Each Ndb object has its own counters. NDB API applications can read the values of the counters for use in optimization or monitoring. For multithreaded clients which use more than one Ndb object concurrently, it is also possible to obtain a summed view of counters from all Ndb objects belonging to a given Ndb_cluster_connection.

Four sets of these counters are exposed. One set applies to the current session only; the other 3 are global. This is in spite of the fact that their values can be obtained as either session or global status variables in the mysql client. This means that specifying the SESSION or GLOBAL keyword with SHOW STATUS has no effect on the values reported for NDB API statistics status variables, and the value for each of these variables is the same whether the value is obtained from the equivalent column of the SESSION_STATUS or the GLOBAL_STATUS table.

- **Session counters (session specific)**
  
  Session counters relate to the Ndb objects in use by (only) the current session. Use of such objects by other MySQL clients does not influence these counts.

  In order to minimize confusion with standard MySQL session variables, we refer to the variables that correspond to these NDB API session counters as "_session variables", with a leading underscore.

- **Replica counters (global)**
  
  This set of counters relates to the Ndb objects used by the replica SQL thread, if any. If this mysqld does not act as a replica, or does not use NDB tables, then all of these counts are 0.

  We refer to the related status variables as "_slave variables" (with a leading underscore).

- **Injector counters (global)**
  
  Injector counters relate to the Ndb object used to listen to cluster events by the binary log injector thread. Even when not writing a binary log, mysqld processes attached to an NDB Cluster continue to listen for some events, such as schema changes.

  We refer to the status variables that correspond to NDB API injector counters as "_injector variables" (with a leading underscore).

- **Server (Global) counters (global)**
  
  This set of counters relates to all Ndb objects currently used by this mysqld. This includes all MySQL client applications, the replica SQL thread (if any), the binlog injector, and the NDB utility thread.

  We refer to the status variables that correspond to these counters as "global variables" or "mysqld-level variables".
You can obtain values for a particular set of variables by additionally filtering for the substring `session`, `slave`, or `injector` in the variable name (along with the common prefix `Ndb_api`). For `session` variables, this can be done as shown here:

```
mysql> SHOW STATUS LIKE 'ndb_api%session';
+--------------------------------------------+---------+
| Variable_name                              | Value   |
+--------------------------------------------+---------+
| Ndb_api_wait_exec_complete_count_session   | 2       |
| Ndb_api_wait_scan_result_count_session     | 0       |
| Ndb_api_wait_meta_request_count_session    | 1       |
| Ndb_api_wait_nanos_count_session           | 8144375 |
| Ndb_api_bytes_sent_count_session           | 68      |
| Ndb_api_bytes_received_count_session       | 84      |
| Ndb_api_trans_start_count_session          | 1       |
| Ndb_api_trans_commit_count_session         | 1       |
| Ndb_api_trans_abort_count_session          | 0       |
| Ndb_api_trans_close_count_session          | 1       |
| Ndb_api_pk_op_count_session                | 1       |
| Ndb_api_uk_op_count_session                | 0       |
| Ndb_api_table_scan_count_session           | 0       |
| Ndb_api_range_scan_count_session           | 0       |
| Ndb_api_pruned_scan_count_session          | 0       |
| Ndb_api_scan_batch_count_session           | 0       |
| Ndb_api_read_row_count_session             | 1       |
| Ndb_api_trans_local_read_row_count_session | 1       |
+--------------------------------------------+---------+
18 rows in set (0.50 sec)
```

To obtain a listing of the NDB API `mysqld`-level status variables, filter for variable names beginning with `ndb_api` and ending in `_count`, like this:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.SESSION_STATUS
    -> WHERE VARIABLE_NAME LIKE 'ndb_api%count';
+------------------------------------+----------------+
| VARIABLE_NAME                      | VARIABLE_VALUE |
+------------------------------------+----------------+
| NDB_API_WAIT_EXEC_COMPLETE_COUNT   | 4              |
| NDB_API_WAIT_SCAN_RESULT_COUNT     | 3              |
| NDB_API_WAIT_META_REQUEST_COUNT    | 28             |
| NDB_API_WAIT_NANOS_COUNT           | 53756398       |
| NDB_API_BYTES_SENT_COUNT           | 1060           |
| NDB_API_BYTES_RECEIVED_COUNT       | 9724           |
| NDB_API_TRANS_START_COUNT          | 3              |
| NDB_API_TRANS_COMMIT_COUNT         | 2              |
| NDB_API_TRANS_ABORT_COUNT          | 0              |
| NDB_API_TRANS_CLOSE_COUNT          | 3              |
| NDB_API_PK_OP_COUNT                | 2              |
| NDB_API_UK_OP_COUNT                | 0              |
| NDB_API_TABLE_SCAN_COUNT           | 1              |
| NDB_API_RANGE_SCAN_COUNT           | 0              |
| NDB_API_PRUNED_SCAN_COUNT          | 0              |
| NDB_API_SCAN_BATCH_COUNT           | 0              |
| NDB_API_READ_ROW_COUNT             | 2              |
| NDB_API_TRANS_LOCAL_READ_ROW_COUNT | 2              |
| NDB_API_EVENT_DATA_COUNT           | 0              |
| NDB_API_EVENT_NONDATA_COUNT        | 0              |
| NDB_API_EVENT_BYTES_COUNT          | 0              |
+------------------------------------+----------------+
21 rows in set (0.09 sec)
```

Not all counters are reflected in all 4 sets of status variables. For the event counters `DataEventsRecvdCount`, `NondataEventsRecvdCount`, and `EventBytesRecvdCount`, only `injector` and `mysqld`-level NDB API status variables are available:

```
mysql> SHOW STATUS LIKE 'ndb_api%event%';
```

3025
_injector status variables are not implemented for any other NDB API counters, as shown here:

```sql
mysql> SHOW STATUS LIKE 'ndb_api%injector%';
+--------------------------------------+-------+
| Variable_name                        | Value |
+--------------------------------------+-------+
| Ndb_api_event_data_count_injector    | 0     |
| Ndb_api_event_nondata_count_injector | 0     |
| Ndb_api_event_bytes_count_injector   | 0     |
+--------------------------------------+-------+
3 rows in set (0.00 sec)
```

The names of the status variables can easily be associated with the names of the corresponding counters. Each NDB API statistics counter is listed in the following table with a description as well as the names of any MySQL server status variables corresponding to this counter.

**Table 18.54 NDB API statistics counters**

<table>
<thead>
<tr>
<th>Counter Name</th>
<th>Description</th>
<th>Status Variables (by statistic type):</th>
</tr>
</thead>
<tbody>
<tr>
<td>WaitExecCompleteCount</td>
<td>Number of times thread has been blocked while waiting for execution of an operation to complete. Includes all <code>execute()</code> calls as well as implicit executes for blob operations and auto-increment not visible to clients.</td>
<td>• Ndb_api_wait_exec_complete_count_session&lt;br&gt;• Ndb_api_wait_exec_complete_count_slave&lt;br&gt;• [none]&lt;br&gt;• Ndb_api_wait_exec_complete_count</td>
</tr>
<tr>
<td>WaitScanResultCount</td>
<td>Number of times thread has been blocked waiting for a scan-based signal, such waiting for additional results, or for a scan to close.</td>
<td>• Ndb_api_wait_scan_result_count_session&lt;br&gt;• Ndb_api_wait_scan_result_count_slave&lt;br&gt;• [none]&lt;br&gt;• Ndb_api_wait_scan_result_count</td>
</tr>
<tr>
<td>WaitMetaRequestCount</td>
<td>Number of times thread has been blocked waiting for a metadata-based signal; this can occur when</td>
<td>• Ndb_api_wait_meta_request_count_session&lt;br&gt;• Ndb_api_wait_meta_request_count_slave&lt;br&gt;• [none]&lt;br&gt;• Ndb_api_wait_meta_request_count</td>
</tr>
<tr>
<td>Counter Name</td>

</tr>
</tbody>
</table>

To see all counts of committed transactions—that is, all `TransCommitCount` counter status variables—you can filter the results of `SHOW STATUS` for the substring `trans_commit_count`, like this:
From this you can determine that 1 transaction has been committed in the current mysql client session, and 2 transactions have been committed on this mysqld since it was last restarted.

You can see how various NDB API counters are incremented by a given SQL statement by comparing the values of the corresponding _session status variables immediately before and after performing the statement. In this example, after getting the initial values from SHOW STATUS, we create in the test database an NDB table, named t, that has a single column:

Now you can execute a new SHOW STATUS statement and observe the changes, as shown here (with the changed rows highlighted in the output):
Similarly, you can see the changes in the NDB API statistics counters caused by inserting a row into `t`:

Insert the row, then run the same `SHOW STATUS` statement used in the previous example, as shown here:

```
mysql> INSERT INTO t VALUES (100);
Query OK, 1 row affected (0.00 sec)
```

```
mysql> SHOW STATUS LIKE 'ndb_api%session%';
+--------------------------------------------+-----------+
| Variable_name                              | Value     |
|--------------------------------------------+-----------|
| Ndb_api_wait_exec_complete_count_session   | 11        |
| Ndb_api_wait_scan_result_count_session     | 6         |
| Ndb_api_wait_meta_request_count_session    | 20        |
| Ndb_api_wait_nanos_count_session           | 70370418  |
| Ndb_api_bytes_sent_count_session           | 2724      |
| Ndb_api_bytes_received_count_session       | 4116      |
| Ndb_api_trans_start_count_session          | 7         |
| Ndb_api_trans_commit_count_session         | 6         |
| Ndb_api_trans_abort_count_session          | 0         |
| Ndb_api_trans_close_count_session          | 7         |
| Ndb_api_pk_op_count_session                | 8         |
| Ndb_api_uk_op_count_session                | 0         |
| Ndb_api_table_scan_count_session           | 1         |
| Ndb_api_range_scan_count_session           | 0         |
| Ndb_api_pruned_scan_count_session          | 0         |
| Ndb_api_scan_batch_count_session           | 0         |
| Ndb_api_read_row_count_session             | 3         |
| Ndb_api_trans_local_read_row_count_session | 2         |
+--------------------------------------------+-----------+
18 rows in set (0.00 sec)
```

We can make a number of observations from these results:

- Although we created `t` with no explicit primary key, 5 primary key operations were performed in doing so (the difference in the “before” and “after” values of `Ndb_api_pk_op_count_session`, or 6 minus 1). This reflects the creation of the hidden primary key that is a feature of all tables using the NDB storage engine.

- By comparing successive values for `Ndb_api_wait_nanos_count_session`, we can see that the NDB API operations implementing the `CREATE TABLE` statement waited much longer (706871709 - 820705 = 706051004 nanoseconds, or approximately 0.7 second) for responses from the data nodes than those executed by the `INSERT` (707370418 - 706871709 = 498709 ns or roughly .0005 second). The execution times reported for these statements in the `mysql` client correlate roughly with these figures.

On platforms without sufficient (nanosecond) time resolution, small changes in the value of the `WaitNanosCount` NDB API counter due to SQL statements that execute very quickly may not always be visible in the values of `Ndb_api_wait_nanos_count_session`, `Ndb_api_wait_nanos_count_slave`, or `Ndb_api_wait_nanos_count`.

- The `INSERT` statement incremented both the `ReadRowCount` and `TransLocalReadRowCount` NDB API statistics counters, as reflected by the increased values of `Ndb_api_read_row_count_session` and `Ndb_api_trans_local_read_row_count_session`. 

3031
18.6.14 ndbinfo: The NDB Cluster Information Database

ndbinfo is a database containing information specific to NDB Cluster.

This database contains a number of tables, each providing a different sort of data about NDB Cluster node status, resource usage, and operations. You can find more detailed information about each of these tables in the next several sections.

ndbinfo is included with NDB Cluster support in the MySQL Server; no special compilation or configuration steps are required; the tables are created by the MySQL Server when it connects to the cluster. You can verify that ndbinfo support is active in a given MySQL Server instance using SHOW PLUGINS; if ndbinfo support is enabled, you should see a row containing ndbinfo in the Name column and ACTIVE in the Status column, as shown here (emphasized text):

```
mysql> SHOW PLUGINS;
+----------------------------------+--------+--------------------+---------+---------+
| Name                             | Status | Type               | Library | License |
+----------------------------------+--------+--------------------+---------+---------+
| binlog                           | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| mysql_native_password            | ACTIVE | AUTHENTICATION     | NULL    | GPL     |
| mysql_old_password               | ACTIVE | AUTHENTICATION     | NULL    | GPL     |
| CSV                              | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| MEMORY                           | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| MRG_MYISAM                       | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| MyISAM                           | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| PERFORMANCE_SCHEMA               | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| BLACKHOLE                        | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| ARCHIVE                          | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| ndbcluster                       | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| ndbinfo                          | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| ndb_transid_mysql_connection_map | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| InnoDB                           | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| INNODB_TRX                       | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_LOCKS                     | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_LOCK_WAITS                | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_CMP                       | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_CMP_RESET                 | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_CMPMEM                    | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_CMPMEM_RESET              | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| partition                        | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
+----------------------------------+--------+--------------------+---------+---------+
22 rows in set (0.00 sec)
```

You can also do this by checking the output of SHOW ENGINES for a line including ndbinfo in the Engine column and YES in the Support column, as shown here (emphasized text):

```
mysql> SHOW ENGINES;
*************************** 1. row ***************************
| Engine: ndbcluster       |
| Support: YES             |
| Comment: Clustered, fault-tolerant tables |
| Transactions: YES       |

```
If `ndbinfo` support is enabled, then you can access `ndbinfo` using SQL statements in `mysql` or another MySQL client. For example, you can see `ndbinfo` listed in the output of `SHOW DATABASES`, as shown here (emphasized text):

```sql
mysql> SHOW DATABASES;
+--------------------+
| Database           |
+--------------------+
| information_schema |
| mysql              |
| ndbinfo            |
| test               |
+--------------------+
```
If the `mysqld` process was not started with the `--ndbcluster` option, `ndbinfo` is not available and is not displayed by `SHOW DATABASES`. If `mysqld` was formerly connected to an NDB Cluster but the cluster becomes unavailable (due to events such as cluster shutdown, loss of network connectivity, and so forth), `ndbinfo` and its tables remain visible, but an attempt to access any tables (other than `blocks` or `config_params`) fails with `Got error 157 'Connection to NDB failed' from NDBINFO`.

With the exception of the `blocks` and `config_params` tables, what we refer to as `ndbinfo` “tables” are actually views generated from internal NDB tables not normally visible to the MySQL Server. You can make these tables visible by setting the `ndbinfo_show_hidden` system variable to `ON` (or `1`), but this is normally not necessary.

All `ndbinfo` tables are read-only, and are generated on demand when queried. Because many of them are generated in parallel by the data nodes while other are specific to a given SQL node, they are not guaranteed to provide a consistent snapshot.

In addition, pushing down of joins is not supported on `ndbinfo` tables; so joining large `ndbinfo` tables can require transfer of a large amount of data to the requesting API node, even when the query makes use of a `WHERE` clause.

`ndbinfo` tables are not included in the query cache. (Bug #59831)

You can select the `ndbinfo` database with a `USE` statement, and then issue a `SHOW TABLES` statement to obtain a list of tables, just as for any other database, like this:

```
mysql> USE ndbinfo;
Database changed

mysql> SHOW TABLES;
+--------------------------------------------------+
| Tables_in_ndbinfo                                |
+--------------------------------------------------+
| arbitrator_validity_detail                      |
| arbitrator_validity_summary                     |
| blocks                                          |
| cluster_operations                              |
| cluster_transactions                            |
| config_params                                   |
| counters                                        |
| dict_obj_types                                  |
| disk_write_speed_aggregate                      |
| disk_write_speed_aggregate_node                 |
| disk_write_speed_base                           |
| diskpagebuffer                                  |
| logbuffers                                      |

| threadblocks                                    |
| threadstat                                      |
| transporters                                    |
+--------------------------------------------------+
26 rows in set (0.00 sec)
```
The \texttt{dict_obj_types}, \texttt{disk_write_speed_aggregate}, \texttt{disk_write_speed_aggregate_node}, \texttt{disk_write_speed_base}, \texttt{restart_info}, and \texttt{operations_per_fragment} tables was added in NDB 7.4.

You can execute \texttt{SELECT} statements against these tables, just as you would normally expect:

\begin{verbatim}
mysql> SELECT * FROM memoryusage;
+---------+---------------------+--------+------------+------------+-------------+
| node_id | memory_type         | used   | used_pages | total      | total_pages |
+---------+---------------------+--------+------------+------------+-------------+
|       5 | Data memory         | 753664 |         23 | 1073741824 |       32768 |
|       5 | Index memory        | 163840 |         20 | 1074003968 |      131104 |
|       5 | Long message buffer |   2304 |          9 |   67108864 |      262144 |
|       6 | Data memory         | 753664 |         23 | 1073741824 |       32768 |
|       6 | Index memory        | 163840 |         20 | 1074003968 |      131104 |
|       6 | Long message buffer |   2304 |          9 |   67108864 |      262144 |
+---------+---------------------+--------+------------+------------+-------------+
6 rows in set (0.02 sec)
\end{verbatim}

More complex queries, such as the two following \texttt{SELECT} statements using the \texttt{memoryusage} table, are possible:

\begin{verbatim}
mysql> SELECT SUM(used) as 'Data Memory Used, All Nodes'
    > FROM memoryusage
    > WHERE memory_type = 'Data memory';
+-----------------------------+
| Data Memory Used, All Nodes |
+-----------------------------+
|                        6460 |
+-----------------------------+
1 row in set (0.37 sec)

mysql> SELECT SUM(max) as 'Total IndexMemory Available'
    > FROM memoryusage
    > WHERE memory_type = 'Index memory';
+-----------------------------+
| Total IndexMemory Available |
+-----------------------------+
|                       25664 |
+-----------------------------+
1 row in set (0.33 sec)
\end{verbatim}

\texttt{ndbinfo} table and column names are case-sensitive (as is the name of the \texttt{ndbinfo} database itself). These identifiers are in lowercase. Trying to use the wrong lettercase results in an error, as shown in this example:

\begin{verbatim}
mysql> SELECT * FROM nodes;
+---------+--------+---------+-------------+
| node_id | uptime | status  | start_phase |
+---------+--------+---------+-------------+
|       1 |  13602 | STARTED |           0 |
|       2 |     16 | STARTED |           0 |
+---------+--------+---------+-------------+
2 rows in set (0.04 sec)

mysql> SELECT * FROM Nodes;
ERROR 1146 (42S02): Table 'ndbinfo.Nodes' doesn't exist
\end{verbatim}

\texttt{mysqldump} ignores the \texttt{ndbinfo} database entirely, and excludes it from any output. This is true even when using the \texttt{--databases} or \texttt{--all-databases} option.

NDB Cluster also maintains tables in the \texttt{INFORMATION_SCHEMA} information database, including the \texttt{FILES} table which contains information about files used for NDB Cluster Disk Data storage, and the \texttt{ndb_transid_mysql_connection_map} table, which shows the relationships between transactions,
18.6.14.1 The ndbinfo arbitrator_validity_detail Table

The arbitrator_validity_detail table shows the view that each data node in the cluster has of the arbitrator. It is a subset of the membership table.

The arbitrator_validity_detail table contains the following columns:

- **node_id**
  This node’s node ID
- **arbitrator**
  Node ID of arbitrator
- **arb_ticket**
  Internal identifier used to track arbitration
- **arb_connected**
  Whether this node is connected to the arbitrator
- **arb_state**
  Arbitration state

**Notes**

The node ID is the same as that reported by `ndb_mgm -e "SHOW"`.

All nodes should show the same arbitrator and arb_ticket values as well as the same arb_state value. Possible arb_state values are `ARBIT_NULL`, `ARBIT_INIT`, `ARBIT_FIND`, `ARBIT_PREP1`, `ARBIT_PREP2`, `ARBIT_START`, `ARBIT_RUN`, `ARBIT_CHOOSE`, `ARBIT_CRASH`, and `UNKNOWN`.

arb_connected shows whether the current node is connected to the arbitrator.

18.6.14.2 The ndbinfo arbitrator_validity_summary Table

The arbitrator_validity_summary table provides a composite view of the arbitrator with regard to the cluster’s data nodes.

The arbitrator_validity_summary table contains the following columns:

- **arbitrator**
  Node ID of arbitrator
- **arb_ticket**
  Internal identifier used to track arbitration
- **arb_connected**
  Whether this arbitrator is connected to the cluster
- **consensus_count**
The `ndbinfo` blocks Table

The blocks table is a static table which simply contains the names and internal IDs of all NDB kernel blocks (see NDB Kernel Blocks). It is for use by the other ndbinfo tables (most of which are actually views) in mapping block numbers to block names for producing human-readable output.

The blocks table contains the following columns:

- **block_number**
  - Block number
- **block_name**
  - Block name

**Notes**

To obtain a list of all block names, simply execute `SELECT block_name FROM ndbinfo.blocks`. Although this is a static table, its content can vary between different NDB Cluster releases.

18.6.14.4 The ndbinfo cluster_operations Table

The cluster_operations table provides a per-operation (stateful primary key op) view of all activity in the NDB Cluster from the point of view of the local data management (LQH) blocks (see The DBLQH Block).

The cluster_operations table contains the following columns:

- **node_id**
  - Node ID of reporting LQH block
- **block_instance**
  - LQH block instance
- **transid**
  - Transaction ID
- **operation_type**
  - Operation type (see text for possible values)
- **state**
ndbinfo: The NDB Cluster Information Database

Operation state (see text for possible values)

- **tableid**
  Table ID

- **fragmentid**
  Fragment ID

- **client_node_id**
  Client node ID

- **client_block_ref**
  Client block reference

- **tc_node_id**
  Transaction coordinator node ID

- **tc_block_no**
  Transaction coordinator block number

- **tc_block_instance**
  Transaction coordinator block instance

Notes

The transaction ID is a unique 64-bit number which can be obtained using the NDB API's `getTransactionId()` method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

The operation_type column can take any one of the values **READ, READ-SH, READ-EX, INSERT, UPDATE, DELETE, WRITE, UNLOCK, REFRESH, SCAN, SCAN-SH, SCAN-EX, or <unknown>**.

The state column can have any one of the values **ABORT_QUEUED, ABORT_STOPPED, COMMITTED, COMMIT_QUEUED, COMMIT_STOPPED, COPY_CLOSE_STOPPED, COPY_FIRST_STOPPED, COPY_STOPPED, COPY_TUPKEY, IDLE, LOG_ABORT_QUEUED, LOG_COMMIT_QUEUED, LOG_COMMIT_QUEUED_WAIT_SIGNAL, LOG_COMMIT_WRITTEN, LOG_COMMIT_WRITTEN_WAIT_SIGNAL, LOG_QUEUED, PREPARED, PREPARED_RECEIVED_COMMIT, SCAN_CHECK_STOPPED, SCAN_CLOSE_STOPPED, SCAN_FIRST_STOPPED, SCAN_RELEASE_STOPPED, SCAN_STATE_USED, SCAN_STOPPED, SCAN_TUPKEY, STOPPED, TC_NOT_CONNECTED, WAIT_ACC, WAIT_ACC_ABORT, WAIT_AI_AFTER_ABORT, WAIT_ATTR, WAIT_SCAN_AI, WAIT_TUP, WAIT_TUPKEYINFO, WAIT_TUP_COMMIT, or WAIT_TUP_TO_ABORT**. (If the MySQL Server is running with `ndbinfo_show_hidden` enabled, you can view this list of states by selecting from the `ndb $db$blqh_tcconnect_state` table, which is normally hidden.)

You can obtain the name of an NDB table from its table ID by checking the output of `ndb_show_tables`.

The fragid is the same as the partition number seen in the output of `ndb_desc --extra-partition-info` (short form `-p`).

In **client_node_id** and **client_block_ref**, client refers to an NDB Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).
The `block_instance` and `tc_block_instance` column provide, respectively, the `DBLQH` and `DBTC` block instance numbers. You can use these along with the block names to obtain information about specific threads from the `threadblocks` table.

18.6.14.5 The ndbinfo cluster_transactions Table

The `cluster_transactions` table shows information about all ongoing transactions in an NDB Cluster.

The `cluster_transactions` table contains the following columns:

- **node_id**
  
  Node ID of transaction coordinator

- **block_instance**
  
  TC block instance

- **transid**
  
  Transaction ID

- **state**
  
  Operation state (see text for possible values)

- **count_operations**
  
  Number of stateful primary key operations in transaction (includes reads with locks, as well as DML operations)

- **outstanding_operations**
  
  Operations still being executed in local data management blocks

- **inactive_seconds**
  
  Time spent waiting for API

- **client_node_id**
  
  Client node ID

- **client_block_ref**
  
  Client block reference

Notes

The transaction ID is a unique 64-bit number which can be obtained using the NDB API's `getTransactionId()` method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

`block_instance` refers to an instance of a kernel block. Together with the block name, this number can be used to look up a given instance in the `threadblocks` table.

The `state` column can have any one of the values `CS_ABORTING, CS_COMMITTING, CS_COMMIT_SENT, CS_COMPLETE_SENT, CS_COMPLETING, CS_CONNECTED, CS_DISCONNECTED, CS_FAIL_ABORTED, CS_FAIL_ABORTING, CS_FAIL_COMMITTED, CS_FAIL_COMMITTING, CS_FAIL_COMPLETED,`
CS_FAIL_PREPARED, CS_PREPARE_TO_COMMIT, CS_RECEIVING, CS_REC_COMMITTING, CS_RESTART, CS_SEND_FIRE_TRIG_REQ, CS_STARTED, CS_START_COMMITTING, CS_START_SCAN, CS_WAIT_ABORT_CONF, CS_WAIT_COMMIT_CONF, CS_WAIT_COMPLETE_CONF, CS_WAIT_FIRE_TRIG_REQ. (If the MySQL Server is running with ndbinfo_show_hidden enabled, you can view this list of states by selecting from the ndb$dbtc_apiconnect_state table, which is normally hidden.)

In client_node_id and client_block_ref, client refers to an NDB Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

The tc_block_instance column provides the DBTC block instance number. You can use this along with the block name to obtain information about specific threads from the threadblocks table.

18.6.14.6 The ndbinfo config_params Table

The config_params table is a static table which provides the names and internal ID numbers of and other information about NDB Cluster configuration parameters.

The config_params table contains the following columns:

- param_number
  The parameter's internal ID number
- param_name
  The name of the parameter

Notes

Although this is a static table, its content can vary between NDB Cluster installations, since supported parameters can vary due to differences between software releases, cluster hardware configurations, and other factors.

18.6.14.7 The ndbinfo counters Table

The counters table provides running totals of events such as reads and writes for specific kernel blocks and data nodes. Counts are kept from the most recent node start or restart; a node start or restart resets all counters on that node. Not all kernel blocks have all types of counters.

The counters table contains the following columns:

- node_id
  The data node ID
- block_name
  Name of the associated NDB kernel block (see NDB Kernel Blocks).
- block_instance
  Block instance
- counter_id
  The counter's internal ID number; normally an integer between 1 and 10, inclusive.
- counter_name
The name of the counter. See text for names of individual counters and the NDB kernel block with which each counter is associated.

- **val**

The counter’s value

### Notes

Each counter is associated with a particular NDB kernel block.

The **OPERATIONS** counter is associated with the **DBLQH** (local query handler) kernel block (see The **DBLQH Block**). A primary-key read counts as one operation, as does a primary-key update. For reads, there is one operation in **DBLQH** per operation in **DBTC**. For writes, there is one operation counted per fragment replica.

The **ATTRINFO**, **TRANSACTIONS**, **COMMTS**, **READS**, **LOCAL_READS**, **SIMPLE_READS**, **WRITES**, **LOCAL_WRITES**, **ABORTS**, **TABLE_SCANS**, and **RANGE_SCANS** counters are associated with the **DBTC** (transaction co-ordinator) kernel block (see The **DBTC Block**).

**LOCAL_WRITES** and **LOCAL_READS** are primary-key operations using a transaction coordinator in a node that also holds the primary fragment replica of the record.

The **READS** counter includes all reads. **LOCAL_READS** includes only those reads of the primary fragment replica on the same node as this transaction coordinator. **SIMPLE_READS** includes only those reads in which the read operation is the beginning and ending operation for a given transaction. Simple reads do not hold locks but are part of a transaction, in that they observe uncommitted changes made by the transaction containing them but not of any other uncommitted transactions. Such reads are “simple” from the point of view of the TC block; since they hold no locks they are not durable, and once **DBTC** has routed them to the relevant LQH block, it holds no state for them.

**ATTRINFO** keeps a count of the number of times an interpreted program is sent to the data node. See **NDB Protocol Messages**, for more information about **ATTRINFO** messages in the **NDB** kernel.

The **LOCAL_TABLE_SCANS_SENT**, **READS_RECEIVED**, **PRUNED_RANGE_SCANS_RECEIVED**, **RANGE_SCANS_RECEIVED**, **LOCAL_READS_SENT**, **CONST_PRUNED_RANGE_SCANS_RECEIVED**, **LOCAL_RANGE_SCANS_SENT**, **REMOTE_READS_SENT**, **REMOTE_RANGE_SCANS_SENT**, **READS_NOT_FOUND**, **SCAN_BATCHES_RETURNED**, **TABLE_SCANS_RECEIVED**, and **SCAN_ROWS_RETURNED** counters are associated with the **DBSPJ** (select push-down join) kernel block (see The **DBSPJ Block**).

The **block_name** and **block_instance** columns provide, respectively, the applicable NDB kernel block name and instance number. You can use these to obtain information about specific threads from the **threadblocks** table.

A number of counters provide information about transporter overload and send buffer sizing when troubleshooting such issues. For each LQH instance, there is one instance of each counter in the following list:

- **LQHKEY_OVERLOAD**: Number of primary key requests rejected at the LQH block instance due to transporter overload

- **LQHKEY_OVERLOAD_TC**: Count of instances of **LQHKEY_OVERLOAD** where the TC node transporter was overloaded

- **LQHKEY_OVERLOAD_READER**: Count of instances of **LQHKEY_OVERLOAD** where the API reader (reads only) node was overloaded.
18.6.14.8 The ndbinfo dict_obj_types Table

The dict_obj_types table is a static table listing possible dictionary object types used in the NDB kernel. These are the same types defined by Object::Type in the NDB API.

The dict_obj_types table contains the following columns:

- type_id
  The type ID for this type
- type_name
  The name of this type

Notes

18.6.14.9 The ndbinfo disk_write_speed_base Table

The disk_write_speed_base table provides base information about the speed of disk writes during LCP, backup, and restore operations.

The disk_write_speed_base table contains the following columns:

- node_id
  Node ID of this node
- thr_no
  Thread ID of this LDM thread
- millis_ago
  Milliseconds since this reporting period ended
- millis_passed
  Milliseconds elapsed in this reporting period
- backup_lcp_bytes_written
  Number of bytes written to disk by local checkpoints and backup processes during this period
- redo_bytes_written
  Number of bytes written to REDO log during this period
- target_disk_write_speed
  Actual speed of disk writes per LDM thread (base data)
Notes

18.6.14.10 The ndbinfo disk_write_speed_aggregate Table

The `disk_write_speed_aggregate` table provides aggregated information about the speed of disk writes during LCP, backup, and restore operations.

The `disk_write_speed_aggregate` table contains the following columns:

- **node_id**
  Node ID of this node

- **thr_no**
  Thread ID of this LDM thread

- **backup_lcp_speed_last_sec**
  Number of bytes written to disk by backup and LCP processes in the last second

- **redo_speed_last_sec**
  Number of bytes written to REDO log in the last second

- **backup_lcp_speed_last_10sec**
  Number of bytes written to disk by backup and LCP processes per second, averaged over the last 10 seconds

- **redo_speed_last_10sec**
  Number of bytes written to REDO log per second, averaged over the last 10 seconds

- **std_dev_backup_lcp_speed_last_10sec**
  Standard deviation in number of bytes written to disk by backup and LCP processes per second, averaged over the last 10 seconds

- **std_dev_redo_speed_last_10sec**
  Standard deviation in number of bytes written to REDO log per second, averaged over the last 10 seconds

- **backup_lcp_speed_last_60sec**
  Number of bytes written to disk by backup and LCP processes per second, averaged over the last 60 seconds

- **redo_speed_last_60sec**
  Number of bytes written to REDO log per second, averaged over the last 10 seconds

- **std_dev_backup_lcp_speed_last_60sec**
  Standard deviation in number of bytes written to disk by backup and LCP processes per second, averaged over the last 60 seconds

- **std_dev_redo_speed_last_60sec**
Standard deviation in number of bytes written to REDO log per second, averaged over the last 60 seconds

- `slowdowns_due_to_io_lag`
  Number of seconds since last node start that disk writes were slowed due to REDO log I/O lag

- `slowdowns_due_to_high_cpu`
  Number of seconds since last node start that disk writes were slowed due to high CPU usage

- `disk_write_speed_set_to_min`
  Number of seconds since last node start that disk write speed was set to minimum

- `current_target_disk_write_speed`
  Actual speed of disk writes per LDM thread (aggregated)

### 18.6.14.11 The ndbinfo disk_write_speed_aggregate_node Table

The `disk_write_speed_aggregate_node` table provides aggregated information per node about the speed of disk writes during LCP, backup, and restore operations.

The `disk_write_speed_aggregate_node` contains the following columns:

- `node_id`
  Node ID of this node

- `backup_lcp_speed_last_sec`
  Number of bytes written to disk by backup and LCP processes in the last second

- `redo_speed_last_sec`
  Number of bytes written to REDO log in the last second

- `backup_lcp_speed_last_10sec`
  Number of bytes written to disk by backup and LCP processes per second, averaged over the last 10 seconds

- `redo_speed_last_10sec`
  Number of bytes written to REDO log per second, averaged over the last 10 seconds

- `backup_lcp_speed_last_60sec`
  Number of bytes written to disk by backup and LCP processes per second, averaged over the last 60 seconds

- `redo_speed_last_60sec`
  Number of bytes written to disk by backup and LCP processes per second, averaged over the last 60 seconds

### 18.6.14.12 The ndbinfo diskpagebuffer Table
The `diskpagebuffer` table provides statistics about disk page buffer usage by NDB Cluster Disk Data tables.

The `diskpagebuffer` table contains the following columns:

- **node_id**
  The data node ID

- **block_instance**
  Block instance

- **pages_written**
  Number of pages written to disk.

- **pages_written_lcp**
  Number of pages written by local checkpoints.

- **pages_read**
  Number of pages read from disk

- **log_waits**
  Number of page writes waiting for log to be written to disk

- **page_requests_direct_return**
  Number of requests for pages that were available in buffer

- **page_requests_wait_queue**
  Number of requests that had to wait for pages to become available in buffer

- **page_requests_wait_io**
  Number of requests that had to be read from pages on disk (pages were unavailable in buffer)

Notes

You can use this table with NDB Cluster Disk Data tables to determine whether `DiskPageBufferMemory` is sufficiently large to allow data to be read from the buffer rather from disk; minimizing disk seeks can help improve performance of such tables.

You can determine the proportion of reads from `DiskPageBufferMemory` to the total number of reads using a query such as this one, which obtains this ratio as a percentage:

