Use the Edit View Criteria dialog to create the view criteria definition for the lookup base view object you defined to query the lookup table. The editor lets you build a WHERE clause using attribute name instead of the target view object's corresponding SQL column names. The resulting definition will include:

- One view criteria row consisting of one view criteria group, with a single view criteria item used to define the lookup view object's `Type` attribute.
- The view criteria item will consist of an `Type` attribute name, the Equal operator, and the value of the `LOOKUP_TYPE` that will filter the query results.

Because a single view criteria is defined, no logical conjunctions are needed to bracket the WHERE clause conditions.

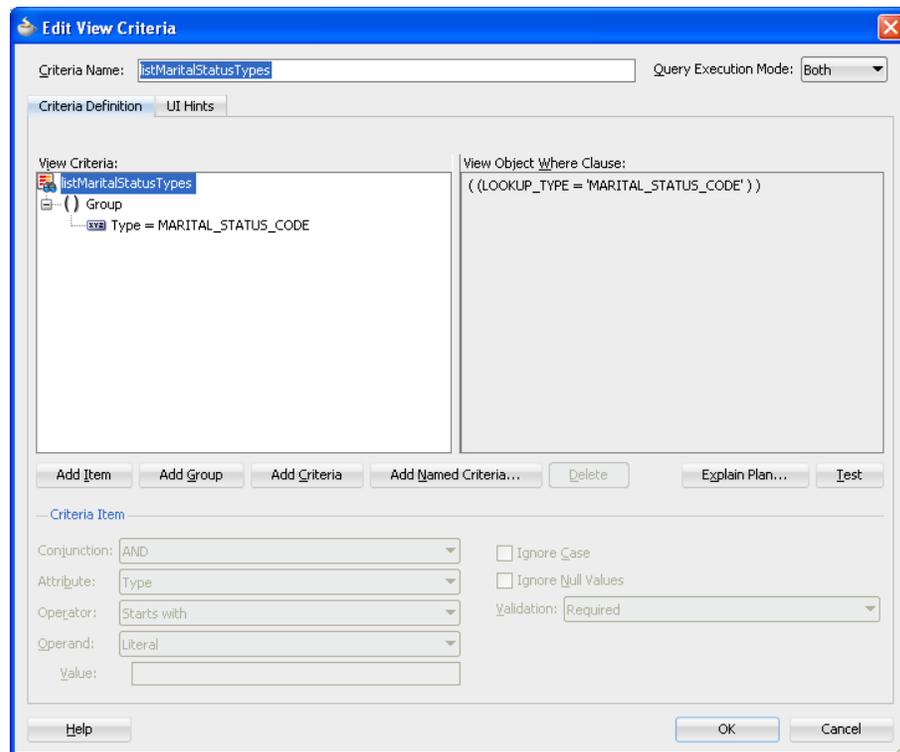

To create `LOOKUP_TYPE` view criteria for the lookup view object:

1. In the Application Navigator, double-click the lookup base view object you defined.
2. In the overview editor, click the **Query** navigation tab.
3. In the Query page, expand the **View Criteria** section, and click the **Create new view criteria** button.
4. In the Create View Criteria dialog, on the View Criteria page, click the **Add Item** button to add a single criteria item to the view criteria group.
5. In the **Criteria Item** panel, define the criteria item as follows:
 - Choose **Type** as the attribute (or other name that you defined for the attribute the view object maps to the `LOOKUP_TYPE` column).
 - Choose **equal to** as the operator.
 - Keep **Literal** as the operand choice and enter the value name that defines the desired type. For example, to query the marital status codes, you might enter the value `MARITAL_STATUS_CODE` corresponding to the `LOOKUP_TYPE` column.

Leave all other settings unchanged.

The view object WHERE clause shown in the editor should display a simple criteria similar to the one shown in [Figure 10-3](#), where the value `MARITAL_STATUS_CODE` is set to filter the `LOOKUP_TYPE` column.

6. Click **OK**.
7. Repeat this procedure to define one view criteria for each `LOOKUP_TYPE` that you wish to query.

Figure 10–3 Edit View Criteria Dialog with Lookup View Object View Criteria Specified

10.3.4 What Happens When You Create a View Criteria with the Editor

The Create View Criteria dialog in JDeveloper lets you easily create view criteria and save them as named definitions. These named view criteria definitions add metadata to the target view object's own definition. Once defined, named view criteria appear by name in the Query page of the overview editor for the view object.

JDeveloper then creates the XML component definition file that represents the view objects's declarative settings and saves it in the directory that corresponds to the name of its package. For example, the XML file created for a view object named LookupsBaseVO in the lookups package is `./lookups/LookupsBaseVO.xml` under the project's source path.

To view the view criteria, expand the desired view object in the Application Navigator, select the XML file under the expanded view object, open the Structure window, and expand the View Criteria node. As shown in [Example 10–4](#), the `LookupsBaseVO.xml` file specifies the `<ViewCriteria>` definition that allows the `LookupsBaseVO` to return only the marital types. Other view criteria added to the `LookupsBaseVO` are omitted from this example for brevity.

Example 10–4 listMaritalStatusTypes View Criteria in the Lookup View Object Definition

```
<ViewObject
  xmlns="http://xmlns.oracle.com/bc4j"
  Name="LookupsBaseVO"
  BindingStyle="OracleName"
  CustomQuery="true"
  PageIterMode="Full"
  UseGlueCode="false">
<SQLQuery>
  <![CDATA[SELECT L.LOOKUP_TYPE
```

```

        ,L.LOOKUP_CODE
        ,L.MEANING
        ,L.DESCRPTION
    FROM LOOKUP_CODES L
    WHERE L.LANGUAGE = SYS_CONTEXT('USERENV','LANG')
    ORDER BY L.MEANING]]>
</SQLQuery>
    ...
<ViewCriteria
    Name="listMaritalStatusTypes"
    ViewObjectName="oracle.fodemo.storefront.lookups.LookupsBaseVO"
    Conjunction="AND"
    Mode="3"
    <Properties>
        <CustomProperties>
            <Property
                Name="autoExecute"
                Value="false"/>
            <Property
                Name="showInList"
                Value="true"/>
            <Property
                Name="mode"
                Value="Basic"/>
        </CustomProperties>
    </Properties>
    <ViewCriteriaRow
        Name="vcrow24">
        <ViewCriteriaItem
            Name="Type"
            ViewAttribute="Type"
            Operator="="
            Conjunction="AND"
            Value="MARITAL_STATUS_CODE"
            Required="Optional"/>
        </ViewCriteriaRow>
    </ViewCriteria>

```

10.3.5 What Happens at Runtime: How a View Instance Accesses Lookup Data

When you create a view instance based on a view criteria, the next time the view instance is executed it augments its SQL query with an additional `WHERE` clause predicate corresponding to the view criteria that you've populated in the view criteria rows.

10.4 Accessing View Instances of the Shared Service

View accessors in ADF Business Components are value accessor objects that point from an entity object attribute (or view object) to a destination view object or shared view instance in the same application workspace. The view accessor returns a row set that by default contains all rows from the destination view object. You can optionally filter this row set by applying view criteria to the view accessor. The base entity object or view object on which you create the view accessor and the destination view object need not be in the same project or application module, but they must be in the same application workspace.

Because view accessors give you the flexibility to reach across application modules to access the queried data, they are ideally suited for accessing view instances of shared

application modules. For details about creating a data model of view instances for a shared application module, see [Section 10.2.1, "How to Create a Shared Application Module Instance."](#)

This ability to access view objects in different application modules makes view accessors particularly useful for:

- Validation rules that you set on the attributes of an entity object. In this case, the view accessor derives the validation rule's values from lookup data corresponding to a view instance attribute in the shared application module.
- List of Value (LOV) that you enable for the attribute of any view object. In this case, the view accessor derives the list of values from lookup data corresponding to a view instance attribute in the shared application module.

Validation rules with accessors are useful when you do not want the UI to display a list of values to the user, but you still need to restrict the list of valid values. Alternatively, consider defining an LOV for view object attributes to simplify the task of working with list controls in the user interface. Because you define the LOV on the individual attributes of business components, you can customize the LOV usage for an attribute once and expect to see the list control in the form wherever the attribute appears.

10.4.1 How to Create a View Accessor for an Entity Object or View Object

Entity-based view objects inherit view accessors that you define on their base entity objects. Thus, defining the view accessor once on the entity object itself allows you to reuse the same view accessor, whether you want to define validation rules for entity object attributes or to create LOV-enabled attributes for that entity object's view object. However, when you do not anticipate using view accessors for validation rules, you can add the view accessor directly to the view object that defines the LOV-enabled attribute.

For example, in the `StoreFrontModule` package of the Fusion Order Demo application, the `AddressEO` entity object defines the `Shared_CountriesVA` view accessor and the `AddressesVO` view object inherits this view accessor. In this case, defining the view accessor on the entity object is useful: the accessor for `AddressEO` defines a validation rule on the `CountryId` attribute and the same accessor for `AddressesVO` enables an LOV on its `CountryId` attribute.

When you create a view accessor that accesses a view instance from a shared application module, you may want to use a prefix like `Shared_` to name the view accessor. This naming convention will help you identify the view accessor when you need to select it for the entity object or view object.

You can further refine the list returned by a view accessor by applying view criteria that you define on the view object. To create view criteria for use with a view accessor, see [Section 10.3.3, "How to Define the WHERE Clause of the Lookup View Object Using View Criteria."](#)

To create the view accessor:

1. In the Application Navigator, double-click the entity object or view object on which you want to define the view accessor.

Whether you create the view accessor on the entity object or on the view object will depend on the view accessor's intended usage. Generally, creating view accessors on the entity object ensures the widest possible usage.

2. In the overview editor, click the **View Accessors** navigation tab and click the **Create new view accessors** button to add the accessor to the entity object or view object definition you are currently editing.
3. In the View Accessors dialog, select the view instance name you created for your lookup table from the shared application module node and shuttle it to the view accessors list.

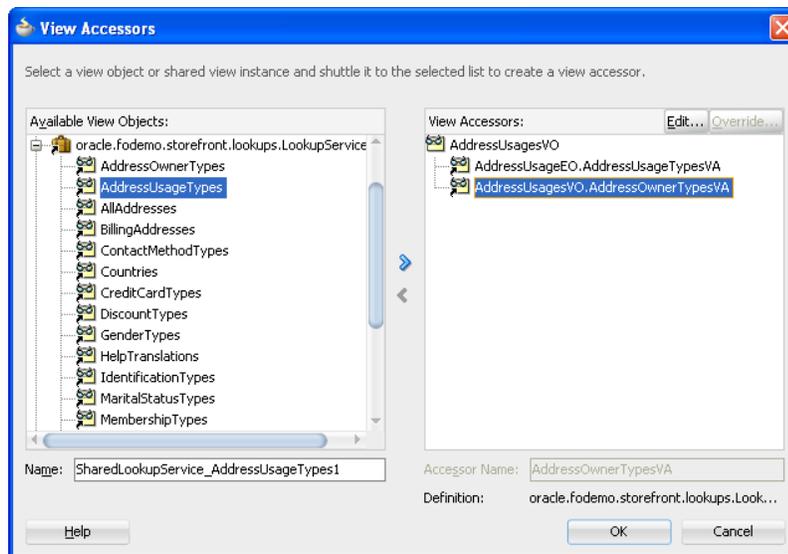

For example, the View Accessors dialog in the Fusion Order Demo application shows the shared application module `LookupServiceAM` with the list of view instances, as shown in [Figure 10-4](#).

The dialog will display all view objects and view instances from your application. If you have not yet enabled application module sharing, you must do so before selecting the view instance. For details, see [Section 10.2.1, "How to Create a Shared Application Module Instance."](#)

By default, the view accessor you create will display the same name as the view object instance (or will have an integer appended when it is necessary to distinguish it from a child view object of the same name). You can edit **Accessor Name** to give it a unique name.

For example, the View Accessors dialog in [Figure 10-4](#) shows the view accessor `AddressUsageTypesVA` for the `AddressUsageTypes` view instance selection in the shared application module `LookupServiceAM`. This view accessor is created on the base entity object `AddressUsagesEO` and accesses the row set of the `AddressUsageTypes` view instance.

Figure 10-4 Defining a View Accessor on an Entity Object

4. Optionally, if you want to apply an existing view criteria to filter the accessor, with the view accessor selected in the overview editor, click the **Edit** icon.

In the Edit View Accessor dialog, click **Edit** and perform the following steps to apply the view criteria:

- a. Select the view criteria that you want to apply and shuttle it to the **Selected** list.

You can add additional view criteria to apply multiple filters (a logical AND operation will be performed at runtime).

- b. Enter the attribute name for the bind variable that defines the controlling attribute for the view accessor row set.

Unlike view criteria that you set directly on a view object (to create a view instance, for example), the controlling attribute of the view accessor's view criteria derives the value from the view accessor's base view object.

- c. Click **OK** to return to the View Accessors dialog.
5. Click **OK**.

10.4.2 How to Validate Against the Attribute Values Specified by a View Accessor

View accessors that you create to access the view rows of a destination view object may be used to verify data that your application solicits from the end user at runtime. For example, when the end user fills out a registration form, individual validation rules can verify the title, marital status, and contact code against lookup table data queried by view instances of the shared application module.

You can apply view accessors you have defined on the entity object to these built-in declarative validation rules:

- The Compare validator performs a logical comparison between an entity attribute and a value. When you specify a view accessor to determine the possible values, the compare validator applies the `Equals`, `NotEquals`, `GreaterThan`, `LessThan`, `LessOrEqualTo`, `GreaterOrEqualTo` operator you select to compare against the values returned by the view accessor.
- The List validator compares an entity attribute against a list of values. When you specify a view accessor to determine the valid list values, the List validator applies an `In` or `NotIn` operator you select against the values returned by the view accessor.
- The Collection validator performs a logical comparison between an operation performed on a collection attribute and a value. When you specify a view accessor to determine the possible values, the Collection validator applies the `Sum`, `Average`, `Count`, `Min`, `Max` operation on the selected collection attribute to compare against the values returned by the view accessor.

Validation rules that you define to allow runtime validation of data for entity-based view objects are always defined on the attributes of the entity object. You use the editor for the entity object to define the validation rule on individual attributes. Any view object that you later define that derives from an entity object with validation rules defined will automatically receive attribute value validation.

Before you begin:

Create the desired entity objects as described in [Section 4.2.1, "How to Create Multiple Entity Objects and Associations from Existing Tables."](#)

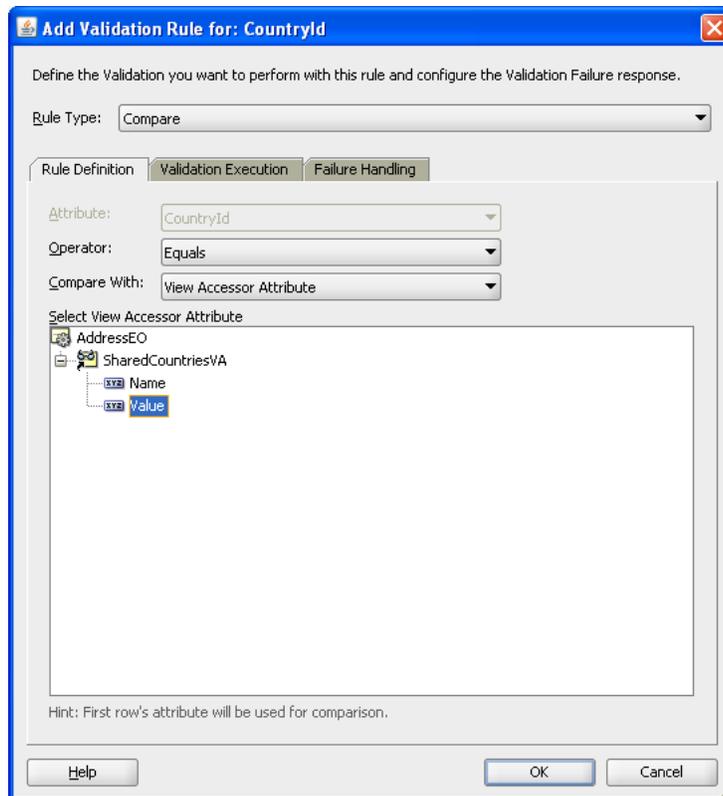

To validate against a view accessor comparison, list, or collection type:

1. In the Application Navigator, double-click the desired entity object.
2. In the overview editor, click the **Business Rules** navigation tab.
3. In the Business Rules page, expand the entity object, select the attribute to be validated and then click the **Create new validator** button to add the validation rule to the entity object attribute.
4. In the Add Validation Rule dialog, in the **Rule Type** dropdown list, select **Compare**, **List**, or **Collection**.

5. Make the selections required by the validator selection.
6. In the **Compare With** or **List Type** dropdown list, select **View Accessor Attribute**.
7. In the **Select View Accessor Attribute** group box, expand the desired view accessor from the shared service and select the attribute you want to provide as validation.

Figure 10–5 shows what the dialog looks like when you use a List validator to select a view accessor attribute.

Figure 10–5 List Validator Using a View Accessor

8. Click the **Failure Handling** tab and enter a message that will be shown to the user if the validation rule fails.
9. Click **OK**.

10.4.3 What Happens When You Define a View Accessor Validator

When you use a List validator, a `<ListValidationBean>` tag is added to an entity object's XML file. Example 10–5 shows the XML code for the `CountryId` attribute in the `Address` entity object. A List validator has been used to validate the user's entry against the list of country ID values as retrieved by the view accessor from the `Countries` view instance.

Example 10–5 List Validator with View Accessor List Type XML Code

```
<Attribute
  Name="CountryId"
  IsNotNull="true"
  Precision="2"
```

```

ColumnName="COUNTRY_ID"
Type="java.lang.String"
ColumnType="CHAR"
SQLType="VARCHAR"
TableName="ADDRESSES">
RetrievedOnUpdate="true"
RetrievedOnInsert="true">
<DesignTime>
  <Attr Name="_DisplaySize" Value="2"/>
</DesignTime>
<ListValidationBean
  xmlns="http://xmlns.oracle.com/adfm/validation"
  Name="CountryId_Rule_1"
  ResId="CountryId_Rule_0"
  OnAttribute="CountryId"
  OperandType="VO_USAGE"
  Inverse="false"
  ViewAccAttrName="Value"
  ViewAccName="SharedCountriesVA">
  <ResExpressions>
    <Expression
      Name="0"><![CDATA[SharedCountriesVA.Value]]>
    </Expression>
  </ResExpressions>
</ListValidationBean>
<Properties>
  <SchemaBasedProperties>
    <LABEL
      ResId="CountryId_LABEL" />
  </SchemaBasedProperties>
</Properties>
</Attribute>

```

10.4.4 What You May Need to Know About Dynamic Filtering with View Accessors

The View Object API `setWhereClause()` method allows you to add a dynamic WHERE clause to a view instance whose view accessor may already have view criteria specified at design time. At runtime, when your view accessor and its view criteria is applied to the view instance and you call the `setWhereClause()` method on the view instance to add an extra WHERE clause, the programmatically set WHERE clause is AND-ed with the WHERE clause of any already applied view criteria.

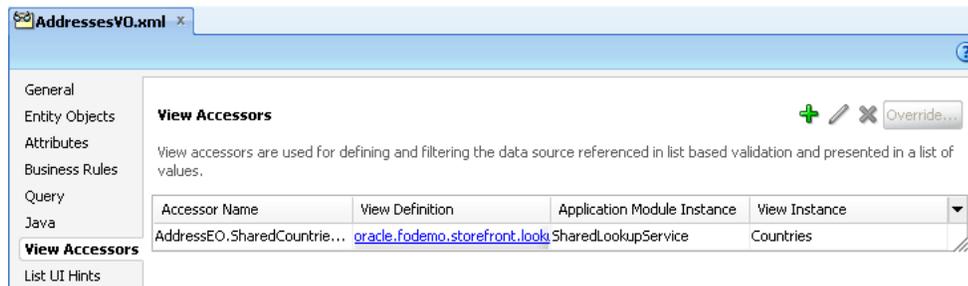

10.4.5 How to Create an LOV Based on a Lookup Table

View accessors that you create to access the view rows of a destination view object may be used to display a list of values to the end user at runtime. You first create a view accessor with the desired view instance as its data source, and then you can add the view accessor to an LOV-enabled attribute of the displaying view object. You will edit the view accessor definition for the LOV-enabled attribute so that it points to the specific lookup attribute of the view instance. Because you want to populate the row set cache for the query with static data, you would locate the destination view instance in a shared application module.

While the list usage is defined on the attribute of a view object bound to a UI list control, the view accessor definition exists on either the view object or the view object's base entity object. If you choose to create the view accessor on the view object's entity object, the View Accessors page of the overview editor for the view object will display the inherited view accessor, as shown in [Figure 10-6](#). Alternatively,

if you choose to create the view accessor on the attribute's view object, you can accomplish this from either the editor for the LOV definition or from the View Accessors page of the overview editor.

Figure 10–6 View Accessors Page of the Overview Editor

For additional examples of how to work with LOV-enabled attributes, see [Section 5.12, "Working with List of Values \(LOV\) in View Object Attributes."](#)

Before you begin:

Create the desired view objects as described in [Section 5.2.1, "How to Create an Entity-Based View Object,"](#) and [Section 5.2.3, "How to Create an Expert Mode, Read-Only View Object."](#)

To create an LOV that displays values from a lookup table:

1. In the Application Navigator, right-click the view object that contains the desired attribute and choose **Open ViewObjectName**.
2. In the overview editor, click the **View Accessors** navigation tab.
3. In the View Accessors page, check to see whether the view object inherited the desired view accessor from its base entity object. If no view accessor is present, either create the view accessor on the desired entity object or click the **Create new view accessors** icon to add the accessor to the view object you are currently editing.

Validation rules that you define are always defined on the attributes of the view object's base entity object. It may therefore be convenient to define view accessors at the level of the base entity objects when you know that you will also validate entity object attributes using a view accessor list.

For details about creating a view accessor, see [Section 10.4.1, "How to Create a View Accessor for an Entity Object or View Object."](#)

4. In the overview editor, click the **Attributes** navigation tab.
5. In the Attributes page, select the attribute that is to display the LOV, and then click the **List of Values** tab and click the **Add list of values** icon.
6. In the Create List of Values dialog, select the view accessor from the **List Data Source** dropdown list.

The view accessor you select, will be the one created for the lookup table view object instances to use as the data source.

7. Select the attribute from this view accessor from the **List Attribute** dropdown list that will return the list of values for the attribute you are currently editing.

The editor creates a default mapping between the view object attribute and the LOV-enabled attribute. In this use case, the attributes are the same. For example,

the attribute `OrderId` from the `OrdersView` view object would map to the attribute `OrderId` from the `Shared_OrdersVA` view accessor.

8. Optionally, when you want to specify supplemental values that your list returns to the base view object, click **Add** icon in **List Return Values** and map the desired view object attributes to the same attributes accessed by the view accessor. Supplemental attribute return values are useful when you do not require the user to make a list selection for the attributes, yet you want those attributes values, as determined by the current row, to participate in the update.

For example, to map the attribute `StartDate` from the `OrdersView` view object, you would choose the attribute `StartDate` from the `Shared_OrdersVA` view accessor. Do not remove the default attribute mapping for the attribute for which the list is defined.

9. Click **OK**.

10.4.6 What Happens When You Define an LOV for a View Object Attribute

When you add an LOV to a view object attribute, JDeveloper updates the view object's XML file with an `LOVName` property in the `<ViewAttribute>` element. The definition of the LOV appears in a new `<ListBinding>` element. The metadata in [Example 10–6](#) shows that the `MaritalStatusCode` attribute refers to the `MaritalStatusLOV` LOV and sets the choice control type to display the LOV. The LOV definition for `MaritalStatusLOV` appears in the `<ListBinding>` element.

Example 10–6 View Object with LOV List Binding XML Code

```
<ViewObject
  xmlns="http://xmlns.oracle.com/bc4j"
  Name="CustomerRegistrationVO"
  ...
  <ViewAttribute Name="MaritalStatusCode" IsNotNull="true" PrecisionRule="true"
    EntityAttrName="MaritalStatusCode" EntityUsage="PersonEO"
    AliasName="MARITAL_STATUS_CODE"
    LOVName="MaritalStatusCodeLOV">
    <Properties>
      <SchemaBasedProperties>
        <CONTROLTYPE Value="choice"/>
      </SchemaBasedProperties>
    </Properties>
  </ViewAttribute>
  ...
<ListBinding
  Name="MaritalStatusLOV"
  ListVOName="PersonEO.MaritalStatusVA"
  ListRangeSize="-1"
  NullValueFlag="start"
  NullValueId="LOVUIHints_NullValueId"
  MRUCount="0">
  <AttrArray Name="AttrNames">
    <Item Value="MaritalStatusCode"/>
  </AttrArray>
  <AttrArray Name="ListAttrNames">
    <Item Value="Value"/>
  </AttrArray>
  <AttrArray Name="ListDisplayAttrNames">
    <Item Value="Name"/>
  </AttrArray>
  <DisplayCriteria/>
```

```
<AttrArray Name="DerivedAttrNames" />
</ListBinding>
...
</ViewObject>
```

10.4.7 How to Automatically Refresh the View Object of the View Accessor

If you need to ensure that your view accessor always queries the latest data from the lookup table, you can set the **Auto Refresh** property on the destination view object. This property allows the view object instance to refresh itself after a change in the database. The typical use case is when you define a view accessor for the destination view object.

Because the auto-refresh feature relies on the database change notification feature, observe these restrictions when enabling auto-refresh for your view object:

- The view objects should query as few read-only tables as possible. This will ensure the best performance and prevent the database invalidation queue from becoming too large.
- The database user must have database notification privileges. For example, to accomplish this with a SQL*Plus command use `grant change notification to <user name>`.

When these restrictions are observed, the refresh is accomplished through the Oracle database change notification feature. Prior to executing the view object query, the framework will use the JDBC API to register the query for database notifications. When a notification arrives, the row sets of the corresponding view object instance are marked for refresh during the next checkout of the application module. Because the shared application module waits until the next checkout, the row set currency of the current transaction is maintained and the end user is not hampered by the update.

For example, assume that an LOV displays a list of zip codes that is managed in read-only fashion by a database administrator. After the administrator adds a new zip code as a row to the database, the shared application module detects a time when there are no outstanding requests and determines that a pending notification exists for the view instance that access the list of zip codes; at that point, the view object refreshes the data and all future requests will see the new zip code.

To enable auto-refresh for a view instance of a shared application module:

1. In the Application Navigator, double-click the view object that you want to receive database change notifications.
2. In the overview editor, click the **General** navigation tab.
3. In the Property Inspector expand the **Tuning** section, and select **True** for the **Auto Refresh** property.

10.4.8 What Happens at Runtime: How the Attribute Displays the List of Values

The ADF Business Components runtime adds functionality in the attribute setters of the view row and entity object to facilitate the LOV-enabled attribute behavior. In order to display the LOV-enabled attribute values in the user interface, the LOV facility fetches the data source, and finds the relevant row attributes and mapped target attributes.

10.4.9 What You May Need to Know About Programmatically Invoking Database Change Notifications

When you create a databound UI component in a web page, you can enable the auto-refresh feature on the corresponding view object, as described in [Section 10.4.7, "How to Automatically Refresh the View Object of the View Accessor."](#) In this case, the ADF Model layer and ADF Business Components will handle processing database change notifications at runtime and the shared application module cache will be updated for you. However, when you create a method to programmatically refresh a view instance of a shared application module, your method needs to invoke the `processChangeNotification()` method on the shared application module before you refresh the view instance. [Example 10-7](#) shows how to use the `processChangeNotification()` method to ensure the shared application module cache gets updated if the corresponding queried data has changed in the database.

Example 10-7 Programmatically Invoking a View Instance and Processing the Database Change Notification

```
public String getProduct(Long id) {
    ApplicationModuleHandle handle = null;
    try {
        handle = Configuration.createRootApplicationModuleHandle
            ("oracle.apps.mlss.model.applicationModule.ProductAM", "ProductAMShared");
        ApplicationModule sam = handle.useApplicationModule();
        sam.processChangeNotifications();

        ViewObject svo = sam.findViewObject("Product");
        svo.setNamedWhereClauseParam("bindProductId", id);
        svo.setNamedWhereClauseParam("bindLang", "US");
        ((ViewObjectImpl)svo).refreshCollection(null, false, false);
        svo.reset();
        while (svo.hasNext()) {
            Row r = svo.next();
            return (String)r.getAttribute("Name");
        }
    } finally {
        if (handle != null)
            Configuration.releaseRootApplicationModuleHandle(handle, false);
    }

    return null;
}
```

10.4.10 What You May Need to Know About Inheritance of AttributeDef Properties

When one view object extends another, you can create the LOV-enabled attribute on the base object. Then when you define the child view object in the overview editor, the LOV definition will be visible on the corresponding view object attribute. This inheritance mechanism allows you to define an LOV-enabled attribute once and apply it later across multiple view objects instances for the same attribute. For details about extending a view object from another view object definition, see [Section 12.9.2, "How To Extend a Component After Creation."](#)

You can also use the overview editor to extend the inherited LOV definition. For example, you may add extra attributes already defined by the base view object's query to display in selection list. Alternatively, you can create a view object instance that uses a custom WHERE clause to query the supplemental attributes not already queried by

the base view object. For information about customizing entity-based view objects, see [Section 5.10, "Working with Bind Variables."](#)

10.4.11 What You May Need to Know About Using Validators

If you have created an LOV-enabled attribute for a view object, there is no need to validate the attribute using a List validator. You use an attribute validator only when you do not want the list to display in the user interface but still need to restrict the list of valid values. A List validator may be a simple static list or it may be a list of possible values obtained through a view accessor you define. Alternatively, you might prefer to use a Key Exists validator when the attribute displayed in the UI is one that references a key value (such as a primary, foreign, or alternate key). For information about declarative validation in ADF Business Components, see [Chapter 7, "Defining Validation and Business Rules Declaratively."](#)

10.5 Testing View Object Instances in a Shared Application Module

JDeveloper includes an interactive application module testing tool that you can use to test all aspects of its data model without having to use your application user interface or write a test client program. Running the Oracle ADF Model Tester can often be the quickest way of exercising the data functionality of your business service during development.

10.5.1 How to Test the Base View Object Using the Oracle ADF Model Tester

The application module is the transactional component that the Oracle ADF Model Tester (or UI client) will use to work with application data. The set of view objects used by an application module defines its data model, in other words, the set of data that a client can display and manipulate through a user interface. You can use the Oracle ADF Model Tester to test that the accessors you defined yield the expected validation result and that they display the correct LOV attribute values.

To create an application module, use the Create Application Module wizard, which is available in the New Gallery. For more information, see [Section 9.2, "Creating and Modifying an Application Module."](#)

To test the view objects you added to an application module, use the Oracle ADF Model Tester, which is accessible from the Application Navigator.

To test view objects in an application module configuration:

1. In the Application Navigator, expand the project containing the desired application module and view objects.
2. Right-click the application module and choose **Run**.

Alternatively, choose **Debug** when you want to run the application in the Oracle ADF Model Tester with debugging enabled. For example, when debugging using the Oracle ADF Model Tester, you can view status message and exceptions, step in and out of source code, and manage breakpoints. JDeveloper opens the debugger process panel in the Log window and the various debugger windows.

For details about receiving diagnostic messages specific to ADF Business Components debugging, see [Section 6.3.8, "How to Enable ADF Business Components Debug Diagnostics."](#)

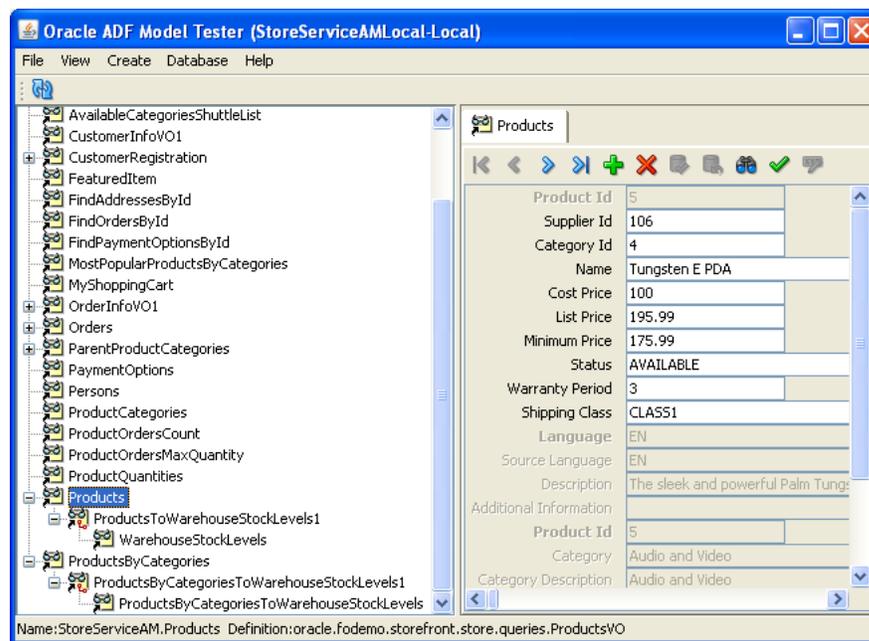

3. In the Select Business Components Configuration dialog, choose the desired application module configuration from the **Business Component Configuration Name** list to run the Oracle ADF Model Tester.

By default, an application module has only its default configurations, named `AppModuleNameLocal` and `AppModuleNameShared`. If you have created additional configurations for your application module and want to test it using one of those instead, just select the desired configuration from the **Business Components Configuration** dropdown list on the Connect dialog before clicking **Connect**.

4. Click **Connect** to start the application module using the selected configuration.
5. To execute a view object in the Oracle ADF Model Tester, expand the tree list and double-click the desired view object node.

Note that the view object instance may already appear executed in the testing session. In this case, the tester panel on the right already displays query results for the view object instance, as shown in [Figure 10–7](#). The fields in the tester panel of a read-only view object will always appear disabled since the data it represents is not editable.

Figure 10–7 Testing the Data Model in the Oracle ADF Model Tester

10.5.2 How to Test LOV-Enabled Attributes Using the Oracle ADF Model Tester

To test the LOV you created for a view object attribute, use the Oracle ADF Model Tester, which is accessible from the Application Navigator. For details about displaying the tester and the supported control types, see [Section 5.12.8, "How to Test LOV-Enabled Attributes Using the Oracle ADF Model Tester."](#)

10.5.3 What Happens When You Use the Oracle ADF Model Tester

When you launch the Oracle ADF Model Tester, JDeveloper starts the tester tool in a separate process and the Oracle ADF Model Tester appears. The tree at the left of the dialog displays all of the view object instances in your application module's data model. [Figure 10–7](#) shows just one instance in the expanded tree, called `ProductImages`. After you double-click the desired view object instance, the Oracle ADF Model Tester will display a panel to inspect the query results, as shown in [Figure 10–7](#).

The test panel will appear disabled for any read-only view objects you display because the data is not editable. But even for the read-only view objects, the tool affords some useful features:

- You can validate that the UI hints based on the Label Text control hint and format masks are defined correctly.
- You can also scroll through the data using the toolbar buttons.

The Oracle ADF Model Tester becomes even more useful when you create entity-based view objects that allow you to simulate inserting, updating, and deleting rows, as described in [Section 6.3.2, "How to Test Entity-Based View Objects Interactively."](#)

10.5.4 What Happens at Runtime: How Another Service Accesses the Shared Application Module Cache

When a shared application module with application scope is requested by an LOV, then the ADF Business Components runtime will create an `ApplicationPool` object for that usage. There is only one `ApplicationPool` created for each shared usage that has been defined in the ADF Business Components project configuration file (`.jspx`). The runtime will then use that `ApplicationPool` to acquire an application module instance that will be used like a user application module instance, to acquire data. The reference to the shared application module instance will be released once the application-scoped application module is reset. The module reference is released whenever you perform an unmanaged release or upon session timeout.

Since multiple threads will be accessing the data caches of the shared application module, it is necessary to partition the iterator space to prevent race conditions between the iterators of different sessions. This will help ensure that the next request from one session does not change the state of the iterator that is being used by another session. The runtime uses ADF Business Components support for multiple iterators on top of a single `RowSet` to prevent these race conditions. So, the runtime will instantiate as many iterators as there are active sessions for each `RowSet`.

An application-scoped shared application module lifecycle is similar to the lifecycle of any application module that is managed by the `ApplicationPool` object. For example, once all active sessions have released their shared application module, then the application module may be garbage-collected by the `ApplicationPool` object. The shared pool may be tuned to meet specific application requirements.

Session-scoped shared application modules are simply created as nested application module instances within the data model of the root, user application module. For details about nested application modules, [Section 9.4, "Defining Nested Application Modules."](#)

Integrating Service-Enabled Application Modules

This chapter describes how to publish ADF application modules to make them available as external services in a Fusion web application, and how to incorporate the published application module as an external service in the Fusion web application.

This chapter includes the following sections:

- [Section 11.1, "About Service-Enabled Application Modules"](#)
- [Section 11.2, "Publishing Service-Enabled Application Modules"](#)
- [Section 11.3, "Accessing Remote Data Over the Service-Enabled Application Module"](#)

11.1 About Service-Enabled Application Modules

Service-enabled application modules are ADF application modules that you advertise through a service interface to service consumers. There are three scenarios for service consumers to consume a published service-enabled application module: web service access, Service Component Architecture (SCA) composite access, and access by another ADF application module.

Service Component Architecture (SCA) provides an open, technology-neutral model for implementing remotable services that are defined in terms of business functionality and that make middleware functions more accessible to application developers. ADF Business Components supports an SCA-compliant solution through application modules you can publish with a service interface.

When you service-enable your application module, JDeveloper generates the necessary artifacts comprising: 1) The Java interface defining the service, 2) an EJB 3.0 session bean that implements this Java interface, 3) a WSDL file that describes the service's operations, and (4) an XML Schema Document (XSD) that defines the service's data structures. The service interface is described for Fusion web application clients in a language-neutral way by the combination of WSDL and XSD.

SCA defines two kinds of service:

- Remoteable services, typically coarse-grained and designed to be published remotely in a loosely coupled SOA architecture
- Local services, typically fine-grained and designed to be used locally by other implementations that are deployed concurrently in a tightly coupled architecture

ADF Business Components services fall into the first category, and should only be used as remoteable services.

ADF Business Components services, including data access and method calls, defined by the remote application modules are interoperable with any other application module. This means the same application module can support interactive web user interfaces using ADF data controls and web service clients.

11.1.1 Service-Enabled Application Module Use Cases and Examples

Any development team can publish a service-enabled application module to contribute to the Fusion web application. The Fusion web application assembled from remote services also does not require the participating services to run on a single application server.

Although the web applications may run on separate application servers, the appearance that SCA provides is one of a unified application. Consuming client projects use the ADF service factory lookup mechanism to access the data and any business methods encapsulated by the service-enabled application module. At runtime, the calling client and the ADF web service may or may not participate in the same transaction, depending on the protocol used to invoke the service (either SOAP or RMI). Only the RMI protocol and a Java Transaction API (JTA) managed transaction support the option to call the service in the same transaction as the calling client. By default, to support the RMI protocol, the ADF web service is configured to participate in the same transaction.

11.1.2 Additional Functionality for Service-Enabled Application Modules

You may find it helpful to understand other ADF features before you start working with ADF Business Components services. Following are links to other functionality that may be of interest.

- For information about the SCA and service data object (SDO) standards, see the Open SOA web site at <http://www.osoa.org>.
- For further background about web services and Oracle WebLogic Server support for web services, see *Oracle Fusion Middleware Introducing Web Services*.
- For details about how to delegate data operations to the SDO data provider through the use of the Business Process Execution Language (BPEL) entity variable, see the *Oracle Fusion Middleware Developer's Guide for Oracle SOA Suite*.
- For local service support, use the ApplicationModule interface and ViewObject interface support described in [Section 9.10, "Working Programmatically with an Application Module's Client Interface."](#)
- For API documentation related to the `oracle.jbo` package, see the following Javadoc reference document:
 - *Oracle Fusion Middleware Java API Reference for Oracle ADF Model*

11.2 Publishing Service-Enabled Application Modules

The application module is ADF Business Components framework component that encapsulates business logic as a set of related business functions. Application modules are mapped to services. You use the overview editor for your application module to enable a web service interface and publish rows of view object data as service data object (SDO) components.

The SDO framework upon which the SDO components are based abstracts the data of the view object and standardizes the way that data structures are passed between Java and XML. This data abstraction simplifies working with heterogeneous data sources in

a service-oriented architecture (SOA) and lets you selectively service-enable view objects using the same view object to support interactive web user interfaces and web service clients.

JDeveloper allows you to expose application modules as web services which use SDO components based on view instance that your application module defines to standardize the way that data structures are passed between Java and XML. JDeveloper also generates the WSDL service description that is used by the web service client in the consuming application.

Note: JDeveloper only supports generating SDO components for view objects of a service-enabled application module. Currently, no other Oracle ADF business components may be defined as SDO components.

The service-enabled application module exposes the view objects, custom methods, built-in data manipulation operations, and specialized find methods based on named view criteria to be used by the client. Once you have enabled the application module service interface, you will need to create an ADF Business Components Service Interface deployment profile and deploy it to the target application server.

You can also expose the view instance data manipulation operations for use with a Business Process Execution Language (BPEL) process service component. BPEL is a language for composing multiple services into an end-to-end business process. For details about how to delegate data operations to the SDO data provider through the use of the BPEL entity variable, see the *Oracle Fusion Middleware Developer's Guide for Oracle SOA Suite*.

Note: It is important to note that you don't implement methods with SDO parameters directly. The SDO framework is used to wrap the view row types during runtime only.

11.2.1 How to Enable the Application Module Service Interface

You edit the application module in JDeveloper to create a web service interface that exposes the top-level view objects and defines the available service operations it supports. The top-level view objects that you select are service-enabled automatically and will be accessible by the service client.

The primary purpose of the standard service operations is to expose data manipulation operations on the view objects. Any business logic that you have defined on the underlying framework objects (for example, business rule validation) will be applied when you invoke a standard service operation. [Table 11-1](#) shows the list of standard operations that service view instances support.

Table 11-1 Standard View Instance Data Manipulation Operations

Operation	Method Name	Operation Description
Create	create<VOName>	Creates a single ADF Business Components view row.
Update	update<VOName>	Updates a single ADF Business Components view row.
Delete	delete<VOName>	Deletes a single ADF Business Components view row.

Table 11–1 (Cont.) Standard View Instance Data Manipulation Operations

Operation	Method Name	Operation Description
Merge	<code>merge<VOName></code>	Updates a ADF Business Components view row if one exists; otherwise, creates a new one.
GetByKey	<code>get<VOName></code>	Gets a single ADF Business Components view row by primary key.
Find (by view object query statement)	<code>find<VOName></code>	Finds and returns a list of ADF Business Components view rows based on the selected view object's query statement. Note that the query must not specify a bind variable defined as required for the query to execute. The service interface does not expose required bind variables at runtime. For details about creating a find method for this scenario, see Section 11.2.8, "How to Expose a Declarative Find Operation Filtered By a Required Bind Variable."
Find (by view criteria)	<code>find<VOName><VCName></code>	Finds and returns a list of single ADF Business Components view rows by SDO-based view criteria. This is the preferred way to filter the ADF Business Components view rows that rely on a required bind variable.
Process	<code>process<VOName></code>	Performs a Create, Update, Delete, or Merge operation on a list of ADF Business Components view rows. The specified operation is applied to all objects in the given list.
ProcessChangeSummary	<code>processCS<VOName></code>	Performs a Create, Update, or Delete operation on a list of ADF Business Components view rows. Different operations may be applied to different objects, depending on what is specified in the ChangeSummary object.

Note: When you generate a SDO class for a parent view object, JDeveloper automatically generates SDO classes for view instances that extend the parent in a polymorphic collection. For details about polymorphic view objects, see [Section 42.6.5, "Working with Polymorphic View Rows."](#)

For information on how to create SDO classes for child view objects, see [Section 11.2.4, "How to Service-Enable Individual View Objects."](#)

Before you begin:

It may be helpful to have an understanding of how the SDO framework supports service-enabled ADF application modules and enables web service clients to access rows of data and perform service operations. For more information, see [Section 11.2, "Publishing Service-Enabled Application Modules."](#)

When you create the service-enabled application module, do not create it in a project that already contains a standard web service (a Java class or interface with the `@WebService` annotation). JDeveloper deployment profiles do not support deploying

a standard web service and an ADF Business Service web service from the same project. If you attempt to deploy the ADF Business Service web service from the same project as a standard web service, the deployment will fail with an Oracle WebLogic Server exception error.

Complete these tasks:

- Create the desired view objects, as described in [Section 5.2.1, "How to Create an Entity-Based View Object,"](#) and [Section 5.2.3, "How to Create an Expert Mode, Read-Only View Object."](#)
- Create the desired application module as described in [Section 9.2.1, "How to Create an Application Module."](#)
- Optionally, set JDeveloper preferences to specify a default suffix for the names of generated SDO classes, modify the default subpackage where the service common interface and classes reside, and set the default namespace prefix for the generated SDO schema and web service as described in [Section 11.2.13, "How to Set Preferences for Generating the ADF Web Service Interface."](#)
- If you want to expose custom find operations on the service, create declarative view criteria to specify the custom query as described in [Section 5.11.1, "How to Create Named View Criteria Declaratively."](#)

To create the web service interface:

1. In the Application Navigator, double-click the application module.
2. In the overview editor, click the **Service Interface** navigation tab and click the **Enable support for Service Interface** button.

Use the Create Service Interface wizard to configure the desired options.

3. In Create Service Interface wizard, on the Service Interface page, enter the name and target namespace for the web service.

The target namespace is a URI for the service that you can assign to group similar services together by entering the same URI.

4. To generate a method that will return the static control hints (UI hints) defined on the view instances that you service enable, select **Generate Control Hints Operation**.

When you enable this option, the wizard adds the `getDefaultCtrlHints()` method to the service interface. The service interface client can invoke this method to resolve UI hints on the server without requiring a database roundtrip. The method takes the view object name and a locale and returns the base UI hints for that locale.

5. To expose the methods of the application module as asynchronous service methods and enable both synchronous and asynchronous operations on the web service, select **Generate Asynchronous Web Service Methods**.

By default, the web service supports synchronous service methods. This forces the invoking client application to wait for the response to return before it can continue with its work. In cases where the response returns immediately, this method of invoking the web service is common. However, because request processing can be delayed, it is often useful for the client application to continue its work and to handle the response later on.

6. On the Service Custom Methods page, add the custom methods you want to expose in the service interface and define the data types of each method's parameters and return value.

The parameters and non-void return value of the custom service methods you enable must be one of the service-interface supported data types, such as a Java primitive type, or a list of the service-interface supported data types (including `oracle.jbo.server.ViewRowImpl`, `java.util.List<ViewRowImpl>`, `oracle.jbo.AttributeList`, `java.util.List<AttributeList>`, or `java.util.List<PrimitiveType>`).

Note that although both `ViewRowImpl` and `AttributeList` data types expose the identical row structure to the web service client, at runtime there will be a fundamental difference. For a description of the supported data types, see [Section 11.2.3, "What You May Need to Know About Method Signatures on the ADF Web Service Interface."](#)

After selecting a qualifying custom method to appear in the service interface, for each parameter and return value using the `ViewRowImpl` or `AttributeList` data type, you must in turn select the name of the view object instance corresponding to the row structure:

- a. In the Selected list, expand **return** or **parameters** and select the item.
- b. Enter the Java element data type in **Element Java Type**.
- c. In the case where the Java element type is `ViewRowImpl` or `AttributeList`, enter the view object instance name to identify the row structure in **Element View Object**.

For example, if you define a custom method to return a single row of the `CustomerInfo` view object instance, you would need a custom method signature like this:

```
public ViewRowImpl findCustomerInfo(int id)
```

Then, after selecting the `findCustomerInfo()` custom method to appear in the service interface, you would select its return value in the tree and configure its **View Object** property to be `CustomerInfo`, the view instance name whose row structure should be used at runtime.

7. To expose service information messages such as warnings and exceptions for a custom method or warnings for process operation methods, select **Include Warnings in Return Service Data Object**. For example, you might want display an informational message when a method returns the total employee compensation and the total is outside of the desired range.

If **Include Warnings** is not selected, no informational messages will be returned with the service response.

This option is only enabled when the method does not return a view row or a list of view rows. When the method returns view rows, the underlying view object determines whether the method supports warnings, as described [Section 11.2.4, "How to Service-Enable Individual View Objects."](#)

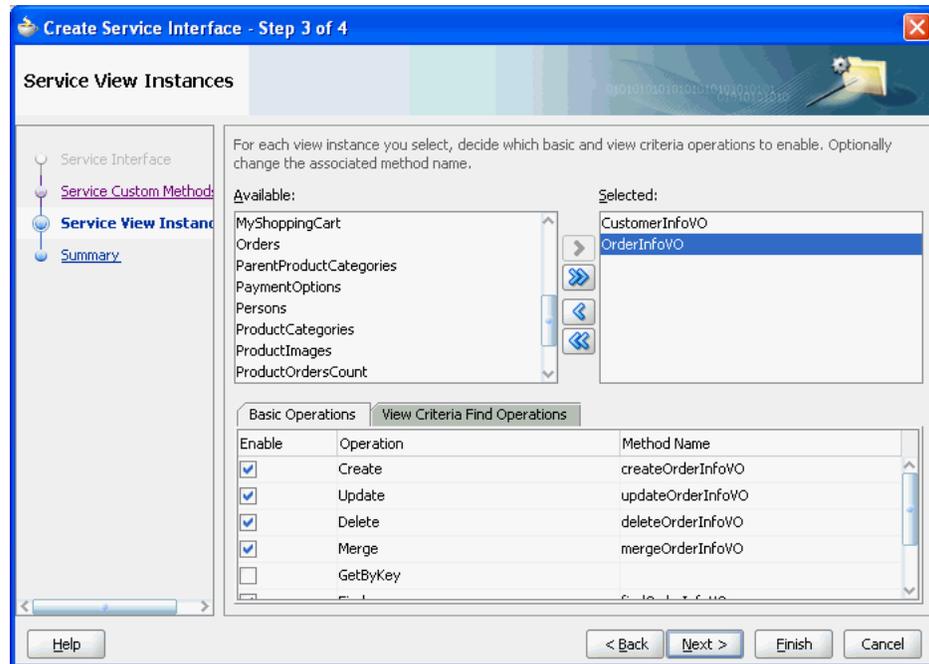

The informational messages (and warnings) are reported as part of the return object. JDeveloper generates appropriate wrappers as the return objects, and the wrappers contain the actual method return and the informational messages.

8. On the Service View Instances page, select the top-level view instances in the application module that you want to expose in the service interface.

View object subtypes of the top-level view instance will automatically be service-enabled.

Also, on this page, you can enable the available data manipulation operations supported on the exposed methods, as shown in [Figure 11-1](#).

Figure 11-1 View Instances and CRUD Operation Selection

- In the Basic Operations tab, select the data manipulation operations for the currently selected view instance and in the **Method Name** field, change the names of the selected service operations to the names that you prefer to expose in the service interface.

The primary purpose of the standard service operations is to expose data manipulation operations on the view objects. Any business logic that you have defined on the underlying framework objects (for example, business rule validation) will be applied when you invoke the service operations. For a description of the operations that service view instances support, see [Table 11-1](#).

In the case of the find method operation that you can select, the find method must not reference a required bind variable in the view object's query statement. A required bind variable is one that makes the query execution dependent on the availability of a valid value for the bind variable. The service interface does not expose required bind variables at runtime. For details about defining a find operation for this scenario, see [Section 11.2.8, "How to Expose a Declarative Find Operation Filtered By a Required Bind Variable."](#)

- To expose declarative find operations, select the **View Criteria Find Operations** tab and click the **Add View Criteria** icon.

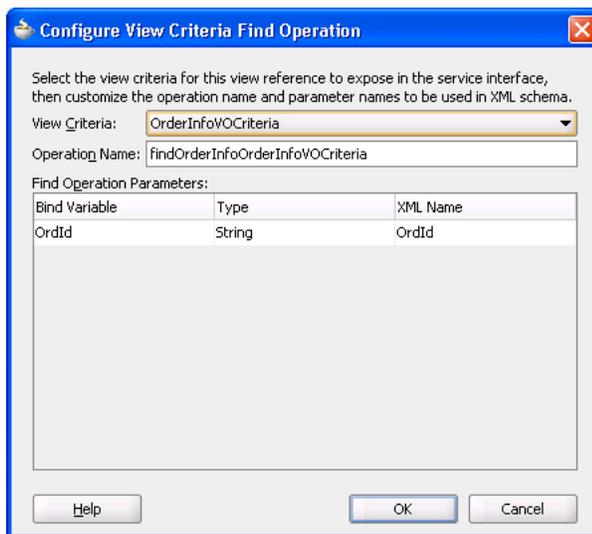

You can define custom find operations when you want the service to support executing a predefined query. For information about defining a named view criteria, see [Section 5.11, "Working with Named View Criteria."](#)

Caution: The service interface find operations are based on specific view criteria that your project defines. This means that the bind variables of the view criteria must match the parameters of the corresponding find operation method. If you change the number or order of the bind variables after the find operation is defined and the service interface generated, the corresponding method will not execute at runtime. Therefore, after changing the underlying view criteria, you must regenerate the service interface.

- a. In the Configure View Criteria Find Operation dialog, choose the named view criteria for the find operation.

The dialog displays the list of view criteria exposed by the referenced view object. For example, `OrderInfoVO` defines `OrderInfoVOCriteria` with a bind variable `OrdId` that specifies the order ID, as shown in [Figure 11–2](#).

Figure 11–2 Specialized Find Methods Based on Named View Criteria

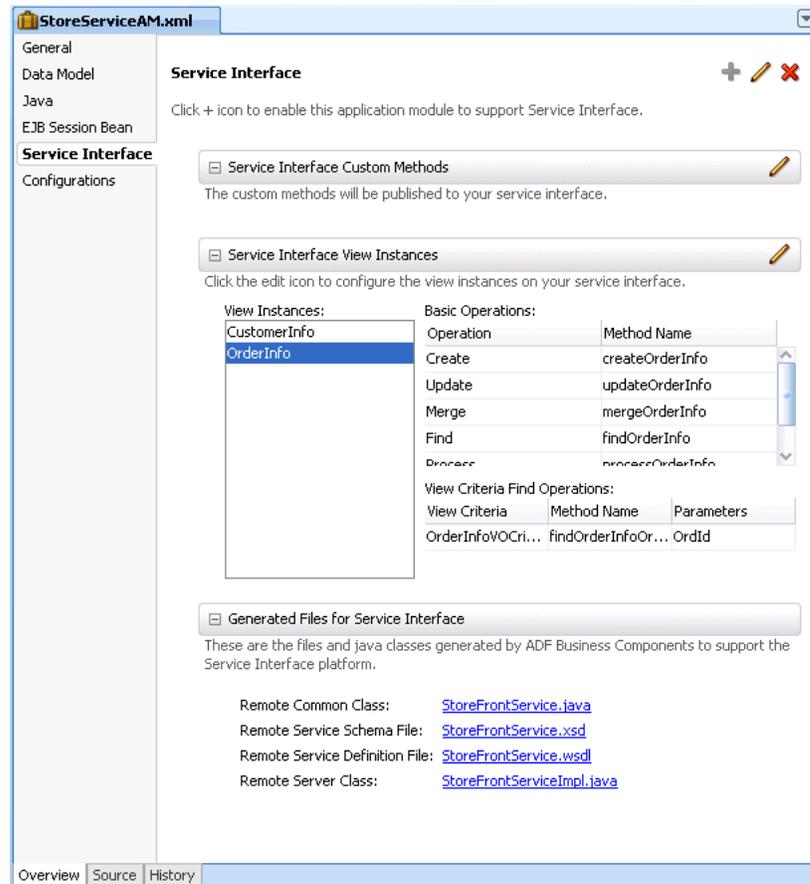

- b. If the view criteria uses a bind variable, you can double-click the XML name to customize the name as it will appear in the XML definition for the service.
11. Click **Next** to review the custom methods that your service view instances will expose.
 12. Click **Finish**.

11.2.2 What Happens When You Create an Application Module Service Interface

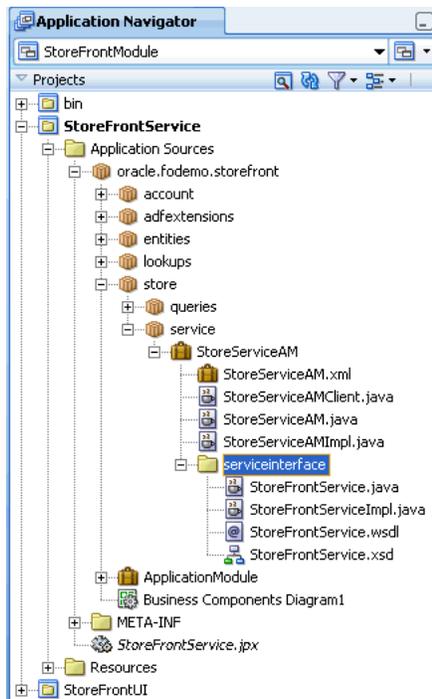

JDeveloper generates the service interface class and enables any view instance options you have chosen, as shown in [Figure 11–3](#).

Do not modify the generated files for the service-enabled application module. The generated files implement required methods of the service interface. An exception to this are use cases that require adding Java annotations to the remote service implementation class. For example, annotations that you add in the remote common interface implementation class let you attach security policies, as described in [Section 11.2.14, "How to Secure the ADF Web Service for Access By SOAP Clients."](#)

Figure 11–3 Service Interface Page of the Overview Editor for an Application Module

The following types of files are generated and are listed in the Application Navigator in the Projects panel, under the application module's **serviceinterface** node, as shown in Figure 11–4.

- Remote common interface, for example, `StoreFrontService.java`
- Remote service schema file, for example, `StoreFrontService.xsd`
- Remote service definition file, for example, `StoreFrontService.wsdl`
- Remote server class, for example, `StoreFrontServiceImpl.java`

Figure 11–4 Service Interface Files Appear Below Application Module

In addition, the `connections.xml` file is created when you first create an ADF Business Components service. Although this file is only used by the web service client (the consuming application), it is generated with the service-enabled application module as a convenience. This file appears in the Application Navigator in the Application Resources panel, under the **Descriptors** and **ADF META-INF** nodes.

11.2.2.1 Remote Common Interface

The remote common interface uses metadata annotations specified by the web service specification (JSR-181) to indicate how the interface should be exposed as a web service. This example shows part of `StoreFrontService.java`, which is the remote common interface class for the `StoreServiceAM` application module in the `StoreFront` module of the Fusion Order Demo.

Example 11–1 Remote Common Interface in Fusion Order Demo

```
package oracle.fodemo.storefront.store.service.common.serviceinterface;
...
import javax.jws.WebMethod;
import javax.jws.WebParam;
import javax.jws.WebResult;
import javax.jws.soap.SOAPBinding;
...
import oracle.fodemo.storefront.store.queries.common.CustomerInfoVOSDO;
import oracle.fodemo.storefront.store.queries.common.OrderInfoVOSDO;
...
import oracle.webservices.annotations.PortableWebService;
import oracle.webservices.annotations.SDODatabinding;
...
@SOAPBinding(parameterStyle = SOAPBinding.ParameterStyle.WRAPPED, style=SOAPBinding.Style.DOCUMENT)
@PortableWebService(targetNamespace="http://www.globalcompany.com/StoreFrontService",
    name="StoreFrontService",
    wsdlLocation=
```

```

        "oracle/fodemo/storefront/store/service/common/serviceinteface/StoreFrontService.wsdl")
@SDODataBinding(schemaLocation=
        "oracle/fodemo/storefront/store/service/common/serviceinteface/StoreFrontService.xsd")
public interface StoreFrontService
{
    public static final String NAME = ("http://www.globalcompany.com/StoreFrontService")

    /**
     * @param orderId
     * @return
     * @throws ServiceException
     */
    @WebMethod(action="www.globalcompany.example.com/getOrderInfoVOSDO",
        operationName="getOrderInfoVOSDO")
    @RequestWrapper(targetNamespace="www.globalcompany.example.com/types/",
        localName="getOrderInfoVOSDO")
    @ResponseWrapper(targetNamespace="www.globalcompany.example.com/types/",
        localName="getOrderInfoVOSDOResponse")
    @WebResult(name="result")
    OrderInfoVOSDO getOrderInfoVOSDO(@WebParam(mode = WebParam.Mode.IN, name="orderId")
        BigInteger orderId) throws ServiceException;
    ...
}

```

11.2.2.2 Remote Service Schema File

The remote service schema file is an XML schema file which represents the web service schema, as shown in [Figure 11–5](#).

Figure 11–5 Remote Service Schema File

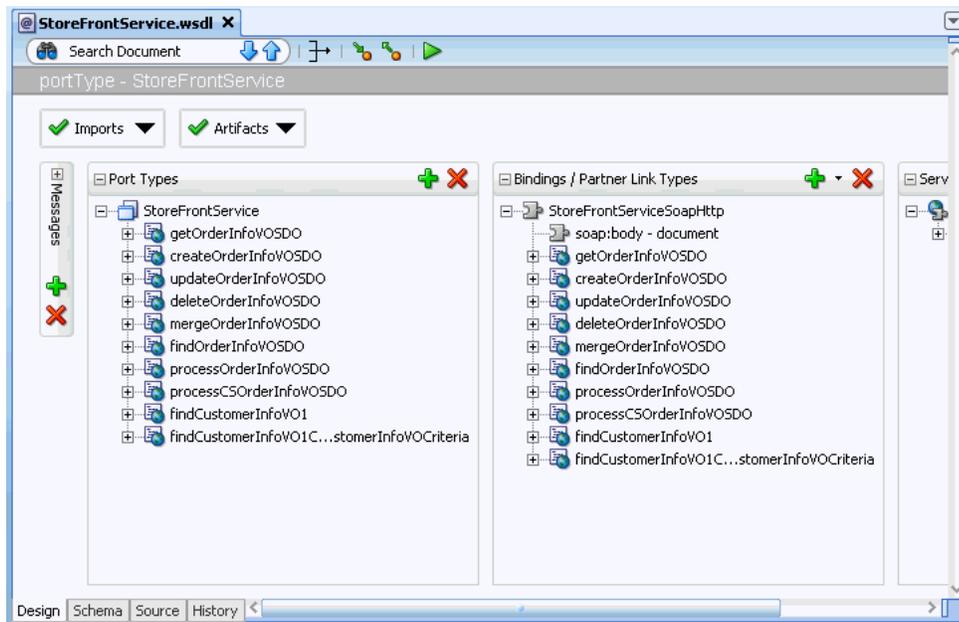

11.2.2.3 Remote Service Definition File

The remote service definition file is a XML-structured document file that conforms to the Web Service Definition Language (WSDL) specification that describes the generated web service as a collection of endpoints, or ports. A port is defined by

associating a network address with a reusable binding. The client application that connects to the web service reads the WSDL to determine what functions are available on the server. The WSDL also specifies the endpoint for the service itself, which you can use to locate and test your deployed service.

Figure 11–6 shows the WSDL for the web service generated for the `StoreServiceAM` application module in the WSDL visual editor. You can see the WSDL as an XML document by selecting the **Source** tab.

Figure 11–6 WSDL Document

11.2.2.4 Remote Server Class

The remote server class is an EJB 3.0 stateless session bean that implements the remote common interface and extends the `ServiceImpl` class, the generic service engine for ADF Business Components. Example 11–2 shows part of `StoreFrontServiceImpl.java`, which is the remote server class for the `StoreServiceAM` application module in the `StoreFront` module of the Fusion Order Demo.

Example 11–2 Remote Server Class Implements the Remote Common Interface

```
package oracle.fodemo.storefront.store.service.server.serviceinterface;
...
import oracle.fodemo.storefront.store.queries.common.CustomerInfoVOSDO;
import oracle.fodemo.storefront.store.queries.common.OrderInfoVOSDO;
import oracle.fodemo.storefront.store.service.common.serviceinterface.StoreFrontService;
...
import oracle.webservices.annotations.PortableWebService;
import weblogic.javaee.CallByReference;
...
@Stateless(name="oracle.fodemo.storefront.store.service.common.StoreFrontServiceBean")
@Remote(StoreFrontService.class)
@PortableWebService(targetNamespace="http://www.globalcompany.com/StoreFrontService",
    serviceName="StoreFrontService", portName="StoreFrontServiceSoapHttpPort",
    endpointInterface="oracle.fodemo.storefront.store.service.common.serviceinterface.StoreFrontService")
```

```

@CallByReference
public class StoreFrontServiceImpl extends ServiceImpl implements StoreFrontService
{
    ...
    /**
     * findCustomerInfoV01: generated method. Do not modify.
     * @param findCriteria
     * @param findControl
     * @return
     * @throws ServiceException
     */
    public List<CustomerInfoVOSDO> findCustomerInfoV01(FindCriteria findCriteria,
                                                       FindControl findControl) throws ServiceException {
        return (List<CustomerInfoVOSDO>)find(findCriteria, findControl,
                                             "CustomerInfoV01",
                                             CustomerInfoVOSDO.class);
    }
    ...
}

```

11.2.2.5 connections.xml

The `connections.xml` file is used by a web service client to look up the service. The ADF Business Components service factory provides the mechanism that allows the service client to look up the service. The service factory relies on ADF connection architecture and the `connections.xml` file to manage service endpoint locations. The `connections.xml` file is created when you first create an ADF Business Components service. This file appears in the Application Navigator in the Application Resources panel, under the **Descriptors** and **ADF META-INF** nodes.

[Example 11-3](#) shows the initial `connections.xml` entry created by JDeveloper when you first create an ADF Business Components service.

Example 11-3 *connections.xml* File Generated by JDeveloper

```

<Reference name="{http://www.globalcompany.com}StoreFrontService"
           className="oracle.jbo.client.svc.Service" xmlns="">
  <Factory className="oracle.jbo.client.svc.ServiceFactory"/>
  <RefAddresses>
    <StringRefAddr addrType="serviceName">
      <Contents>oracle.fodemo.storefront.store.service.common.serviceinterface.
        StoreFrontService</Contents>
    </StringRefAddr>
    <StringRefAddr addrType="serviceEndpointProvider">
      <Contents>ADFBC</Contents>
    </StringRefAddr>
    <StringRefAddr addrType="jndiName">
      <Contents>oracle.fodemo.storefront.store.service.common.
        StoreFrontServiceBean</Contents>
    </StringRefAddr>
    <StringRefAddr addrType="serviceSchemaName">
      <Contents>StoreFrontService.xsd</Contents>
    </StringRefAddr>
    <StringRefAddr addrType="serviceSchemaLocation">
      <Contents>oracle/fodemo/storefront/store/service/common/
        serviceinterface/</Contents>
    </StringRefAddr>
  </RefAddresses>
</Reference>

```

11.2.3 What You May Need to Know About Method Signatures on the ADF Web Service Interface

You can define two different kinds of interfaces for an application module: the client interface and the service interface. The client interface is used by the ADF Model layer for UI clients. The service interface is for application integration and is used by external web services or other application services (either programmatically or automatically using the service-enabled entity feature).

An application module can support no interface at all, only client interfaces, only service interfaces, or both client interfaces and service interfaces combined. However, be aware that the two kinds of interfaces differ in the data types that are supported for the parameters and/or return values of your custom methods that you define for the respective interfaces. The types supported on the client interface are described in [Section 9.9.5, "What You May Need to Know About Method Signatures on the Client Interface."](#)

The service interface, in contrast to the client interface, supports a more narrow set of data types for custom method parameters and return values and is limited to:

- Java primitive types and their object wrapper types (for example, `int`, `Integer`, and `Long`)
- `java.lang.String`
- `java.math.BigDecimal`
- `java.math.BigInteger`
- `java.sql.Date`
- `java.sql.Time`
- `java.sql.Timestamp`
- `java.util.Date`
- `oracle.jbo.AttributeList`
- `oracle.jbo.domain.BlobDomain`
- `oracle.jbo.domain.Char`
- `oracle.jbo.domain.ClobDomain`
- `oracle.jbo.domain.DBSequence`
- `oracle.jbo.domain.Date`
- `oracle.jbo.domain.NClobDomain`
- `oracle.jbo.domain.Number`
- `oracle.jbo.domain.Timestamp`
- `oracle.jbo.domain.TimestampLTZ`
- `oracle.jbo.domain.TimestampTZ`
- `oracle.jbo.server.ViewRowImpl` or any subtype
- `java.util.List<aType>`, where *aType* is any of the service-interface supported data types, including Java primitive type

You can define a custom method that returns a type of `AttributeList` when you want the client developer to work with the list of service-enabled entity object or view object attributes to perform custom operations without the need to involve framework

behavior before running the custom method. As an alternative, when the client developer wants the framework to manage rows (create, find, and populate), define custom methods that return `ViewRowImpl` instead. In summary, if your method signature defines `ViewRowImpl` as the data type, then the application automatically:

1. Looks up the row in the corresponding view object instance by primary key and/or alternate key
2. If the row is not found, then creates a new row
3. Applies the attribute changes in the found or new row

Whereas, if your method signature defines the `AttributeList` data type, then no automatic behavior is provided, and the actions performed and data modified by the custom method will be limited to your custom method's code.

11.2.4 How to Service-Enable Individual View Objects

As a result of enabling the web service interface using the overview editor for the application module, JDeveloper automatically enables your parent view instance selections as Service Data Object (SDO) components. The generated SDO components for each view instance will reference the same namespace and will be configured with the same settings for options such as whether or not warnings are supported. You can use the Java page of the overview editor to customize the SDO definition of these existing service-enabled view objects. You can also use the Java page to service-enable view objects that were not added already to the service interface. For example, if you selected a parent view object that represents the master in a master-detail relationship, the child view object will not be automatically service-enabled. You can use the Java page of the overview editor for the child view object to individually add it to the service interface.

You use the Java page of the overview editor for the view object to configure the SDO name and namespace for a view object, or to selectively service-enable child view objects.

Before you begin:

It may be helpful to have an understanding of how the SDO framework supports service-enabled ADF view objects and enables web service clients to access rows of data and perform service operations. For more information, see [Section 11.2, "Publishing Service-Enabled Application Modules."](#)

Complete these tasks:

1. Create the desired view objects, as described in [Section 5.2.1, "How to Create an Entity-Based View Object,"](#) and [Section 5.2.3, "How to Create an Expert Mode, Read-Only View Object."](#)
2. Optionally, set JDeveloper preferences to specify a default suffix for the names of generated SDO classes and set the default namespace prefix for the generated SDO schema and web service as described in [Section 11.2.13, "How to Set Preferences for Generating the ADF Web Service Interface."](#)

To set the SDO name and namespace for a view object:

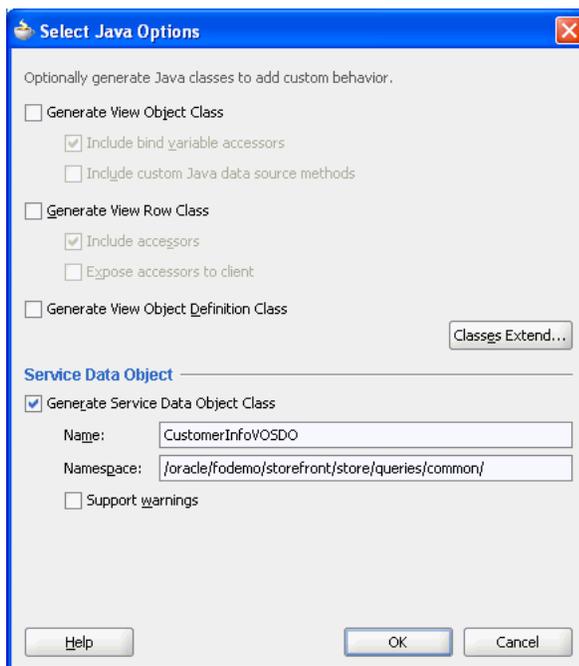

1. In the Application Navigator, double-click the view object.
2. In the overview editor, click the **Java** navigation tab and click the **Edit java options** button.