```
SELECT
  node_id,
  100 * page_requests_direct_return / (page_requests_direct_return + page_requests_wait_io) AS hit_ratio
FROM ndbinfo.diskpagebuffer;
```

The result from this query should be similar to what is shown here, with one row for each data node in the cluster (in this example, the cluster has 4 data nodes):
**hit_ratio** values approaching 100% indicate that only a very small number of reads are being made from disk rather than from the buffer, which means that Disk Data read performance is approaching an optimum level. If any of these values are less than 95%, this is a strong indicator that the setting for **DiskPageBufferMemory** needs to be increased in the **config.ini** file.

**Note**

A change in **DiskPageBufferMemory** requires a rolling restart of all of the cluster’s data nodes before it takes effect.

The **block_instance** column provides the NDB kernel block instance number. You can use this to obtain information about specific threads from the **threadblocks** table.

### 18.6.14.13 The ndbinfo logbuffers Table

The **logbuffer** table provides information on NDB Cluster log buffer usage.

The **logbuffers** table contains the following columns:

- **node_id**
  
  The ID of this data node.

- **log_type**
  
  Type of log, one of: **REDO** or **DD-UNDO**.

- **log_id**
  
  The log ID.

- **log_part**
  
  The log part number.

- **total**
  
  Total space available for this log.

- **used**
  
  Space used by this log.

**Notes**

Beginning with NDB 7.6.5, **logbuffers** table rows reflecting two additional log types are available when performing an NDB backup. One of these rows has the log type **BACKUP-DATA**, which shows the amount of data buffer used during backup to copy fragments to backup files. The other row has the log type **BACKUP-LOG**, which displays the amount of log buffer used during the backup to record changes made after the backup has started. One each of these **log_type** rows is shown in the **logbuffers** table.
for each data node in the cluster. These rows are not present unless an NDB backup is currently being performed. (Bug #25822988)

18.6.14.14 The ndbinfo logspaces Table

This table provides information about NDB Cluster log space usage.

The logspaces table contains the following columns:

- node_id
  The ID of this data node.
- log_type
  Type of log; one of: REDO or DD-UNDO.
- log_id
  The log ID.
- log_part
  The log part number.
- total
  Total space available for this log.
- used
  Space used by this log.

18.6.14.15 The ndbinfo membership Table

The membership table describes the view that each data node has of all the others in the cluster, including node group membership, president node, arbitrator, arbitrator successor, arbitrator connection states, and other information.

The membership table contains the following columns:

- node_id
  This node's node ID
- group_id
  Node group to which this node belongs
- left_node
  Node ID of the previous node
- right_node
  Node ID of the next node
- president
  President's node ID
• successor
  Node ID of successor to president
• succession_order
  Order in which this node succeeds to presidency
• Conf_HB_order
  -
• arbitrator
  Node ID of arbitrator
• arb_ticket
  Internal identifier used to track arbitration
• arb_state
  Arbitration state
• arb_connected
  Whether this node is connected to the arbitrator
• connected_rank1_arbs
  Connected arbitrators of rank 1
• connected_rank2_arbs
  Connected arbitrators of rank 1

Notes

The node ID and node group ID are the same as reported by \texttt{ndb\_mgm -e \"SHOW\"}.

\texttt{left\_node} and \texttt{right\_node} are defined in terms of a model that connects all data nodes in a circle, in order of their node IDs, similar to the ordering of the numbers on a clock dial, as shown here:

\textbf{Figure 18.18 Circular Arrangement of NDB Cluster Nodes}

In this example, we have 8 data nodes, numbered 5, 6, 7, 8, 12, 13, 14, and 15, ordered clockwise in a circle. We determine “left” and “right” from the interior of the circle. The node to the left of node 5 is
The NDB Cluster Information Database

node 15, and the node to the right of node 5 is node 6. You can see all these relationships by running the following query and observing the output:

```
mysql> SELECT node_id, left_node, right_node
    -> FROM ndbinfo.membership;
```

<table>
<thead>
<tr>
<th>node_id</th>
<th>left_node</th>
<th>right_node</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>15</td>
<td>6</td>
</tr>
<tr>
<td>6</td>
<td>5</td>
<td>7</td>
</tr>
<tr>
<td>7</td>
<td>6</td>
<td>8</td>
</tr>
<tr>
<td>8</td>
<td>7</td>
<td>12</td>
</tr>
<tr>
<td>12</td>
<td>8</td>
<td>13</td>
</tr>
<tr>
<td>13</td>
<td>12</td>
<td>14</td>
</tr>
<tr>
<td>14</td>
<td>13</td>
<td>15</td>
</tr>
<tr>
<td>15</td>
<td>14</td>
<td>5</td>
</tr>
</tbody>
</table>

8 rows in set (0.00 sec)

The designations “left” and “right” are used in the event log in the same way.

The president node is the node viewed by the current node as responsible for setting an arbitrator (see NDB Cluster Start Phases). If the president fails or becomes disconnected, the current node expects the node whose ID is shown in the successor column to become the new president. The succession_order column shows the place in the succession queue that the current node views itself as having.

In a normal NDB Cluster, all data nodes should see the same node as president, and the same node (other than the president) as its successor. In addition, the current president should see itself as 1 in the order of succession, the successor node should see itself as 2, and so on.

All nodes should show the same arb_ticket values as well as the same arb_state values. Possible arb_state values are ARBIT_NULL, ARBIT_INIT, ARBIT_FIND, ARBIT_PREP1, ARBIT_PREP2, ARBIT_START, ARBIT_RUN, ARBIT_CHOOSE, ARBIT_CRASH, and UNKNOWN.

arb_connected shows whether this node is connected to the node shown as this node’s arbitrator.

The connected_rank1_arbs and connected_rank2_arbs columns each display a list of 0 or more arbitrators having an ArbitrationRank equal to 1, or to 2, respectively.

---

### Note

Both management nodes and API nodes are eligible to become arbitrators.

#### 18.6.14.16 The ndbinfo memoryusage Table

Querying this table provides information similar to that provided by the ALL REPORT MemoryUsage command in the ndb_mgm client, or logged by ALL DUMP 1000.

The memoryusage table contains the following columns:

- **node_id**
  
  The node ID of this data node.

- **memory_type**
  
  One of Data memory, Index memory, or Long message buffer.

- **used**
Number of bytes currently used for data memory or index memory by this data node.

- **used_pages**
  Number of pages currently used for data memory or index memory by this data node; see text.

- **total**
  Total number of bytes of data memory or index memory available for this data node; see text.

- **total_pages**
  Total number of memory pages available for data memory or index memory on this data node; see text.

**Notes**

The **total** column represents the total amount of memory in bytes available for the given resource (data memory or index memory) on a particular data node. This number should be approximately equal to the setting of the corresponding configuration parameter in the `config.ini` file.

Suppose that the cluster has 2 data nodes having node IDs 5 and 6, and the `config.ini` file contains the following:

```
[ndbd default]
DataMemory = 1G
IndexMemory = 1G
```

Suppose also that the value of the `LongMessageBuffer` configuration parameter is allowed to assume its default (64 MB in NDB 7.3.5 and later).

The following query shows approximately the same values:

```sql
mysql> SELECT node_id, memory_type, total
    > FROM ndbinfo.memoryusage;
```

<table>
<thead>
<tr>
<th>node_id</th>
<th>memory_type</th>
<th>total</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>Data memory</td>
<td>1073741824</td>
</tr>
<tr>
<td>5</td>
<td>Index memory</td>
<td>1074003968</td>
</tr>
<tr>
<td>5</td>
<td>Long message buffer</td>
<td>67108864</td>
</tr>
<tr>
<td>6</td>
<td>Data memory</td>
<td>1073741824</td>
</tr>
<tr>
<td>6</td>
<td>Index memory</td>
<td>1074003968</td>
</tr>
<tr>
<td>6</td>
<td>Long message buffer</td>
<td>67108864</td>
</tr>
</tbody>
</table>

6 rows in set (0.00 sec)

In this case, the **total** column values for index memory are slightly higher than the value set of `IndexMemory` due to internal rounding.

For the **used_pages** and **total_pages** columns, resources are measured in pages, which are 32K in size for `DataMemory` and 8K for `IndexMemory`. For long message buffer memory, the page size is 256 bytes.

Long message buffer information can be found in this table beginning with NDB 7.3.5; in earlier versions of NDB Cluster, only data memory and index memory were included.

**18.6.14.17 The ndbinfo memory_per_fragment Table**

The **memory_per_fragment** table provides information about the usage of memory by individual fragments.
The `memory_per_fragment` table contains the following columns:

- **fq_name**
  Name of this fragment
- **parent_fq_name**
  Name of this fragment's parent
- **type**
  Type of object; see text for possible values
- **table_id**
  Table ID for this table
- **node_id**
  Node ID for this node
- **block_instance**
  Kernel block instance ID
- **fragment_num**
  Fragment ID (number)
- **fixed_elem_alloc_bytes**
  Number of bytes allocated for fixed-sized elements
- **fixed_elem_free_bytes**
  Free bytes remaining in pages allocated to fixed-size elements
- **fixed_elem_size_bytes**
  Length of each fixed-size element in bytes
- **fixed_elem_count**
  Number of fixed-size elements
- **fixed_elem_free_count**
  Number of free rows for fixed-size elements
- **var_elem_alloc_bytes**
  Number of bytes allocated for variable-size elements
- **var_elem_free_bytes**
  Free bytes remaining in pages allocated to variable-size elements
- **var_elem_count**
  Number of variable-size elements
• **hash_index_alloc_bytes**
  Number of bytes allocated to hash indexes

**Notes**

The `type` column from this table shows the dictionary object type used for this fragment (`Object::Type`, in the NDB API), and can take any one of the values shown in the following list:

- System table
- User table
- Unique hash index
- Hash index
- Unique ordered index
- Ordered index
- Hash index trigger
- Subscription trigger
- Read only constraint
- Index trigger
- Reorganize trigger
- Tablespace
- Log file group
- Data file
- Undo file
- Hash map
- Foreign key definition
- Foreign key parent trigger
- Foreign key child trigger
- Schema transaction

You can also obtain this list by executing `SELECT * FROM ndbinfo.dict_obj_types` in the `mysql` client.

The `block_instance` column provides the NDB kernel block instance number. You can use this to obtain information about specific threads from the `threadblocks` table.

**18.6.14.18 The ndbinfo nodes Table**

This table contains information on the status of data nodes. For each data node that is running in the cluster, a corresponding row in this table provides the node's node ID, status, and uptime. For nodes that are starting, it also shows the current start phase.

The `nodes` table contains the following columns:
• **node_id**
  The data node's unique node ID in the cluster.

• **uptime**
  Time since the node was last started, in seconds.

• **status**
  Current status of the data node; see text for possible values.

• **start_phase**
  If the data node is starting, the current start phase.

• **config_generation**
  The version of the cluster configuration file in use on this data node.

**Notes**

The **uptime** column shows the time in seconds that this node has been running since it was last started or restarted. This is a **BIGINT** value. This figure includes the time actually needed to start the node; in other words, this counter starts running the moment that **ndbd** or **ndbmt.d** is first invoked; thus, even for a node that has not yet finished starting, **uptime** may show a nonzero value.

The **status** column shows the node's current status. This is one of: **NOTHING**, **CMVMI**, **STARTING**, **STARTED**, **SINGLEUSER**, **STOPPING_1**, **STOPPING_2**, **STOPPING_3**, or **STOPPING_4**. When the status is **STARTING**, you can see the current start phase in the **start_phase** column (see later in this section). **SINGLEUSER** is displayed in the **status** column for all data nodes when the cluster is in single user mode (see Section 18.6.6, “NDB Cluster Single User Mode”). Seeing one of the **STOPPING** states does not necessarily mean that the node is shutting down but can mean rather that it is entering a new state. For example, if you put the cluster in single user mode, you can sometimes see data nodes report their state briefly as **STOPPING_2** before the status changes to **SINGLEUSER**.

The **start_phase** column uses the same range of values as those used in the output of the **ndb_mgm** client **node_id STATUS** command (see Section 18.6.1, “Commands in the NDB Cluster Management Client”). If the node is not currently starting, then this column shows 0. For a listing of NDB Cluster start phases with descriptions, see Section 18.6.4, “Summary of NDB Cluster Start Phases”.

The **config_generation** column shows which version of the cluster configuration is in effect on each data node. This can be useful when performing a rolling restart of the cluster in order to make changes in configuration parameters. For example, from the output of the following **SELECT** statement, you can see that node 3 is not yet using the latest version of the cluster configuration **(6)** although nodes 1, 2, and 4 are doing so:

```
mysql> USE ndbinfo;
Database changed
mysql> SELECT * FROM nodes;
+---------+--------+---------+-------------+-------------------+
<table>
<thead>
<tr>
<th>node_id</th>
<th>uptime</th>
<th>status</th>
<th>start_phase</th>
<th>config_generation</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>10462</td>
<td>STARTED</td>
<td>0</td>
<td>6</td>
</tr>
<tr>
<td>2</td>
<td>10460</td>
<td>STARTED</td>
<td>0</td>
<td>6</td>
</tr>
<tr>
<td>3</td>
<td>10457</td>
<td>STARTED</td>
<td>0</td>
<td>5</td>
</tr>
<tr>
<td>4</td>
<td>10455</td>
<td>STARTED</td>
<td>0</td>
<td>6</td>
</tr>
</tbody>
</table>
+---------+--------+---------+-------------+-------------------+
2 rows in set (0.04 sec)
```
Therefore, for the case just shown, you should restart node 3 to complete the rolling restart of the cluster.

Nodes that are stopped are not accounted for in this table. Suppose that you have an NDB Cluster with 4 data nodes (node IDs 1, 2, 3 and 4), and all nodes are running normally, then this table contains 4 rows, 1 for each data node:

```sql
mysql> USE ndbinfo;
Database changed
mysql> SELECT * FROM nodes;
+---------+--------+---------+-------------+-------------------+
<table>
<thead>
<tr>
<th>node_id</th>
<th>uptime</th>
<th>status</th>
<th>start_phase</th>
<th>config_generation</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>11776</td>
<td>STARTED</td>
<td>0</td>
<td>6</td>
</tr>
<tr>
<td>2</td>
<td>11774</td>
<td>STARTED</td>
<td>0</td>
<td>6</td>
</tr>
<tr>
<td>3</td>
<td>11771</td>
<td>STARTED</td>
<td>0</td>
<td>6</td>
</tr>
<tr>
<td>4</td>
<td>11769</td>
<td>STARTED</td>
<td>0</td>
<td>6</td>
</tr>
</tbody>
</table>
+---------+--------+---------+-------------+-------------------+
4 rows in set (0.04 sec)
```

If you shut down one of the nodes, only the nodes that are still running are represented in the output of this `SELECT` statement, as shown here:

```shell
ndb_mgm> 2 STOP
Node 2: Node shutdown initiated
Node 2: Node shutdown completed.
Node 2 has shutdown.
```

```sql
mysql> SELECT * FROM nodes;
+---------+--------+---------+-------------+-------------------+
<table>
<thead>
<tr>
<th>node_id</th>
<th>uptime</th>
<th>status</th>
<th>start_phase</th>
<th>config_generation</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>11807</td>
<td>STARTED</td>
<td>0</td>
<td>6</td>
</tr>
<tr>
<td>3</td>
<td>11802</td>
<td>STARTED</td>
<td>0</td>
<td>6</td>
</tr>
<tr>
<td>4</td>
<td>11800</td>
<td>STARTED</td>
<td>0</td>
<td>6</td>
</tr>
</tbody>
</table>
+---------+--------+---------+-------------+-------------------+
3 rows in set (0.02 sec)
```

### 18.6.14.19 The ndbinfo operations_per_fragment Table

The `operations_per_fragment` table provides information about the operations performed on individual fragments and fragment replicas, as well as about some of the results from these operations.

The `operations_per_fragment` table contains the following columns:

- **fq_name**
  
  Name of this fragment

- **parent fq_name**
  
  Name of this fragment's parent

- **type**
  
  Type of object; see text for possible values

- **table_id**
  
  Table ID for this table

- **node_id**
  
  Node ID for this node
• block_instance
  Kernel block instance ID
• fragment_num
  Fragment ID (number)
• tot_key_reads
  Total number of key reads for this fragment replica
• tot_key_inserts
  Total number of key inserts for this fragment replica
• tot_key_updates
  Total number of key updates for this fragment replica
• tot_key_writes
  Total number of key writes for this fragment replica
• tot_key_deletes
  Total number of key deletes for this fragment replica
• tot_key_refs
  Number of key operations refused
• tot_key_attrinfo_bytes
  Total size of all attrinfo attributes
• tot_key_keyinfo_bytes
  Total size of all keyinfo attributes
• tot_key_prog_bytes
  Total size of all interpreted programs carried by attrinfo attributes
• tot_key_inst_exec
  Total number of instructions executed by interpreted programs for key operations
• tot_key_bytes_returned
  Total size of all data and metadata returned from key read operations
• tot_frag_scans
  Total number of scans performed on this fragment replica
• tot_scan_rows_examined
  Total number of rows examined by scans
• tot_scan_rows_returned
Total number of rows returned to client

- `tot_scan_bytes_returned`
  Total size of data and metadata returned to the client

- `tot_scan_prog_bytes`
  Total size of interpreted programs for scan operations

- `tot_scan_bound_bytes`
  Total size of all bounds used in ordered index scans

- `tot_scan_inst_exec`
  Total number of instructions executed for scans

- `tot_qd_frag_scans`
  Number of times that scans of this fragment replica have been queued

- `conc_frag_scans`
  Number of scans currently active on this fragment replica (excluding queued scans)

- `conc_qd_frag_scans`
  Number of scans currently queued for this fragment replica

- `tot_commits`
  Total number of row changes committed to this fragment replica

Notes

The `fq_name` contains the fully qualified name of the schema object to which this fragment replica belongs. This currently has the following formats:

- **Base table:** `DbName/def/TblName`
- **BLOB table:** `DbName/def/NDB$BLOB_BaseTblId_ColNo`
- **Ordered index:** `sys/def/BaseTblId/IndexName`
- **Unique index:** `sys/def/BaseTblId/IndexName$unique`

The `$unique` suffix shown for unique indexes is added by `mysqld`; for an index created by a different NDB API client application, this may differ, or not be present.

The syntax just shown for fully qualified object names is an internal interface which is subject to change in future releases.

Consider a table `t1` created and modified by the following SQL statements:

```sql
CREATE DATABASE mydb;
USE mydb;
CREATE TABLE t1 {
    a INT NOT NULL,
```
CREATE UNIQUE INDEX ix1 ON t1(b) USING HASH;

If `t1` is assigned table ID 11, this yields the `fq_name` values shown here:

- **Base table**: `mydb/def/t1`
- **BLOB table**: `mydb/def/NDB$BLOB_11_2`
- **Ordered index (primary key)**: `sys/def/11/PRIMARY`
- **Unique index**: `sys/def/11/ix1$unique`

For indexes or BLOB tables, the `parent_fq_name` column contains the `fq_name` of the corresponding base table. For base tables, this column is always `NULL`.

The `type` column shows the schema object type used for this fragment, which can take any one of the values `System table`, `User table`, `Unique hash index`, or `Ordered index`. BLOB tables are shown as `User table`.

The `table_id` column value is unique at any given time, but can be reused if the corresponding object has been deleted. The same ID can be seen using the `ndb_show_tables` utility.

The `block_instance` column shows which LDM instance this fragment replica belongs to. You can use this to obtain information about specific threads from the `threadblocks` table. The first such instance is always numbered 0.

Since there are typically two fragment replicas, and assuming that this is so, each `fragment_num` value should appear twice in the table, on two different data nodes from the same node group.

Since NDB does not use single-key access for ordered indexes, the counts for `tot_key_reads`, `tot_key_inserts`, `tot_key_updates`, `tot_key_writes`, and `tot_key_deletes` are not incremented by ordered index operations.

---

**Note**

When using `tot_key_writes`, you should keep in mind that a write operation in this context updates the row if the key exists, and inserts a new row otherwise. (One use of this is in the NDB implementation of the `REPLACE` SQL statement.)

The `tot_key_refs` column shows the number of key operations refused by the LDM. Generally, such a refusal is due to duplicate keys (inserts), `Key not found` errors (updates, deletes, and reads), or the operation was rejected by an interpreted program used as a predicate on the row matching the key.

The `attrinfo` and `keyinfo` attributes counted by the `tot_key_attrinfo_bytes` and `tot_key_keyinfo_bytes` columns are attributes of an `LQHKEYREQ` signal (see The NDB Communication Protocol) used to initiate a key operation by the LDM. An `attrinfo` typically contains tuple field values (inserts and updates) or projection specifications (for reads); `keyinfo` contains the primary or unique key needed to locate a given tuple in this schema object.

The value shown by `tot_frag_scans` includes both full scans (that examine every row) and scans of subsets. Unique indexes and BLOB tables are never scanned, so this value, like other scan-related counts, is 0 for fragment replicas of these.

`tot_scan_rows_examined` may display less than the total number of rows in a given fragment replica, since ordered index scans can be limited by bounds. In addition, a client may choose to end a scan before...
all potentially matching rows have been examined; this occurs when using an SQL statement containing a `LIMIT` or `EXISTS` clause, for example. `tot_scan_rows_returned` is always less than or equal to `tot_scan_rows_examined`.

`tot_scan_bytes_returned` includes, in the case of pushed joins, projections returned to the `DBSPJ` block in the NDB kernel.

`tot_qd_frag_scans` can be effected by the setting for the `MaxParallelScansPerFragment` data node configuration parameter, which limits the number of scans that may execute concurrently on a single fragment replica.

### 18.6.14.20 The ndbinfo resources Table

This table provides information about data node resource availability and usage.

These resources are sometimes known as *super-pools*.

The `resources` table contains the following columns:

- **node_id**
  - The unique node ID of this data node.

- **resource_name**
  - Name of the resource; see text.

- **reserved**
  - The amount reserved for this resource.

- **used**
  - The amount actually used by this resource.

- **max**
  - The maximum amount of this resource used, since the node was last started.

#### Notes

The `resource_name` can be any one of the names shown in the following table:

- **RESERVED**: Reserved by the system; cannot be overridden.

- **DISK_OPERATIONS**: If a log file group is allocated, the size of the undo log buffer is used to set the size of this resource. This resource is used only to allocate the undo log buffer for an undo log file group; there can only be one such group. Overallocation occurs as needed by `CREATE LOGFILE GROUP`.

- **DISK_RECORDS**: Records allocated for Disk Data operations.

- **DATA_MEMORY**: Used for main memory tuples, indexes, and hash indexes. Sum of DataMemory and IndexMemory, plus 8 pages of 32 KB each if IndexMemory has been set. Cannot be overallocated.

- **JOBBUFFER**: Used for allocating job buffers by the NDB scheduler; cannot be overallocated. This is approximately 2 MB per thread plus a 1 MB buffer in both directions for all threads that can communicate. For large configurations this consume several GB.

- **FILE_BUFFERS**: Used by the redo log handler in the `DBLQH` kernel block; cannot be overallocated. Size is `NoOfFragmentLogParts * RedoBuffer`, plus 1 MB per log file part.
**TRANSPORTER_BUFFERS**: Used for send buffers by `ndbmtd`; the sum of `TotalSendBufferMemory` and `ExtraSendBufferMemory`. This resource can be overallocated by up to 25 percent. `TotalSendBufferMemory` is calculated by summing the send buffer memory per node, the default value of which is 2 MB. Thus, in a system having four data nodes and eight API nodes, the data nodes have 12 * 2 MB send buffer memory. `ExtraSendBufferMemory` is used by `ndbmtd` and amounts to 2 MB extra memory per thread. Thus, with 4 LDM threads, 2 TC threads, 1 main thread, 1 replication thread, and 2 receive threads, `ExtraSendBufferMemory` is 10 * 2 MB. Overallocation of this resource can be performed by setting the `SharedGlobalMemory` data node configuration parameter.

**DISK_PAGE_BUFFER**: Used for the disk page buffer; determined by the `DiskPageBufferMemory` configuration parameter. Cannot be overallocated.

**QUERY_MEMORY**: Used by the `DBSPJ` kernel block.

**SCHEMA_TRANS_MEMORY**: Minimum is 2 MB; can be overallocated to use any remaining available memory.

### 18.6.14.21 The ndbinfo restart_info Table

The `restart_info` table contains information about node restart operations. Each entry in the table corresponds to a node restart status report in real time from a data node with the given node ID. Only the most recent report for any given node is shown.

The `restart_info` table contains the following columns:

- **node_id**: Node ID in the cluster
- **node_restart_status**: Node status; see text for values. Each of these corresponds to a possible value of `node_restart_status_int`.
- **node_restart_status_int**: Node status code; see text for values.
- **secs_to_complete_node_failure**: Time in seconds to complete node failure handling
- **secs_to_allocate_node_id**: Time in seconds from node failure completion to allocation of node ID
- **secs_to_include_in_heartbeat_protocol**: Time in seconds from allocation of node ID to inclusion in heartbeat protocol
- **secs_until_wait_for_ndbcntr_master**: Time in seconds from being included in heartbeat protocol until waiting for `NDBCNTR` master began
- **secs_wait_for_ndbcntr_master**: Time in seconds spent waiting to be accepted by `NDBCNTR` master for starting
- **secs_to_get_start_permitted**: 3059
Time in seconds elapsed from receiving of permission for start from master until all nodes have accepted start of this node

• **secs_to_wait_for_lcp_for_copy_meta_data**
  Time in seconds spent waiting for LCP completion before copying metadata

• **secs_to_copy_meta_data**
  Time in seconds required to copy metadata from master to newly starting node

• **secs_to_include_node**
  Time in seconds waited for GCP and inclusion of all nodes into protocols

• **secs_starting_node_to_request_local_recovery**
  Time in seconds that the node just starting spent waiting to request local recovery

• **secs_for_local_recovery**
  Time in seconds required for local recovery by node just starting

• **secs_restore.fragments**
  Time in seconds required to restore fragments from LCP files

• **secs_undo_disk_data**
  Time in seconds required to execute undo log on disk data part of records

• **secs_exec_redo_log**
  Time in seconds required to execute redo log on all restored fragments

• **secs_index_rebuild**
  Time in seconds required to rebuild indexes on restored fragments

• **secs_to_synchronize_starting_node**
  Time in seconds required to synchronize starting node from live nodes

• **secs_wait_lcp_for_restart**
  Time in seconds required for LCP start and completion before restart was completed

• **secs_wait_subscription_handover**
  Time in seconds spent waiting for handover of replication subscriptions

• **total_restart_secs**
  Total number of seconds from node failure until node is started again

**Notes**

The following list contains values defined for the `node_restart_status_int` column with their internal status names (in parentheses), and the corresponding messages shown in the `node_restart_status` column:
- 0 (ALLOCATED_NODE_ID)
  Allocated node id
- 1 (INCLUDED_IN_HB_PROTOCOL)
  Included in heartbeat protocol
- 2 (NDBCNTR_START_WAIT)
  Wait for NDBCNTR master to permit us to start
- 3 (NDBCNTR_STARTED)
  NDBCNTR master permitted us to start
- 4 (START_PERMITTED)
  All nodes permitted us to start
- 5 (WAIT_LCP_TO_COPY_DICT)
  Wait for LCP completion to start copying metadata
- 6 (COPY_DICT_TO_STARTING_NODE)
  Copying metadata to starting node
- 7 (INCLUDE_NODE_IN_LCP_AND_GCP)
  Include node in LCP and GCP protocols
- 8 (LOCAL_RECOVERY_STARTED)
  Restore fragments ongoing
- 9 (COPY_FRAGMENTS_STARTED)
  Synchronizing starting node with live nodes
- 10 (WAIT_LCP_FOR_RESTART)
  Wait for LCP to ensure durability
- 11 (WAIT_SUMA_HANOVER)
  Wait for handover of subscriptions
- 12 (RESTART_COMPLETED)
  Restart completed
- 13 (NODE_FAILED)
  Node failed, failure handling in progress
- 14 (NODE FAILURE COMPLETED)
  Node failure handling completed
- 15 (NODE GETTING PERMIT)
All nodes permitted us to start

- **16** (NODE_GETTING_INCLUDED)
  Include node in LCP and GCP protocols

- **17** (NODE_GETTING_SYNCHED)
  Synchronizing starting node with live nodes

- **18** (NODE_GETTING_LCP_WAITED)
  [none]

- **19** (NODE_ACTIVE)
  Restart completed

- **20** (NOT_DEFINED_IN_CLUSTER)
  [none]

- **21** (NODE_NOT_RESTARTED_YET)
  Initial state

Status numbers 0 through 12 apply on master nodes only; the remainder of those shown in the table apply to all restarting data nodes. Status numbers 13 and 14 define node failure states; 20 and 21 occur when no information about the restart of a given node is available.

See also Section 18.6.4, “Summary of NDB Cluster Start Phases”.

### 18.6.14.22 The ndbinfo server_operations Table

The `server_operations` table contains entries for all ongoing NDB operations that the current SQL node (MySQL Server) is currently involved in. It effectively is a subset of the `cluster_operations` table, in which operations for other SQL and API nodes are not shown.

The `server_operations` table contains the following columns:

- **mysql_connection_id**
  MySQL Server connection ID

- **node_id**
  Node ID

- **block_instance**
  Block instance

- **transid**
  Transaction ID

- **operation_type**
  Operation type (see text for possible values)
ndbinfo: The NDB Cluster Information Database

- **state**
  Operation state (see text for possible values)
- **tableid**
  Table ID
- **fragmentid**
  Fragment ID
- **client_node_id**
  Client node ID
- **client_block_ref**
  Client block reference
- **tc_node_id**
  Transaction coordinator node ID
- **tc_block_no**
  Transaction coordinator block number
- **tc_block_instance**
  Transaction coordinator block instance

**Notes**

The `mysql_connection_id` is the same as the connection or session ID shown in the output of `SHOW PROCESSLIST`. It is obtained from the `INFORMATION_SCHEMA` table `NDB_TRANSID_MYSQL_CONNECTION_MAP`.

`block_instance` refers to an instance of a kernel block. Together with the block name, this number can be used to look up a given instance in the `threadblocks` table.

The transaction ID (`transid`) is a unique 64-bit number which can be obtained using the NDB API's `getTransactionId()` method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

The `operation_type` column can take any one of the values: `READ`, `READ-SH`, `READ-EX`, `INSERT`, `UPDATE`, `DELETE`, `WRITE`, `UNLOCK`, `REFRESH`, `SCAN`, `SCAN-SH`, `SCAN-EX`, or `<unknown>`.

The `state` column can have any one of the values: `ABORT_QUEUED`, `ABORT_STOPPED`, `COMMITTED`, `COMMIT_QUEUED`, `COMMIT_STOPPED`, `COPY_CLOSE_STOPPED`, `COPY_FIRST_STOPPED`, `COPY_STOPPED`, `COPY_TUPKEY`, `IDLE`, `LOG_ABORT_QUEUED`, `LOG_ABORT_WRITTEN`, `LOG_COMMIT_QUEUED`, `LOG_COMMIT_QUEUED_WAIT_SIGNAL`, `LOG_COMMIT_WRITTEN`, `LOG_COMMIT_WRITTEN_WAIT_SIGNAL`, `LOG_QUEUED`, `PREPARED`, `PREPARED_RECEIVED_COMMIT`, `SCAN_CHECK_STOPPED`, `SCAN_CLOSE_STOPPED`, `SCAN_FIRST_STOPPED`, `SCAN_RELEASE_STOPPED`, `SCAN_STATE_USED`, `SCAN_STOPPED`, `SCAN_TUPKEY`, `STOPPED`, `TC_NOT_CONNECTED`, `WAIT_ACC`, `WAIT_ACC_ABORT`, `WAIT_AI_AFTER_ABORT`, `WAIT_ATTR`, `WAIT_SCAN_AI`, `WAIT_TUP`, `WAIT_TUPKEYINFO`, `WAIT_TUP_COMMIT`, or `WAIT_TUP_TO_ABORT`. (If the MySQL Server is running with `ndbinfo_show_hidden` enabled, you can view this list of states by selecting from the `ndb $db1qh_tccconnect_state` table, which is normally hidden.)
You can obtain the name of an NDB table from its table ID by checking the output of `ndb_show_tables`.

The `fragid` is the same as the partition number seen in the output of `ndb_desc --extra-partition-info` (short form `-p`).

In `client_node_id` and `client_block_ref`, `client` refers to an NDB Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

The `block_instance` and `tc_block_instance` column provide NDB kernel block instance numbers. You can use these to obtain information about specific threads from the `threadblocks` table.

## 18.6.14.23 The ndbinfo server_transactions Table

The `server_transactions` table is a subset of the `cluster_transactions` table, but includes only those transactions in which the current SQL node (MySQL Server) is a participant, while including the relevant connection IDs.

The `server_transactions` table contains the following columns:

- `mysql_connection_id`
  MySQL Server connection ID
- `node_id`
  Transaction coordinator node ID
- `block_instance`
  Transaction coordinator block instance
- `transid`
  Transaction ID
- `state`
  Operation state (see text for possible values)
- `count_operations`
  Number of stateful operations in the transaction
- `outstanding_operations`
  Operations still being executed by local data management layer (LQH blocks)
- `inactive_seconds`
  Time spent waiting for API
- `client_node_id`
  Client node ID
- `client_block_ref`
  Client block reference
Notes

The `mysql_connection_id` is the same as the connection or session ID shown in the output of `SHOW PROCESSLIST`. It is obtained from the `INFORMATION_SCHEMA` table `NDB_TRANSID_MYSQL_CONNECTION_MAP`.

`block_instance` refers to an instance of a kernel block. Together with the block name, this number can be used to look up a given instance in the `threadblocks` table.

The transaction ID (`transid`) is a unique 64-bit number which can be obtained using the NDB API's `getTransactionId()` method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

The `state` column can have any one of the values `CS_ABORTING`, `CS_COMMITTING`, `CS_COMMIT_SENT`, `CS_COMPLETE_SENT`, `CS_COMPLETING`, `CS_CONNECTED`, `CS_DISCONNECTED`, `CS_FAIL_ABORTED`, `CS_FAIL_ABORTING`, `CS_FAIL_COMMITTED`, `CS_FAIL_COMMITTING`, `CS_FAIL_COMPLETED`, `CS_FAIL_PREPARED`, `CS_PREPARE_TO_COMMIT`, `CS_RECEIVING`, `CS_REC_COMMITTING`, `CS_RESTART`, `CS_SEND_FIRE_TRIG_REQ`, `CS_STARTED`, `CS_START_COMMITTING`, `CS_START_SCAN`, `CS_WAIT_ABORT_CONF`, `CS_WAIT_COMMIT_CONF`, `CS_WAIT_COMPLETE_CONF`, `CS_WAIT_FIRE_TRIG_REQ`. (If the MySQL Server is running with `ndbinfo_show_hidden` enabled, you can view this list of states by selecting from the `ndb$dbtc_apiconnect_state` table, which is normally hidden.)

In `client_node_id` and `client_block_ref`, `client` refers to an NDB Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

The `block_instance` column provides the DBTC kernel block instance number. You can use this to obtain information about specific threads from the `threadblocks` table.

18.6.14.24 The `ndbinfo tc_time_track_stats` Table

The `tc_time_track_stats` table provides time-tracking information obtained from the DBTC block (TC) instances in the data nodes, through API nodes access NDB. Each TC instance tracks latencies for a set of activities it undertakes on behalf of API nodes or other data nodes; these activities include transactions, transaction errors, key reads, key writes, unique index operations, failed key operations of any type, scans, failed scans, fragment scans, and failed fragment scans.

A set of counters is maintained for each activity, each counter covering a range of latencies less than or equal to an upper bound. At the conclusion of each activity, its latency is determined and the appropriate counter incremented. `tc_time_track_stats` presents this information as rows, with a row for each instance of the following:

- Data node, using its ID
- TC block instance
- Other communicating data node or API node, using its ID
- Upper bound value

Notes

Each row contains a value for each activity type. This is the number of times that this activity occurred with a latency within the range specified by the row (that is, where the latency does not exceed the upper bound).

The `tc_time_track_stats` table contains the following columns:

- `node_id`
Requesting node ID

- **block_number**
  TC block number

- **block_instance**
  TC block instance number

- **comm_node_id**
  Node ID of communicating API or data node

- **upper_bound**
  Upper bound of interval (in microseconds)

- **scans**
  Based on duration of successful scans from opening to closing, tracked against the API or data nodes requesting them.

- **scan_errors**
  Based on duration of failed scans from opening to closing, tracked against the API or data nodes requesting them.

- **scan_fragments**
  Based on duration of successful fragment scans from opening to closing, tracked against the data nodes executing them

- **scan_fragment_errors**
  Based on duration of failed fragment scans from opening to closing, tracked against the data nodes executing them

- **transactions**
  Based on duration of successful transactions from beginning until sending of commit ACK, tracked against the API or data nodes requesting them. Stateless transactions are not included.

- **transaction_errors**
  Based on duration of failing transactions from start to point of failure, tracked against the API or data nodes requesting them.

- **read_key_ops**
  Based on duration of successful primary key reads with locks. Tracked against both the API or data node requesting them and the data node executing them.

- **write_key_ops**
  Based on duration of successful primary key writes, tracked against both the API or data node requesting them and the data node executing them.

- **index_key_ops**
Based on duration of successful unique index key operations, tracked against both the API or data node requesting them and the data node executing reads of base tables.

- **key_op_errors**
  Based on duration of all unsuccessful key read or write operations, tracked against both the API or data node requesting them and the data node executing them.

The **block_instance** column provides the DBTC kernel block instance number. You can use this together with the block name to obtain information about specific threads from the **threadblocks** table.

The **tc_time_track_stats** table was added in NDB 7.4.9 (Bug #78533, Bug #21889652).

### 18.6.14.25 The ndbinfo threadblocks Table

The **threadblocks** table associates data nodes, threads, and instances of NDB kernel blocks.

The **threadblocks** table contains the following columns:

- **node_id**
  Node ID
- **thr_no**
  Thread ID
- **block_name**
  Block name
- **block_instance**
  Block instance number

**Notes**

The value of the **block_name** in this table is one of the values found in the **block_name** column when selecting from the **ndbinfo.blocks** table. Although the list of possible values is static for a given NDB Cluster release, the list may vary between releases.

The **block_instance** column provides the kernel block instance number.

### 18.6.14.26 The ndbinfo threadstat Table

The **threadstat** table provides a rough snapshot of statistics for threads running in the NDB kernel.

The **threadstat** table contains the following columns:

- **node_id**
  Node ID
- **thr_no**
  Thread ID
- **thr_nm**
  Thread name
• c_loop
  Number of loops in main loop
• c_exec
  Number of signals executed
• c_wait
  Number of times waiting for additional input
• c_l_sent_prioa
  Number of priority A signals sent to own node
• c_l_sent_priob
  Number of priority B signals sent to own node
• c_r_sent_prioa
  Number of priority A signals sent to remote node
• c_r_sent_priob
  Number of priority B signals sent to remote node
• os_tid
  OS thread ID
• os_now
  OS time (ms)
• os_ru_utime
  OS user CPU time (µs)
• os_ru_stime
  OS system CPU time (µs)
• os_ru_minflt
  OS page reclaims (soft page faults)
• os_ru_majflt
  OS page faults (hard page faults)
• os_ru_nvcsw
  OS voluntary context switches
• os_ru_nivcsw
  OS involuntary context switches
Notes

`os_time` uses the system `gettimeofday()` call.

The values of the `os_ru_utime`, `os_ru_stime`, `os_ru_minflt`, `os_ru_majflt`, `os_ru_nvcsw`, and `os_ru_nivcsw` columns are obtained using the system `getrusage()` call, or the equivalent.

Since this table contains counts taken at a given point in time, for best results it is necessary to query this table periodically and store the results in an intermediate table or tables. The MySQL Server's Event Scheduler can be employed to automate such monitoring. For more information, see Section 20.4, “Using the Event Scheduler”.

18.6.14.27 The `ndbinfo` transporters Table

This table contains information about NDB transporters.

The `transporters` table contains the following columns:

- `node_id`
  This data node's unique node ID in the cluster
- `remote_node_id`
  The remote data node's node ID
- `status`
  Status of the connection
- `remote_address`
  Name or IP address of the remote host
- `bytes_sent`
  Number of bytes sent using this connection
- `bytes_received`
  Number of bytes received using this connection
- `connect_count`
  Number of times connection established on this transporter
- `overloaded`
  1 if this transporter is currently overloaded, otherwise 0
- `overload_count`
  Number of times this transporter has entered overload state since connecting
- `slowdown`
  1 if this transporter is in slowdown state, otherwise 0
- `slowdown_count`
  Number of times this transporter has entered slowdown state since connecting
Notes

For each running data node in the cluster, the `transporters` table displays a row showing the status of each of that node’s connections with all nodes in the cluster, including itself. This information is shown in the table’s `status` column, which can have any one of the following values: `CONNECTING`, `CONNECTED`, `DISCONNECTING`, or `DISCONNECTED`.

Connections to API and management nodes which are configured but not currently connected to the cluster are shown with status `DISCONNECTED`. Rows where the `node_id` is that of a data node which is not currently connected are not shown in this table. (This is similar omission of disconnected nodes in the `ndbinfo.nodes` table.

The `remote_address` is the host name or address for the node whose ID is shown in the `remote_node_id` column. The `bytes_sent` from this node and `bytes_received` by this node are the numbers, respectively, of bytes sent and received by the node using this connection since it was established. For nodes whose status is `CONNECTING` or `DISCONNECTED`, these columns always display 0.

Assume you have a 5-node cluster consisting of 2 data nodes, 2 SQL nodes, and 1 management node, as shown in the output of the `SHOW` command in the `ndb_mgm` client:

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
---------------------
  [ndbd(NDB)]  2 node(s)
id=1    @10.100.10.1  (5.6.51-ndb-7.4.35, Nodegroup: 0, *)
id=2    @10.100.10.2  (5.6.51-ndb-7.4.35, Nodegroup: 0)
  [ndb_mgmd(MGM)]  1 node(s)
id=10   @10.100.10.10  (5.6.51-ndb-7.4.35)
  [mysqld(API)]   2 node(s)
id=20   @10.100.10.20  (5.6.51-ndb-7.4.35)
id=21   @10.100.10.21  (5.6.51-ndb-7.4.35)
```

There are 10 rows in the `transporters` table—5 for the first data node, and 5 for the second—assuming that all data nodes are running, as shown here:

```
mysql> SELECT node_id, remote_node_id, status
    ->    FROM ndbinfo.transporters;
```

<table>
<thead>
<tr>
<th>node_id</th>
<th>remote_node_id</th>
<th>status</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>DISCONNECTED</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>CONNECTED</td>
</tr>
<tr>
<td>1</td>
<td>10</td>
<td>CONNECTED</td>
</tr>
<tr>
<td>1</td>
<td>20</td>
<td>CONNECTED</td>
</tr>
<tr>
<td>1</td>
<td>21</td>
<td>CONNECTED</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>CONNECTED</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
<td>DISCONNECTED</td>
</tr>
<tr>
<td>2</td>
<td>10</td>
<td>CONNECTED</td>
</tr>
<tr>
<td>2</td>
<td>20</td>
<td>CONNECTED</td>
</tr>
<tr>
<td>2</td>
<td>21</td>
<td>CONNECTED</td>
</tr>
</tbody>
</table>

10 rows in set (0.04 sec)

If you shut down one of the data nodes in this cluster using the command 2 STOP in the `ndb_mgm` client, then repeat the previous query (again using the `mysql` client), this table now shows only 5 rows—1 row for each connection from the remaining management node to another node, including both itself and the data node that is currently offline—and displays `CONNECTING` for the status of each remaining connection to the data node that is currently offline, as shown here:
The `connect_count`, `overloaded`, `overload_count`, `slowdown`, and `slowdown_count` counters are reset on connection, and retain their values after the remote node disconnects. The `bytes_sent` and `bytes_received` counters are also reset on connection, and so retain their values following disconnect (until the next connection resets them).

The `overload` state referred to by the `overloaded` and `overload_count` columns occurs when this transporter's send buffer contains more than `OverloadLimit` bytes (default is 80% of `SendBufferMemory`, that is, 0.8 * 2097152 = 1677721 bytes). When a given transporter is in a state of overload, any new transaction that tries to use this transporter fails with Error 1218 (Send Buffers overloaded in NDB kernel). This affects both scans and primary key operations.

The `slowdown` state referenced by the `slowdown` and `slowdown_count` columns of this table occurs when the transporter's send buffer contains more than 60% of the overload limit (equal to 0.6 * 2097152 = 1258291 bytes by default). In this state, any new scan using this transporter has its batch size reduced to minimize the load on the transporter.

Common causes of send buffer slowdown or overloading include the following:

- Data size, in particular the quantity of data stored in `TEXT` columns or `BLOB` columns (or both types of columns)
- Having a data node (ndbd or ndbmttd) on the same host as an SQL node that is engaged in binary logging
- Large number of rows per transaction or transaction batch
- Configuration issues such as insufficient `SendBufferMemory`
- Hardware issues such as insufficient RAM or poor network connectivity

See also Section 18.4.3.12, “Configuring NDB Cluster Send Buffer Parameters”.

18.6.15 Quick Reference: NDB Cluster SQL Statements

This section discusses several SQL statements that can prove useful in managing and monitoring a MySQL server that is connected to an NDB Cluster, and in some cases provide information about the cluster itself.

- `SHOW ENGINE NDB STATUS, SHOW ENGINE NDBCLUSTER STATUS`

  The output of this statement contains information about the server's connection to the cluster, creation and usage of NDB Cluster objects, and binary logging for NDB Cluster replication.

  See Section 13.7.5.16, “SHOW ENGINE Statement”, for a usage example and more detailed information.

- `SHOW ENGINES`
This statement can be used to determine whether or not clustering support is enabled in the MySQL server, and if so, whether it is active.

See Section 13.7.5.17, “SHOW ENGINES Statement”, for more detailed information.

**Note**

This statement does not support a `LIKE` clause. However, you can use `LIKE` to filter queries against the `INFORMATION_SCHEMA.ENGINES` table, as discussed in the next item.

- **SELECT * FROM INFORMATION_SCHEMA.ENGINES [WHERE ENGINE LIKE 'NDB%']**

This is the equivalent of `SHOW ENGINES`, but uses the `ENGINES` table of the `INFORMATION_SCHEMA` database. Unlike the case with the `SHOW ENGINES` statement, it is possible to filter the results using a `LIKE` clause, and to select specific columns to obtain information that may be of use in scripts. For example, the following query shows whether the server was built with `NDB` support and, if so, whether it is enabled:

```
mysql> SELECT SUPPORT FROM INFORMATION_SCHEMA.ENGINES
    -> WHERE ENGINE LIKE 'NDB%';
```

<table>
<thead>
<tr>
<th>support</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENABLED</td>
</tr>
</tbody>
</table>

See Section 21.3.7, “The INFORMATION_SCHEMA ENGINES Table”, for more information.

- **SHOW VARIABLES LIKE 'NDB%'**

This statement provides a list of most server system variables relating to the `NDB` storage engine, and their values, as shown here:

```
mysql> SHOW VARIABLES LIKE 'NDB%';
```

<table>
<thead>
<tr>

See Section 5.1.7, “Server System Variables”, for more information.

- SELECT * FROM INFORMATION_SCHEMA.GLOBAL_VARIABLES WHERE VARIABLE_NAME LIKE 'NDB%';

This statement is the equivalent of the SHOW VARIABLES statement described in the previous item, and provides almost identical output, as shown here:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.GLOBAL_VARIABLES
    -> WHERE VARIABLE_NAME LIKE 'NDB%';
+--------------------------------------+---------------------------------------+
| VARIABLE_NAME                        | VARIABLE_VALUE                        |
+--------------------------------------+---------------------------------------+
| NDB_CACHE_CHECK_TIME                 | 0                                     |
| NDB_TABLE_TEMPORARY                  | OFF                                   |

```
Unlike the case with the `SHOW VARIABLES` statement, it is possible to select individual columns. For example:

```sql
mysql> SELECT VARIABLE_VALUE
    -> FROM INFORMATION_SCHEMA.GLOBAL_VARIABLES
    -> WHERE VARIABLE_NAME = 'ndb_force_send';
```

See Section 21.3.10, "The INFORMATION_SCHEMA GLOBAL_VARIABLES and SESSION_VARIABLES Tables", and Section 5.1.7, "Server System Variables", for more information.

- `SHOW STATUS LIKE 'NDB%'`

This statement shows at a glance whether or not the MySQL server is acting as a cluster SQL node, and if so, provides the MySQL server's cluster node ID, the host name and port for the cluster management server to which it is connected, and the number of data nodes in the cluster, as shown here:

18.6.16 NDB Cluster Security Issues

This section discusses security considerations to take into account when setting up and running NDB Cluster.

Topics covered in this section include the following:

• NDB Cluster and network security issues
• Configuration issues relating to running NDB Cluster securely
• NDB Cluster and the MySQL privilege system
• MySQL standard security procedures as applicable to NDB Cluster

18.6.16.1 NDB Cluster Security and Networking Issues

In this section, we discuss basic network security issues as they relate to NDB Cluster. It is extremely important to remember that NDB Cluster “out of the box” is not secure; you or your network administrator must take the proper steps to ensure that your cluster cannot be compromised over the network.

Cluster communication protocols are inherently insecure, and no encryption or similar security measures are used in communications between nodes in the cluster. Because network speed and latency have a direct impact on the cluster’s efficiency, it is also not advisable to employ SSL or other encryption to network connections between nodes, as such schemes effectively slow communications.

It is also true that no authentication is used for controlling API node access to an NDB Cluster. As with encryption, the overhead of imposing authentication requirements would have an adverse impact on Cluster performance.

In addition, there is no checking of the source IP address for either of the following when accessing the cluster:

• SQL or API nodes using “free slots” created by empty [mysqld] or [api] sections in the config.ini file

This means that, if there are any empty [mysqld] or [api] sections in the config.ini file, then any API nodes (including SQL nodes) that know the management server’s host name (or IP address) and port can connect to the cluster and access its data without restriction. (See Section 18.6.16.2, “NDB Cluster and MySQL Privileges”, for more information about this and related issues.)

Note

You can exercise some control over SQL and API node access to the cluster by specifying a HostName parameter for all [mysqld] and [api] sections in the
NDB Cluster Security Issues

config.ini file. However, this also means that, should you wish to connect an API node to the cluster from a previously unused host, you need to add an [api] section containing its host name to the config.ini file.

More information is available elsewhere in this chapter about the HostName parameter. Also see Section 18.4.1, “Quick Test Setup of NDB Cluster”, for configuration examples using HostName with API nodes.

- Any ndb_mgm client

This means that any cluster management client that is given the management server’s host name (or IP address) and port (if not the standard port) can connect to the cluster and execute any management client command. This includes commands such as ALL STOP and SHUTDOWN.

For these reasons, it is necessary to protect the cluster on the network level. The safest network configuration for Cluster is one which isolates connections between Cluster nodes from any other network communications. This can be accomplished by any of the following methods:

1. Keeping Cluster nodes on a network that is physically separate from any public networks. This option is the most dependable; however, it is the most expensive to implement.

We show an example of an NDB Cluster setup using such a physically segregated network here:

Figure 18.19 NDB Cluster with Hardware Firewall

This setup has two networks, one private (solid box) for the Cluster management servers and data nodes, and one public (dotted box) where the SQL nodes reside. (We show the management and data nodes connected using a gigabit switch since this provides the best performance.) Both networks are protected from the outside by a hardware firewall, sometimes also known as a network-based firewall.

This network setup is safest because no packets can reach the cluster’s management or data nodes from outside the network—and none of the cluster’s internal communications can reach the outside—without going through the SQL nodes, as long as the SQL nodes do not permit any packets to be forwarded. This means, of course, that all SQL nodes must be secured against hacking attempts.

Important

With regard to potential security vulnerabilities, an SQL node is no different from any other MySQL server. See Section 6.1.3, “Making MySQL Secure Against
2. Using one or more software firewalls (also known as *host-based firewalls*) to control which packets pass through to the cluster from portions of the network that do not require access to it. In this type of setup, a software firewall must be installed on every host in the cluster which might otherwise be accessible from outside the local network.

The host-based option is the least expensive to implement, but relies purely on software to provide protection and so is the most difficult to keep secure.

This type of network setup for NDB Cluster is illustrated here:

*Figure 18.20 NDB Cluster with Software Firewalls*

Using this type of network setup means that there are two zones of NDB Cluster hosts. Each cluster host must be able to communicate with all of the other machines in the cluster, but only those hosting SQL nodes (dotted box) can be permitted to have any contact with the outside, while those in the zone containing the data nodes and management nodes (solid box) must be isolated from any machines that are not part of the cluster. Applications using the cluster and user of those applications must *not* be permitted to have direct access to the management and data node hosts.

To accomplish this, you must set up software firewalls that limit the traffic to the type or types shown in the following table, according to the type of node that is running on each cluster host computer:

*Table 18.55 Node types in a host-based firewall cluster configuration*

<table>
<thead>
<tr>
<th>Node Type</th>
<th>Permitted Traffic</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQL or API node</td>
<td>• It originates from the IP address of a management or data node (using any TCP or UDP port).</td>
</tr>
</tbody>
</table>
### Node Type | Permitted Traffic
--- | ---
 | • It originates from within the network in which the cluster resides and is on the port that your application is using.
Data node or Management node | • It originates from the IP address of a management or data node (using any TCP or UDP port).
 | • It originates from the IP address of an SQL or API node.

Any traffic other than that shown in the table for a given node type should be denied.

The specifics of configuring a firewall vary from firewall application to firewall application, and are beyond the scope of this Manual. `iptables` is a very common and reliable firewall application, which is often used with `APF` as a front end to make configuration easier. You can (and should) consult the documentation for the software firewall that you employ, should you choose to implement an NDB Cluster network setup of this type, or of a “mixed” type as discussed under the next item.

3. It is also possible to employ a combination of the first two methods, using both hardware and software to secure the cluster—that is, using both network-based and host-based firewalls. This is between the first two schemes in terms of both security level and cost. This type of network setup keeps the cluster behind the hardware firewall, but permits incoming packets to travel beyond the router connecting all cluster hosts to reach the SQL nodes.

One possible network deployment of an NDB Cluster using hardware and software firewalls in combination is shown here:

**Figure 18.21 NDB Cluster with a Combination of Hardware and Software Firewalls**

In this case, you can set the rules in the hardware firewall to deny any external traffic except to SQL nodes and API nodes, and then permit traffic to them only on the ports required by your application.
NDB Cluster Security Issues

Whatever network configuration you use, remember that your objective from the viewpoint of keeping the cluster secure remains the same—to prevent any unessential traffic from reaching the cluster while ensuring the most efficient communication between the nodes in the cluster.

Because NDB Cluster requires large numbers of ports to be open for communications between nodes, the recommended option is to use a segregated network. This represents the simplest way to prevent unwanted traffic from reaching the cluster.

Note

If you wish to administer an NDB Cluster remotely (that is, from outside the local network), the recommended way to do this is to use `ssh` or another secure login shell to access an SQL node host. From this host, you can then run the management client to access the management server safely, from within the cluster’s own local network.

Even though it is possible to do so in theory, it is not recommended to use `ndb_mgm` to manage a Cluster directly from outside the local network on which the Cluster is running. Since neither authentication nor encryption takes place between the management client and the management server, this represents an extremely insecure means of managing the cluster, and is almost certain to be compromised sooner or later.

18.6.16.2 NDB Cluster and MySQL Privileges

In this section, we discuss how the MySQL privilege system works in relation to NDB Cluster and the implications of this for keeping an NDB Cluster secure.

Standard MySQL privileges apply to NDB Cluster tables. This includes all MySQL privilege types (`SELECT` privilege, `UPDATE` privilege, `DELETE` privilege, and so on) granted on the database, table, and column level. As with any other MySQL Server, user and privilege information is stored in the `mysql` system database. The SQL statements used to grant and revoke privileges on NDB tables, databases containing such tables, and columns within such tables are identical in all respects with the `GRANT` and `REVOKE` statements used in connection with database objects involving any (other) MySQL storage engine. The same thing is true with respect to the `CREATE USER` and `DROP USER` statements.

It is important to keep in mind that, by default, the MySQL grant tables use the MyISAM storage engine. Because of this, those tables are not normally duplicated or shared among MySQL servers acting as SQL nodes in an NDB Cluster. In other words, changes in users and their privileges do not automatically propagate between SQL nodes by default. If you wish, you can enable automatic distribution of MySQL users and privileges across NDB Cluster SQL nodes; see Section 18.6.12, “Distributed Privileges Using Shared Grant Tables”, for details.

Conversely, because there is no way in MySQL to deny privileges (privileges can either be revoked or not granted in the first place, but not denied as such), there is no special protection for NDB tables on one SQL node from users that have privileges on another SQL node; (This is true even if you are not using automatic distribution of user privileges. The definitive example of this is the MySQL root account, which can perform any action on any database object. In combination with empty `[mysqld]` or `[api]` sections of the `config.ini` file, this account can be especially dangerous. To understand why, consider the following scenario:

- The `config.ini` file contains at least one empty `[mysqld]` or `[api]` section. This means that the NDB Cluster management server performs no checking of the host from which a MySQL Server (or other API node) accesses the NDB Cluster.
- There is no firewall, or the firewall fails to protect against access to the NDB Cluster from hosts external to the network.
• The host name or IP address of the NDB Cluster management server is known or can be determined from outside the network.

If these conditions are true, then anyone, anywhere can start a MySQL Server with `--ndbcluster` `--ndb-connectstring=management_host` and access this NDB Cluster. Using the MySQL root account, this person can then perform the following actions:

• Execute metadata statements such as `SHOW DATABASES` statement (to obtain a list of all NDB databases on the server) or `SHOW TABLES FROM some_ndb_database` statement to obtain a list of all NDB tables in a given database

• Run any legal MySQL statements on any of the discovered tables, such as:
  • `SELECT * FROM some_table` to read all the data from any table
  • `DELETE FROM some_table` to delete all the data from a table
  • `DESCRIBE some_table` or `SHOW CREATE TABLE some_table` to determine the table schema
  • `UPDATE some_table SET column1 = some_value` to fill a table column with “garbage” data; this could actually cause much greater damage than simply deleting all the data

More insidious variations might include statements like these:

```
UPDATE some_table SET an_int_column = an_int_column + 1
```

or

```
UPDATE some_table SET a_varchar_column = REVERSE(a_varchar_column)
```

Such malicious statements are limited only by the imagination of the attacker.

The only tables that would be safe from this sort of mayhem would be those tables that were created using storage engines other than NDB, and so not visible to a “rogue” SQL node.

A user who can log in as root can also access the `INFORMATION_SCHEMA` database and its tables, and so obtain information about databases, tables, stored routines, scheduled events, and any other database objects for which metadata is stored in `INFORMATION_SCHEMA`.

It is also a very good idea to use different passwords for the root accounts on different NDB Cluster SQL nodes unless you are using distributed privileges.

In sum, you cannot have a safe NDB Cluster if it is directly accessible from outside your local network.

**Important**

Never leave the MySQL root account password empty. This is just as true when running MySQL as an NDB Cluster SQL node as it is when running it as a standalone (non-Cluster) MySQL Server, and should be done as part of the MySQL installation process before configuring the MySQL Server as an SQL node in an NDB Cluster.

If you wish to employ NDB Cluster’s distributed privilege capabilities, you should not simply convert the system tables in the `mysql` database to use the NDB storage engine manually. Use the stored procedure provided for this purpose instead; see Section 18.6.12, “Distributed Privileges Using Shared Grant Tables”.

Otherwise, if you need to synchronize `mysql` system tables between SQL nodes, you can use standard MySQL replication to do so, or employ a script to copy table entries between the MySQL servers.
Summary. The most important points to remember regarding the MySQL privilege system with regard to NDB Cluster are listed here:

1. Users and privileges established on one SQL node do not automatically exist or take effect on other SQL nodes in the cluster. Conversely, removing a user or privilege on one SQL node in the cluster does not remove the user or privilege from any other SQL nodes.

2. You can distribute MySQL users and privileges among SQL nodes using the SQL script, and the stored procedures it contains, that are supplied for this purpose in the NDB Cluster distribution.

3. Once a MySQL user is granted privileges on an NDB table from one SQL node in an NDB Cluster, that user can “see” any data in that table regardless of the SQL node from which the data originated, even if you are not using privilege distribution.

18.6.16.3 NDB Cluster and MySQL Security Procedures

In this section, we discuss MySQL standard security procedures as they apply to running NDB Cluster.

In general, any standard procedure for running MySQL securely also applies to running a MySQL Server as part of an NDB Cluster. First and foremost, you should always run a MySQL Server as the `mysql` operating system user; this is no different from running MySQL in a standard (non-Cluster) environment. The `mysql` system account should be uniquely and clearly defined. Fortunately, this is the default behavior for a new MySQL installation. You can verify that the `mysqld` process is running as the `mysql` operating system user by using the system command such as the one shown here:

```
$> ps aux | grep mysql
```

```
root    10467  0.0  0.1   3616  1380 pts/3    S    11:53   0:00 \
        /bin/sh ./mysqld_safe --ndbcluster --ndb-connectstring=localhost:1186
mysql   10512  0.2  2.5  58528 26636 pts/3    Sl   11:53   0:00 \
        /usr/local/mysql/libexec/mysqld --basedir=/usr/local/mysql \
        --datadir=/usr/local/mysql/var --user=mysql --ndbcluster \
        --ndb-connectstring=localhost:1186 --pid-file=/usr/local/mysql/var/mothra.pid \
        --log-error=/usr/local/mysql/var/mothra.err
jon     10579  0.0  0.0   2736   688 pts/0    S+   11:54   0:00 grep mysql
```

If the `mysqld` process is running as any other user than `mysql`, you should immediately shut it down and restart it as the `mysql` user. If this user does not exist on the system, the `mysql` user account should be created, and this user should be part of the `mysql` user group; in this case, you should also make sure that the MySQL data directory on this system (as set using the `--datadir` option for `mysqld`) is owned by the `mysql` user, and that the SQL node’s `my.cnf` file includes `user=mysql` in the `[mysqld]` section. Alternatively, you can start the MySQL server process with `--user=mysql` on the command line, but it is preferable to use the `my.cnf` option, since you might forget to use the command-line option and so have `mysqld` running as another user unintentionally. The `mysqld_safe` startup script forces MySQL to run as the `mysql` user.

Important

Never run `mysqld` as the system root user. Doing so means that potentially any file on the system can be read by MySQL, and thus—should MySQL be compromised—by an attacker.

As mentioned in the previous section (see Section 18.6.16.2, “NDB Cluster and MySQL Privileges”), you should always set a root password for the MySQL Server as soon as you have it running. You should also delete the anonymous user account that is installed by default. You can accomplish these tasks using the following statements:

```
$> mysql --u root
```
NDB Cluster Replication

mysql> UPDATE mysql.user
    -> SET Password=PASSWORD('secure_password')
    -> WHERE User='root';

mysql> DELETE FROM mysql.user
    -> WHERE User='';

mysql> FLUSH PRIVILEGES;

Be very careful when executing the DELETE statement not to omit the WHERE clause, or you risk deleting all MySQL users. Be sure to run the FLUSH PRIVILEGES statement as soon as you have modified the mysql.user table, so that the changes take immediate effect. Without FLUSH PRIVILEGES, the changes do not take effect until the next time that the server is restarted.

Note

Many of the NDB Cluster utilities such as ndb_show_tables, ndb_desc, and ndb_select_all also work without authentication and can reveal table names, schemas, and data. By default these are installed on Unix-style systems with the permissions wxr-xr-x (755), which means they can be executed by any user that can access the mysql/bin directory.

See Section 18.5, “NDB Cluster Programs”, for more information about these utilities.

18.7 NDB Cluster Replication

NDB Cluster supports asynchronous replication, more usually referred to simply as “replication”. This section explains how to set up and manage a configuration in which one group of computers operating as an NDB Cluster replicates to a second computer or group of computers. We assume some familiarity on the part of the reader with standard MySQL replication as discussed elsewhere in this Manual. (See Chapter 17, Replication).

Note

NDB Cluster does not support replication using GTIDs; semisynchronous replication is also not supported by the NDB storage engine.

Normal (non-clustered) replication involves a source server (formerly called a “master”) and a replica server (formerly referred to as a “slave”), the source being so named because operations and data to be replicated originate with it, and the replica being the recipient of these. In NDB Cluster, replication is conceptually very similar but can be more complex in practice, as it may be extended to cover a number of different configurations including replicating between two complete clusters. Although an NDB Cluster itself depends on the NDB storage engine for clustering functionality, it is not necessary to use NDB as the storage engine for the replica's copies of the replicated tables (see Replication from NDB to other storage engines). However, for maximum availability, it is possible (and preferable) to replicate from one NDB Cluster to another, and it is this scenario that we discuss, as shown in the following figure:
In this scenario, the replication process is one in which successive states of a source cluster are logged and saved to a replica cluster. This process is accomplished by a special thread known as the NDB binary log injector thread, which runs on each MySQL server and produces a binary log (binlog). This thread ensures that all changes in the cluster producing the binary log—and not just those changes that are effected through the MySQL Server—are inserted into the binary log with the correct serialization order. We refer to the MySQL source and replica servers as replication servers or replication nodes, and the data flow or line of communication between them as a replication channel.

For information about performing point-in-time recovery with NDB Cluster and NDB Cluster Replication, see Section 18.7.9.2, “Point-In-Time Recovery Using NDB Cluster Replication”.

**NDB API replica status variables.** NDB API counters can provide enhanced monitoring capabilities on replica clusters. These counters are implemented as NDB statistics _slave status variables, as seen in the output of `SHOW STATUS`, or in the results of queries against the `SESSION_STATUS` or `GLOBAL_STATUS` table in a `mysql` client session connected to a MySQL Server that is acting as a replica in NDB Cluster Replication. By comparing the values of these status variables before and after the execution of statements affecting replicated NDB tables, you can observe the corresponding actions taken on the NDB API level by the replica, which can be useful when monitoring or troubleshooting NDB Cluster Replication. Section 18.6.13, “NDB API Statistics Counters and Variables”, provides additional information.

**Replication from NDB to non-NDB tables.** It is possible to replicate NDB tables from an NDB Cluster acting as the replication source to tables using other MySQL storage engines such as InnoDB or MyISAM.
on a replica `mysqld`. This is subject to a number of conditions; see Replication from NDB to other storage engines, and Replication from NDB to a nontransactional storage engine, for more information.

### 18.7.1 NDB Cluster Replication: Abbreviations and Symbols

Throughout this section, we use the following abbreviations or symbols for referring to the source and replica clusters, and to processes and commands run on the clusters or cluster nodes:

Table 18.56 Abbreviations used throughout this section referring to source and replica clusters, and to processes and commands run on cluster nodes

<table>
<thead>
<tr>
<th>Symbol or Abbreviation</th>
<th>Description (Refers to...)</th>
</tr>
</thead>
<tbody>
<tr>

### 18.7.2 General Requirements for NDB Cluster Replication

A replication channel requires two MySQL servers acting as replication servers (one each for the source and replica). For example, this means that in the case of a replication setup with two replication channels (to provide an extra channel for redundancy), there should be a total of four replication nodes, two per cluster.

Replication of an NDB Cluster as described in this section and those following is dependent on row-based replication. This means that the replication source MySQL server must be running with `--binlog-format=ROW` or `--binlog-format=MIXED`, as described in Section 18.7.6, “Starting NDB Cluster Replication (Single Replication Channel)”. For general information about row-based replication, see Section 17.1.2, “Replication Formats”.

❗️ **Important**

If you attempt to use NDB Cluster Replication with `--binlog-format=STATEMENT`, replication fails to work properly because the
Known Issues in NDB Cluster Replication

```
ndb_binlog_index table on the source cluster and the epoch column of the ndb_apply_status table on the replica cluster are not updated (see Section 18.7.4, “NDB Cluster Replication Schema and Tables”). Instead, only updates on the MySQL server acting as the replication source propagate to the replica, and no updates from any other SQL nodes in the source cluster are replicated.

The default value for the --binlog-format option is MIXED.
```

Each MySQL server used for replication in either cluster must be uniquely identified among all the MySQL replication servers participating in either cluster (you cannot have replication servers on both the source and replica clusters sharing the same ID). This can be done by starting each SQL node using the --server-id=id option, where id is a unique integer. Although it is not strictly necessary, we assume for purposes of this discussion that all NDB Cluster binaries are of the same release version.

It is generally true in MySQL Replication that both MySQL servers (mysqld processes) involved must be compatible with one another with respect to both the version of the replication protocol used and the SQL feature sets which they support (see Section 17.4.2, “Replication Compatibility Between MySQL Versions”). It is due to such differences between the binaries in the NDB Cluster and MySQL Server 5.6 distributions that NDB Cluster Replication has the additional requirement that both mysqld binaries come from an NDB Cluster distribution. The simplest and easiest way to assure that the mysqld servers are compatible is to use the same NDB Cluster distribution for all source and replica mysqld binaries.

We assume that the replica server or cluster is dedicated to replication of the source cluster, and that no other data is being stored on it.

All NDB tables being replicated must be created using a MySQL server and client. Tables and other database objects created using the NDB API (with, for example, Dictionary::createTable()) are not visible to a MySQL server and so are not replicated. Updates by NDB API applications to existing tables that were created using a MySQL server can be replicated.

```
Note

It is possible to replicate an NDB Cluster using statement-based replication. However, in this case, the following restrictions apply:

- All updates to data rows on the cluster acting as the source must be directed to a single MySQL server.
- It is not possible to replicate a cluster using multiple simultaneous MySQL replication processes.
- Only changes made at the SQL level are replicated.