3. In the Select Java Options dialog, in the **Service Data Object** section, select **Generate Service Data Object Class**. Enter a value for the service data object name and the service data object's target namespace.

The target namespace is a URI for the SDO component that you can assign to group similar SDO components together by entering the same URI.

A default SDO namespace is created for you based on the SDO component's package name with periods replaced by "/". If you have defined a prefix for the namespace in the View Objects page of the Preferences dialog, the prefix will be added at runtime to the beginning of the namespace. For example, [Figure 11-7](#) shows the default namespace based on the package name.

Figure 11-7 Service Data Object Name and Namespace Options

4. Optionally, select **Support Warnings** when you want to be able to extract warnings associated with the view rows of the service interface object. For example, your view object might have a range validator defined on the `Salary` attribute and failure handling for the validator is specified as Informational Warning.

If **Support Warnings** is not selected, no informational messages will be returned with the service response.

When enabled and a warning is generated from the underlying ADF business component object for one of the standard service operations or custom operations, the warning information will be captured by the response object. You can use the methods generated for the service object result class to extract the messages from the view rows, as described in [Section 11.2.7.4, "Service Data Object Result Class and Interface."](#)

5. Click **OK**.

11.2.5 How to Customize the SDO Properties of Service-Enabled View Objects

You can use the overview editor for the view object to customize the SDO component definition of the service-enabled view object. By default, all attributes of the service-enabled view object will be exposed as SDO properties. By customizing the view object definition, you can exclude individual SDO properties from participating in the service interface. In the case of SDO properties that define numeric values, you can associate two properties so they appear as a single complex type in the service interface. For example, you can associate one property that defines a currency code or unit of measure with another property that displays the numeric value. Currently, only the complex service types `AmountType` (a currency code) and `MeasureType` (a unit of measure) are supported.

11.2.5.1 Excluding Individual SDO Properties in a Generated SDO Component

As a result of enabling the web service interface using the overview editor for the application module, JDeveloper automatically enables your parent view instance selections as SDO components. Additionally, you can selectively service-enable individual child view objects and generate SDO components. By default, generated SDO components expose all attributes of their base view object definition as SDO properties. You can hide any attribute that you do not want the service interface to return as an SDO property.

You use the Attributes page of the overview editor to select the view object attribute that you want to exclude from the service interface. You then use the Details tab in the overview editor for the view object to hide the selected attribute from the SDO component.

Before you begin:

It may be helpful to have an understanding of how the SDO framework supports service-enabled ADF view objects and enables web service clients to access rows of data and perform service operations. For more information, see [Section 11.2, "Publishing Service-Enabled Application Modules."](#)

You will need to complete these tasks:

1. Create the desired view objects, as described in [Section 5.2.1, "How to Create an Entity-Based View Object,"](#) and [Section 5.2.3, "How to Create an Expert Mode, Read-Only View Object."](#)
2. Service-enable the desired view object, as described in [Section 11.2.4, "How to Service-Enable Individual View Objects."](#)

To exclude an SDO property from a service-enabled view object:

1. In the Application Navigator, double-click the view object.
2. In the overview editor, click the **Attributes** navigation tab.
3. In the Attributes page of the overview editor, select the attribute corresponding to the property that you want to exclude and then click the **Details** tab and deselect **SDO Property**.

11.2.5.2 Associating Related SDO Properties Using Complex Data Types

As a result of service-enabling the view object, JDeveloper automatically exposes SDO properties as XSD-defined service types that correspond to the data types of the underlying view object's attributes. In the case of attributes that define numeric values, you can change the SDO property's service type to associate a related property using one of these predefined service types:

- AmountType service type, for use with any property that defines a currency code
- MeasureType service type, for use with any property that defines a unit of measure

When you change the service type of an SDO property to either of these complex types, the service interface associates the two properties together and returns them as a single XML element. Both properties of the SDO component must be defined by attributes in the base service-enabled view object.

For example, suppose that your view object defines the OrderTotal attribute and a CurrencyCode attribute to specify the currency code of allowed countries. By default, the service interface exposes these attributes as SDO properties and returns each property as a separate XML element:

```
<OrderTotal>100.00</Price>
<CurrencyCode>USD</CurrencyCode>
```

If you change the type of the OrderTotal property (assume that the XSD file defines this property as a decimal type) to the complex type AmountType and then associate the CurrencyCode property, the service interface will return them as one XML element:

```
<OrderTotal CurrencyCode="USD">123.00</OrderTotal>
```

Also, when you generate a web service proxy, as described in [Section 9.12.1.3, "Calling a Web Service Method Using the Proxy Class in an Application Module,"](#) the class treats the two values as one object:

```
AmountType price;
...
price.setValue(123.00);
price.setCurrencyCode("USD");
```

You use the Attributes page of the overview editor to select the view object attribute whose service type you want to customize. You use the Edit Attribute dialog that you display from the Attributes page of the overview editor to associate SDO properties for the selected attribute and select the predefined complex service type.

Before you begin:

It may be helpful to have an understanding of how the SDO framework supports service-enabled ADF view objects and enables web service clients to access rows of data and perform service operations. For more information, see [Section 11.2, "Publishing Service-Enabled Application Modules."](#)

Complete these tasks:

1. Create the desired view objects, as described in [Section 5.2.1, "How to Create an Entity-Based View Object,"](#) and [Section 5.2.3, "How to Create an Expert Mode, Read-Only View Object."](#)
2. Service-enable the desired view object, as described in [Section 11.2.4, "How to Service-Enable Individual View Objects."](#)

To associate SDO properties in a service-enabled view object:

1. In the Application Navigator, double-click the view object.
2. In the overview editor, click the **Attributes** navigation tab.

3. In the Attributes page, select the attribute corresponding to the property that you will associate with another SDO property, and then click the **Edit selected attribute** button.

The attribute you select must define a numeric type. For example, to associate a currency code with the attribute that displays the amount paid by a customer, you might select the `OrderTotal` attribute in the `Orders` service-enabled view object.

4. In the Edit Attribute dialog, in the View Attribute page, choose the desired XSD Type.

If the **XSD Type** field is not enabled, return to the overview editor and select an attribute of type numeric. Attributes whose values are not a numeric type cannot be associated with the available complex service types.

The SDO framework supports the complex service types `AmountType` and `MeasureType`. Choose **AmountType** when the property you want to associate specifies currency information. Choose **MeasureType** when the property you want to associate specifies a unit of measure.

5. In the **currencyCode** or **unitCode** dropdown list, select the view object attribute to define the complex type.

The dialog changes to display the dropdown list appropriate to the XSD type selection. You can choose any numeric attribute that the view object defines.

6. Click OK.

11.2.6 How to Support Nested Processing in Service-Enabled Master-Detail View Objects

When your data model defines master-detail relationships between parent and child view objects, the service operations that you enable for the master view object may not automatically be executed on the detail view object. Post operations on the detail view object are supported by default when the primary entity object of the master view object is composed with the primary entity object of the detail view object. This master-detail relationship is known as a composition association and is the default type associate created in JDeveloper, as described in [Section 4.3.6, "What You May Need to Know About Composition Associations."](#)

To support create/merge/update/process methods that post child details along with the parent, you you have created a view link to define the master-detail relationship according to one of these scenarios:

- The view link uses the default composition association, then post operations on the detail view object are supported by default.
- The view link is based on an association, and the association has the destination accessor generated, and the association has a custom property `SERVICE_PROCESS_CHILDREN=true` defined.
- The view link is not based on an association but has a custom property `SERVICE_PROCESS_CHILDREN=true` defined.

The custom property provides an alternative to using a composition association that makes it convenient to support nested processing for any view objects with a view link defined. You can define `SERVICE_PROCESS_CHILDREN` as a custom property in the overview editor for either the view link or the view link's association (when present).

To support get and find methods that retrieve child details along with the parent, the view link between the master and detail view objects must have the destination

accessor generated. The destination accessor permits traversal of the hierarchy from the master to the detail view object.

Before you begin:

It may be helpful to have an understanding of how the SDO framework supports service-enabled ADF view objects and enables web service clients to access rows of data and perform service operations. For more information, see [Section 11.2, "Publishing Service-Enabled Application Modules."](#)

You may also find it helpful to have an understanding of how master-detail relationships are defined using view links or entity associations:

- For more information about view links, see [Section 5.6, "Working with Multiple Tables in a Master-Detail Hierarchy."](#)
- For more information about associations, see [Section 4.3, "Creating and Configuring Associations."](#)

Complete these tasks:

1. Create the desired view objects and service-enable the child view object in the master-detail hierarchy, as described in [Section 11.2.4, "How to Service-Enable Individual View Objects."](#)
2. If the view link is not based on an association, confirm that a destination accessor exists for the view link by opening the view link in the overview editor and viewing the Relationship page. To generate the accessor so it appears in the Relationship page, click the **Edit Accessors** button, and then, in the View Link Properties dialog, select **Generate Accessor in View Object** for the destination accessor.

If the view link is based on an association, then the destination accessor must exist for the association's destination entity object. To generate one, use the Relationship page of the overview editor for the association.

To support nested processing in a master-detail hierarchy:

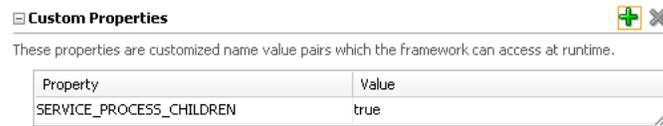

1. If the view link for the master-detail hierarchy is not based on an association, then in the Application Navigator, double-click the view link; otherwise, if the view is based on an association, then in the Application Navigator, double-click the association.

You can confirm how the view link was created in the Relationship page of the overview editor. The Attributes section names the source and destination attributes. When the view link is based on an association, the attribute hyperlinks will contain the names of the association. Otherwise, the hyperlinks will contain the names of the base entity objects.

2. In the overview editor, click the **General** navigation tab.

The overview editor for the view link and the association display similar selections.

3. In the General page, expand the Custom Properties section, and then click the **Add Custom Property** icon and enter `SERVICE_PROCESS_CHILDREN` for the property and enter `true` for the property value, as shown in [Figure 11-8](#).

Figure 11–8 Custom Property to Support Nested Processing

Property	Value
SERVICE_PROCESS_CHILDREN	true

11.2.7 What Happens When You Create SDO Classes

When you create SDO classes, the following files are generated and appear in the Application Navigator under the owning view object:

- Service data object interface
- Service data object class
- Service data object schema file
- Service data object result class and Interface, generated when **Support Warnings** is enabled in the Select Java Options dialog

Do not modify the files generated for service-enabled view objects. The generated files implement required methods of the view object SDO interface.

11.2.7.1 Service Data Object Interface

The view object SDO interface contains strongly typed accessors for the SDO properties, as shown in [Example 11–4](#).

Example 11–4 SDO Interface Contains Strongly Typed Accessors for SDO Properties

```
package oracle.fodemo.storefront.store.queries.common;
public interface AddressesVOSDO {
    public java.math.BigInteger getAddressId();
    public void setAddressId(java.math.BigInteger value);
    ...}

```

11.2.7.2 Service Data Object Class

The view object SDO class implements the view object SDO interface and extends the `SDODataObject` class, which is Oracle's implementation of the SDO specification.

At runtime an instance of an SDO object represents a row in memory.

The SDO class is similar to the view row class, as shown in [Example 11–5](#).

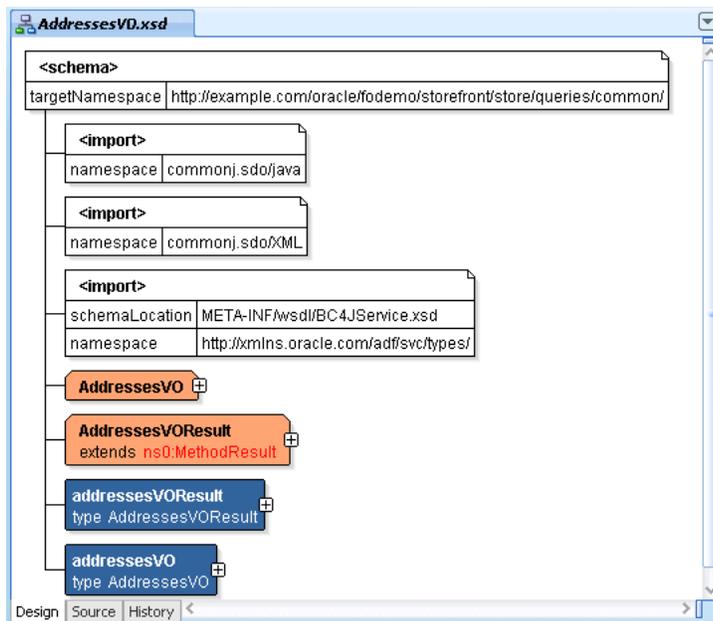

Example 11–5 SDO Class Implements View Object SDO Interface

```
package oracle.fodemo.storefront.store.queries.common;
import commonj.sdo.Type;
import oracle.sdo.SDODataObject;
public class AddressesVOSDOImpl extends SDODataObject implements AddressesVOSDO
{
    ...
}

```

11.2.7.3 Service Data Object Schema File

The view object SDO schema file, as shown in [Figure 11–15](#), is an XML Schema file which represents the SDO schema.

Figure 11–9 Generated SDO Schema

11.2.7.4 Service Data Object Result Class and Interface

The view object SDO result class is a container object that allows a service operation to return a list of view rows (wrapped in service data objects) and a list of warnings associated with these view rows. Specifically, the service get operation returns the original object, while the create/update/merge/find/process operations return a wrapper object that contains a list of the original object and a list of information messages, and the delete operation returns only the informational message. If you have enabled the **Support Warnings** option for the service-enabled view object, you can use the generated method result interface to extract warnings.

The view object SDO result class, as shown in [Example 11–6](#), is similar to the view row class.

Example 11–6 SDO Result Class Defines Methods to Get Warnings from List

```
package oracle.fodemo.storefront.store.queries.common;
import oracle.sdo.SDODataObject;
public class OrderInfoVOSDOResultImpl extends
    oracle.jbo.common.service.types.MethodResultImpl implements OrderInfoVOResult {

    public static final int START_PROPERTY_INDEX =
        oracle.jbo.common.service.types.MethodResultImpl.END_PROPERTY_INDEX + 1;
    public static final int END_PROPERTY_INDEX = START_PROPERTY_INDEX + 0;
    public OrderInfoVOResultImpl() {}
    public java.util.List getValue() {
        return getList(START_PROPERTY_INDEX + 0);
    }

    public void setValue(java.util.List value) {
        set(START_PROPERTY_INDEX + 0 , value);
    }
}
```

11.2.8 How to Expose a Declarative Find Operation Filtered By a Required Bind Variable

The ADF service interface framework allows you to expose declarative find operations to execute the query define by a view object you select. However, when that query uses a bind variable to filter the query results, the bind variable must not be specified as **Required** and **Updatable**. Because the service interface does not expose required, updatable bind variables, a find operation that you execute for such a view object would fail to return any result.

When you want to filter a query result using bind parameters, use the view criteria and expose it as a find operation on the service interface. A service interface find operation based on a view criteria that you create can specify required bind variables.

Before you begin:

It may be helpful to have an understanding of how the SDO framework supports service-enabled ADF view objects and enables web service clients to access rows of data and perform service operations. For more information, see [Section 11.2, "Publishing Service-Enabled Application Modules."](#)

You may also find it helpful to have an understanding of how to filter view object queries using bind variables. For more information, see [Section 5.10, "Working with Bind Variables."](#)

Complete these tasks:

1. Create the desired application module as described in [Section 9.2.1, "How to Create an Application Module."](#)
2. Create the view criteria as described in [Section 5.11.1, "How to Create Named View Criteria Declaratively."](#) In the Edit View Criteria dialog, set the criteria item as a bind variable and set the **Validation** field to **Required**. This selection ensures that the query will not execute without a valid value.

To expose a find operation for a view criteria with required bind variable:

1. In the Application Navigator, double-click the application module.
2. In the overview editor, click the **Service Interface** navigation tab and click the **Edit attributes of Service Interface** icon.

Alternatively, you can select **Edit Service Custom Methods** if you have already defined the service interface.

3. In the Edit Service Interface dialog, select **Service View Instances** from the navigation list and add the view object that you want to filter with its named view criteria to the **Selected** list.
4. To expose the find operation, select the view instance, click the **View Criteria Find Operations** tab, and then click the **Add View Criteria** button.
5. In the Configure View Criteria Find Operation dialog, choose the named view criteria for the find operation.

The dialog displays the bind variable for the selected view criteria.

6. You can double-click the XML name to customize the bind variable name shown in the XML definition for the service.
7. Click **OK**.

11.2.9 How to Expose a Custom Find Method Filtered By a Required Bind Variable

As an alternative to exposing a declarative find operation that relies on a view criteria, you can define a service method in your data model project's application module implementation class. The class you create for this purpose allows you to encapsulate business service functionality into a single method that you implement. For details about the purpose of the custom application module implementation class, see [Section 9.7, "Customizing an Application Module with Service Methods."](#)

[Example 11-7](#) shows a custom find method implemented in the `AppModuleImpl.java` file to set the bind variable and execute the view object instance query. It uses `setNamedWhereClauseParam()` on the view object instance to set the bind variable. Before executing the query, the find method sets the view object in forward-only mode to prevent caching the view rows that the find method iterates over.

Example 11-7 Find Method Added to Application Module Implementation Class

```
public class AppModuleImpl extends ApplicationModuleImpl
{
    public List<ViewRowImpl> findProducts(String location)
    {
        List<ViewRowImpl> result = new ArrayList<ViewRowImpl>();
        ViewObjectImpl vo = getProductsView1();
        vo.setNamedWhereClauseParam("TheLocation", location);
        vo.setForwardOnly(true);
        vo.executeQuery();
        while (vo.hasNext()) {
            result.add((ViewRowImpl)vo.next());
        }
        return result;
    }
}
```

Before you begin:

It may be helpful to have an understanding of how the SDO framework supports service-enabled view objects and enables web service clients to access rows of data and perform service operations. For more information, see [Section 11.2, "Publishing Service-Enabled Application Modules."](#)

You may also find it helpful to have an understanding of how to filter view object queries using bind variables. For more information, see [Section 5.10, "Working with Bind Variables."](#)

Complete these tasks:

1. Create the custom application module class as described in [Section 9.7.1, "How to Generate a Custom Class for an Application Module."](#)
2. Create the custom find method to programmatically filter a query result and set the required bind variable as described in [Section 5.10.5, "How to Add a WHERE Clause with Named Bind Variables at Runtime."](#)

To expose a find method that sets a required bind variable:

1. In the Application Navigator, double-click the application module.
2. In the overview editor, click the **Service Interface** navigation tab and click the **Edit attributes of Service Interface** icon.

Alternatively, you can click the **Edit Service Custom Methods** icon if you have already defined the service interface.

3. In the Edit Service Interface dialog, select **Service View Instances** from the navigation list and add the find method that you defined to the **Selected** list.
4. Click **OK**.

11.2.10 How to Generate Asynchronous ADF Web Service Methods

By default, the web service supports synchronous service methods. This forces the invoking client application to wait for the response to return before it can continue with its work. In cases where the response returns immediately, this method of invoking the web service is common. However, because request processing can be delayed, it is often useful for the client application to continue its work and to handle the response later on.

Before you begin:

It may be helpful to have an understanding of how the SDO framework supports service-enabled view objects and enables web service clients to access rows of data and perform service operations. For more information, see [Section 11.2, "Publishing Service-Enabled Application Modules."](#)

You may also find it helpful to have an understanding of invoking web services using asynchronous request-response. For more information, see *Oracle Fusion Middleware Concepts Guide for Oracle Infrastructure Web Services*.

Complete this task:

Before you can deploy an asynchronous web service, you must configure the queues used to store the request and response. For information about configuring the request and response queues, see the *Oracle Fusion Middleware Concepts Guide for Oracle Infrastructure Web Services*.

To expose asynchronous web service methods:

1. In the Application Navigator, double-click the application module.
2. In the overview editor, click the **Service Interface** navigation tab and click the **Edit attributes of Service Interface** icon.
3. In the Edit Service Interface dialog, select **Generate Asynchronous Web Service Methods**.
4. Click **OK**.

11.2.11 What Happens When You Generate Asynchronous ADF Web Service Methods

JDeveloper generates the remote common interface for the service and enables the asynchronous service operation. As shown in [Example 11-8](#), the class annotation `@AsyncWebService` declares the `EmpService` service interface asynchronous and for each synchronous method in the interface, the service exposes an asynchronous method with the same method name and "Async" appended.

Exposing both synchronous and asynchronous methods in the same interface allows the web service client developer to decide how to invoke the operation through a web service proxy: by calling the appropriately named method. Note that developers should not invoke asynchronous methods through the ADF Business Components service proxy directly.

In this example, because the `EmpService` service is enabled for asynchronous operation, the interface exposes the `getEmployeeAsync()` method and declares the `getEmployee()` method synchronous using the method annotation `@CallbackMethod(exclude=true)` to override the default operation (it is the `exclude=true` part that declares a method in the asynchronous service as synchronous). No annotation is required to declare the asynchronous service methods when the class annotation `@AsyncWebService` is present.

Example 11–8 Remote Common Interface with Asynchronous Service Methods

```
import javax.xml.ws.Action;
...
import oracle.webservices.annotations.async.AsyncWebService;
import oracle.webservices.annotations.async.CallbackMethod;

@SOAPBinding(parameterStyle=SOAPBinding.ParameterStyle.WRAPPED, style=SOAPBinding.Style.DOCUMENT)
@PortableWebService(targetNamespace="http://xmlns.example.com/apps/service/", name="EmpService",
    wsdlLocation="oracle/apps/service/EmpService.wsdl")
@SDDatabinding(schemaLocation="oracle/apps/service/EmpService.xsd")
@AsyncWebService
public interface EmpService
{
    ...

    @WebMethod(action="http://xmlns.example.com/apps/service/getEmployee",
        operationName="getEmployee")
    @RequestWrapper(targetNamespace="http://xmlns.example.com/apps/service/types/",
        localName="getEmployee")
    @ResponseWrapper(targetNamespace="http://xmlns.example.com/apps/service/types/",
        localName="getEmployeeResponse")
    @WebResult(name="result")
    @CallbackMethod(exclude=true)
    Emp getEmployee(@WebParam(mode = WebParam.Mode.IN, name="empno") Integer empno)
        throws ServiceException;

    @WebMethod(action="http://xmlns.example.com/apps/service/getEmployeeAsync",
        operationName="getEmployeeAsync")
    @RequestWrapper(targetNamespace="http://xmlns.example.com/apps/service/types/",
        localName="getEmployeeAsync")
    @ResponseWrapper(targetNamespace="http://xmlns.example.com/apps/service/types/",
        localName="getEmployeeAsyncResponse")
    @WebResult(name="result")
    @Action(input="http://xmlns.example.com/apps/service/getEmployeeAsync",
        output="http://xmlns.example.com/apps/service/getEmployeeAsyncResponse")
    Emp getEmployeeAsync(@WebParam(mode = WebParam.Mode.IN, name="empno") Integer empno);
}
```

The duplicate asynchronous methods delegate to the synchronous methods in the service implementation, as shown in [Example 11–9](#). This ensures that the underlying business logic is the same for operations declared as either synchronous or asynchronous.

Example 11–9 Remote Server Class Implements Asynchronous Service Methods

```
...
import oracle.webservices.annotations.async.AsyncWebService;

@Stateless(name="oracle.apps.service.EmpServiceBean", mappedName="EmpServiceBean")
@Remote(EmpService.class)
@PortableWebService(targetNamespace="http://xmlns.oracle.com/apps/service/",
```

```

        serviceName="EmpService", portName="EmpServiceSoapHttpPort",
        endpointInterface="oracle.apps.service.EmpService")
@Interceptors(ServiceContextInterceptor.class)
@AsyncWebService
public class EmpServiceImpl extends ServiceImpl implements EmpService
{
    ...

    /**
     * getEmployee: generated method. Do not modify.
     */
    public Emp getEmployee(Integer empno)
        throws ServiceException
    {
        return (Emp) get(new Object[] { empno }, "Employee", Emp.class);
    }

    /**
     * getEmployeeAsync: generated method. Do not modify.
     */
    public Emp getEmployeeAsync(Integer empno)
        throws ServiceException
    {
        return getEmployee(empno);
    }
}

```

11.2.12 What Happens at Runtime: How the Asynchronous Call Is Made

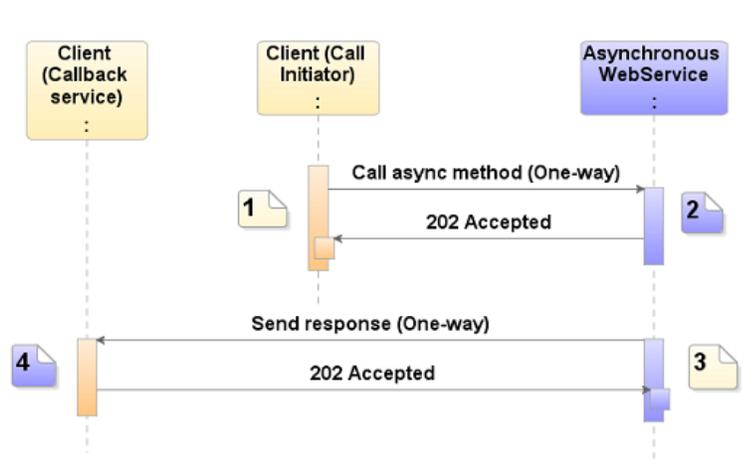

From the client's point of view, an asynchronous call consists of two one-way message exchanges. The sequence diagram in [Figure 11-10](#) depicts the following flow:

1. The client calls for the asynchronous operation. (In the figure, Step 1.)
2. The asynchronous service receives the request and returns the HTTP acknowledgement back to the client without actually processing the request. (In the figure, step 2)
3. Eventually the asynchronous operation will complete and the module on the server side will send the response to the client side. (In the figure, step 3.)

To receive the response at the client side, the client must have some kind of HTTP listener, for example, a servlet or a web service.

4. The client side-generated web service (the Callback Service) receives the asynchronous responses. (In the figure, step 4.)

The module in step 3 on the server side acts like a client to the callback service and so is referred as the callback client.

Figure 11–10 Asynchronous Call Sequence

11.2.13 How to Set Preferences for Generating the ADF Web Service Interface

You have additional control of the service generated by JDeveloper. You can set JDeveloper preferences to use a default suffix for the names of generated SDO classes, modifying the default subpackage where the service common interface and classes go.

To set the SDO class name suffix:

1. From the main menu, choose **Tools > Preferences**.
2. In the Preferences dialog, expand **ADF Business Components** and choose **Class Naming**.
3. In the **View Object** suffix list, enter a suffix for **SDO**, for example, *SDO*.

To set the default subpackage for the generated service interface:

1. From the main menu, choose **Tools > Preferences**.
2. In the Preferences dialog, expand **ADF Business Components** and choose **Packages**.
3. In the **Relative Package Specification for Classes** list, specify the default package names:
 - To set the Service Interface package name, enter a value for the **Client Interface**. (The **Service Interface** displays the same package name you specify for the client interface). The default package name is *common*.
 - Enter a value for the **Service Interface Subpackage** of the **Service Interface**. The default subpackage name is *serviceinterface*.

For example, if you enter *common* for **Service Interface** and *serviceinterface* for **Service Interface Subpackage** (the defaults), service interfaces for data model components in the data model package *oracle.storefront.store.service* will be placed in the subpackage *oracle.storefront.store.service.common.serviceinterface*.

To set the default namespace prefix for the generated SDO schema and web service:

1. From the main menu, choose **Tools > Preferences**.

2. In the Preferences dialog, expand **ADF Business Components** and choose **View Objects**.
3. Enter a value for the **Service Data Object Namespace Prefix** to be added to the beginning of the target namespace of the generated SDO schema and web service. For example, `http://example.com/`.

11.2.14 How to Secure the ADF Web Service for Access By SOAP Clients

At runtime, the web service client will invoke the service-enable methods of the application module through the SOAP protocol. You can configure a Oracle Web Service Manager (Oracle WSM) security policy to enable authentication and authorization on the service. The security policy that you select will require the SOAP client call to provide credential information (or SAML token) as part of the SOAP header. You can also configure other policies to enable message protection (integrity and confidentiality) for inbound SOAP requests, for instance.

To secure the web service for SOAP clients:

1. Configure an Oracle WSM authentication policy.
2. Configure an Oracle WSM authorization policy.

You can enable authentication to require users to supply credentials before they have access to the service methods on the service interface. The type of authentication required is configured on the remote server class using an Oracle WSM authentication policy annotation.

You can enable permission checking to enable only users with sufficient privileges to invoke a service method on the service interface. Permission checking is configured on the remote server class using this Oracle WSM authorization annotation:

- `binding_permission_authorization_policy`

This policy provides simple permission-based authorization for the request based on the authenticated Subject at the SOAP binding level. This policy ensures that the Subject has permission to perform the operation. This policy should follow an authentication policy where the Subject is established and can be attached to any SOAP-based endpoint.

As an alternative to the permission checking policy, you can configure one of these role-based Oracle WSM security policies:

- `binding_authorization_denyall_policy`

This policy provides simple role-based authorization for the request based on the authenticated Subject at the SOAP binding level. This policy denies all users with any roles. It should follow an authentication policy where the Subject is established and can be attached to any SOAP-based endpoint.

- `binding_authorization_permitall_policy`

This policy provides a simple role-based authorization for the request based on the authenticated Subject at the SOAP binding level. This policy permits all users with any roles. It should follow an authentication policy where the Subject is established and can be attached to any SOAP-based endpoint.

For further details about the authorization policies, see the *Oracle Fusion Middleware Security and Administrator's Guide for Web Services*.

ADF service interface framework also provides an EJB interceptor `ServicePermissionCheckInterceptor` which does the same permission check as `oracle/binding_permission_authorization_policy`, and additionally

covers RMI invocation to services. If your services will always be invoked through SOAP, you should attach the Oracle WSM `oracle/binding_permission_authorization_policy` authorization policy. If your services will also be invoked through RMI, you should attach the EJB interceptor `ServicePermissionCheckInterceptor`.

Before you begin:

It may be helpful to have an understanding of how the SDO framework supports service-enabled ADF view objects and enables web service clients to access rows of data and perform service operations. For more information, see [Section 11.2, "Publishing Service-Enabled Application Modules."](#)

You may also find it helpful to have an understanding of the predefined authentication policies supported by Oracle WSM. For more information, see the *Oracle Fusion Middleware Security and Administrator's Guide for Web Services*.

Complete this task:

- Grant users access to the service, as described in [Section 11.2.16, "How to Grant Test Users Access to the Service."](#)

To configure an authentication and authorization:

1. In the Application Navigator, expand the application module, expand the **serviceinterface** node, and then double-click the remote server class (*AppModuleServiceImpl.java* file).

In the web service generated from the `StoreServiceAM` application module in the `StoreFrontModule` application of the Fusion Order Demo, the remote server class is `StoreFrontServiceImpl.java`.

2. In the source for the remote server class, place your cursor on the `@PortableWebService` annotation.

For example, `StoreFrontServiceImpl.java` shows the annotation for the service as follows:

```
...
@PortableWebService(targetNamespace="www.globalcompany.example.com",
    serviceName="StoreFrontService", portName="StoreFrontServiceSoapHttpPort",
    endpointInterface=
        "oracle.fodemo.storefront...common.serviceinterface.StoreFrontService")
...
```

3. Open the Property Inspector and expand the **Web Services Extension** section, and then click the ellipsis button next to the **Security** field for Oracle WSM Policies.
4. In the Edit Property: Security dialog, select the desired authentication security policy and click **OK**.

For details about the available security policies supported by Oracle WSM, see the *Oracle Fusion Middleware Security and Administrator's Guide for Web Services*.

5. Return to the source file and note that new annotation `@SecurityPolicy` has been added.

The `@SecurityPolicy` annotation that you define for the remote server class specifies the security requirements to potential clients. For example, if you had selected **oracle/wss11_saml_or_username_token_with_message_protection_service_policy** in the dialog, the following `@SecurityPolicy` annotation and `@CallbackSecurityPolicy` (for asynchronous service) would appear below the `@PortableWebService` annotation:

```

...
@PortableWebService(targetNamespace="www.globalcompany.example.com",
    serviceName="StoreFrontService",
    portName="StoreFrontServiceSoapHttpPort",
    endpointInterface=
        "oracle.fodemo.storefront.store.service.common.
            serviceinterface.StoreFrontService")
@SecurityPolicy( { "oracle/wss11_saml_or_username_token_with_message_protec
    tion_service_policy" })
@CallSecurityPolicy("oracle/wss11_saml_or_username_token_with_message_protec
    tion_service_policy")
...

```

6. If your services will always be invoked exclusively through SOAP (and not RMI), you should use an Oracle WSM authorization policy as follows:
 - a. Open the Property Inspector and expand the **Web Services Extension** section, and then click the ellipsis button next to the **Security** field for Oracle WSM Policies.
 - b. In the Edit Property: Security dialog, select the desired security policy and click **OK**.

For details about the security policies supported by Oracle WSM, see the *Oracle Fusion Middleware Security and Administrator's Guide for Web Services*.

- c. Return to the source file and note that annotation `@SecurityPolicy` is configured.

The `@SecurityPolicy` annotation that you define for the remote server class specifies the security requirements to potential clients. In this example, the annotation shows both the permission-checking authorization policy (`oracle/binding_permission_authorization_policy`) and an authentication policy:

```

...
@PortableWebService(targetNamespace="www.globalcompany.example.com",
    serviceName="StoreFrontService",
    portName="StoreFrontServiceSoapHttpPort",
    endpointInterface=

        "oracle.fodemo.storefront...common.serviceinterface.StoreFrontService")
    @SecurityPolicy( { "oracle/binding_permission_authorization_policy",
        "oracle/wss_username_token_service_policy" })

```

If your services will be invoked through SOAP and RMI, you should use `ServicePermissionCheckInterceptor` only (there is no need to use an Oracle WSM authorization policy) as follows:

- a. In the source editor, place your cursor in the `@Interceptors` annotation and add `ServicePermissionCheckInterceptor.class` to enable permission checking at runtime.

```

...
@SecurityPolicy( { "oracle/wss11_saml_or_username_token_with_message_
    protection_service_policy" })
@CallSecurityPolicy("oracle/wss11_saml_or_username_token_with_message_
    protection_service_policy")
@Interceptors( {ServiceContextInterceptor.class,
                ServicePermissionCheckInterceptor.class})

```

7. Save the remote server class file.

11.2.15 How to Secure the ADF Web Service for Access By RMI Clients

Because the ADF web service is implemented as an EJB and deployed on Oracle WebLogic Server as Oracle Web Service's `PortableWebService`, the client application can invoke the service-enabled methods of the application module through the RMI protocol.

To secure the web service for RMI clients:

1. Configure JNDI context properties to enable authentication.
2. Enable permission checking to configure an authorization policy.

Before you begin:

It may be helpful to have an understanding of the predefined authorization policies supported by Oracle WSM. For more information, see the *Oracle Fusion Middleware Security and Administrator's Guide for Web Services*.

11.2.15.1 Enabling Authentication for RMI Clients

When the ADF web service is invoked through RMI, authentication is handled with the common JAAS login module. The login module can be passed the principal and credential as part of the JNDI initial context for the EJB in the calling application. If you do not define the JNDI context properties, the login module will attempt to obtain the caller's current security context.

When you choose to define remote JNDI context information, then these four JNDI context properties need to be added to the `connections.xml` file.

Note: When you intend to test the service in JDeveloper using Integrated WebLogic Server, before deploying the service you can edit the JNDI context properties in the `connections.xml` file directly. However, when you deploy the service to standalone Oracle WebLogic Server, you will use Oracle Enterprise Manager to configure the JNDI context properties.

- `jndiFactoryInitial` should be set to `weblogic.jndi.WLInitialContextFactory`.
- `jndiProviderURL` is the JNDI provider URL that indicates the location of the JNDI server. The URL should be composed as `t3://<hostname>:<server port>`.

When you test the service in JDeveloper, and your service is deployed to Integrated WebLogic Server, specify the JNDI provider URL of Integrated WebLogic Server: `t3://<hostname>:7101`.

When you deploy the service to remote Oracle WebLogic Server, specify a URL like: `t3://localhost:8888`, where `t3` is the Oracle WebLogic protocol, `localhost` is the host name that the remote Oracle WebLogic Server instance runs in, `8888` is the port number.

- `jndiSecurityPrincipal` specifies the principal (user name) with permission to access the remote JNDI.

As [Example 11-10](#) shows, when you test the service in JDeveloper Integrated WebLogic Server, you should omit this context property since no security is configured for the JNDI server on Integrated WebLogic Server.

As [Example 11–11](#) and [Example 11–12](#) show, when you deploy the service to standalone Oracle WebLogic Server, the user name can be read from the file.

- `jndiSecurityCredentials` specifies the credentials (password) to be used for the security principal.

As [Example 11–10](#) shows, when you test the service in JDeveloper Integrated WebLogic Server, you should omit this context property since no security is configured for the JNDI server on Integrated WebLogic Server.

As [Example 11–11](#) shows, when you deploy the service to standalone Oracle WebLogic Server in a test environment, you can specify credentials in plain text for the JNDI provider. For example, you can specify `weblogic/weblogic1` which are the default administrator user name/password credentials with sufficient privileges to access JNDI provider for Oracle WebLogic Server.

When you deploy the service to a production environment, you must remove the plain text password to avoid creating a security vulnerability. As [Example 11–12](#) shows, the `connections.xml` file must contain `<SecureRefAddr addrType="jndiSecurityCredentials"/>` with no password. To configure the service password for standalone Oracle WebLogic Server, you must use Oracle Enterprise Manager, which will store the encrypted password in Oracle's credential store.

Before you begin:

It may be helpful to have an understanding of how the SDO framework supports service-enabled ADF view objects and enables web service clients to access rows of data and perform service operations. For more information, see [Section 11.2, "Publishing Service-Enabled Application Modules."](#)

To configure JNDI context properties to handle authentication:

1. In the Application Navigator in the Application Resources panel, expand the **Descriptors** and **ADF META-INF** nodes, and then double-click the `connections.xml` file.
2. If the source editor, use the JNDI context properties to specify the principal and credentials.

If you are testing the service in JDeveloper's Integrated WebLogic Server, you only need to specify the `jndiProviderURL` property, as shown in [Example 11–10](#).

Example 11–10 JNDI Properties for JDeveloper Integrated WebLogic Server

```
<References xmlns="http://xmlns.oracle.com/adf/jndi">
  <Reference name="{www.globalcompany.com}StoreFrontService"
    className="oracle.jbo.client.svc.Service" xmlns="">
    <Factory className="oracle.jbo.client.svc.ServiceFactory"/>
  <RefAddresses>
    ...
    <StringRefAddr addrType="jndiFactoryInitial">
      <Contents>weblogic.jndi.WLInitialContextFactory</Contents>
    </StringRefAddr>
    <StringRefAddr addrType="jndiProviderURL">
      <Contents>t3://a_hostname:7101</Contents>
    </StringRefAddr>
    ...
  </RefAddresses>
</Reference>
...
```

```
</References>
```

If you are deploying the service for testing purposes to standalone Oracle WebLogic Server, you can use the `connections.xml` file to specify credentials for the JNDI provider. For example, as shown in [Example 11–11](#), you can specify `weblogic/weblogic1` which are the default administrator user name/password credentials with sufficient privileges to access JNDI provider for Oracle WebLogic Server.

Example 11–11 JNDI Properties for a Test Environment

```
<References xmlns="http://xmlns.oracle.com/adf/jndi">
  <Reference name="{www.globalcompany.com}StoreFrontService"
    className="oracle.jbo.client.svc.Service" xmlns="">
    <Factory className="oracle.jbo.client.svc.ServiceFactory"/>
  <RefAddresses>
    ...
    <StringRefAddr addrType="jndiFactoryInitial">
      <Contents>weblogic.jndi.WLInitialContextFactory</Contents>
    </StringRefAddr>
    <StringRefAddr addrType="jndiProviderURL">
      <Contents>t3://localhost:8888</Contents>
    </StringRefAddr>
    <StringRefAddr addrType="jndiSecurityPrincipal">
      <Contents>welcome</Contents>
    </StringRefAddr>
    <SecureRefAddr addrType="jndiSecurityCredentials">
      <Contents>weblogic1</Contents>
    </SecureRefAddr>
    ...
  </RefAddresses>
</Reference>
...
</References>
```

If you are deploying the service to production Oracle WebLogic Server, you can use the `connections.xml` file to specify the user name. As shown in [Example 11–12](#), you must not specify the password.

Example 11–12 JNDI Properties for a Production Environment

```
<References xmlns="http://xmlns.oracle.com/adf/jndi">
  <Reference name="{www.globalcompany.com}StoreFrontService"
    className="oracle.jbo.client.svc.Service" xmlns="">
    <Factory className="oracle.jbo.client.svc.ServiceFactory"/>
  <RefAddresses>
    ...
    <StringRefAddr addrType="jndiFactoryInitial">
      <Contents>weblogic.jndi.WLInitialContextFactory</Contents>
    </StringRefAddr>
    <StringRefAddr addrType="jndiProviderURL">
      <Contents>t3://localhost:8888</Contents>
    </StringRefAddr>
    <StringRefAddr addrType="jndiSecurityPrincipal">
      <Contents>a_username</Contents>
    </StringRefAddr>
    <SecureRefAddr addrType="jndiSecurityCredentials/">
    ...
  </RefAddresses>
</Reference>
```

```
...
</References>
```

3. Save the file.

11.2.15.2 Enabling Authorization for RMI Clients

You can enable permission checking to allow only users with sufficient privileges to invoke a service method on the service interface. In order to enable permission checking, the ADF service interface framework provides an EJB interceptor named `ServicePermissionCheckInterceptor`. This EJB interceptor ensures permission checking is enforced at runtime. Currently, the interceptor is configured to use the Oracle Web Services Manager (Oracle WSM) authorization policy `binding_permission_authorization_policy`.

Before you begin:

It may be helpful to have an understanding of how the SDO framework supports service-enabled ADF view objects and enables web service clients to access rows of data and perform service operations. For more information, see [Section 11.2, "Publishing Service-Enabled Application Modules."](#)

You may also find it helpful to have an understanding of the `binding_permission_authorization_policy` authorization policy supported by Oracle WSM. For more information, see the *Oracle Fusion Middleware Security and Administrator's Guide for Web Services*.

Complete these tasks:

1. Configure the authentication policy for the service in the `connections.xml` file of the client application (the one invoking the service), as described in [Section 11.2.15.1, "Enabling Authentication for RMI Clients."](#)
2. Grant users access to the service, as described in [Section 11.2.16, "How to Grant Test Users Access to the Service."](#)

To configure a permission-based authorization policy:

1. In the Application Navigator, expand the **META-INF** node of the web service project and double-click the `ejb-jar.xml` node.
2. In the source editor, add the following `JpsInterceptor` definition required by the EJB for application roles evaluation.

```
<?xml version = '1.0' encoding = 'windows-1252'?>
<ejb-jar xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://java.sun.com/xml/ns/javaee
  http://java.sun.com/xml/ns/j2ee/ejb-jar_3_0.xsd" version="3.0"
  xmlns="http://java.sun.com/xml/ns/javaee">
  <enterprise-beans>
    ...
  </enterprise-beans>
  <interceptors>
    <interceptor>
      <interceptor-class>
        oracle.security.jps.ee.ejb.JpsInterceptor
      </interceptor-class>
      <env-entry>
        <env-entry-name>application.name</env-entry-name>
        <env-entry-type>java.lang.String</env-entry-type>
        <env-entry-value>ApplicationName</env-entry-value>
        <injection-target>
```

```

        <injection-target-class>
            oracle.security.jps.ee.ejb.JpsInterceptor
        </injection-target-class>
        <injection-target-name>
            application_name
        </injection-target-name>
    </injection-target>
</env-entry>
</interceptor>
...
<interceptors>
<assembly-descriptor>
    <interceptor-binding>
        <ejb-name>*</ejb-name>
        <interceptor-class>
            oracle.security.jps.ee.ejb.JpsInterceptor
        </interceptor-class>
    </interceptor-binding>
</assembly-descriptor>
</ejb-jar>

```

3. In the Application Navigator, expand the application module, expand the **serviceinterface** node, and then double-click the remote server class (**AppModuleServiceImpl.java**) node.
4. In the source editor, place your cursor at the end of your annotations section and add the annotation named `ServicePermissionCheckInterceptor` to enable permission checking at runtime.

```

...
@Stateless(name="oracle.fodemo.storefront.store.service.common.
            StoreFrontServiceBean")

@Remote(StoreFrontService.class)
@PortableWebService(targetNamespace="http://www.globalcompany.com/
            StoreFrontService", serviceName="StoreFrontService",
            portName="StoreFrontServiceSoapHttpPort",
            endpointInterface="oracle.fodemo.storefront.
            service.common.serviceinterface.StoreFrontService")

@CallByReference
@Interceptors({ServiceContextInterceptor.class,
            ServicePermissionCheckInterceptor.class})

```

5. Save the files.

11.2.16 How to Grant Test Users Access to the Service

After you have configured the authorization policy for the service, you must configure the Oracle Platform Security Services (OPSS) security provider to specify which users can invoke method on the service. At design time, you perform this task by editing the `jazn-data.xml` configuration file to create application roles and make an invoke permission grant to the desired application roles. Then when you deploy the service, the administrator for the target Oracle WebLogic Server will associate enterprise users with the application roles you specify. This allows you to confer the right to invoke a service method to any user who is a member of that application role. Users who are members of a role that has not been granted the invoke permission, will denied access to the service method.

The invoke permission for Oracle Web Services is defined by the `oracle.wsm.security.WSFunctionPermission` class. You can grant the invoke

permission to the application roles you define for all the methods of the service or just to individual methods.

Before you begin:

It may be helpful to have an understanding of how the SDO framework supports service-enabled ADF view objects and enables web service clients to access rows of data and perform service operations. For more information, see [Section 11.2, "Publishing Service-Enabled Application Modules."](#)

You may also find it helpful to have an understanding of application roles and the OPSS security provides. For more information, see the *Oracle Fusion Middleware Security Guide*.

Complete these tasks:

1. Configure authentication and authorization policies for your service, as described in [Section 11.2.14, "How to Secure the ADF Web Service for Access By SOAP Clients,"](#) or [Section 11.2.15, "How to Secure the ADF Web Service for Access By RMI Clients."](#)
2. Add the OPSS security provider configuration file to your project by creating a `jazn-data.xml` deployment descriptor as described in "Creating and Editing a Deployment Descriptor" in the Deploying Applications section of the JDeveloper online help.

Note that in JDeveloper you open the New Gallery, expand **General**, select **Deployment Descriptors** and then **Oracle Deployment Descriptors**, and click **OK**.

3. Create the desired application roles that you want to make grants to, as described in [Section 35.4, "Creating Application Roles."](#)
4. For the purpose of testing your web service in JDeveloper using Integrated WebLogic Server, you can populate the application roles with test users, as described in [Section 35.6, "Creating Test Users."](#)

To grant the web service permission to application roles in the `jazn-data.xml` file:

1. From the Application menu, choose **Secure > Resource Grants** or choose **Secure > Entitlement Grants**.

You can grant multiple privileges to an application role as an entitlement set or you can grant individual privileges to a resource. Create an entitlement grant to aggregate privileges that together secure a specific end user duty. For details about entitlement grants, see [Section 35.5.11, "How to Aggregate Resource Grants as Entitlement Grants."](#)

2. In the editor window for the `jazn-data.xml` file, select the **Source** tab.
3. In the source for the `jazn-data.xml` file, expand the `<policy-store>` element to view all ADF security policies that you already defined for your application.

Currently, this release does not provide an editor to create an application security policy; you will need to manually create the policy in the source for the `jazn-data.xml` file.

4. Inside the `<jazn-policy>` element, create a `<grant>` element that defines the `<grantee>` with the desired application role and the `<permission>` with the fully qualified class name of the Oracle WSM permission class (`oracle.wsm.security.WSFunctionPermission`), the permission target name that uniquely identifies the service method, and the invoke method action that you want to grant to the application role principal.

Your finished source should look similar to this:

```
<grant>
  <grantee>
    <principals>
      <principal>
        <class>oracle.security.jps.service.policystore.ApplicationRole</class>
        <name>customers</name>
      </principal>
    </principals>
  </grantee>
  <permissions>
    <permission>
      <class>oracle.wsm.security.WSFunctionPermission</class>
      <name>www.globalcompany.example.com/
                                     StoreFrontService#CreateAccount</name>

      <actions>invoke</actions>
    </permission>
  </permissions>
</grant>
```

The `<principal>` element is defined by the application role class name `oracle.security.jps.service.policystore.ApplicationRole` and an application role name that you already created. For example, if you created an application role `customers` and you want to grant `invoke` service method permission to the members of that role, then enter `customers`.

The `<permission>` element is defined by the Oracle WSM class name `oracle.wsm.security.WSFunctionPermission` and the permission target name. The permission target name is formed by appending `/serviceInterfaceName` and `#serviceName` (or wildcard character) to the service target namespace.

Tip: You can find the target namespace and service name from the WSDL definition file for the service. In the Application Navigator, double-click the WSDL file under the **serviceinterface** node to view the name and `targetNamespace` definitions.

For example, in the Fusion Order Demo, the WSDL definition file defines the following name and namespace:

```
<wsdl:definitions
  name="StoreFrontService"
  targetNamespace="www.globalcompany.example.com"
```

Assume that you want to grant a permission to allow authorized users to invoke a `CreateAccount` service method on the service interface with these Fusion Order Demo name and namespace, you would enter the target name like this:

```
www.globalcompany.example.com/StoreFrontService#CreateAccount
```

Alternatively, you can enter the target name using the wildcard character `*` to grant all operations of the service interface in a single permission:

```
www.globalcompany.example.com/StoreFrontService#*
```

The actions that you can enter are defined by the permission class. In this case, `oracle.wsm.security.WSFunctionPermission` defines the single action `invoke`.

5. Save the changes to the `jazn-data.xml` file.

11.2.17 How to Enable Support for Binary Attachments for SOAP Clients

The ADF service interface framework supports using Message Transmission Optimization Mechanism (MTOM) to handle sending binary data in any service method that operates on a `ViewRow` with a `BlobDomain/ClobDomain` attribute. This permits binary data to accompany XML messages, for example when images are required to document an insurance claim. The SDO data objects of the service-enabled application module maps `BlobDomain/ClobDomain` to `javax.activation.DataHandler`. These `DataHandler` properties could be passed as attachments during SDO data object marshalling/unmarshalling when the web service is called using the SOAP protocol.

To enable MTOM support for your SOAP protocol, you must add the `@MTOM` annotation to the service interface implementation class (for example, `StoreFrontServiceImpl.java`) and your method must operate on a `ViewRow` with `BlobDomain/ClobDomain` attribute.

Before you begin:

It may be helpful to have an understanding of how the SDO framework supports service-enabled ADF view objects and enables web service clients to access rows of data and perform service operations. For more information, see [Section 11.2, "Publishing Service-Enabled Application Modules."](#)

To enable support for sending binary data attachments:

1. In the Application Navigator, expand the application module, expand the **serviceinterface** node, and then double-click the remote server class (`AppModuleServiceImpl.java`) file.

In the web service generated from the `StoreServiceAM` application module in the `StoreFrontModule` application of the Fusion Order Demo, the remote server class is `StoreFrontServiceImpl.java`.

2. In the source for the remote server class, place your cursor anywhere in the annotation section.

For example, in the `StoreFrontServiceImpl.java` the annotation section for the service is:

```
...
@Stateless(name="oracle.fodemo.storefront...common.StoreFrontServiceBean",
    mappedName="StoreFrontServiceBean")
@Remote(StoreFrontService.class)
@PortableWebService(targetNamespace="www.globalcompany.example.com",
    serviceName="StoreFrontService", portName="StoreFrontServiceSoapHttpPort",
    endpointInterface=
        "oracle.fodemo.storefront...common.serviceinterface.StoreFrontService")
...
```

3. Open the Property Inspector and expand the **Web Services** section, then select **Enable MTOM**.

JDeveloper adds the `@MTOM` annotation to the annotations section of the file.

```
...
@Stateless(name="oracle.fodemo.storefront...common.StoreFrontServiceBean",
    mappedName="StoreFrontServiceBean")
@Remote(StoreFrontService.class)
@MTOM
```

```

@PortableWebService(targetNamespace="www.globalcompany.example.com",
    serviceName="StoreFrontService", portName="StoreFrontServiceSoapHttpPort",
    endpointInterface=
        "oracle.fodemo.storefront...common.serviceinterface.StoreFrontService")
@MTOM
...

```

11.2.18 How to Test the Web Service Using Integrated WebLogic Server

You can run the web service in JDeveloper using Integrated WebLogic Server. You can also deploy the web service to Oracle WebLogic Server to test the service.

To run and test using Integrated WebLogic Server:

1. In the Application Navigator, expand the application module, expand the **serviceinterface** node, and then select the remote server class (*AppModuleServiceImpl.java*) file.

In the web service generated from the *StoreServiceAM* application module in the *StoreFrontModule* application of the Fusion Order Demo, the remote server class is *StoreFrontServiceImpl.java*.

2. Right-click the remote server class file, and choose **Run** or **Debug**.

The Configure Default Domain dialog displays the first time you run the application and start a new domain in Integrated WebLogic Server. Use the dialog to define an administrator password for the new domain. Passwords you enter can be eight characters or more and must have a numeric character.

JDeveloper initializes the server instance, and then deploys the application and starts the web service. During this time, the output from these processes is displayed in the **Running** tab of the Log window. After the web service has started, the target URL is also displayed in the Log window.

Tip: In the Log window, you can click the target URL link to launch the HTTP Analyzer. This is a convenient shortcut for testing with JDeveloper Integrated WebLogic Server. For more information about the HTTP Analyzer, see the "Auditing and Profiling Applications" chapter in the *Oracle Fusion Middleware User Guide for Oracle JDeveloper*.

3. Copy the target URL (beginning with `http://`) from the Log window.

For example, if the Log window displays:

```
http://<ipaddress>/ADFServiceDemo-ADFModel-context-root
```

Integrated WebLogic Server will display the service endpoint URL. So there is no need to append the service name.

4. Launch a web browser, paste the target URL you copied from the Log window into the browser address field, and submit the HTTP request.
5. In the test page, choose the operation you want to invoke from the **Operations** dropdown list and enter sample data in its parameter fields.
6. When you are ready, press **Invoke** to submit the operation and view the results for the operation in the Test Results page.

The Test Results page displays the XML Soap format of the information returned by the operation.

11.2.19 How to Prevent Custom Service Methods from Timing Out

When you test the web service you may find that some of your custom methods exceed the established timeout limitation established by the Java Transaction API (JTA). The JTA timeout setting establishes an execution boundary for service methods that by default may not exceed 30 seconds. You can use the Administration Console for Oracle WebLogic Server to increase the JTA timeout setting. If you still receive a timeout exception or you anticipate that the custom methods of the service interface may be long running, you can specify an EJB transaction attribute for the stateless session bean to prevent the EJB from executing those methods in a JTA transaction.

To make a custom method exempt from timing out, you set `TransactionAttributeType.NOT_SUPPORTED` in the Property Inspector specifically for that method. JDeveloper updates the method by adding the annotation `@TransactionAttribute(TransactionAttributeType.NOT_SUPPORTED)`.

Example 11–13 NOT_SUPPORTED Annotation in Custom Service Method

```
@TransactionAttribute(TransactionAttributeType.NOT_SUPPORTED)
public void updateCustomerInterests(List<String> pCategoryIds) throws
    ServiceException {
    invokeCustom((Method) _map.get("updateCustomerInterests"),
        new Object[] { pCategoryIds }, new String[] { null }, false);
}
```

Because a method with this transaction attribute setting will not be executed in the JTA transaction, it is your responsibility to enforce control over the transaction using the ADF Business Components methods of the `oracle.jbo.ApplicationModule` and `oracle.jbo.Transaction` interfaces. For instance, as [Example 11–14](#) shows, the methods of the implementation class of the application module that you service-enabled, will need to call `am.getDBTransaction().commit()` or `rollback()` in order to complete the transaction.

Example 11–14 Custom Code to Handle Transaction Execution in Implementation Method

```
public void updateCustomerInterests(List pCategoryIds) {
    try
    {
        if (pCategoryIds != null && pCategoryIds.size() > 0) {
            List<Integer> copyOfCategoryIds = (List<Integer>)
                this.cloneList(pCategoryIds);
            ViewObject selectedCategories =
                this.getSelectedCategoriesShuttleList();
            RowSetIterator rsi = selectedCategories.createRowSetIterator(null);
            // remove rows for the current user not in the list of product keys
            while (rsi.hasNext()) {
                Row r = rsi.next();
                Number interestId = (Number)r.getAttribute("CategoryId");
                // existing row is in the list, we're ok, so remove from list.
                if (copyOfCategoryIds.contains(interestId)) {
                    copyOfCategoryIds.remove(interestId);
                }
                // if the existing row is in not list, remove it.
                else {
                    r.remove();
                }
            }
            rsi.closeRowSetIterator();
            // at this point, add new rows for the keys that are left
        }
    }
}
```

```

        for (int i = 0 ; i < copyOfCategoryIds.size(); i++ ) {
            Row newRow = selectedCategories.createRow();
            selectedCategories.insertRow(newRow);
            newRow.setAttribute("CategoryId", (String)
                copyOfCategoryIds.get(i).toString());
        }
        this.getTransaction().commit();
    }
}
catch (JboException e)
{
    this.getTransaction().rollback();
    throw e;
}
}

```

You should not change the default transaction attribute setting for the standard service methods generated for the service interface (see [Table 11-1](#)). The standard methods will execute within the default execution boundary set for the JTA transaction.

Before you begin:

It may be helpful to have an understanding of how the SDO framework supports service-enabled ADF view objects and enables web service clients to access rows of data and perform service operations. For more information, see [Section 11.2, "Publishing Service-Enabled Application Modules."](#)

To prevent custom methods from executing in a JTA transaction:

1. In the Application Navigator, expand the application module, expand the **serviceinterface** node, then double-click the remote server class (*AppModuleServiceImpl.java*) file.

In the web service generated from the *StoreServiceAM* application module in the *StoreFrontModule* application of the Fusion Order Demo, the remote server class is *StoreFrontServiceImpl.java*.

2. In the source editor, locate the custom method that you want to prevent from timing out and place your cursor on the method.
3. In the Property Inspector, expand **Stateless Session Bean** and choose **TransactionAttributeType.NOT_SUPPORTED** from the **TransactionAttribute** dropdown list.

As shown in *updateCustomerInterests()* in [Example 11-13](#), JDeveloper updates the custom service method with the annotation.

4. Save the remote server class.
5. In the Application Navigator, double-click the application module implementation class (*AppModuleImpl.java*) file.

The implementation class defines the custom methods that the you exposed through the service interface. In the Fusion Order Demo, the application module implementation class is *StoreServiceAMImpl.java*.

6. In the source editor, in the custom method that implements the service method that you previously set the **TransactionAttribute** property on, add the custom code that will commit and rollback the transaction.

As [Example 11-14](#) shows, if you configured the **TransactionAttribute** property on the service method named *updateCustomerInterests()*, then you would

open the implementation class for the application module, locate the custom method `updateCustomerInterests()`, and add `am.getDBTransaction().commit()` and `rollback()` as part of the method's try and catch statements.

7. Save the application module implementation class.

11.2.20 How to Deploy Web Services to Oracle WebLogic Server

You can deploy the web service to Oracle WebLogic Server, for example to perform a second stage of testing the service.

Before you begin:

1. If your project contains a standard web service (a Java class or interface with the `@WebService` annotation), you must remove the `@WebService` annotation from the Java class before you can deploy the Business Components web service. If you attempt to deploy the Business Components web service from the same project as the standard web service, deployment will fail with an Oracle WebLogic Server exception error. It is therefore necessary to create standard web services in a separate project from your ADF Business Components service.
2. If you created an asynchronous web service, before you can deploy the service you must configure the queues used to store the request and response. For information about configuring the request and response queues, see the *Oracle Fusion Middleware Concepts Guide for Oracle Infrastructure Web Services*.
3. If you configured authorization for the web service as described in [Section 11.2.14, "How to Secure the ADF Web Service for Access By SOAP Clients,"](#) edit the `weblogic-application.xml` file to define application ID parameters. This file appears in the Application Navigator in the Application Resources panel, under the **Descriptors** and **META-INF** nodes.

Add the following `<application-param>` definition as the first element:

```
<weblogic-application
xmlns="http://www.bea.com/ns/weblogic/weblogic-application"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation=

"http://www.bea.com/ns/weblogic/weblogic-application.xsd">
  <application-param>
    <param-name>jps.policystore.applicationid</param-name>
    <param-value>ApplicationName</param-value>
  </application-param>
  ...
</weblogic-application>
```

Note that the `ApplicationName` that you enter must match the name identified in the `jazn-data.xml` policy store definition:

```
<jazn-data>
  <policy-store>
    <applications>
      <application>
        <name>ApplicationName</name>
        <app-roles>
          ...
        </app-roles>
      </application>
    </applications>
  </policy-store>
  ...
</jazn-data>
```

```

        </jaza-policy>
    </application>
</applications>
</policy-store>
</jaza-data>

```

4. Edit the `ejb-jar.xml` file to add the following `JpsInterceptor` definition required by the EJB for application roles evaluation. This file appears in the Application Navigator under the **META-INF** node of the web service project.

```

<?xml version = '1.0' encoding = 'windows-1252'?>
<ejb-jar xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://java.sun.com/xml/ns/javaee
    http://java.sun.com/xml/ns/j2ee/ejb-jar_3_0.xsd" version="3.0"
    xmlns="http://java.sun.com/xml/ns/javaee">
    <enterprise-beans>
        ...
    </enterprise-beans>
    <interceptors>
        <interceptor>
            <interceptor-class>
                oracle.security.jps.ee.ejb.JpsInterceptor
            </interceptor-class>
            <env-entry>
                <env-entry-name>application.name</env-entry-name>
                <env-entry-type>java.lang.String</env-entry-type>
                <env-entry-value>ApplicationName</env-entry-value>
                <injection-target>
                    <injection-target-class>
                        oracle.security.jps.ee.ejb.JpsInterceptor
                    </injection-target-class>
                    <injection-target-name>
                        application_name
                    </injection-target-name>
                </injection-target>
            </env-entry>
        </interceptor>
        ...
    </interceptors>
    <assembly-descriptor>
        <interceptor-binding>
            <ejb-name>*</ejb-name>
            <interceptor-class>
                oracle.security.jps.ee.ejb.JpsInterceptor
            </interceptor-class>
        </interceptor-binding>
    </assembly-descriptor>
</ejb-jar>

```

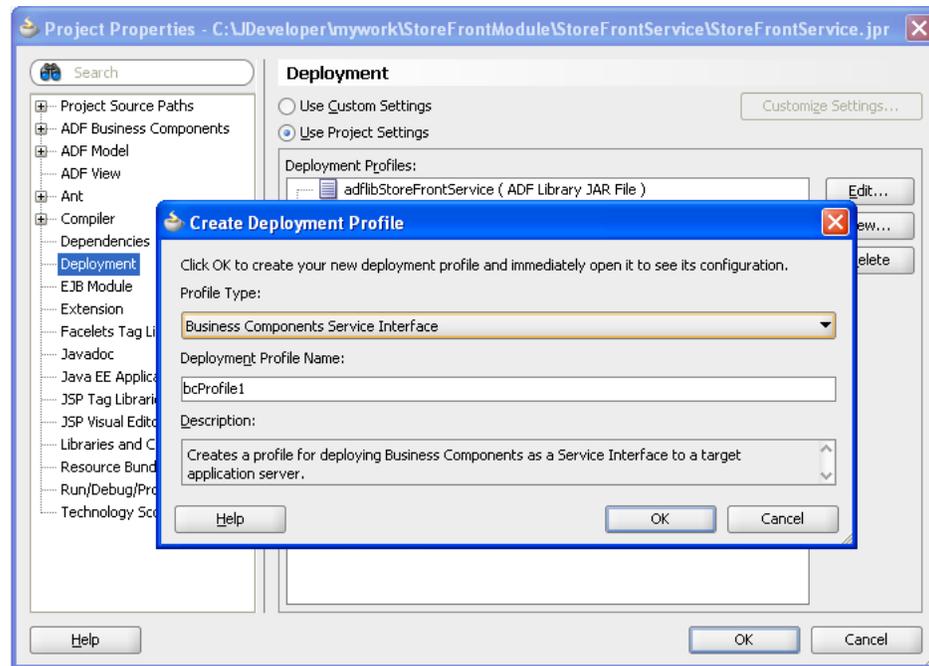

Note that *ApplicationName* must also match the application name identified in the `jaza-data.xml` policy store definition.

To deploy to Oracle WebLogic Server:

1. Create an application server connection to Oracle WebLogic Server:
 - a. From the main menu, choose **View > Application Server Navigator**.
 - b. In the Application Server Navigator, right-click the **Application Servers** node and choose **New Application Server**, and complete the Create Application Server Connection wizard.

2. Create a service deployment profile:
 - a. In the Application Navigator, right-click the project contain the web service and choose **Project Properties**.
 - b. In the Project Properties dialog, open the Deployment page and click **New**.
 - c. In the Create Deployment Profile dialog, choose **Business Components Service Interface** as the archive type, as shown in Figure 11–11.

Figure 11–11 Dialog for Creating a Business Components Service Deployment Profile

3. From the **Application** menu, choose **Deploy > deployment profile** for the deployment profile you created.
4. In the Deploy wizard, on the Deployment Action page, select **Deploy to Application Server** and click **Next**.
5. On the **Select Server** page, select the application server connection.
6. Click **OK**.

11.3 Accessing Remote Data Over the Service-Enabled Application Module

ADF Business Components application modules offer built-in support for web services and for publishing rows of view object data as service data objects (SDOs). Entity objects that you create in your local data model project can utilize the SDO services that the service-enabled application module exposes on its service interface. By creating service-backed entity objects in your local project, you avoid having to work directly with the service proxy and SDOs programmatically for all common remote service data access tasks.

The Create Entity Object wizard makes it easy for you to choose between a local database and the remote ADF Business Components service when you create the entity object, as described in [Section 11.3.1, "How to Use Service-Enabled Entity](#)

[Objects and View Objects.](#)" In this way, service-enabled application modules provide an alternative way to access data that is not available locally in the database.

Once you create the service-backed entity object, you will be able to create view objects, view links, and view criteria to filter the data at runtime. You will also be able to utilize these view objects in your data model as though you were working with locally available data accessed from database tables.

The following sections describe how to augment your data model project using a service-enabled ADF application module.

11.3.1 How to Use Service-Enabled Entity Objects and View Objects

You will want to use the service-backed components as part of your application design strategy when one of the following conditions is true:

- The client data model project needs to work with data from a service-enabled application that is part of a separate business process.
- The client data model project needs to work with data from a pluggable, external service.

In the first case, you provide both sides of the service. In the second case, you may not know what the external service looks like and you may need to perform the following:

1. Even though you might not need a Fusion implementation of the service, since the service-enabled application module's service interface is the supported unit of pluggability and the supported way of creating service-backed entity objects and view objects, you create an application module with a service interface that describes the shape you want your "canonical" pluggable service to have.
2. After generating the service-enabled application module as described in [Section 11.2.1, "How to Enable the Application Module Service Interface,"](#) you then build service-back entity objects and view objects.
3. Finally, you can create an EJB session bean (or an SCA composite) that supports the same service interface as the "canonical" service-enabled application module that you created in Step 2 and configure the `connections.xml` file of the client project containing the service-enabled business components based on this service interface to use this "plugged" version instead.

For details about how to expose an application module as a web service, see [Section 11.2, "Publishing Service-Enabled Application Modules."](#)

11.3.1.1 Creating Entity Objects Backed by SDO Services

You create the service-backed entity object using the Create Entity Object wizard by specifying the URL for the WSDL document that describes the deployed service already running on an application server. The wizard uses the WSDL service description to display the list of available service view instances. In the wizard, you select among the displayed view instances to specify the entity object's data source. At the time you run the wizard, the service endpoint must be accessible in order to locate the WSDL document.

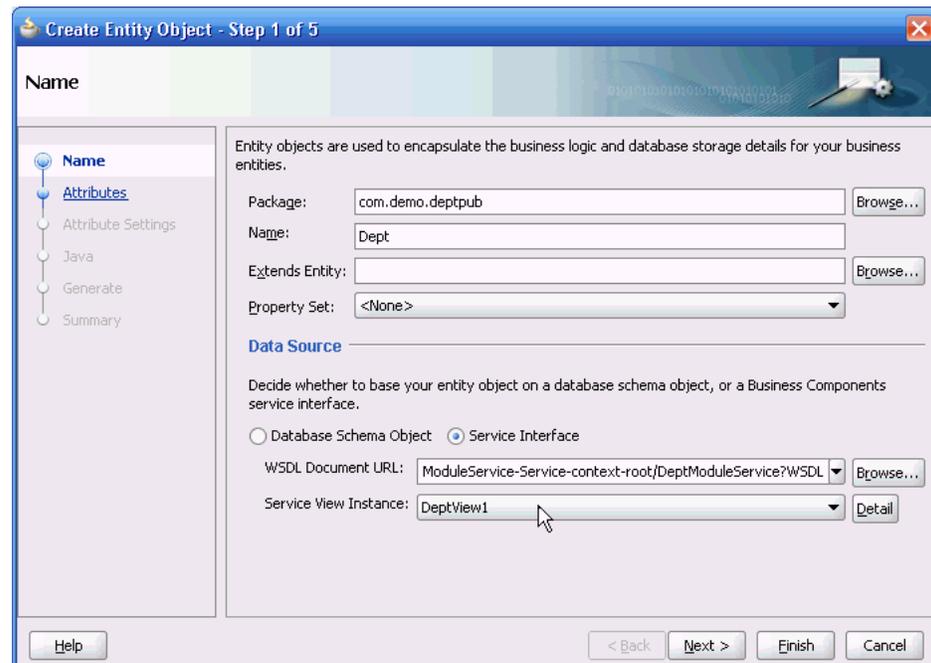

To create the entity object that uses a service view instance as its data source:

1. In the Application Navigator, right-click the project in which you want to create the entity object and choose **New**.
2. In the New Gallery, expand the **Business Tier** node, select **ADF Business Components** and then **Entity Object**, and click **OK**.

3. On the Name page of the Create Entity Object wizard, do the following to create the entity object:
 - Enter the package name in which the entity object will be created and enter the entity object name.
 - Select **Service Interface** as the data source for which you want to create the entity object.
 - Enter the WSDL document URL for the published web service or click **Browse** to use the Find Web Services wizard to locate the remote service from the UDDI registry.
 - Select **Service View Instance** from the dropdown list, as shown in [Figure 11-12](#).

The wizard will attempt to connect with the service endpoint and populate the list from the WSDL service description. If the endpoint is unavailable, the list will remain empty.

Figure 11-12 Service Interface as Data Source in the Create Entity Object Wizard

4. Click **Next** and modify the attributes of the entity object.
For example, on the Attributes page, you can remove an attribute when you do not want the service-backed entity object to reference it.
5. Click **Next** and modify the attributes settings of the entity object before you complete the wizard.
For example, on the Attributes Settings page, you can enable the **Refresh After Insert** and **Refresh After Update** options for attributes that you anticipate will be modified whenever the entity is modified. Typical candidates include a version number column or an updated date column in the row.
6. Click **Finish**.

11.3.1.2 Creating View Objects Backed by SDO Services

After you add the service-backed entity object to your project, you can create service-backed view objects to query and optionally filter the data from the remote service for use in the user interface. A service-backed view object is a view object whose single entity usage references an entity object that is backed an SDO service. You cannot make existing view objects service-backed. Instead, when you create the view object, the new view object will automatically be service-backed if its entity usage is a service-backed entity object.

Before you begin:

Create the service-backed entity object as described in [Section 11.3.1.1, "Creating Entity Objects Backed by SDO Services."](#)

To create a view object from the service-backed entity object:

1. In the Application Navigator, right-click the service-backed entity object and choose **New Default View Object**.
2. In the Create Default View Object dialog, enter the package name in which the view object will be created and enter the view object name, as shown in [Figure 11–13](#).

The generated view object will contain the same attributes as the entity object. You can optionally edit the view object in the overview editor to customize the query. You can also define view criteria for the view object when you want to filter the data from the remote service. For details about filtering query results, see [Section 5.11, "Working with Named View Criteria."](#)

Figure 11–13 View Object Can Be Created from Service-Backed Entity Object

11.3.2 What Happens When You Create Service-Backed Business Components

The service-backed entity object is an entity object that encapsulates the details of accessing and, if necessary, modifying a row of data from a remote ADF Business Components service. After you use the Create Entity Object wizard to create the service-backed entity object, JDeveloper saves additional service-related metadata in the `<Datasource>` element of the entity component definition, as shown in [Example 11–15](#).

The service-backed view object references the single, service-backed entity object in its metadata just as any entity-based view object does. You can use the service-backed view object just as you would use any other view object. For details about working with view objects, see [Chapter 5, "Defining SQL Queries Using View Objects."](#) The ADF runtime handles the interaction with the remote ADF Business Components service.

Example 11–15 Entity Object Metadata Shows Service View as Data Source

```
<Entity
  xmlns="http://xmlns.example.com/bc4j"
  Name="CustomerSEO"
```

```

DBObjectType="table"
AliasName="CustomerSEO"
BindingStyle="OracleName"
UseGlueCode="false">
<DataSource
  DataSourceClass="oracle.jbo.datasource.svc.SIEODataSourceImpl"
  Type="ServiceInterface">
<ServiceInterface
  ServiceName="{http://www.globalcompany.com/oesvc/}OrderEntryService"
  SDOName="{http://www.globalcompany.com/oesvc/}CustomersSVO"
  SVIName="{http://www.globalcompany.com/oesvc/}CustomersSVO"
  CreateOpName="createCustomer"
  UpdateOpName="updateCustomer"
  DeleteOpName="deleteCustomer"
  GetOpName="getCustomer"
  FindOpName="findCustomers"
  ProcessOpName="processCustomers"/>
</DataSource>
<Attribute
  Name="CustomerId"
  IsNotNull="true"
  Precision="6"
  Scale="0"
  ColumnName="CustomerId"
  Type="oracle.jbo.domain.Number"
  ColumnType="NUMBER"
  SQLType="NUMERIC"
  PrimaryKey="true">
</Attribute>
<!-- ... Other Attribute elements here ... -->
</Entity>

```

11.3.3 How to Update the Data Model for Service-Backed Business Components

Because the service interface exposes individual view instances, you are responsible for defining hierarchical relationships between service-backed entity objects (through associations) and service-backed view objects (through view links) in your consuming project. View links and associations are not automatically created when you create the service-backed business component. For example, if the application module of the published ADF Business Components service defines a master-detail relationship that you want to utilize, then you must define a view link for the corresponding view objects in your own project to preserve this hierarchy.

Furthermore, while you can create view links between view objects that query their data locally and service-backed view objects (and the other way around), once you define the view link, you will not be able to create entity-based view objects with the following entity object usages:

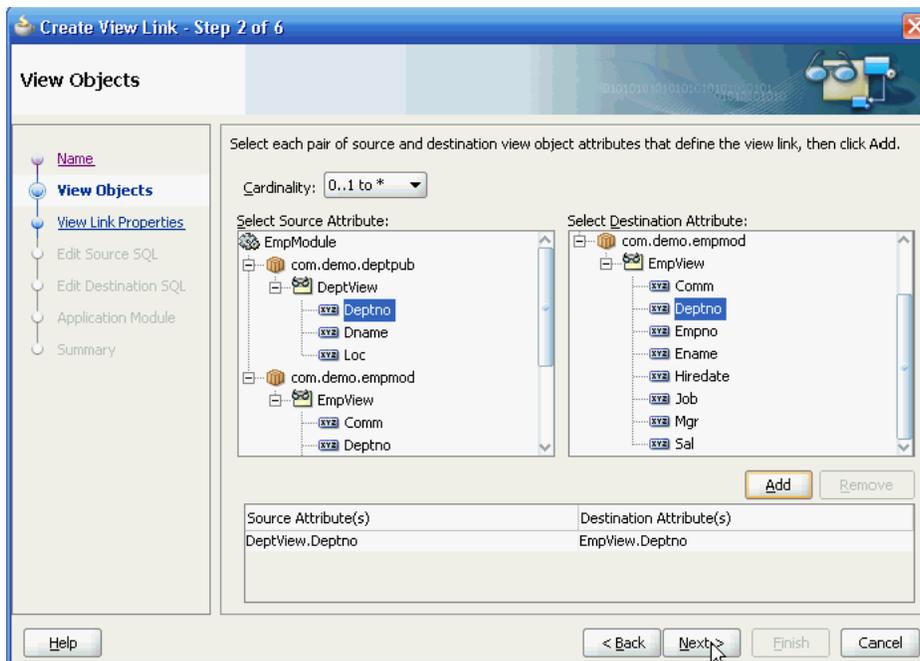

- The view object will not be able to reference a secondary entity usage that is a service-backed entity object.
- The view object will not be able to reference a primary entity usage that is a service-backed entity object with secondary entity usages.

The same restrictions apply to associations in the client project between regular entity objects and service-backed entity objects: while you can create the associations, you will not be able to create view objects.

You use the Create View Link wizard to specify relationships between the view objects that your project defines, as shown in [Figure 11-14](#). For details about creating view

links, see [Section 5.6.2, "How to Create a Master-Detail Hierarchy for Entity-Based View Objects."](#)

Figure 11–14 One to Many Relationship Defined in Create View Link Wizard

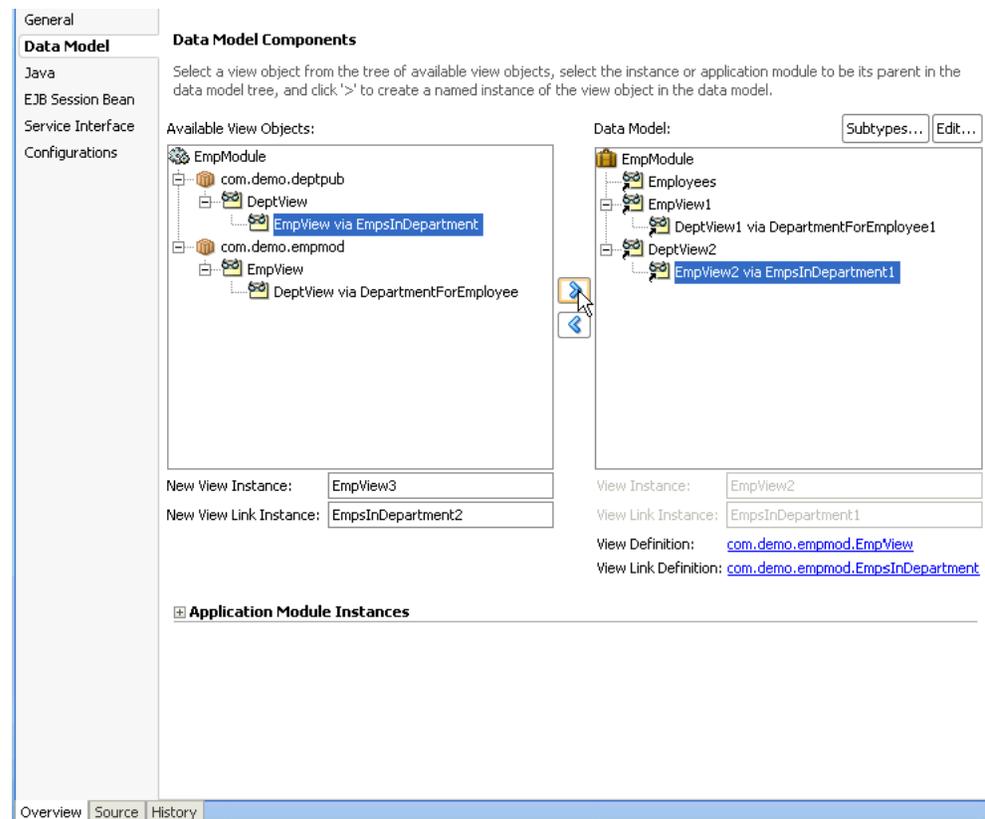

View links you create may define relationships between service-backed view objects and view objects that query locally accessed database tables. For example, you might choose to drive a database-derived detail view object with a service-backed master view object. You can create view links with the combinations shown in [Table 11–2](#).

Table 11–2 Supported View Link Combinations Involving Service-Backed View Objects

Use Case	Master View Object Type	View Linked Detail View Object Type	View Link Cardinality
Local master rows with remote details	Query-based	Service-backed	One-to-many
Remote master rows with local details	Service-backed	Query-based	One-to-many
Local master rows with remote reference information	Query-based	Service-backed	Many-to-one
Remote master rows with local reference information	Service-backed	Query-based	Many-to-one

Once you have defined the desired view hierarchy, using the Create View Link wizard, you use the overview editor for your project’s application module to define new view instances on the data model, as shown in [Figure 11–15](#). The updated data model allows you to expose the view objects as ADF data controls that enable databinding with the user interface components of the Fusion web application. For details about updating the data model, see [Section 9.2.3.2, "Adding Master-Detail View Object Instances to an Application Module."](#)

Figure 11–15 Data Model Contains Service View Instances

11.3.4 How to Configure the Service-Backed Business Components Runtime

Before you can run your application and interact with the published service-enabled ADF application module to invoke service operations, you need to describe the published service, including the service's endpoint provider type and other configuration information. The ADF Business Components `ServiceFactory` class (`oracle.jbo.client.svc.ServiceFactory`) returns a proxy for the service, then uses the service proxy to invoke the service operations. The service factory can return proxies for three different service endpoint providers, to support these transport protocols:

- When the service endpoint provider is ADF Business Component, the transport protocol is EJB RMI.
- When the service endpoint provider is SOA Fabric, the transport protocol is SOA Fabric SDO binding.
- When the service endpoint provider is SOAP (for JAX-WS clients), the transport protocol is SOAP.

To configure the consuming application to invoke published service operations:

1. Add the `bcProfileName_Common.jar` file for the SDO's generated classes to the client project's classpath.
2. Update the `connections.xml` file in the client project's `.adf/META-INF` folder to describe the published ADF Business Components service.

The updates you make to the file will depend on the transport protocol your application uses: EJB RMI protocol, SOA Fabric SDO binding, or SOAP protocol (for JAX-WS clients).

11.3.4.1 Adding the SDO Client Library to the Classpath

Before your application can access the published service, the service consuming project must have access to the generated SDO classes and their schema definitions. These files are packaged in the *bcProfileName_Common.jar* file generated by the development team responsible for publishing the service.

To make the SDO classes and their schema definitions available to your application, obtain the *bcProfileName_Common.jar* file from the service-provider team and place this JAR file in a folder of your local project. For example, you may copy the JAR file into your project's `deploy` folder. You can then use JDeveloper to add the JAR file to your project's classpath with a SDO client library you create. For steps to generate the SDO classes JAR file, see [Section 11.2.20, "How to Deploy Web Services to Oracle WebLogic Server."](#)

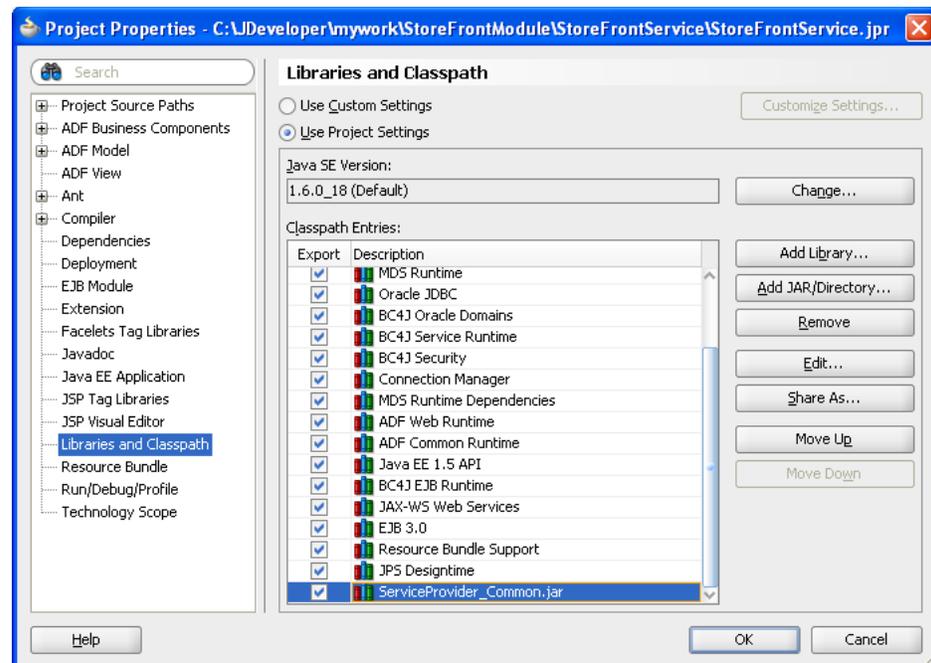

To add the SDO client library to the classpath:

1. In the Application Navigator, right-click your project node and choose **Project Properties**.
2. In the Project Properties dialog, select **Libraries and Classpath** and click **Add Libraries**.
3. In the Add Library dialog, click **New** to create the SDO client library.
4. In the Create Library dialog, click **Add Entry** to add a classpath entry.
5. In the Select Path Entry dialog, browse to the folder that contains the *bcProfileName_Common.jar* file and select the file to view it in the Create Library dialog.

The Select Path Entry dialog lets you browse the file system or local area network to locate the JAR file. If you cannot browse the `deploy` folder of the service-provider's application workspace to obtain the JAR file, you must obtain the file and copy it into your own project's folder. For example, you may have copied the JAR file into your project's `deploy` folder.

6. Click **OK** in the dialogs to display the Project Properties dialog with the SDO client library selected. Click **OK** to add the library to the classpath.

[Figure 11-16](#) shows the SDO client library with the name `ServiceProvider_Common.jar` selected. In this case, the library name is the same as the JAR file name. Optionally, you can edit the library name in the Create Library dialog.

Figure 11–16 SDO Client Library Classpath Entry

11.3.4.2 Registering the ADF Business Components Service in the Consuming Application's connections.xml for the EJB RMI Protocol

When the service endpoint provider is ADF Business Components, the service factory will return an EJB object proxy bound to a stateless session bean running in the EJB container. You must provide the JNDI context information to allow the consuming application to look up the published service.

Lookup information that you provide to register the published ADF Business Components service appears in the consuming Fusion web application's `connections.xml` file, located in the `.adf/META-INF` folder relative to the application. The ADF connection architecture uses this file to encapsulate the details of the service endpoint provider.

The JNDI lookup information you provide will depend on whether the published service runs locally (in the same JVM) with the consuming application or runs remotely on a separate server from the consuming application. Typically, the ADF Business Components service is in a different application from the consuming application and is therefore run remotely.

To register the published service with your client application, update the `connections.xml` file following the example in [Example 11–16](#). When the ADF Business Components service runs local to the consuming application (as occurs when you run within JDeveloper), the service factory needs only the JNDI name to look up the service.

Note: When you deploy the calling application to standalone Oracle WebLogic Server, you will use Oracle Enterprise Manager to configure the JNDI context properties instead of editing the `connections.xml` file. For instructions, refer to the online documentation in Oracle Enterprise Manager.

Example 11–16 Client connections.xml File Registers the Local EJB ADF Business Components Service

```

<References xmlns="http://xmlns.oracle.com/adf/jndi">
  <Reference name="{www.globalcompany.com}StoreFrontService"
    className="oracle.jbo.client.svc.Service" xmlns="">
    <Factory className="oracle.jbo.client.svc.ServiceFactory"/>
    <RefAddresses>
      <StringRefAddr addrType="serviceInterfaceName">
        <Contents>oracle.foddemo.storefront.store.service.common.
          serviceinterface.StoreFrontService</Contents>
      </StringRefAddr>
      <StringRefAddr addrType="serviceEndpointProvider">
        <Contents>ADFBC</Contents>
      </StringRefAddr>
      <StringRefAddr addrType="jndiName">
        <Contents>StoreFrontServiceBean#oracle.fodemo.storefront.store.service.common.
          serviceinterface.StoreFrontService</Contents>
      </StringRefAddr>
      <StringRefAddr addrType="serviceSchemaName">
        <Contents>StoreFrontAMService.xsd</Contents>
      </StringRefAddr>
      <StringRefAddr addrType="serviceSchemaLocation">
        <Contents>oracle/fodemo/storefront/store/service/common/serviceinterface/</Contents>
      </StringRefAddr>
    </RefAddresses>
  </Reference>
  ...
</References>

```

When the ADF Business Components service runs remotely to the calling client, then remote JNDI context information needs to be added to the `connections.xml` file. You can edit these JNDI context properties in the `connections.xml` file, as shown in [Example 11–17](#):

- `jndiFactoryInitial` should be set to `weblogic.jndi.WLInitialContextFactory`.
- `jndiProviderURL` is the JNDI provider URL that indicates the location of the JNDI server. The URL should be composed as `t3://<hostname>:<server port>`.
For example, specify a URL like: `t3://localhost:8888`, where `t3` is the Oracle WebLogic protocol, `localhost` is the host name that the remote Oracle WebLogic Server instance runs in, `8888` is the port number.
- `jndiSecurityPrincipal` specifies the principal (user name) with permission to access the remote JNDI.
When you deploy the service to standalone Oracle WebLogic Server, the user name can be read from the file.
- `jndiSecurityCredentials` specifies the credentials (password) to be used for the security principal.

As [Example 11–11](#) shows, when you deploy the service to standalone Oracle WebLogic Server in a test environment, you can specify credentials in plain text for the JNDI provider. For example, you can specify `weblogic/weblogic1` which are the default administrator user name/password credentials with sufficient privileges to access JNDI provider for Oracle WebLogic Server.

When you deploy the service to a production environment, you must remove the plain text password to avoid creating a security vulnerability. As [Example 11–17](#) shows, the `connections.xml` file must contain `<SecureRefAddr`

`addrType="jndiSecurityCredentials"/>` with no password. To configure the service password for standalone Oracle WebLogic Server, you must use Oracle Enterprise Manager, which will store the encrypted password in Oracle's credential store.

Example 11–17 Client connections.xml File Registers the Remote EJB ADF Business Components Service

```
<References xmlns="http://xmlns.oracle.com/adf/jndi">
  <Reference name="{www.globalcompany.com}StoreFrontService"
    className="oracle.jbo.client.svc.Service" xmlns="">
    <Factory className="oracle.jbo.client.svc.ServiceFactory"/>
    <RefAddresses>
      <StringRefAddr addrType="serviceInterfaceName">

          serviceinterface.StoreFrontService</Contents>
      </StringRefAddr>
      <StringRefAddr addrType="jndiFactoryInitial">
        <Contents>weblogic.jndi.WLInitialContextFactory</Contents>
      </StringRefAddr>
      <StringRefAddr addrType="jndiProviderURL">
        <Contents>t3://localhost:8888</Contents>
      </StringRefAddr>
      <StringRefAddr addrType="jndiSecurityPrincipal">
        <Contents>a_username</Contents>
      </StringRefAddr>
      <SecureRefAddr addrType="jndiSecurityCredentials"/>
      <StringRefAddr addrType="serviceSchemaName">
        <Contents>StoreFrontAMService.xsd</Contents>
      </StringRefAddr>
      <StringRefAddr addrType="serviceSchemaLocation">
        <Contents>oracle/fodemo/storefront/store/service/common/serviceinterface/</Contents>
      </StringRefAddr>
    </RefAddresses>
  </Reference>
  ...
</References>
```

11.3.4.3 Registering the ADF Business Components Service in the Consuming Application's connections.xml for the SOAP Protocol

When the service endpoint provider is SOAP, the service factory will create a dynamic JAX-WS client proxy. You must provide the WSDL URL and port name to allow the consuming application to look up the published service. Additionally, for the SOAP client, Oracle Web Service Manager (Oracle WSM) client security policy can be attached as part of the SOAP header.

Lookup information that you provide to register the published ADF Business Components service appears in the consuming Fusion web application's `connections.xml` file, located in the `.adf/META-INF` folder relative to the application. The ADF connection architecture uses this file to encapsulate the details of the service endpoint provider.

Note: When you deploy the calling application to standalone Oracle WebLogic Server, you will use Oracle Enterprise Manager to configure the JNDI context properties instead of editing the `connections.xml` file. For instructions, refer to the online documentation in Oracle Enterprise Manager.

To register the published service with your client application for the SOAP protocol, depending on whether your application uses identity propagation or identity switching, update the `connections.xml` file following the example in either [Example 11–18](#) or [Example 11–19](#). Identity propagation and switching are similar in that each process involves propagating an identity. In Fusion web applications, identity propagation involves propagating the identity that is currently executing code. Identity switching, on the other hand, involves propagating an application identity that is different from that currently executing code.

To register the published service with your client application so the the user identity will be switched based on the credential key, specify the clientside policy `oracle/wss11_username_token_with_message_protection_client_policy` in the `connections.xml` file following the example in [Example 11–18](#).

Note: The `connections.xml` file supports Oracle WSM security policy client overrides. When the security policy is `oracle/wss11_username_token_with_message_protection_client_policy`, the `csf-key` property can be overridden to specify the consuming application's credentials.

Example 11–18 Client connections.xml File Registers the Remote Business Components Service for the SOAP Protocol Using Identify Switching

```
<Reference name="{http://xmlns.oracle.com/apps/sample/hrService/}HrService"

                    service="{http://xmlns.oracle.com/apps/sample/hrService/}HrService">
                        <model
                            name="{http://xmlns.oracle.com/apps/sample/hrService/}HrService"
                            xmlns="http://oracle.com/ws/model">
                                <service
                                    name="{http://xmlns.oracle.com/apps/sample/hrService/}HrService">
                                        <port name="HrServiceSoapHttpPort"
                                            binding="{http://xmlns.oracle.com/apps/sample/hrService/}HrServiceSoapHttp"
                                            portType="{http://xmlns.oracle.com/apps/sample/hrService/}HrService">
                                            <policy-references xmlns="http://oracle.com/adf">
                                                <policy-reference category="security"
                                                    uri="oracle/wss11_saml_token_with_message_protection_client_policy"
                                                    enabled="true"
                                                    id="oracle/wss11_saml_token_with_message_protection_client_policy"
                                                    xmlns="" />
                                            </policy-references>
                                            <soap addressUrl="http://rws65094fwks:7202/MySampleSvc/HrService"
                                                xmlns="http://schemas.xmlsoap.org/wsdl/soap/" />
                                        </port>
                                    </service>
                                </model>
                            </wsconnection>
                        </Contents>
                    </XmlRefAddr>
                </RefAddresses>
            </Reference>

```

11.3.4.4 Registering the ADF Business Components Service in the Consuming Application's connections.xml for Fabric SDO Binding

When the service endpoint provider is Fabric, the service factory will return a SOA Fabric composite proxy and call the service running inside a Fabric composite through Fabric's SDO binding. You must provide the name of the Fabric composite to allow the consuming application to look up the published service.

Lookup information that you provide to register the published ADF Business Components service appears in the consuming Fusion web application's `connections.xml` file, located in the `.adf/META-INF` folder relative to the application. The ADF connection architecture uses this file to encapsulate the details of the service endpoint provider.

Note: When you deploy the calling application to standalone Oracle WebLogic Server, you will use Oracle Enterprise Manager to configure the JNDI context properties instead of editing the `connections.xml` file. For instructions, refer to the online documentation in Oracle Enterprise Manager.

To register the published service with your client application for the Fabric protocol, update the `connections.xml` file following the example in [Example 11–20](#), where `fabricAddress` is the name of the Fabric composite for the published service.

Example 11–20 Client connections.xml File Registers the Remote Business Components Service for the SOA Fabric SDO Binding

```
<References xmlns="http://xmlns.oracle.com/adf/jndi">
  <Reference name="(www.globalcompany.com)StoreFrontService"
    className="oracle.jbo.client.svc.Service" xmlns="">
    <Factory className="oracle.jbo.client.svc.ServiceFactory"/>
    <RefAddresses>
      <StringRefAddr addrType="serviceInterfaceName">
        <Contents>oracle.foddemo.storefront.store.service.common.
          serviceinterface.StoreFrontService</Contents>
      </StringRefAddr>
      <StringRefAddr addrType="serviceEndpointProvider">
        <Contents>Fabric</Contents>
      </StringRefAddr>
      <StringRefAddr addrType="fabricAddress">
        <Contents>fabric_StoreFrontService</Contents>
      <StringRefAddr addrType="serviceSchemaName">
        <Contents>StoreFrontAMService.xsd</Contents>
      </StringRefAddr>
      <StringRefAddr addrType="serviceSchemaLocation">
        <Contents>oracle/fodemo/storefront/store/service/common/serviceinterface/</Contents>
      </StringRefAddr>
    </RefAddresses>
  </Reference>
  ...
</References>
```

11.3.5 How to Test the Service-Backed Components in the Oracle ADF Model Tester

Before you can launch the Oracle ADF Model Tester, your project must meet the runtime requirements as described in [Section 11.3.4, "How to Configure the Service-Backed Business Components Runtime."](#) The Oracle ADF Model Tester will display the view objects you create from the remote service and allow you to interact with the service to perform standard CRUD operations.

Because the application module that you run can access locally queried data and remotely queried data together, service-backed view objects and database-derived view objects will display in the same tester. If the endpoint is unavailable at the time you select the service-backed view object in the Oracle ADF Model Tester, you will get a runtime exception.

For details about running the Oracle ADF Model Tester, see [Section 6.3.1, "How to Run the Oracle ADF Model Tester."](#)

11.3.6 How to Invoke Operations of the Service-Backed Components in the Consuming Application

The ADF Business Components service interface requires that you return a service proxy to ensure that operations you invoke use the transport protocol specified by the published service.

Before you begin:

You need to ensure that the consuming application has the correct libraries on the classpath. In the Application Navigator, double-click the project and in the Project Properties dialog, select **Libraries and Classpath** and confirm the following libraries appear:

- **Java EE 1.5**
- **Oracle XML Parser v2**
- **BC4J Service Client**
- **JAX-WS Client**
- The service's common JAR file

As [Example 11–21](#) shows, when you invoke the operation, you perform the following tasks:

1. Import the `oracle.jbo.client.svc.ServiceFactory` class and published service class.
2. Call `getServiceProxy()` on the service factory object and pass in the service name in the form `<serviceName>.NAME`. The ADF service factory embeds a `SDOHelperContext` ID in the service proxy object returned by this method to ensure delivery of the latest ADF Business Component service schema metadata to the SDO.

The schema (`.xsd` files) for the service object may be stored in MDS and may have been extended for example to add more business component attributes, extend existing types, or define new types. The local helper context allows customization of individual service's schema definitions without affecting other service's SDO metadata or requiring restarting the application.

3. Call `create()` on a data factory object, where the proxy object is obtained from the `getServiceProxy()` call.
4. Invoke the operation on the proxy object and return a data object.
5. Save the data object return as XML.

Example 11–21 Obtaining and Invoking a Service Proxy in the Consuming Application

```
import commonj.sdo.DataObject;
import commonj.sdo.helper.DataFactory;
import commonj.sdo.helper.XMLHelper;
import hr.common.Dept;
import hr.common.serviceinterface.HRAppService;
import oracle.jbo.client.svc.ServiceFactory;
...
{
    HRAppService proxy = (HRAppService) ServiceFactory.getServiceProxy(HRAppService.NAME);

    Dept dept = (Dept)
        ServiceFactory.getDataFactory(proxy).create("http://example.com/hr/common/" + "Dept");
    dept.setDname("ENGINEERING");
}
```

```

...
dept = proxy.createDept(dept);
String xml = ServiceFactory.getXMLHelper(proxy).save((DataObject) dept,
    "http://example.com/hr/common/", "dept");
out.print(xml);
}

```

11.3.7 What You May Need to Know About Creating Service Data Objects in the Consuming Application

The ADF service interface framework defines a set of common data objects, such as `oracle.jbo.common.service.types.FindCriteria`, `oracle.jbo.common.service.types.FindControl`, `oracle.jbo.common.service.types.ProcessControl`, and so on. Those data objects are used in standard `findXxx()` method and `processXxx()` method calls. You can create these data objects in the consuming application and pass them to the standard service methods. As [Example 11-22](#) shows, you can need to call the data factory class' `create()` method to construct those data objects before passing them into the `findXxx()` or `processXxx()` methods.

Example 11-22 *Creating Data Objects in the Consuming Application*

```

FindCriteria fc = (FindCriteria) ServiceFactory.getDataFactory(proxy).create
    ("http://xmlns.oracle.com/adf/svc/types/", "FindCriteria");

```

11.3.8 What Happens at Runtime: How the Application Accesses the Published Application Module

The ADF runtime obtains the data source information from the service-backed entity object XML definition to automate interactions with the service interface methods as needed. By using the service-backed entity object, you avoid having to work directly with the service proxy and service data objects programmatically for all common remote service data access tasks. The ADF service factory looks up the service and then uses the service interface you specified in the `connections.xml` to invoke the service methods.

When your application accesses a remote ADF Business Components service, each remote call is stateless, and the remote service will not participate in the same transaction as the business component that uses a service-enabled application module's service interface.

In the majority of the cases, calls to remote services will be informational in nature and will not make changes to remote objects. However, if you must use a remote service to make changes, then keep these points in mind:

- An exception thrown by the remote service will cause the local transaction to fail.
- If you successfully call a remote service that results in modifying data, and then subsequently your local transaction fails for any reason, then it is the responsibility of your error handling code to perform a compensating transaction against the remote service to "undo" the previous change made.

11.3.9 What You May Need to Know About Service-Backed Entity Objects and View Objects

You will use some web services to access reference information. However, other services you call may modify data. This data modification might be in your own company's database if the service was written by a member of your own or another

team in your company. If the web service is outside your firewall, of course the database being modified will be managed by another company. In either of these situations, it is important to understand that any data modifications performed by a web service you invoke will occur in its own distinct transaction unrelated to the service-enabled application module's current unit of work. For example, if you have invoked a web service that modifies data and then you later call `rollback()` to cancel the pending changes in the application module's current unit of work, rolling back the changes has no effect on the changes performed by the web service you called in the process. You may need to invoke a corresponding web service method to perform a compensating change to account for your rollback of the application module's transaction.

At runtime, ADF handles the interaction with the remote ADF Business Components service. However, you should be aware that service-backed business components have the following design time restrictions that may restrict your application's runtime behavior. For more details about how these restrictions apply at design time, see [Section 11.3.3, "How to Update the Data Model for Service-Backed Business Components."](#)

- View objects that you create cannot reference a service-backed entity object as a secondary entity object usage.
- View objects that you create cannot produce a flattened join from two or more related entity objects when at least one of those entity objects is a service-backed entity object.
- Service-backed view objects that you create from service-backed entity objects will not reference secondary entity usages.

For more details about how these restrictions apply at design time, see [Section 11.3.3, "How to Update the Data Model for Service-Backed Business Components."](#)

Extending Business Components Functionality

This chapter describes techniques for extending all types of ADF Business Components objects.

This chapter includes the following sections:

- [Section 12.1, "About Extending Business Components Functionality"](#)
- [Section 12.2, "Globally Extending ADF Business Components Functionality"](#)
- [Section 12.3, "Creating a Layer of Framework Extensions"](#)
- [Section 12.4, "Customizing Framework Behavior with Extension Classes"](#)
- [Section 12.5, "Creating Generic Extension Interfaces"](#)
- [Section 12.6, "Invoking Stored Procedures and Functions"](#)
- [Section 12.7, "Accessing the Current Database Transaction"](#)
- [Section 12.8, "Customizing Business Components Error Messages"](#)
- [Section 12.9, "Creating Extended Components Using Inheritance"](#)
- [Section 12.10, "Substituting Extended Components in a Delivered Application"](#)

12.1 About Extending Business Components Functionality

When you need to add custom code to extend the base functionality of the ADF Business Components framework, you can enable a custom Java class for any of the key types of ADF business components you create. You enable the generation of custom classes for a component on the Java page of its respective overview editor in JDeveloper. When you enable this option, JDeveloper creates a Java source file for a custom class related to the component whose name follows a configurable naming standard. This class, whose name is recorded in the component's XML component definition, provides a place where you can write the custom Java code required by that component.

When used without customization, your component is completely defined by its XML component definition and it will be fully functional without custom Java code or even a Java class file for the component. If you have no need to extend the built-in functionality of a component in ADF Business Components, and no need to write any custom code to handle its built-in events, you can use the component in this XML-only fashion.

12.1.1 Extending Business Components Use Cases and Examples

An ADF Business Components framework extension class is Java class you write that extends one of the framework's base classes to:

- Augment a built-in feature works with additional, generic functionality
- Change how a built-in feature works, or even to
- Workaround a bug you encounter in a generic way

12.1.2 Additional Functionality for Extending Business Components

You may find it helpful to understand other ADF features before you start working with the ADF Business Components framework. Following are links to other functionality that may be of interest.

- For details about creating a reusable library to make your framework extension layer classes easier to package, see [Chapter 38, "Reusing Application Components."](#)
- For details about using the customization features provided by Oracle Metadata Services (MDS) to create applications that can be customized and subsequently deployed by a customer, see [Chapter 39, "Customizing Applications with MDS."](#)
- For a quick reference to the most common code that you will typically write, use, and override in your custom classes, see [Appendix D, "Most Commonly Used ADF Business Components Methods."](#)
- For API documentation related to the `oracle.jbo` package, see the following Javadoc reference document:
 - *Oracle Fusion Middleware Java API Reference for Oracle ADF Model*

12.2 Globally Extending ADF Business Components Functionality

One of the powerful features of framework-based development is the ability to extend the base framework to change a built-in feature to behave differently or to add a new feature that can be used by all of your applications.

Note: To experiment with the examples in this chapter, use the `AdvancedExamples` workspace in the `StandaloneExamples` module of the Fusion Order Demo application, as described in [Section 2.4.3, "Standalone Applications in the AdvancedExamples Application Workspace."](#) For information about how to obtain and install the Fusion Order Demo, see [Section 2.2, "Setting Up the Fusion Order Demo Application."](#)

12.2.1 How To Create a Framework Extension Class

An ADF Business Components framework extension class is Java class you write that extends one of the framework's base classes to:

- Augment a built-in feature works with additional, generic functionality
- Change how a built-in feature works, or even to
- Workaround a bug you encounter in a generic way

Once you've created a framework extension class, any new ADF components you create can be based on your *customized* framework class instead of the base one. Of

course, you can also update the definitions of existing components to use the new framework extension class as well.

To create a framework extension class:

1. Identify a project to contain the framework extension class.

You can create it in the same project as your business service components if you believe it will only be used by components in that project. Alternatively, if you believe you might like to reuse the framework extension class across multiple Fusion web applications, create a separate `FrameworkExtensions` project to contain the framework extension classes.

2. Ensure the **BC4J Runtime** library is in the project's libraries list.

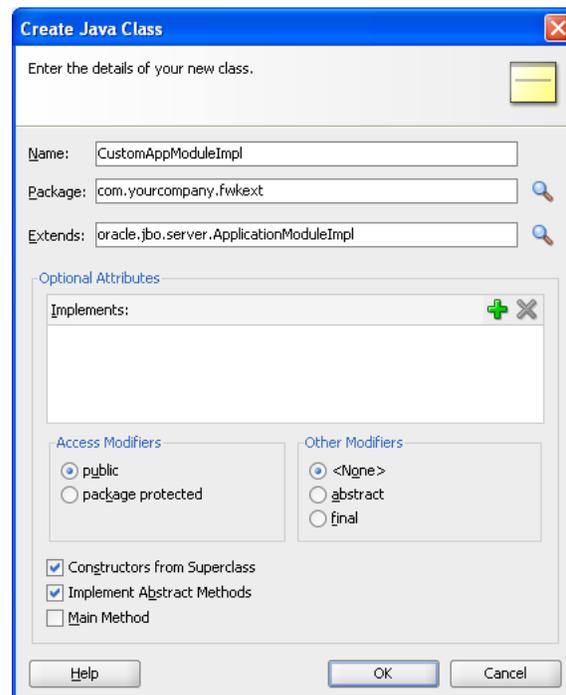

Use the **Libraries** page of the **Project Properties** dialog to verify this and to add the library if missing.

3. In the **New Gallery**, in the **General** category, select **Java Class** to create the new class.

4. In the Create Java Class dialog, specify the appropriate framework base class from the `oracle.jbo.server` package in the **Extends** field.

Figure 12–1 illustrates what it would look like to create a custom framework extension class named `CustomAppModuleImpl` in the `com.yourcompany.fwkext` package to customize the functionality of the base application module component. To quickly find the base class you're looking for, use the **Browse** button next to the **Extends** field that launches the **JDeveloper Class Browser**. Using its **Search** tab, you can type in part of the class name (including using `*` as a wildcard) to quickly subset the list of classes to find the one you're looking for.

Figure 12–1 *Creating a Framework Extension Class for an Application Module*

When you click **OK**, JDeveloper creates the custom framework extension class for you in the directory of the project's source path corresponding to the package name you've chosen.

Note: Some ADF Business Components component classes exist in both a server-side and a remote-client version. For example, if you use the JDeveloper **Class Browser** and type `ApplicationModuleImpl` into the **Match Class Name** field on the **Search** tab, the list will show two `ApplicationModuleImpl` classes: one in the `oracle.jbo.server` package and the other in the `oracle.jbo.client.remote` package. When creating framework extension classes, use the base ADF classes in the `oracle.jbo.server` package.

12.2.2 What Happens When You Create a Framework Extension Class

After creating a new framework extension class, it will not automatically be used by your application. You must decide which components in your project should make use of it. The following sections describe the available approaches for basing your ADF components on your own framework extension classes.

12.2.3 How to Base an ADF Component on a Framework Extension Class

You can set the base classes for any ADF component using the **Java** page of any ADF Business Components wizard or editor.

Before you begin:

- Create the framework extension class as described in [Section 12.2.1, "How To Create a Framework Extension Class."](#)
- If you created your framework extension classes in a separate project, visit the **Dependencies** page of the Project Properties dialog for the project containing your business components and mark the `FrameworkExtension` project as a project dependency.
- If you have packaged your framework extension classes in a Java archive (JAR) file, create a named library definition to reference its JAR file and also list that library in the library list of the project containing your business components. To create a library if missing, use the Manage Libraries dialog available from the **Tools > Manage Libraries** main menu item. To verify or adjust the project's library list, use the **Libraries** page of the Project Properties dialog.

After you ensure the framework classes are available to reference, you can create the ADF component. Every ADF Business Components wizard and editor displays the same **Class Extends** button on the **Java** page so you can use the technique to choose your desired framework extension base class(es) both for new components or existing ones.

There is no fixed limit on how many levels of framework extension classes you create. For example, after creating a company-level `CustomAppModuleImpl` to use for all application modules in all Fusion web applications that your company creates, some later project team might encounter the need to further customize that framework extension class. That team could create a `SomeProjectCustomAppModuleImpl` class that extends the `CustomAppModuleImpl` and then include the project-specific custom application module code in there as shown in [Example 12-1](#).

Example 12–1 Extending a Custom Class

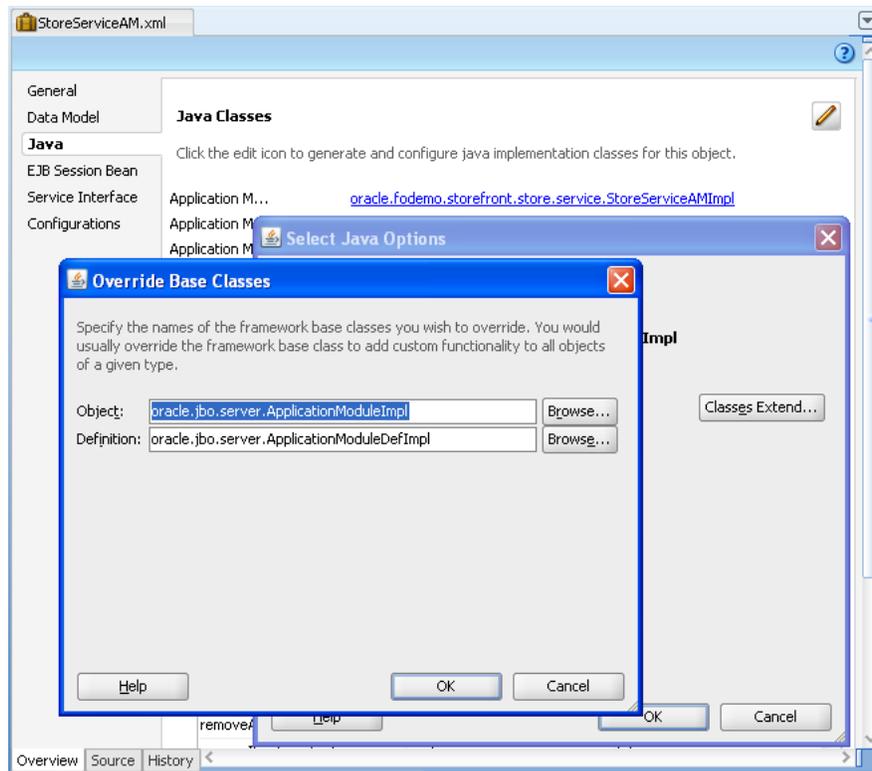

```
public class SomeProjectCustomAppModuleImpl
    extends CustomAppModuleImpl {
    /*
     * Custom application module code specific to the
     * "SomeProject" project goes here.
     */
}
```

Then, any application modules created as part of the implementation of this specific project can use the `SomeProjectCustomAppModuleImpl` as their base class instead of the `CustomAppModuleImpl`.

To create an ADF component based on a framework extension class:

1. In the Application Navigator, double-click the desired component.
2. In the overview editor, click the **Java** navigation tab and click the **Edit Java options** button.
3. In the Select Java Options dialog, click **Classes Extends**.
4. In the Override Base Classes dialog, enter the fully-qualified name of the framework base classes you wish to override. You can also use the **Browse** button to use the JDeveloper Class Browser to find the classes quickly.

When you use the Class Browser to select a custom base class for the component, the list of available classes is automatically filtered to show only classes that are appropriate. For example, when clicking **Browse** in [Figure 12–2](#) to select an application module **Object** base class, the list will only show classes available in the current project's library list which extend the `oracle.jbo.server.ApplicationModule` class either directly or indirectly. If you don't see the class you're looking for, either you extended the incorrect base class or you have chosen the wrong component class name to override.

Figure 12–2 Specifying a Custom Base Class for a New Application Module

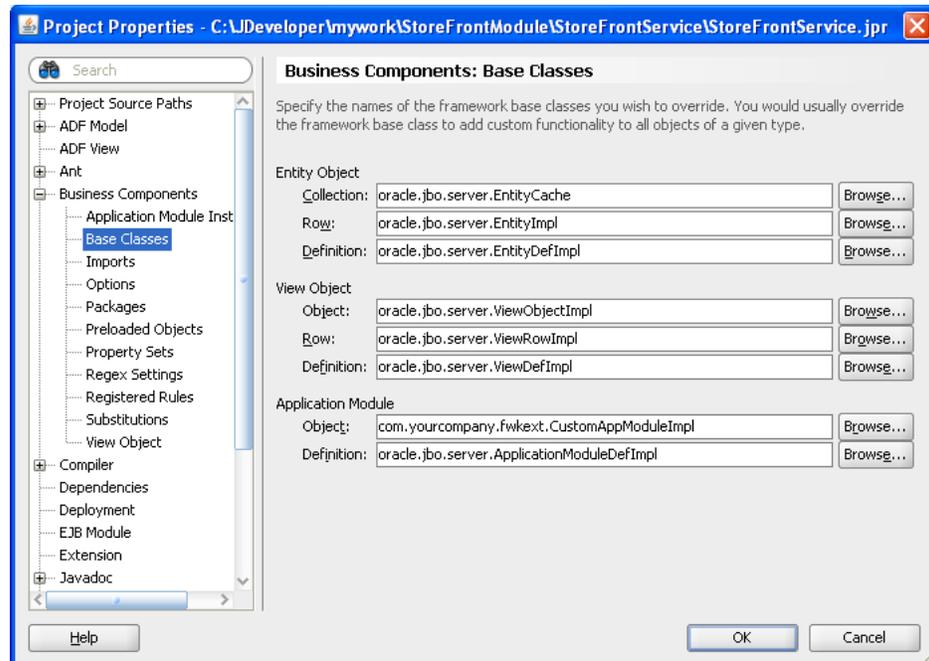

12.2.4 How to Define Framework Extension Classes for All New Components

If you decide to use a specific set of framework extension classes as a standard for a given project, you can use the Project Properties dialog to define your preferred base classes for each component type. Setting these preferences for base classes does not affect any existing components in the project, but the component wizards will use the preferences for any new components created.

To define project-level preferences for framework extension classes:

1. In the Application Navigator, right-click the data model project that will contain the extension classes and choose **Project Properties**.
2. In the Project Properties dialog, expand **Business Components > Base Classes** in the tree.
3. On the Business Components page, enter the fully-qualified name of that class in the **Application Module Object** class name field.

For example, to indicate that any new application modules created in the project should use the `CustomAppModuleImpl` class by default, enter the fully-qualified name of that class in the *componentName* **Object** class name field as shown in [Figure 12–3](#).

Figure 12–3 Setting Project-Level Preferences for ADF Component Base Classes

12.2.5 How to Define Framework Extension Classes for All New Projects

When you want to apply the same base class preferences to each new project that you create in JDeveloper, you can define the preferences at a global level using the Preferences dialog. Base classes that you specify at the global level will not alter your existing projects containing ADF components.

To define global preferences for framework extension classes:

1. In the Tools menu, choose Preferences.
2. In the Preferences dialog, expand **Business Components > Base Classes** in the tree.
3. On the Business Components page, enter the fully-qualified name of that class in *componentName Object* class name field.

The page displays the same options for specifying the preferred base classes for each component type as shown in [Figure 12–3](#).

12.2.6 What Happens When You Base a Component on a Framework Extension Class

When an ADF component you create extends a custom framework extension class, JDeveloper updates its XML component definition to reflect the custom class name you've chosen.

12.2.6.1 XML-Only Components

For example, assume you've created the *YourService* application module in the `com.yourcompany.yourapp` package, with a custom application module base class of `CustomAppModuleImpl`. If you have opted to leave the component as an XML-only component with no custom Java file, its XML component definition (*YourService.xml*) will look like what you see in [Example 12–2](#). The value of the

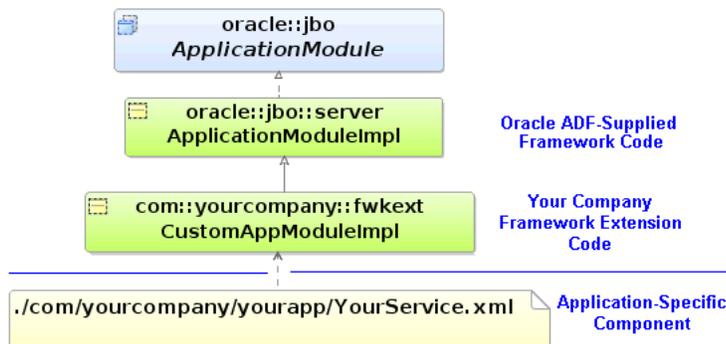

ComponentClass attribute of the <AppModule> tag is read at runtime to identify the Java class to use to represent the component.

Example 12–2 Custom Base Class Names Are Recorded in XML Component Definition

```
<AppModule
  Name="YourService"
  ComponentClass="com.yourcompany.fwkext.CustomAppModuleImpl" >
  <!-- etc. -->
</AppModule>
```

Figure 12–4 illustrates how the XML-only YourService application module relates to your custom extension class. At runtime, it uses the CustomAppModuleImpl class which inherits its base behavior from the ApplicationModuleImpl class.

Figure 12–4 XML-Only Component Reference an Extended Framework Base Class

12.2.6.2 Components with Custom Java Classes

If your component requires a custom Java class, as you've seen in previous chapters you open the **Java** page of the component editor and check the appropriate checkbox to enable it. For example, when you enable a custom application module class for the YourServer application module, JDeveloper creates the appropriate YourServiceImpl.java class. As shown in Example 12–3, it also updates the component's XML component definition to reflect the name of the custom component class.

Example 12–3 Custom Component Class Recorded in XML Component Definition

```
<AppModule
  Name="YourService"
  ComponentClass="com.yourcompany.yourapp.YourServiceImpl" >
  <!-- etc. -->
</AppModule>
```

JDeveloper also updates the component's custom Java class to modify its extends clause to reflect the new custom framework base class, as shown in Example 12–4.

Example 12–4 Component's Custom Java Class Updates to Reflect New Base Class

```
package com.yourcompany.yourapp;
import com.yourcompany.fwkext.CustomAppModuleImpl;
// -----
// --- File generated by Oracle ADF Business Components Design Time.
// --- Custom code may be added to this class.
// --- Warning: Do not modify method signatures of generated methods.
// -----
```

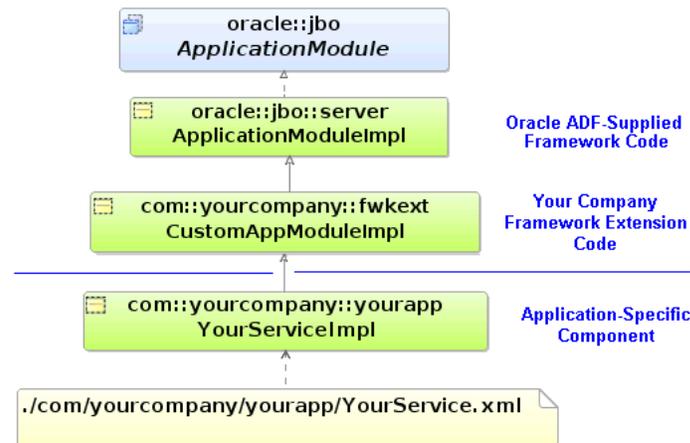

```

public class YourServiceImpl extends CustomAppModuleImpl {
    /**This is the default constructor (do not remove) */
    public YourServiceImpl() {}
    // etc.
}

```

Figure 12–5 illustrates how the `YourService` application module with its custom `YourServiceImpl` class is related to your framework extension class. At runtime, it uses the `YourServiceImpl` class which inherits its base behavior from the `CustomAppModuleImpl` framework extension class which, in turn, extends the base `ApplicationModuleImpl` class.

Figure 12–5 Component with Custom Java Extending Customized Framework Base Class

12.2.7 What You May Need to Know About Updating the Extends Clause in Custom Component Java Files

If you have an ADF component with a custom Java class and later decide to base the component on a framework extension class, use the **Class Extends** button on the **Java** page of the component's overview editor to change the component's base class. Doing this updates the component's XML component definition to reflect the new base class, and *also* modifies the `extends` clause in the component's custom Java class. If you manually update the `extends` clause without using the component editor, the component's XML component definition will not reflect the new inheritance and the next time you open the editor, your manually modified `extends` clause will be overwritten with what the component editor believes is the correct component base class.

12.3 Creating a Layer of Framework Extensions

Before you begin to develop application-specific business components, Oracle recommends that you consider creating a complete layer of framework extension classes and setting up your project-level preferences to use that layer by default. You might not have any custom code in mind to put in these framework extension classes yet, but you will be glad you heeded this recommendation the first time you encounter a need to:

- Add a generic feature that all your company's application modules require
- Augment a built-in feature with some custom, generic processing

- Workaround a bug you encounter in a generic way

Failure to set up these preferences at the outset can present your team with a substantial inconvenience if you discover mid-project that all of your entity objects, for example, require a new generic feature, augmented built-in feature, or a generic bug workaround. Putting a complete layer of framework classes in place at the start of your project is an insurance policy against this inconvenience and the wasted time related to dealing with it later in the project. JDeveloper will automatically use framework classes when you create them.

12.3.1 How to Create Your Layer of Framework Extension Layer Classes

A common set of customized framework base classes in a package name of your own choosing like *com.yourcompany.adfextensions*, each importing the `oracle.jbo.server.*` package, would consist of the following classes:

- `public class CustomEntityImpl extends EntityImpl`
- `public class CustomEntityDefImpl extends EntityDefImpl`
- `public class CustomViewObjectImpl extends ViewObjectImpl`
- `public class CustomViewRowImpl extends ViewRowImpl`
- `public class CustomApplicationModuleImpl extends ApplicationModuleImpl`
- `public class CustomDBTransactionImpl extends DBTransactionImpl2`
- `public class CustomDatabaseTransactionFactory extends DatabaseTransactionFactory`

To make your framework extension layer classes easier to package as a reusable library, create them in a separate project from the projects that use them.

For details about using the custom `DBTransactionImpl` class, see [Section 12.8.4.2, "Configuring an Application Module to Use a Custom Database Transaction Class."](#)

Note: For your convenience, the `FrameworkExtensions` project of the `AdvancedExamples` workspace in the `StandaloneExamples` module of the Fusion Order Demo application contains a set of these classes. You can select the `com.yourcompany.adfextensions` package in the Application Navigator and choose the **Refactor > Rename** option from the context menu to change the package name of all the classes to a name you prefer.

For completeness, you may also want to create customized framework classes for the following classes as well, note however that overriding anything in these classes would be a fairly rare requirement.

- `public class CustomViewDefImpl extends ViewDefImpl`
- `public class CustomEntityCache extends EntityCache`
- `public class CustomApplicationModuleDefImpl extends ApplicationModuleDefImpl`

12.3.2 How to Package Your Framework Extension Layer in a JAR File

Use the **Create Deployment Profile: JAR File** dialog to create a JAR file containing the classes in your framework extension layer. This is available in the **New Gallery** in the **General > Deployment Files** category.

Give the deployment profile a name like `FrameworkExtensions` and click **OK**. By default the JAR file will include all class files in the project. Since this is exactly what you want, when the **JAR Deployment Profile Properties** dialog appears, you can just click **OK** to finish.

Note: Do not use the **ADF Library JAR** archive type to package your framework extension layer. You create the ADF Library JAR file when you want to package reusable components to share in the JDeveloper Resource Catalog. For details about working with ADF components and the ADF Library JAR archive type, see [Section 38.3, "Packaging a Reusable ADF Component into an ADF Library."](#)

Finally, to create the JAR file, right-click the project node in the Application Navigator and choose **Deploy - YourProfileName - to JAR File** on the context menu. A **Deployment** tab appears in the JDeveloper **Log window** that should display feedback like:

```
---- Deployment started. ---- Feb 14, 2008 1:42:39 PM
Running dependency analysis...
Wrote JAR file to ...\FrameworkExtensions\deploy\FrameworkExtensions.jar
Elapsed time for deployment: 2 seconds
---- Deployment finished. ---- Feb 14, 2008 1:42:41 PM
```

12.3.3 How to Create a Library Definition for Your Framework Extension JAR File

JDeveloper uses named libraries as a convenient way to organize the one or more JAR files that comprise reusable component libraries.

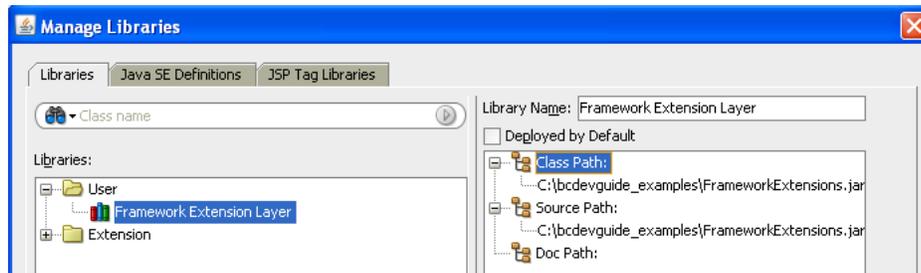

To define a library for your framework extensions JAR file:

1. Choose **Tools > Manage Libraries** from the main menu.
2. In the **Manage Libraries** dialog, select the **Libraries** tab.
3. Select the **User** node in the tree and click the **New** button.
4. In the **Create Library** dialog that appears, name the library "Framework Extension Layer" and select the **Class Path** node and click **Add Entry**.
5. Use the **Select Path Entry** dialog that appears to select the `FrameworkExtensions.jar` file that contains the class files for the framework extension components, then click **Select**.
6. Select the **Source Path** node and click **Add Entry**.
7. Use the **Select Path Entry** dialog that appears to select the `..\FrameworkExtensions\src` directory where the source files for the framework extension classes reside, then click **Select**.
8. Click **OK** to dismiss the **Create Library** dialog and define the new library.

When finished, you will see your new "Framework Extension Layer" user-defined library, as shown in [Figure 12-6](#). You can then add this library to the library list of any project where you will be building business services, and your custom framework

extension classes will be available to reference as the preferred component base classes.

Figure 12–6 *New User-Defined Library for Your Framework Extensions Layer*

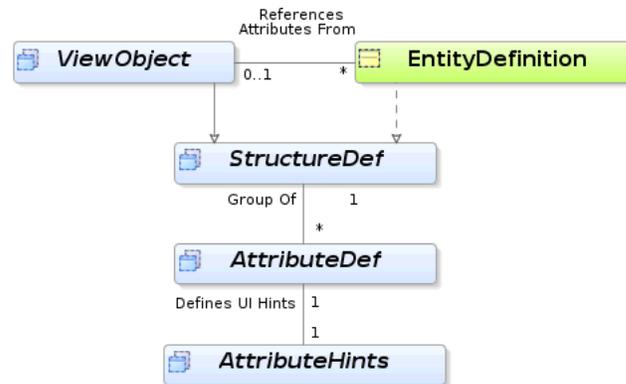

12.4 Customizing Framework Behavior with Extension Classes

One of the common tasks you'll perform in your framework extension classes is implementing custom application functionality. Since framework extension code is written to be used by all components of a specific type, the code you write in these classes often needs to work with component attributes in a generic way. To address this need, ADF provides API's that allow you to access component metadata at runtime. It also provides the ability to associate custom metadata properties with any component or attribute. You can write your generic framework extension code to leverage runtime metadata and custom properties to build generic functionality, which if necessary, only is used in the presence of certain custom properties.

Note: The example in this section refers to the `ProgrammaticallySetProperties` project of the `AdvancedExamples` application workspace in the `StandaloneExamples` module of the Fusion Order Demo application.

12.4.1 How to Access Runtime Metadata For View Objects and Entity Objects

Figure 12–7 illustrates the three primary interfaces ADF provides for accessing runtime metadata about view objects and entity objects. The `ViewObject` interface extends the `StructureDef` interface. The class representing the entity definition (`EntityDefImpl`) also implements this interface. As its name implies, the `StructureDef` defines the structure and the component and provides access to a collection of `AttributeDef` objects that offer runtime metadata about each attribute in the view object row or entity row. Using an `AttributeDef`, you can access its companion `AttributeHints` object to reference hints like the display label, format mask, tooltip, etc.

Figure 12–7 Runtime Metadata Available for View Objects and Entity Objects

12.4.2 How to Implement Generic Functionality Using Runtime Metadata

In [Section 6.4.1, "ViewObject Interface Methods for Working with the View Object's Default RowSet"](#) you learned that for read-only view objects the `findByKey()` method and the `setCurrentRowWithKey` builtin operation only work if you override the `create()` method on the view object to call `setManageRowsByKey(true)`. This can be a tedious detail to remember if you create a lot of read-only view objects, so it is a great candidate for automating in a framework extension class for view objects.

Assume a `FrameworkExtensions` project contains a `FODViewObjectImpl` class that is the base class for all view objects in the application. This framework extension class for view objects extends the base `ViewObjectImpl` class and overrides the `create()` method as shown in [Example 12–5](#) to automate this task. After calling the `super.create()` to perform the default framework functionality when a view object instance is created at runtime, the code tests whether the view object is a read-only view object with at least one attribute marked as a key attribute. If this is the case, it invokes `setManageRowsByKey(true)`.

The `isReadOnlyNonEntitySQLViewWithAtLeastOneKeyAttribute()` helper method determines whether the view object is read-only by testing the combination of the following conditions:

- `isFullSql()` is true

This method returns true if the view object's SQL query is completely specified by the developer, as opposed to having the select list derived automatically based on the participating entity usages.
- `getEntityDefs()` is null

This method returns an array of `EntityDefImpl` objects representing the view object's entity usages. If it returns null, then the view object has no entity usages.

It goes on to determine whether the view object has any key attributes by looping over the `AttributeDef` array returned by the `getAttributeDefs()` method. If the `isPrimaryKey()` method returns true for any attribute definition in the list, then you know the view object has a key.

Example 12–5 Automating Setting Manage Rows By Key

```
public class FODViewObjectImpl extends ViewObjectImpl {
    protected void create() {
        super.create();
        if (isReadOnlyNonEntitySQLViewWithAtLeastOneKeyAttribute()) {
```

```

        setManageRowsByKey(true);
    }
}
boolean isReadOnlyNonEntitySQLViewWithAtLeastOneKeyAttribute() {
    if (getViewDef().isFullSql() && getEntityDefs() != null) {
        for (AttributeDef attrDef : getAttributeDefs()) {
            if (attrDef.isPrimaryKey()) {
                return true;
            }
        }
    }
    return false;
}
// etc.
}

```

12.4.3 How to Implement Generic Functionality Driven by Custom Properties

When you create application modules, view objects, and entity objects you can select the **General** navigation tab in the overview editor for these business components and expand the **Custom Properties** section to define custom metadata properties for any component. These are name/value pairs that you can use to communicate additional declarative information about the component to the generic code that you write in framework extension classes. You can use the `getProperty()` method in your code to conditionalize generic functionality based on the presence of, or the specific value of, one of these custom metadata properties.

For example, the `FODViewObjectImpl` framework extension class overrides the view object's `insertRow()` method as shown in [Example 12–6](#) to conditionally force a row to be inserted and to appear as the last row in the row set. If any view object extending this framework extension class defines a custom metadata property named `InsertNewRowsAtEnd`, then this generic code executes to insert new rows at the end. If a view object does not define this property, it will have the default `insertRow()` behavior.

Example 12–6 *Conditionally Inserting New Rows at the End of a View Object's Default RowSet*

```

public class FODViewObjectImpl extends ViewObjectImpl {
    private static final String INSERT_NEW_ROWS_AT_END = "InsertNewRowsAtEnd";
    public void insertRow(Row row) {
        super.insertRow(row);
        if (getProperty(INSERT_NEW_ROWS_AT_END) != null) {
            row.removeAndRetain();
            last();
            next();
            getDefaultRowSet().insertRow(row);
        }
    }
}
// etc.
}

```

In addition to defining component-level custom properties, you can also define properties on view object attributes, entity object attributes, and domains. At runtime, you access them using the `getProperty()` method on the `AttributeDef` interface for a given attribute.

12.4.4 What You May Need to Know About the Kinds of Attributes

In addition to providing information about an attribute's name, Java type, SQL type, and many other useful pieces of information, the `AttributeDef` interface contains the `getAttributeKind()` method that you can use to determine the kind of attribute it represents. This method returns a `byte` value corresponding to one of the public constants in the `AttributeDef` interface listed in [Table 12-1](#).

Table 12-1 Entity Object and View Object Attribute Kinds

Public <code>AttributeDef</code> Constant	Attribute Kind Description
<code>ATTR_PERSISTENT</code>	Persistent attribute
<code>ATTR_TRANSIENT</code>	Transient attribute
<code>ATTR_ENTITY_DERIVED</code>	View object attribute mapped to an entity-level transient attribute
<code>ATTR_SQL_DERIVED</code>	SQL-Calculated attribute
<code>ATTR_DYNAMIC</code>	Dynamic attribute
<code>ATTR_ASSOCIATED_ROWITERATOR</code>	Accessor attribute returning a <code>RowSet</code> of set of zero or more Rows
<code>ATTR_ASSOCIATED_ROW</code>	Accessor attribute returning a single Row

12.4.5 What You May Need to Know About Custom Properties

You may find it handy to programmatically set custom property values at runtime. While the `setProperty()` API to perform this function is by design not available to clients on the `ViewObject`, `ApplicationModule`, or `AttributeDef` interfaces in the `oracle.jbo` package, code you write *inside* your ADF components' custom Java classes can use it.

12.5 Creating Generic Extension Interfaces

In addition to creating framework extension classes, you can create custom interfaces that all of your components can implement by default. The client interface is very useful for exposing methods from your application module that might be invoked by UI clients, for example. This section considers an example for an application module, however, the same functionality is possible for a custom extended view object and view row interface as well. For more information about client interfaces, see also [Section 9.9, "Publishing Custom Service Methods to UI Clients"](#) and [Section 9.10, "Working Programmatically with an Application Module's Client Interface."](#)

Assume that you have a `CustomApplicationModuleImpl` class that extends `ApplicationModuleImpl` and that you want to expose two custom methods like this:

```
public void doFeatureOne(String arg);
public int anotherFeature(String arg);
```

Perform the following steps to create a custom extension interface `CustomApplicationModule` and have your `CustomApplicationModuleImpl` class implement it.

1. Create a custom interface that contains the methods you would like to expose globally on your application module components. For this scenario, that interface would look like this:

```
package devguide.advanced.customintf.fwkext;
```

```

/**
 * NOTE: This does not extend the
 * ===== oracle.jbo.ApplicationModule interface.
 */
public interface CustomApplicationModule {
    public void doFeatureOne(String arg);
    public int anotherFeature(String arg);
}

```

Notice that the interface does *not* extend the `oracle.jbo.ApplicationModule` interface.

2. Modify your `CustomApplicationModuleImpl` application module framework extension class to implement this new `CustomApplicationModule` interface.

```

package devguide.advanced.customintf.fwkext;
import oracle.jbo.server.ApplicationModuleImpl;
public class CustomApplicationModuleImpl
    extends ApplicationModuleImpl
    implements CustomApplicationModule {
    public void doFeatureOne(String arg) {
        System.out.println(arg);
    }
    public int anotherFeature(String arg) {
        return arg == null ? 0 : arg.length();
    }
}

```

3. Rebuild your project.

The ADF wizards will only "see" your interfaces after they have been successfully compiled.

After you have implemented your `CustomApplicationModuleImpl` class, you can create a new application module which exposes the global extension interface and is based on your custom framework extension class. For this purpose you use the overview editor for application modules.

To create a custom application module interface:

1. In the Application Navigator, double-click the application module for which you want to create the custom interface.

For example, you might create a new `ProductModule` application module which exposes the global extension interface `CustomApplicationModule` and is based on the `CustomApplicationModuleImpl` framework extension class.

2. In the overview editor, select the **Java** navigation tab and click the **Edit Java options** icon.

The Java Classes page should show an existing Java class for the application module identified as **Application Module Class**.

By default, JDeveloper generates the Java class for application modules you create. However, if you disabled this feature, click the **Edit Java options** button in the Java Classes section and select **Generate Application Module Class**. Click **OK** to add a Java class to the project from which you will create the custom interface.

3. In the Select Java Options dialog, click **Class Extends**.
4. In the Override Base Classes dialog, specify the name of the framework base class you want to override and click **OK**.

For example, you might select `CustomApplicationModuleImpl` as the base class for the application module.

5. In the Java Classes page of the overview editor, expand the **Client Interface** section and click the **Edit application module client interface** button.
6. In the Edit Client Interface dialog, click the **Interfaces** button.
7. In the Select Interfaces to Extend dialog, select the desired custom application module interface from the available list and click **OK**.

For example, you might shuttle the `CustomApplicationModule` interface to the **Selected** list to be one of the custom interfaces that clients can use with your component.

8. In the Edit Client Interfaces dialog, ensure that at least one method appears in the **Selected** list.

Note: You need to select at least one method in the **Selected** list in the Edit Client Interfaces dialog, even if it means redundantly selecting one of the methods on the global extension interface. Any method will do in order to get JDeveloper to generate the custom interface.

9. Click **OK**.

The Java Classes page displays the new custom interface for the application module identified as **Application Module Client Interface**.

When you dismiss the Edit Client Interfaces dialog and return to the application module overview editor, JDeveloper generates the application module custom interface. For example, the custom interface `ProductModule` automatically extends *both* the base `ApplicationModule` interface and your `CustomApplicationModule` extension interface like this:

```
package devguide.advanced.customintf.common;
import devguide.advanced.customintf.fwkext.CustomApplicationModule;

import oracle.jbo.ApplicationModule;
// -----
// ---   File generated by Oracle ADF Business Components Design Time.
// -----
public interface ProductModule
    extends CustomApplicationModule, ApplicationModule {
    void doSomethingProductRelated();
}
```

Once you've done this, then client code can cast your `ProductModule` application module to a `CustomApplicationModule` interface and invoke the generic extension methods it contains in a strongly-typed way.

Note: The basic steps are the same for exposing methods on a `ViewObjectImpl` framework extension class, as well as for a `ViewRowImpl` extension class.

12.6 Invoking Stored Procedures and Functions

You can write code in the custom Java classes for your business components to invoke database stored procedures and functions. Here you'll consider some simple examples based on procedures and functions in a PL/SQL package; however, using the same techniques, you also can invoke procedures and functions that are not part of a package.

Consider the PL/SQL package shown in [Example 12-7](#).

Example 12-7 PL/SQL Package with Example Procedures

```
create or replace package devguidepkg as
  procedure proc_with_no_args;
  procedure proc_with_three_args(n number, d date, v varchar2);
  function  func_with_three_args(n number, d date, v varchar2) return varchar2;
  procedure proc_with_out_args(n number, d out date, v in out varchar2);
end devguidepkg;
```

The following sections explain how to invoke each of the example procedures and functions in this package.

Note: The example in this section refers to the `StoredProcedureInvocation` project of the `AdvancedExamples` application workspace in the `StandaloneExamples` module of the Fusion Order Demo application.

12.6.1 How to Invoke Stored Procedures with No Arguments

If you need to invoke a stored procedure that takes no arguments, you can use the `executeCommand()` method on the `DBTransaction` interface (in the `oracle.jbo.server` package as shown in [Example 12-8](#)).

Example 12-8 Executing a Stored Procedure with No Arguments

```
// In StoredProcTestModuleImpl.java
public void callProcWithNoArgs() {
  getDBTransaction().executeCommand(
    "begin devguidepkg.proc_with_no_args; end;");
}
```

12.6.2 How to Invoke Stored Procedure with Only IN Arguments

Invoking stored procedures that accept only `IN`-mode arguments — which is the default PL/SQL parameter mode if not specified — requires using a JDBC `PreparedStatement` object. The `DBTransaction` interface provides a `createPreparedStatement()` method to create this object for you in the context of the current database connection. You could use a helper method like the one shown in [Example 12-9](#) to simplify the job of invoking a stored procedure of this kind using a `PreparedStatement`. Importantly, by using a helper method, you can encapsulate the code that closes the JDBC `PreparedStatement` after executing it. The code performs the following basic tasks:

1. Creates a JDBC `PreparedStatement` for the statement passed in, wrapping it in a PL/SQL `begin...end` block.
2. Loops over values for the bind variables passed in, if any.
3. Sets the value of each bind variable in the statement.

Notice that since JDBC bind variable API's use one-based numbering, the code adds one to the zero-based for loop index variable to account for this.