These are in addition to the other limitations of statement-based replication as opposed to row-based replication; see Section 17.1.2.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”, for more specific information concerning the differences between the two replication formats.
```

18.7.3 Known Issues in NDB Cluster Replication

This section discusses known problems or issues when using replication with NDB Cluster.

**Loss of connection between source and replica.**  A loss of connection can occur either between the source cluster SQL node and the replica cluster SQL node, or between the source SQL node and the...
Known Issues in NDB Cluster Replication

data nodes of the source cluster. In the latter case, this can occur not only as a result of loss of physical connection (for example, a broken network cable), but due to the overflow of data node event buffers; if the SQL node is too slow to respond, it may be dropped by the cluster (this is controllable to some degree by adjusting the MaxBufferedEpochs and TimeBetweenEpochs configuration parameters). If this occurs, it is entirely possible for new data to be inserted into the source cluster without being recorded in the source SQL node's binary log. For this reason, to guarantee high availability, it is extremely important to maintain a backup replication channel, to monitor the primary channel, and to fail over to the secondary replication channel when necessary to keep the replica cluster synchronized with the source. NDB Cluster is not designed to perform such monitoring on its own; for this, an external application is required.

The source SQL node issues a “gap” event when connecting or reconnecting to the source cluster. (A gap event is a type of “incident event,” which indicates an incident that occurs that affects the contents of the database but that cannot easily be represented as a set of changes. Examples of incidents are server failures, database resynchronization, some software updates, and some hardware changes.) When the replica encounters a gap in the replication log, it stops with an error message. This message is available in the output of `SHOW SLAVE STATUS`, and indicates that the SQL thread has stopped due to an incident registered in the replication stream, and that manual intervention is required. See Section 18.7.8, “Implementing Failover with NDB Cluster Replication”, for more information about what to do in such circumstances.

Important

Because NDB Cluster is not designed on its own to monitor replication status or provide failover, if high availability is a requirement for the replica server or cluster, then you must set up multiple replication lines, monitor the source `mysqld` on the primary replication line, and be prepared fail over to a secondary line if and as necessary. This must be done manually, or possibly by means of a third-party application. For information about implementing this type of setup, see Section 18.7.7, “Using Two Replication Channels for NDB Cluster Replication”, and Section 18.7.8, “Implementing Failover with NDB Cluster Replication”.

If you are replicating from a standalone MySQL server to an NDB Cluster, one channel is usually sufficient.

Circular replication.

NDB Cluster Replication supports circular replication, as shown in the next example. The replication setup involves three NDB Clusters numbered 1, 2, and 3, in which Cluster 1 acts as the replication source for Cluster 2, Cluster 2 acts as the source for Cluster 3, and Cluster 3 acts as the source for Cluster 1, thus completing the circle. Each NDB Cluster has two SQL nodes, with SQL nodes A and B belonging to Cluster 1, SQL nodes C and D belonging to Cluster 2, and SQL nodes E and F belonging to Cluster 3.

Circular replication using these clusters is supported as long as the following conditions are met:

- The SQL nodes on all source and replica clusters are the same.
- All SQL nodes acting as sources and replicas are started with the `log_slave_updates` system variable enabled.

This type of circular replication setup is shown in the following diagram:
In this scenario, SQL node A in Cluster 1 replicates to SQL node C in Cluster 2; SQL node C replicates to SQL node E in Cluster 3; SQL node E replicates to SQL node A. In other words, the replication line (indicated by the curved arrows in the diagram) directly connects all SQL nodes used as sources and replicas.

It should also be possible to set up circular replication in which not all source SQL nodes are also replicas, as shown here:
In this case, different SQL nodes in each cluster are used as sources and replicas. However, you must not start any of the SQL nodes with the `log_slave_updates` system variable enabled. This type of circular replication scheme for NDB Cluster, in which the line of replication (again indicated by the curved arrows in the diagram) is discontinuous, should be possible, but it should be noted that it has not yet been thoroughly tested and must therefore still be considered experimental.

**Note**

The NDB storage engine uses *idempotent execution mode*, which suppresses duplicate-key and other errors that otherwise break circular replication of NDB Cluster. This is equivalent to setting the global `slave_exec_mode` system variable.
Known Issues in NDB Cluster Replication

Known Issues in NDB Cluster Replication

| NDB Cluster replication and primary keys. | In the event of a node failure, errors in replication of NDB tables without primary keys can still occur, due to the possibility of duplicate rows being inserted in such cases. For this reason, it is highly recommended that all NDB tables being replicated have explicit primary keys. |
| NDB Cluster Replication and Unique Keys. | In older versions of NDB Cluster, operations that updated values of unique key columns of NDB tables could result in duplicate-key errors when replicated. This issue is solved for replication between NDB tables by deferring unique key checks until after all table row updates have been performed. |

Deferring constraints in this way is currently supported only by NDB. Thus, updates of unique keys when replicating from NDB to a different storage engine such as InnoDB or MyISAM are still not supported.

The problem encountered when replicating without deferred checking of unique key updates can be illustrated using NDB table such as t, is created and populated on the source (and transmitted to a replica that does not support deferred unique key updates) as shown here:

```sql
CREATE TABLE t (  
  p INT PRIMARY KEY,  
  c INT,  
  UNIQUE KEY u (c)  
) ENGINE NDB;

INSERT INTO t  
VALUES (1,1), (2,2), (3,3), (4,4), (5,5);
```

The following UPDATE statement on t succeeds on the source, since the rows affected are processed in the order determined by the ORDER BY option, performed over the entire table:

```
UPDATE t SET c = c - 1 ORDER BY p;
```

The same statement fails with a duplicate key error or other constraint violation on the replica, because the ordering of the row updates is performed for one partition at a time, rather than for the table as a whole.

**Note**

Every NDB table is implicitly partitioned by key when it is created. See Section 19.2.5, “KEY Partitioning”, for more information.

**GTIDs not supported.** Replication using global transaction IDs is not compatible with the NDB storage engine, and is not supported. Enabling GTIDs is likely to cause NDB Cluster Replication to fail.

**Multithreaded replicas not supported.** NDB Cluster does not support multithreaded replicas, and setting related system variables such as slave_parallel_workers, slave_checkpoint_group, and slave_checkpoint_group (or the equivalent mysqld startup options) has no effect.

This is because the replica may not be able to separate transactions occurring in one database from those in another if they are written within the same epoch. In addition, every transaction handled by the NDB storage engine involves at least two databases—the target database and the mysql system database—due to the requirement for updating the mysql.ndb_apply_status table (see Section 18.7.4, “NDB Cluster Replication Schema and Tables”). This in turn breaks the requirement for multithreading that the transaction is specific to a given database.

**Restarting with --initial.** Restarting the cluster with the --initial option causes the sequence of GCI and epoch numbers to start over from 0. (This is generally true of NDB Cluster and not limited to
replication scenarios involving Cluster.) The MySQL servers involved in replication should in this case be restarted. After this, you should use the `RESET MASTER` and `RESET SLAVE` statements to clear the invalid `ndb_binlog_index` and `ndb_apply_status` tables, respectively.

**Replication from NDB to other storage engines.** It is possible to replicate an NDB table on the source to a table using a different storage engine on the replica, taking into account the restrictions listed here:

- Multi-source and circular replication are not supported (tables on both the source and the replica must use the NDB storage engine for this to work).
- Using a storage engine which does not perform binary logging for tables on the replica requires special handling.
- Use of a nontransactional storage engine for tables on the replica also requires special handling.
- The source `mysqld` must be started with `--ndb-log-update-as-write=0` or `--ndb-log-update-as-write=OFF`.

The next few paragraphs provide additional information about each of the issues just described.

**Multiple sources not supported when replicating NDB to other storage engines.** For replication from NDB to a different storage engine, the relationship between the two databases must be one-to-one. This means that bidirectional or circular replication is not supported between NDB Cluster and other storage engines.

In addition, it is not possible to configure more than one replication channel when replicating between NDB and a different storage engine. (An NDB Cluster database can simultaneously replicate to multiple NDB Cluster databases.) If the source uses NDB tables, it is still possible to have more than one MySQL Server maintain a binary log of all changes, but for the replica to change sources (fail over), the new source-replica relationship must be explicitly defined on the replica.

**Replicating NDB tables to a storage engine that does not perform binary logging.** If you attempt to replicate from an NDB Cluster to a replica that uses a storage engine that does not handle its own binary logging, the replication process aborts with the error `Statement cannot be written atomically since more than one engine involved and at least one engine is self-logging` (Error 1595). It is possible to work around this issue in one of the following ways:

- **Turn off binary logging on the replica.** This can be accomplished by setting `sql_log_bin = 0`.

- **Change the storage engine used for the mysql.ndb_apply_status table.** Causing this table to use an engine that does not handle its own binary logging can also eliminate the conflict. This can be done by issuing a statement such as `ALTER TABLE mysql.ndb_apply_status ENGINE=MyISAM` on the replica. It is safe to do this when using a storage engine other than NDB on the replica, since you do not need to worry about keeping multiple replicas synchronized.

- **Filter out changes to the mysql.ndb_apply_status table on the replica.** This can be done by starting the replica with `--replicate-ignore-table=mysql.ndb_apply_status`. If you need for other tables to be ignored by replication, you might wish to use an appropriate `--replicate-wild-ignore-table` option instead.

**Important**

You should not disable replication or binary logging of `mysql.ndb_apply_status` or change the storage engine used for this table when replicating from one NDB Cluster to another. See Replication and binary log filtering rules with replication between NDB Clusters, for details.
Replication from NDB to a nontransactional storage engine.  When replicating from NDB to a nontransactional storage engine such as MyISAM, you may encounter unnecessary duplicate key errors when replicating `INSERT ... ON DUPLICATE KEY UPDATE` statements. You can suppress these by using `--ndb-log-update-as-write=0`, which forces updates to be logged as writes, rather than as updates.

Replication and binary log filtering rules with replication between NDB Clusters.  If you are using any of the options `--replicate-do-`, `--replicate-ignore-`, `--binlog-do-db`, or `--binlog-ignore-db` to filter databases or tables being replicated, you must take care not to block replication or binary logging of the `mysql.ndb_apply_status`, which is required for replication between NDB Clusters to operate properly. In particular, you must keep in mind the following:

1. Using `--replicate-do-db=db_name` (and no other `--replicate-do-*` or `--replicate-ignore-*` options) means that only tables in database `db_name` are replicated. In this case, you should also use `--replicate-do-db=mysql, --binlog-do-db=mysql, or --replicate-do-table=mysql.ndb_apply_status` to ensure that `mysql.ndb_apply_status` is populated on replicas.

   Using `--binlog-do-db=db_name` (and no other `--binlog-do-db` options) means that changes only to tables in database `db_name` are written to the binary log. In this case, you should also use `--replicate-do-db=mysql, --binlog-do-db=mysql, or --replicate-do-table=mysql.ndb_apply_status` to ensure that `mysql.ndb_apply_status` is populated on replicas.

2. Using `--replicate-ignore-db=mysql` means that no tables in the `mysql` database are replicated. In this case, you should also use `--replicate-do-table=mysql.ndb_apply_status` to ensure that `mysql.ndb_apply_status` is replicated.

   Using `--binlog-ignore-db=mysql` means that no changes to tables in the `mysql` database are written to the binary log. In this case, you should also use `--replicate-do-table=mysql.ndb_apply_status` to ensure that `mysql.ndb_apply_status` is replicated.

You should also remember that each replication rule requires the following:

1. Its own `--replicate-do-*` or `--replicate-ignore-*` option, and that multiple rules cannot be expressed in a single replication filtering option. For information about these rules, see Section 17.1.4, “Replication and Binary Logging Options and Variables”.

2. Its own `--binlog-do-db` or `--binlog-ignore-db` option, and that multiple rules cannot be expressed in a single binary log filtering option. For information about these rules, see Section 5.4.4, “The Binary Log”.

If you are replicating an NDB Cluster to a replica that uses a storage engine other than NDB, the considerations just given previously may not apply, as discussed elsewhere in this section.

NDB Cluster Replication and IPv6.  While the NDB API and MGM API (and thus data nodes and management nodes) do not support IPv6 in NDB 7.3 and 7.4, MySQL Servers—including those acting as SQL nodes in an NDB Cluster—can use IPv6 to contact other MySQL Servers. This means that you can replicate between NDB Clusters using IPv6 to connect the source and replica SQL nodes as shown by the dotted arrow in the following diagram:
All connections originating within the NDB Cluster —represented in the preceding diagram by solid arrows—must use IPv4. In other words, all NDB Cluster data nodes, management servers, and management clients must be accessible from one another using IPv4. In addition, SQL nodes must use IPv4 to communicate with the cluster.

Since there is currently no support in the NDB and MGM APIs for IPv6, any applications written using these APIs must also make all connections using IPv4.

**Attribute promotion and demotion.** NDB Cluster Replication includes support for attribute promotion and demotion. The implementation of the latter distinguishes between lossy and non-lossy type conversions, and their use on the replica can be controlled by setting the `slave_type_conversions` global server system variable.

For more information about attribute promotion and demotion in NDB Cluster, see Row-based replication: attribute promotion and demotion.

### 18.7.4 NDB Cluster Replication Schema and Tables

- `ndb_apply_status Table`
- `ndb_binlog_index Table`
- `ndb_replication Table`

Replication in NDB Cluster makes use of a number of dedicated tables in the `mysql` database on each MySQL Server instance acting as an SQL node in both the cluster being replicated and in the replica. This is true regardless of whether the replica is a single server or a cluster.

The `ndb_binlog_index` and `ndb_apply_status` tables are created in the `mysql` database. They should not be explicitly replicated by the user. User intervention is normally not required to create or
maintain either of these tables, since both are maintained by the NDB binary log (binlog) injector thread. This keeps the source mysqld process updated to changes performed by the NDB storage engine. The NDB binlog injector thread receives events directly from the NDB storage engine. The NDB injector is responsible for capturing all the data events within the cluster, and ensures that all events which change, insert, or delete data are recorded in the ndb_binlog_index table. The replica I/O thread transfers the events from the source’s binary log to the replica’s relay log.

The ndb_replication table must be created manually. This table can be updated by the user to perform filtering by database or table. See ndb_replication Table, for more information. ndb_replication is also used in NDB Replication conflict detection and resolution for conflict resolution control; see Conflict Resolution Control.

Even though ndb_binlog_index and ndb_apply_status are created and maintained automatically, it is advisable to check for the existence and integrity of these tables as an initial step in preparing an NDB Cluster for replication. It is possible to view event data recorded in the binary log by querying the mysql.ndb_binlog_index table directly on the source. This can be also be accomplished using the SHOW BINLOG EVENTS statement on either the source or replica SQL node. (See Section 13.7.5.3, “SHOW BINLOG EVENTS Statement”.)

You can also obtain useful information from the output of SHOW ENGINE NDB STATUS.

Note

When performing schema changes on NDB tables, applications should wait until the ALTER TABLE statement has returned in the MySQL client connection that issued the statement before attempting to use the updated definition of the table.

ndb_apply_status Table

ndb_apply_status is used to keep a record of the operations that have been replicated from the source to the replica. If the ndb_apply_status table does not exist on the replica, ndb_restore re-creates it.

Unlike the case with ndb_binlog_index, the data in this table is not specific to any one SQL node in the (replica) cluster, and so ndb_apply_status can use the NDBCLUSTER storage engine, as shown here:

```sql
CREATE TABLE `ndb_apply_status` ( 
  `server_id`   INT(10) UNSIGNED NOT NULL, 
  `epoch`       BIGINT(20) UNSIGNED NOT NULL, 
  `log_name`    VARCHAR(255) CHARACTER SET latin1 COLLATE latin1_bin NOT NULL, 
  `start_pos`   BIGINT(20) UNSIGNED NOT NULL, 
  `end_pos`     BIGINT(20) UNSIGNED NOT NULL, 
  PRIMARY KEY (`server_id`) USING HASH
) ENGINE=NDBCLUSTER DEFAULT CHARSET=latin1;
```

The ndb_apply_status table is populated only on replicas, which means that, on the source, this table never contains any rows; thus, there is no need to allot any DataMemory to ndb_apply_status there.

Because this table is populated from data originating on the source, it should be allowed to replicate; any replication filtering or binary log filtering rules that inadvertently prevent the replica from updating ndb_apply_status, or that prevent the source from writing into the binary log may prevent replication between clusters from operating properly. For more information about potential problems arising from such filtering rules, see Replication and binary log filtering rules with replication between NDB Clusters.

0 in the epoch column of this table indicates a transaction originating from a storage engine other than NDB.

ndb_binlog_index Table
NDB Cluster Replication uses the `ndb_binlog_index` table for storing the binary log's indexing data. Since this table is local to each MySQL server and does not participate in clustering, it uses the InnoDB storage engine. This means that it must be created separately on each mysqld participating in the source cluster. (The binary log itself contains updates from all MySQL servers in the cluster.) This table is defined as follows:

```sql
CREATE TABLE `ndb_binlog_index` (
    `Position` BIGINT(20) UNSIGNED NOT NULL,
    `File` VARCHAR(255) NOT NULL,
    `epoch` BIGINT(20) UNSIGNED NOT NULL,
    `inserts` INT(10) UNSIGNED NOT NULL,
    `updates` INT(10) UNSIGNED NOT NULL,
    `deletes` INT(10) UNSIGNED NOT NULL,
    `schemaops` INT(10) UNSIGNED NOT NULL,
    `orig_server_id` INT(10) UNSIGNED NOT NULL,
    `orig_epoch` BIGINT(20) UNSIGNED NOT NULL,
    `gci` INT(10) UNSIGNED NOT NULL,
    `next_position` bigint(20) unsigned NOT NULL,
    `next_file` varchar(255) NOT NULL,
    PRIMARY KEY (`epoch`,`orig_server_id`,`orig_epoch`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1;
```

**Note**

Prior to NDB 7.5.2, this table always used the MyISAM storage engine. If you are upgrading from an earlier release, you can use `mysql_upgrade` with the `--force` and `--upgrade-system-tables` options after starting the server. The system table upgrade causes an `ALTER TABLE ... ENGINE=INNODB` statement to be executed for this table. Use of the MyISAM storage engine for this table continues to be supported for backward compatibility.

`ndb_binlog_index` may require additional disk space after being converted to InnoDB. If this becomes an issue, you may be able to conserve space by using an InnoDB tablespace for this table, changing its `ROW_FORMAT` to `COMPRESSED`, or both. For more information, see Section 13.1.18, “CREATE TABLESPACE Statement”, and Section 13.1.17, “CREATE TABLE Statement”, as well as Section 14.6.3, “Tablespaces”.

The size of the `ndb_binlog_index` table is dependent on the number of epochs per binary log file and the number of binary log files. The number of epochs per binary log file normally depends on the amount of binary log generated per epoch and the size of the binary log file, with smaller epochs resulting in more epochs per file. You should be aware that empty epochs produce inserts to the `ndb_binlog_index` table, even when the `--ndb-log-empty-epochs` option is OFF, meaning that the number of entries per file depends on the length of time that the file is in use; this relationship can be represented by the formula shown here:

\[
\text{number of epochs per file} = \frac{\text{time spent per file}}{\text{TimeBetweenEpochs}}
\]

A busy NDB Cluster writes to the binary log regularly and presumably rotates binary log files more quickly than a quiet one. This means that a “quiet” NDB Cluster with `--ndb-log-empty-epochs=ON` can actually have a much higher number of `ndb_binlog_index` rows per file than one with a great deal of activity.

When `mysqld` is started with the `--ndb-log-orig` option, the `orig_server_id` and `orig_epoch` columns store, respectively, the ID of the server on which the event originated and the epoch in which the event took place on the originating server, which is useful in NDB Cluster replication setups employing multiple sources. The `SELECT` statement used to find the closest binary log position to the highest applied epoch on the replica in a multi-source setup (see Section 18.7.10, “NDB Cluster Replication: Bidirectional and Circular Replication”) employs these two columns, which are not indexed. This can lead
to performance issues when trying to fail over, since the query must perform a table scan, especially when
the source has been running with `--ndb-log-empty-epochs=ON`. You can improve multi-source failover
times by adding an index to these columns, as shown here:

```
ALTER TABLE mysql.ndb_binlog_index
  ADD INDEX orig_lookup USING BTREE (orig_server_id, orig_epoch);
```

Adding this index provides no benefit when replicating from a single source to a single replica, since
the query used to get the binary log position in such cases makes no use of `orig_server_id` or `orig_epoch`.

See Section 18.7.8, “Implementing Failover with NDB Cluster Replication”, for more information about
using the `next_position` and `next_file` columns.

The following figure shows the relationship of the NDB Cluster replication source server, its binary log
injector thread, and the `mysql.ndb_binlog_index` table.

**Figure 18.26 The Replication Source Cluster**

```
ndb_replication Table

The `ndb_replication` table is used to control binary logging and conflict resolution, and acts on a per-
table basis. Each row in this table corresponds to a table being replicated, determines how to log changes
to the table and, if a conflict resolution function is specified, and determines how to resolve conflicts for that
table.