4. Executes the statement.
5. Closes the statement.

Example 12–9 Helper Method to Simplify Invoking Stored Procedures with Only IN Arguments

```
protected void callStoredProcedure(String stmt, Object[] bindVars) {
    PreparedStatement st = null;
    try {
        // 1. Create a JDBC PreparedStatement for
        st = getDBTransaction().createPreparedStatement("begin "+stmt+"end;",0);
        if (bindVars != null) {
            // 2. Loop over values for the bind variables passed in, if any
            for (int z = 0; z < bindVars.length; z++) {
                // 3. Set the value of each bind variable in the statement
                st.setObject(z + 1, bindVars[z]);
            }
        }
        // 4. Execute the statement
        st.executeUpdate();
    }
    catch (SQLException e) {
        throw new JboException(e);
    }
    finally {
        if (st != null) {
            try {
                // 5. Close the statement
                st.close();
            }
            catch (SQLException e) {}
        }
    }
}
```

With a helper method like this in place, calling the `proc_with_three_args` procedure shown in [Example 12–7](#) would look like this:

```
// In StoredProcTestModuleImpl.java
public void callProcWithThreeArgs(Number n, Date d, String v) {
    callStoredProcedure("devguidepkg.proc_with_three_args(?,?,?)",
        new Object[]{n,d,v});
}
```

Notice the question marks used as JDBC bind variable placeholders for the arguments passed to the function. JDBC also supports using named bind variables, but using these simpler positional bind variables is also fine since the helper method is just setting the bind variable values positionally.

12.6.3 How to Invoke Stored Function with Only IN Arguments

Invoking stored functions that accept only IN-mode arguments requires using a JDBC `CallableStatement` object in order to access the value of the function result after executing the statement. The `DBTransaction` interface provides a `createCallableStatement()` method to create this object for you in the context of the current database connection. You could use a helper method like the one shown in

Example 12–10 to simplify the job of invoking a stored function of this kind using a `CallableStatement`. The helper method encapsulates both the creation and clean up of the JDBC statement being used.

The code performs the following basic tasks:

1. Creates a JDBC `CallableStatement` for the statement passed in, wrapping it in a PL/SQL `begin...end` block.
2. Registers the first bind variable for the function return value.
3. Loops over values for the bind variables passed in, if any.
4. Sets the value of each bind user-supplied bind variable in the statement.

Notice that since JDBC bind variable API's use one-based numbering, and since the function return value is already the first bind variable in the statement, the code adds *two* to the zero-based for loop index variable to account for these.

5. Executes the statement.
6. Returns the value of the first bind variable.
7. Closes the statement.

Example 12–10 Helper Method to Simplify Invoking Stored Functions with Only IN Arguments

```
// Some constants
public static int NUMBER = Types.NUMERIC;
public static int DATE = Types.DATE;
public static int VARCHAR2 = Types.VARCHAR;

protected Object callStoredFunction(int sqlReturnType, String stmt,
                                   Object[] bindVars) {
    CallableStatement st = null;
    try {
        // 1. Create a JDBC CallableStatement
        st = getDBTransaction().createCallableStatement(
            "begin ? := "+stmt+";end;",0);
        // 2. Register the first bind variable for the return value
        st.registerOutParameter(1, sqlReturnType);
        if (bindVars != null) {
            // 3. Loop over values for the bind variables passed in, if any
            for (int z = 0; z < bindVars.length; z++) {
                // 4. Set the value of user-supplied bind vars in the stmt
                st.setObject(z + 2, bindVars[z]);
            }
        }
        // 5. Set the value of user-supplied bind vars in the stmt
        st.executeUpdate();
        // 6. Return the value of the first bind variable
        return st.getObject(1);
    }
    catch (SQLException e) {
        throw new JboException(e);
    }
    finally {
        if (st != null) {
            try {
                // 7. Close the statement
                st.close();
            }
        }
    }
}
```

```

        catch (SQLException e) {}
    }
}

```

With a helper method like this in place, calling the `func_with_three_args` procedure shown in [Example 12-7](#) would look like this:

```

// In StoredProcTestModuleImpl.java
public String callFuncWithThreeArgs(Number n, Date d, String v) {
    return (String)callStoredFunction(VARCHAR2,
        "devguidepkg.func_with_three_args(?,?,?)",
        new Object[]{n,d,v});
}

```

Notice the question marks are used as JDBC bind variable placeholders for the arguments passed to the function. JDBC also supports using named bind variables, but using these simpler positional bind variables is also fine since the helper method is just setting the bind variable values positionally.

12.6.4 How to Call Other Types of Stored Procedures

Calling a stored procedure or function like `devguidepkg.proc_with_out_args` that includes arguments of OUT or IN OUT mode requires using a `CallableStatement` as in the previous section, but is a little more challenging to generalize into a helper method. [Example 12-11](#) illustrates the JDBC code necessary to invoke the `devguidepkg.proc_with_out_args` procedure.

The code performs the following basic tasks:

1. Defines a PL/SQL block for the statement to invoke.
2. Creates the `CallableStatement` for the PL/SQL block.
3. Registers the positions and types of the OUT parameters.
4. Sets the bind values of the IN parameters.
5. Executes the statement.
6. Creates a JavaBean to hold the multiple return values

The `DateAndStringBean` class contains bean properties named `dateVal` and `stringVal`.
7. Sets the value of its `dateVal` property using the first OUT param.
8. Sets value of its `stringVal` property using second OUT param.
9. Returns the result.
10. Closes the JDBC `CallableStatement`.

Example 12-11 Calling a Stored Procedure with Multiple OUT Arguments

```

public Date callProcWithOutArgs(Number n, String v) {
    CallableStatement st = null;
    try {
        // 1. Define the PL/SQL block for the statement to invoke
        String stmt = "begin devguidepkg.proc_with_out_args(?,?,?); end;";
        // 2. Create the CallableStatement for the PL/SQL block
        st = getDBTransaction().createCallableStatement(stmt,0);
        // 3. Register the positions and types of the OUT parameters
        st.registerOutParameter(2,Types.DATE);
    }
}

```

```

    st.registerOutParameter(3,Types.VARCHAR);
    // 4. Set the bind values of the IN parameters
    st.setObject(1,n);
    st.setObject(3,v);
    // 5. Execute the statement
    st.executeUpdate();
    // 6. Create a bean to hold the multiple return values
    DateAndStringBean result = new DateAndStringBean();
    // 7. Set value of dateValue property using first OUT param
    result.setDateVal(new Date(st.getDate(2)));
    // 8. Set value of stringValue property using 2nd OUT param
    result.setStringVal(st.getString(3));
    // 9. Return the result
    return result;
} catch (SQLException e) {
    throw new JboException(e);
} finally {
    if (st != null) {
        try {
            // 10. Close the JDBC CallableStatement
            st.close();
        }
        catch (SQLException e) {}
    }
}
}
}

```

The `DateAndString` bean used in [Example 12–11](#) is a simple JavaBean with two bean properties like this:

```

package devguide.advanced.storedproc;
import java.io.Serializable;
import oracle.jbo.domain.Date;
public class DateAndStringBean implements Serializable {
    Date dateVal;
    String stringVal;
    public void setDateVal(Date dateVal) {this.dateVal=dateVal;}
    public Date getDateVal() {return dateVal;}
    public void setStringVal(String stringVal) {this.stringVal=stringVal;}
    public String getStringVal() {return stringVal;}
}

```

Note: In order to allow the custom method to be a legal candidate for inclusion in an application module's custom service interface (if desired), the bean needs to implement the `java.io.Serializable` interface. Since this is a "marker" interface, this involves simply adding the `implements Serializable` keywords without needing to code the implementation of any interface methods.

12.7 Accessing the Current Database Transaction

Since the ADF Business Components components abstract all of the lower-level database programming details for you, you typically won't need *direct* access to the JDBC Connection object. Unless you use the reserved release mode described in [Section 43.2.2.3.3, "About Reserved Release Level,"](#) there is no guarantee at runtime that your application will use the exact same application module instance or JDBC Connection instance across different web page requests. Since inadvertently holding

a reference to the JDBC Connection object in this type of pooled services environment can cause unpredictable behavior at runtime, by design, ADF Business Components has no direct API to obtain the JDBC Connection. This is an intentional attempt to discourage its direct use and inadvertent abuse.

However, on occasion it may come in handy when you're trying to integrate third-party code with ADF Business Components, so you can use a helper method like the one shown in [Example 12–12](#) to access the connection.

Example 12–12 Helper Method to Access the Current JDBC Connection

```
/**
 * Put this method in your XXXImpl.java class where you need
 * to access the current JDBC connection
 */
private Connection getCurrentConnection() throws SQLException {
    /* Note that we never execute this statement, so no commit really happens */
    PreparedStatement st = getDBTransaction().createPreparedStatement("commit",1);
    Connection conn = st.getConnection();
    st.close();
    return conn;
}
```

Caution: Never cache the JDBC connection obtained using the helper method from [Example 12–12](#) in your own code anywhere. Instead, call the helper method each time you need it to avoid inadvertently holding a reference to a JDBC Connection that might be used in another request by another user at a later time do to the pooled services nature of the ADF runtime environment.

12.8 Customizing Business Components Error Messages

Note: The example in this section refers to the CustomizedErrorMessage project of the AdvancedExamples application workspace in the StandaloneExamples module of the Fusion Order Demo application.

You can customize any of the builtin ADF Business Components error messages by providing an alternative message string for the error code in a custom message bundle.

Note: For your convenience, the `CustomizedErrorMessage`s project in the `AdvancedExamples` workspace of the Fusion Order Demo lets you test the custom message bundle sample described in this section. Before you run the `ProductModule`, you will need to run the `addProductsTableConstraint.sql` script to set up the sample with the corresponding database constraint. When you run the `ProductModule` application module in the Oracle ADF Model Tester, you can blank out the **ProductId** attribute and click the **Validate** button. This will show the custom error message for the JBO error. Rollback the change and then enter `undefined` in the **ProductName** attribute. You can view the custom error message for the database error by clicking **Commit** (clicking **Validate** won't perform a commit to the database, so the database error is not generated in that case).

12.8.1 How to Customize Base ADF Business Components Error Messages

Assume you want to customize the builtin error message:

```
JBO-27014: Attribute Name is Product is required
```

If you have requested the Oracle Application Development Framework (Oracle ADF) source code from Oracle Worldwide Support, you can look in the `CSMessageBundle.java` file in the `oracle.jbo` package to see that this error message is related to the combination of the following lines in that message bundle file:

```
public class CSMessageBundle extends CheckedListResourceBundle {
    // etc.
    public static final String EXC_VAL_ATTR_MANDATORY          = "27014";
    // etc.
    private static final Object[][] sMessageStrings = {
        // etc.
        {EXC_VAL_ATTR_MANDATORY, "Attribute {2} in {1} is required"},
        // etc.
    }
}
```

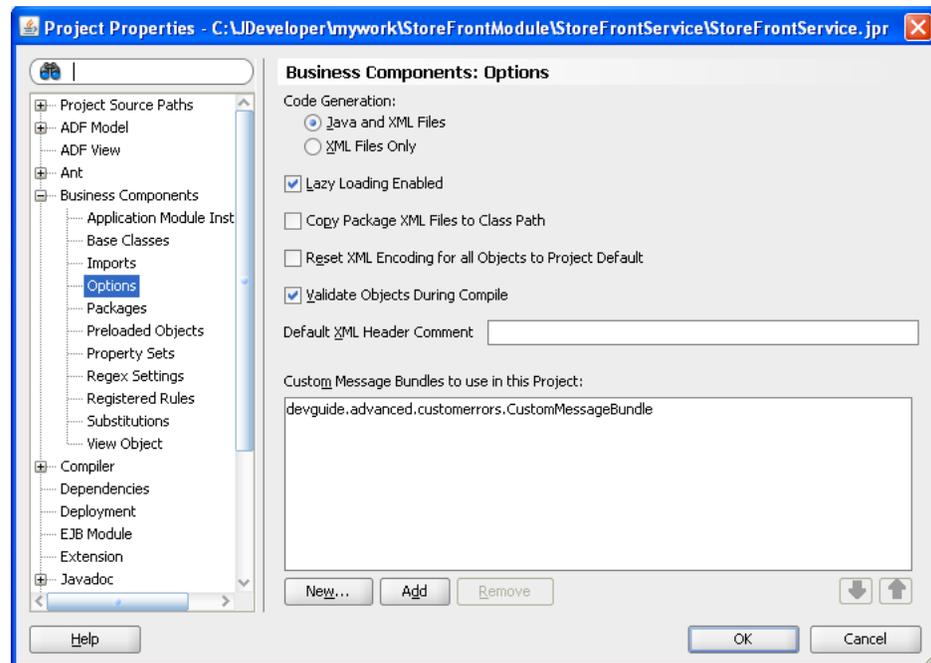

The numbered tokens `{2}` and `{1}` are error message placeholders. In this example the `{1}` is replaced at runtime with the name of the entity object and the `{2}` with the name of the attribute.

To create a custom message bundle file:

1. In the Application Navigator, right-click the data model project that you want to add the message bundle file to and choose **Project Properties**.
2. In the Project Properties dialog, select **Business Components > Options**.
The **Custom Message Bundles to use in this Project** list displays at the bottom of the dialog.
3. Click **New**.
4. Enter a name and package for the custom message bundle in the **Create MessageBundle class** dialog and click **OK**.

Note: If the fully-qualified name of your custom message bundle file does not appear in the **Custom Message Bundles to use in this Project** list, click the **Remove** button, then click the **Add** button to add the new message bundle file created. When the custom message bundle file is correctly registered, its fully-qualified class name should appear in the list, as shown in [Figure 12–8](#).

Figure 12–8 *Project Properties Displays Message Resource Bundles*

5. Click **OK** to dismiss the **Project Properties** dialog and open the new custom message bundle class in the source editor.
6. Edit the two-dimensional `String` array in the custom message bundle class to contain any customized messages you'd like to use.

[Example 12–13](#) illustrates a custom message bundle class that overrides the error message string for the `JBO-27014` error.

Example 12–13 *Custom ADF Business Components Message Bundle*

```
package devguide.advanced.customerrors;
import java.util.ListResourceBundle;
public class CustomMessageBundle extends ListResourceBundle {
    private static final Object[][] sMessageStrings
        = new String[][] {
        {"27014", "You must provide a value for {2}"}
    };
    protected Object[][] getContents() {
        return sMessageStrings;
    }
}
```

12.8.2 What Happens When You Customize Base ADF Business Components Error Messages

After adding this message to your custom message bundle file, if you test the application using the Oracle ADF Model Tester and try to blank out the value of a mandatory attribute, you'll now see your custom error message instead of the default one:

```
JBO-27014: You must provide a value for Name
```

You can add as many messages to the message bundle as you want. Any message whose error code key matches one of the built-in error message codes will be used at runtime instead of the default one in the `oracle.jbo.CSMessageBundle` message bundle.

12.8.3 How to Customize Error Messages for Database Constraint Violations

If you enforce constraints in the database, you might want to provide a custom error message in your Fusion web application to display to the end user when one of those constraints is violated. For example, assume a constraint called `NAME_CANNOT_BEGIN_WITH_U` gets added to the application's `PRODUCTS_BASE` table using the following DDL statement shown in [Example 12-14](#).

Example 12-14 DDL Statement Specifies Constraint Name

```
alter table products_base add (
  constraint name_cannot_begin_with_u
    check (upper(substr(product_name,1,1)) != 'U')
);
```

To define a custom error message in your application, you add a message to a custom message bundle with the constraint name as the message key. [Example 12-15](#) shows the `CustomMessageBundle.java` class when it defines a message with the key `NAME_CANNOT_BEGIN_WITH_U` which matches the name of the database constraint name defined in [Example 12-14](#).

Example 12-15 Customizing Error Message for Database Constraint Violation

```
package devguide.advanced.customerrors;
import java.util.ListResourceBundle;
public class CustomMessageBundle extends ListResourceBundle {
  private static final Object[][] sMessageStrings
    = new String[][] {
    {"27014", "You must provide a value for {2}"},
    {"NAME_CANNOT_BEGIN_WITH_U",
     "The name cannot begin with the letter u!"}
  };
  protected Object[][] getContents() {
    return sMessageStrings;
  }
}
```

12.8.4 How to Implement a Custom Constraint Error Handling Routine

If the default facility for assigning a custom message to a database constraint violation does not meet your needs, you can implement your own custom constraint error handling routine. Doing this requires creating a custom framework extension class for

the ADF transaction class, which you then configure your application module to use at runtime.

12.8.4.1 Creating a Custom Database Transaction Framework Extension Class

To write a custom framework extension class for the ADF transaction, create a class like the `CustomDBTransactionImpl` shown in [Example 12–16](#). This example overrides the transaction object's `postChanges()` method to wrap the call to `super.postChanges()` with a `try/catch` block in order to perform custom processing on any `DMLConstraintException` errors that might be thrown. In this simple example, the only custom processing being performed is a call to `ex.setExceptions(null)` to clear out any nested detail exceptions that the `DMLConstraintException` might have. Instead of this, you could perform any other kind of custom exception processing required by your application, including throwing a *custom* exception, provided your custom exception extends `JboException` directly or indirectly.

Example 12–16 Custom Database Transaction Framework Extension Class

```
package devguide.advanced.customerrors;
import oracle.jbo.DMLConstraintException;
import oracle.jbo.server.DBTransactionImpl2;
import oracle.jbo.server.TransactionEvent;
public class CustomDBTransactionImpl extends DBTransactionImpl2 {
    public void postChanges(TransactionEvent te) {
        try {
            super.postChanges(te);
        }
        /*
         * Catch the DML constraint exception
         * and perform custom error handling here
         */
        catch (DMLConstraintException ex) {
            ex.setExceptions(null);
            throw ex;
        }
    }
}
```

12.8.4.2 Configuring an Application Module to Use a Custom Database Transaction Class

In order for your application module to use a custom database transaction class at runtime, you must:

1. Provide a custom implementation of the `DatabaseTransactionFactory` class that overrides the `create()` method to return an instance of the customized transaction class.
2. Configure the value of the `TransactionFactory` property to be the fully-qualified name of this custom transaction factory class.

[Example 12–17](#) shows a custom database transaction factory class that does this. It returns a new instance of the `CustomDBTransactionImpl` class when the framework calls the `create()` method on the database transaction factory.

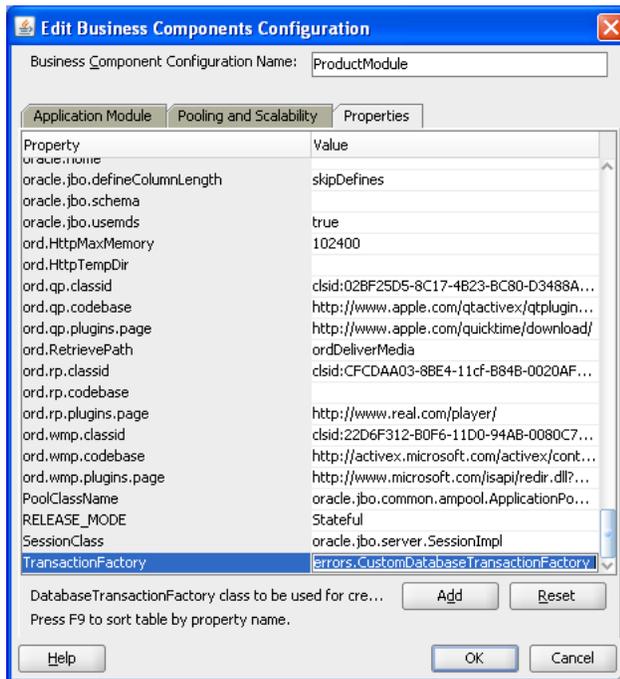

Example 12–17 Custom Database Transaction Factory Class

```
package devguide.advanced.customerrors;
import oracle.jbo.server.DBTransactionImpl2;
```

```
import oracle.jbo.server.DatabaseTransactionFactory;
public class CustomDatabaseTransactionFactory
    extends DatabaseTransactionFactory {
    public CustomDatabaseTransactionFactory() {
    }
    /**
     * Return an instance of our custom ToyStoreDBTransactionImpl class
     * instead of the default implementation.
     *
     * @return instance of custom CustomDBTransactionImpl implementation.
     */
    public DBTransactionImpl2 create() {
        return new CustomDBTransactionImpl();
    }
}
```

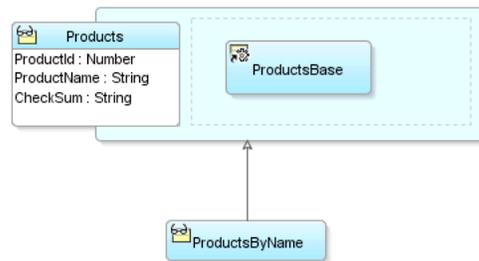

To complete the job, use the Properties tab of the Create Business Components Configuration dialog to assign the value `devguide.advanced.customerrors.CustomDatabaseTransactionFactory` to the `TransactionFactory` property, as shown in Figure 12–9. You can open the Create Business Components Configuration dialog from the Configuration page of the overview editor for the application module by clicking the **Create new configuration objects** button. When you run the application using this configuration, your custom transaction class will be used.

Figure 12–9 ADF Business Components Can Use Custom Database Transaction Class

12.9 Creating Extended Components Using Inheritance

Whenever you create a new business component, if necessary, you can extend an existing one to create a customized version of the original. As shown in Figure 12–10, the `ProductsByName` view object extends the `Products` view object to add a named bind variable named `TheStatus` and to customize the `WHERE` clause to reference that bind variable.

Figure 12–10 ADF Business Components Can Extend Another Component

While the figure shows a view object example, this component inheritance facility is available for all component types. When one component extends another, the extended component inherits all of the metadata and behavior from the parent it extends. In the extended component, you can add new features or customize existing features of its parent component both through metadata and Java code.

Note: The example in this section refers to the `BaseProject` project of the `AdvancedExamples` workspace in the `StandaloneExamples` module of the Fusion Order Demo application.

12.9.1 How To Create a Component That Extends Another

To create an extended component, use the component wizard in the **New Gallery** for the type of component you want to create. For example, to create an extended view object, you use the **Create View Object** wizard. On the **Name** page of the wizard — in addition to specifying a name and a package for the new component — provide the fully-qualified name of the component that you want to extend in the **Extends** field. To pick the component name from a list, use the **Browse** button next to the **Extends** field. Then, continue to create the extended component in the normal way using the remaining panels of the wizard.

12.9.2 How To Extend a Component After Creation

After you define an extended component, JDeveloper lets you change the parent component from which an extended component inherits. You can use the overview editor for the component to accomplish this.

To change the parent component after creation:

1. Double-click the component.
2. In the overview editor for the component, click the **General** navigation tab and click the **Refactor object extends** button next to the **Extends** field.
3. In the **Select Parent** dialog, choose the desired component to extend from the package list.

To change the extended component to not inherit from any parent, select the **None** checkbox in the **Select Parent** dialog. This has the same effect as if you deleted the component and recreated to accomplish this.

12.9.3 What Happens When You Create a Component That Extends Another

ADF business components you create are comprised of an XML component definition and an optional Java class. When you create a component that extends another,

JDeveloper reflects this component inheritance in both the XML component definition and in any generated Java code for the extended component.

12.9.3.1 Understanding an Extended Component's XML Descriptor

JDeveloper notes the name of the parent component in the new component's XML component definition by adding an `Extends` attribute to the root component element. Any new declarative features you add or any aspects of the parent component's definition you've overridden appear in the extended component's XML component definition. In contrast, metadata that is purely inherited from the parent component is not repeated for the extended component.

[Example 12-18](#) shows what the `ProductsByName.xml` XML component definition for the `ProductsByName` view object looks like. Notice the `Extends` attribute on the `<ViewObject>` element, the `<Variable>` element related to the additional bind variable added in the extended view object, and the overridden value of the `Where` attribute for the `WHERE` clause that was modified to reference the `theProductName` bind variable.

Example 12-18 Extended Component Reflects Parent in Its XML Descriptor

```
<ViewObject
  xmlns="http://xmlns.oracle.com/bc4j"
  Name="ProductsByName"
  Extends="devguide.advanced.baseproject.extsub.Products"
  Where="UPPER(PRODUCT_NAME) LIKE UPPER(:theProductName) || '%' "
  BindingStyle="OracleName"
  CustomQuery="false"
  RowClass="devguide.advanced.baseproject.extsub.ProductsByNameRowImpl"
  ComponentClass="devguide.advanced.baseproject.extsub.ProductsByNameImpl"
  ...
  <Variable
    Name="theProductName"
    Kind="where"
    Type="java.lang.String"/>
  ...
</ViewObject>
```

12.9.3.2 Understanding Java Code Generation for an Extended Component

If you enable custom Java code for an extended component, JDeveloper automatically generates the Java classes to extend the respective Java classes of its parent component. In this way, the extended component can override any aspect of the parent component's programmatic behavior as necessary. If the parent component is an XML-only component with no custom Java class of its own, the extended component's Java class extends whatever base Java class the parent would use at runtime. This could be the default ADF Business Components framework class in the `oracle.jbo.server` package, or could be your own framework extension class if you have specified that in the **Extends** dialog of the parent component.

In addition, if the extended component is an application module or view object and you enable client interfaces on it, JDeveloper automatically generates the extended component's client interfaces to extend the respective client interfaces of the parent component. If the respective client interface of the parent component does not exist, then the extended component's client interface directly extends the appropriate base ADF Business Components interface in the `oracle.jbo` package.

12.9.4 What You May Need to Know

12.9.4.1 You Can Use Parent Classes and Interfaces to Work with Extended Components

Since an extended component is a customized version of its parent, code you write that works with the *parent* component's Java classes or its client interfaces works without incident for either the parent component *or* any customized version of that parent component.

For example, assume you have a base `Products` view object with custom Java classes and client interfaces like:

- `class ProductsImpl`
- `row class ProductsRowImpl`
- `interface Products`
- `row interface ProductsRow`

If you create a `ProductsByName` view object that extends `Products`, then you can use the base component's classes and interface to work both with `Products` and `ProductsByName`.

[Example 12–19](#) illustrates a test client program that works with the `Products`, `ProductsRow`, `ProductsByName`, and `ProductsByNameRow` client interfaces. A few interesting things to note about the example are the following:

1. You can use parent `Products` interface for working with the `ProductsByName` view object that extends it.
2. Alternatively, you can cast an instance of the `ProductsByName` view object to its own more specific `ProductsByName` client interface.
3. You can test if row `ProductsRow` is actually an instance of the more specific `ProductsByNameRow` before casting it and invoking a method specific to the `ProductsByNameRow` interface.

Example 12–19 Working with Parent and Extended Components

```
package devguide.advanced.baseproject.extsub;
/* imports omitted */
public class TestClient {
    public static void main(String[] args) {
        String      amDef = "devguide.advanced.baseproject.extsub.ProductModule";
        String      config = "ProductModuleLocal";
        ApplicationModule am =
        Configuration.createRootApplicationModule(amDef, config);
        Products products = (Products)am.findViewObject("Products");
        products.executeQuery();
        ProductsRow product = (ProductsRow)products.first();
        printAllAttributes(products, product);
        testSomethingOnProductsRow(product);
        // 1. You can use parent Products interface for ProductsByName
        products = (Products)am.findViewObject("ProductsById");
        // 2. Or cast it to its more specific ProductsByName interface
        ProductsByName productsById = (ProductsByName)products;
        productsById.setProductName("Ice");
        productsById.executeQuery();
        product = (ProductsRow)productsById.first();
    }
}
```

```

        printAllAttributes(productsById,product);
        testSomethingOnProductsRow(product);
        am.getTransaction().rollback();
        Configuration.releaseRootApplicationModule(am,true);
    }
    private static void testSomethingOnProductsRow(ProductsRow product) {
        try {
            // 3. Test if row is a ProductsByNameRow before casting
            if (product instanceof ProductsByNameRow) {
                ProductsByNameRow productByName = (ProductsByNameRow)product;
                productByName.someExtraFeature("Test");
            }
            product.setName("Q");
            System.out.println("Setting the Name attribute to 'Q' succeeded.");
        }
        catch (ValidationException v) {
            System.out.println(v.getLocalizedMessage());
        }
    }
    private static void printAllAttributes(ViewObject vo, Row r) {
        String viewObjName = vo.getName();
        System.out.println("Printing attribute for a row in VO '"+
            viewObjName+"'");
        StructureDef def = r.getStructureDef();
        StringBuilder sb = new StringBuilder();
        int numAttrs = def.getAttributeCount();
        AttributeDef[] attrDefs = def.getAttributeDefs();
        for (int z = 0; z < numAttrs; z++) {
            Object value = r.getAttribute(z);
            sb.append(z > 0 ? " " : "");
            .append(attrDefs[z].getName())
            .append("=")
            .append(value == null ? "<null>" : value)
            .append(z < numAttrs - 1 ? "\n" : "");
        }
        System.out.println(sb.toString());
    }
}

```

Running the test client produces the results shown in [Example 12–20](#).

Example 12–20 Results of Running TestClient.java

```

Printing attribute for a row in VO 'Products'
ProdId=100
    Name=Washing Machine W001
    Checksum=I am the Product Class
Setting the Name attribute to 'Q' succeeded.
Printing attribute for a row in VO 'ProductsById'
ProdId=119
    Name=Ice Maker I012
    Checksum=I am the Product Class
    SomeExtraAttr=SomeExtraAttrValue
## Called someExtraFeature of ProductsByNameRowImpl
Setting the Name attribute to 'Q' succeeded.

```

Note: In this example, `Products` is an entity-based view object based on the `Product` entity object. The `Product` entity object includes a transient `Checksum` attribute that returns the string "I am the Product class". You'll learn more about why this was included in the example in [Section 12.10, "Substituting Extended Components in a Delivered Application."](#)

12.9.4.2 Class Extends is Disabled for Extended Components

When you create an extended component, the **Class Extends** button on the Java page of the extended component's wizard is disabled. Additionally, in the application module editor's Java page, when you click **Edit java options**, the **Class Extends** button in the Java dialog appears disabled. This is due to the fact that JDeveloper automatically extends the appropriate class of its parent component, so it does not make sense to allow you to select a different class.

12.9.4.3 Interesting Aspects You Can Extend for Key Component Types

Entity Objects

When you create an extended entity object, you can introduce new attributes, new associations, new validators, and new custom code. You can override certain declarative aspects of existing attributes as well as overriding any method from the parent component's class.

View Objects

When you create an extended view object, you can introduce new attributes, new view links, new bind variables, and new custom code. You can override certain declarative aspects of existing attributes as well as overriding any method from the parent component's class.

Application Modules

When you create an extended application module, you can introduce new view object instances or new nested application module instance and new custom code. You can also override any method from the parent component's class.

12.9.4.4 Extended Components Have Attribute Indices Relative to Parent

If you add new attributes in an extended entity object or view object, the attribute index numbers are computed relative to the parent component. For example, consider the `Products` view object mentioned in [Section 12.9.4.1, "You Can Use Parent Classes and Interfaces to Work with Extended Components."](#) If you enable a custom view row class, it might have attribute index constants defined in the `ProductsRowImpl.java` class like this:

```
public class ProductsRowImpl extends ViewRowImpl
    implements ProductsRow {
    public static final int PRODID = 0;
    public static final int NAME = 1;
    public static final int CHECKSUM = 2;
    //etc.
}
```

When you create an extended view object like `ProductsByName`, if that view object adds an addition attribute like `SomeExtraAttr` and has a custom view row class enabled, then its attribute constants will be computed relative to the maximum value of the attribute constants in the parent component:

```
public class ProductsByNameRowImpl extends ProductsRowImpl
    implements ProductsByNameRow {
    public static final int MAXATTRCONST =
        ViewDefImpl.getMaxAttrConst("devguide.advanced.baseproject.extsub.Products");
    public static final int SOMEEXTRAATTR = MAXATTRCONST;
```

Additional attributes would have index values of MAXATTRCONST+1, MAXATTRCONST+2, etc.

12.10 Substituting Extended Components in a Delivered Application

If you deliver packaged applications that can require on-site customization for each potential client of your solution, ADF Business Components offers a useful feature to simplify that task.

Note: The example in this section refers to the `BaseProject` project and the `ExtendAndSubstitute` project of the `AdvancedExamples` workspace in the `StandaloneExamples` module of the Fusion Order Demo application.

All too often, on-site application customization is performed by making direct changes to the source code of the delivered application. This approach demonstrates its weaknesses whenever you deliver patches or new feature releases of your original application to your clients. Any customizations they had been applied to the base application's source code need to be painstakingly re-applied to the patched or updated version of the base application. Not only does this render the application customization a costly, ongoing maintenance expense, it can introduce subtle bugs due to human errors that occur when reapplying previous customizations to new releases.

ADF Business Components offers a superior, component-based approach to support application customization that doesn't require changing — or even having access to — the base application's source code. To customize your delivered application, your customers can:

1. Import one or more packages of components from the base application into a new project.
2. Create new components to effect the application customization, extending appropriate parent components from the base application as necessary.
3. Define a list of global component substitutions, naming their customized components to substitute for your base application's appropriate parent components.

When the customer runs your delivered application with a global component substitution list defined, their customized application components are used by your delivered application without changing any of its code. When you deliver a patched or updated version of the original application, their component customizations apply to the updated version the next time they restart the application without needing to re-apply any customizations.

12.10.1 How To Substitute an Extended Component

To define global component substitutions, use the Project Properties dialog in the project where you have created extended components based on the imported components from the base application.

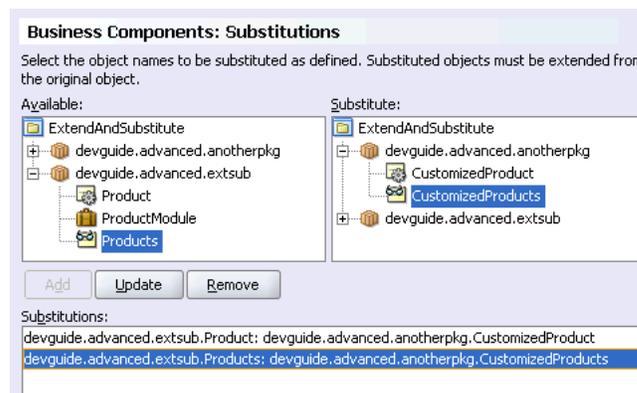

Note: You can only substitute a component in the base application with an extended component that inherits directly or indirectly from the base one.

To substitute an extended component:

1. In the Application Navigator, right-click the data model project that you want to add the extended component to and choose **Project Properties**.
2. In the Project Properties dialog, select **Business Components > Substitutions**.
3. In the Substitutions page, select the base application's component in the **Available** list.
4. Select the customized, extended component to substitute in the **Substitute** list.
5. Click **Add**.

For example, assume that you have created the view object `CustomizedProducts` in a package that extends the base view object `Products`. To substitute the `CustomizedProducts` view object for the legacy `Products` view object, you would select these view objects as shown in [Figure 12–11](#) to define the component substitution.

Figure 12–11 Defining Business Components Substitutions

12.10.2 What Happens When You Substitute

When you define a list of global component substitutions in a project named *YourExtendsAndSubstitutesProject*, the substitution list is saved in the *YourExtendsAndSubstitutesProject*.jpx in the root directory of the source path.

The file will contain `<Substitute>` elements as shown in [Example 12–21](#), one for each component to be substituted.

Example 12–21 Component Substitution List Saved in the Project's JPX File

```
<JboProject
  Name="ExtendAndSubstitute"
  SeparateXMLFiles="true"
  PackageName=" " >
  <Containeer
    Name="anotherpkg"
    FullName="devguide.advanced.anotherpkg.anotherpkg"
```

```

        ObjectType="JboPackage" >
    </Containee>
    <Containee
        Name="extsub"
        FullName="devguide.advanced.extsub"
        ObjectType="JboPackage" >
        <DesignTime>
            <Attr Name="_LocationURL"
                Value="../../BaseProject/deploy/BaseProjectCSMT.jar" />
        </DesignTime>
    </Containee>
    <Substitutes>
        <Substitute OldName="devguide.advanced.extsub.Product"
            NewName="devguide.advanced.anotherpkg.CustomizedProduct" />
        <Substitute OldName="devguide.advanced.extsub.Products"
            NewName="devguide.advanced.anotherpkg.CustomizedProducts" />
    </Substitutes>
</JboProject>

```

12.10.3 How to Enable the Substituted Components in the Base Application

To have the original application use the set of substituted components, define the Java system property `Factory-Substitution-List` and set its value to the name of the project whose `*.jpx` file contains the substitution list. The value should be just the project name without any `*.jpr` or `*.jpx` extension.

Consider a simple example that customizes the `Product` entity object and the `Products` view object described in [Section 12.9.4.1, "You Can Use Parent Classes and Interfaces to Work with Extended Components."](#) To perform the customization, assume you create new project named `ExtendsAndSubstitutes` that:

- Defines a library for the JAR file containing the base components
- Imports the package containing `Product` and `Products`
- Creates new extended components in a distinct package name called `CustomizedProduct` and `CustomizedProducts`
- Defines a component substitution list to use the extended components.

When creating the extended components, assume that you:

- Added an extra view attribute named `ExtraViewAttribute` to the `CustomizedProducts` view object.
- Added a new validation rule to the `CustomizedProduct` entity object to enforce that the product name cannot be the letter "Q".
- Overrode the `getChecksum()` method in the `CustomizedProduct.java` class to return **"I am the CustomizedProduct Class"**.

If you define the `Factory-Substitution-List` Java system property set to the value `ExtendsAndSubstitutes`, then when you run the exact same test client class shown in [Example 12-19](#) the output of the sample will change to reflect the use of the substituted components as shown in [Example 12-22](#).

Example 12-22 Results of Running TestClient.java with System Property Set

```

Printing attribute for a row in VO 'Products'
ProdId=100
Name=Washing Machine W001
Checksum=I am the CustomizedProduct Class
ExtraViewAttribute=Extra Attr Value

```

```
The name cannot be Q!  
Printing attribute for a row in VO 'ProductsById'  
ProdId=119  
  Name=Ice Maker I012  
  Checksum=I am the CustomizedProduct Class  
  SomeExtraAttr=SomeExtraAttrValue  
## Called someExtraFeature of ProductsByNameRowImpl  
The name cannot be Q!
```

Compared to the output from [Example 12-19](#), notice that in the presence of the factory substitution list, the `Products` view object in the original test program now has the additional `ExtraViewAttribute`, now reports a `Checksum` attribute value of "I am the CustomizedProduct Class", and now disallows the assignment of the product name to have the value "Q". These component behavior changes were performed without needing to modify the original Java or XML source code of the delivered components.

Part III

Using the ADF Model Layer

Part III contains the following chapters:

- [Chapter 13, "Using ADF Model in a Fusion Web Application"](#)
- [Chapter 14, "Exposing Web Services Using the ADF Model Layer"](#)
- [Chapter 15, "Exposing URL Services Using the ADF Model Layer"](#)
- [Chapter 16, "Using Validation in the ADF Model Layer"](#)
- [Chapter 17, "Designing a Page Using Placeholder Data Controls"](#)

Using ADF Model in a Fusion Web Application

This chapter describes how an application module's data model and business service interface methods appear at design time for drag and drop data binding, how they are accessible at runtime by the ADF Model data binding layer using the application module data control, and how developers can use the Data Controls panel to create databound pages.

This chapter includes the following sections:

- [Section 13.1, "About ADF Data Binding"](#)
- [Section 13.2, "Additional Functionality"](#)
- [Section 13.3, "Exposing Application Modules with Oracle ADF Data Controls"](#)
- [Section 13.4, "Using the Data Controls Panel"](#)
- [Section 13.5, "Working with the DataBindings.cpx File"](#)
- [Section 13.6, "Configuring the ADF Binding Filter"](#)
- [Section 13.7, "Working with Page Definition Files"](#)
- [Section 13.8, "Creating ADF Data Binding EL Expressions"](#)
- [Section 13.9, "Using Simple UI First Development"](#)

13.1 About ADF Data Binding

ADF Model implements the two concepts in JSR-227 that enable decoupling the user interface technology from the business service implementation: *data controls* and *declarative bindings* (for more information about JSR-227, see <http://jcp.org/en/jsr/detail?id=227>).

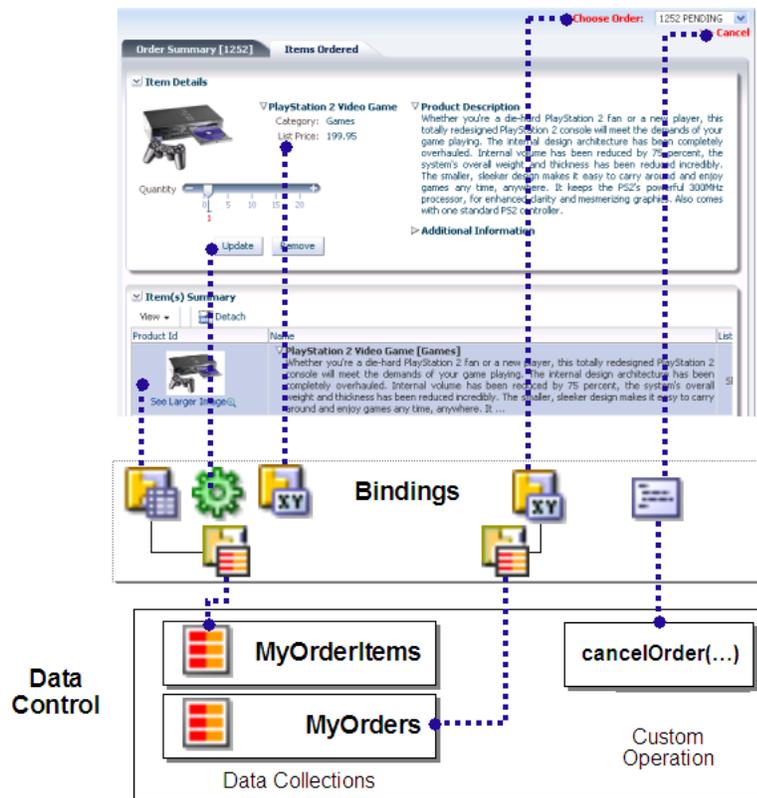

Data controls abstract the implementation technology of a business service by using standard metadata interfaces to describe the service's operations and data collections, including information about the properties, methods, and types involved. In an application that uses business components, a data control is automatically created when you create an application module, and it contains all the functionality of the application module. Developers can then use the representation of the data control displayed in JDeveloper's Data Controls panel to create UI components that are automatically bound to the application module. At runtime, the ADF Model layer reads the information describing the data controls and bindings from the appropriate XML files and then implements the two-way connection between the user interface and the business service.

Declarative bindings abstract the details of accessing data from data collections in a data control and of invoking its operations. There are three basic kinds of declarative binding objects:

- Executable bindings: Included in executable bindings are iterator bindings, which simplify the building of user interfaces that allow scrolling and paging through collections of data and drilling-down from summary to detail information. Executable bindings also include bindings that allow searching and nesting a series of pages within another page, as well as bindings that cause operations to occur immediately.
- Value bindings: Used by UI components that display data. Value bindings range from the most basic variety that work with a simple text field to more sophisticated list and tree bindings that support the additional needs of list, table, and tree UI controls.
- Action bindings: Used by UI components like hyperlinks or buttons to invoke built-in or custom operations on data collections or a data control without writing code.

Figure 13–1 shows how bindings connect UI components to data control collections and methods.

Figure 13–1 Bindings Connect UI Components to Data Controls

The group of bindings supporting the UI components on a page are described in a page-specific XML file called the *page definition file*. The ADF Model layer uses this file at runtime to instantiate the page's bindings. These bindings are held in a request-scoped map called the *binding container*, accessible during each page request

using the EL expression `#bindings`. This expression always evaluates to the binding container for the current page.

Tip: The current binding container is also available from `AdfContext` for programmatic access.

You can design a databound user interface by dragging an item from the Data Controls panel and dropping it on a page as a specific UI component. When you use data controls to create a UI component, JDeveloper automatically creates the various code and objects needed to bind the component to the data control you selected.

Note: Using the ADF Model layer to perform business service access ensures that the view and the business service stay in sync. For example, while you could call a method on an application module by class-casting the data control reference to the application module instance and then calling the method directly, doing so would bypass the model layer and it would then become unaware of any changes.

13.2 Additional Functionality

You may find it helpful to understand other ADF features before you configure or use the ADF Model layer. Additionally, you may want to read about what you can do with your model layer configurations. Following are links to other functionality that may be of interest.

- ADF model and data binding rely on the business layer. In most cases, you will be working with representations of your view objects. For more information, see [Chapter 5, "Defining SQL Queries Using View Objects."](#) You may also want to be familiar with advanced functionality discussed in [Chapter 42, "Advanced View Object Techniques."](#)
- You can use the ADF Model layer to create your view pages. After reading this chapter for the basic information on how data binding in the view layer works, you should refer to the chapters in [Part V, "Creating a Databound Web User Interface"](#) for information about using data binding to create specific view functionality.
- For information about how ADF Model works with the page lifecycle, see [Chapter 25, "Understanding the Fusion Page Lifecycle."](#)
- For a complete list of configuration parameters that affect the model layer, see [Section A.7, "DataBindings.cpx"](#) and [Section A.8, "pageNamePageDef.xml."](#)
- For a complete list of binding properties, see [Appendix B, "Oracle ADF Binding Properties."](#)

13.3 Exposing Application Modules with Oracle ADF Data Controls

The application module data control is a thin adapter over an application module pool that automatically acquires an available application module instance at the beginning of the request. During the current request, the application module data control holds a reference to the application module instance on behalf of the current user session. At the end of the request, the data control releases the instance back to the pool. Importantly, the application module component directly implements the interfaces that the binding objects expect for data collections, built-in operations, and service

methods. This optimized interaction allows the bindings to work *directly* with the application module instances in its data model in the following ways:

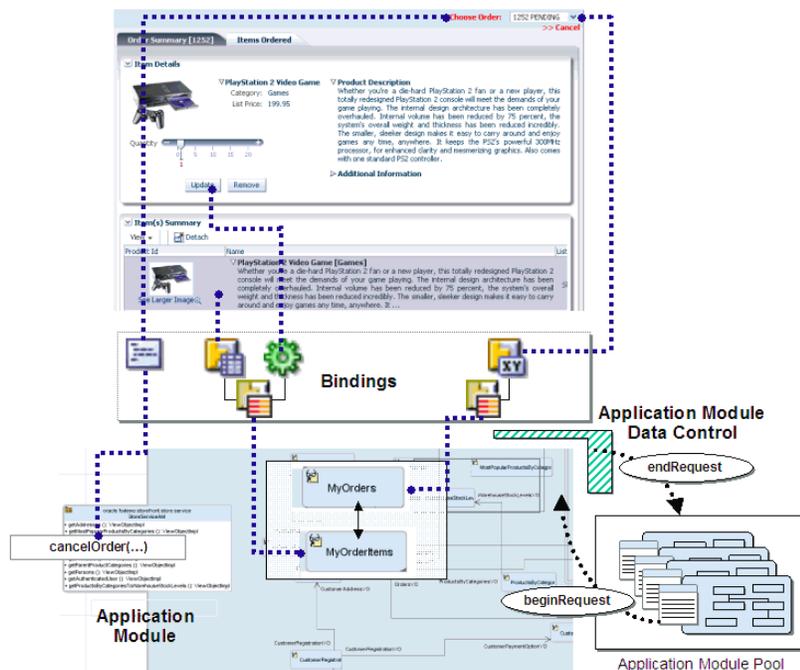

- Iterator bindings directly bind to the default row set iterator of the default row set of any view object instance. The row set iterator manages the current object and current range information.

Tip: You can also use the iterator binding to bind to a secondary named row set that you have created. To bind to a secondary row set iterator, you need to use the RSName. For more information about the difference between the default row set and secondary row sets and how to create them, see [Section 42.1.10, "Working with Multiple Row Sets and Row Set Iterators."](#)

- Action bindings directly bind to either:
 - Custom methods on the data control client interface
 - Built-in operations of the application module and view objects

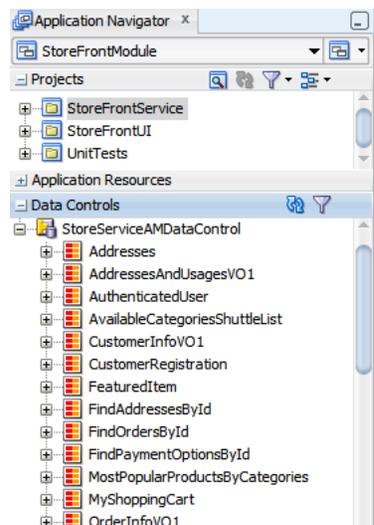

Figure 13–2 illustrates the pool management role the application module data control plays and highlights the direct link between the bindings and the application module instance.

Figure 13–2 Bindings Connect Directly to View Objects and Methods of an Application Module from a Pool

13.3.1 How an Application Module Data Control Appears in the Data Controls Panel

You use the Data Controls panel to create databound UI components by dragging and dropping icons from the panel onto the visual editor for a page. [Figure 13–3](#) shows the Data Controls panel displaying the data controls for the StoreFront module.

Figure 13–3 Data Controls Panel in JDeveloper

The Data Controls panel lists all the data controls that have been created for the application's business services and exposes all the collections (row sets of data objects), methods, and built-in operations that are available for binding to UI components.

Note: If you've configured JDeveloper to expose them, any view link accessor returns are also displayed. For more information, see [Section 5.6, "Working with Multiple Tables in a Master-Detail Hierarchy."](#) To view the accessor methods:

1. From the JDeveloper main menu, choose **Tools > Preferences**.
 2. Select the **Data Controls Panel** node.
 3. Select **Show Underlying Accessor Nodes** to activate the checkbox.
-

For example, in an application that uses ADF Business Components to define the business services, each data control on the Data Controls panel represents a specific application module, and exposes the view object instances in that application's data model. The hierarchy of objects in the data control is defined by the view links between view objects that have specifically been added to the application module data model. For information about creating view objects and view links, see [Chapter 5, "Defining SQL Queries Using View Objects."](#) For information about adding view links to the data model, see [Section 5.6.4, "How to Enable Active Master-Detail Coordination in the Data Model."](#)

Tip: You can open the overview editor for a view object by right-clicking the associated data control object and choosing **Edit Definition**.

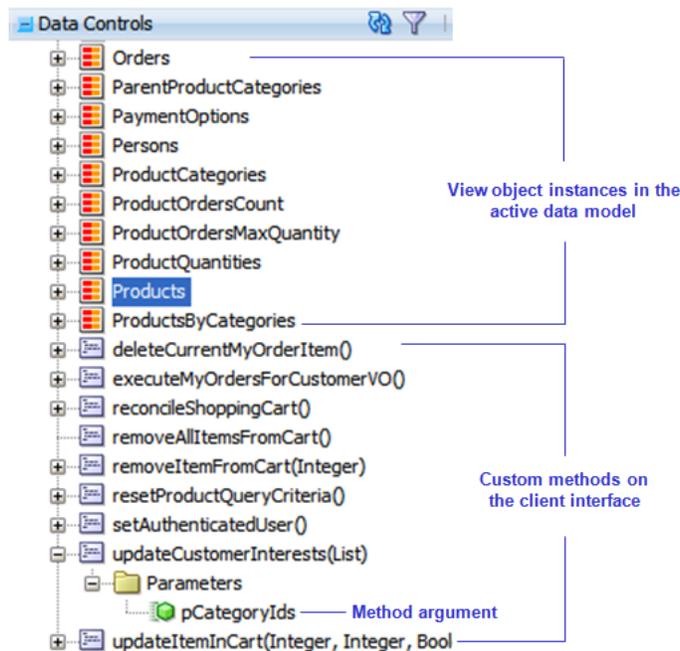

For example, the `StoreServiceAMDataControl` application module implements the business service layer of the StoreFront module application. Its data model contains numerous view object instances, including several master-detail hierarchies. The view layer of the ADF sample application consists of JSF pages whose UI components are bound to data from the view object instances in the `StoreServiceAMDataControl`'s data model, and to built-in operations and service methods on its client interface.

13.3.1.1 How the Data Model and Service Methods Appear in the Data Controls Panel

Each view object instance appears as a named data collection whose name matches the view object instance name. Figure 13-4 illustrates how the Data Controls panel displays the view object instances in the `StoreServiceAMDataControl`'s data model (note that for viewing simplicity, the figure omits some details in the tree that appear for each view object). The Data Controls panel reflects the master-detail hierarchies in your application module data model by displaying detail data collections nested under their master data collection.

The Data Controls panel also displays each custom method on the application module's client interface as a named data control custom operation whose name matches the method name. If a method accepts arguments, they appear in a Parameters node as operation parameters nested inside the operation's node.

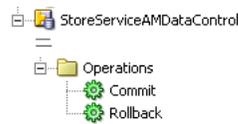

Figure 13-4 How the Data Model Appears in the Data Controls Panel

13.3.1.2 How Transaction Control Operations Appear in the Data Controls Panel

The application module data control exposes two data control built-in operations named `Commit` and `Rollback`, as shown in Figure 13-5 (note that the Operations node in the data controls tree omits all of the data collections and custom operations for a more streamlined view). At runtime, when these operations are invoked by the data binding layer, they delegate to the `commit()` and `rollback()` methods of the `Transaction` object associated with the current application module instance.

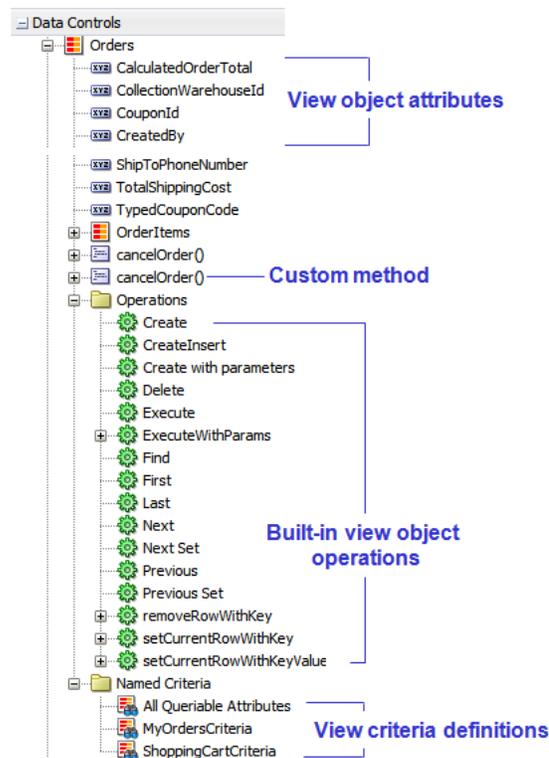

Note: In an application module with many view object instances and custom methods, you may need to scroll the Data Controls panel display to find the Operations node that is the direct child node of the data control. This node is the one that contains these built-in operations.

Figure 13–5 How Transaction Control Operations Appear in the Data Controls panel

13.3.1.3 How View Objects Appear in the Data Controls Panel

The view object attributes are displayed as immediate child nodes of the corresponding data collection, as are any custom methods you've created. [Figure 13–6](#) shows how each view object instance in the application module's data model appears in the Data Controls panel. If you have selected any custom methods to appear on the view object's client interface, they appear as custom methods immediately following the view object attributes at the same level. If the method accepts arguments, these appear in a nested Parameters node as operation parameters.

By default, implicit view criteria are created for each attribute that is able to be queried on a view object. They appear as the All Queriable Attributes node under the Named Criteria node, as shown in [Figure 13–6](#). If any named view criteria were created for the view object, they appear under the Named Criteria node. The View Criteria expressions (both implicit and named) appear as method returns. The conjunction used in the query, along with the criteria items and if applicable, any nested criteria, are shown as children. These items are used to create quick search forms, as detailed in [Chapter 31, "Creating ADF Databound Search Forms."](#)

Figure 13–6 How View Objects Appear in the Data Controls Panel

As shown in [Figure 13–6](#), the Operations node under the data collection displays all its available built-in operations. If an operation accepts one or more parameters, then

those parameters appear in a nested Parameters node. At runtime, when one of these data collection operations is invoked by name by the data binding layer, the application module data control delegates the call to an appropriate method on the `ViewObject` interface to handle the built-in functionality. The built-in operations fall into three categories: operations that affect the current row, operations that refresh the data collection, and all other operations.

Operations that affect the current row:

- `Create`: Creates a new row that becomes the current row, but does not insert it.
- `CreateInsert`: Creates a new row that becomes the current row, and inserts the new blank row into the data source.
- `Create with Parameters`: Creates a new row taking parameter values. The passed parameters can supply the create-time value for the following:
 - A discriminator for a polymorphic view object
 - A composing parent's foreign key attribute needed for the creation of a polymorphic view object
 - A composed child view object row when it is not created in the context of a parent row

For more information about polymorphic view objects, see [Section 42.6, "Using View Objects to Work with Multiple Row Types."](#)

- `Delete`: Deletes the current row.
- `First`: Sets the current row to be the first row in the row set.
- `Last`: Sets the current row to be the last row in the row set.
- `Next`: Sets the row to be the next row in the row set.
- `Next Set`: Navigates backward one full set of rows.
- `Previous`: Sets the current row to be the previous row in the row set.
- `Previous Set`: Navigates forward one full set of rows.
- `setCurrentRowWithKey`: Tries to find a row using the serialized string representation of row key passed as a parameter. If found, that row becomes the current row.
- `setCurrentRowWithKeyValue`: Tries to find a row using the primary key attribute value passed as a parameter. If found, that row becomes the current row.

Operations that refresh the data collection:

- `Execute`: Refreshes the data collection by executing or reexecuting the view object's query, leaving any bind parameters at their current values.
- `ExecuteWithParams`: Refreshes the data collection by first assigning new values to the named bind variables passed as parameters, then executing or reexecuting the view object's query.

Note: The `executeWithParams` operation appears only for view objects that have defined one or more named bind variables at design time.

All other operations:

- `removeRowWithKey`: Tries to find a row using the serialized string representation of row key passed as a parameter. If found, the row is removed.
- `Find`: Toggles "Find Mode" on and off for the data collection.

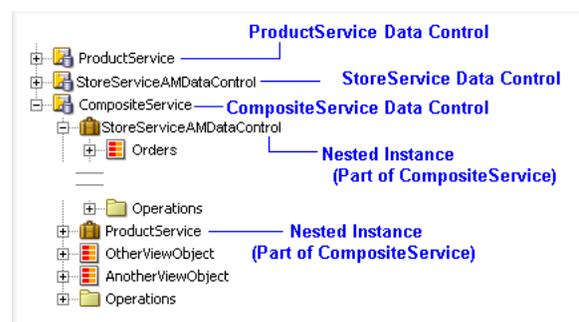

13.3.1.4 How Nested Application Modules Appear in the Data Controls Panel

If you build composite application modules by including nested instances of other application modules, the Data Controls panel reflects this component assembly in the tree hierarchy. For example, assume that, in addition to the `StoreServiceAMDataControl` application module, you have also created the following application modules in the same package:

- An application module named `ProductService`, and renamed its data control to `ProductService`
- An application module named `CompositeService`, and renamed its data control to `CompositeService`

Then assume that you've added two view object instances named `OtherViewObject` and `AnotherViewObject` to the data model of `CompositeService` and that on the Application Modules page of the Edit Application Module dialog you have added an instance of the `StoreServiceAMDataControl` application module and an instance of the `ProductService` application module to reuse them as part of `CompositeService`. Figure 13-7 illustrates how your `CompositeService` would appear in the Data Controls panel (note that much of the structure of the nested `StoreServiceAMDataControl` has been omitted for clarity). The nested instances of `StoreServiceAMDataControl` and `ProductService` appear in the panel tree display nested inside of the `CompositeService` data control. The entire data model and set of client methods that the nested application module instances expose to clients are automatically available as part of the `CompositeService` that reuses them.

Figure 13-7 How Nested Application Modules Appear in the Data Controls Panel

One possibly confusing point is that even though you have reused nested instances of `StoreServiceAMDataControl` and `ProductService` inside of `CompositeService`, the `StoreServiceAMDataControl` and `ProductService` application modules also appear themselves as top-level data control nodes in the panel tree. JDeveloper assumes that you might want to sometimes use `StoreServiceAMDataControl` or `ProductService` on their own as separate data controls from `CompositeService`, so it displays all three of them. You need to be careful to perform your drag-and-drop data binding from the correct data control. If you want your page to use a view object instance from the nested `StoreServiceAMDataControl` instance's data model that is an aggregated part of the `CompositeService` data control, then ensure that you select the data collection that appears as part of the `CompositeService` data control node in the panel.

It is important to do the drag -and-drop operation that corresponds to your intended usage. When you drop a data collection from the *top-level* `StoreServiceAMDataControl` data control node in the panel, at runtime your page will use an instance of the `StoreServiceAMDataControl` application module acquired from a pool of `StoreServiceAMDataControl` components. When you drop a data collection from the *nested* instance of `StoreServiceAMDataControl` that is part of `CompositeService`, at runtime your page will use an instance of the `CompositeService` application module acquired from a pool of `CompositeService` components. Since different types of application module data controls will have distinct transactions and database connections, inadvertently mixing and matching data collections from both a nested application module and a top-level data control will lead to unexpected runtime behavior.

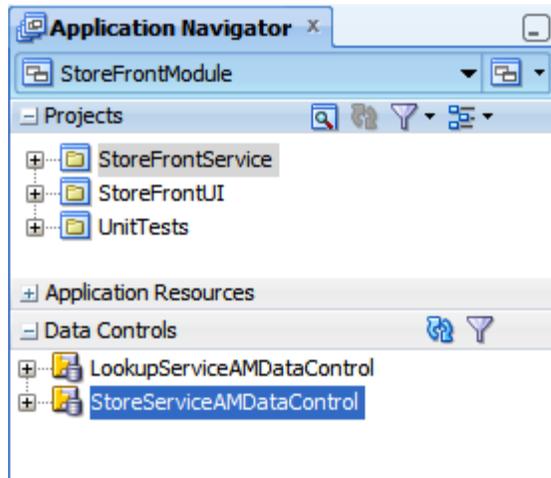

13.3.2 How to Open the Data Controls Panel

The Data Controls panel is a panel within the Application Navigator, located at the top left of JDeveloper. To view its contents, click the panel header to expand the panel. If you do not see the panel header, then the Application Navigator may not be displaying.

To open the Application Navigator and Data Controls panel:

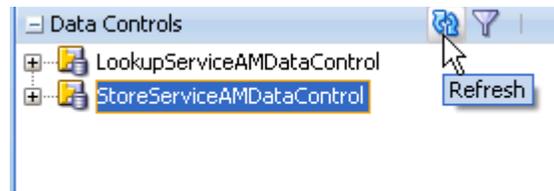

1. From the main menu, choose **View > Application Navigator**.
2. To open the Data Controls accordion panel, click the expand icon in the Data Controls header, as shown in [Figure 13–8](#).

Figure 13–8 Data Controls Panel in the Application Navigator

13.3.3 How to Refresh the Data Controls Panel

Any time changes are made to the application module or underlying services, you need to manually refresh the data control in order to view the changes. To refresh the application module data control, click the **Refresh** icon in the header of the Data Controls panel, as shown in [Figure 13–9](#).

Figure 13–9 Refresh Icon on Data Controls Panel

When you click **Refresh**, the Data Controls panel looks for all available data controls, and therefore will now reflect any structural changes made to the data control.

13.3.4 Packaging a Data Control for Use in Another Project

You can package up data controls so that they can be used in another project. For example, one development group might be tasked with creating the services and data controls, while another development group might be tasked with creating the UI. The first group would create the services and data controls, and then package them up as an Oracle ADF Library and send it to the second group. The second group can then add the data controls to their project using the Resource Palette. For more information, see [Chapter 38, "Reusing Application Components."](#)

13.4 Using the Data Controls Panel

You can design a databound user interface by dragging an item from the Data Controls panel and dropping it on a page as a specific UI component. When you use data controls to create a UI component, JDeveloper automatically creates the various code and objects needed to bind the component to the data control you selected.

In the Data Controls panel, each data control object is represented by a specific icon. [Table 13–1](#) describes what each icon represents, where it appears in the Data Controls panel hierarchy, and what components it can be used to create.

Table 13–1 Data Controls Panel Icons and Object Hierarchy

Icon	Name	Description	Used to Create...
	Data Control	<p>Represents a data control. You cannot use the data control itself to create UI components, but you can use any of the child objects listed under it. Depending on how your business services were defined, there may be more than one data control.</p> <p>Usually, there is one data control for each application module. However, you may have additional data controls that were created for other types of business services (for example, for web services). For information about creating data controls for web services, see Chapter 14, "Exposing Web Services Using the ADF Model Layer."</p>	Serves as a container for the other object and is not used to create anything.
	Collection	<p>Represents a named data collection. A <i>data collection</i> represents a set of data objects (also known as a <i>row set</i>) in the data model. Each object in a data collection represents a specific structured data item (also known as a <i>row</i>) in the data model. Throughout this guide, <i>data collection</i> and <i>collection</i> are used interchangeably.</p> <p>For application modules, the data collection is the default row set contained in a view object instance. The name of the collection matches the view object instance name.</p> <p>A view link creates a master-detail relationship between two view objects. If you explicitly add an instance of a detail view object (resulting from a view link) to the application module data model, the collection contained in that detail view object appears as a child of the collection contained in the master view object. For information about adding detail view objects to the data model, see Section 5.6.4, "How to Enable Active Master-Detail Coordination in the Data Model."</p> <p>The children under a collection may be attributes of the collection, other collections that are related by a view link, custom methods that return a value from the collection, or built-in operations that can be performed on the collection.</p> <p>If you've configured JDeveloper to display viewlink accessor returns, then those are displayed as well.</p>	<p>Forms, tables, graphs, trees, range navigation components, and master-detail components.</p> <p>For more information about using collections on a data control to create forms, see Chapter 26, "Creating a Basic Databound Page."</p> <p>For more information about using collections to create tables, see Chapter 27, "Creating ADF Databound Tables."</p> <p>For more information about using master-detail relationships to create UI components, see Chapter 29, "Displaying Master-Detail Data."</p> <p>For information about creating graphs, charts, and other visualization UI components, see Chapter 33, "Creating Databound ADF Data Visualization Components."</p>
	Attribute	<p>Represents a discrete data element in an object (for example, an attribute in a row). Attributes appear as children under the collections or method returns to which they belong.</p> <p>Only the attributes that were included in the view object are shown under a collection. If a view object joins one or more entity objects, that view object's collection will contain selected attributes from all of the underlying entity objects.</p>	<p>Label, text field, date, list of values, and selection list components.</p> <p>For information about using attributes to create fields on a page, see Section 26.2, "Using Attributes to Create Text Fields."</p> <p>For information about creating lists, see Chapter 30, "Creating Databound Selection Lists and Shuttles."</p>

Table 13–1 (Cont.) Data Controls Panel Icons and Object Hierarchy

Icon	Name	Description	Used to Create...
	Structured Attribute	Represents a returned object that is neither a Java primitive type (represented as an attribute) nor a collection of any type. An example of a structured attribute would be a domain, which is a developer-created data type used to simplify application maintenance. For more information about domains, see Section 4.15, "Creating Custom, Validated Data Types Using Domains."	Label, text field, date, list of values, and selection list components.
	Method	Represents an operation in the data control or one of its exposed structures that may accept parameters, perform some business logic and optionally return single value, a structure, or a collection. In application module data controls, custom methods are defined in the application module itself and usually return either nothing or a single scalar value. For more information about creating custom methods, see Chapter 9, "Implementing Business Services with Application Modules."	Command components For methods that accept parameters: command components and parameterized forms.
	Method Return	Represents an object that is returned by a custom method. The returned object can be a single value or a collection. If a custom method defined in the application module returns anything at all, it is usually a single scalar value. Application module methods do not need to return a set of data to the view layer, because displaying the latest changes to the data is handled by the view objects in the data model (for more information, see Section 3.4, "Overview of the Oracle ADF Active Data Model"). However, custom methods in non-application module data controls (for example, a data control for a CSV file) can return collections to the view layer. A method return appears as a child under the method that returns it. The objects that appear as children under a method return can be attributes of the collection, other methods that perform actions related to the parent collection, or operations that can be performed on the parent collection.	The same components as for collections and attributes. For named criteria: query or quick query forms. For more information, see Chapter 31, "Creating ADF Databound Search Forms." When a single-value method return is dropped, the method is not invoked automatically by the framework. You need either to create an invoke action as an executable, or to drop the corresponding method as a button to invoke the method. For more information about executables, see Section 13.7.2.2, "Executable Binding Objects Defined in the Page Definition File."
	Operation	Represents a built-in data control operation that performs actions on the parent object. Data control operations are located in an Operations node under collections or method returns, and also under the root data control node. The operations that are children of a particular collection or method return operate on those objects only, while operations under the data control node operate on all the objects in the data control. If an operation requires one or more parameters, they are listed in a Parameters node under the operation.	UI command components, such as buttons, links, and menus. For more information, see Section 26.4, "Incorporating Range Navigation into Forms," and Section 26.5, "Creating a Form to Edit an Existing Record."
	Parameter	Represents a parameter value that is declared by the method or operation under which it appears. Parameters appear in the Parameters node under a method or operation.	Label, text, and selection list components.

13.4.1 How to Use the Data Controls Panel

JDeveloper provides you with a predefined set of UI components from which to choose for each data control item you can drop.

Before you begin:

It may be helpful to have an understanding of the different objects in the Data Controls panel. For more information, see [Section 13.4, "Using the Data Controls Panel."](#)

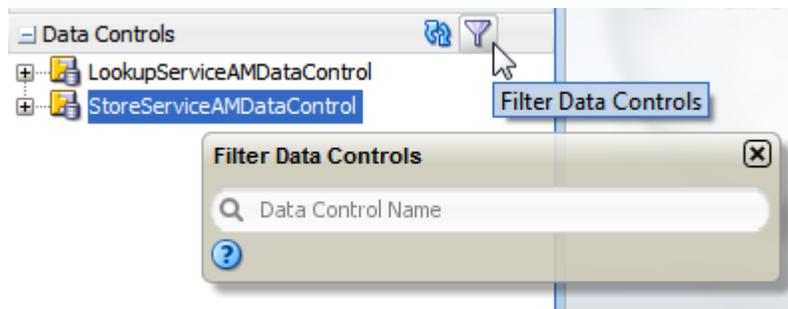

To use the Data Controls panel to create UI components:

1. Select an item in the Data Controls panel and drag it onto the visual editor for your page. For a definition of each item in the panel, see [Table 13-1](#).

Tip: If you need to drop an operation or method onto a method activity in a task flow, you can simply drag and drop it onto the activity in the diagram.

Tip: You can use the Filter icon in the Data Controls Panel header to search for a specific item, as shown in [Figure 13-10](#).

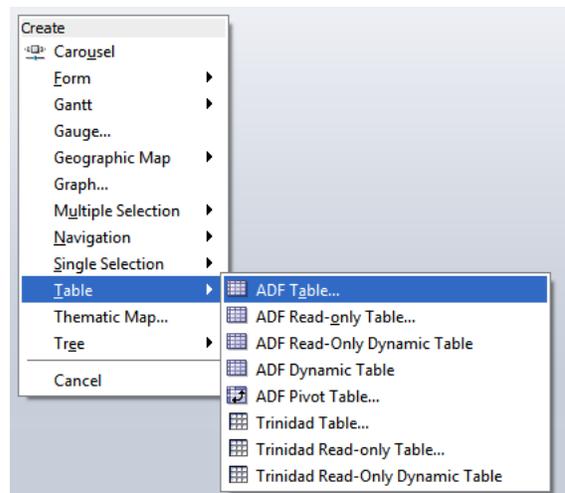

Figure 13-10 Filtering the Data Controls Panel

2. From the ensuing context menu, select a UI component.

When you drag an item from the Data Controls panel and drop it on a page, JDeveloper displays a context menu of all the default UI components available for the item you dropped. The components displayed are based on the libraries in your project.

[Figure 13-11](#) shows the context menu displayed when a data collection from the Data Controls panel is dropped on a page.

Figure 13–11 Data Controls Panel Context Menu

Depending on the component you select from the context menu, JDeveloper may display a dialog that enables you to define how you want the component to look. For example, if you select **ADF Read-only Table** from the context menu, the Edit Table Columns dialog launches. This dialog enables you to define which attributes you want to display in the table columns, what the column labels are, what types of text fields you want use for each column, and what functionality you want to include, such as row selection or column sorting. For more information about creating tables, see [Chapter 27, "Creating ADF Databound Tables."](#)

The UI components selected by default are determined first by any UI control hints set on the corresponding business object. If no control hints have been set, then JDeveloper uses input components for standard forms and tables, and output components for read-only forms and tables. Components for lists are determined based on the type of list you chose when dropping the data control object.

Once you select a component, JDeveloper inserts the UI component on the page in the visual editor. For example, if you drag a collection from the Data Controls panel and choose **ADF Read-only Table** from the context menu, a read-only table appears in the visual editor, as shown in [Figure 13–12](#).

Figure 13–12 Databound UI Component: ADF Read-Only Table

Product Id	Supplier Id	Category Id	Name
#{...ProductId}	#{...SupplierId}	#{...CategoryId}	#{...ProductName}
#{...ProductId}	#{...SupplierId}	#{...CategoryId}	#{...ProductName}
#{...ProductId}	#{...SupplierId}	#{...CategoryId}	#{...ProductName}

By default, the UI components created when you use the Data Controls panel use ADF Faces components, are bound to attributes in the ADF data control, and may have one or more built-in features, including:

- Databound labels
- Tooltips
- Formatting
- Basic navigation buttons

- Validation, if validation rules are attached to a particular attribute. For more information, see [Chapter 7, "Defining Validation and Business Rules Declaratively."](#)

The default components are fully functional without any further modifications. However, you can modify them to suit your particular needs. Each component and its various features are discussed further in [Part V, "Creating a Databound Web User Interface"](#).

Tip: If you want to change the type of ADF databound component used on a page, the easiest method is to use either the visual editor or the structure window to delete the component, and then drag and drop a new one from the Data Controls panel. When you use the visual editor or the structure window to delete a databound component from a page, if the related binding objects in the page definition file are not referenced by any other component, JDeveloper automatically deletes those binding objects for you (automatic deletion of binding objects will not happen if you use the source editor).

13.4.2 What Happens When You Use the Data Controls Panel

When an Oracle ADF web application is built using the JSF framework, it requires a few additional application object definitions to render and process a page containing ADF databound UI components. If you do not use the Data Controls panel, you will have to manually configure these various files yourself. However, when you use the Data Controls panel, JDeveloper does all of the following required steps:

- Creates a `DataBindings.cpx` file in the default package for the project (if one does not already exist), and adds an entry for the page.

`DataBindings.cpx` files define the *binding context* for the application. The binding context is a container object that holds a list of available data controls and data binding objects. For more information, see [Section 13.4.3, "What Happens at Runtime: How the Binding Context Works."](#) Each `DataBindings.cpx` file maps individual pages to the binding definitions in the page definition file and registers the data controls used by those pages. For more information, see [Section 13.5, "Working with the DataBindings.cpx File."](#)

- Creates the `adfm.xml` file in the META-INF directory. This file creates a registry for the `DataBindings.cpx` file, which allows the application to locate it at runtime so that the binding context can be created.
- Registers the ADF binding filter in the `web.xml` file.

The ADF binding filter preprocesses any HTTP requests that may require access to the binding context. For more information about the binding filter configuration, see [Section 13.6, "Configuring the ADF Binding Filter."](#)

- Adds the following libraries to the view project:
 - ADF Faces Databinding Runtime
 - Oracle XML Parser v2
 - JDeveloper Runtime
 - ADF Model Runtime
 - BC4J Runtime
 - Oracle JDBC

- Connection Manager
- BC4J Oracle Domains
- Adds a page definition file (if one does not already exist for the page) to the page definition subpackage. The default subpackage is `view.pageDefs` in the `adfmsrc` directory.

Tip: You can set the package configuration (such as name and location) in the ADF Model settings page of the Project Properties dialog (accessible by double-clicking the project folder).

The page definition file (`pageNamePageDef.xml`) defines the ADF binding container for each page in an application's view layer. The binding container provides runtime access to all the ADF binding objects for a page. In later chapters, you will see how the page definition files are used to define and edit the binding object definitions for specific UI components. For more information about the page definition file, see [Section 13.7, "Working with Page Definition Files."](#)

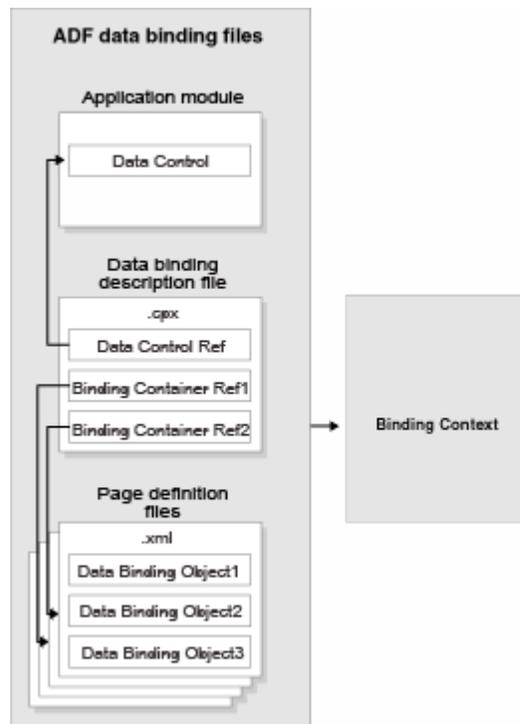

- Configures the page definition file, which includes adding definitions of the binding objects referenced by the page.
- Adds ADF Faces components to the JSF page.
These prebuilt components include ADF data binding expression language (EL) expressions that reference the binding objects in the page definition file. For more information, see [Section 13.8, "Creating ADF Data Binding EL Expressions."](#)
- Adds all the libraries, files, and configuration elements required by ADF Faces components. For more information, see the "ADF Faces Configuration" appendix in the *Oracle Fusion Middleware Web User Interface Developer's Guide for Oracle Application Development Framework*.

13.4.3 What Happens at Runtime: How the Binding Context Works

When a page contains ADF bindings, at runtime the interaction with the business services initiated from the client or controller is managed by the application through a single object known as the *binding context*. The binding context is a runtime map (named `data` and accessible through the EL expression `#{data}`) of all data controls and page definitions within the application.

The ADF lifecycle creates the Oracle ADF binding context from the application module, `DataBindings.cpx`, and page definition files, as shown in [Figure 13–13](#). The union of all the `DataControls.dcx` files and any application modules in the workspace define the available data controls at design time, but the `DataBindings.cpx` files define what data controls are available to the application at runtime. A `DataBindings.cpx` file lists all the data controls that are being used by pages in the application and maps the binding containers, which contain the binding objects defined in the page definition files, to web page URLs. The page definition files define the binding objects used by the application pages. There is one page definition file for each page.

The binding context does not contain real live instances of these objects. Instead, the map contains references that become data control or binding container objects on demand. When the object (such as a page definition) is released from the application, for example when a task flow ends or when the binding container or data control is released at the end of the request, data controls and binding containers turn back into reference objects. For information about the ADF lifecycle, see [Chapter 25, "Understanding the Fusion Page Lifecycle."](#)

Figure 13–13 ADF File Binding Runtime Usage

13.5 Working with the DataBindings.cpx File

The `DataBindings.cpx` files define the binding context for the entire application and provide the metadata from which the Oracle ADF binding objects are created at runtime. An application may have more than one `DataBindings.cpx` file if a component, for example a region, was created outside of the project and then imported. These files map individual pages to page definition files and declare which data controls are being used by the application. At runtime, only the data controls listed in the `DataBindings.cpx` files are available to the current application.

13.5.1 How JDeveloper Creates a DataBindings.cpx File

The first time you use the Data Controls panel to add a component to a page or an operation to an activity, JDeveloper automatically creates a `DataBindings.cpx` file in the default package of the view project. It resides in the `adfmsrc` directory for the project. Once the `DataBindings.cpx` file is created, JDeveloper adds an entry for the first page or task flow activity. Each subsequent time you use the Data Controls panel, JDeveloper adds an entry to the `DataBindings.cpx` for that page or activity, if one does not already exist.

Tip: JDeveloper supports refactoring. That is, you can safely rename or move many of the objects referenced in the `DataBindings.cpx` file, and the references will be updated. For more information, see [Chapter 37, "Refactoring a Fusion Web Application."](#)

13.5.2 What Happens When JDeveloper Creates a DataBindings.cpx File

Once JDeveloper creates a `DataBindings.cpx` file, you can open it in the overview editor. [Figure 13–14](#) shows the `DataBindings.cpx` file from the StoreFront module application, as viewed in the overview editor (note that it's been truncated).

Figure 13–14 DataBindings.cpx File in the Overview Editor**Data Binding Registry**

This file defines the Oracle ADF binding context for your application. JDeveloper creates this file the first time you data bind a UI component.

  <BC4JDataControl id="StoreServiceAMDataControl"
                  Package="oracle.fodemo.storefront.store.service"
                  FactoryClass="oracle.adf.model.bc4j.DataControlFactoryImpl"
                  SupportsTransactions="true" SupportsFindMode="true"
                  SupportsRangeSize="true" SupportsResetState="true"
                  SupportsSortCollection="true"
                  Configuration="StoreServiceAMLocalWeb" syncMode="Immediate"
                  xmlns="http://xmlns.oracle.com/adfm/datacontrol"/>
  <BC4JDataControl id="LookupServiceAMDataControl"
                  Package="oracle.fodemo.storefront.lookups"
                  FactoryClass="oracle.adf.model.bc4j.DataControlFactoryImpl"
                  SupportsTransactions="true" SupportsFindMode="true"
                  SupportsRangeSize="true" SupportsResetState="true"
                  SupportsSortCollection="true"
                  Configuration="LookupServiceAMLocal" syncMode="Immediate"
                  xmlns="http://xmlns.oracle.com/adfm/datacontrol"/>
</dataControlUsages>
</Application>

```

The **Page Mappings** section of the editor maps each JSF page or task flow activity to its corresponding page definition file using an ID. The **Page Definition Usages** section maps the page definition ID to the absolute path for page definition file in the application. The **Data Control Usages** section identifies the data controls being used by the binding objects defined in the page definition files. These mappings allow the binding container to be initialized when the page is invoked.

You can use the overview editor to change the ID name for page definition files or data controls by double-clicking the current ID name and editing inline. Doing so will update all references in the application. Note, however, that JDeveloper updates only the ID name, it does not update the file name. Be sure that you do not change a data control name to a reserved word. For more information, see [Section 9.2.5, "How to Edit an Existing Application Module."](#)

You can also click an element in the Structure window and then use the Property Inspector to change property values. For more information about the elements and attributes in the `DataBindings.cpx` file, see [Section A.7, "DataBindings.cpx."](#)

13.6 Configuring the ADF Binding Filter

The ADF binding filter is a servlet filter that is an instance of the `oracle.adf.model.servlet.ADFBindingFilter` class. ADF web applications use the ADF binding filter to preprocess any HTTP requests that may require access to the binding context. To do this, the ADF binding filter must be aware of all `DataBindings.cpx` files that exist for an application.

13.6.1 How JDeveloper Configures the ADF Binding Filter

The first time you add a databound component to a page using the Data Controls panel, JDeveloper automatically configures the filter for you in the application's `web.xml` file.

13.6.2 What Happens When JDeveloper Configures an ADF Binding Filter

To configure the binding filter, JDeveloper adds the following elements to the `web.xml` file:

- An ADF binding filter class: Specifies the name of the binding filter object, which implements the `javax.servlet.Filter` interface.

The ADF binding filter is defined in the `web.xml` file, as shown in [Example 13-2](#). The `filter-name` element must contain the value `adfBindings`, and the `filter-class` element must contain the fully qualified name of the binding filter class, which is `oracle.adf.model.servlet.ADFBindingFilter`.

Example 13-2 Binding Filter Class Defined in the web.xml File

```
<filter>
  <filter-name>adfBindings</filter-name>
  <filter-class>oracle.adf.model.servlet.ADFBindingFilter</filter-class>
</filter>
```

- Filter mappings: Link filters to static resources or servlets in the web application.

At runtime, when a mapped resource is requested, a filter is invoked. Filter mappings are defined in the `web.xml` file, as shown in [Example 13-3](#). The `filter-name` element must contain the value `adfBindings`.

Example 13-3 Filter Mapping Defined in the web.xml File

```
<filter-mapping>
  <filter-name>adfBindings</filter-name>
  <servlet-name>Faces Servlet</servlet-name>
  <dispatcher>FORWARD</dispatcher>
  <dispatcher>REQUEST</dispatcher>
</filter-mapping>
```

Tip: If you have multiple filters defined in the `web.xml` file, be sure to list them in the order in which you want them to run. At runtime, the filters are executed in the sequence in which they appear in the `web.xml` file.

The `adfBindings` filter should appear after the Trinidad filter and before any filters that depend on the ADF context to be initialized.

13.6.3 What Happens at Runtime: How the ADF Binding Filter Works

At runtime, the ADF binding filter performs the following functions:

- Overrides the character encoding when the filter is initialized with the name specified as a filter parameter in the `web.xml` file. The parameter name of the filter `init-param` element is `encoding`.
- Instantiates the `ADFContext` object, which is the execution context for a Fusion web application and contains context information about ADF, including the security context and the environment class that contains the request and response object.

- Initializes the binding context for a user's HTTP session. To do this, it first loads the bindings as defined in the `DataBindings.cpx` file in the current project's `adfmsrc` directory. If the application contains `DataBindings.cpx` files that were imported from another project, those files are present in the application's class path. The filter additively loads any auxiliary `.cpx` files found in the class path of the application.
- Serializes incoming HTTP requests from the same browser (for example, from frame sets) to prevent multithreading problems.
- Notifies data control instances that they are about to receive a request, allowing them to do any necessary per-request setup.
- Notifies data control instances after the response has been sent to the client, allowing them to do any necessary per-request cleanup.

13.7 Working with Page Definition Files

Page definition files define the binding objects that populate the data in UI components at runtime. For every page that has ADF bindings, there must be a corresponding page definition file that defines the binding objects used by that page. Page definition files provide design time access to all the ADF bindings. At runtime, the binding objects defined by a page definition file are instantiated in a binding container, which is the runtime instance of the page definition file.

Note: When multiple windows are open to the same page, the ADF Controller assigns each window its own `DataControlFrame`. This ensures that each window has its own binding container.

13.7.1 How JDeveloper Creates a Page Definition File

The first time you use the Data Controls panel, JDeveloper automatically creates a page definition file for that page and adds definitions for each binding object referenced by the component. For each subsequent databound component you add to the page, JDeveloper automatically adds the necessary binding object definitions to the page definition file.

By default, the page definition files are located in the `view.PageDefs` package in the Application Sources directory of the view project. If the corresponding JSF page is saved to a directory other than the default (`public_html`), or to a subdirectory of the default, then the page definition will also be saved to a package of the same name. For example, if you save your JSF file to the `public_html/myDirectory` directory, the page definition will be saved to the `myDirectory` package. You can change the location of the page definition files using the ADF Model Settings page of the Project Properties dialog.

JDeveloper names the page definition files using the following convention:

`pageNamePageDef.xml`

where `pageName` is the name of the JSF page. For example, if the JSF page is named `home.jsp`, the default page definition file name is `homePageDef.xml`. If you organize your pages into subdirectories, JDeveloper prefixes the directory name to the page definition file name using the following convention:

`directoryName_pageNamePageDef.xml`

For example, in the StoreFront module, the name of the page definition file for the `updateUserInfo` page, which is in the `account` subdirectory of the Web Content node is `account_updateUserInfoPageDef.xml`.

Tip: Page definitions for task flows follow the same naming convention.

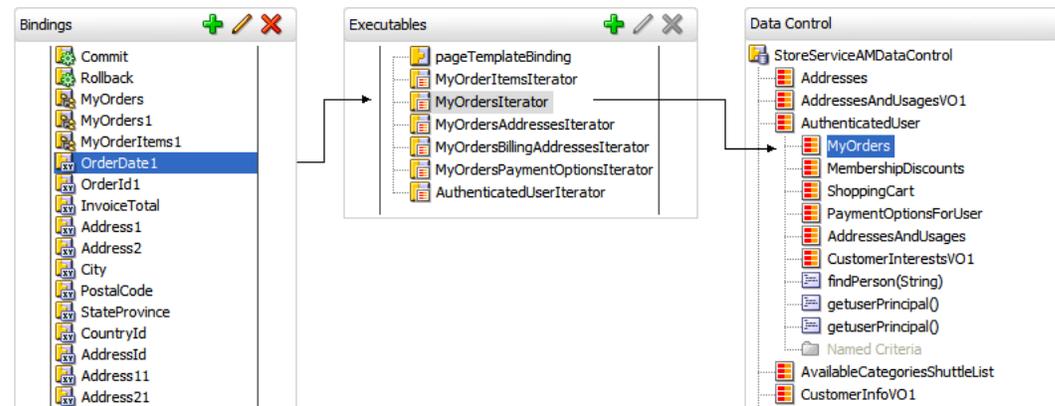

To open a page definition file, you can right-click directly on the page or activity in the visual editor, and choose **Go to Page Definition**, or for a JSF page, you can click the **Bindings** tab of the editor and click the Page Definition File link.

Tip: While JDeveloper automatically creates a page definition for a JSF page when you create components using the Data Controls panel, or for a task flow when you drop an item onto an activity, it does not delete the page definition when you delete the associated JSF page or task flow activity (this is to allow bindings to remain when they are needed without a JSF page, for example when using desktop integration). If you no longer want the page definition, you need to delete the page definition and all references to it manually. Note however, that as long as a corresponding page or activity is never called, the page definition will never be used to create a binding context. It is therefore not imperative to remove any unused page definition files from your application.

13.7.2 What Happens When JDeveloper Creates a Page Definition File

When JDeveloper creates a page definition file, it is displayed in the overview editor. [Figure 13–15](#) shows the page definition file in the overview editor that was created for the `myOrders.jspx` page in the StoreFront module application.

Figure 13–15 Page Definition File in the Overview Editor

The overview editor contains the following tabs, which allow you to view and configure bindings, contextual events, and parameters for a page:

- **Bindings and Executables:** The Bindings and Executables tab of the page definition overview editor shows three different types of objects: bindings, executables, and the associated data controls (note that the data controls do not display unless you select a binding or executable). For example, in [Figure 13–15](#), you can see that the binding for the `OrderDate1` attribute uses the `MyOrdersIterator` iterator to get its value. The iterator accesses the `MyOrders` collection on the

StoreServiceAMDataControl data control. For more information, see [Section 13.7.2.2, "Executable Binding Objects Defined in the Page Definition File."](#)

By default, the model binding objects are named after the data control object that was used to create them. If a data control object is used more than once on a page, JDeveloper adds a number to the default binding object names to keep them unique. In [Section 13.8, "Creating ADF Data Binding EL Expressions,"](#) you will see how the ADF data binding EL expressions reference the binding object names.

[Table 13–2](#) shows the icons for each of the binding objects, as displayed in the overview editor (note that while parameter objects are shown in the **Parameter** section of the editor, they are also considered binding objects).

Table 13–2 Binding Object Icons

Binding Object Type	Icon	Description
Parameter		Represents a parameter binding object.
Bindings		Represents an attribute value binding object.
		Represents a list value binding object.
		Represents a tree value binding object.
		Represents a method action binding object.
Bindings/ Executables		Represents an action binding object. Also represents an invoke action executable binding object and an event.
Executables		Represents an iterator binding object.
		Represents a task flow executable binding object.

- **Contextual Events:** You can create contextual events that artifacts in an application can subscribe to. For example, in the StoreFront module, contextual events are used in the customer registration page to display the appropriate informational topic. The `register.jspx` page contains two regions. One region contains the customer registration task flow, and the other contains the informational topic task flow. A contextual event is passed from the customer registration region to the informational topic region so that the informational topic task flow can display the correct information topic. At design time, the event name, producer region, consumer region, consumer handler, and other information is stored in the event map section of the page definition file.
- **Parameters:** Parameter binding objects declare the parameters that the page evaluates at the beginning of a request. (For more information about the ADF lifecycle, see [Chapter 25, "Understanding the Fusion Page Lifecycle."](#)) You can define the value of a parameter in the page definition file using static values, or EL expressions that assign a static value.

[Example 13–4](#) shows how parameter binding objects can be defined in a page definition file.

Example 13–4 parameters Element of a Page Definition File

```
<parameters>
  <parameter id="filedBy"
    value="{bindings.userId}"/>
  <parameter id="status"
    value="{param.status != null ? param.status : 'Open'}/>
</parameters>
```

The value of the `filedBy` parameter is defined by a binding on the `userId` data attribute, which would be an attribute binding defined later in the `bindings` element. The value of the `status` parameter is defined by an EL expression, which assigns a static value.

Tip: The EL expression for the parameter values uses the dollar sign (\$) because these expressions need to be resolved eagerly, so that the result is returned immediately, as the page is rendered. Most EL expressions in a JSF application use the hash sign (#), which defers the expression evaluation so that the model is prepared before the values are accessed.

When you click an item in the overview editor (or the associated node in the Structure window), you can use the Property Inspector to view and edit the attribute values for the item, or you can edit the XML source directly by clicking the **Source** tab.

[Example 13–5](#) shows abbreviated XML code for the page definition file shown in [Figure 13–15](#).

Example 13–5 Page Definition File

```
<pageDefinition xmlns="http://xmlns.oracle.com/adfm/uiamodel"
  version="11.1.1.44.61" id="myOrdersPageDef"
  Package="oracle.fodemo.storefront.pageDefs"
  EnableTokenValidation="false">
  <parameters/>
  <executables>
    <page path="oracle.fodemo.storefront.pageDefs.
      templates_StoreFrontTemplatePageDef"
      id="pageTemplateBinding"/>
    <iterator Binds="MyOrderItems" RangeSize="25"
      DataControl="StoreServiceAMDataControl"
      id="MyOrderItemsIterator"/>
    <iterator Binds="MyOrders" RangeSize="-1"
      DataControl="StoreServiceAMDataControl" id="MyOrdersIterator"/>
    .
    .
    .
  </executables>
  <bindings>
    <action id="Commit" InstanceName="StoreServiceAMDataControl"
      DataControl="StoreServiceAMDataControl" RequiresUpdateModel="true"
      Action="commitTransaction"/>
    <action id="Rollback" InstanceName="StoreServiceAMDataControl"
      DataControl="StoreServiceAMDataControl" RequiresUpdateModel="false"
      Action="rollbackTransaction"/>
    <methodAction id="executeMyOrdersForCustomerVO" RequiresUpdateModel="true"
      Action="invokeMethod"
      MethodName="executeMyOrdersForCustomerVO"
      IsViewObjectMethod="false"
      DataControl="StoreServiceAMDataControl"
      InstanceName="StoreServiceAMDataControl.dataProvider"/>
  </bindings>
```

```

<tree IterBinding="MyOrdersIterator" id="MyOrders">
  <nodeDefinition DefName="oracle.fodemo.storefront.store.queries.OrdersVO">
    <AttrNames>
      <Item Value="OrderId" />
      <Item Value="OrderDate" />
      <Item Value="OrderShippedDate" />
      <Item Value="OrderStatusCode" />
      <Item Value="OrderTotal" />
      <Item Value="CustomerId" />
      <Item Value="ShipToName" />
      <Item Value="ShipToAddressId" />
      <Item Value="ShipToPhoneNumber" />
      <Item Value="ShippingOptionId" />
      <Item Value="PaymentOptionId" />
      <Item Value="CalculatedOrderTotal" />
      <Item Value="TotalShippingCost" />
      <Item Value="DiscountAmount" />
      <Item Value="InvoiceTotal" />
      <Item Value="LastUpdateDate" />
      <Item Value="TypedCouponCode" />
    </AttrNames>
  </nodeDefinition>
</tree>
<attributeValues IterBinding="MyOrdersIterator" id="OrderDate1">
  <AttrNames>
    <Item Value="OrderDate" />
  </AttrNames>
</attributeValues>
<attributeValues IterBinding="MyOrdersIterator" id="OrderId1">
  <AttrNames>
    <Item Value="OrderId" />
  </AttrNames>
</attributeValues>
.
.
.
</bindings>
</pageDefinition>

```

In later chapters, you will see how the page definition file is used to define and edit the bindings for specific UI components. For a description of all the possible elements and attributes in the page definition file, see [Section A.8, "pageNamePageDef.xml."](#)

13.7.2.1 Bindings Binding Objects Defined in the Page Definition File

There are three types of Bindings binding objects used to bind UI components to objects on the data control:

- Value: Displays data in UI components by referencing an iterator binding. Each discrete UI component on a page that will display data from the data control is bound to a value binding object. Value binding objects include:
 - Attribute Values: Binds text fields to a specific attribute in an object (also referred to as an *attribute binding* object.)
 - List: Binds the list items to all values of an attribute in a data collection.
 - Tree: Binds an entire table to a data collection and can also bind the root node of a tree to a data collection.
 - Button (boolean): Binds a checkbox to a boolean value for an attribute.

- Graph: Binds a graph directly to the source data.
- Method Action: Binds command components, such as buttons or links, to custom methods on the data control. A method action binding object encapsulates the details about how to invoke a method and what parameters (if any) the method is expecting.
- Action: Binds command components, such as buttons or links, to built-in data control operations (such as, Commit or Rollback) or to built-in collection-level operations (such as, Create, Delete, Next, or Previous).

Collectively, the binding objects are referred to as *control* binding objects, because they work with the UI controls on a page.

[Example 13–6](#) shows a sample bindings element, which defines one action binding called `Commit`, one attribute binding for a text field called `PaymentOptionId1`, and one list binding called `PaymentTypeCode`.

Example 13–6 bindings Element of a Page Definition File

```
<bindings>
  <action id="Commit" InstanceName="StoreServiceAMDataControl"
    DataControl="StoreServiceAMDataControl" RequiresUpdateModel="true"
    Action="commitTransaction" />
  <attributeValues IterBinding="PaymentOptionsForUserIterator"
    id="PaymentOptionId1">
    <AttrNames>
      <Item Value="PaymentOptionId" />
    </AttrNames>
  </attributeValues>
  <list IterBinding="PaymentOptionsForUserIterator" id="PaymentTypeCode"
    Uses="LOV_PaymentTypeCode" StaticList="false">
    <AttrNames>
      <Item Value="PaymentTypeCode" />
    </AttrNames>
  </list>
</bindings>
```

The binding object defined in the action element encapsulates the information needed to invoke the built-in `commit` operation on the `StoreServiceAMDataControl` data control. The value of `true` in the `RequiresUpdateModel` attribute specifies that the model layer needs to be updated before the operation is executed.

If this operation also raised a contextual event, an event definition would appear well. If the page contained bindings that consumed an event, the event mapping would also appear.

The `attributeValues` element defines the value bindings for the text fields on the page. In the example, the `PaymentOptionId1` attribute binding will display the value of the `PaymentOptionId`, which is defined in the `AttrNames` element. The `IterBinding` attribute references the iterator binding that manages the data to be displayed in the text field (for more information, see [Section 13.7.2.2, "Executable Binding Objects Defined in the Page Definition File"](#)).

The `PaymentTypeCode` element defines the list binding used to display the list of payment type codes by accessing the LOV created on the `PaymentOptions` view object. For more information about creating lists using LOVs on view objects, see [Chapter 30, "Creating Databound Selection Lists and Shuttles."](#)

13.7.2.2 Executable Binding Objects Defined in the Page Definition File

There are seven types of executable binding objects:

- **Iterator:** Binds to an iterator that iterates over view object collections. There is one iterator binding for each collection used on the page. All of the value bindings on the page must refer to an iterator binding in order for the component values to be populated with data at runtime.

When you drop a collection or an attribute of a collection on the page, an iterator binding is automatically added as an executable. Iterator binding objects bind to an underlying ADF `RowSetIterator` object, which manages the current object and current range information. The iterator binding exposes the current object and range state to the other binding objects used by the page.

By default, iterator bindings are configured so that any submitted data changes are cached until the data is committed back to the data source. When a data change is submitted, any components on the page whose bindings are associated with the iterator are refreshed to show the changed data. For more information, see [Section 25.2.1, "What You May Need to Know About Partial Page Rendering and Iterator Bindings."](#)

The iterator *range* represents the current set of objects to be displayed on the page. The maximum number of objects in the current range is defined in the `rangeSize` attribute of the iterator. For example, if a collection in the data control contains products and the iterator range size is 25, the first 25 products in the collection are displayed on the page. If the user scrolls down, the next set of 25 is displayed, and so on. If the user scrolls up, the previous set of 25 is displayed. If your view object uses range paging, then you can configure the iterator binding to return a set of ranges at one time. For more information, see [Section 42.1.5, "Efficiently Scrolling Through Large Result Sets Using Range Paging."](#)

Note: If you have two pages each with an iterator binding bound to the iterator on the same view object (which you will if you drop the same collection, for example, on two different pages), then you should ensure that the `rangeSize` attribute is the same for both pages' iterator bindings. If not, the page with a smaller range size may cause the iterator to reexecute, causing unexpected results on the other page.

- **Method Iterator:** Binds to an iterator that iterates over the collections returned by custom methods in the data control.

A method iterator binding is always related to a method action binding object. The method action binding encapsulates the details about how to invoke the method and what parameters (if any) the method is expecting. The method action binding is itself bound to the method iterator, which provides the data.

You will see method iterator executable binding objects only if you drop a method return collection or an attribute of a method return collection from a custom method on the data control. If you are using only application module data controls, you will see only iterator binding objects.

- **Variable Iterator:** Binds to an iterator that exposes all the variables in the binding container to the other bindings. While there is an iterator binding for each collection, there is only one variable iterator binding for all variables used on the page. (The variable iterator is like an iterator pointing to a collection that contains only one data object whose attributes are the binding container variables.)

Page variables are local to the binding container and exist only while the binding container object exists. When you use a data control method (or an operation) that requires a parameter that is to be collected from the page, JDeveloper automatically defines a variable for the parameter in the page definition file. Attribute bindings can reference the page variables.

A variable iterator can contain one of two types of variables: `variable` and `variableUsage`. A `variable` type variable is a simple value holder, while a `variableUsage` type variable is a value holder that is related to a view object's named bind parameter. Defining a variable as a `variableUsage` type allows it to inherit the default value and UI control hints from the view object named bind variable to which it is bound.

- **Invoke Action:** Binds to a method that invokes the operations or methods defined in action or method action bindings during any phase of the page lifecycle.

Tip: If you know you want a method to execute before the page is rendered, you should use a method call activity in the task flow to invoke the method, rather than an invoke action in the page definition file. Using the method call activity makes invoking page logic easier, and allows you to show more information on the task flow, making the diagram more readable and useful to anyone else who might be using it. However, if you need the method to be executed in more than one phase of the page's lifecycle, or if you plan to reuse the page and page definition file and want the method to be tied to the page, or if your application does not use ADFc, then you should use an invoke action to invoke the method.

- **Page:** Binds to the template's page definition file (if a template is used). For more information about how this works with templates, see [Section 24.2, "Using Page Templates."](#)

Note: You can also use the page element to bind to another page definition file. However, at runtime, only the current incoming page's (or if the rendered page is different from the incoming, the rendered page's) binding container is automatically prepared by the framework during the current request. Therefore, to successfully access a bound value in another page from the current page, you must programmatically prepare that page's binding container in the current request (for example, using a backing bean). Otherwise, the bound values in that page may not be available or valid in the current request.

- **Search Region:** Binds named criteria to the iterator, so that the search can be executed.
- **Task Flow:** Instantiates the binding container for a region's task flow.
- **Multi Task Flow:** instantiates the binding container for a region's task flow from an array of task flows. This is useful when you have a page that contains an unknown number of regions, for example a `panelTabbed` component where each tab is a region, and users can add and delete tabs at runtime. For more information, see [Section 21.10, "Configuring a Page To Render an Unknown Number of Regions."](#)

At runtime, executable bindings are refreshed based on the value of their `Refresh` attribute. Refreshing an iterator binding reconnects it with its underlying `RowSetIterator` object. Refreshing an invoke action binding invokes the action. Before refreshing any bindings, the ADF runtime evaluates any `Refresh` and `RefreshCondition` attributes specified in the executables. The `Refresh` attribute specifies the ADF lifecycle phase within which the executable should be invoked. The `RefreshCondition` attribute specifies the conditions under which the executable should be invoked. You can specify the `RefreshCondition` value using a boolean EL expression. If you leave the `RefreshCondition` attribute blank, it evaluates to `true`.

By default, the `Refresh` value is set to `deferred`. This means the binding will not be executed unless its value is accessed (for example by an EL expression on a JSF page). Once called, it will not reexecute unless any parameter values for the binding have changed, or if the binding itself has changed.

For more information about how bindings are refreshed and how to set the `Refresh` and `RefreshCondition` attributes, see [Section 25.2, "About the JSF and ADF Page Lifecycles."](#)

[Example 13–7](#) shows an example of executable binding objects.

Example 13–7 executable Binding Objects in a Page Definition File

```
<executables>
  <page path="/oracle.fodemo.storefront.pageDefs.
                                templates_StoreFrontTemplatePageDef"
        id="pageTemplateBinding" />
  <iterator Binds="MyOrderItems" RangeSize="25"
           DataControl="StoreServiceAMDataControl"
           id="MyOrderItemsIterator" />
  <iterator Binds="MyOrders" RangeSize="-1"
           DataControl="StoreServiceAMDataControl" id="MyOrdersIterator" />
```

The iterator binding named `MyOrderItems` was created by dropping the `MyOrderItems` collection on the page as a table. The iterator binding named `MyOrders` was created by dropping the `MyOrders` collection, which has a master-detail relationship with the `MyOrderItems` collection. For more information, see [Chapter 29, "Displaying Master-Detail Data."](#)

The `Binds` attribute of the `iterator` element defines the collection the iterator will iterate over. The `RangeSize` attribute defines the number of objects the iterator is to display on the page at one time. A `RangeSize` value of `-1` causes the iterator to display *all* the objects from the collection.

Tip: Normally, an iterator binding's default range size is 25. However, when an iterator binding is created from the Edit List Binding dialog, the range size defaults to `-1` so that all choices display in the list, not just the first 25.

Performance Tip: When you want to reduce the number of roundtrips the iterator requires to fetch the data objects from the view object in the ADF Business Components layer, you can set the `rangeSize` attribute to `-1`, and the objects will be fetched in a single round trip to the server, rather than in multiple trips as the user navigates through the objects.

13.8 Creating ADF Data Binding EL Expressions

To display data from the data model, web page UI components are bound to binding objects using JSF Expression Language (EL) expressions. These EL expressions reference a specific binding object in a binding container. At runtime, the JSF runtime evaluates an EL expression and pulls the value from the binding object to populate the component with data when the page is displayed. If the user updates data in the UI component, the JSF runtime pushes the value back into the corresponding binding object based on the same EL expression.

Tip: There may be cases when you need to use EL expressions within managed beans. For information on working with EL expressions within managed beans, see the "Creating EL Expressions" section in the *Oracle Fusion Middleware Web User Interface Developer's Guide for Oracle Application Development Framework*.

13.8.1 How to Create an ADF Data Binding EL Expression

When you use the Data Controls panel to create a component, the ADF data binding expressions are created for you. The expressions are added to every component attribute that will either display data from or reference properties of a binding object. Each prebuilt expression references the appropriate binding objects defined in the page definition file. You can edit these binding expressions or create your own, as long as you adhere to the basic ADF binding expression syntax. ADF data binding expressions can be added to any component attribute that you want to populate with data from a binding object.

In JSF pages, a typical ADF data binding EL expression uses the following syntax to reference any of the different types of binding objects in the binding container:

```
{bindings.BindingObject.propertyName}
```

where:

- `bindings` is a variable that identifies that the binding object being referenced by the expression is located in the binding container of the current page. All ADF data binding EL expressions must start with the `bindings` variable.
- `BindingObject` is the ID, or for attributes the name, of the binding object as it is defined in the page definition file. The binding `objectID` or name is unique to that page definition file. An EL expression can reference any binding object in the page definition file, including parameters, executables, or value bindings.
- `propertyName` is a variable that determines the default display characteristics of each databound UI component and sets properties for the binding object at runtime. There are different binding properties for each type of binding object. For more information about binding properties, see [Section 13.8.2, "What You May Need to Know About ADF Binding Properties."](#)

For example, in the following expression that might appear on a JSF page:

```
{bindings.ProductName.inputValue}
```

the `bindings` variable references a bound value in the current page's binding container. The binding object being referenced is `ProductName`, which is an attribute binding object. The binding property is `inputValue`, which returns the value of the first `ProductName` attribute.

Tip: While the binding expressions in the page definition file can use either a dollar sign (\$) or hash sign (#) prefix, the EL expressions in JSF pages can use only the hash sign (#) prefix.

As stated previously, when you use the Data Controls panel to create UI components, these expressions are built for you. However, you can also manually create them if you need to. The JDeveloper Expression Builder is a dialog that helps you build EL expressions by providing lists of binding objects defined in the page definition files, as well as other valid objects to which a UI component may be bound. It is particularly useful when creating or editing ADF databound expressions because it provides a hierarchical list of ADF binding objects and their most commonly used properties. For information about binding properties, see [Section 13.8.2, "What You May Need to Know About ADF Binding Properties."](#)

13.8.1.1 Opening the Expression Builder from the Property Inspector

You can select an item in the visual editor, and then create EL expressions for specific attributes using the Property Inspector.

To open the Expression Builder from the Property Inspector:

1. Select a UI component in the Structure window or the visual editor.
2. In the Property Inspector, click the dropdown list next to a field, and choose **Expression Builder**.

13.8.1.2 Using the Expression Builder

Once the Expression Builder is open, you can use it to create EL expressions.

Before you begin:

It may be helpful to have an understanding of how to create EL expressions when using the ADF Model layer. For more information, see [Section 13.8, "Creating ADF Data Binding EL Expressions."](#)

To use the Expression Builder:

1. Open the Expression Builder dialog.
2. Use the Expression Builder to edit or create ADF binding expressions using the following features:
 - Use the **Variables** tree to select items that you want to include in the binding expression. The tree contains a hierarchical representation of the binding objects. Each icon in the tree represents various types of binding objects that you can use in an expression (see [Table 13–3](#) for a description of each icon).
To narrow down the tree, you can either use the dropdown filter or enter search criteria in the search field. Double-click an item in the tree to move it to the **Expression** box.
 - Use the operator buttons to add logical or mathematical operators to the expression.

Tip: You can also type the expression directly in the **Expression** box.

Table 13–3 Icons Under the ADF Bindings Node of the Expression Builder

Icon	Description
 bindings	Represents the bindings container variable, which references the binding container of the current page. Opening the bindings node exposes all the binding objects for the current page.
 data	Represents the data binding variable, which references the entire binding context (created from all the .cpx files in the application). Opening the data node exposes all the page definition files in the application.
	Represents an action binding object. Opening a node that uses this icon exposes a list of valid action binding properties.
	Represents an iterator binding object. Opening a node that uses this icon exposes a list of valid iterator binding properties.
	Represents an attribute binding object. Opening a node that uses this icon exposes a list of valid attribute binding properties.
	Represents a list binding object. Opening a node that uses this icon exposes a list of valid list binding properties.
	Represents a table or tree binding object. Opening a node that uses this icon exposes a list of valid table and tree binding properties.
	Represents an ADF binding object property. For more information about ADF properties, see Section 13.8.2, "What You May Need to Know About ADF Binding Properties."
	Represents a parameter binding object.
	Represents a JavaBean.
	Represents a method.

13.8.2 What You May Need to Know About ADF Binding Properties

When you create a databound component using the Expression Builder, the EL expression might reference specific ADF binding properties. At runtime, these binding properties can define such things as the default display characteristics of a databound UI component or specific parameters for iterator bindings. The ADF binding properties are defined by Oracle APIs. For a full list of the available properties for each binding type, see [Appendix B, "Oracle ADF Binding Properties."](#)

Values assigned to certain properties are defined in the page definition file. For example, iterator bindings have a property called `RangeSize`, which specifies the number of rows the iterator should display at one time. The value assigned to `RangeSize` is specified in the page definition file, as shown in [Example 13–8](#).

Example 13–8 Iterator Binding Object with the RangeSize Property

```
<iterator Binds="ProductsByCategory1" RangeSize="25"
  DataControl="StoreFrontModuleDataControl"
  id="Products2Iterator" />
```

13.9 Using Simple UI First Development

While the Data Controls panel enables you to design and create bound components in a single drag-and-drop action, in some cases, it may be preferable to create the basic UI components first and add the bindings later. For example, if your page will use declarative components, you will first need to drop the declarative component, and then bind it to the correct ADF control. Declarative components are reusable, composite UI components that are made up of other ADF Faces components. Once imported into a project, declarative components can be dropped onto a page from the Component Palette, similar to standard ADF Faces components. While the entire declarative component cannot use ADF data binding, you can use ADF data binding on the individual components that make up the declarative component, once the declarative component is dropped on the page. For more information about declarative components, see the "Using Declarative Components" section of the *Oracle Fusion Middleware Web User Interface Developer's Guide for Oracle Application Development Framework*.

Note: If you know the UI components on your page will eventually use ADF data binding, but you need to develop the pages before the data controls are ready, then you should consider using placeholder data controls, rather than manually binding the components. Using placeholder data controls will provide the same declarative development experience as using developed data controls. For more information, see [Chapter 17, "Designing a Page Using Placeholder Data Controls."](#)

When designing web pages, keep in mind that ADF bindings can be added only to certain ADF Faces tags or their equivalent JSF HTML tags. [Table 13–4](#) lists the ADF Faces and JSF tags to which you can later add ADF bindings.

Tip: To enable the use of JSF Reference Implementation UI component tags with ADF bindings, you must choose the **Include JSF HTML Widgets for JSF Databinding** option in the **ADF View Settings** of the project properties. However, using ADF Faces tags, especially with ADF bindings, provides greater functionality than does using the reference implementation JSF tags.

Table 13–4 Tags That Can Be Used for ADF Bindings

ADF Faces Tags Used in ADF Bindings	Equivalent JSF HTML Tags
Text Fields	
af:inputText	h:inputText
af:outputText	h:outputText
af:outputLabel	h:outputLabel
af:inputDate	n/a
Tables	
af:table	h:dataTable
Actions	
af:commandButton	h:commandButton

Table 13–4 (Cont.) Tags That Can Be Used for ADF Bindings

ADF Faces Tags Used in ADF Bindings	Equivalent JSF HTML Tags
af:commandLink	h:commandLink
af:commandMenuItem	n/a
af:commandToolBarButton	n/a
Selection Lists	
af:inputListOfValues	n/a
af:selectOneChoice	h:selectOneMenu
af:selectOneListbox	h:selectOneListbox
af:selectOneRadio	h:selectOneRadio
af:selectBooleanCheckbox	h:selectBooleanCheckbox
Queries	
af:query	n/a
af:quickQuery	n/a
Trees	
af:tree	n/a
af:treeTable	n/a

Before adding binding to the UI components, ensure that you follow these guidelines:

- When creating the JSF page using the Create JSF JSP wizard, choose the **Do not Automatically Expose UI Components in a Managed Bean** option on the **Managed Bean** tab.
 This option turns off JDeveloper's auto-binding feature, which automatically associates every UI component in the page to a corresponding property in the backing bean for eventual programmatic manipulation. If you intend to add ADF bindings to a page, do not use the auto-binding feature. If you use the auto-binding feature, you will have to remove the managed bean bindings later, after you have added the ADF bindings. The managed bean UI component property bindings do not affect the ADF bindings, but their presence may be confusing in the JSF code. For information about managed beans, see [Section 24.4, "Using a Managed Bean in a Fusion Web Application."](#)
- Add the ADF Faces tag libraries.
 While you can add ADF bindings to JSF components, the ADF Faces components provide greater functionality, especially when combined with ADF bindings.

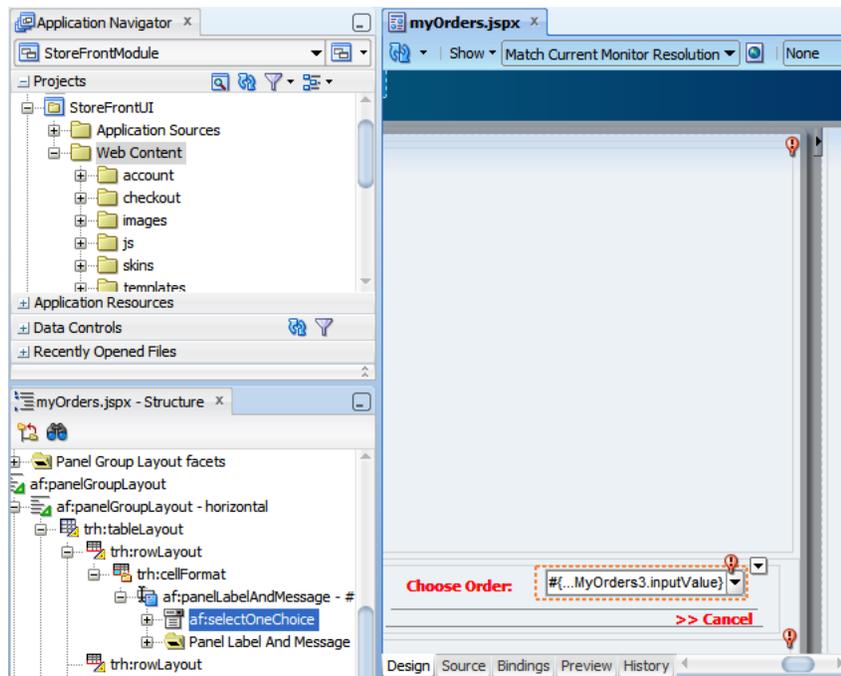

13.9.1 How to Apply ADF Model Data Binding to Existing UI Components

You apply ADF model binding to components using the Structure window.

To apply ADF Model data binding:

1. In the Design page of the visual editor, select the UI component to which you want to add ADF bindings.

The component must be one of the tags listed in [Table 13–4](#). When you select a component in the visual editor, JDeveloper simultaneously selects that component tag in the Structure window, as shown in [Figure 13–16](#).

Figure 13–16 The Structure Window in JDeveloper

2. In the Structure window, right-click the UI component, and from the context menu, choose **Bind to ADF Control**.

Note: Your project must already contain data controls for the **Bind to ADF Control** menu option to appear. If yours does not, you should consider using placeholder data controls, as described in [Chapter 17, "Designing a Page Using Placeholder Data Controls."](#)

3. In the Bind to ADF Control dialog, select the data control to which you want the UI component bound. JDeveloper will notify you if you choose a control that is not compatible with the selected UI component.

13.9.2 What Happens When You Apply ADF Model Data Binding to UI Components

When you use the Data Controls panel all of the required ADF objects are automatically created for you, as described in [Section 13.4.2, "What Happens When You Use the Data Controls Panel."](#)

Exposing Web Services Using the ADF Model Layer

This chapter describes how to call a third-party web service and work directly with the service proxy and service data objects (SDOs) programmatically for all common remote service data access tasks. It also describes how to create ADF data controls for third-party web services when you want to work with the web service in the user interface.

This chapter includes the following sections:

- [Section 14.1, "About Web Services in Fusion Web Applications"](#)
- [Section 14.2, "Creating Web Service Data Controls"](#)
- [Section 14.3, "Creating a New Web Service Connection"](#)
- [Section 14.4, "Securing Web Service Data Controls"](#)

14.1 About Web Services in Fusion Web Applications

Web services allow enterprises to expose business functionality irrespective of the platform or language of the originating application because the business functionality is exposed in such a way that it is abstracted to a message composed of standard XML constructs that can be recognized and used by other applications.

Web services are modular business services that can be easily integrated and reused, and it is this that makes them ideally suited as components within SOA. JDeveloper helps you to create top-down web services (services created starting from a WSDL), bottom-up web services (created from the underlying implementation such as a Java class or a PL/SQL stored procedure in a database), and services created from existing functionality, such as exposing an application module as a service.

14.1.1 Web Services Use Cases and Examples

You can consume web services in web applications, and common reasons for wanting to do so are:

- To add functionality which would be time-consuming to develop with the application, but which is readily available as a web service
- To access an application that runs on different architecture
- To access an application that is owned by another team when their application must be independently installed, upgraded, and maintained, especially when its data is not replicated locally (for example, when other methods of accessing their application cannot be used).

14.1.2 Additional Functionality for Web Services in Fusion Applications

You may find it helpful to understand other ADF features before you start working with web services. Following are links to other functionality that may be of interest.

- You can design a databound user interface by dragging an item from the Data Controls panel and dropping it on a page as a specific UI component. For more information, see [Section 13.4.1, "How to Use the Data Controls Panel."](#)
- If you are working behind a firewall and you want to use a web service that is outside the firewall, you must configure the web browser and proxy settings in JDeveloper, as described in [Section 9.12.4.3, "Setting Browser Proxy Information."](#)
- For information about creating data controls for application modules, see [Chapter 13, "Using ADF Model in a Fusion Web Application."](#) For information about other types of data controls, see [Appendix H, "Data Controls in Fusion Web Applications."](#)

The following chapters provide information about specific objects you can use in data controls:

- For information about using collections on a data control to create forms, see [Chapter 26, "Creating a Basic Databound Page."](#)
- For information about using collections to create tables, see [Chapter 27, "Creating ADF Databound Tables."](#)
- For information about using master-detail relationships to create UI components, see [Chapter 29, "Displaying Master-Detail Data."](#)
- For information about creating lists, see [Chapter 30, "Creating Databound Selection Lists and Shuttles."](#)
- For information about creating graphs, charts, and other visualization UI components, see [Chapter 33, "Creating Databound ADF Data Visualization Components."](#)

14.2 Creating Web Service Data Controls

The most common way of using web services in an application developed using Oracle ADF is to create a data control for an external web service. A typical reason for doing this is to add functionality that is readily available as a web service, but which would be time consuming to develop with the application, or to access an application that runs on a different architecture.

Additionally, you can reuse components created by Oracle ADF to make them available as web services for other applications to access.

14.2.1 How to Create a Web Service Data Control

JDeveloper allows you to create a data control for an existing web service using just the WSDL for the service. You can browse to a WSDL on the local file system, locate one in a UDDI registry, or enter the WSDL URL directly.

Note: If you are working behind a firewall and you want to use a web service that is outside the firewall, you must configure the web browser and proxy settings in JDeveloper. For more information, see [Section 9.12.4.3, "Setting Browser Proxy Information."](#)

Before you begin:

It may be helpful to have an understanding of how web service data controls are used in ADF applications. For more information, see [Section 14.2, "Creating Web Service Data Controls."](#)

You may also find it helpful to understand additional functionality that can be added using other web services features. For more information, see [Section 14.1.2, "Additional Functionality for Web Services in Fusion Applications."](#)

To create a web service data control:

1. In the Application Navigator, right-click an application and choose **New**.
2. In the New Gallery, expand **Business Tier**, select **Web Services** and then **Web Service Data Control**, and click **OK**.
3. In the Create Web Service Data Control wizard, on the Data Source page, specify a name for the data control, a WSDL URL, and the specific web service to be accessed by the data control.
4. On the Data Control Operations page, select the operations you want the data control to support.
5. On the Response Format page, specify the format of the SOAP response.
6. On the Endpoint Authentication page, specify the authentication details for the endpoint URL, and click **Finish**.

14.2.2 How to Adjust the Endpoint for a Web Service Data Control

After developing a web service data control, you can modify the endpoint. This is useful, for example, when you migrate the application from a test environment to production.

Before you begin:

It may be helpful to have an understanding of how web service data controls are used in ADF applications. For more information, see [Section 14.2, "Creating Web Service Data Controls."](#)

You may also find it helpful to understand additional functionality that can be added using other web services features. For more information, see [Section 14.1.2, "Additional Functionality for Web Services in Fusion Applications."](#)

To change the endpoint for a web service data control:

1. In the Application Navigator, select the `.dcx` file for the web service data control.
2. In the Structure window, right-click the web service data control and choose **Edit Web Service Connection** from the context menu.
3. In the Edit Web Service Connection dialog, make the necessary changes to the endpoint URL and port name.
4. Click **OK**.

14.2.3 How to Refresh a Web Service Data Control

After creating a web service data control, you might find that a web service operation has changed in its method signature, return type, or structure. When this happens, you can update the data control without having to re-create it.

Before you begin:

It may be helpful to have an understanding of how web service data controls are used in ADF applications. For more information, see [Section 14.2, "Creating Web Service Data Controls."](#)

You may also find it helpful to understand additional functionality that can be added using other web services features. For more information, see [Section 14.1.2, "Additional Functionality for Web Services in Fusion Applications."](#)

To refresh an operation in a web service data control:

1. In the Application Navigator, select the `.dcx` file for the web service data control.
2. In the Structure window, right-click the desired web service operation and choose **Update** from the context menu.

JDeveloper queries the web service and updates the web service data control to reflect the current state of the selected operation.

14.2.4 What You May Need to Know About Web Service Data Controls

As with other kinds of data controls, you can design a databound user interface by dragging an item from the Data Controls panel and dropping it on a page as a specific UI component. For more information, see [Section 13.4.1, "How to Use the Data Controls Panel."](#)

In the Data Controls panel, each data control object is represented by an icon. [Table 14-1](#) describes what each icon represents, where it appears in the Data Controls panel hierarchy, and what components it can be used to create.

Table 14–1 Data Controls Panel Icons and Object Hierarchy for Web Services

Icon	Name	Description	Used to Create...
	Data Control	<p>Represents a data control. You cannot use the data control itself to create UI components, but you can use any of the child objects listed under it. Depending on how your web services are defined, there may be more than one data control.</p> <p>Typically, there is one data control for each web service. However, you may have additional data controls that were created for other types of business services (for example, application modules). For information about creating data controls for application modules, see Chapter 13, "Using ADF Model in a Fusion Web Application."</p>	Serves as a container for other objects and is not used to create anything
	Collection	<p>Represents a named data collection. A <i>data collection</i> represents a set of data objects (also known as a <i>row set</i>) in the data model. Each object in a data collection represents a specific structured data item (also known as a <i>row</i>) in the data model. Throughout this guide, <i>data collection</i> and <i>collection</i> are used interchangeably.</p> <p>For more information about using collections on a data control to create forms, see Chapter 26, "Creating a Basic Databound Page."</p> <p>For more information about using collections to create tables, see Chapter 27, "Creating ADF Databound Tables."</p> <p>For more information about using master-detail relationships to create UI components, see Chapter 29, "Displaying Master-Detail Data."</p> <p>For information about creating graphs, charts, and other visualization UI components, see Chapter 33, "Creating Databound ADF Data Visualization Components."</p>	Forms, tables, graphs, trees, range navigation components, and master-detail components.
	Attribute	<p>Represents a discrete data element in an object (for example, an attribute in a row). Attributes appear as children under the collections or method returns to which they belong.</p> <p>For information about using attributes to create fields on a page, see Section 26.2, "Using Attributes to Create Text Fields."</p> <p>For information about creating lists, see Chapter 30, "Creating Databound Selection Lists and Shuttles."</p>	Label, text field, date, list of values, and selection list components.
	Structured Attribute	<p>Represents a returned object that is not one of the Java primitive types (which are represented as attributes) and is also not a collection of any type. An example of a structured attribute would be a domain, which is a developer-created data type used to simplify application maintenance.</p> <p>For more information about domains, see Section 4.15, "Creating Custom, Validated Data Types Using Domains."</p>	Label, text field, date, list of values, and selection list components
	Method	<p>Represents an operation in the data control or one of its exposed structures that may accept parameters, perform some business logic and optionally return single value, a structure or a collection of those.</p>	Command components For methods that accept parameters: command components and parameterized forms

Table 14–1 (Cont.) Data Controls Panel Icons and Object Hierarchy for Web Services

Icon	Name	Description	Used to Create...
	Method Return	<p>Represents an object that is returned by a web service method. The returned object can be a single value or a collection.</p> <p>If a custom method returns anything at all, it is usually a single scalar value. However, some custom methods can return collections.</p> <p>A method return appears as a child under the method that returns it. The objects that appear as children under a method return can be attributes of the collection, other methods that perform actions related to the parent collection, and operations that can be performed on the parent collection.</p> <p>When a single-value method return is dropped, the method is not invoked automatically by the framework. You should either drop the corresponding method as a button to invoke the method, or if working with task flows you can create a method activity for it. For more information about executables, see Section 13.7.2.2, "Executable Binding Objects Defined in the Page Definition File."</p>	The same components as for collections and attributes.
	Operation	<p>Represents a built-in data control operation that performs actions on the parent object. Data control operations are located in an Operations node under collections or method returns, and also under the root data control node. The operations that are children of a particular collection or method return operate on those objects only, while operations under the data control node operate on all the objects in the data control.</p> <p>If an operation requires one or more parameters, they are listed in a Parameters node under the operation.</p> <p>The standard operations supported by the web service data control are for form navigation: First, Last, Next, and Previous. Because the web service data control is not an updateable data control, you cannot use built-in operations like commit, rollback, and execute.</p>	<p>UI command components, such as buttons, links, and menus.</p> <p>For more information, see Section 26.4, "Incorporating Range Navigation into Forms," and Section 26.5, "Creating a Form to Edit an Existing Record."</p>
	Parameter	<p>Represents a parameter value that is declared by the method or operation under which it appears. Parameters appear in the Parameters node under a method or operation.</p> <p>Array and structured parameters are exposed as updateable structured attributes and collections under the data control, which can be dropped as an ADF form or an updateable table on the UI. You can use the UI to build a parameter that is an array or a complex object (not a standard Java type).</p>	Label, text, and selection list components.

14.3 Creating a New Web Service Connection

After developing a web service proxy, you can generate additional connections for the proxy that you can use in testing and deployment situations. For example, you might want to create a connection that includes user name and password for testing purposes.

14.3.1 How to Create a New Web Service Connection

The connection information is stored in the `connections.xml` file along with the other connections in your application. This abstraction of the endpoint URL also allows you to edit the connection after deployment using Enterprise Manager without requiring modification to the client code.

Before you begin:

It may be helpful to have an understanding of how web service connections are used in ADF applications. For more information, see [Section 14.3, "Creating a New Web Service Connection."](#)

You may also find it helpful to understand additional functionality that can be added using other data controls and web services features. For more information, see [Section 14.1.2, "Additional Functionality for Web Services in Fusion Applications."](#)

To create a new web service connection:

1. In the Application Navigator, right-click a web service proxy and choose **Create ADF Web Service Connection**.

The New ADF Web Service Connection dialog displays the default settings for a connection associated with the selected proxy.

2. Modify the connection information as necessary, and click **OK**.

WARNING: If you create a new web service connection with the same name as an existing connection, the existing connection will be overwritten with the new information.

After you create a new web service connection, you can modify your client to use this connection. You could use code similar to that shown in [Example 14–1](#) to access the connection from your client.

Example 14–1 Accessing a Web Service Connection from a Client

```
Context ctx = ADFContext.getCurrent().getConnectionsContext();
WebServiceConnection wsc = (WebServiceConnection) ctx.lookup("MyAppModuleService");
MyAppModuleService proxy = wsc.getJaxWSPort(MyAppModuleService.class);
```

The argument that you pass to the `lookup()` method is the name that you gave to the web service connection. In this example, it is `MyAppModuleService`.

14.4 Securing Web Service Data Controls

Web services allow applications to exchange data and information through defined application programming interfaces. SSL (Secure Sockets Layer) provides secure data transfer over unreliable networks, but SSL only works point to point. Once the data reaches the other end, the SSL security is removed and the data becomes accessible in its raw format. A complex web service transaction can have data in multiple messages being sent to different systems, and SSL cannot provide the end-to-end security that would keep the data invulnerable to eavesdropping.

Any form of security for web services has to address the following issues:

- The authenticity and integrity of data
- Data privacy and confidentiality
- Authentication and authorization
- Non-repudiation
- Denial of service attacks

Throughout this section the "client" is the web service data control, which sends SOAP messages to a deployed web service. The deployed web service may be:

- A web service running on Oracle Application Server
- A web service running anywhere in the world that is accessible through the Internet

14.4.1 WS-Security Specification

The WS-Security specification unifies multiple security technologies to make secure web services interoperable between systems and platforms.

WS-Security addresses the following aspects of web services security issues:

- Authentication and authorization
The identity of the sender of the data is verified, and the security system ensures that the sender has privileges to perform the data transaction.
The type of authentication can be a basic username/password pair transmitted in plain text, or trusted X509 certificate chains. SAML assertion tokens can also be used to allow the client to authenticate against the service, or allow it to participate in a federated SSO environment, where authenticated details are shared between domains in a vendor-independent manner.
- Data authenticity, integrity, and non-repudiation
XML digital signatures, which use industry-standard messages, digest algorithms to digitally sign the SOAP message.
- Data privacy
XML encryption that uses industry-standard encryption algorithms to encrypt the message.
- Denial of service attacks
Defines XML structures to time-stamp the SOAP message. The server uses the time stamp to invalidate the SOAP message after a defined interval.

14.4.2 Using Key Stores

A web service data control can be configured for message-level security using key stores. For more information about creating and using key stores for message protection, see the section about managing keystores, wallets, and certificates in the *Oracle Fusion Middleware Administrator's Guide*, and the section about configuring policies in the *Oracle Application Server Web Services Security Guide*.

14.4.3 How to Define Web Service Data Control Security

After you create a web services data control in a JDeveloper project, you can define security for the data control using the Edit Data Control Policies dialog.

Before you begin:

It may be helpful to have an understanding of how security is used in web service data controls. For more information, see [Section 14.4, "Securing Web Service Data Controls."](#)

You may also find it helpful to understand additional functionality that can be added using other web services features. For more information, see [Section 14.1.2, "Additional Functionality for Web Services in Fusion Applications."](#)

To define security for a web service data control:

1. In the Application Navigator, select the web service data control .dcx file.

2. In the Structure window, right-click the web service data control, and choose **Define Web Service Security**.

JDeveloper displays the Edit Data Control Policies dialog, which shows the Policy Store location. To select an alternative policy store, use the **WS Policy Store** page of the Preferences dialog.

3. From the **Ports** dropdown list, select the port to which you want the specified policies are applied.
4. From the **MTOM** dropdown list, select the MTOM (message transmission optimization mechanism) policy you want to use. If you leave this field blank, no MTOM policy is used.
5. From the **Reliability** dropdown list, select the reliability policy you want to use. If you leave this field blank, no reliability policy is used.
6. From the **Addressing** dropdown list, select the addressing policy you want to use. If you leave this field blank, no addressing policy is used.
7. In the **Security** list, you can optionally specify additional security policies to apply. To add a policy, click the Add security policy icon.
8. In the **Management** list, you can optionally specify additional management policies to apply. To add a policy, click the Add management policy icon.
9. If necessary, you can also remove policies from the **Security** list and the **Management** list by selecting the appropriate policy and clicking the corresponding delete icon.
10. You can optionally override properties for the policies in the **Security** list and the **Management** list by clicking **Override Properties**.
11. After you have selected the appropriate policies for your web service data control, click **OK** to apply your selections and close the dialog.

For more information about predefined policies and configuring policies and their properties, see the *Oracle Application Server Web Services Security Guide*.

Exposing URL Services Using the ADF Model Layer

This chapter explains how to expose URL services using the ADF Model layer.

This chapter includes the following sections:

- [Section 15.1, "About Using ADF Model with URL Services"](#)
- [Section 15.2, "Exposing URL Services with ADF Data Controls"](#)
- [Section 15.3, "Using URL Service Data Controls"](#)

15.1 About Using ADF Model with URL Services

A URL service can be simply a URL against which a query is posted, so that the URL can be exposed as an ADF form. For example, say you have a URL service that allows you to access employee data for your company. This data can be retrieved using a URL as shown in [Example 15-1](#).

Example 15-1 Sample URL that Accesses a URL Service

```
http://example.com/getEmployee?empId=20+deptId=10
```

This simple URL that accesses employee data can become an ADF data control with a method (`getEmployee`) and two parameters (`empId` and `deptId`), that can then be dropped on a page as a form.

URL services can also utilize representational state transfer (REST) actions. REST services are web services that can be accessed using a simple HTTP URL, rather than a more complex SOAP protocol. The HTTP actions (`GET`, `PUT`, `POST`, `DELETE`) are mapped to service operations that access and manipulate data at the service implementation. The response data can be returned in delimiter separated value and XML formats, and you can specify an XSD URL to define the input format for the `PUT` and `POST` actions.

15.1.1 URL Services Use Cases and Examples

The REST architecture simplifies web service invocation by representing a web service as an HTTP resource, so that web service methods and operations look like a resources on the server that can be accessed through an HTTP URL.

For example, say a web service has a method called `getEmployee(int EmpID)`. Using the REST architecture, this can become

```
http://mywebservice.com/myService/getEmployee?EmpID=20. When
```

represented as a plain HTTP URL, it is easy to use the URL service data control to quickly create a databound page that accesses this service.

15.1.2 Additional Functionality for URL Services

You may find it helpful to understand other data access features before you start working with URL services. Following are links to other functionality that may be of interest.

- You can design a databound user interface by dragging an item from the Data Controls panel and dropping it on a page as a specific UI component. For more information, see [Section 13.4.1, "How to Use the Data Controls Panel."](#)
- For information about creating data controls for application modules, see [Chapter 13, "Using ADF Model in a Fusion Web Application."](#)
- For information about creating web service data controls, see [Chapter 14, "Exposing Web Services Using the ADF Model Layer."](#)
- For information about other types of data controls, see [Appendix H, "Data Controls in Fusion Web Applications."](#)

15.2 Exposing URL Services with ADF Data Controls

The URL service data control enables you to access and consume the data stream from a specified URL. Each URL service data control represents a single operation of the service. For example, the GET operation and the PUT operation for a given URL service are represented by two different data controls. Typically, all of the actions for a given URL service will share a common URL connection.

15.2.1 How to Create a URL Connection

You use the Create URL Connection dialog to create a URL connection by supplying a name and the connection details required to access a URL endpoint.

Before you begin:

It may be helpful to have an understanding of how URL service data controls are used in ADF applications. For more information, see [Section 15.1, "About Using ADF Model with URL Services."](#)

You may also find it helpful to understand additional functionality that can be added using other URL services features. For more information, see [Section 15.1.2, "Additional Functionality for URL Services."](#)

You must have access to the URL service that the data control will access, and launch JDeveloper.

To create a URL connection:

1. From the main menu, choose **File > New**.
2. In the New Gallery, expand **General**, select **Connections** and then **URL Connection**, and click **OK**.
3. In the Create URL Connection dialog, select where to create the connection.

Select **Application Resources** if you want the URL connection to be available only within the application. Select **Resource Palette** if you want the URL connection to be available from the Resource Palette for use in other applications.

4. Enter a name for the connection.
5. In the **URL Endpoint** field, enter the URL of the desired data stream.
Typically, this includes just the host and port. Do not include any URL parameters (or example, `http://service.example.com:7101/`)
6. Select the level of authentication from the **Authentication Type** dropdown.
None is the default authentication type and disables authentication. Use **Digest** when security is desired. In this way, the password will be transmitted across the network as an MD5 digest of the user's password and cannot be determined by sniffing network traffic. **Basic** authentication is primarily only useful when service access over the network does not require high security.
7. If digest or basic authentication is selected, specify the user name and password required to access the web site.
8. If the URL is associated with a protected area of the overall web site, enter the authentication realm.
9. After you have entered the name and endpoint, you can click Test Connection to verify URL connection is valid.
10. Click **OK** to create the connection.

15.2.2 How to Create a URL Service Data Control

You can create a URL Service data control using the Create URL Service Data Control wizard, which is available from the New Gallery. When you create URL service data controls, you use the wizard to create each operation, one at a time.

Before you begin:

It may be helpful to have an understanding of how URL service data controls are used in ADF applications. For more information, see [Section 15.1, "About Using ADF Model with URL Services."](#)

You may also find it helpful to understand additional functionality that can be added using other URL services features. For more information, see [Section 15.1.2, "Additional Functionality for URL Services."](#)

You must have access to the URL service that the data control will access.

You should have already created the URL connection you will use, as described in [Section 15.2.1, "How to Create a URL Connection."](#)

You must launch JDeveloper, and open the application to which you want to add the URL service data control.

To create a URL service data control:

1. In the Application Navigator, right-click the data model project and choose **New**.
2. In the New Gallery, expand **Business Tier**, select **Data Controls** and then **URL Service Data Control**, and click **OK**.

Note: If you don't see the **URL Service Data Control** item in the New Gallery, click the **All Features** tab.

3. In the Create URL Service Data Control wizard (on the Data Source page), provide a name for the data control.

Because each data control represents a single operation for the URL service, the name should reflect both the service and the operation. For example, you might name the data control for the GET operation of the `EmployeeData` URL service `emp_get`.

4. Select the URL connection for the data control to use.
 - If you have not yet created a URL connection, select **Create New Connection** from the **Connection** dropdown. You will specify the connection details and the action (HTTP method) for this data control on the connection page.
 - If you have already created a URL connection, select the connection you want to use from the **Connection** dropdown.
5. From the HTTP Method dropdown, choose the action for this data control.
6. Enter the source for the URL service (for example, `servicepath/servicename`), and click **Next**.

If this operation requires a parameter, you can use the format `?symbol=##ParamName##` to specify it (for example, `servicepath/servicename?symbol=##id##`). You can also use a parameter to provide dynamic input for the source path (for example, `servicepath/##servicename##?symbol=##id##`).

7. On the Parameters page, supply default values for any parameters you specified, and click **Next**.

For the `PUT` and `POST` operations, you must also provide a URL that points to the XML schema definition that defines the format of the input.
8. On the Data Format page, select the data format of the data source and set the associated properties, then click **Next**.

You can choose either XML format (for which you provide URLs for the XSD and XSL) or delimiter separated value (for which you specify the delimiter, text qualifier, and encoding for the data).
9. On the Finish page, you can click **Test URL Connection** to verify that the URL data connection is valid, and click **Finish**.

15.2.3 What You May Need to Know About URL Service Data Controls

Because the URL Service data control is not updatable, there are limitations on some of the objects in the Data Controls panel. For example, the Create Method object is not available and the only operations available are retrieval and navigation. Also, in a URL Service data control, the parameter object is the parameter that a user passes in the URL. For more information, see [Table 15-1](#).

15.3 Using URL Service Data Controls

As with other kinds of data controls, you can design a databound user interface by dragging an item from the Data Controls panel and dropping it on a page as a specific UI component. For more information, see [Section 13.4.1, "How to Use the Data Controls Panel."](#)

In the Data Controls panel, each data control object is represented by an icon. [Table 15–1](#) describes what each icon represents, where it appears in the Data Controls panel hierarchy, and what components it can be used to create.

Table 15–1 Data Controls Panel Icons and Object Hierarchy for the URL Service Data Control

Icon	Name	Description	Used to Create...
	Data Control	<p>Represents a data control. You cannot use the data control itself to create UI components, but you can use the child objects listed under the data control. There may be more than one data control, each representing a logical grouping of data functions.</p> <p>Typically, there is one data control for a given source. However, you may have additional data controls that were created for other types of objects (for example, application modules or web services).</p>	Serves as a container for the other objects. Not used to create anything.
	Method	<p>Represents a custom method on the data control that may accept parameters, perform some action or business logic, and return data or data collections. If the method is a <code>get</code> method of a <code>map</code> and returns a data collection, a method return icon appears as a child under it. If a method requires a parameter, a folder appears under the method, which lists the required parameters.</p> <p>The URL Service data control exposes only one method <code>loadData()</code> which retrieves the contents of the URL.</p>	UI actions such as buttons or links.
	Method Return	<p>Represents a data collection that is returned by a custom method. A method return appears as a child under the method that returns it. The objects that appear as children under a method return may be attributes of the collection, accessor returns that represent collections related to the parent collection, other methods that perform actions related to the parent collection, and operations that can be performed on the parent collection.</p>	Forms, tables, trees, and range navigation components.
	Accessor Return	<p>Represents an object returned by a bean-style accessor method on the business service. An accessor method is used when the objects returned are JavaBeans. Accessor returns appear as children under method returns, other accessor returns, or in the Attributes node under built-in create methods. Accessor returns are objects that are related to the current object in the parent collection. This relationship is usually based on a common unique attribute in both objects. For example, if a method returns a collection of users, an accessor return that is a child of that collection might be a collection of service requests that are assigned to a particular user. In ADF, the relationship between parent and child collections is called a master-detail relationship. For more information about master-detail objects, see Chapter 29, "Displaying Master-Detail Data."</p> <p>Accessor returns can be either collections or single objects. For example, if a method returns a collection of service requests, one accessor return under that method might be a collection of service history details for the current service request, while another accessor return might be a single user assigned to the current service request. By default, when data controls are created from session beans over POJOs, the names of accessors that return collections end in <code>Collection</code> (for example, <code>OrderCollection</code>). The UI components available from the Data Controls panel context menu differ depending on whether the accessor return is a collection or a single object.</p> <p>The children under an accessor return may be attributes of the collection or object, other accessor returns, custom methods that return a value from the collection or object, and operations that can be performed on the collection or object. The accessor returns under a built-in create method are always a single object and never have any children.</p>	<p>For collections: Forms, tables, trees, range navigation components, and master-detail widgets.</p> <p>For single objects: Forms, master-detail widgets, and selection lists.</p> <p>For single objects under a constructor: selection lists only.</p>

Table 15–1 (Cont.) Data Controls Panel Icons and Object Hierarchy for the URL Service Data Control

Icon	Name	Description	Used to Create...
	Attribute	Represents a discrete data element in an object. Attributes appear as children under method returns or accessor returns.	Label, text field, and selection list components.
	Operation	<p>Represents a built-in data control operation that performs actions on the parent object. If an operation requires a parameter, a folder appears under the method, which lists the required parameters. Data control operations are located in an Operations node under method returns or accessor returns and under the root data control node. The operations that are children of a particular method or accessor return operate on that return object only, while operations under the data control node operate on all the objects represented by the data control.</p> <p>Because the URL Service data control is not updateable, only retrieval and navigation operations are available.</p>	UI actions such as buttons or links.
	Parameter	<p>Represents a parameter value that is declared by the method or operation under which it appears. Parameters appear in a folder under a method or operation.</p> <p>The parameter for a URL Service data control is the parameter that a user passes in the URL. These show up as a parameters to the <code>loadData()</code> method when the URL Service data control is created. For example, say you create a data control to the URL <code>http://www.example.org?id=##param##</code>. On the Data Controls panel, you would see that the <code>loadData()</code> method has one parameter with the name <code>param</code>. The value supplied to this parameter is substituted in the URL when the invocation occurs.</p>	Label, text, and selection list components.

Using Validation in the ADF Model Layer

This chapter explains how to use validation rules in the model layer of your applications.

This chapter contains the following sections:

- [Section 16.1, "About ADF Model Layer Validation"](#)
- [Section 16.2, "Defining Validation Rules in the ADF Model Layer"](#)
- [Section 16.3, "Customizing Error Handling"](#)

16.1 About ADF Model Layer Validation

In the model layer, ADF Model validation rules can be set for a binding's attribute on a particular page. When a user edits or enters data in a field and submits the form, the bound data is validated against any set rules and conditions. If validation fails, the application displays an error message.

Note that you don't need to add additional ADF Model validation if you have already set validation rules in the business domain layer of your entity objects. In an ADF Business Components-based Fusion web application, you won't need to use ADF Model validation unless you use data controls other than your application module data controls.

16.1.1 ADF Model Layer Validation Use Cases and Examples

If your application uses data controls that are not based on ADF Business Components, you can use ADF Model layer validation to ensure the quality of user-entered data.

Best Practice: Use business layer validation whenever possible. However, the following are examples of when you might need to use model layer validation:

- When your business layer does not support declarative validation.
- When you want to validate before an expensive roundtrip begins (for example, for a binding to a web service).
- When you need to validate a form created using parameters (for example, using the `executeWithParams` operation).

You can also use client-side validation for cases where you want to validate before a roundtrip to the server. For more information, see the "Adding Validation" section in the *Oracle Fusion Middleware Web User Interface Developer's Guide for Oracle Application Development Framework*.

Many of the declarative validation features available for ADF Business Components objects are also available at the model layer, should your application warrant the use of model-layer validation in addition to business-layer validation.

16.1.2 Additional Functionality for ADF Model Layer Validation

You may find it helpful to understand other ADF validation features before you use model layer validation. Following are links to other functionality that may be of interest.

- When you use the ADF Business Components application module data control, you do not need to use model-layer validation. Consider defining all or most of your validation rules in the centralized, reusable, and easier to maintain entity objects of your business layer. For more information, see [Chapter 7, "Defining Validation and Business Rules Declaratively."](#)
- Many of the declarative validation features available at the page level are also available at the bean level, which you would implement on the data control structure file. This can be very useful, because validation rules on the data control structure file apply to all usages of the data control. For information about implementing validation rules on the data control structure file, see the "Adding Business Logic to Data Controls" chapter in the *Oracle Fusion Middleware Java EE Developer's Guide for Oracle Application Development Framework*.

16.2 Defining Validation Rules in the ADF Model Layer

You can configure ADF Model validation for a binding's attributes on the page definition file. Validation rules in the model layer are executed for a binding's attribute on a particular page when the containing form is submitted.

You can optionally set the `skipValidation` property to `true` to bypass the ADF Model validation. You can set `skipValidation` to `skipDataControls` to validate the bound objects without validating the transaction. For example, set `skipValidation` to `skipDataControls` if you have a table action that opens a popup window to accept data entries and you want to allow the view layer to validate those entries before the commit on the table. The `skipValidation` property can be found in the Property Inspector after you have selected the root node of the page definition file in the Structure window.

16.2.1 How to Add Validation

You set ADF Model validation on the page definition file. You define the validation rule, and set an error message to display when the rule is broken.

[Table 16–1](#) describes the ADF Model validation rules that you can configure for a binding's attributes.

Table 16–1 ADF Model Validation Rules

Validator Rule Name	Description
Compare	Compares the attribute's value with a literal value
List	Validates whether or not the value is in a list of values
Range	Validates whether or not the value is within a range of values
Length	Validates the value's character or byte size against a size and operand (such as greater than or equal to)

Table 16–1 (Cont.) ADF Model Validation Rules

Validator Rule Name	Description
Regular Expression	Validates the data using Java regular expression syntax
Required	Validates whether or not a value exists for the attribute

Before you begin:

It may be helpful to have an understanding of the use of validation rules in the model layer. For more information, see [Section 16.2, "Defining Validation Rules in the ADF Model Layer."](#)

You may also find it helpful to understand additional functionality that can be added using other validation features. For more information, see [Section 16.1.2, "Additional Functionality for ADF Model Layer Validation."](#)

You will need to complete this task:

- Create a component on the page. The component must have binding attributes.

To create an ADF Model validation rule:

1. Open the page definition that contains the binding for which you want to create a rule.
2. In the Structure window, select the attribute, list, or table binding.
3. In the Property Inspector, select **More** and then **Edit Validation Rule**.
4. In the Edit Validation Rules dialog, expand the binding node, select the attribute name, and click **New**.
5. In the Add Validation Rule dialog, select a validation rule and configure the rule as needed.
6. Select the **Failure Handling** tab and configure the message to display when the rule is broken.

16.2.2 What Happens at Runtime: Model Validation Rules

When a user submits data, as long as the submitted value is a non-null value or a string value of at least one character, then all validators on a component are called one at a time. Because the `f:validator` tag on the component is bound to the `validator` property on the binding, any validation routines set on the model are accessed and executed.

The process then continues to the next component. If all validations are successful, the Update Model Values phase starts and a local value is used to update the model. If any validation fails, the current page is redisplayed along with an error message.

16.3 Customizing Error Handling

You can report errors using a custom error handler that extends the default `DCErrorHandlerImpl` class. You are not required to write any code to register your custom exception handler class. Instead, you select the root node of the `DataBindings.cpx` file in the Structure window, and then use the Property Inspector to set the `ErrorHandlerClass` property to the fully qualified name of the error handler you want it to use.

Your custom error handler can contain the following overridable methods:

- `reportException()`: Called to report any exception that occurs. It can be overridden to analyze reported exceptions.
- `getDisplayMessage()`: Returns the message that will be reported to JSF for each error that occurs. Returning `null` is the way your custom error handler signals that a given exception should not be reported to the client.
- `getDetailedDisplayMessage()`: Returns the detail portion of the message as a `String` object or `HTML` that will be reported to JSF for each error that occurs. Returning `null` is the way your custom error handler signals that a given exception should not be reported to the client.

[Example 16–1](#) illustrates a custom error handler that extends the `DCErrorHandlerImpl` class.

Example 16–1 Custom Error Handler

```
package view.controller.fwkext;
import java.util.ArrayList;
import java.util.List;
import oracle.adf.model.binding.DCBindingContainer;
import oracle.adf.model.binding.DCErrorHandlerImpl;
import oracle.jbo.CSMessagesBundle;
import oracle.jbo.DMLConstraintException;
import oracle.jbo.JboException;
public class CustomErrorHandler extends DCErrorHandlerImpl {
    List<ExceptionMapper> exceptionMapperList = new
    ArrayList<ExceptionMapper>();
    public CustomErrorHandler() {
        this(true);
    }
    public CustomErrorHandler(boolean setToThrow) {
        super(setToThrow);
        exceptionMapperList.add(new DisableJboExceptionCodesMapper());
    }
    public void reportException(DCBindingContainer bc, Exception ex) {
        for (ExceptionMapper mapper : exceptionMapperList) {
            if (mapper.canMapException(ex)) {
                ex = mapper.mapException(ex);
            }
        }
        super.reportException(bc, ex);
    }
}
```

You must change the constructor to `MyErrorHandler()`. The exception error handler must have a default constructor, as shown in [Example 16–2](#).

Example 16–2 Default Constructor

```
ErrorHandlerClass="viewcontroller.MyErrorHandler"
public MyErrorHandler()
{
    super(true);
}
```

16.3.1 How to Customize the Detail Portion of a Message

If you plan to customize and use the detail portion of a message, you can create a custom error handler and implement the `getDetailedDisplayMessage` method to

retrieve and process that message. The finalized message will be passed to the view layer to be integrated with other messages.

To customize the detail portion of a message:

1. Create a custom error handler class that extends the default `DCErrHandlerImpl` class.
2. In that class, override the `getDetailedDisplayMessage` method that returns a `DCErrMessage` object.

[Example 16-3](#) shows an implementation of the `getDetailedDisplayMessage` method in the custom error handler class.

Example 16-3 Custom Error Handler Class with `getDetailDisplayMessage` Method

```
public final class MyErrorMessageHandler extends DCErrHandlerImpl {
    public MyErrorMessageHandler () {
        super(false);
    }
    public DCErrMessage getDetailedDisplayMessage(BindingContext ctx,
                                                RegionBinding ctr,
                                                Exception ex) {
        ...
        return new MyDCErrMessage(ctr, ex);
    }
}
```

3. Create a custom class that implements the `DCErrMessage` interface. The class must implement the `getHTMLText` method and the `getText` method.

You will add code to the `getHTMLText` method to perform the actual processing, but you must also implement `getText` to satisfy the interface requirements.

4. In the `getHTMLText` implementation, add code to create and process the error message.

`getHTMLText` of `getDetailedDisplayMessage` should return the finalized version of the error message as an HTML fragment that will be inserted into the HTML code of the page. For this reason, you should perform all necessary preprocessing on the text message before the message is returned by `getDetailedDisplayMessage`. For instance, you may want to retrieve the localized version of the message or change the right-to-left ordering of the message before it is returned.

[Example 16-4](#) shows an implementation of this interface.

Example 16-4 Implementing the `DCErrMessage` Interface

```
public final class MyDCErrMessage implements DCErrMessage {
    RegionBinding m_regionBinding;
    Exception m_ex;
    public MyDCErrMessage(RegionBinding ctr, Exception ex) {
        super();
        this.m_regionBinding = ctr;
        this.m_ex = ex;
    }
    public String getText() {
        ...
        return "Message String";
    }
    public String getHTMLText() {
```

```
...
/* Add code to process the message, including localization */
/* and right-to-left directional requirements. */
/* Return the message as the finalized HTML fragment.*/
return "<b>error</b> message details";
    }
}
```

16.3.2 How to Write an Error Handler to Deal with Multiple Threads

Oracle ADF constructs an instance of the custom error handler for each `BindingContext` object that is created. Because Oracle ADF serializes simultaneous web requests from the same logical end-user session, multiple threads generally will not use the same error handler at the same time. However, to guarantee a thread-safe custom error handler, use the `setProperty()` API on `JboException`. This method stores in the exception objects themselves any hints you might need later during the phase when exceptions are translated to JSF `FacesMessage` objects for display.

Designing a Page Using Placeholder Data Controls

This chapter describes how to create and use placeholder data controls. It shows you how to create placeholder data types, including master-detail relationships. It also describes how to create and import sample data.

This chapter includes the following sections:

- [Section 17.1, "About Placeholder Data Controls"](#)
- [Section 17.2, "Creating Placeholder Data Controls"](#)
- [Section 17.3, "Creating Placeholder Data Types"](#)
- [Section 17.4, "Using Placeholder Data Controls"](#)

17.1 About Placeholder Data Controls

Application development is typically divided into two separate processes: technical implementation and user interface design. More often than not, they are undertaken by separate teams with very different skill sets. The two teams can work together either in a *data-first* approach or a *UI-first* approach, or with some overlap between the two. With either approach, the teams usually work together iteratively, refining the application with each cycle.

In a data-first approach, the model, or data control is built first. Then the designer creates the layout and page flow by dragging and dropping the data controls onto pages as UI components. The model data is automatically bound to the components. This approach requires the data model to be available before the designer can proceed.

In a UI-first approach, the designer creates the layout using components from the Component Palette. When the data controls do become available, UI components are then bound to them. With this approach, you should be able to see most of the layout and page flows to make a development evaluation. However, until the data controls are available and bound to components, the application may not fully convey the intent of its design. For instance, an application that has a master-detail relationship is best reviewed when there is actual data that dynamically drives that relationship.

Placeholder data controls are easy-to-create, yet fully functional, stand-in data controls that can efficiently speed up the design-development process. UI designers can use placeholder data controls to create page layouts and page flows without the need to have real data controls available. These placeholder controls can be loaded with sample data to realistically simulate application execution for design evaluations. When the real data controls are ready, the UI components can be easily rebound to complete the application.

Creating placeholder data controls is a purely declarative process and does not require coding. It does not require in-depth knowledge of the underlying model, data source technology, actual database schema, or any of the complex relationships in an actual production data control. Placeholder data controls do not require an existing data source or a database connection. You can define multiple data types with multiple attributes. You can also define nested master-detail hierarchies between data types. Placeholder data controls have the same built-in operations such as Execute, Next, and Create. An implicitly created named criteria item allows the user to create search forms as if view objects and view criteria were available.

17.1.1 Placeholder Data Controls Use Cases and Examples

For many complex applications, the UI design may actually drive the development of the model, or data source. In this UI-first scenario, having placeholder data controls with sample data is essential to properly model the behavior of the application. In some cases, even if production data controls are available, UI designers may opt to use placeholder data controls because of their flexibility and ease of use.

Placeholder data controls can be used in many situations. In addition to being used for design review and development, they can be used to develop realistic runtime mock-ups for usability studies, or for proof-of-concept requirements. They can be used to create demos when the data model is not yet ready.

17.1.2 Additional Functionality for Placeholder Data Controls

You may find it helpful to understand some data access features before you start working with placeholder data controls. Following are links to other functionality that may be of interest.

- After your initial design with placeholder data controls, when the final data controls are available, you can simply rebind the components. For more information about rebinding components, see [Chapter 26, "Creating a Basic Databound Page"](#) and [Chapter 27, "Creating ADF Databound Tables."](#)
- A placeholder data type attribute can be configured to be a list of values (LOV). For more information about LOVs, see [Section 5.12, "Working with List of Values \(LOV\) in View Object Attributes."](#)
- You can create master-detail relationships between placeholder data types, similar to the master-detail data collections in a standard data control. For more information on master-detail forms and tables, see [Chapter 29, "Displaying Master-Detail Data."](#)
- When you define placeholder data types in a master-detail hierarchy, JDeveloper creates view links that define that relationship. For more information about view links, see [Section 5.6, "Working with Multiple Tables in a Master-Detail Hierarchy."](#)
- Placeholder data controls can be used for the development of search forms. For more information about query search forms, see [Chapter 31, "Creating ADF Databound Search Forms."](#)
- You might want to package placeholder data controls into reusable components as ADF Library JARs. For more information about reusable components and the ADF Library, see [Chapter 38, "Reusing Application Components."](#)

17.2 Creating Placeholder Data Controls

You add placeholder data controls to a project using the New Gallery. After the placeholder data control has been created, it appears as a node in the Data Controls panel. It has a different icon than do standard data controls. Instead of an Operations node, the placeholder data control has a Built-in Operations node. Although the Built-in Operations node contains Commit and Rollback operations, these operations do not perform commits or rollbacks because there is not an actual data source for the data.

When a data control is initially created, it does not have any data types associated with it. You will need to manually create the data types as described in [Section 17.3, "Creating Placeholder Data Types."](#)

17.2.1 How to Create a Placeholder Data Control

Placeholder data controls are defined at the project level in JDeveloper. You must already have created a project before you can create placeholder data controls.

Before you begin:

It may be helpful to have an understanding of the options you have for creating placeholder data controls. For more information, see [Section 17.2, "Creating Placeholder Data Controls."](#)

You may also find it helpful to understand additional functionality that can be added after using placeholder data controls. For more information, see [Section 17.1.2, "Additional Functionality for Placeholder Data Controls."](#)

To create a placeholder data control:

1. In the Application Navigator, right-click the project and choose **New**.
2. In the New Gallery, expand **Business Tier**, select **Data Controls** and then **Placeholder Data Control**, and click **OK**.
3. In the Placeholder Data Control dialog, as shown in [Figure 17–1](#), enter:
 - **Placeholder Name:** The name of the placeholder data control.
 - **Directory Name:** The package name that will be used to reference the placeholder data control.
 - **Description:** Optional description of the placeholder data control.

Figure 17–1 New Placeholder Data Control

4. Click **OK**.

17.2.2 What Happens When You Create a Placeholder Data Control

When you create a placeholder data control, the package you selected to contain the data control appears under the project node in the Application Navigator. A data control XML file *PlaceholderDataControl.xml* appears under the package, where *PlaceholderDataControl* is the name of the placeholder data control.

[Example 17-1](#) shows a sample file called *StoreFrontPlaceHolder.xml*, which was created when the *StoreFrontPlaceHolder* data control was created.

Example 17-1 Sample placeholderdatacontrol.xml

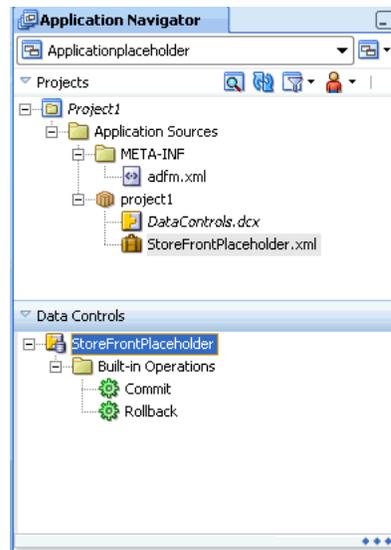

```
<?xml version='1.0' encoding='windows-1252' ?>
<AppModule
  xmlns="http://xmlns.oracle.com/placeholder"
  Name="StoreFrontPlaceholder" >
</AppModule>
```

JDeveloper also creates a *DataControls.dcx* file if it has not yet been defined, and adds entries for the placeholder data control, as shown in [Example 17-2](#).

Example 17-2 Placeholder Data Control entry in DataControls.dcx

```
<?xml version="1.0" encoding="UTF-8" ?>
<DataControlConfigs xmlns="http://xmlns.oracle.com/adfm/configuration"
  version="11.1.1.44.30" id="DataControls"
  Package="storefront">
  <PlaceholderDataControl SupportsTransactions="true" SupportsFindMode="true"
    SupportsResetState="true" SupportsRangesize="true"
    SupportsSortCollection="true"
    FactoryClass=
      "oracle.adf.model.placeholder.DataControlFactoryImpl"
    id="StoreFrontPlaceholder"
    xmlns="http://xmlns.oracle.com/adfm/datacontrol"
    Definition="storefront.StoreFrontPlaceholder"
    Package="storefront"/>
</DataControlConfigs>
```

In the Data Controls panel, the placeholder data control appears alongside other data controls in the root tree. A placeholder data control that does not yet have data types defined will have only the Commit and Rollback built-in operations available, as shown in [Figure 17-2](#).

Figure 17–2 Application Navigator and Data Controls Panel

17.3 Creating Placeholder Data Types

A standard data control obtains its data collections and attributes from its underlying data source in the model or business service layer. For example, an application module data control obtains its data collections from the view objects and associated database tables.

For a placeholder data control, instead of data collections, it has placeholder data types. A *placeholder data type* is analogous to a data collection. It can be dropped onto a page to create complex components such as forms, tables, and trees. It also has a set of attributes that can be dropped onto pages as individual components such as input text, output text, and select choice. Some attributes may be defined as LOVs.

When you first create a placeholder data control, it is devoid of any data types because there are no underlying database tables for the placeholder data control to reference. You must declaratively create one or more placeholder data types. For each data type, you specify attribute names, types, default UI components, and other options. You can create multiple data types for a data control, similar to the multiple data collections in an application module.

After you have created a placeholder data type, it appears as a child node of the placeholder data control. It also has a Built-in operations node with the standard set of operations. It has a Named Criteria node that contains an All Queriable Attributes item that is analogous to the named view criteria of a view object in a standard data control. You can drag and drop the All Queriable Attributes item onto a page to create a query or quick query search form. In a standard data control, you can create multiple view criteria on a view object. Because there is no real view object in a placeholder data type, only one All Queriable Attributes item is available. For more information about query search forms, see [Chapter 31, "Creating ADF Databound Search Forms."](#)

You can create master-detail relationships between placeholder data types, similar to the master-detail data collections in a standard data control. You can drop master-detail data types onto pages to create master-detail forms and tables. For more information on master-detail forms and tables, see [Chapter 29, "Displaying Master-Detail Data."](#)

JDeveloper allows you to reuse placeholder data types created for other placeholder data controls in the same project. When you are creating a data type, you can select an option to load existing data types from another placeholder data control. If you select the **Copy Data Type** option, the attributes from the imported data type will be added to the list of existing attributes.

You can also select an option to copy the sample data associated with the imported data type when the attributes are added.

Note: Although you do not need sample data until you run the application, you should add sample data to provide a consistent design time rendering of the components.

17.3.1 How to Create a Placeholder Data Type

After you have created a placeholder data control, you can proceed to create data types. You define a name for the data type, and define each of its individual attributes. For each attribute, you then define its type, format, default UI component, and whether it should be an LOV.

In order to simplify the process of creating placeholder data types, you can select from a list of four of the most common types: *String*, *Boolean*, *Date*, and *Number*. Because placeholder attributes are typed, you can create column labels and include UI control hints in the design.

If you have a sample data file in comma-separated value or CSV format, you can automatically create all the attributes and load sample data using the sample data file import function. You do not need to create the attributes. JDeveloper will automatically create them for you from the format of the CSV file, which should be a comma-separated value list of column headings. The attributes default to type *String*. You can manually reset each attribute to another type as required. For instructions to import sample data, see [Section 17.3.6, "How to Add Sample Data."](#)

Before you begin:

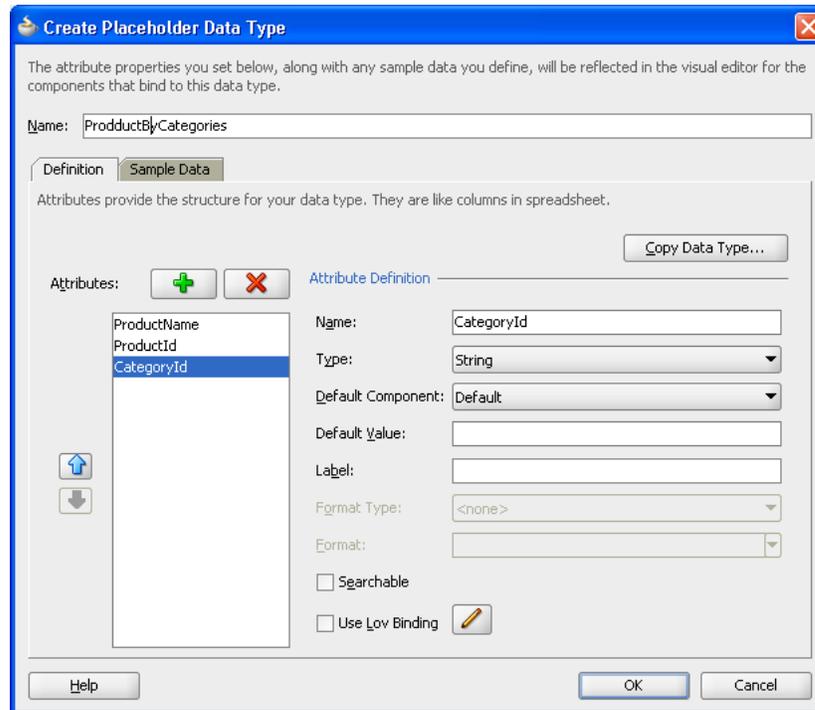

It may be helpful to have an understanding of the options you have for creating placeholder data types. For more information, see [Section 17.3, "Creating Placeholder Data Types."](#)

You may also find it helpful to understand additional functionality that can be added after using placeholder data controls. For more information, see [Section 17.1.2, "Additional Functionality for Placeholder Data Controls."](#)

To create a placeholder data type manually:

1. In the Data Controls panel, right-click the placeholder data control and choose **Create Placeholder Data Type**.

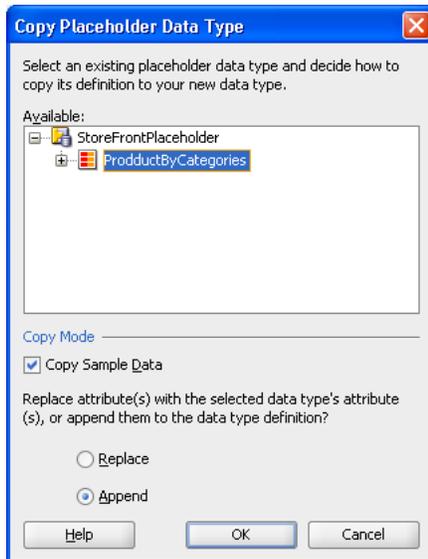

[Figure 17-3](#) shows the Create Placeholder Data Type dialog.

Figure 17-3 Create Placeholder Data Type Dialog

Note: If you had already added placeholder data types previously and want only to add or edit them, choose **Edit Placeholder Data Type** from the context menu instead. The dialog that appears will be the Edit Placeholder Data Type dialog. It has the same options as the Create Placeholder Data Type dialog.

2. If you already have data types defined for another placeholder data control, and you want to copy or append them, click **Copy Data Type**.
 - a. In the Copy Placeholder Data Type dialog, as shown in [Figure 17-4](#), select the placeholder data type you want. Select **Replace** to replace the current attributes with the attributes from the file, or select **Append** to add the attributes from the file to the list of current attributes.
 - b. Select the **Copy Sample Data** checkbox to load sample data from the file.
 - c. Click **OK**.

Figure 17–4 Copy Placeholder Data Type

3. In the Create Placeholder Data Type dialog, enter a name for the placeholder data type, and then in the **Attributes Definition** section, enter:

- **Name:** Enter a name for the attribute.
- **Type:** Select a type for the attribute from the dropdown list. The supported types are *String*, *Boolean*, *Date*, and *Number*.
- **Default Component:** Select a default component for the attribute from the dropdown list. For an LOV, select **Combo Box List of Values**.
- **Default Value:** Enter the initial value for the attribute.
- **Label:** Enter a label for the attribute. The label will be used when the component is displayed.
- **Format Type:** This field is enabled only when the type is *Date* or *Number*. Select a format type from the dropdown list.
- **Format:** This field is enabled only when a format mask has been defined for that format type.
- **Searchable:** Select this checkbox to make the attribute searchable.
- **Use Lov Binding:** Select this checkbox if you want the attribute to be an LOV. To configure the attribute, see [Section 17.3.3, "How to Configure a Placeholder Data Type Attribute to Be an LOV."](#)

Click the **Add** icon to add more attributes.

4. To add data, use the **Sample Data** tab. For that procedure, see [Section 17.3.6, "How to Add Sample Data."](#)

You need sample data for runtime and for a consistent design time.

5. Click **OK**.

17.3.2 What Happens When You Create a Placeholder Data Type

When you create a placeholder data type, JDeveloper creates a *PlaceholderDataType.xml* file, where *PlaceholderDataType* is the name of the placeholder data type you had specified.

The *PlaceholderDataType.xml* file has the same format as a view object XML file. It includes the name of the view object and the name and values of each placeholder attribute that was defined.

[Example 17-3](#) shows a *PlaceholderDataType.xml* for the Supplier data type. Two attributes were declarative defined: *Supplier_Id* and *Supplier_Name*.

Example 17-3 Sample Placeholder Data Type Suppliers.xml file

```
<?xml version='1.0' encoding='windows-1252' ?>
<ViewObject
  xmlns="http://xmlns.oracle.com/placeholder"
  Name="Suppliers"
  BindingStyle="OracleName"
  CustomQuery="true"
  ComponentClass="oracle.adf.model.placeholder.PlaceholderVOImpl"
  UseGlueCode="false" >
  <ViewAttribute
    Name="Supplier_Id"
    Type="oracle.jbo.domain.Number"
    PrimaryKey="true" >
  </ViewAttribute>
  <ViewAttribute
    Name="Supplier_Name"
    Type="java.lang.String" >
  </ViewAttribute>
  <StaticList
    Name="Suppliers"
    Rows="2"
    Columns="2" >
  </StaticList>
  <ResourceBundle >
    <PropertiesBundle
      xmlns="http://xmlns.oracle.com/bc4j"
      PropertiesFile="storefrontproject.StoreFrontProjectBundle" >
    </PropertiesBundle>
  </ResourceBundle>
</ViewObject>
```

Since a data type is similar to a data collection and is based on a view object, each data type will have a corresponding *PlaceholderDataType.xml* file.

JDeveloper also adds entries for each placeholder data type to the *PlaceholderDataControl.xml* file. For example, after the Suppliers data type has been created, the *StoreFrontPlaceholder.xml* file includes a new *ViewUsage* entry for the Suppliers data type, as shown in [Example 17-4](#).

Example 17-4 Sample PlaceholderDataControl.xml File After Addition of Placeholder Data Type

```
<?xml version='1.0' encoding='windows-1252' ?>
<AppModule
  xmlns="http://xmlns.oracle.com/placeholder"
```

```

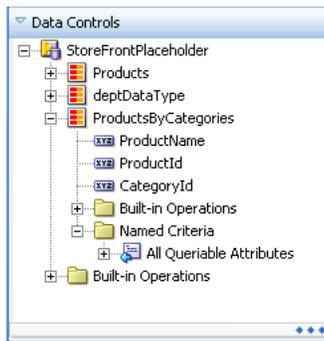

Name="StoreFrontPlaceholder" >
  <ViewUsage
    Name="Suppliers"
    ViewObjectName="storefrontproject.Suppliers" >
  </ViewUsage>
</AppModule>

```

In the Data Controls panel, a placeholder data type node appears under the placeholder data control. Expanding the node reveals the presence of each of the attributes, the Built-in Operations node, and the Named Criteria node.

Figure 17–5 shows a placeholder data control as it appears in the Data Controls panel.

Figure 17–5 Data Controls Panel Showing Placeholder Data Control

17.3.3 How to Configure a Placeholder Data Type Attribute to Be an LOV

A placeholder data type attribute can be configured to be a list of values (LOV). An LOV-formatted attribute binds to UI components that display dropdown lists or list picker dialogs. For more information about LOVs, see [Section 5.12, "Working with List of Values \(LOV\) in View Object Attributes."](#)

When you are creating a placeholder data type, you can select an option to bring up a dialog to configure that attribute to be an LOV.

If you have only one data source, you can only create a fixed LOV. To create a dynamic LOV, there must be more than one placeholder data type available to be the source.

17.3.3.1 Configuring an Attribute to Be a Fixed LOV

Before you begin, you should determine which attribute you want to be a fixed LOV and which values should be in the fixed list.

Before you begin:

It may be helpful to have an understanding of the options you have for creating placeholder data types. For more information, see [Section 17.3, "Creating Placeholder Data Types."](#)

You may also find it helpful to understand additional functionality that can be added after using placeholder data controls. For more information, see [Section 17.1.2, "Additional Functionality for Placeholder Data Controls."](#)

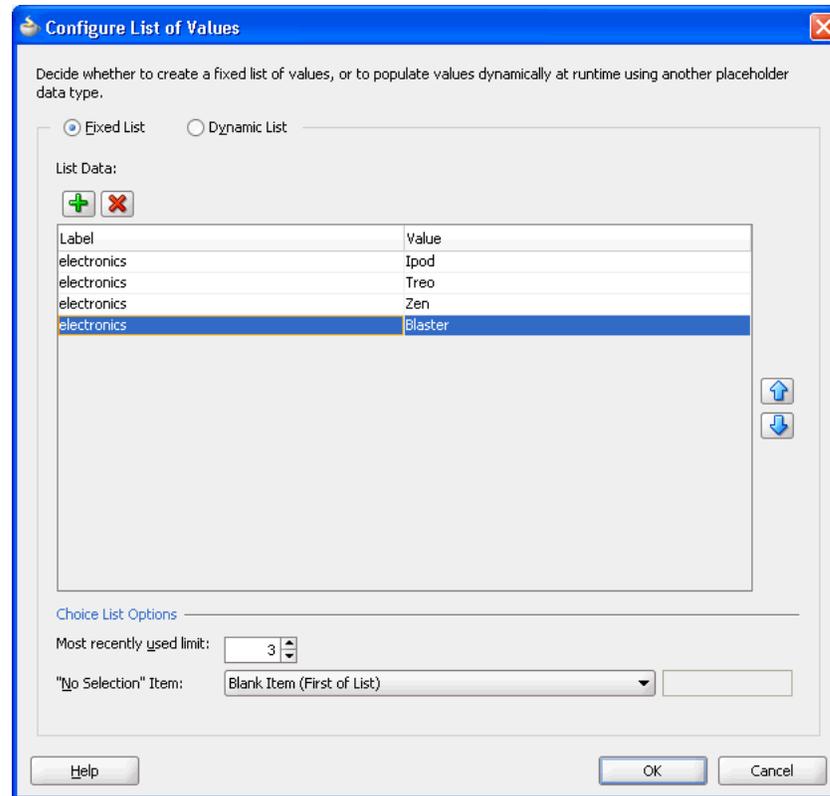

To configure an attribute to be a fixed LOV:

1. In the Data Controls panel, right-click the placeholder data control and choose **Create Placeholder Data Type** or **Edit Placeholder Data Type**.

- In the Create Placeholder Data type or Edit Placeholder Datatype dialog, select the **Use Lov Binding** checkbox.

The Configure List of Values dialog appears, as shown in [Figure 17–6](#).

Figure 17–6 *Configure List of Values Dialog for a Fixed LOV*

- In the dialog, select **Fixed List**.
- Click the **Add** icon to enable adding an entry to the list of values.
- For each entry, enter a label and a value.
When the user selects an item from the list of values, the value entry will be entered into the input field.
- Select the maximum number of the most recently used items that will be displayed in the dropdown list.
- From the **No Selection Item** dropdown list, select an option for how you want the "no selection" item to be displayed.
For instance, selecting **Blank Item (First of List)** will display the "no selection" item as a blank at the beginning of the list.
- Click **OK**.

17.3.3.2 Configuring an Attribute to Be a Dynamic LOV

Using a placeholder data type to serve as the source, you can configure an attribute to be a dynamic LOV.

Before you begin:

It may be helpful to have an understanding of the options you have for creating placeholder data types. For more information, see [Section 17.3, "Creating Placeholder Data Types."](#)

You may also find it helpful to understand additional functionality that can be added after using placeholder data controls. For more information, see [Section 17.1.2, "Additional Functionality for Placeholder Data Controls."](#)

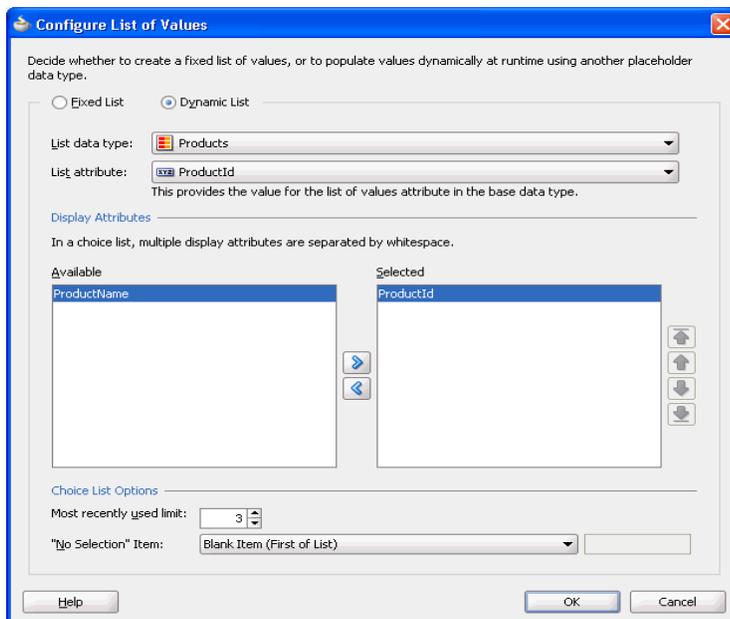

Also, you should have already created another placeholder data type to serve as the source of the dynamic LOV.

To configure an attribute to be a dynamic LOV:

1. In the Data Controls panel, right-click the placeholder data control and choose **Create Placeholder Data Type** or **Edit Placeholder Data Type**.
2. In the Create Placeholder Data type or Edit Placeholder Data type dialog, select the **Use Lov Binding** checkbox.

The Configure List of Values dialog appears, as shown in [Figure 17-7](#).

Figure 17-7 Configure List of Values Dialog for a Dynamic LOV

3. In the dialog, select **Dynamic List**.
4. Select the list data type with the source attribute. You must have a source placeholder data type for this selection to be available.
5. Select the list attribute.
6. Shuttle the attribute from the **Available** list to the **Selected** list.
7. Select the maximum number of the most recently used items that will be displayed in the dropdown list.
8. From the **No Selection Item** dropdown list, select an option for how you want the "no selection" item to be displayed. For instance, selecting **Blank Item (First of List)** will display the "no selection" item as a blank at the beginning of the list.

9. Click OK.

17.3.4 How to Create Master-Detail Data Types

You create master-detail relationships between data types in the same way you create master-detail hierarchies between tables. In a standard data control, you can use view links to define source and target view objects that would become the master and the detail objects. For more information about master-detail relationships, see [Chapter 29, "Displaying Master-Detail Data."](#)

You first create a master data type and its attributes. Then you create a detail data type as a child of the master data type. You define the source attribute in the master data type that defines the relationship to the detail data type.

Before you begin:

It may be helpful to have an understanding of the options you have for creating placeholder data types. For more information, see [Section 17.3, "Creating Placeholder Data Types."](#)

You may also find it helpful to understand additional functionality that can be added after using placeholder data controls. For more information, see [Section 17.1.2, "Additional Functionality for Placeholder Data Controls."](#)

Before you create a master-detail hierarchy, you must determine the data structure of the master data type and the data structure of the detail data type. You must also determine which attribute in the master will be the source for the detail data type.

To create master-detail hierarchical data types:

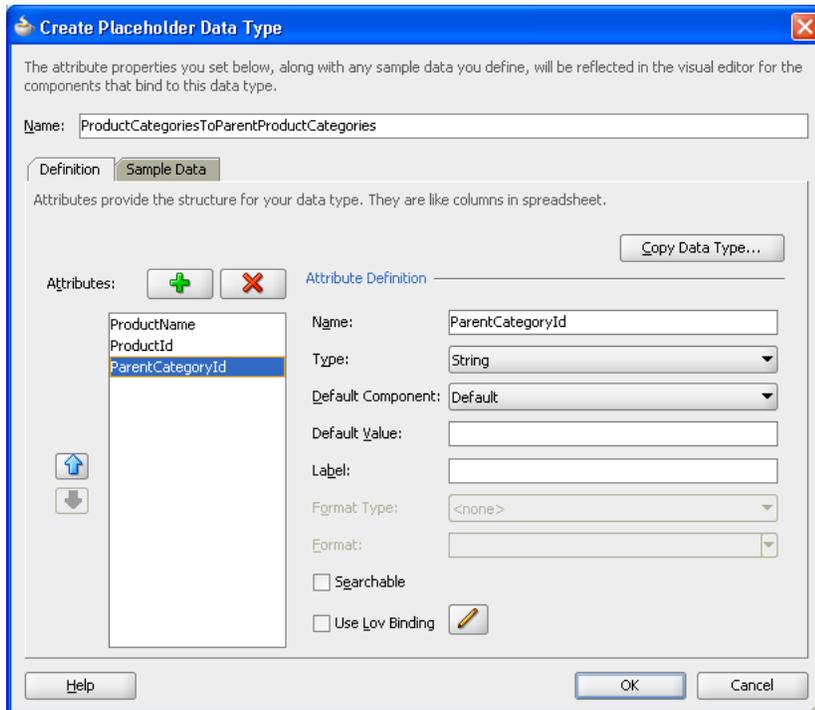

1. Create a placeholder data type to be the master as described in [Section 17.3.1, "How to Create a Placeholder Data Type,"](#) or select an existing data type to be the master.

For example, you could use the `ProductsByCategories` data type as the master.

2. In the Data Controls panel, right-click the master placeholder data type and choose **Create Placeholder Data Type**.

[Figure 17–8](#) shows the Create Placeholder Data Type dialog for entering detail data type attributes.

Figure 17–8 Create Placeholder Data Type Dialog

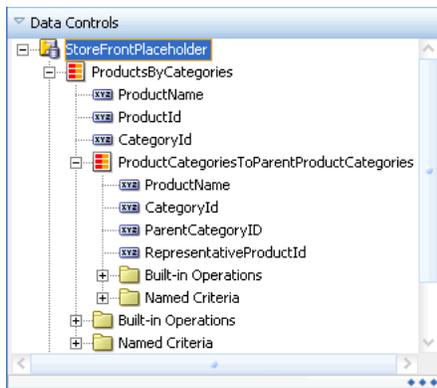

3. In the Create Placeholder Data Type dialog, enter a name for the detail data type.
4. The first attribute in the master data type appears in the **Attributes** section. This attribute provides the foreign key relationship.

Add attributes for the detail data type, copy data type attributes from another data type, or create attributes automatically by importing sample data from a CSV file. For the procedure to add attributes, see [Section 17.3.1, "How to Create a Placeholder Data Type."](#)

5. Click **OK**.

The Data Controls panel should display the detail data type as a child of the master data type, as shown in [Figure 17–9](#).

Figure 17–9 Master Detail Hierarchy in Placeholder Data Control

17.3.5 What Happens When You Create a Master-Detail Data Type

A master-detail relationship is implemented in the same way as is a standard master-detail relationship, using view object and view links. When you define placeholder data types in a master-detail hierarchy, JDeveloper creates a `DTLink.xml` file that contains metadata entries for view links that define that relationship. For more information about view links, see [Section 5.6, "Working with Multiple Tables in a Master-Detail Hierarchy."](#) For example, in the relationship between the master data type `Video` and the detail data type `Brand` associated with a key `dvdpayer`, JDeveloper creates a `DTLink.xml` file in the form of a view link file to define that relationship, as shown in [Example 17-5](#).

Example 17-5 `DTLink.xml` file for Master-Detail Data Type Relationships

```
<?xml version='1.0' encoding='windows-1252' ?>
<ViewLink
  xmlns="http://xmlns.oracle.com/placeholder"
  Name="DTLink" >
  <ViewLinkDefEnd
    Name="sourceEnd"
    Cardinality="1"
    Owner="project1.ProductsByCategories"
    Source="true" >
    <AttrArray Name="Attributes">
      <Item Value="project1.ProductsByCategories.ProductName" />
    </AttrArray>
  </ViewLinkDefEnd>
  <ViewLinkDefEnd
    Name="destEnd"
    Cardinality="-1"
    Owner="project1.ProductCategoriesToParentProductCategories" >
    <AttrArray Name="Attributes">
      <Item
Value="project1.ProductCategoriesToParentProductCategories.ProductName" />
    </AttrArray>
  </ViewLinkDefEnd>
</ViewLink>
```

17.3.6 How to Add Sample Data

If you intend to run an application using the placeholder data control, you will need to add sample data for execution. You can add sample data to the placeholder data type attributes manually or by importing the data from a CSV file. Although having sample data is mandatory only at runtime, you should add sample data for a consistent design time rendering of the components.

Before you begin to add sample data to a placeholder data type, you should have already created a placeholder data control and a placeholder data type. If you are entering the data manually, you should have the data ready. If you are loading the data from a CSV file, you need to have the location of the file.

17.3.6.1 Adding Sample Data Manually

You can use the Sample Data page of the Edit Placeholder Data Type dialog to manually enter sample data for your placeholder data control.

Before you begin:

It may be helpful to have an understanding of the options you have for creating placeholder data types. For more information, see [Section 17.3, "Creating Placeholder Data Types."](#)

You may also find it helpful to understand additional functionality that can be added after using placeholder data controls. For more information, see [Section 17.1.2, "Additional Functionality for Placeholder Data Controls."](#)

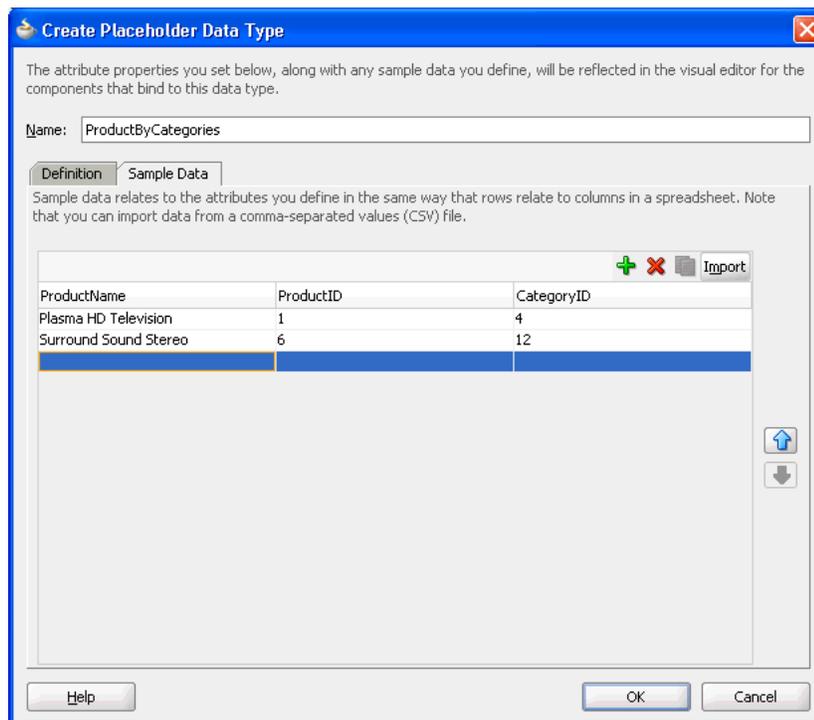

Also, you should have already prepared the sample data.

To add sample data to placeholder data types manually:

1. In the Data Controls panel, right-click the placeholder data control and choose **Create Placeholder Data Type** or **Edit Placeholder Data Type**.
2. In the Create Placeholder Data Type or Edit Placeholder Data Type dialog, click the **Sample Data** tab.
3. For each row of data, enter a value for each attribute that was defined. Click the **Add** icon to create each row.

For example, in [Figure 17–10](#), for the first row, Plasma HD Television was entered for the ProductName attribute, 1 was entered for the ProductID attribute, and 4 was entered for the CategoryID attribute.

Figure 17–10 Adding Sample Data

4. Click **OK**.

17.3.6.2 Importing Sample Data

You can use the Sample Data page of the Edit Placeholder Data Type dialog to import sample data for your placeholder data control from a file.

Before you begin:

It may be helpful to have an understanding of the options you have for creating placeholder data types. For more information, see [Section 17.3, "Creating Placeholder Data Types."](#)

You may also find it helpful to understand additional functionality that can be added after using placeholder data controls. For more information, see [Section 17.1.2, "Additional Functionality for Placeholder Data Controls."](#)

Additionally, you should have the sample data file available on your file system so it can be found in the Select File dialog.

To import sample data from CSV files into placeholder data types:

1. In the Data Controls panel, right-click the placeholder data control and choose **Create Placeholder Data Type** or **Edit Placeholder Data Type**.
2. In the Create Placeholder Datatype or Edit Placeholder Datatype dialog, click the **Sample Data** tab.

Tip: If you already have a CSV file for importing, you do not need to manually create the attributes for each column. JDeveloper automatically creates the attributes from the first row of the CSV file. For more information, see [Section 17.3.1, "How to Create a Placeholder Data Type."](#)

3. If you are also importing attributes, you must delete the default "attribute" in the first row.

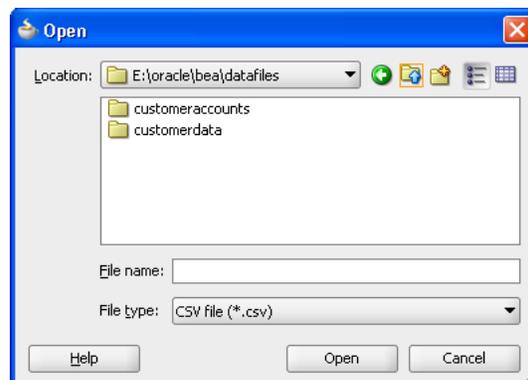

This default attribute appears when you first navigate to the **Sample Data** tab. If you do not remove this default attribute, JDeveloper will assume that this is a declaratively created attribute and will not import any other columns except for the first column.

4. Click **Import**.

In the Open dialog, navigate to and select the import file, and click **Open**, as shown in [Figure 17–11](#).

The data from the CSV file, including column heading and values, should appear as sample data.

Figure 17–11 *Importing Placeholder Sample Data*

5. Click **OK**.

17.3.7 What Happens When You Add Sample Data

Placeholder sample data, whether manually added using the dialog or from an imported CSV file, is stored in message bundle properties files within the placeholder data control packages. JDeveloper creates a text-based file for each data type that has sample data. The properties file name is `placeholderdatatypenameMsgBundle.properties`. [Example 17-6](#) shows a sample data properties file for the Televisions data type that has three attributes of brand, size, and type.

Example 17-6 Sample Data Properties File `TelevisionMsgBundle.properties`

```
SL_0_0=sony
SL_0_1=42
SL_0_2=lcd
SL_1_0=panasonic
SL_1_1=50
SL_1_2=plasma
SL_2_0=mitsubishi
SL_2_1=60
SL_2_2=projection
```

17.4 Using Placeholder Data Controls

You use placeholder data controls in the same way you would use standard data controls. You can drag data types onto pages and use the context menus to drop the data types as forms, tables, trees, graphs, and other components. You can drop individual attributes onto pages as text, lists of values, single selections, and other components. You can use any of the built-in operations such as Create, Execute, and Next by dropping them as buttons, command links, and menu items.

You can work in several ways to take advantage of placeholder data controls:

- Build a page using the placeholder data controls and rebind to real data controls later.
- Build a page using components, bind them to placeholder data controls, and rebind to real data controls later.
- Build a page using some combination of components from the Component Palette, components from the placeholder data controls, and then bind or rebind to the real data controls later.

17.4.1 Limitations of Placeholder Data Controls

You can use placeholder data controls in your application development in many situations. For most UI design evaluations, placeholder data controls should be able to fully substitute for real data controls.

There are a few limitations:

- Because data types are not tied to an underlying data source, the Commit and Rollback operations do not perform real transactions, nor do they update the cache.
- Placeholder data controls can only be created declaratively. You cannot create custom methods like you can with a real application module or data control.

- Placeholder data controls cannot be used when there is a need either for custom data or for filtering or custom code to fetch data. Placeholder data controls will disable those operations.

17.4.2 Creating Layout

Use the drag-and-drop feature to create the page using the placeholder data controls, any available real data controls, and components from the Component Palette. If you intend to run a page or application that requires real data, enter sample data for your placeholder data types. If you have a large amount of sample data, you may be able to create CSV files from the data source and load them into the data type. You may also use spreadsheets and other tools to create CSV sample data files.

17.4.3 Creating a Search Form

In a standard data control, you can create view criteria on view objects to modify the query. These view criteria are also used for drag-and-drop creation of query and quick query search forms. The named view criteria items appear under the Named Criteria node for a data collection. For more information about query and quick query search forms, see [Chapter 31, "Creating ADF Databound Search Forms."](#)

For placeholder data controls, there is also a Named Criteria node under each data type node. An automatically created All Queriable Attributes item appears under this node and can be used to drag and drop onto pages to create the query or quick query search forms.

17.4.4 Binding Components

Instead of building the page using the data controls, for instance, if you are unsure of the shape of your data, you can lay out the page first using the Component Palette and later bind it to the data types, attributes, or operations of the placeholder data controls.

17.4.5 Rebinding Components

After the final data controls are available, you can simply rebind the components. You can select the component in the Structure window and use the context menu to open the relevant rebind dialog. You can also drag and drop the data control item onto the UI component to initiate a rebinding editor. The rebinding procedures are the same whether the component was originally bound to a placeholder data control or a standard data control.

For more information about rebinding components, see [Chapter 26, "Creating a Basic Databound Page"](#) and [Chapter 27, "Creating ADF Databound Tables."](#)

17.4.6 Packaging Placeholder Data Controls to ADF Library JARs

A useful feature of placeholder data controls is that they allow parallel development and division of labor among developers and designers. You may be able to leverage that further by packaging placeholder data controls into reusable components as ADF Library JARs. ADF Libraries are JARs that have been packaged to contain all the necessary artifacts of an ADF component. For more information about reusable components and the ADF Library, see [Chapter 38, "Reusing Application Components."](#) You can create libraries of placeholder data controls and distribute them to multiple designers working on the same UI project. Because they are lightweight, you can even use them in place of available real data controls for the earlier phases of UI design.

Part IV

Creating ADF Task Flows

Part III contains the following chapters:

- [Chapter 18, "Getting Started with ADF Task Flows"](#)
- [Chapter 19, "Working with Task Flow Activities"](#)
- [Chapter 20, "Using Parameters in Task Flows"](#)
- [Chapter 21, "Using Task Flows as Regions"](#)
- [Chapter 22, "Creating Complex Task Flows"](#)
- [Chapter 23, "Using Dialogs in Your Application"](#)

Getting Started with ADF Task Flows

This chapter introduces ADF task flows. ADF task flows enable navigation, encapsulation, reuse, managed bean lifecycles, and transactions within a Fusion web application. The chapter also includes the basic steps for creating a task flow by adding activities and control flows to the task flow diagram, plus testing and running the finished task flow.

This chapter includes the following sections:

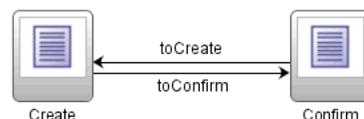

- [Section 18.1, "About ADF Task Flows"](#)
- [Section 18.2, "Creating a Task Flow"](#)
- [Section 18.3, "Adding Activities to a Task Flow"](#)
- [Section 18.4, "Adding Control Flow Rules to Task Flows."](#)
- [Section 18.5, "Testing Task Flows"](#)
- [Section 18.6, "Refactoring to Create New Task Flows and Task Flow Templates"](#)
- [Section 18.7, "What You Should Know About Task Flow Constraints"](#)

18.1 About ADF Task Flows

ADF task flows provide a modular approach for defining control flow in a Fusion web application. Instead of representing an application as a single large JSF page flow, you can break it up into a collection of reusable task flows. Each task flow contains a portion of the application's navigational graph. The nodes in the task flows are activities. An *activity node* represents a simple logical operation such as displaying a page, executing application logic, or calling another task flow. The transitions between the activities are called *control flow cases*.

[Figure 18-1](#) shows two view activities called `Create` and `Confirm`. These view activities are similar to page nodes within a JSF page flow.

Figure 18-1 ADF Task Flow

There are two types of ADF task flow:

- Unbounded task flow: A set of activities, control flow rules, and managed beans that interact to allow a user to complete a task. The unbounded task flow consists of all activities and control flows in an application that are not included within a bounded task flow.
- Bounded task flow: A specialized form of task flow that, in contrast to the unbounded task flow, has a single entry point (an entry point is a view activity that can be directly requested by a browser) and zero or more exit points. It contains its own set of private control flow rules, activities, and managed beans. A bounded task flow allows reuse, parameters, transaction management, reentry, and can render within an ADF region in a JSF page.

For a description of the activity types that you can add to an unbounded or bounded task flow see [Chapter 19, "Working with Task Flow Activities"](#).

By default, JDeveloper proposes the following filename for the source file of a bounded task flow:

```
task-flow-definitionN.xml
```

where *N* is a number that increments each time that you create a new bounded task flow. You can choose a filename for the bounded task flow. For example, you might use `checkout-task-flow.xml` if the purpose of the bounded task flow is to allow customers check out from a shopping application.

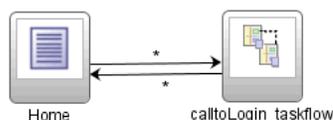

The source file contains the metadata for the bounded task flow. Multiple bounded task flows can be included within the same source file using the following metadata:

```
<task-flow-definition id="TaskFlowID1">
  ...
</task-flow-definition>
<task-flow-definition id="TaskFlowID2">
  ...
</task-flow-definition>
```

However, as JDeveloper's visual editors show one bounded task flow per file, we do not recommend that you include more than one bounded task flow within the same source file.

A typical application is a combination of the unbounded task flow and one or more bounded task flows. For example, JDeveloper, by default, creates an empty unbounded task flow (source file name is `adfc-config.xml`) when you create an application using the Fusion Web Application template. At runtime, the Fusion web application can call bounded task flows from activities that you added to the unbounded task flow.

As shown in [Figure 18-2](#), the first activity to execute in an application is often a view activity within the unbounded task flow. A view activity represents a JSF page that displays as part of the application. The activity shown in [Figure 18-2](#) starts with the Home view activity and then calls a bounded task flow. The `calltoLogin_taskFlow` activity calls a bounded task flow that enables a user to log into the application.

Figure 18–2 Unbounded Task Flow Calling a Bounded Task Flow

You can also design an application in which all application activities reside within the unbounded flow. This mimics a JSF application, but does not take advantage of bounded task flow functionality. To take full advantage of task flow functionality, use bounded task flows.

[Table 18–1](#) describes the advantages that the control flow provided by ADF task flows offers over the control flow offered by JSF page flow. In certain scenarios you may need to use JSF page flow. For example, using phase listeners, as described in [Section 25.4, "Customizing the ADF Page Lifecycle,"](#) involves using the JSF page flow's `faces-config.xml` configuration file. In general, it is not recommended that you mix JSF page flow and ADF task flows in your application.

Table 18–1 ADF Task Flow Advantages

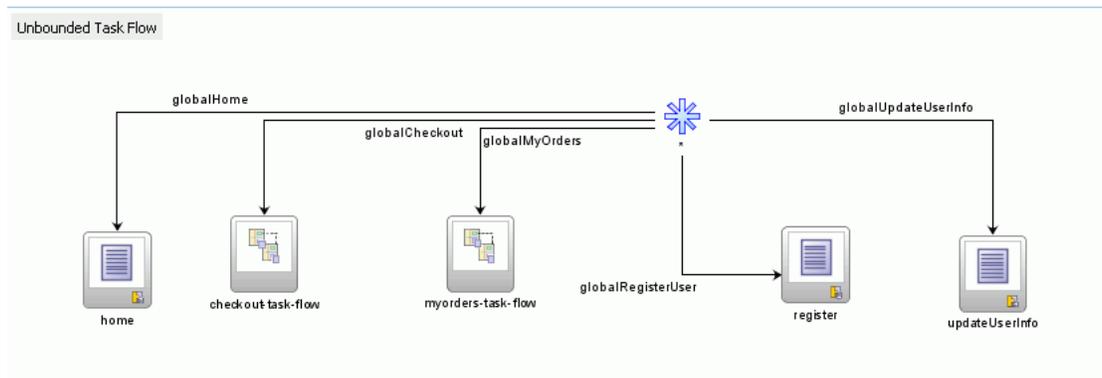

JSF Page Flow	ADF Task Flow
The entire application must be represented in a single page navigation file (<code>faces-config.xml</code>). Although you can have multiple copies of <code>faces-config.xml</code> in a project, the application loads these files as one at runtime.	The application can be broken up into a series of modular flows that call one another.
All nodes within a JSF page flow must be JSF pages. No other types of objects can exist within the JSF page flow.	You can add to the task flow diagram nodes such as views, method calls, and calls to other task flows.
Navigation is only between pages.	Navigation is between pages as well as other activities, including routers. For more information, see Section 19.4, "Using Router Activities" .
Application fragments cannot be reused.	ADF task flows are reusable within the same or an entirely different application. After you break up your application into task flows, you may decide to reuse task flows containing common functionality. For more information see Chapter 38, "Reusing Application Components" .
There is no shared memory scope between multiple requests except for session scope.	Shared memory scope (for example, page flow scope) enables data to be passed between activities within the task flow. Page flow scope defines a unique storage area for each instance of a bounded task flow.

18.1.1 About Unbounded Task Flows

A Fusion web application always contains an *ADF unbounded task flow*, which contains the entry point or points to the application. An entry point is a view activity that can be directly requested by a browser. A Fusion web application only has one unbounded task flow. By default, the source file for the unbounded task flow is the

`adfc-config.xml` file. Although you can create additional source files for unbounded task flows, the application combines all source files at runtime into the `adfc-config.xml` file. [Figure 18–3](#) displays the diagram for the unbounded task flow from the Fusion Order Demo Application. This task flow contains a number of view activities that are all entry points to the application.

Figure 18–3 Unbounded Task Flow in Fusion Order Demo Application

You typically use the unbounded task flow instead of a bounded task flow if:

- You want to take advantage of ADF Controller features not offered by bounded task flows, such as bookmarkable view activities. For more information, see [Section 19.2.2, "Bookmarking View Activities"](#).
- The task flow will not be called by another task flow.
- The application has multiple points of entry. In [Figure 18–3](#), the task flow can be entered through any of the pages represented by the view activity icons on the unbounded task flows.
- You want to bookmark more than one activity on the task flow. See [Section 19.2.2, "Bookmarking View Activities"](#) for more information.

The unbounded task flow cannot declaratively specify parameters. In addition, it cannot contain a *default activity*, an activity designated as the first to run in the unbounded task flow. This is because the unbounded task flow does not have a single point of entry. To perform any of these requires a bounded task flow.

In order to take advantage of completely declarative ADF Controller transaction and reentry support, use a bounded task flow rather than the unbounded task flow.

18.1.2 About Bounded Task Flows

An *ADF bounded task flow* is used to encapsulate a reusable portion of an application. A bounded task flow is similar to a Java method in that it:

- Has a single entry point
- May accept input parameters
- May generate return values
- Has its own collection of activities and control flow rules
- Has its own memory scope and managed bean lifespan (a page flow scope instance)

For more information about memory scopes, see [Section 18.2.4, "What You May Need to Know About Memory Scope for Task Flows."](#)

- Can determine whether or not it has an isolated data control frame

For more information about access to data control frames, see [Section 20.4, "Sharing Data Controls Between Task Flows."](#)

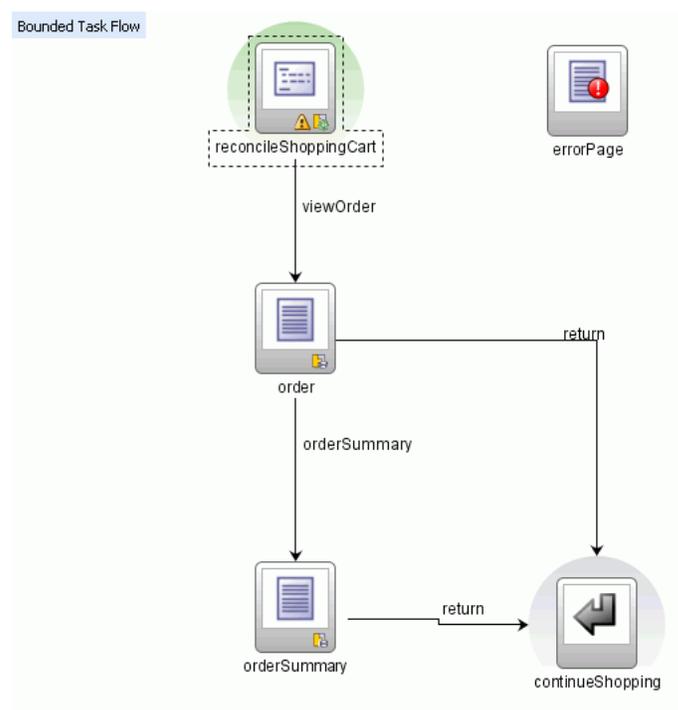

- Can define an activity as an exception handling activity

For more information about exception handling in bounded task flows, see [Section 22.4, "Handling Exceptions in Task Flows."](#)

The `checkout-task-flow` activity in [Figure 18-3](#) is a call to a bounded task flow. The unbounded task flow can call a bounded task flow, but cannot be called by another task flow. A bounded task flow can call another bounded task flow, which can call another and so on. There is no limit to the depth of the calls.

The checkout process is created as a separate bounded task flow, as shown in [Figure 18-4](#).

Figure 18-4 Checkout Bounded Task Flow in Fusion Order Demo Application

The reasons for creating the `checkout-task-flow` activity as a called bounded task flow are:

- The bounded task flow always specifies a default activity, a single point of entry that must execute immediately upon entry of the bounded task flow.

In the checkout task flow, the activity labeled `reconcileShoppingCart` invokes a method that returns a list of items that an anonymous user (one who has not yet logged in to the application) may have chosen to purchase. Any items chosen before authentication are included in the shopping cart after the user has logged in. Because it is the default activity, the method is always invoked before the shopping cart order page displays.

- `checkout-task-flow` is reusable. For example, it can be included in other applications requiring an item checkout process. The bounded task flow can also be reused within the same application.
- Any managed beans you decide to use within `checkout-task-flow` can be specified in page flow scope, so are isolated from the rest of the application. These managed beans (with page flow scope) are automatically released when the task flow completes.

The main features of bounded task flows are summarized in [Table 18-2](#).

Table 18-2 Bounded Task Flow Features

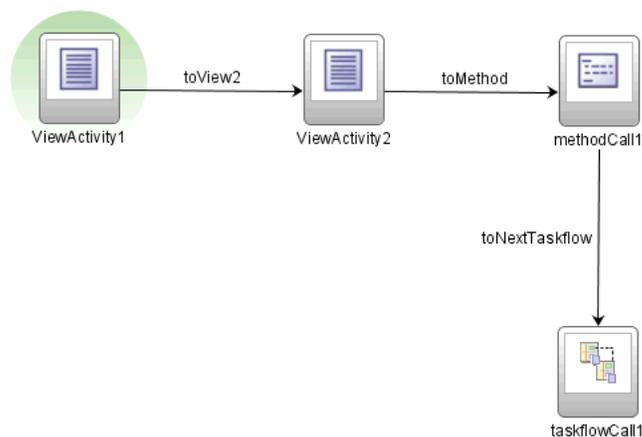

Feature	Description
Well-defined boundary	A bounded task flow consists of its own set of private control flow rules, activities, and managed beans. A caller requires no internal knowledge of such things as page names, method calls, child bounded task flows, managed beans, and control flow rules within the bounded task flow boundary. Input parameters can be passed into the bounded task flow, and return values can be passed out on exit of the bounded task flow. Data controls can be shared between task flows.
Single point of entry	A bounded task flow has a single point of entry, a default activity that executes before all other activities in the task flow. For more information, see Section 18.2.3, "What You May Need to Know About the Default Activity in a Bounded Task Flow" .
Page flow memory scope	You can specify page flow scope as the memory scope for passing data between activities within the bounded task flow. Page flow scope defines a unique storage area for each instance of a bounded task flow. Its lifespan is the bounded task flow, which is longer than request scope and shorter than session scope. For more information, see Section 18.2.4, "What You May Need to Know About Memory Scope for Task Flows" .
Addressable	You can access a bounded task flow by specifying its unique identifier within the XML source file for the bounded task flow and the file name of the XML source file. For more information, see Section 19.6.8, "What Happens When You Add a Task Flow Call Activity" .
Reuse	<p>You can identify an entire group of activities as a single entity, a bounded task flow, and reuse the bounded task flow in another application within an ADF region. For example, the Hot Items and Start Shopping tabs on the home page of the Fusion Order Demo application reuse the same task flow embedded in a region. Different parameters are passed to each region to determine the lists of products that display. For more information, see Section 21.3, "Specifying Parameters for an ADF Region."</p> <p>You can also reuse an existing bounded task flow simply by calling it. For example, one task flow can call another bounded task flow using a task flow call activity or a URL.</p> <p>In addition, you can use task flow templates to capture common behaviors for reuse across different bounded task flows. For more information, see Section 22.8, "Creating Task Flow Templates".</p>
Parameters and return values	<p>A caller can pass input parameters to a bounded task flow and accept return values from it. For more information, see Section 20.3, "Passing Parameters to a Bounded Task Flow".</p> <p>In addition, you can share data controls between bounded task flows. For more information, see Section 20.4, "Sharing Data Controls Between Task Flows".</p>

Table 18–2 (Cont.) Bounded Task Flow Features

Feature	Description
Transaction management	A bounded task flow can represent a transactional unit of work. You can declaratively specify options on the bounded task flow that determine whether, when entering the task flow, the task flow creates a new transaction, joins an existing one or is not part of the existing transaction. For more information, see Section 22.2, "Managing Transactions in Task Flows" .
Reentry	You can specify options on the bounded task flow that determine whether or not it can be reentered. For more information, see Section 22.3, "Reentering Bounded Task Flows" .
On-demand loading of metadata	Bounded task flow metadata is loaded on demand when entering a bounded task flow.
Security	You can secure a bounded task flow by defining the privileges that are required for someone to use it. For more information, see Section 35, "Enabling ADF Security in a Fusion Web Application."

18.1.3 About Control Flows

A task flow consists of activities and control flow cases that define the transitions between activities. [Figure 18–5](#) shows a control flow rule, labeled `toView2`, that defines the transition between the `ViewActivity1` and `ViewActivity2` view activities. The `ViewActivity1` view activity displays before the `ViewActivity2` view activity when the task flow in [Figure 18–5](#) executes.

Figure 18–5 Task Flow with Activities and Control Flow Cases

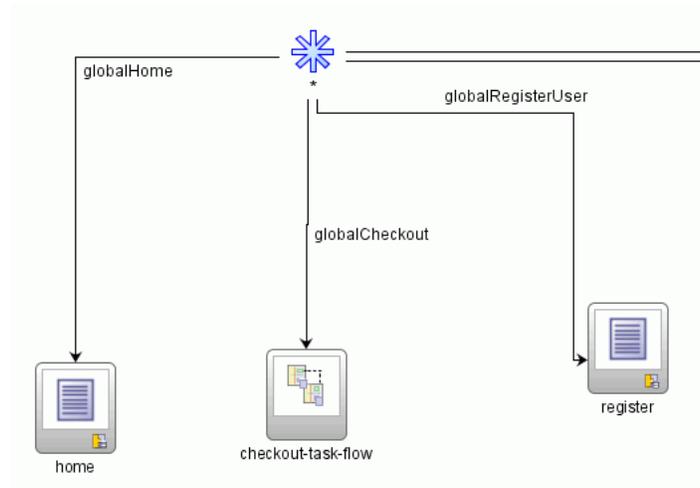

The task flow in [Figure 18–5](#) also contains a method call activity (`methodCall1`) that invokes after the `ViewActivity2` view activity and before the `taskflowCall1` task flow call activity. In a task flow, you invoke an activity such as a method call activity before or after a page renders. Invoking a method call activity outside of a particular page can facilitate reuse because you can reuse the page in other contexts that don't require the method (for example, a different task flow). For more information about control flow rules, see [Section 18.4, "Adding Control Flow Rules to Task Flows."](#)

A wildcard control flow rule represents a control flow `from-activity-id` that contains a trailing wildcard (`foo*`) or a single wildcard character (`*`). Use the single wildcard character when you want to pass control from any activity in the task flow to

the wildcard control flow rule. Alternatively, use a trailing wildcard when you want to constrain the activities that can pass control to the wildcard control flow rule.

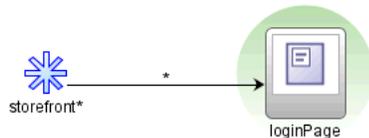

In [Figure 18–6](#), the wildcard control flow rule contains a single wildcard character, indicating that control can pass to the activities connected to it in the task flow diagram from any activity within the task flow.

Figure 18–6 Wildcard Control Flow Rule With Single Wildcard

The trailing wildcard in [Figure 18–7](#) indicates that control flow can pass to the loginPage view from any valid source activity whose activity-id begins with the characters storefront.

Figure 18–7 Wildcard Control Flow Rule with Trailing Wildcard

For more information about wildcard control flow rules, see [Section 18.4.2, "How to Add a Wildcard Control Flow Rule."](#)

18.1.4 ADF Task Flow Use Cases and Examples

[Figure 18–8](#) shows a screen from the Fusion Order Demo application described in [Chapter 2, "Introduction to the ADF Sample Application."](#) End users can invoke a number of bounded task flows from this screen. The **Register as a customer** command button invokes the customer registration task flow (`customer-registration-task-flow.xml`) that allows a potential customer to register to use the application. This task flow renders screens where the user enters data such as name, email address, and so on. The **Register as an employee** command button invokes the employee registration task flow (`employee-registration-task-flow.xml`) that enables employees to register. Where appropriate, the customer registration and employee registration task flows reuse the same view activities. A third task flow in [Figure 18–8](#) is the `help-task-flow.xml` task flow that renders in the **Registration Help** area. This task

flow provides assistance to the users as they navigate the tasks in the customer and employee registration task flows.

Figure 18–8 Task Flows for Registration and User Assistance

Task flows can also be used to secure your Fusion web application by reducing the number of access points that you expose to end users. For example, configure an unbounded task flow to display one page that provides navigation to the remaining pages in your application. Use bounded task flows for the remaining pages in the application. By setting the URL Invoke property of these bounded task flows to `url-invoke-disallowed`, your application has one access point (the page on the unbounded task flow). For more information about the URL Invoke property, see [Section 19.6.4, "How to Call a Bounded Task Flow Using a URL."](#) For more information about securing your Fusion web application, see [Chapter 35, "Enabling ADF Security in a Fusion Web Application."](#)

18.1.5 Additional Functionality for ADF Task Flows

You may find it helpful to understand other ADF features before you configure or use ADF task flows. Additionally, you may want to read about what you can do with your task flow configurations. Following are links to other functionality that may be of interest.

- Task flows can invoke managed beans. For more information about defining managed beans for use with a task flow, the supported memory scopes, and other related information, see [Section 18.2.4, "What You May Need to Know About Memory Scope for Task Flows"](#) and [Section 24.4, "Using a Managed Bean in a Fusion Web Application"](#).
- Task flows are reusable. For more information about reusing functionality in your application, [Chapter 38, "Reusing Application Components."](#)
- Task flows can be secured by defining the privileges that are required for someone to use it. For more information, see [Chapter 35, "Enabling ADF Security in a Fusion Web Application."](#)
- You can extend the functionality that your task flows implement by writing custom code. For example, you can write a custom exception handler that a task flow passes control to when a task flow activity raises an exception. For more

information, see [Section 22.4.3, "How to Designate Custom Code as an Exception Handler."](#)

Make sure when you write custom code that you do not import packages that are marked internal, as in the following example:

```
import oracle.adfinternal.controller.*;
```

For information about the APIs that you can use to write custom code, see the following reference documents:

- *Oracle Fusion Middleware Java API Reference for Oracle ADF Controller*
- *Oracle Fusion Middleware Java API Reference for Oracle ADF Faces*

18.2 Creating a Task Flow

A task flow is made up of the task flow itself, plus a number of activities with control flow rules between those activities. In most cases, the majority of the activities are view activities which represent the different pages in the flow. When some method or operation needs to be called, for example before a page is rendered, you use a method call activity with a control flow case from that activity to the appropriate next activity. When you want to call another task flow, you use a task flow call activity. If the flow requires some sort of branching, you use a router activity. At the end of a bounded task flow, you use a return activity which allows the flow to exit and control is sent back to the flow that called this bounded task flow.

For more detailed information and procedures regarding the individual components of a task flow, including the metadata created for each and additional configuration that you can set, see [Section 18.3, "Adding Activities to a Task Flow."](#)

18.2.1 How to Create a Task Flow

The processes for creating bounded and unbounded task flows are similar. The main difference is that you select the **Create as Bounded Task Flow** checkbox in the Create Task Flow dialog to create a bounded task flow.

Note: When you create the project, you may not need to create the unbounded task flow for it. If **ADF Page Flow** is specified as a selected technology on a Technology Scope page of the Project Properties dialog, the new `adfc-config.xml` source file is automatically created within the project. The `adfc-config.xml` source file is the main source file for the unbounded task flow.

Before you begin:

It may be helpful to have an understanding of what constitutes a task flow. For more information, see [Section 18.2, "Creating a Task Flow."](#)

You may also find it helpful to understand functionality that can be added using other task flow features. For more information, see [Section 18.1.5, "Additional Functionality for ADF Task Flows."](#)

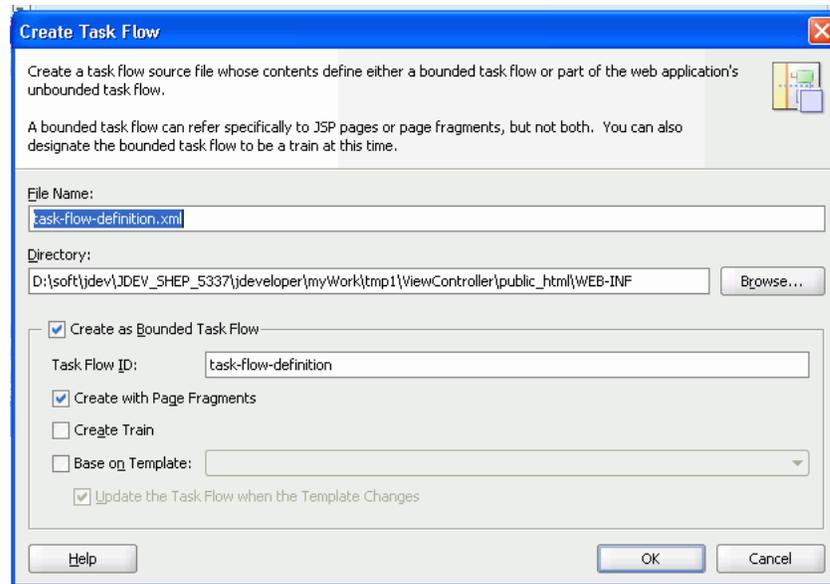

To create a task flow:

1. Create the task flow:
 - a. In the Application Navigator, right-click the project where you want to create the task flow and choose **New**.

- b. In the New Gallery, expand **Web Tier**, select **JSF/Facelets** and then select **ADF Task Flow**, and click **OK**.

The dialog shown in [Figure 18–9](#) displays.

Figure 18–9 Create Task Flow Dialog

- c. In the Create Task Flow dialog, the **Create as Bounded Task Flow** checkbox is selected by default. Deselect it to create a source file that will be incorporated into the application's unbounded task flow.

Deselecting the checkbox automatically changes the default value in the **File Name** field. This value will be used to name the XML source file for the task flow you are creating. The XML source file contains metadata describing the activities and control flow rules in the task flow.

Tip: The default name for the unbounded task flow is `adfc-config.xml`. The default name for the source file for a bounded task flow matches the value specified in the **Task Flow ID** field.

Because a single project can contain multiple task flows, a number may be added to the default value in the **File Name** field in order to give the source file a unique name, for example, `task-flow-definition3.xml`.

- d. In the Create Task Flow dialog, the **Create with Page Fragments** checkbox is selected by default.

Clear this checkbox if you want the view activities that you add to the task flow to reference JSF pages that render in the main browser window as the root page. Leave the **Create with Page Fragments** checkbox selected if you want the view activities that you add to the task flow to reference page fragments files (`.jsff`) that the task flow displays in an ADF region at runtime.

- e. Click **OK**.

A diagram representing the task flow displays in the editor.

Tip: You can view a thumbnail of the entire task flow diagram by clicking the diagram and then choosing **View > Thumbnail** from the main menu.

- f. After you create the task flow, you can update it using the diagram, overview, and source editors

You can also use the Structure window to update the task flow.

Tip: There are other ways to create task flows, for example, by refactoring the contents of an existing task flow into a new task flow. For more information, see [Section 18.6, "Refactoring to Create New Task Flows and Task Flow Templates"](#).

2. In the ADF Task Flow page of the Component Palette, from the Component panel, drag and drop an activity onto the diagram.

Normally, you would start with a view activity. For more detailed procedures for adding any type of activity, see [Section 18.3.1, "How to Add an Activity to a Task Flow."](#)

- If you drag a view activity onto the diagram, you can double-click it to display the wizard for the JSF page or page fragment that the task flow is configured to invoke. Use the wizard to define characteristics for the page or page fragment. For more information, see [Section 19.2, "Using View Activities"](#).

Note: You can also add a view activity to a task flow by dragging a page from the Application Navigator and dropping it on the diagram for the task flow.

- If you drag a router activity onto the diagram, you can use the Property Inspector to create an expression whose evaluation will determine which control flow rule will be followed. For more information, see [Section 19.4, "Using Router Activities."](#)
 - If you drag a method call activity onto the diagram, you can use the Property Inspector to configure the method to be called. For more information, see [Section 19.5, "Using Method Call Activities."](#)
 - If you drag a task flow call activity onto the diagram, you can double-click it to display the Create Bounded Task Flow dialog where you can define settings for a new bounded task flow. For more information, see [Section 19.6, "Using Task Flow Call Activities"](#).
 - If you are creating a bounded task flow, and you drag a task flow return activity onto the diagram, you can use the Property Inspector to configure the activity. For more information, see [Section 19.7, "Using Task Flow Return Activities."](#)
3. Create control flow cases between the activities (for more information and detailed procedures, see [Section 18.4.1, "How to Add a Control Flow Rule to a Task Flow"](#)):
 - a. In the ADF Task Flow page of the Component Palette, select **Control Flow Case**.
 - b. On the diagram, click a source activity, for example a view, and then click the destination activity. For example in [Figure 18–15](#), two activities have been

linked with a control flow. Both source (`view1`) and the destination (`view2`) activities are linked.

- c. Set the outcome value, using either the **From Action** attribute (if the outcome is to be determined by a method) or the **From Outcome** attribute (if the outcome can be set as a `String`).
4. If you are creating a bounded task flow, once that flow is complete, you may want to designate one of the activities as the default activity. Doing so makes sure that this specific activity executes first whenever the task flow runs. By default, the first activity you added to the task flow is the default. To change to a different activity, right-click the appropriate activity in the diagram and choose **Mark Activity > Default Activity**. For more information, see [Section 18.2.3, "What You May Need to Know About the Default Activity in a Bounded Task Flow."](#)

18.2.2 What Happens When You Create a Task Flow

A new XML source file is created every time you create a new unbounded or bounded task flow. By default, the XML source file for the unbounded task flow is called `adfc-config.xml`.

As shown in [Example 18–1](#), `<adfc-config>` appears first as the top-level element in all ADF Controller XML source files. Bounded task flows, activities and control flow rules are defined inside the `<adfc-config>` element. Bounded task flows are identified within the source file by the `<task-flow-definition>` metadata element.

Example 18–1 Bounded Task Flow XML Source File

```
<?xml version="1.0" encoding="windows-1252" ?>
<adfc-config xmlns="http://xmlns.oracle.com/adf/controller" version="1.2" id="__
1">
  <task-flow-definition id="task-flow-definition">
    <use-page-fragments/>
  </task-flow-definition>
</adfc-config>
```

A bounded task flow is identified by its task flow reference, which is comprised of a unique combination of identifier and document name. [Example 18–2](#) shows a sample task flow reference within a task flow call activity.

Example 18–2 Task Flow Reference

```
<adfc-config xmlns="http://xmlns.oracle.com/adf/Controller" version="1.2">
  <task-flow-definition id="task-flow-definition">
    <use-page-fragments/>
    .
    .
    <task-flow-call id="taskFlowCall">
      <task-flow-reference>
        <document>/WEB-INF/target-task-flow-definition.xml</document>
        <id>my-task-flow</id>
      </task-flow-reference>
    </task-flow-call>
    .
    .
  </task-flow-definition>
</adfc-config>
```

Note: If you use JDeveloper to create the bounded task flow, specify only one ID (indicating one bounded task flow) per document.

You assign both identifier and document name when you create the bounded task flow. As shown in [Example 18–2](#), the identifier is the value in the **Task Flow ID** field. The document name is the value in the **File Name** field.

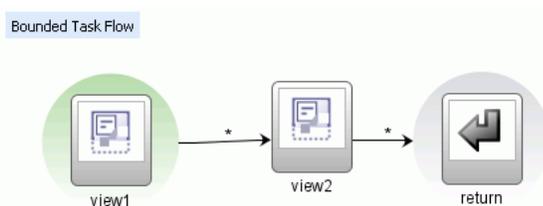

18.2.3 What You May Need to Know About the Default Activity in a Bounded Task Flow

The default activity is the first activity to execute in a bounded task flow. For example, the default activity always executes first when a task flow call activity passes control to the bounded task flow.

Unbounded task flows do not have default activities.

As shown in [Figure 18–10](#), a green circle identifies the default activity in a task flow diagram.

Figure 18–10 Default Activity in a Bounded Task Flow

The first activity that you add to a new bounded task flow diagram is automatically identified as the default activity. You can also right-click any activity in the task flow diagram and choose **Mark Activity > Default Activity**. The default can be any activity type and it can be located anywhere in the control flow of the bounded task flow. To find the default activity, right-click anywhere on the task flow diagram and choose **Go to Default Activity**.

A bounded task flow can have only one default activity. If you mark a second activity as the default, the first is unmarked automatically. To unmark an activity manually, right-click the activity in the task flow diagram and choose **Unmark Activity > Default Activity**.

You should not specify a train stop in the middle of a train as a default activity (for more information, see [Section 22.7, "Using Train Components in Bounded Task Flows"](#)).

[Example 18–3](#) contains sample metadata for a default activity called `SurveyPrompt` in a bounded task flow:

Example 18–3 Default Activity Metadata in a Bounded Task Flow

```
<task-flow-definition id="survey">
  <default-activity>SurveyPrompt</default-activity>
  <view id="SurveyPrompt">
    <page>/SurveyPrompt.jsff</page>
  </view>
  <use-page-fragments/>
</task-flow-definition>
```

18.2.4 What You May Need to Know About Memory Scope for Task Flows

Each task flow in your Fusion web application defines a pageFlow scope to manage state. The pageFlow scope begins when the task flow begins and ends when the task flow ends. A pageFlow scope defines a unique storage area for each instance of a task flow within an application which is used to pass data values between the activities in the task flow. When one task flow calls another, the calling task flow cannot access the called task flow's pageFlow scope. This means, for example, that a UI component on a page referenced by a task flow's view activity cannot access the pageFlow scope of another task flow even if this task flow is an ADF region embedded in the same page as the UI component.

You can define multiple managed beans with task flows. [Figure 18–11](#) shows examples from the Fusion Order Demo application where the default unbounded task flow (`adfc-config.xml`) and the customer registration task flow reference multiple managed beans with varying scope values. You can determine the scope assigned to a managed bean.

Figure 18–11 Managed Beans Registered with Task Flows

The screenshot shows two windows in the Oracle ADF IDE. The top window is titled 'customer-registration-task-flow.xml' and shows a table of Managed Beans with the following data:

Name *	Class *	Scope *
custRegBasicInformationBean	oracle.fodemo.storefront.account.view.managed....	view
custRegDefineAddressesBean	oracle.fodemo.storefront.account.view.managed....	view

The bottom window is titled 'adfc-config.xml' and shows a table of Managed Beans with the following data:

Name *	Class *	Scope *
homePag...	oracle.fodemo.storefront.store.view.managed.HomeBean	request
shopping...	oracle.fodemo.storefront.cart.view.managed.ShoppingCartBean	session
navigatio...	oracle.fodemo.storefront.store.view.managed.NavigationBean	request
orderPag...	oracle.fodemo.storefront.store.view.managed.OrderBean	session
userInfoB...	oracle.fodemo.storefront.store.view.managed.UserInfoBean	session
myOrders...	oracle.fodemo.storefront.orders.view.managed.MyOrdersBean	request

[Table 18–3](#) lists available scopes for managed beans and describes when it is appropriate to use each scope in a managed bean that you define with a task flow. The table lists the scopes in order of their life span. For example, the application scope has a longer life span than the request scope. For more information the life span of object scopes, see [Section 25.3, "About Object Scope Lifecycles."](#)

Table 18–3 Memory Scope for ADF Managed Beans

Scope	Description
application	The application scope lasts until the application stops. Values that you store in a managed bean with this scope are available to every session and every request that uses the application. Avoid using this scope in a task flow because it persists beyond the life span of the task flow.

Table 18–3 (Cont.) Memory Scope for ADF Managed Beans

Scope	Description
session	<p>The session scope begins when a user first accesses a page in the application and ends when the user's session times out due to inactivity, or when the application invalidates the session.</p> <p>Use this scope only for information that is relevant to the whole session, such as user or context information. Avoid using it to pass values from one task flow to another. Instead, use parameters to pass values between task flows. Using parameters gives your task flow a clear contract with other task flows that call it or are called by it. Another reason to avoid use of session scope is because it may persist beyond the life span of the task flow. Finally, if an end user opens multiple browser windows within the same session, session scoped values are shared across these browser windows. Conflicts can occur between these browser windows.</p>
pageFlow	<p>Choose this scope if you want the managed bean to be accessible across the activities within a task flow. A managed bean that has a pageFlow scope shares state with pages from the task flow that access it. A managed bean that has a pageFlow scope exists for the life span of the task flow.</p>
view	<p>Use this scope for managed bean objects that are needed only within the current view activity and not across view activities.</p> <p>The life span of this scope begins and ends when the current <code>viewId</code> of a view port changes. If you specify <code>view</code>, the application retains managed bean objects used on a page as long as the user continues to interact with the page. These objects are automatically released when the user leaves the page.</p> <p>Both JSF and Oracle ADF have an implementation of this scope. In a Fusion web application, when you use <code>view</code> scope in an expression, it resolves to the Oracle ADF implementation.</p>
request	<p>Use request scope when the managed bean does not need to persist longer than the current request.</p>
backingBean	<p>A backing bean is a convention to describe a managed bean that stores accessors for UI components and event handling code on a JSF page. It exists for the duration of a request and should not be used to maintain state.</p> <p>Use this scope if it is possible that your task flow appears in two ADF regions on the same JSF page and you want to isolate each instance of ADF region.</p>

When you define a managed bean with a task flow, JDeveloper generates an entry similar to the following in the task flow's source file:

```
<managed-bean id="__15">
  <managed-bean-name id="__16">egBackingBean</managed-bean-name>
  <managed-bean-class id="__13">oracle...egBackingBean</managed-bean-class>
  <managed-bean-scope id="__14">backingBean</managed-bean-scope>
</managed-bean>
```

The `<managed-bean-scope>` element holds the value for the scope of the managed bean (`backingBean` in the example).

When you bind a UI component to a managed bean, JDeveloper appends `Scope` to the scope name in the EL expression that it generates to reference the managed bean. For example, the binding attribute of a table component that references the managed bean has the following EL expression:

```
<af:table id="cartTab"
  ...
  binding="#{backingBeanScope.egBackingBean.table}"
  ...
</af:table>
```

Restrict the scope of the managed bean that you reference through a UI component's binding attribute to `backingBean` or `request` scope. Instances of UI components cannot be serialized. Objects in scopes other than `backingBean` and `request` are expected to be serializable. For this reason, you should not bind UI components to managed beans that have a scope other than `backingBean` or `request`. Note that JDeveloper defaults the binding attribute for UI components and region fragments to use the `backingBean` scope.

Note: Write EL expressions that explicitly qualify the scope to access when writing EL expressions to access custom scopes unique to Oracle ADF (`pageFlow`, `backingBean`, and `view` scopes). For example, write an EL expression to access a `pageFlow` scope as follows:

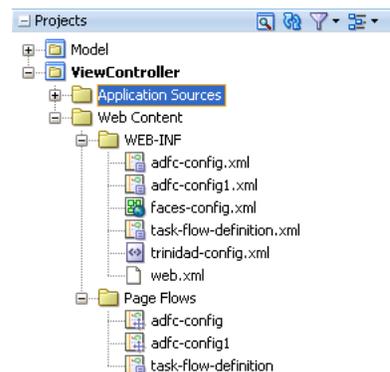

```
# {pageFlowScope.inpTxtBB.uiComponent}
```

18.2.5 What Happens at Runtime: Using Task Flows

A single application can have multiple unbounded task flow XML source files and multiple bounded task flow XML source files. The set of files that combine to produce the unbounded task flow is referred to as the application's *ADF Controller bootstrap configuration files*. The unbounded task flow is assembled at runtime by combining one or more ADF Controller bootstrap configuration files. All activities within the bootstrap configuration files that are not contained within a bounded task flow are considered to be within the unbounded task flow.

The names of the source files within a single application must be different. The example in [Figure 18–12](#) contains two unbounded task flows (`adfc-config`, `adfc-config2`) and a bounded task flow (`task-flow-definition`).

Figure 18–12 Application with Two Unbounded Task Flow XML Source Files

18.3 Adding Activities to a Task Flow

After you create a task flow, you add activities to the task flow and configure the control flow between the activities. The Component Palette in JDeveloper displays available activities and control flows. You drag and drop the activities and control flows from the Component Palette to the diagram for the task flow. You can then configure control flow between the activities so that the task flow performs the task you want it to perform.

18.3.1 How to Add an Activity to a Task Flow

After you create a task flow, a task flow diagram and the Component Palette automatically display. The task flow diagram is a visual editor on which you can add the activities and control flows for the task flow. You can add them to the diagram by dragging them from the Component Palette.

Before you begin:

It may be helpful to have an understanding of what activities you can add to a task flow. For more information, see [Section 18.3, "Adding Activities to a Task Flow."](#)

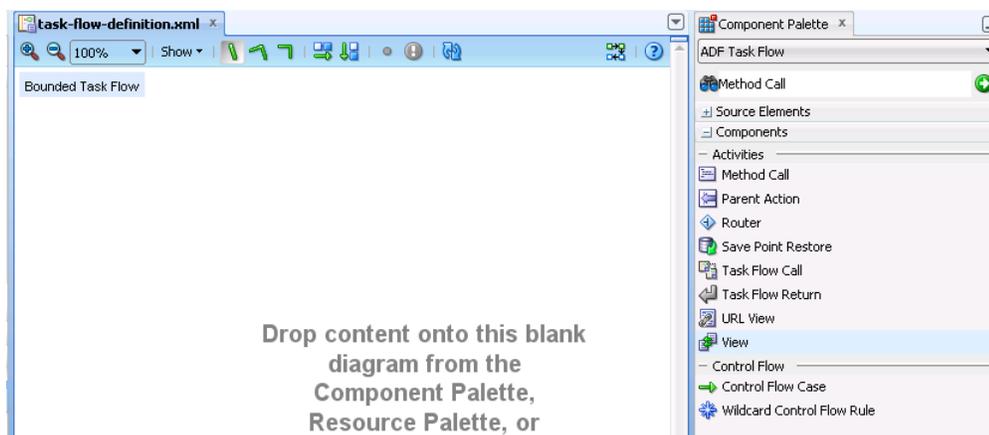

You may also find it helpful to understand functionality that can be added to task flows using other ADF features. For more information, see [Section 18.1.5, "Additional Functionality for ADF Task Flows."](#)

To add an activity to a task flow:

1. In the Application Navigator, double-click a task flow source file.

For example, [Figure 18–13](#) shows the editor and the Component Palette that automatically appears when you double-click a task flow source file (`task-flow-definition.xml`).

Figure 18–13 Task Flow Diagram

2. In the ADF Task Flow page of the Component Palette, from the Component panel, drag and drop an activity onto the diagram
 - If you drag a view activity onto the diagram, you can double-click it to display the wizard to create a JSF page or page fragment. For more information, see [Section 19.2, "Using View Activities"](#).
 - If you drag a task flow call activity onto the diagram, you can double-click it to display the Create Bounded Task Flow dialog where you can define settings for a new bounded task flow. For more information, see [Section 19.6, "Using Task Flow Call Activities"](#).

Tip: Each activity you drag to the task flow diagram can display optional status icons and a tooltip that provides additional information about the activity. For example, after you drag a view activity to the task flow diagram, it may display a warning icon until you associate it with a JSF page.

To turn on the icons, select **Show** at the top of the task flow diagram, and then select **Status** and one of the following:

- **Error:** Displays when there is a problem in the task flow metadata which prevents it from running. For example, a view activity in the metadata can contain a `<bookmark>` or `<redirect>` element, but not both.
- **Warning:** Displays when an activity is incomplete. For example, a view activity that doesn't have a physical page associated with it or a task flow call that doesn't have a task flow reference associated with it are both considered incomplete activities. The resulting task flow metadata may prevent it from running.

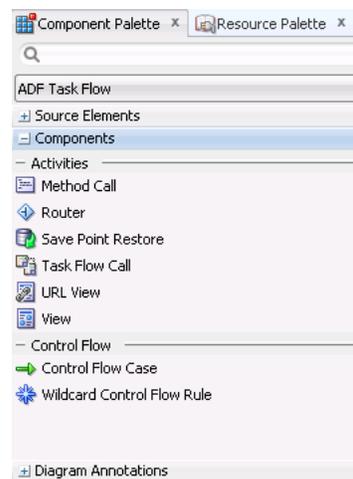

You can drag your mouse over a secondary icon to read a tooltip describing the icon's meaning.

18.3.2 What Happens When You Add an Activity to a Task Flow

As shown in [Figure 18–14](#), the Component Palette contains separate sections for components and diagram annotations. The contents of the **Components** section differ slightly depending on whether you are creating a bounded or the unbounded task flow. For example, if you are creating a bounded task flow, the **Components** section contains an additional task flow return activity.

[Figure 18–14](#) displays the activities you can add to the unbounded task flow.

Figure 18–14 Component Palette for an Unbounded Task Flow

18.4 Adding Control Flow Rules to Task Flows

An ADF Controller control flow rule defines how control passes from one activity to another in a task flow. A control flow rule can contain one or more control flow cases. A control flow case identifies the activity to which control flow passes. A control case also has options that allow you to configure conditional navigation (using the `<if>`

element) and/or limit navigation based on the value of the action from where the control flow originates (using the `from-action` element).

Control flow rules are based on JSF navigation rules, but capture additional information. JSF navigation is always between pages, whereas control flow rules describe transitions between activities. For example, a control flow rule can indicate a transition between a view activity and a subsequent method call activity. Or, it can indicate that control passes from the page (view activity) to another task flow.

The following task flow activities cannot be the source of a control flow rule:

- Save Point Restore
- Task Flow Return
- URL View

The basic structure of a control flow rule mimics a JSF navigation rule. [Table 18–4](#) describes how metadata maps from JSF navigation rules to ADF Controller control flow rules.

Table 18–4 Mapping of JSF Navigation Rules to ADF Controller Control Flow Rules

JSF Navigation Rule	ADF Controller Control Flow Rule
Navigation Rule	Control Flow Rule
From View ID	From Activity ID
Navigation Case	Control Flow Case
From Action	From Action
From Outcome	From Outcome
If	If
To View ID	To Activity ID

When using ADF task flows, perform all application navigation using ADF Controller control flow rules instead of using JSF navigation rules in the `faces-config.xml` file. ADF Controller delegates navigation handling when it does not find a matching control flow case in its metadata. However, not all ADF Controller functionality is guaranteed to work correctly if navigation is performed by a non-ADF Controller navigation handler. For more information about how ADF Controller evaluates control flow rules, see [Section 18.4.4, "What Happens at Runtime: Evaluating Control Flow Rules."](#)

Use the task flow diagram as a starting point for creating basic control flows between activities. Later, you can edit control flow properties in the Structure window, Property Inspector or overview editor for the task flow diagram.

Tip: You can drag and drop an activity onto an existing control flow. This splits the existing control flow into two, with the activity in the center.

18.4.1 How to Add a Control Flow Rule to a Task Flow

You create a control flow rule by dragging a Control Flow Case from the ADF Task Flow page of the Component Palette and dropping it on a source task flow activity and a target task flow activity.

Before you begin:

It may be helpful to have an understanding of what a control flow rule is. For more information, see [Section 18.4, "Adding Control Flow Rules to Task Flows."](#)

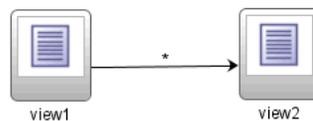

You may also find it helpful to understand functionality that can be added using other task flow features. For more information, see [Section 18.1.5, "Additional Functionality for ADF Task Flows."](#)

To add a control flow rule to a task flow:

1. In the Application Navigator, double-click the source file for the task flow where you want to add a control flow rule. For example, `adfc-config.xml`.
2. In the ADF Task Flow page of the Component Palette, select **Control Flow Case**.
3. On the diagram, click a source task flow activity, for example a view activity, and then click the destination task flow activity.

[Figure 18–15](#) shows two task flow activities (**view1**) and (**view2**) that have been linked with a control flow case.

Figure 18–15 Control Flow Case

JDeveloper adds the control flow case to the diagram. Each line that JDeveloper adds between task flow activities represents a control flow case. The arrow indicates the direction of the control flow case. The **From Outcome** element contains a value that can be matched against values specified in the `action` attribute of UI components.

4. To change the value of **From Outcome**, select the text next to the control flow in the diagram. By default, this text is the wildcard `*` character as shown in [Figure 18–15](#). You can overwrite the text with a new value, for example, `toView2`.
5. To change the values of **From Activity ID** (identifies the source activity) or **To Activity ID** (identifies the target activity), drag either end of the arrow in the diagram to a new activity.

Tip: After you select the control flow in the task flow diagram, you can also change its properties in the Property Inspector or the Structure window. The Structure window is helpful for displaying the relationship between control rules and cases.

You can also click **Control Flows** on the overview editor for the task flow diagram to add cases, as shown in [Figure 18–16](#). To add a case, make sure that the **From Activity** (source activity) and the **To Activity** (target activity) for the rule have already been added to the task flow.

Figure 18–16 Control Flows on Overview Editor for the Task Flow

From Activity ▲	From Outcome	To Activity
view1	toView2	view2
view1	toView3	view3

- Optionally, in the Property Inspector expand the **Behavior** section, and write an EL expression in the **If** field that must evaluate to `true` before control can pass to the activity identified by **To Activity ID**.

18.4.2 How to Add a Wildcard Control Flow Rule

You can add a wildcard control flow rule to an unbounded or bounded task flow. The steps for adding it are similar to those for adding any activity to a task flow diagram.

Before you begin:

It may be helpful to have an understanding of the control flow rule options available to you. For more information, see [Section 18.4, "Adding Control Flow Rules to Task Flows."](#)

You may also find it helpful to understand functionality that can be added using other task flow features. For more information, see [Section 18.1.5, "Additional Functionality for ADF Task Flows."](#)

To add a wildcard control flow rule:

- In the Application Navigator, double-click the source file for a task flow to display the task flow diagram. For example, double-click `adf-config.xml`.
- In the ADF Task Flow page of the Component Palette, from the Component panel, drag and drop a **Wildcard Control Flow Rule** onto the diagram.
- Select **Control Flow Case** in the ADF Task Flow page list of the Component Palette.
- In the task flow diagram, drag the control flow case from the wildcard control flow rule to the target activity.

The target can be any activity type.

- By default, the label below the wildcard control flow rule is `*`. This is the value for the **From Activity ID** element. To change this value, select the wildcard control flow rule in the diagram. In the Property Inspector for the wildcard control flow rule, enter a new value in the **From Activity ID** field. For example, enter `project*`. The wildcard must be a trailing character in the new label.

Tip: You can also change the **From Activity ID** value in the overview editor for the task flow diagram.

- Optionally, in the Property Inspector expand the **Behavior** section, and write an EL expression in the **If** field that must evaluate to `true` before control can pass to the activity identified by **To Activity ID**.

18.4.3 What Happens When You Create a Control Flow Rule

Understanding the elements that define the rules in the source file for the task flow helps when creating control flow rules directly in the task flow diagram, task flow

overview editor, or Structure window, or when adding them directly in the XML source file. [Example 18-4](#) shows the general syntax of a control flow rule element in the task flow source file.

Example 18-4 Control Flow Rule Syntax in the Source File

```
<control-flow-rule>
  <from-activity-id>from-view-activity</from-activity-id>
  <control-flow-case>
    <from-action>actionmethod</from-action>
    <from-outcome>outcome</from-outcome>
    <to-activity-id>destinationActivity</to-activity-id>
    <if>#{myBean.someCondition}</if>
  </control-flow-case>
  <control-flow-case>
    ...
  </control_flow-case>
</control-flow-rule>
```

Control flow rules can consist of the following metadata:

- `control-flow-rule`: A mandatory wrapper element for control flow case elements.
- `from-activity-id`: The identifier of the activity where the control flow rule originates, for example, `source`.

A trailing wildcard (*) character in `from-activity-id` is supported. The rule will apply to all activities that match the wildcard pattern. For example, `login*` matches any logical activity ID name beginning with the literal `login`. If you specify a single wildcard character in the metadata (not a trailing wildcard), the control flow automatically converts to a wildcard control flow rule activity in the diagram. For more information, see [Section 18.4.2, "How to Add a Wildcard Control Flow Rule"](#).

- `control-flow-case`: A mandatory wrapper element for each case in the control flow rule. Each case defines a different control flow for the same source activity. A control flow rule must have at least one control flow case.
- `from-action`: An optional element that limits the application of the rule to outcomes from the specified action method. The action method is specified as an EL binding expression, such as `#{backing_bean.cancelButton_action}`.

In [Example 18-4](#), control passes to `destinationActivity` only if `outcome` is returned from `actionmethod`.

The value in `from-action` applies only to a control flow originating from a view activity, not from any other activity types. Wildcards are not supported in `from-action`.

- `from-outcome`: Identifies a control flow case that will be followed based on a specific originating activity outcome. All possible originating activity outcomes should be accommodated with control flow cases.

If you leave both the `from-action` and the `from-outcome` elements empty, the case applies to all outcomes not identified in any other control flow cases defined for the activity, thus creating a default case for the activity. Wildcards are not supported in `from-outcome`.

- `to-activity-id`: A mandatory element that contains the complete identifier of the activity to which the navigation is routed if the control flow case is performed. Each control flow case can specify a different `to-activity-id`.

- `if`: An optional element that accepts an EL expression as a value. If the EL expression evaluates to `true` at runtime, control flow passes to the activity identified by the `to-activity-id` element.

18.4.4 What Happens at Runtime: Evaluating Control Flow Rules

At runtime, ADF Controller evaluates control flow rules from the most specific to the least specific match to determine the next transition between activities. Evaluation is based on the following priority, which is similar to that for JSF navigation rules:

1. `from-activity-id`, `from-action`, `from-outcome`
2. `from-activity-id`, `from-outcome`
3. `from-activity-id`

ADF Controller first searches for a match in all three elements: `from-activity-id`, `from-action`, and `from-outcome`. If there is no match, ADF Controller searches for a match in just the `from-activity-id` and `from-outcome` elements. Finally, ADF Controller searches for a match in the `from-activity-id` element alone.

If ADF Controller cannot find a control flow rule within its metadata to match a request, it allows the standard JSF navigation handler to find a match.

The unbounded task flow can have more than one ADF Controller XML source file. Because control flow rules can be defined in more than one ADF Controller XML source file, similar rules may be defined in different files. If there is a conflict in which two or more cases have the same `from-activity-id`, and the same `from-action` or `from-outcome` values, the last case (as listed in the `adfc-config.xml`, bootstrap, or bounded task flow source file) is used. If the conflict is among rules defined in different source files, the rule in the last source file to be loaded is used.

ADF Controller also implements the following interface with a number of restrictions:

```
javax.faces.application.ConfigurableNavigationHandler
```

The restrictions are:

- The `Map` object returned by `getNavigationCases()` is not modifiable. Any runtime changes to control flow rules must be made with the customization features provided with the MDS framework. For more information, see [Chapter 39, "Customizing Applications with MDS."](#)
- Do not invoke the `performNavigation()` method after the JSF Invoke Application phase. This is to make sure that the view ID does not change between the ADF Prepare Render phase and the JSF Render Response phase. For more information about how the JSF and ADF phases integrate in the lifecycle of a page request, see [Chapter 25, "Understanding the Fusion Page Lifecycle."](#)
- The metadata values for a task flow view activity's bookmark and redirect properties populate the corresponding information for the navigation case objects returned by the `getNavigationCases()`.

18.5 Testing Task Flows

The procedure for running and debugging task flows differs depending on whether the task flow is bounded or unbounded, whether it contains pages or page fragments, or whether it accepts input parameters.

JDeveloper and Oracle ADF provides a number of features that facilitate your testing of the task flows that you create. Among these is the ability to set ADF declarative

breakpoints on task flow activities. For more information, see [Section 36.9.1, "How to Set and Use Task Flow Activity Breakpoints."](#) In addition, you can also modify a task flow's metadata for an application that is currently executing in the Integrated WebLogic Server. The changes that you make to the task flow can be deployed to the application without stopping the application and redeploying it to the Integrated WebLogic Server (also known as *hot reloading*). To do this, you invoke the make command on the modified task flow (right-click the task flow and select **Make** from the context menu that appears). This deploys the modified task flow to the application executing in the Integrated WebLogic Server. For more information about hot reloading, see the [Section 36.4, "Reloading Oracle ADF Metadata in Integrated WebLogic Server."](#)

The Configure Default Domain dialog displays the first time you run your application and start a new domain in Integrated WebLogic Server. Use the dialog to define an administrator password for the new domain. Passwords you enter can be eight characters or more and must have a numeric character.

18.5.1 How to Run a Bounded Task Flow That Contains Pages

You can run or debug a bounded task flow that contains view activities that are pages. For information on running a bounded task flow that contains view activities that are page fragments, see [Section 18.5.2, "How to Run a Bounded Task Flow That Uses Page Fragments"](#).

Note: You can select a view activity inside a task flow diagram or the Application Navigator and choose **Run** to run a bounded task flow.

In a bounded task flow, you must designate the view as a default activity and run the task flow from the Application Navigator. For more information, see [Section 18.2.3, "What You May Need to Know About the Default Activity in a Bounded Task Flow"](#).

If the first activity that runs in the task flow is an activity type other than view, you must use a bounded task flow.

Before you begin:

It may be helpful to have an understanding of the factors that affect how you test a task flow. For more information, see [Section 18.5, "Testing Task Flows."](#)

You may also find it helpful to understand functionality that can be added using other task flow features. For more information, see [Section 18.1.5, "Additional Functionality for ADF Task Flows."](#)

To run or debug a bounded task flow that uses pages:

- In the task flow diagram, right-click the task flow and choose either **Run** or **Debug**.
- You can also run the task flow directly by entering its URL in the browser. For example:

```
http://somecompany.com/internalApp/MyApp/faces/adf.task-flow?
adf.tfId=displayHelp&adf.tfDoc=%2FWEB-INF%2Fdisplayhelp.xml&t
opic=createPurchaseOrder
```

For more information, see [Section 19.6.6, "What You May Need to Know About Calling a Bounded Task Flow Using a URL."](#)

- You can right-click the bounded task flow in the Application Navigator and choose either **Run** or **Debug**.

18.5.2 How to Run a Bounded Task Flow That Uses Page Fragments

Bounded task flows that use page fragments are intended to run only within an ADF region. A *page fragment* is a JSF document that renders as content in another JSF page. For more information, see [Section 21.1.1, "About Page Fragments and ADF Regions"](#).

Before you begin:

It may help to understand what factors affect how you test a task flow. For more information, see [Section 18.5, "Testing Task Flows."](#)

You may also find it helpful to understand functionality that can be added using other task flow features. For more information, see [Section 18.1.5, "Additional Functionality for ADF Task Flows."](#)

To run or debug a bounded task flow that uses page fragments:

1. If you have not done so already, create a JSF page containing a region that binds to the bounded task flow. JDeveloper automatically creates the region for you in a JSF page when you drop a bounded task flow containing page fragments on a page. For more information about creating regions, see [Section 21.2, "Creating an ADF Region."](#)
2. Create a view activity in the project's unbounded task flow that refers to the page. See [Section 18.3.1, "How to Add an Activity to a Task Flow"](#) for more information.
3. Right-click the view activity in the Application Navigator or in the task flow diagram and choose **Run**.

18.5.3 How to Run a Bounded Task Flow That Has Parameters

Before you run a bounded task flow with parameters, you must first run a bounded task flow containing pages. For more information about bounded task flow input parameters, see [Chapter 20, "Using Parameters in Task Flows"](#).

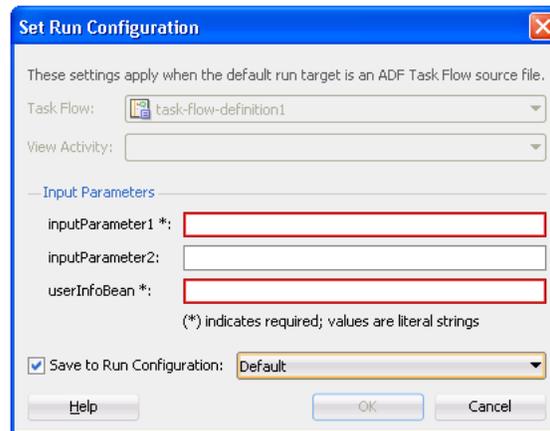

Before you begin:

It may be helpful to have an understanding of the factors that affect how you test a task flow. For more information, see [Section 18.5, "Testing Task Flows."](#)

You may also find it helpful to understand functionality that can be added using other task flow features. For more information, see [Section 18.1.5, "Additional Functionality for ADF Task Flows."](#)

To run a bounded task flow that has input parameter definitions:

1. If the bounded task flow has defined input parameters, the Set Run Configuration dialog displays after you select either **Run** or **Debug**, as shown in [Figure 18–17](#).

Figure 18–17 Set Run Configuration dialog

2. In the **Input Parameters** list, enter values that you want to be passed as input parameters to the task flow. If you do not specify a value, the input parameter is not used when calling the bounded task flow.

Each required input parameter in the list displays with an asterisk, as shown in [Figure 18–17](#). You must specify the parameter value as a literal string. You cannot specify an EL expression.

3. Click **OK**.

18.5.4 How to Run a JSF Page When Testing a Task Flow

You can run a JSF page by right-clicking the page in the Application Navigator and choosing **Run**. However, if the page contains navigation UI components, such as a button or link, navigation is not guaranteed to work.

Before you begin:

It may be helpful to have an understanding of the factors that affect how you test a task flow. For more information, see [Section 18.5, "Testing Task Flows."](#)

You may also find it helpful to understand functionality that can be added using other task flow features. For more information, see [Section 18.1.5, "Additional Functionality for ADF Task Flows."](#)

To run a JSF Page with fully functioning navigation:

1. Create a bounded or unbounded task flow. See [Section 18.2.1, "How to Create a Task Flow"](#) for more information.
2. Add a view activity to the task flow. See [Section 18.3.1, "How to Add an Activity to a Task Flow"](#) for more information.
3. In the Application Navigator, select the JSF page you want to run and drop it on top of the view activity in the task flow diagram.
This associates the view activity with the JSF page.
4. In the diagram, right-click the view activity and choose **Run**.

18.5.5 How to Run the Unbounded Task Flow

To run or debug the unbounded task flow, you select a specific view activity with which to start the unbounded task flow.

Before you begin:

It may be helpful to have an understanding of the factors that affect how you test a task flow. For more information, see [Section 18.5, "Testing Task Flows."](#)

You may also find it helpful to understand functionality that can be added using other task flow features. For more information, see [Section 18.1.5, "Additional Functionality for ADF Task Flows."](#)

To run a view activity in the unbounded task flow:

- In the task flow diagram, right-click the view activity and choose either **Run** or **Debug**.
The unbounded task flow runs beginning with the selected view activity.
- If you have selected something other than a single view activity (or have nothing selected), you are prompted to select one in the Set Run Configuration dialog.

18.5.6 How to Set a Run Configuration for a Project

A *run configuration* contains settings that determine how projects run, such as specifying the first activity to run in a task flow. You can define one or more run configurations for a project. Within a run configuration, you can designate an ADF Controller source file as the default run target. When you run the project, the source file is the first to run.

Before you begin:

It may be helpful to have an understanding of the factors that affect how you test a task flow. For more information, see [Section 18.5, "Testing Task Flows."](#)

You may also find it helpful to understand functionality that can be added using other task flow features. For more information, see [Section 18.1.5, "Additional Functionality for ADF Task Flows."](#)

To define a default task flow run target:

1. Select the project in the Application Navigator.
2. From the main menu, choose **Run > Choose Active Run Configuration > Manage Run Configurations**.
3. In the Manage Run Configurations dialog, choose **Run/Debug/Profile** and choose **New**.
4. In the New dialog, enter the name for the new run configuration.
5. If you want to base the new configuration on an existing one, choose a configuration in the **Copy Settings From** dropdown list.
6. Click **OK** to exit the dialog.
7. Click **Edit**.
8. In the **Default Run Target** field in the Edit Run Configuration dialog, specify a source file for the task flow that should run first when you run the project.
Once you choose a task flow, you can set a view activity (for the unbounded task flow) or input parameters (for bounded task flows).
9. In the left panel of the Edit Configuration dialog, click **ADF Task Flow**.
10. In the **Task Flow** dropdown list, located on the right panel, select the task flow containing the run target.

11. If you are running the unbounded task flow, the Edit Run Configuration dialog displays the **Run Target Activity** list. Select the view activity that will run first in the application.

12. Click **Open**.

The next time you run the project, the saved run configuration will be available in the **Run > Choose Active Run Configuration** menu.

If you are running a bounded task flow that has been set up to accept input parameters, a dialog will display a section for specifying values for all input parameters defined for the bounded task flow. See [Chapter 18.5.3, "How to Run a Bounded Task Flow That Has Parameters"](#) for more information.

18.6 Refactoring to Create New Task Flows and Task Flow Templates

You can convert existing activities, JSF page flows, and JSF pages into new ADF Controller components such as bounded task flows and task flow templates.

18.6.1 How to Create a Bounded Task Flow from Selected Activities

You can create a new bounded task flow based on activities you select in an existing bounded or unbounded task flow.

Before you begin:

It may be helpful to have an understanding of the factors that affect how you refactor a task flow. For more information, see [Section 18.6, "Refactoring to Create New Task Flows and Task Flow Templates."](#)

You may also find it helpful to understand functionality that can be added using other task flow features. For more information, see [Section 18.1.5, "Additional Functionality for ADF Task Flows."](#)

To create a new bounded task flow from selected activities:

1. In the Application Navigator, double-click the source file for the unbounded or bounded task flow containing the activities you want to extract to a new bounded task flow.
2. In the task flow diagram, select one or more activities.

Tip: To select multiple activities in a diagram, click the left mouse button and drag the cursor over the activities.

You can also press the Ctrl key while selecting each activity.

3. Right-click your selection and choose **Extract Task Flow** from the context menu that appears.

The Extract Bounded Task Flow dialog displays. This dialog allows you to specify the file name and directory location for the new bounded task flow. For more information, see [Section 18.2, "Creating a Task Flow"](#).

The new bounded task flow displays in the task flow diagram. [Table 18-5](#) describes the properties that JDeveloper automatically sets for the new bounded task flow.

Table 18–5 Properties Updated in the New Bounded Task Flow

Property	Value
Task flow definition ID	Value you entered in the File Name field in the Extract Bounded Task Flow dialog.
Default activity	Determined as the destination of all incoming control flow cases. If more than one destination exists, an error is flagged and the entire operation is rolled back.
Control flow rules	Control flow cases with selected source activities are included in the new bounded task. A <i>source activity</i> is an activity from which a control flow leads. The new bounded task flow includes the following types of control flow cases: <ul style="list-style-type: none"> ■ Both the source and target activities in the control flow case were selected to create the new task flow. ■ Only the source activity was selected to create the new task flow. Destinations are changed to the corresponding new task flow return activities added for each outcome.

The following changes automatically occur in the originating task flow (the task flow containing the activities you selected as the basis for the new task flow):

- A new task flow call activity is added to the originating task flow. The task flow call activity calls the new bounded task flow.
- The selected activities are removed from the originating task flow.
- Existing control flow cases associated with the activities you selected are removed from the originating task flow. They are replaced with new control flow cases:
 - An incoming control flow case to the old activity is redirected to the new task flow call activity.
 - An outgoing control flow case from the old activity is redirected from the new task flow call activity.

18.6.2 How to Create a Task Flow from JSF Pages

You can create a new bounded task flow based on selected pages in a JSF page flow. JDeveloper converts the JSF pages that are part of a flow (that is, those that are linked by JSF navigation cases) to view activities in the new task flow.

Before you begin:

It may be helpful to have an understanding of the factors that affect how you refactor a task flow. For more information, see [Section 18.6, "Refactoring to Create New Task Flows and Task Flow Templates."](#)

You may also find it helpful to understand functionality that can be added using other task flow features. For more information, see [Section 18.1.5, "Additional Functionality for ADF Task Flows."](#)

To create a new task flow from selected JSF pages in a page flow.

1. In the Application Navigator, double-click the source file for the page flow containing the pages you want to use in the new bounded task flow.
2. In the task flow diagram, select one or more JSF pages.

Tip: To select multiple elements in a diagram, click the left mouse button and drag the cursor over the elements.

You can also press the Ctrl key while selecting each element.

3. Right-click your selection and choose **Generate ADF Task Flow**.

The Create Task Flow dialog displays, which allows you to create a new unbounded or bounded task flow. For more information, see [Section 18.2, "Creating a Task Flow"](#).

18.6.3 How to Convert Bounded Task Flows

You can convert an existing bounded task flow to an unbounded task flow or change whether the views it contains are pages or page fragments. [Table 18–6](#) describes the results of each conversion.

Table 18–6 *Converting Bounded Task Flows*

Conversion	Result
Bounded task flow to unbounded task flow	Loses all metadata not valid for unbounded task flows, such as parameter definitions and transactions.
Bounded task flow to use JSF pages	Converts page fragments associated with any view activities in the task flow to JSF pages. Old page fragments are saved if you select the Keep Page Fragment checkbox. New JSF page names default to the name of the old page fragment.
Bounded task flow to use page fragments	Converts all pages associated with view activities in the bounded task flow to page fragments. Old pages are saved if you select the Keep Page checkbox. New page fragment names default to the name of the old page.

Before you begin:

It may be helpful to have an understanding of the factors that affect how you refactor a task flow. For more information, see [Section 18.6, "Refactoring to Create New Task Flows and Task Flow Templates."](#)

You may also find it helpful to understand functionality that can be added using other task flow features. For more information, see [Section 18.1.5, "Additional Functionality for ADF Task Flows."](#)

To convert a bounded task flow:

1. In the Application Navigator, double-click the source file for the bounded task flow that you want to convert.
2. In the task flow diagram, right-click anywhere other than on an activity or control flow.
3. Choose the appropriate menu option:
 - **Convert to Unbounded Task Flow**
 - **Convert to Task Flow with Page Fragments**
 - **Convert to Task Flow with Pages**

18.7 What You Should Know About Task Flow Constraints

[Table 18–7](#) summarizes assumptions about and constraints for using task flows, activities, and other associated ADF Controller features.

Table 18–7 ADF Controller Features Assumptions and Constraints

Feature Area	Assumption/Constraint	Description
ADF Controller objects and diagram UI	JSF view layer	ADF Controller operates in a JSF environment. Oracle's web-based Fusion web application strategy focuses on JSF as the sole view layer technology.
	Dependent on Oracle ADF Faces	ADF Controller extensions are implemented on top of Oracle ADF Faces. They are dependent on the ADF Faces libraries, but ADF Controller can run against any JSF implementation, providing these libraries are present.
	Navigation and state management encapsulated	ADF Controller encapsulates both navigation and, to some extent, state management. JSF and the Servlet API are still available for the basic management of state at the application, session, and request levels.
	Model layer	ADF model layer is used to implement the application's model layer.
	Dependent on MDS	ADF Controller metadata is stored in MDS. However, MDS is currently not capable of loading <code>faces-config.xml</code> . If the customization features that MDS provides are required, you should use ADF task flows exclusively in order to define managed beans and control flow rules.
	No supported migration path from struts or model 1	There is no support for a migration from Struts or Model 1 to the Fusion ADF Controller. However, you can create a new ADF bounded task flow based on selected pages in a JSF page flow. For more information, see Section 18.6.2, "How to Create a Task Flow from JSF Pages" .
Bounded task flow	Exposed as page flow-scoped state	ADF Controller manages implementation of a page flow scoped-state. Any auto-management functions provided by the framework, such as back button support and state cleanup function, assume page flow-scoped data. In order for an application to fully implement such functions for all of its pages, the entire application should be exposed as an ADF bounded task flow, using nested bounded task flows as needed. The application should store any state requiring versioning within the page flow scope.
	Transactional boundaries	The developer will use ADF bounded task flows to manage transaction boundaries.

Table 18–7 (Cont.) ADF Controller Features Assumptions and Constraints

Feature Area	Assumption/ Constraint	Description
Page flow scope	Access availability within ADF lifecycle	<p>An application cannot attempt to access the page flow scope early in the ADF lifecycle before ADF Controller is ready to provide it.</p> <p>Page flow scope is not guaranteed to be available for access until after Before and After listeners have executed on the Restore View phase. ADF Controller uses before and after listeners on the Restore View phase to synchronize the server side state with the request. This is where things such as browser back-button detection and bookmark dereference are handled.</p>
Navigation	Navigation	<p>When using ADF Controller task flows, perform all application navigation should be performed using ADF Controller control flow rules instead of using navigation rules in <code>faces-config.xml</code>.</p> <p>Although the ADF Controller delegates navigation handling when no matching control flow cases are found in ADF Controller metadata, not all ADF Controller functionality is guaranteed to work correctly if navigation is performed by a non-ADF Controller <code>NavigationHandler</code>.</p>

Working with Task Flow Activities

This chapter describes how to use activities in your task flows. The chapter contains detailed information about each task flow activity that displays in the Component Palette and its properties.

This chapter includes the following sections:

- [Section 19.1, "About Task Flow Activities"](#)
- [Section 19.2, "Using View Activities"](#)
- [Section 19.3, "Using URL View Activities"](#)
- [Section 19.4, "Using Router Activities"](#)
- [Section 19.5, "Using Method Call Activities"](#)
- [Section 19.6, "Using Task Flow Call Activities"](#)
- [Section 19.7, "Using Task Flow Return Activities"](#)
- [Section 19.8, "Using Save Point Restore Activities"](#)
- [Section 19.9, "Using Parent Action Activities"](#)
- [Section 19.10, "Using Task Flow Activities with Page Definition Files"](#)

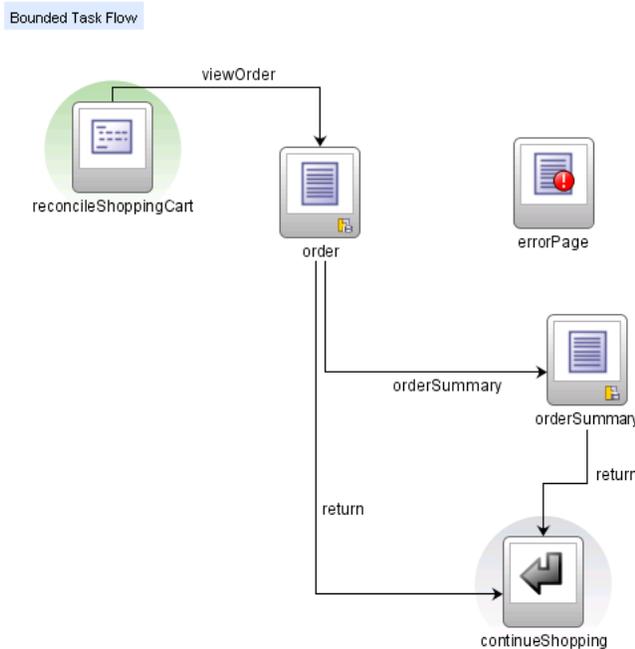

19.1 About Task Flow Activities

An *activity* represents a piece of work that is performed when the task flow runs. It displays in the task flow's diagram editor as a node. You can add most activities to both bounded and unbounded task flows, although some activity types can be added only to a bounded task flow.

The bounded task flow shown in [Figure 19-1](#) contains activities that run in order to check out a user from the shopping application:

1. A call to a method synchronizes the items a user may have chosen before logging in with those selected after logging in
2. A page (view activity) that displays the items the user has currently selected and another page that summarizes the order
3. An activity that causes control to return back to the calling unbounded task flow shown in [Figure 19-1](#)

Figure 19–1 Checkout Bounded Task Flow in Fusion Order Demo Application

A task flow consists of activities and control flow cases that define the transitions between activities. Table 19–1 describes the types of activities and control flows you can add to a task flow by dragging and dropping from the Component Palette.

Table 19–1 Task Flow Activities and Control Flows

Icon	Component Name	Description
	Method Call	Invokes a method, typically a method on a managed bean. A method call activity can be placed anywhere within an application’s control flow to invoke application logic based on control flow rules. See Section 19.5, "Using Method Call Activities" for more information.
	Parent Action	Allows a bounded task flow to generate outcomes that are passed to its parent view activity. See Section 19.9, "Using Parent Action Activities" for more information.
	Router	Evaluates an EL expression and returns an outcome based on the value of the expression. For example, a router in a credit check task flow might evaluate the return value from a previous method call and generate success, failure, or retry outcomes based on various cases. These outcomes can then be used to route control to other activities in the task flow. See Section 19.4, "Using Router Activities" for more information.
	Save Point Restore	Restores a previous persistent save point, including application state and data, in an application supporting save for later functionality. See Section 22.6, "Using Save Points in Task Flows" for more information.

Table 19–1 (Cont.) Task Flow Activities and Control Flows

Icon	Component Name	Description
	Task Flow Call	Calls a bounded task flow from the unbounded task flow or another bounded task flow. See Section 19.6, "Using Task Flow Call Activities" for more information.
	Task Flow Return	Identifies when a bounded task flow completes and sends control flow back to the caller. (Available for bounded task flows only). See Section 19.7, "Using Task Flow Return Activities" for more information.
	URL View	Redirects the root view port (for example, a browser page) to any URL-addressable resource, even from within the context of an ADF region. See Section 19.3, "Using URL View Activities" for more information.
	View	Displays a JSF page or page fragment. Multiple view activities can represent the same page or same page fragment. See Section 19.2, "Using View Activities" for more information. See Section 24.3, "Creating a Web Page" for more information about pages and page fragments.
	Control Flow Case	Identifies how control passes from one activity to the next in the application. See Section 18.1.3, "About Control Flows" for more information.
	Wildcard Control Flow Rule	Represents a control flow case that can originate from any activities whose IDs match a wildcard expression. For example, it can represent a control case <code>from-activity-id</code> containing a trailing wildcard such as <code>foo*</code> . See Section 18.4.2, "How to Add a Wildcard Control Flow Rule" for more information.

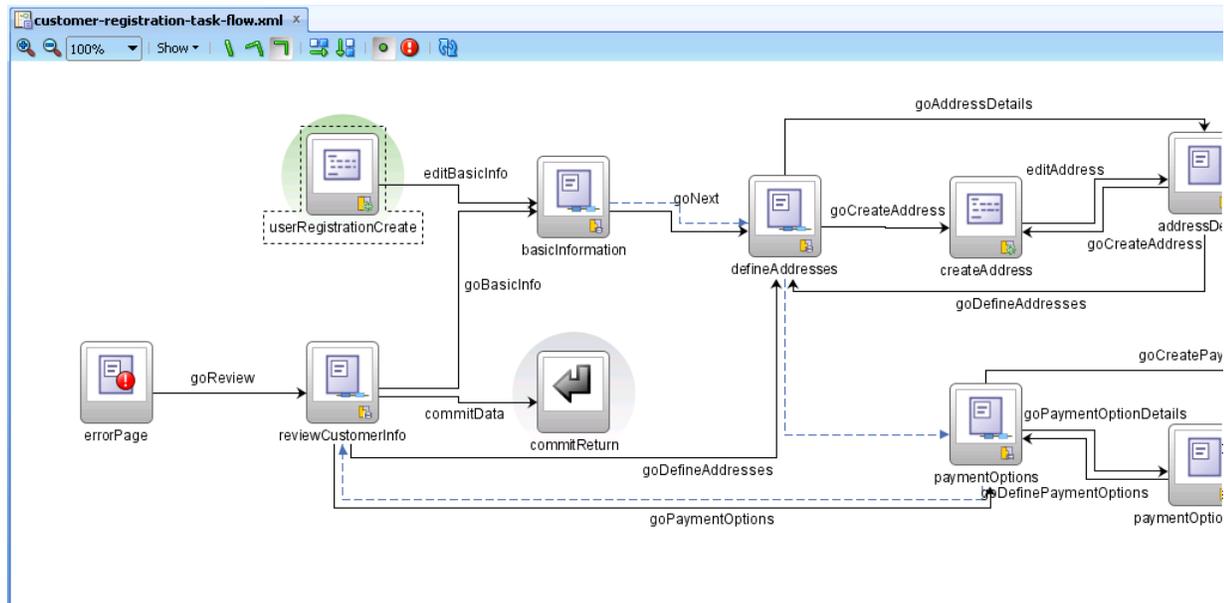

[Table 19–2](#) describes the annotations (notes and attachments) you can add to a task flow.

Table 19–2 Task Flow Diagram Annotations

Icon	Icon Name	Description
	Note	Adds a note to the task flow diagram. You can select the note in the diagram to add or edit text.
	Note Attachment	Attaches an existing note to an activity or a control flow case in the diagram.

19.1.1 Task Flow Activities Use Cases and Examples

[Figure 19–2](#) shows the diagram for the customer registration task flow in the Fusion Order Demo application. This task flow uses many of the activities that a bounded task flow supports in order to register a customer. For more information about the Fusion Order Demo application, see [Chapter 2, "Introduction to the ADF Sample Application."](#)

Figure 19–2 Customer Registration Task Flow

19.1.2 Additional Functionality for Task Flow Activities

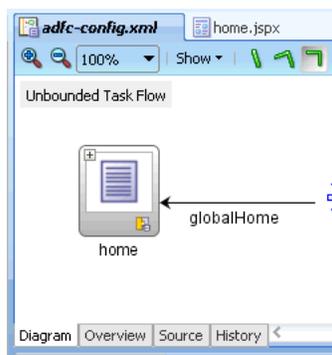

You may find it helpful to understand other ADF features before you configure or use task flow activities. Additionally, you may want to read about what you can do with your configured task flows. Following are links to other functionality that may be of interest.

- Task flows can invoke managed beans. For more information about managed beans, see [Section 24.4, "Using a Managed Bean in a Fusion Web Application."](#)
- Bounded task flows can be secured by defining the privileges that are required for someone to use them. For more information, see [Section 35, "Enabling ADF Security in a Fusion Web Application."](#)
- Bounded task flows can be packaged in ADF Library JARs. For more information, see [Section 38.3, "Packaging a Reusable ADF Component into an ADF Library."](#)
- Task flow activities can be associated with page definition files. For more information about page definition files, see [Section 13.7, "Working with Page Definition Files."](#)

19.2 Using View Activities

One of the primary types of task flow activity is the view activity. A view activity displays a JSF page or page fragment. A *page fragment* is a JSF document that renders as content in another JSF page. Page fragments are typically used in bounded task flows that can be added to a JSF page as a region, as described in [Section 21.2, "Creating an ADF Region."](#)

[Figure 19–3](#) shows the home view activity in the Fusion Order Demo application.

Figure 19–3 View Activity

Tip: Click the + icon in the upper-left part of the view activity to see a thumbnail preview of the referenced page or page fragment.

XML metadata in the source file of the task flow associates a view activity with a physical JSF page or page fragment. An `id` attribute identifies the view activity. The `<page>` element identifies the page or page fragment's file name. [Example 19–1](#) shows the metadata that corresponds to the view activity in [Figure 19–3](#):

Example 19–1 Metadata for a View Activity

```
<view id="home">
  <page>/home.jspx</page>
</view>
```

The view activity ID and page name do not have to be the same.

The steps for adding a view activity to a task flow are the same as those for adding any activity to a task flow diagram. For more information, see [Section 18.3.1, "How to Add an Activity to a Task Flow."](#) After you add the view activity, you can double-click it to display a wizard that allows you to create a new page or page fragment. The wizard allows you to choose between one of the following two document types for the JSF page or page fragments that you create:

- **Facelets**
The file extension for pages in this document type is `.jsf` and `.jsff` for page fragments.
- **JSP XML**
The file extension for pages in this document type is `.jspx` and `.jsff` for page fragments.

Use one document type only in your task flows. For example, do not use the Facelets document type for view activities in one task flow and the JSP XML document type for view activities in another task flow. For more information about the document types, see [Section 1.3.7, "Implementing the User Interface with JSF."](#)

You also use the wizard to choose the page layout for the page or page fragment that you create. For more information about page layouts, see the "Using Quick Start Layouts" section in the *Oracle Fusion Middleware Web User Interface Developer's Guide for Oracle Application Development Framework*. In addition, you can specify whether or not to automatically expose UI components on the page or page fragment in a managed bean. For more information, see [Section 24.4, "Using a Managed Bean in a Fusion Web Application."](#)

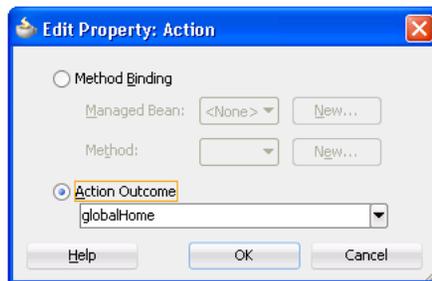

After you complete the wizard, JDeveloper automatically associates the completed page or page fragment with the view activity. As an alternative to using the wizard, you can associate a page or page fragment with a view activity by dragging an existing page or page fragment from the Application Navigator and dropping it on top of an existing view activity. If no view activity exists, drag a page or page fragment to any other location on the diagram. When you drop the page or page fragment, JDeveloper automatically creates a new view activity associated with the page or page fragment. During creation, a default `id` for the view activity is automatically generated (for example `Home`) based on the name of the page or page fragment.

19.2.1 Passing Control Between View Activities

You can configure view activities in your task flow to pass control to each other at runtime. For example, to pass control from one view activity (view activity A) to a second view activity (view activity B), you could configure a command component (a button or a link) on the page associated with view activity A. Set the command component's **Action** attribute to the control flow case `from-outcome` that corresponds to the task flow activity that you want to invoke (in our example, view activity B). At runtime, the end user initiates the control flow case by invoking the command component. You can navigate from a view activity to another activity using either a constant or dynamic value on the **Action** attribute of the UI component.

A constant value of the component's **Action** attribute is an action outcome, as shown in [Figure 19-4](#), that always triggers the same control flow case. When an end user clicks the component, the activity specified in the control flow case is performed. There are no alternative control flows.

Figure 19-4 Edit Property dialog

A dynamic value of the component's **Action** attribute is bound to a managed bean or a method. The value returned by the method binding determines the next control flow case to invoke. For example, a method might verify user input on a page and return one value if the input is valid and another value if the input is invalid. Each of these different action values trigger different navigation cases, causing the application to navigate to one of two possible target pages.

You can also write an EL expression that must evaluate to `true` before control passes to the target view activity. You write the EL expression as a value for the `<if>` child element of the control flow case in the task flow. For more information, see [Section 18.4.1, "How to Add a Control Flow Rule to a Task Flow."](#)

19.2.1.1 How to Pass Control Between View Activities

You pass control to a view activity by specifying the value of the control flow case's `from-outcome` attribute as the value for the `action` attribute of the command component.

Before you begin:

It may be helpful to have an understanding of the options that are available to you when you configure the passing of control between view activities. For more information, see [Section 19.2.1, "Passing Control Between View Activities."](#)

You may also find it helpful to understand functionality that can be added using other ADF features. For more information, see [Section 19.1.2, "Additional Functionality for Task Flow Activities."](#)

The following procedure assumes that you have already created a:

- Target view activity to receive control after an end user invokes the command component at runtime
- Page that hosts a command component for the end user to invoke at runtime

To pass control to a view activity:

1. Add a UI component to the JSF page using one of the following techniques:
 - Open the JSF page. In the ADF Faces page of the Component Palette, from the General Controls panel, drag a navigation UI component, such as **Button**, and drop it on the page.
 - Open the JSF page. From the Data Controls panel, drag and drop an operation or a method onto the JSF page and choose **Rich Command Button** or **Rich Command Link** from the context menu.
2. Select the UI component and open the Property Inspector.
3. On the Common page, expand the **Button Action** section.
4. From the **Action** dropdown menu, choose **Edit**.
5. Select **Action Outcome**.
6. From the **Action Outcome** dropdown list select a value.

The list contains control flow case `from-outcomes` already defined for the view activity associated with the page.

Tips: The `action` attribute of the UI component can be bound either to a literal string to hardcode a navigation case, or it can be bound to a method binding expression that points to a method, which takes no arguments and returns a String. It can't be bound to any other type of EL expression.

7. Click **OK**.

19.2.1.2 What Happens When You Pass Control Between View Activities

[Example 19-2](#) contains an example of a control flow case defined in the XML source file for a bounded or unbounded task flow.

Example 19-2 Control Flow Case Defined in XML Source File

```
<control-flow-rule>
  <from-activity-id>Start</from-activity-id>
  <control-flow-case>
    <from-outcome>toOffices</from-outcome>
    <to-activity-id>WesternOffices</to-activity-id>
  </control-flow-case>
</control-flow-rule>
```

As shown in [Example 19–3](#), a button on a JSF page associated with the Start view activity specifies `toOffices` as the **action** attribute. When the user clicks the button, control flow passes to the `WesternOffices` activity specified as the `to-activity-id` in the control flow metadata.

Example 19–3 Static Navigation Button Defined in a View Activity

```
<af:commandButton text="Go" action="toOffices">
```

19.2.2 Bookmarking View Activities

Bookmarking is available only for view activities within unbounded task flows.

When an end user bookmarks a page associated with a view activity, the URL that displays in the browser’s address field for the view is saved as the bookmark. In most cases, this URL cannot be used to redisplay the page associated with the view. For example, the URL may contain Microsoft OS Windows state information that cannot be used to redisplay the page.

The bookmark URL should contain information that enables dynamic content on the page to be reproduced. For example, if an end user bookmarks a page displaying a customer's contact information, the bookmark URL needs to contain not only the page but also some identifier for the customer. This will enable contact information for the same customer to display when he returns to the page using the bookmark.

To ensure that the URL for a page displayed in a browser can be used as a bookmark, identify the view activity associated with the page as bookmarkable.

At runtime, you can identify if a view activity within the unbounded task flow has been designated as bookmarkable using the `ViewBookmarkable()` method. The method is located off the view port context.

After you designate a view activity as bookmarkable, you can optionally specify one or more URL parameters. The value of `url-parameter` is an EL expression. The EL expression specifies where the parameters that will be included in the URL are retrieved when the bookmarkable URL is generated. The EL expression also stores a value from the URL when the bookmarkable URL is dereferenced. The `converter` option identifies a method that performs conversion and validation when parameters are passed via bookmarkable view activity URLs.

In addition, you can specify an optional method that is invoked after updating the application model with submitted URL parameter values and before rendering the view activity. You can use this method to retrieve additional information based on URL parameter key values.

[Example 19–4](#) contains the URL syntax for a bookmarked view activity.

Example 19–4 Unbounded Task Flow View Activity URL Syntax

```
<server root>/<app_context>/faces/<view activity id>?<param name>=<param value>&...
```

The syntax of the URL for the bookmarked view activity is:

- `<server root>`: Provided by customization at site or admin level, for example, `http://mycompany.com/internalApp`.

- `<app context>`: The web application context root, for example, `myapp`. The context root is the base path of a web application. For example, `<app_context>` maps to the physical location of the WEB-INF node on the server.
- `faces`: The faces servlet mapping. The value in `faces` points to the node containing the `faces-config.xml` configuration file.
- `<view activity id>`: The identifier for the bookmarked view activity, for example, `edit-customers`.
- `<param name>`: The name of the bookmarked view activity URL parameter, for example, `customer-id`.
- `<param value>`: The parameter value, derived from an EL expression, for example, `#{pageFlowScope.employee.id}`. The value of the EL expression must be capable of being represented as a string.

[Example 19-5](#) contains a sample URL for a bookmarkable view activity in an unbounded task flow.

Example 19-5 Sample URL for Bookmarkable View Activity

`http://mycompany.com/internalApp/MyApp/faces/edit-customers?customer-id=1234&...`

19.2.2.1 How to Create a Bookmarkable View Activity

To create a bookmarkable view activity, designate a view activity as bookmarkable, specify a URL parameter in the bookmark, and specify a method that is executed after the bookmark is dereferenced.

Before you begin:

It may be helpful to have an understanding of the syntax required to create a bookmarkable view activity. For more information, see [Section 19.2.2, "Bookmarking View Activities."](#)

You may also find it helpful to understand functionality that uses other task flow features. [Section 19.1.2, "Additional Functionality for Task Flow Activities."](#)

To designate a view activity as bookmarkable:

1. In the unbounded task flow diagram, select the view activity.
2. In the Property Inspector, click **Bookmark**.
3. In the **bookmark** dropdown list, select **true**.
4. Expand the **URL Parameters** section to add optional URL parameters that will be included in the URL for the bookmarked view activity:
 - **name**: A name for the parameter.
 - **value**: A settable EL expression that, when evaluated, specifies the parameter value, for example, `#{pageFlowScope.employeeID}`. The value must be capable of being represented as a string.
 - **converter**: (optional): An EL expression to an object that implements `oracle.adf.controller.URLParameterConverter`.

The **value** is where the parameters that will be included in the URL are retrieved from when the bookmarkable URL is generated. In addition, parameters are stored here when the bookmarkable URL is dereferenced.

If the EL expression entered in value returns `NULL`, the parameter is omitted from the bookmarked view activity URL.

The **name** and **value** are used to append a bookmark parameter to the view activity URL, as shown in [Example 19-5](#).

5. In the **converter** field, you can enter an optional value binding to use for each bookmark URL parameter value, for example, `#{pageFlowScope.employee.idConverter}`.

A URL parameter converter's `getAsObject()` method takes a single string value as its input parameter and returns an object of the appropriate type. ADF Controller invokes the converter method on the URL parameters before applying the parameter value to the application's model objects. Similarly, the converter's `getAsString()` method takes an object as its input parameter and returns a string representation that is used on the URL.

In a JSF application, data values are converted and validated using the converters and validators specified with the UI components on the submitting page. In a Fusion web application using a bookmark URL, there is no submitting page to handle the conversion and validation. Therefore, you have the option of designating a converter to use for each URL parameter.

19.2.2.2 What Happens When You Designate a View as Bookmarkable

When you designate a view activity as bookmarkable, a bookmark element is added to the metadata for the view activity, as shown in [Example 19-6](#). The bookmark element can optionally contain metadata specifying URL parameters and a method that is executed after the bookmark is dereferenced.

Example 19-6 Sample Metadata for a Bookmarkable View Activity

```
<view id="employee-view">
  <page>/folderA/folderB/display-employee-info.jsp</page>
  <bookmark>
    <url-parameter>
      <name>employee-id</name>
      <value>#{pageFlowScope.employee.id}</value>
      <converter>#{pageFlowScope.employee.validateId}</converter>
    </url-parameter>
    <method>#{pageFlowScope.employee.queryData}</method>
  </bookmark>
</view>
```

19.2.3 Specifying HTTP Redirect for a View Activity

You can configure a view activity so that it redirects at runtime to a URL in response to a client request. This causes ADF Controller to create a new browser URL for the view activity. The original URL for the view activity is no longer used. You cannot configure HTTP redirect for a view activity if you have already made the view activity bookmarkable, as described in [Section 19.2.2, "Bookmarking View Activities."](#)

19.2.3.1 How to Specify HTTP Redirect for a View Activity

You set a view activity's `redirect` property to `true`.

Before you begin:

It may be helpful to have an understanding of the affect of setting a view activity's `redirect` property to `true`. For more information, see [Section 19.2.3, "Specifying HTTP Redirect for a View Activity."](#)

You may also find it helpful to understand functionality that can be added using other task flow features. For more information, see [Section 19.1.2, "Additional Functionality for Task Flow Activities."](#)

To specify HTTP redirect for a view activity:

1. In the task flow diagram, select the view activity.
2. In the Property Inspector, expand the **General** section.
3. In the **Redirect** dropdown list, select **true**.

19.2.3.2 What Happens When You Specify HTTP Redirect for a View Activity

The ADF Controller issues an HTTP redirect in response to a view activity request. The redirected request creates a new browser URL for the view activity. The original view URL is no longer used.

When specified, a HTTP redirect occurs in response to a client GET request. For a client GET, the `#{bindings}` EL scope is invalid until the ADF Controller and ADF Model layer set up a new bindings context for the page. Therefore, you cannot use EL expressions, such as the following, for view activities for which you specified HTTP redirect:

```
#{bindings.foo}
```

Note: If you want `http://www.mycompany.org/x.html` to instead display what is at `http://www.mycompany.org/y.html`, do not use refresh techniques such as:

```
<META HTTP-EQUIV=REFRESH CONTENT="1;
URL=http://www.example.org/bar">
```

This technique could adversely affect back button behavior. If an end user clicks a browser back button, the refresh occurs again, and navigation is forward, not backward as expected.

In this situation, use HTTP redirect instead.

19.3 Using URL View Activities

You can use a URL view activity to redirect the root view port (for example, a browser page) to any URL-addressable resource, even from within the context of an ADF region. URL addressable resources include:

- Bounded task flows
- View activities in the unbounded task flow
- Addresses external to the current web application (for example, <http://www.oracle.com>)

To display the resource, you specify an EL expression that evaluates at runtime to generate the URL to the resource. In addition, you can specify EL expressions that, when evaluated, are added as parameters and parameter values to the URL.

A URL view activity redirects the client regardless of the view port (root view port or an ADF region) from which it is executed. The `<redirect>` element of a view activity performs in a similar way, except that it can be used only if the view activity is within the root view port. The `<redirect>` element is ignored within the context of an ADF region. For more information, see [Section 19.2.3, "Specifying HTTP Redirect for a View Activity"](#).

Redirecting elsewhere within the same application using URL view activities (not the `<redirect>` element) is handled similarly to back button navigation since the task flow stack is cleaned up. Redirecting out of the web application is handled like dereferencing a URL to a site external to the application.

19.3.1 How to Add a URL View Activity to a Task Flow

You can add a URL view activity to a bounded or unbounded task flow.

Before you begin:

It may be helpful to have an understanding of the affect of adding a URL view to the functionality of a task flow. For more information, see [Section 19.3, "Using URL View Activities."](#)

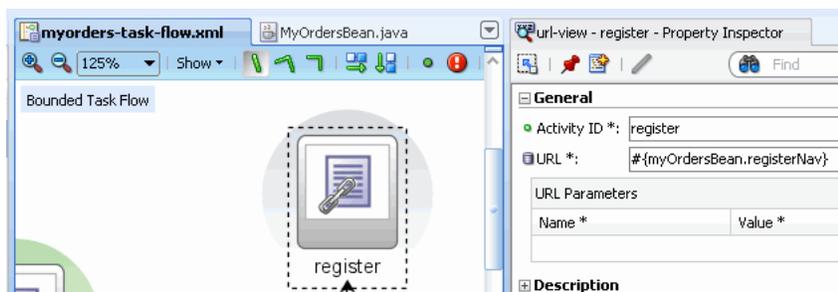

You may also find it helpful to understand functionality that can be added using other task flow features. For more information, see [Section 19.1.2, "Additional Functionality for Task Flow Activities."](#)

To add a URL view activity to a task flow:

1. In the ADF Task Flow page of the Component Palette, from the Component panel, drag and drop a URL view activity onto the diagram.
2. In the task flow diagram, select the URL view activity.
3. On the General page of the Property Inspector, in the **Activity ID** field, enter an ID that identifies the URL view activity.
4. Click the button next to the **URL** field to invoke the Expression Builder and write an EL expression that renders a URL at runtime.

For example, [Figure 19–5](#) shows a URL activity (**register**) in the Fusion Order Demo application's `myorders-task-flow.xml` bounded task flow with an EL expression (`{myOrdersBean.registerNav}`) that retrieves a URL at runtime.

Figure 19–5 URL View Activity

5. Expand the **URL Parameters** section to add optional URL parameters that will be included in the URL:
 - **name:** A name for the parameter.

- **value:** An EL expression that, when evaluated, generates the parameter value.
- **converter:** A settable EL expression that, when evaluated, specifies a method to perform conversion and validation when parameters are passed via bookmarkable view activity URLs. For more information, see [Section 35.3, "Enabling ADF Security"](#).

19.3.2 What You May Need to Know About URL View Activities

Task flow URL view activities can be used within JSF portlets. Create the URL using one of the following options if you configure a task flow URL view activity for use within a JSF portlet:

- Invoke one of the following methods from the `ControllerContext` class in the `oracle.adf.controller` package:
 - `getLocalViewActivityURL()`
 - `getGlobalViewActivityURL()`

Do not invoke the `encodeActionURL()` method from the `ADFPortletContainerExternalContext` class with the response from the `getLocalViewActivityURL()` or `getGlobalViewActivityURL()` methods before you invoke the `redirect()` method from the `ADFPortletContainerExternalContext` class. The `getLocalViewActivityURL()` and `getGlobalViewActivityURL()` methods both perform the necessary encoding of the URL.

- Supply a fully-qualified absolute URL.
- Supply a context path relative URL.
- Supply a URL relative to the current view.

A task flow URL view activity in a JSF portlet behaves as follows:

- If the redirect URL refers to a location in the JSF portlet application and does not contain a `queryString` parameter named `x_DirectLink` with a value of `true`, the portlet in the containing page navigates to the URL specified in the URL view activity.
- Otherwise, the client redirects to the URL specified in the URL view activity.

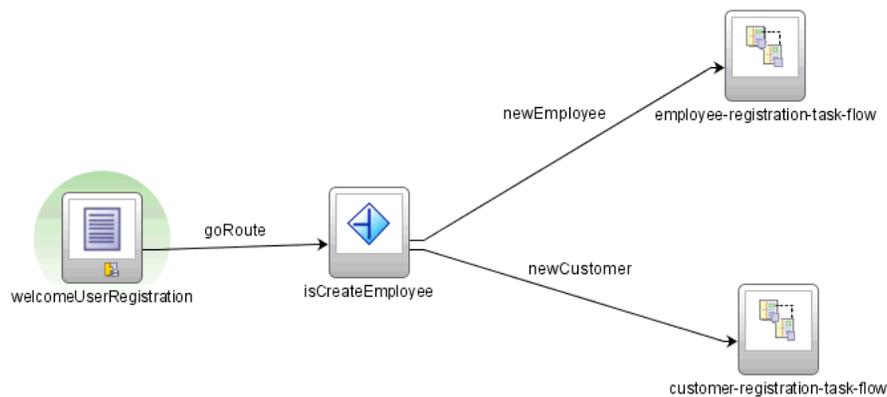

For more information about using a task flow's URL view activity, see [Section 19.3, "Using URL View Activities."](#)

For information about the methods that you can use to get a URL, see the following reference documents:

- *Oracle Fusion Middleware Java API Reference for Oracle ADF Controller*

19.4 Using Router Activities

Use a router activity to route control to activities based on the runtime evaluation of EL expressions. [Figure 19–6](#) shows a router activity (**isCreateEmployee**) can branch to different control flows leading from it to different activities.

Figure 19–6 Router for Alternate Control Flow Cases

Each control flow corresponds to a different router case. Each router case uses the following elements to choose the activity to which control is next routed:

- **expression:** an EL expression that evaluates to `true` or `false` at runtime.
The router returns the outcome that corresponds to the EL expression that returns `true`.
- **outcome:** a value returned by the router activity if the EL expression evaluates to `true`, for example, `newCustomer`.

If the router case **outcome** matches a **from-outcome** on a control flow case, control passes to the activity that the control flow case points to. If none of the cases for the router activity evaluate to `true`, or if no router activity cases are specified, the **outcome** specified in the router **Default Outcome** field (if any) is used.

For example, if you want to configure control flow on whether a user clicks the **Create a New Customer** or **Create a New Employee** button on the `welcomeUserRegistration` page fragment view activity in [Figure 19–6](#). You add a router case where the EL expression evaluates if the user entered a new customer in the input text field on the `welcomeUserRegistration` page fragment and an outcome (for example, `newCustomer`) for the router activity to return if the EL expression returns `true` (the user entered a new customer)

In [Figure 19–6](#), if the EL expression to determine if a user entered a new customer evaluates to `true`, control passes to the `customer-registration-task-flow` task flow call activity, based on the control flow case **from-outcome**.

Best Practice:

Use a router activity if your routing condition can be expressed in an EL expression.

Using a router activity allows you to do more when you are designing the task flow that contains it. The router activity allows you to show more information about the condition on the task flow. This makes it more readable and useful to someone who looks at the diagram for your task flow.

Using a router activity also makes it easier to modify your application later. For example, you may want to modify or add a routing condition later.

19.4.1 How to Configure Control Flow Using a Router Activity

You define a control flow by dragging a router activity from the Component Palette to the diagram for the task flow. You configure the properties of the router activity (Activity ID and Default Outcome) and add router cases to the router activity.

Before you begin:

It may be helpful to have an understanding of the properties of a router activity that can affect functionality. For more information, see [Section 19.4, "Using Router Activities."](#)

You may also find it helpful to understand other functionality that can be added using other task flow activity features. For more information, see [Section 19.1.2, "Additional Functionality for Task Flow Activities."](#)

To configure control flow using the router activity:

1. In the ADF Task Flow page of the Component Palette, drag and drop a router activity onto the diagram.
2. In the task flow diagram, select the router activity.
3. From JDeveloper's main menu, choose **View > Property Inspector**.
4. In the Property Inspector, expand the **General** category and set values for the following properties:
 - **Activity ID:** write a value that identifies the router activity in the task flow's source file.
 - **Default Outcome:** specify an activity that the router activity passes control to if no control flow cases evaluate to `true` or if no control flow case is specified.
5. Click the **Add** icon next to **Cases** and specify values for each router case that you add, as described in the following list:
 - **Expression:** An EL expression that evaluates to `true` or `false` at runtime.

For example, to reference the value in an input text field of a view activity, write an EL expression similar to the following:

```
#{pageFlowScope.value=='view2' }
```

If this EL expression returns `true`, the router activity invokes the outcome that you specify in the **Outcome** field.

- **Outcome:** the outcome the router activity invokes if the EL expression specified by **Expression** returns `true`.

Create a control flow case or a wildcard control flow rule for each outcome in the diagram of your task flow. For example, for each outcome in a control flow case, make sure that there is a corresponding `from-outcome`. In [Figure 19-6](#), the value for both the case outcome and the control flow case element `from-outcome` is `newCustomer`. This makes sure that control flow passes to the `newCustomer` activity, the target of the control flow element.

19.4.2 What Happens When You Configure Control Flow Using a Router Activity

JDeveloper writes values to the source file of the task flow based on the values that you specify for the properties of the router activity. [Example 19-7](#) shows the values that JDeveloper writes where values are specified for the router activity as follows:

- The value of Default Outcome is `toRegion3`.
- Two control flow cases are specified. If the input value is `1`, the outcome is `toRegion1` and if input value is `2`, the outcome is `toRegion2`.

At runtime, the router activity passes control to the outcome in the control flow case where the EL expression returned `true`.

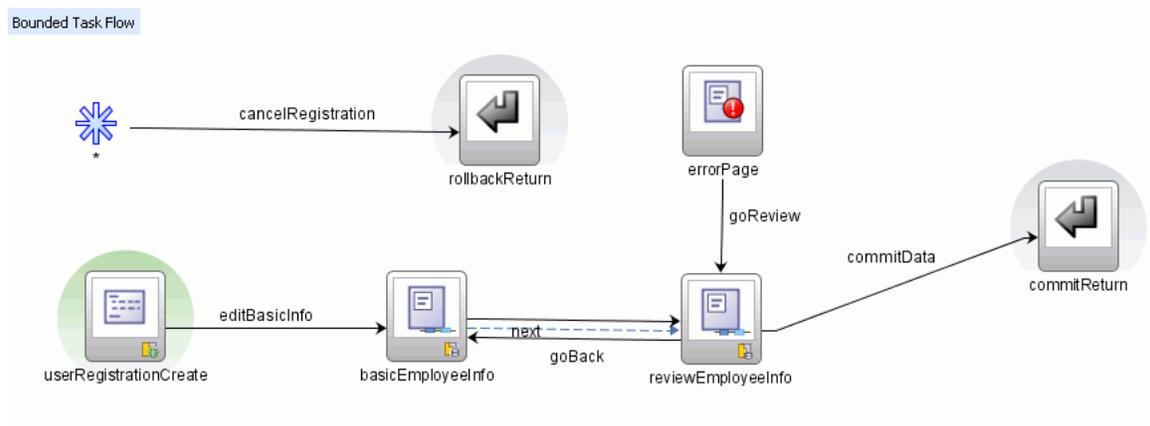

Example 19-7 Router Activity Metadata in a Task Flow Source File

```
<default-activity id="__3">Router1</default-activity>
<router id="Router1">
  <case>
    <expression>#{binding.Region.InputValue='1'}</expression>
    <outcome id="__4">toRegion1</outcome>
  </case>
  <case>
    <expression>#{binding.Region.InputValue='2'}</expression>
    <outcome id="__5">toRegion2</outcome>
  </case>
  <default-outcome>toRegion3</default-outcome>
</router>
```

19.5 Using Method Call Activities

A *method call* activity allows you to call a custom or built-in method that invokes application logic from anywhere within an application's control flow. You can specify methods to perform tasks such as initialization before displaying a page, cleanup after exiting a page, exception handling, and so on.

[Figure 19-7](#) shows where the Fusion Order Demo application uses a method call activity in the Employee Registration bounded task flow. The activity calls `userRegistrationCreate`, a method exposed on the `StoreServiceAM` data control.

Figure 19–7 Method Call Activity in employee-registration-task-flow

You can set an outcome for the method that specifies a control flow case to pass control to after the method finishes. You can specify the outcome as either:

- **fixed-outcome:** On successful completion, the method always returns this single outcome, for example, `success`. If the method does not complete successfully, an outcome is not returned. If the method type is `void`, you must specify a fixed-outcome, not a `to-string`.
- **to-string:** If specified as `true`, the outcome is based on calling the `toString()` method on the Java object returned by the method. For example, if `toString()` returns `editBasicInfo`, navigation goes to the `editBasicInfo` control flow case shown in [Figure 19–7](#).

As shown in [Example 19–8](#), the method outcome and the method result are two different values. The `<return-value>` element specifies where to put the result of the `calculateSalesTax` method. The `<outcome>` element indicates which control flow case to use after the method finishes.

Example 19–8 Method Call Activity Metadata with Return and Outcome Elements

```

<method-call id="calculateSalesTax">
  <method>#{pageFlowScope.taxService.calculateSalesTax}</method>
  <return-value>#{pageFlowScope.result}</return-value>
  <outcome>
    <fixed-outcome>gotoError</fixed-outcome>
  </outcome>
</method-call>

```

For more information about control flows, see [Section 18.1.3, "About Control Flows."](#)

Best Practice:

You can use a method call on a task flow to invoke a method before a page renders, or you can use an `invokeAction` on a page definition.

If you want your method to execute before the application renders the page, it is usually best to use a method call activity in the task flow rather than an `invokeAction` in the page definition file. By adding your method as a method activity on a task flow, it is easier to invoke logic between pages. This allows you to do more at the time you're designing the task flow. You can also show more information on the task flow, thus making it more readable and useful to someone else who looks at your diagram.

You might want to use an `invokeAction` instead of a method call for one of the following reasons:

- You want the method to be executed in more than one phase of the page's lifecycle.
 - You plan to reuse the page and page definition file, and want the method to be tied to the page.
 - You are not using ADF Controller.
-

19.5.1 How to Add a Method Call Activity

Drag a method call activity from the Component Palette to the task flow diagram. You can associate the method call activity with an existing method by dropping a data control operation from the Data Controls panel directly onto the method call activity in the task flow diagram.

In the Fusion Order Demo application, for example, you could drag a `setCurrentRowWithKey` or `setCurrentRowWithKeyValues` operation to the diagram from the Data Control Iterator to display or select the current row in a table.

Note: Parameters for data control method parameters are defined in the page definition for the corresponding page rather than within ADF Controller metadata.

You can also drag methods and operations directly to the task flow diagram. A new method call activity is created automatically after you drop it on the diagram. You can specify an EL expression and other options for the method.

Tip: To identify the method that a method call activity invokes, right-click the method call activity in the diagram of the task flow and choose **Go to Method**. JDeveloper navigates to the method that the method call activity invokes.

Before you begin:

Create a bounded or unbounded task flow. For more information, see [Section 18.2, "Creating a Task Flow."](#)

It may be helpful to have an understanding of how the properties of a method call activity affect the functionality of a task flow. For more information, see [Section 19.5, "Using Method Call Activities."](#)

You may also find it helpful to understand other functionality that can be added using other task flow activity features. For more information, see [Section 19.1.2, "Additional Functionality for Task Flow Activities."](#)

To add a method call activity to a task flow:

1. In the ADF Task Flow page of the Component Palette, from the Component panel, drag and drop a method call activity onto the diagram.

The method call activity optionally displays a default ID, `methodCall1`, and a warning icon that indicates that a method EL expression has not yet been specified.

For more information about turning on the warning icons, see [Section 18.3.1, "How to Add an Activity to a Task Flow"](#).

2. If you want to change the default ID, click the text that appears under the method call activity in the task flow diagram.

You can enter a name for the method call, for example, `addItemToCart`.

3. In the task flow diagram, select the method call activity.
4. On the General page of the Property Inspector, enter an EL expression for the method in the **Method** field.

For example, enter an EL binding expression similar to the following:

```
#{bindings.addItemstoCart.execute}
```

Note: The `bindings` variable in the EL expression references an ADF Model binding from the current binding container. In order to specify the `bindings` variable, you must specify a binding container definition or page definition. For more information, see [Section 13.7, "Working with Page Definition Files"](#).

You can also use the Edit Property dialog box shown in [Figure 19–8](#) to build the EL expression for the method:

- a. In the General page of the Property Inspector, from the **Method** dropdown menu, choose **Expression Builder**.
- b. In the Expression Builder dialog, expand a node, for example, **ADF Bindings** and choose a method. Or, under the **ADF Managed Beans** node, navigate to the managed bean containing the method you want to call and select the method.
- c. Click **Insert Into Expression**.

The Expression Builder dialog should look similar to [Figure 19–8](#). In [Figure 19–8](#), for example, the `addItemToCart` method and `shoppingCartBean` combine to form the EL expression shown at the top of the Expression Builder.

If parameters have not already been created by associating the method call activity to an existing method, add the parameters yourself.

Before you begin:

It may be helpful to have an understanding of how the properties of a method call activity affect the functionality of a task flow. For more information, see [Section 19.5, "Using Method Call Activities."](#)

You may also find it helpful to understand other functionality that can be added using other task flow activity features. For more information, see [Section 19.1.2, "Additional Functionality for Task Flow Activities."](#)

To add method parameters:

1. Add a method call activity to the task flow diagram.
For more information, see [Section 19.5.1, "How to Add a Method Call Activity."](#)
2. In the task flow diagram, select the method call activity.
3. In the Property Inspector, click **Parameters**.
4. On the Parameter page, expand the **Parameters** section.
5. Click the plus **Add** icon.
6. In the **class** field, enter the parameter class, for example, `java.lang.Double`.
7. In the **value** field, enter an EL expression indicating where the value for the parameter will be retrieved, for example, `{pageFlowScope.shoppingCart.totalPurchasePrice}`.

Tip: You can click the icon next to the **value** field and choose **Expression Builder** to search for the method parameters.

8. In the **return-value** field, enter an EL expression indicating where to store the method return value, for example, `{pageFlowScope.Return}`.
9. Click **OK**.
10. Repeat the above steps to add additional parameters.

19.5.3 What Happens When You Add a Method Call Activity

After you specify parameters and return values for a method, the XML source file is updated. [Example 19-9](#) shows how a method call to `userRegistrationCreate` appears in the XML source file for a bounded task flow.

Example 19-9 Call to `userRegistrationCreate` method

```
<method-call id="userRegistrationCreate">
  <method>#{bindings.userRegistrationCreate.execute}</method>
  <outcome>
    <fixed-outcome>editBasicInfo</fixed-outcome>
  </outcome>
</method-call>
```

19.6 Using Task Flow Call Activities

You can use a task flow call activity to call a bounded task flow from either the unbounded task flow or a bounded task flow. A task flow call activity allows you to call a bounded task flow located within the same or a different application.

The called bounded task flow executes its default activity first. There is no limit to the number of bounded task flows that can be called. For example, a called bounded task flow can call another bounded task flow, which can call another, and so on.

To pass parameters into a bounded task flow, you must specify input parameter values on the task flow call activity. These values must correspond to the input parameter definitions on the called bounded task flow. For more information, see [Section 19.6.3, "How to Specify Input Parameters on a Task Flow Call Activity"](#).

Also note the following:

- The value on the task flow call activity **Input Parameter** specifies where the value will be taken from within the calling task flow.
- The value on the **Input Parameter Definition** for the called task flow specifies where the value will be stored within the called bounded task flow once it is passed.

Tip: When a bounded task flow is associated with a task flow call activity, input parameters are automatically inserted on the task flow call activity based on the input parameter definitions defined on the bounded task flow. Therefore, the application developer needs only to assign values to the task flow call activity input parameters.

By default, all objects are passed by reference. Primitive types (for example, int, long, or boolean) are always passed by value.

The technique for passing return values out of the bounded task flow to the caller is similar to the way that input parameters are passed. See [Section 20.5, "Specifying a Return Value from a Bounded Task Flow"](#) for more information.

19.6.1 How to Call a Bounded Task Flow Using a Task Flow Call Activity

Add a task flow call activity to the calling bounded or unbounded task flow to call a bounded task flow.

Before you begin:

It may be helpful to have an understanding of how a task flow call activity interacts with a task flow. For more information, see [Section 19.6, "Using Task Flow Call Activities."](#)

You may also find it helpful to understand other functionality that can be added using other task flow activity features. For more information, see [Section 19.1.2, "Additional Functionality for Task Flow Activities."](#)

To call a bounded task flow:

1. Open the calling task flow in the diagram editor.
2. In the ADF Task Flow page of the Component Palette, from the Component panel, drag and drop a **Task Flow Call** activity onto the diagram.
3. Identify the called task flow using one of the following techniques:
 - In the task flow diagram, double-click the task flow call activity.

The Create Bounded Task Flow dialog displays, where you specify options for creating a new bounded task flow.

- Drag an existing bounded task flow from the Application Navigator and drop it on the task flow call activity.

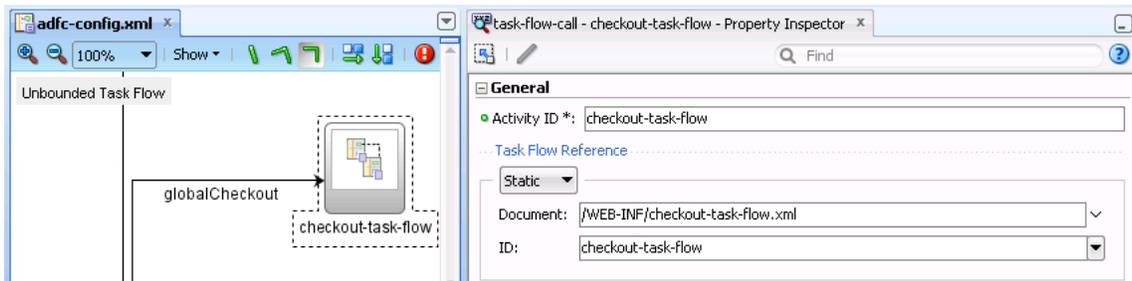

Tips: You can drop a bounded task flow on a page or page fragment. If the bounded task flow consists of pages (not page fragments), you can choose to add a Go Link or Go Button UI component on the page where you drop the task flow. An end user can click the button or link to call the task flow. This may in turn automatically generate the task flow call activity if the page is already associated with an existing view activity in a task flow.

You cannot drop a bounded task flow from one application to a task flow diagram contained in another application using the Application Navigator, even though both applications appear in the navigator. In addition, you cannot drop a bounded task flow contained in one project onto a task flow diagram contained in another project.

Instead, you can package the bounded task flow in an ADF library, then reuse it in your current application or project. You can then drag the bounded task flow from the Resource Catalog or from the Component Palette page that is created when you import the library. For more information, see [Section 38.2.2, "Using the Resource Palette"](#).

- If you know the name of the bounded task flow that you want to invoke, carry out the following steps:
 - a. In the task flow diagram, select the task flow call activity.
 - b. On the General page of the Property Inspector, select **Static** from the Task Flow Reference dropdown list.
 - c. In the **Document** field, enter the name of the source file for the bounded task flow to call. For example, `called-task-flow-definition.xml`.
 - d. In the **ID** field, enter the bounded task flow ID contained in the XML source file for the called bounded task flow, for example, `targetTaskFlow`.
- If you do not know the name of the bounded task flow to invoke and it is dependent on an end user selection at runtime, carry out the following steps:
 - a. In the task flow diagram, select the task flow call activity.
 - b. On the General page of the Property Inspector, select **Dynamic** from the Task Flow Reference dropdown list.
 - c. Select **Expression Builder** from the **Dynamic Task Flow Reference** dropdown menu.
 - d. Write an EL expression that identifies the ID of the bounded task flow to invoke at runtime.

[Figure 19-10](#) shows the checkout-task-flow task flow call activity in an unbounded task flow of the Fusion Order Demo application. This task flow call activity invokes the checkout-task-flow located in the `checkout-task-flow.xml` file.

Figure 19–10 Task Flow Call Activity That Invokes a Bounded Task Flow

19.6.2 What Happens When You Call a Bounded Task Flow Using a Task Flow Call Activity

JDeveloper generates metadata entries in the source file for the task flow that calls the bounded task flow. [Example 19–10](#) shows an example from the Fusion Order Demo application's `adfc-config.xml` that references the `checkout-task-flow.xml` bounded task flow (`checkout-task-flow.xml`). At runtime, the task flow call activity calls the checkout bounded task flow.

Example 19–10 Task Flow Call Activity in Fusion Order Demo Application's `adfc-config.xml` File

```
<task-flow-call id="checkout-task-flow">
  <task-flow-reference>
    <document>/WEB-INF/checkout-task-flow.xml</document>
    <id>checkout-task-flow</id>
  </task-flow-reference>
</task-flow-call>
```

19.6.3 How to Specify Input Parameters on a Task Flow Call Activity

The suggested method for mapping parameters between a task flow call activity and its called bounded task flow is to first specify input parameter definitions for the called bounded task flow. Then you can drag the bounded task flow from the Application Navigator and drop it on the task flow call activity. The task flow call activity input parameters will be created automatically based on the bounded task flow's input parameter definition. For more information, see [Section 20.3, "Passing Parameters to a Bounded Task Flow"](#).

You can, of course, first specify input parameters on the task flow call activity. Even if you have defined them first, they will automatically be replaced based on the input parameter definitions of the called bounded task flow, once it is associated with the task flow call activity.

If you haven't yet created the called bounded task flow, you may still find it useful to specify input parameters on the task flow call activity. Doing so at this point allows you to identify any input parameters you expect the task flow call activity to eventually map when calling a bounded task flow.

Before you begin:

It may be helpful to have an understanding of how a task flow call activity interacts with a task flow. For more information, see [Section 19.6, "Using Task Flow Call Activities."](#)

You may also find it helpful to understand other functionality that can be added using other task flow activity features. For more information, see [Section 19.1.2, "Additional Functionality for Task Flow Activities."](#)

To specify input parameters on a task flow call activity:

1. Select the task flow call activity in the diagram for the task flow.
2. In the Property Inspector, expand the **Parameters** section and click the **Add** icon to enter a name for the parameter.

Tip: Dropping a bounded task flow on a task flow call activity in a diagram automatically populates the name field.

3. Enter a parameter value, for example, `{pageFlowScope.callingTaskflowParm}`.

The value specifies where the parameter value will be taken from within the calling task flow.

By default, all objects are passed by reference. Primitive types (for example, `int`, `long`, or `boolean`) are always passed by value.

4. After you have specified an input parameter, you can specify a corresponding input parameter definition for the called bounded task flow. For more information, see [Section 20.3, "Passing Parameters to a Bounded Task Flow"](#).

19.6.4 How to Call a Bounded Task Flow Using a URL

You can call a bounded task flow that does not use page fragments (`.jsff`) in another web application using a URL. You use a task flow call activity to call the bounded task flow that you want to invoke. You write an EL expression for the task flow call activity's `remote-app-url` property that, when evaluated, returns a URL.

In addition to writing a value for the `remote-app-url` property, you specify values for task flow reference properties that identify the bounded task flow to call. The task flow reference and the `remote-app-url` property are combined at runtime to generate a URL to the called bounded task flow in the remote web application.

You also need to set visibility properties for the bounded task flow in the remote web application that you want to call so that it invokes when it receives the URL generated from the task flow call activity in the calling task flow.

Be aware that JSF portlets provide all content from the same web application. As a result, do not configure your web application to invoke a remote task flow using a URL if plan to use your web application in a JSF portlet.

Note: If, in JDeveloper's Application Navigator, you right-click the bounded task flow that you want to call using a URL and select **Run** from the context menu, the bounded task flow executes as if it were called using a URL at runtime. For this reason, make sure to set the visibility properties for the bounded task flow even if you want to execute it as part of testing in JDeveloper.

Before you begin:

It may be helpful to have an understanding of how a task flow call activity interacts with a task flow. For more information, see [Section 19.6, "Using Task Flow Call Activities."](#)

You may also find it helpful to understand other functionality that can be added using other task flow activity features. For more information, see [Section 19.1.2, "Additional Functionality for Task Flow Activities."](#)

To call a bounded task flow using a URL:

1. Open the task flow in your web application that you want to configure to invoke a bounded task flow in a remote web application.
2. In the ADF Task Flow page of the Component Palette, from the Component panel, drag a **Task Flow Call** activity and drop it on the diagram for the task flow.
3. In the Property Inspector, expand the **General** section and write values for the properties to invoke a bounded task flow.

For more information, see [Section 19.6.1, "How to Call a Bounded Task Flow Using a Task Flow Call Activity"](#).

4. For the **Remote Application URL** property, use the Expression Builder to write an EL expression that, when evaluated, returns a string with the parts required to construct a URL of the remote web application.

For example, the following example EL expression invokes a managed bean method that returns a string with the parts required to construct a URL:

```
#{myOrdersBean.createOrder}
```

5. Open the bounded task flow that you specified values for in step 3.

Note: The bounded task flow you specify cannot use page fragments (.jsff).

6. In the Structure window, right-click the node for the bounded task flow (task flow definition) and choose **Go to Properties**.
7. In the Property Inspector, expand the **General** category and set values for the following properties:
 - **URL Invoke:** select `url-invoke-allowed` from the dropdown list if you want to allow a URL to invoke the bounded task flow. Select `url-invoke-disallowed` if you do not want to allow a URL to invoke the bounded task flow. Selecting this value returns a HTTP 403 status code if a URL attempts to invoke the bounded task flow. The default value (calculated) allows a URL to invoke the bounded task flow if the bounded task flow does not specify an initializer and it has a view activity as its default activity. If the bounded task flow does not meet these conditions, a HTTP 403 status code is returned. Selecting `url-invoke-allowed` or `url-invoke-disallowed` overrides the default behavior.
 - **Library Internal:** set to `true` if you want the bounded task flow to be internal when you package it in an ADF Library JAR. The default value is `false`.

For more information about packaging a bounded task flow in an ADF Library JAR, see [Section 38.3, "Packaging a Reusable ADF Component into an ADF Library"](#).

8. Save and close the bounded task flow.

19.6.5 What Happens When You Configure a Bounded Task Flow to be Invoked by a URL

JDeveloper generates metadata entries in the source file of the task flow that invokes the task flow call activity to the bounded task flow in a remote web application.

[Example 19–11](#) shows an example entries for a task flow call activity.

Example 19–11 Metadata Entries for a Task Flow Call Activity to a Bounded Task Flow

```
<task-flow-call id="createOrder">
  <task-flow-reference>
    <document id="__6">myorders-task-flow.xml</document>
    <id id="__5">myorders-task-flow</id>
  </task-flow-reference>
  <remote-app-url id="__7">#{myOrdersBean.createOrder}</remote-app-url>
</task-flow-call>
```

The `createOrder` method in [Example 19–11](#) returns a string with the URL syntax required to invoke a bounded task flow. For more information about the URL syntax, including descriptions of the required parts in the returned string and an example URL, see [Section 19.6.6, "What You May Need to Know About Calling a Bounded Task Flow Using a URL."](#)

JDeveloper also generates entries in the source file for the bounded task flow to invoke when you configure it so it can be called by a URL. [Example 19–12](#) shows sample metadata entries that allow a bounded task flow to be invoked by a URL.

Example 19–12 Metadata Entries to Allow a URL Invoke a Bounded Task Flow

```
<task-flow-definition id="task-flow-definition3">
  <visibility id="__2">
    <url-invoke-allowed/>
    <library-internal/>
  </visibility>
</task-flow-definition>
```

19.6.6 What You May Need to Know About Calling a Bounded Task Flow Using a URL

Adding a context parameter in your local application's deployment descriptor may ease the administration of interaction with a remote web application.

Context Parameter for Remote Web Application

Consider adding a context parameter to the deployment descriptor (`web.xml`) for your Fusion web application (local application) if you use a URL to invoke a bounded task flow in another Fusion web application (remote application). Set the value of the context parameter to the URL of the remote application. Use the context parameter name when writing EL expressions in the local application, as shown in the following example where `remoteAppUrl` is the name of the context parameter:

```
#{initParam.remoteAppUrl}
```

If the URL of the remote application changes, you can update the context parameter to reference the changed URL.

URL Syntax to Invoke a Bounded Task Flow

Typically, you write an EL expression that references a managed bean method which, in turn, retrieves the required parts of the URL or you could write an EL expression that renders the URL directly, as shown in [Example 19–13](#).

Example 19–13 Example URL to Invoke a Bounded Task Flow

```
http://somecompany.com/internalApp/MyApp/faces/adf.task-flow?adf.tfId=displayHelp&
adf.tfDoc=%2FWEB-INF%2Fdisplayhelp.xml&topic=createPurchaseOrder
```

[Example 19–14](#) describes the parts of the URL syntax to invoke a bounded task flow.

Example 19–14 URL Syntax for a Call to a Bounded Task Flow Using Named Parameters

```
<server root>/<app_context>/faces/adf.task-flow?adf.tfId=<task flow definition
ID>&adf.tfDoc=<document name>&<named parameter>=<named parameter value>
```

The following list describes each part of the URL syntax in [Example 19–14](#):

- `<server root>`: Provided by customization at site or admin level. For example:

```
http://mycompany.com/internalApp
```

The `<server root>` value depends on the application server where you deploy the bound task flow. The bounded task flow URL is a resource within the JSF servlet's URL path.
- `<app context>`: The Web application context root, for example, `MyApp`. The context root is the base path of a Web application.
- `faces`: Faces servlet mapping.
- `adf.task-flow`: A reserved keyword that identifies the ADF Controller for the remote web application.
- `adf.tfId`: A URL parameter that supplies the task flow ID to call.
- `<task flow ID>`: The identifier of the bounded task flow to call, for example, `displayHelp`. This is the same task flow ID that is used when calling locally. Note that this identifier is not the same as the task flow call activity instance ID. The parameter value must be represented as a string.
- `adf.tfDoc`: A URL parameter that supplies the document name containing the bounded task flow ID to be called.
- `<document name>`: A document name containing the bounded task flow ID to be called, for example, `%2FWEB-INF%2FtoUppercase%2FdisplayHelp.xml`. If you are handcrafting the bounded task flow URL, you are responsible for the appropriate encoding.
- `<named parameter>`: (optional) The name of an input parameter definition for the called bounded task flow, for example, `topic`. You must supply all required input parameter definitions.
- `<named parameter value>`: (optional) The value of the input parameter.

Note: URL parameter names that begin with an underscore ('_') are intended for internal use only and should not be used. Although you may see these names on URLs generated by ADF Controller, you should not attempt to use or depend on them.

Object Type for Parameter Converters

Parameter converters, if specified, can be used to convert task flow parameter values to and from the string representations used in a URL. A parameter converter is an EL expression that evaluates to an object of the following type:

```
oracle.adf.controller.UrlParameterConverter
```

If you do not specify a parameter converter, a default converter checks the parameters for cross-site-scripting (XSS) attacks. If you know that the parameter values used in your application contain special characters, you should create your own implementation of `UrlParameterConverter` and use it to perform conversion of the task flow parameter values.

19.6.7 How to Specify Before and After Listeners

Task flow call activity before and after listeners are used to identify the start and end of a bounded task flow. Specifying a listener in the task flow call activity means that the listener executes on that specific usage of the called bounded task flow.

You specify the listener as an EL expression for a method that will be called upon entry or exit of a bounded task flow, for example,

```
<before-listener>#{global.showState}</before-listener>. The method cannot have parameters.
```

- Before listener: An EL expression for a Java method called before a bounded task flow is entered. It is used when the caller needs to know when a bounded task flow is being initiated.
- After listener: An EL expression for a Java method called after a bounded task flow returns. It is used when the caller needs to know when a bounded task flow exits and control flow returns to the caller.

If multiple before listeners or multiple after listeners are specified, they are called in the order in which they appear in the source document for the unbounded or bounded task flow. A task flow call activity can have only have before listener and one after listener.

In order for the task flow call after listeners to be called, control flow must return from the bounded task flow using a control flow rule. If an end user leaves a bounded task flow using the browser back button or other URL, task flow call after listeners will not be called. You must use a bounded task flow finalizer to release all acquired resources and perform cleanup of a bounded task flow that the end user left by clicking a browser back button.

Before you begin:

It may be helpful to have an understanding of how a task flow call activity interacts with a task flow. For more information, see [Section 19.6, "Using Task Flow Call Activities."](#)

You may also find it helpful to understand other functionality that can be added using other task flow activity features. For more information, see [Section 19.1.2, "Additional Functionality for Task Flow Activities."](#)

To specify a before or after listener on a task flow call activity:

1. In the diagram of the calling bounded task flow, select the task flow call activity.
2. In the Property Inspector, click **Listeners**.
3. Click the button next to either **before-listener** or **after-listener**.

4. In the Expression Builder dialog, drill down to the Java class containing the method for the listener.
5. Open the class node and select the listener method.

When you are done, your EL expression might look like
`{pageFlowscope.managedBean.methodListener}`.

6. Click OK.

19.6.8 What Happens When You Add a Task Flow Call Activity

After you add a task flow call activity to a task flow diagram, you must specify a reference to the called bounded task flow using one of the methods described in [Section 19.6.1, "How to Call a Bounded Task Flow Using a Task Flow Call Activity"](#). For example, if you drop an existing bounded task flow on the task flow call activity, JDeveloper generates the task flow reference automatically. The task flow reference is used to invoke the called bounded task flow.

If the task flow reference is static, each task flow reference consists of:

- **id**: The bounded task flow id contained in the XML source file for the called bounded task flow. For example, a called task flow might have an ID called `targetFlow`. The same XML source file can contain multiple bounded task flows, each bounded task flow identified by a unique ID.

Note: If you use JDeveloper to create the bounded task flow, there is only one bounded task flow per document.

- **document**: The name of the XML source file containing the ID of the called bounded task flow. If **document** is not specified, `adfc-config.xml` is assumed.

The document is a physical XML file and must be accessible via MDS.

[Example 19–15](#) contains an example static task flow reference within a task flow call activity. In order to invoke a bounded task flow, you need to know its id and name of the file containing the id.

Example 19–15 Static Task Flow Reference

```
<adfc-config xmlns="http://xmlns.oracle.com/adf/controller" version="1.2" id="__
1">
...
<task-flow-definition id="task-flow-definition">
  <default-activity>view1</default-activity>
  <task-flow-call id="taskFlowCall">
    <task-flow-reference>
      <document>/WEB-INF/called-task-flow-definition.xml</document>
      <id>called-task-flow-definition</id>
    </task-flow-reference>
  </task-flow-call>
</task-flow-definition>
...
</adfc-config>
```

[Example 19–16](#) shows the metadata that JDeveloper generates for a dynamic task flow reference within a task flow call activity.

Example 19–16 Dynamic Task Flow Reference

```
<?xml version="1.0" encoding="windows-1252" ?>
<adfc-config xmlns="http://xmlns.oracle.com/adf/controller" version="1.2"
  id="__1">
  <task-flow-definition id="bounded_tf">
    <default-activity id="__2">taskFlowCall1</default-activity>
    <task-flow-call id="taskFlowCall1">
      <dynamic-task-flow-reference id="__3">#{EL_Expression_Retrieve_
        TaskflowID}</dynamic-task-flow-reference>
    </task-flow-call>
  </task-flow-definition>
</adfc-config>
```

19.6.9 What Happens at Runtime When a Task Flow Call Activity Invokes a Task Flow

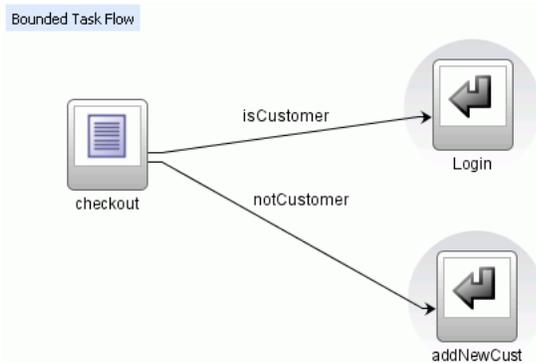

The ADF Controller performs the following steps when a bounded task flow is called using a task flow call activity:

1. Verifies that the user is authorized to call the bounded task flow.
2. Invokes task flow call activity before listener or listeners, if specified (see [Section 19.6.7, "How to Specify Before and After Listeners"](#)).
3. Evaluates the input parameter values on the bounded task flow.
4. Pushes the called bounded task flow onto the stack and initializes its page flow scope.
5. Sets input parameter values in the called bounded task flow's context.
6. Invokes a bounded task flow initializer method, if one is specified.
7. Executes the bounded task flow's default activity.

19.7 Using Task Flow Return Activities

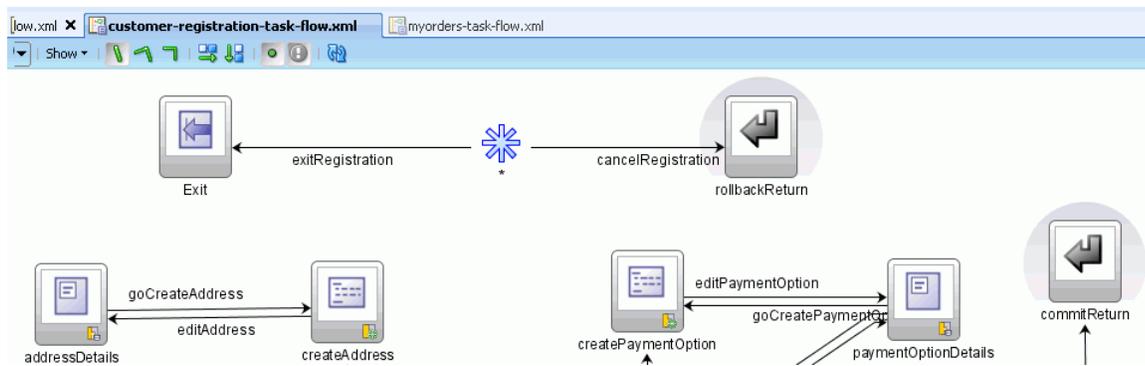

A task flow return activity identifies the point in an application's control flow where a bounded task flow completes and sends control flow back to the caller. You can use a task flow return activity only within a bounded task flow.

A gray circle around a task flow return activity icon indicates that the activity is an exit point for a bounded task flow. A bounded task flow can have zero to many task flow return activities. [Figure 19–11](#) shows a bounded task flow with task flow return activities named **Login** and **addNewCust**.

Figure 19–11 Multiple Task Flow Return Activities

Each task flow return activity specifies an *outcome* that is returned to the calling task flow. For example, the *outcome* for the `rollbackReturn` task flow return activity in the Fusion Order Demo application customer registration bounded task flow is `cancelCreateCust`.

Figure 19–12 shows an extract of the customer registration bounded task flow (`customer-registration-task-flow.xml`). This task flow contains two task flow return activities (`rollbackReturn` and `commitReturn`). The `rollbackReturn` task flow return activity's *outcome* is `cancelCreateCust`. In contrast, the `commitReturn` task flow return activity's *outcome* returns `globalhome`.

Figure 19–12 Task Flow Return Activities Specifying Different Outcomes

The *outcome* returned to the task flow that invokes the customer registration task flow depends on the end user action. You can configure control flow cases in the invoking task flow to determine the next action by the invoking task flow. Set the *from-outcome* element of a control flow case to the value returned by the task flow return activity's *outcome* to invoke an action based on that *outcome*. This determines control flow upon return from the customer registration task flow.

Set a value for the **Restore Save Point** property to specify if model changes made in a bounded task flow are saved or discarded when the bounded task flow exits by using a task flow return activity. Set to `true` to roll back transactions to the ADF Model save point that was created when the Fusion web application first entered the bounded task flow. The default value is `false`. You can specify a value for this property only if the bounded task flow on which the task flow return activity is located was entered without starting a new transaction. For more information, see [Section 22.2.1, "How to Enable Transactions in a Bounded Task Flow"](#).

Before you begin:

It may be helpful to have an understanding of how a task flow return activity interacts with a task flow. For more information, see [Section 19.7, "Using Task Flow Return Activities."](#)

You may also find it helpful to understand other functionality that can be added using other task flow activity features. For more information, see [Section 19.1.2, "Additional Functionality for Task Flow Activities."](#)

To add a task flow return activity to a bounded task flow:

1. In the ADF Task Flow page of the Component Palette, from the Component panel, drag and drop a task flow return activity onto the diagram for the bounded task flow.
2. In the task flow diagram, select the task flow return activity.
3. On the Common page of the Property Inspector, expand the **Outcome** section.
4. In the **Name** field, enter an outcome, for example, `preferredCustomer`.

Specifying this returns an outcome to the caller when the bounded task flow exits. You can specify only one outcome per task flow return activity. The calling task flow should define control flow rules to handle control flow upon return. See [Section 18.4.1, "How to Add a Control Flow Rule to a Task Flow"](#) for more information.

5. In the Property Inspector, expand the **Behavior** section.
6. In the **Reentry** dropdown list, choose one of the following options:
 - **reentry-allowed**: Reentry is allowed on any view activity within the bounded task flow.
 - **reentry-not-allowed**: Reentry of the bounded task flow is not allowed.

If you specify **reentry-not-allowed** on a bounded task flow, an end user can still click the browser back button and return to a page within the bounded task flow. However, if the user does anything on the page such as clicking a button, an exception (for example, `InvalidTaskFlowReentry`) is thrown indicating the bounded task flow was reentered improperly. The actual reentry condition is identified upon the submit of the reentered page.

Your selection defines the default behavior when the bounded task flow is reentered by an end user clicking a browser's Back button. This selection applies only if **reentry-outcome-dependent** has been set on the bounded task flow where the task flow return activity is located. For more information, see [Section 22.3, "Reentering Bounded Task Flows"](#).

7. In the **End Transaction** dropdown list, choose one of the following options:
 - **commit**: Select to commit the existing transaction to the database.
 - **rollback**: Select to roll back the transaction to what it was on entry of the called task flow. This has the same effect as canceling the transaction, since it rolls back a new transaction to its initial state when it was started on entry of the bounded task flow.

If you do not specify commit or rollback, the transaction is left open to be closed by calling bounded task flow.

8. In the **Restore Save Point** dropdown list, select **true** when either of the following conditions apply:

- If **Always Begin New Transaction** (`new-transaction`) is not selected on the bounded task flow on which the task flow return activity is located
- ADF model changes made within a bounded task flow should be discarded when exiting using the task flow call activity. The transaction is rolled back to the save point created on entry of the bounded task flow.

For more information, see [Section 22.2.1, "How to Enable Transactions in a Bounded Task Flow"](#).

19.8 Using Save Point Restore Activities

The save point restore activity allows you to restore a previous persistent save point in an application supporting save for later functionality. A save point captures a snapshot of the Fusion web application at a specific instance. Save point restore enables the application to restore whatever was captured when the save point was originally created.

When a save point is restored, ADF Controller terminates the saved application and restarts the application that was executing when the end user performed a save. The end user's original location in the application is displayed. Once the `save-point-id` is restored, it is deleted from its method of persistence (database or Java object cache).

A save point restore activity is not required within every individual application supporting save for later capabilities. It is only required within the applications responsible for restoring the previously persistent `save-point-ids`. For example, a save point restore activity would not be required within a Create Expense Report application, but would be within the application used to select previously saved expense reports for further updates.

[Section 22.6, "Using Save Points in Task Flows"](#) contains detailed information about enabling save for later capabilities in a task flow and provides an example of how to use the save point restore activity to retrieve the saved application state and data.

19.9 Using Parent Action Activities

A bounded task flow running in an ADF region may need to trigger navigation of its parent view activity. The parent action activity allows a bounded task flow running in an ADF region to generate outcomes that it passes to the parent view activity. The outcomes are used to navigate the task flow containing the parent view activity rather than navigating the task flow of the ADF region.

For more information, see [Section 21.7.1, "How to Trigger Navigation Outside of an ADF Region's Task Flow."](#)

19.10 Using Task Flow Activities with Page Definition Files

Page definition files define the binding objects that populate data at runtime. They are typically used in a Fusion web application to bind page UI components to data controls. A number of task flow activities can also use page definition files to bind to data controls. These are:

- Method call
You can drag and drop a data control operation from the Data Control panel onto a task flow to create a method call activity or onto an existing method call activity. In both cases, the method call activity binds to the data control operation.
- Router

Associating a page definition file with a router activity creates a binding container. At runtime, this binding container makes sure that the router activity references the correct binding values when it evaluates the router activity cases' EL expressions. Each router activity case specifies an `outcome` to return if its EL expression evaluates to `true`. For this reason, only add data control operations to the page definition file that evaluate to `true` or `false`.

- Task flow call

Associating a page definition file with a task flow call activity creates a binding container. At runtime, the binding container is in context when the task flow call activity passes input parameters. The binding container makes sure that the task flow call activity references the correct values if it references binding values when passing input parameters from a calling task flow to a called task flow.

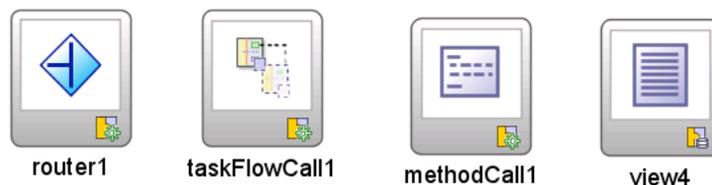

- View

You cannot directly associate a view activity with a page definition file. Instead, you associate the page that the view activity references.

If you right-click any of the above task flow activities (except view activity) in the diagrammer for a task flow, JDeveloper displays an option on the context menu that enables you to create a page definition file (**Create Page Definition**) if one does not yet exist. If a page definition file does exist, JDeveloper displays a context menu option for all task flow activities to go to the page definition file (**Go to Page Definition**). JDeveloper also displays a context menu option (**Edit Binding**) when you right-click a method call activity that is associated with a page definition file.

A task flow activity that is associated with a page definition file displays an icon in the lower-right section of the task flow activity icon. [Figure 19-13](#) shows an example for each of the task flow activities.

Figure 19-13 Task Flow Activities Associated with Page Definition Files

19.10.1 How to Associate a Page Definition File with a Task Flow Activity

JDeveloper provides a context menu option that you can access from the task flow activity. You use this context menu option to associate the task flow activity with a page definition file.

Before you begin:

It may be helpful to have an understanding of how task flow activities use page definition files. For more information, see [Section 19.10, "Using Task Flow Activities with Page Definition Files."](#)

You may also find it helpful to understand other functionality that can be added using other task flow activity features. For more information, see [Section 19.1.2, "Additional Functionality for Task Flow Activities."](#)

To associate a page definition file with a task flow activity

1. In the diagrammer for the task flow, right-click the task flow activity for which you want to create a page definition file.
2. Choose **Create Page Definition** from the context menu that appears.
3. In the resulting page definition file, add the bindings that you want your task flow activity to reference at runtime.

For more information about page definition files, see [Section 13.7, "Working with Page Definition Files"](#).

19.10.2 What Happens When You Associate a Page Definition File with a Task Flow Activity

At design time, JDeveloper generates a page definition file for the task flow activity. The filename of the page definition file comprises the originating task flow and either the name of the task flow activity or the data control operation to invoke. For example, `taskflowName_taskflowName_methodCall1PageDef.xml` or `taskflowName_taskflowName_CreateInsertPageDef.xml`.

JDeveloper also generates an EL expression from the task flow activity to the binding in the created page definition file. [Example 19-17](#) shows a method call activity that references a `CreateInsert` action binding.

Example 19-17 Task Flow Activity Referencing an Action Binding

```
<method-call id="CreateInsert">
  <method>#{bindings.CreateInsert.execute}</method>
  <outcome>
    <fixed-outcome>CreateInsert</fixed-outcome>
  </outcome>
</method-call>
```

At runtime, a binding container makes sure that a task flow activities' EL expressions reference the correct value.

Using Parameters in Task Flows

This chapter describes how to specify parameters in view activities and in bounded task flows.

This chapter includes the following sections:

- [Section 20.1, "About Using Parameters in Task Flows"](#)
- [Section 20.2, "Passing Parameters to a View Activity"](#)
- [Section 20.3, "Passing Parameters to a Bounded Task Flow"](#)
- [Section 20.4, "Sharing Data Controls Between Task Flows"](#)
- [Section 20.5, "Specifying a Return Value from a Bounded Task Flow"](#)

20.1 About Using Parameters in Task Flows

A task flow's ability to accept input parameters and return parameter values allow you to manipulate data in task flows and share data between task flows. Using these abilities, you can optimize the reuse of task flows in your Fusion web application.

You can use view activity input page parameters as aliases. The alias allows you to map bounded task flow input parameters to page parameters. The view activity input page parameters map managed beans and any information available to the calling task flow to a managed bean on the page itself. To pass values out of view activities, store values in page flow scope or managed beans. For information about using view activities in a task flow, see [Section 19.2, "Using View Activities"](#).

For example, a page might specify `#{pageFlowScope.empNo}` as a page parameter and a bounded task flow might specify `#{pageFlowScope.employeeID}` as the value of an input parameter definition.

The `from`-value on the view activity input page parameter would be `#{pageFlowScope.employeeID}` and the `to`-value would be `#{pageFlowScope.empNo}`. This enables reuse of both the page definition and bounded task flow because you do not have to redefine parameters for every context in which each is used.

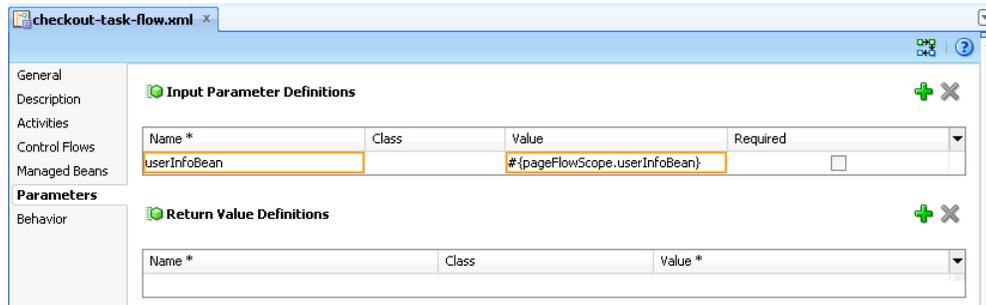

Other values contained within the task flow can be mapped to input page parameters, not just bounded task flow input parameter definition values.

20.1.1 Task Flow Parameters Use Cases and Examples

[Figure 20-1](#) shows how the check out bounded task flow in the Fusion Order Demo application defines input parameters to receive data about a customer who wants to purchase a product. For more information about the Fusion Order Demo, including

how to access the source files, see [Chapter 2, "Introduction to the ADF Sample Application."](#)

Figure 20–1 Check Out Task Flow

20.1.2 Additional Functionality for Task Flows Using Parameters

You may find it helpful to understand other ADF features before you configure or use a task flow with parameters. Additionally, you may want to read about what you can do with your configured task flows. Following are links to other functionality that may be of interest.

- Data controls can be shared between task flows. For more information about data controls, see [Chapter 13.3, "Exposing Application Modules with Oracle ADF Data Controls."](#)
- Task flows can invoke managed beans. For more information about managed beans, see [Section 24.4, "Using a Managed Bean in a Fusion Web Application."](#)
- Bounded task flows can be secured by defining the privileges that are required for someone to use them. For more information, see [Chapter 35, "Enabling ADF Security in a Fusion Web Application."](#)

20.2 Passing Parameters to a View Activity

[Figure 20–2](#) illustrates how to specify an input page parameter mapping. You can pass a parameter to the Employee activity as a pageFlowScope value or a value on a managed bean. The Employee activity can pass a value to the Target activity by placing it within pageFlowScope or a managed bean to the Target activity, based on the EL expression you specified in the to-value.

Figure 20–2 Task Flow with Two Activities

20.2.1 How to Pass Parameters to a View Activity

You add one or more input page parameters to the view activity that you want to pass parameters to.

Before you begin:

It may be helpful to have an understanding of the configuration options available to you before you define an input page parameter for a view activity. For more information, see [Section 20.2, "Passing Parameters to a View Activity."](#)

You may also find it helpful to understand functionality that can be added using other task flow features. For more information, see [Section 20.1.2, "Additional Functionality for Task Flows Using Parameters."](#)

To define an input page parameter for a view activity:

1. In the Application Navigator, double-click the source file for the task flow that contains the view activity to which you want to pass a parameter.
2. Select the view activity in the diagram for the task flow and, in the Property Inspector, expand the **Page Parameters** category.
3. In the Property Inspector, click **Page Parameters**.
4. In the **Input Page Parameter** section, click the **Add** icon and enter values as follows:
 - **From Value:** write an EL expression that, when evaluated, specifies where the view activity retrieves the value for the input page parameter. For example, write an EL expression similar to the following:

```
{pageFlowScope.EmployeeID}
```

You can configure the view activity to retrieve a value that is input to the task flow if you write an EL expression for **From Value** that corresponds to the value for the input parameter that you defined for the task flow, as described in [Section 20.3.1, "How to Pass an Input Parameter to a Bounded Task Flow."](#)

- **To Value:** write an EL expression, that when evaluated, specifies where the page associated with the view activity can retrieve the value of the input page parameter. For example, write an EL expression similar to the following:

```
{pageFlowScope.EmployeeNo}
```

20.2.2 What Happens When You Pass Parameters to a View Activity

JDeveloper writes entries to the source file of the task flow at design time, as illustrated in [Example 20–1](#).

Example 20–1 Metadata to Define an Input Page Parameter on a View Activity

```
<view id="reducedAccess">
  <page>/secured/Information.jsp</page>
  <input-page-parameter>
    <from-value>#{res['infoUsage.reducedAccess.messageHeader']}</from-value>
    <to-value>#{pageFlowScope.infoPageHeaderText}</to-value>
  </input-page-parameter>
  <input-page-parameter>
    <from-value>#{res['infoUsage.reducedAccess.messageHeader']}</from-value>
    <to-value>#{pageFlowScope.infoPageMsg}</to-value>
  </input-page-parameter>
  <input-page-parameter>
    <from-value>info</from-value>
    <to-value>#{pageFlowScope.infoPageType}</to-value>
  </input-page-parameter>
</view>
```

At runtime, the view activity retrieves the value of the input parameter from the location you specified in the `<from-value>` element. The view activity makes the value of the parameter available to its associated page in the location you specified in the `<to-value>` element.

20.2.3 What You May Need to Know About Specifying Parameter Values

You can specify parameter values using standard EL expression if you call a bounded task flow using a task flow call activity or you render the bounded task flow in an ADF region or an ADF dynamic region. For example, you can specify parameters using the following syntax for EL expressions:

- `#{bindings.bindingId.inputValue}`
- `#{bindings.bindingId}`
- `#{inputValue}`

Example 20–2 shows the metadata for a task flow binding that renders in an ADF region.

Example 20–2 ADF Region taskFlow Binding

```
<taskFlow id="Department1" taskFlowId="/WEB-INF/Department.xml#Department"
  xmlns="http://xmlns.oracle.com/adf/Controller/binding"
  Refresh="ifNeeded">
  <parameters>
    <parameter id="DepartmentId" value="#{bindings.DepartmentId.inputValue}"
      xmlns="http://xmlns.oracle.com/adfm/uimodel"/>
  </parameters>
</taskFlow>
```

Appending `inputValue` to the EL expression makes sure that you assign the parameter the value of the binding rather than the actual binding object.

20.3 Passing Parameters to a Bounded Task Flow

A called bounded task flow can accept input parameters from the task flow that calls it. To pass an input parameter to a bounded task flow, you specify one or more:

- Input parameters on the task flow call activity in the calling task flow
Input parameters specify where the calling task flow stores parameter values.
- Input parameter definitions on the called bounded task flow
Input parameter definitions specify where the called bounded task flow can retrieve parameter values at runtime.

Specify the same name for the input parameter that you define on the task flow call activity in the calling task flow and the input parameter definition on the called bounded task flow. Do this so you can map input parameter values to the called bounded task flow.

If you do not specify an EL expression to reference the value of the input parameter, the EL expression for `value` defaults to the following at runtime:

```
#{pageFlowScope.parmName}
```

where `parmName` is the value you entered for the input parameter name.

In an input parameter definition for a called bounded task flow, you can specify an input parameter as required. If the input parameter does not receive a value at runtime

or design time, the task flow raises an error. An input parameter that you do not specify as required can be ignored during task flow call activity creation.

Task flow call activity input parameters can be passed by reference or passed by value when calling a task flow using a task flow call activity unless you are calling a task flow in an ADF region. If the task flow renders in an ADF region, the task flow call activity passes the input parameters by reference. By default, primitive types (for example, `int`, `long`, or `boolean`) are passed by value (`pass-by-value`).

The Pass By Value check box applies only to objects, not primitives and is used to override the default setting of passing by reference. Mixing the two, however, can lead to unexpected behavior in cases where parameters reference each other. If input parameter A on the task flow call activity is passed by value and if input parameter B on the task flow call activity is passed by reference, and B has a reference to A, the result can be two different instances of A and B.

[Section 20.3.1, "How to Pass an Input Parameter to a Bounded Task Flow,"](#) describes how to pass an input parameter from a calling task flow to a called bounded task flow using a task flow call activity. Although you can pass parameter values from any activity on the calling task flow, the passed parameter in [Section 20.3.1, "How to Pass an Input Parameter to a Bounded Task Flow"](#) contain the value of an input text field on a page in the calling task flow.

If you call a bounded task flow using a URL rather than a task flow call activity, you pass parameters and values on the URL itself. For more information, see [Section 19.6.4, "How to Call a Bounded Task Flow Using a URL"](#).

Instead of explicitly passing data controls as parameters between task flows, you can simply share them by specifying the `data-control-scope` option on the called bounded task flow. For more information, see [Section 20.4, "Sharing Data Controls Between Task Flows"](#).

A called task flow can also return values to the task flow that called it when it exits. For more information about returning values from a bounded task flow, see [Section 20.5, "Specifying a Return Value from a Bounded Task Flow."](#)

20.3.1 How to Pass an Input Parameter to a Bounded Task Flow

You define values on the calling task flow and the called task flow.

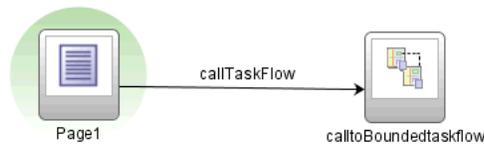

Before you begin:

- Create a calling and called task flow

The calling task flow can be bounded or unbounded. The called task flow must be bounded. For more information about creating task flows, see [Section 18.2, "Creating a Task Flow."](#)

- Add a task flow call activity to the calling task flow

[Figure 20–3](#) shows an example where the view activity passes control to the task flow call activity.

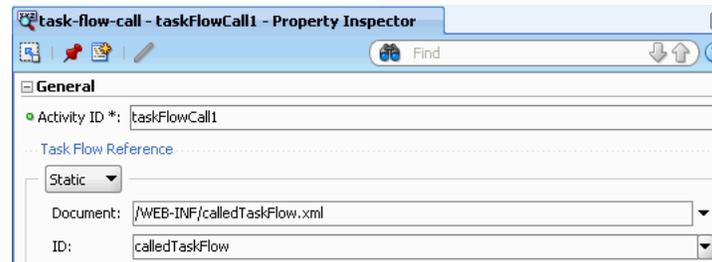

Figure 20–3 Calling Task Flow

- It may be helpful to have an understanding of the configuration options available to you before you configure a bounded task flow to receive an input parameter. For more information, [Section 20.3, "Passing Parameters to a Bounded Task Flow."](#)
- You may also find it helpful to understand functionality that can be added using other task flow features. For more information, see [Section 20.1.2, "Additional Functionality for Task Flows Using Parameters."](#)

To pass an input parameter to a bounded task flow:

1. In the Application Navigator for your project, double-click the JSF page that contains an input component where an end user enters a value that gets passed to a bounded task flow as a parameter at runtime.
The JSF page that you open should be referenced by a view activity in the calling task flow.
2. Select an input text component on the JSF page where an end user enters a value at runtime.
3. In the Property Inspector, enter a value for the input text component.
You can specify the value as an EL expression, for example `{pageFlowScope.inputValue}`.