Unlike the `ndb_apply_status` and `ndb_replication` tables, the `ndb_replication` table must be
created manually, using the SQL statement shown here:

```
CREATE TABLE mysql.ndb_replication  (
  db VARBINARY(63),
  table_name VARBINARY(63),
  server_id INT UNSIGNED,
  binlog_type INT UNSIGNED,
  conflict_fn VARBINARY(128),
  PRIMARY KEY USING HASH (db, table_name, server_id)
) ENGINE=NDB
PARTITION BY KEY(db,table_name);
```

The columns of this table are listed here, with descriptions:
• **db** column

The name of the database containing the table to be replicated.

You may employ either or both of the wildcards _ and % as part of the database name. (See Matching with wildcards, later in this section.)

• **table_name** column

The name of the table to be replicated.

The table name may include either or both of the wildcards _ and %. See Matching with wildcards, later in this section.

• **server_id** column

The unique server ID of the MySQL instance (SQL node) where the table resides.

0 in this column acts like a wildcard equivalent to %, and matches any server ID. (See Matching with wildcards, later in this section.)

• **binlog_type** column

The type of binary logging to be employed. See text for values and descriptions.

• **conflict_fn** column

The conflict resolution function to be applied; one of NDB$OLD(column_name), NDB$MAX(column_name), NDB$MAX_DELETE_WIN(), NDB$EPOCH(), NDB$EPOCH_TRANS(), NDB$EPOCH2(), NDB$EPOCH2_TRANS(); NULL indicates that conflict resolution is not used for this table.

See Conflict Resolution Functions, for more information about these functions and their uses in NDB Replication conflict resolution.

Some conflict resolution functions (NDB$OLD(), NDB$EPOCH(), NDB$EPOCH_TRANS()) require the use of one or more user-created exceptions tables. See Conflict Resolution Exceptions Table.

To enable conflict resolution with NDB Replication, it is necessary to create and populate this table with control information on the SQL node or nodes on which the conflict should be resolved. Depending on the conflict resolution type and method to be employed, this may be the source, the replica, or both servers. In a simple source-replica setup where data can also be changed locally on the replica this is typically the replica. In a more complex replication scheme, such as bidirectional replication, this is usually all of the sources involved. See Section 18.7.11, “NDB Cluster Replication Conflict Resolution”, for more information.

The **ndb_replication** table allows table-level control over binary logging outside the scope of conflict resolution, in which case conflict_fn is specified as NULL, while the remaining column values are used to control binary logging for a given table or set of tables matching a wildcard expression. By setting the proper value for the binlog_type column, you can make logging for a given table or tables use a desired binary log format, or disabling binary logging altogether. Possible values for this column, with internal values and descriptions, are shown in the following table:

<table>
<thead>
<tr>
<th>Value</th>
<th>Internal Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>NBT_DEFAULT</td>
<td>Use server default</td>
</tr>
</tbody>
</table>
### NDB Cluster Replication Schema and Tables

<table>
<thead>
<tr>
<th>Value</th>
<th>Internal Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>NBT_NO_LOGGING</td>
<td>Do not log this table in the binary log (same effect as \texttt{sql_log_bin = 0}, but applies to one or more specified tables only)</td>
</tr>
<tr>
<td>2</td>
<td>NBT_UPDATED_ONLY</td>
<td>Only updated attributes are logged (same effect as \texttt{--ndb-log-updated-only}, but applies to one or more specified tables only)</td>
</tr>
<tr>
<td>3</td>
<td>NBT_FULL</td>
<td>Log full row, even if not updated (MySQL server default behavior)</td>
</tr>
<tr>
<td>4</td>
<td>NBT_USE_UPDATE</td>
<td>(For generating \texttt{NBT_UPDATED_ONLY_USE_UPDATE} and \texttt{NBT_FULL_USE_UPDATE} values only; not intended for separate use)</td>
</tr>
<tr>
<td>5</td>
<td>[Not used]</td>
<td>---</td>
</tr>
<tr>
<td>6</td>
<td>NBT_UPDATED_ONLY_USE_UPDATE</td>
<td>Use updated attributes, even if values are unchanged</td>
</tr>
<tr>
<td>7</td>
<td>NBT_FULL_USE_UPDATE</td>
<td>Use full row, even if values are unchanged</td>
</tr>
<tr>
<td>8</td>
<td>NBT_UPDATED_ONLY_MINIMAL</td>
<td>Log update as UPDATE_ROW; log only primary key columns in before image, and only updated columns in after image (same effect as \texttt{--ndb-log-update-minimal}, but applies to one or more specified tables only)</td>
</tr>
<tr>
<td>9</td>
<td>NBT_UPDATED_FULL_MINIMAL</td>
<td>Log update as UPDATE_ROW; log only primary key columns in before image, and all columns other than primary key columns in after image</td>
</tr>
</tbody>
</table>

Binary logging can be set to different formats for different tables by inserting rows into the \texttt{ndb\_replication} table using the appropriate \texttt{db}, \texttt{table\_name}, and \texttt{binlog\_type} column values. The internal integer value shown in the preceding table should be used when setting the binary logging format.

The following two statements set binary logging to logging of full rows (\texttt{NBT\_FULL}, internal value 3) for table \texttt{test\_a}, and to logging of updates only (\texttt{NBT\_UPDATED\_ONLY}, internal value 2) for table \texttt{test\_b}:

```sql
# Table test.a: Log full rows
INSERT INTO mysql.ndb_replication VALUES("test", "a", 0, 3, NULL);

# Table test.b: log updates only
INSERT INTO mysql.ndb_replication VALUES("test", "b", 0, 2, NULL);
```

To disable logging for one or more tables, use 1 (\texttt{NBT\_NO\_LOGGING}) for \texttt{binlog\_type}, as shown here:

```sql
# Disable binary logging for table test.t1
INSERT INTO mysql.ndb_replication VALUES("test", "t1", 0, 1, NULL);
```
# Disable binary logging for any table in 'test' whose name begins with 't'
INSERT INTO mysql.ndb_replication VALUES("test", "t%", 0, 1, NULL);

Setting **NBT_NO_LOGGING** for a given table is the equivalent of setting `sql_log_bin = 0`, except that it applies to one or more tables individually. **NBT_NO_LOGGING** is effectively implemented at the data nodes; if an SQL node is not performing binary logging for a given table, it is not sent the row change events for those tables. This means that it is not receiving all changes and discarding some, but rather it is not subscribing to these changes.

**NBT_NO_LOGGING** can be useful for a number of reasons, including those listed here:

- Not sending changes across the network generally saves bandwidth, buffering, and CPU resources.
- Not logging changes to tables with very frequent updates but whose value is not great is a good fit for transient data (such as session data) that may be relatively unimportant in the event of a complete failure of the cluster.
- Using a session variable (or `sql_log_bin`) and application code, it is also possible to log (or not to log) certain SQL statements or types of SQL statements; for example, it may be desirable in some cases not to record DDL statements on one or more tables.
- Splitting replication streams into two (or more) binary logs can be done for reasons of performance, a need to replicate different databases to different places, use of different binary logging types for different databases, and so on.

**Matching with wildcards.** In order not to make it necessary to insert a row in the `ndb_replication` table for each and every combination of database, table, and SQL node in your replication setup, **NDB** supports wildcard matching on the this table's `db`, `table_name`, and `server_id` columns. Database and table names used in, respectively, `db` and `table_name` may contain either or both of the following wildcards:

- `_` (underscore character): matches zero or more characters
- `%` (percent sign): matches a single character

(These are the same wildcards as supported by the MySQL **LIKE** operator.)

The `server_id` column supports `0` as a wildcard equivalent to `_` (matches anything). This is used in the examples shown previously.

A given row in the `ndb_replication` table can use wildcards to match any of the database name, table name, and server ID in any combination. Where there are multiple potential matches in the table, the best match is chosen, according to the table shown here, where `W` represents a wildcard match, `E` an exact match, and the greater the value in the **Quality** column, the better the match:

### Table 18.58 Weights of different combinations of wildcard and exact matches on columns in the `mysql.ndb_replication` table

<table>
<thead>
<tr>
<th>db</th>
<th>table_name</th>
<th>server_id</th>
<th>Quality</th>
</tr>
</thead>
<tbody>
<tr>
<td>W</td>
<td>W</td>
<td>W</td>
<td>1</td>

</tbody>
</table>
Preparing the NDB Cluster for Replication

Thus, an exact match on database name, table name, and server ID is considered best (strongest), while the weakest (worst) match is a wildcard match on all three columns. Only the strength of the match is considered when choosing which rule to apply; the order in which the rows occur in the table has no effect on this determination.

### 18.7.5 Preparing the NDB Cluster for Replication

Preparing the NDB Cluster for replication consists of the following steps:

1. Check all MySQL servers for version compatibility (see Section 18.7.2, “General Requirements for NDB Cluster Replication”).

2. Create a replication account on the source Cluster with the appropriate privileges, using the following SQL statement:

```sql
mysql>
GRANT REPLICATION SLAVE
-> ON *.* TO 'replica_user'@'replica_host'
-> IDENTIFIED BY 'replica_password';
```

In the previous statement, `replica_user` is the replication account user name, `replica_host` is the host name or IP address of the replica, and `replica_password` is the password to assign to this account.

For example, to create a replica user account with the name `myreplica`, logging in from the host named `replica-host`, and using the password `53cr37`, use the following GRANT statement:

```sql
mysql>
GRANT REPLICATION SLAVE
-> ON *.* TO 'myreplica'@'replica-host'
-> IDENTIFIED BY '53cr37';
```

For security reasons, it is preferable to use a unique user account—not employed for any other purpose—for the replication account.

3. Set up the replica to use the source. Using the `mysql` client, this can be accomplished with the following `CHANGE MASTER TO` statement:

```sql
mysql>
CHANGE MASTER TO
-> MASTER_HOST='source_host',
-> MASTER_PORT=source_port,
-> MASTER_USER='replica_user',
-> MASTER_PASSWORD='replica_password';
```

In the previous statement, `source_host` is the host name or IP address of the replication source, `source_port` is the port for the replica to use when connecting to the source, `replica_user` is the user name set up for the replica on the source, and `replica_password` is the password set for that user account in the previous step.

For example, to tell the replica to use the MySQL server whose host name is `rep-source` with the replication account created in the previous step, use the following statement:

```sql
mysql>
CHANGE MASTER TO
-> MASTER_HOST='rep-source',
-> MASTER_PORT=3306,
-> MASTER_USER='myreplica',
-> MASTER_PASSWORD='53cr37';
```
For a complete list of options that can be used with this statement, see Section 13.4.2.1, "CHANGE MASTER TO Statement".

To provide replication backup capability, you also need to add an `--ndb-connectstring` option to the replica's `my.cnf` file prior to starting the replication process. See Section 18.7.9, "NDB Cluster Backups With NDB Cluster Replication", for details.

For additional options that can be set in `my.cnf` for replicas, see Section 17.1.4, "Replication and Binary Logging Options and Variables".

4. If the source cluster is already in use, you can create a backup of the source and load this onto the replica to cut down on the amount of time required for the replica to synchronize itself with the source. If the replica is also running NDB Cluster, this can be accomplished using the backup and restore procedure described in Section 18.7.9, "NDB Cluster Backups With NDB Cluster Replication".

```shell
ndb-connectstring=management_host[:port]
```

In the event that you are not using NDB Cluster on the replica, you can create a backup with this command on the source:

```shell
S> mysqldump --master-data=1
```

Then import the resulting data dump onto the replica by copying the dump file over to it. After this, you can use the `mysql` client to import the data from the dumpfile into the replica database as shown here, where `dump_file` is the name of the file that was generated using `mysqldump` on the source, and `db_name` is the name of the database to be replicated:

```shell
S> mysql -u root -p db_name < dump_file
```

For a complete list of options to use with `mysqldump`, see Section 4.5.4, "mysqldump — A Database Backup Program".

**Note**

If you copy the data to the replica in this fashion, you should make sure that the replica is started with the `--skip-slave-start` option on the command line, or else include `skip-slave-start` in the replica's `my.cnf` file to keep it from trying to connect to the source to begin replicating before all the data has been loaded. Once the data loading has completed, follow the additional steps outlined in the next two sections.

5. Ensure that each MySQL server acting as a replication source is assigned a unique server ID, and has binary logging enabled, using the row-based format. (See Section 17.1.2, "Replication Formats".) In addition, we recommend enabling the `slave_allow_batching` system variable, and possibly increasing the values used with the `--ndb-batch-size` and `--ndb-blob-write-batch-bytes` options as well. All of these options can be set either in the source server's `my.cnf` file, or on the command line when starting the source `mysqld` process. See Section 18.7.6, "Starting NDB Cluster Replication (Single Replication Channel)", for more information.

**18.7.6 Starting NDB Cluster Replication (Single Replication Channel)**

This section outlines the procedure for starting NDB Cluster replication using a single replication channel.

1. Start the MySQL replication source server by issuing this command, where `id` is this server's unique ID (see Section 18.7.2, "General Requirements for NDB Cluster Replication"):

```shell
S> mysqld --ndbcluster --server-id=id
```
Starting NDB Cluster Replication (Single Replication Channel)

```
--log-bin --ndb-log-bin &
```

This starts the server's `mysqld` process with binary logging enabled using the proper logging format.

**Note**
You can also start the source with `--binlog-format=MIXED`, in which case row-based replication is used automatically when replicating between clusters. Statement-based binary logging is not supported for NDB Cluster Replication (see Section 18.7.2, “General Requirements for NDB Cluster Replication”).

2. Start the MySQL replica server as shown here:

```
shell> mysqld --ndbcluster --server-id=id &
```

In the command just shown, `id` is the replica server's unique ID. It is not necessary to enable logging on the replica.

**Note**
You should use the `--skip-slave-start` option with this command or else you should include `skip-slave-start` in the replica server's `my.cnf` file, unless you want replication to begin immediately. With the use of this option, the start of replication is delayed until the appropriate `START SLAVE` statement has been issued, as explained in Step 4 below.

3. It is necessary to synchronize the replica server with the source server's replication binary log. If binary logging has not previously been running on the source, run the following statement on the replica:

```
mysql> CHANGE MASTER TO
    -> MASTER_LOG_FILE='',
    -> MASTER_LOG_POS=4;
```

This instructs the replica to begin reading the source server's binary log from the log's starting point. Otherwise—that is, if you are loading data from the source using a backup—see Section 18.7.8, “Implementing Failover with NDB Cluster Replication”, for information on how to obtain the correct values to use for `MASTER_LOG_FILE` and `MASTER_LOG_POS` in such cases.

4. Finally, instruct the replica to begin applying replication by issuing this command from the `mysql` client on the replica:

```
mysql> START SLAVE;
```

This also initiates the transmission of data and changes from the source to the replica.

It is also possible to use two replication channels, in a manner similar to the procedure described in the next section; the differences between this and using a single replication channel are covered in Section 18.7.7, “Using Two Replication Channels for NDB Cluster Replication”.

It is also possible to improve cluster replication performance by enabling batched updates. This can be accomplished by setting the `slave_allow_batching` system variable on the replicas' `mysqld` processes. Normally, updates are applied as soon as they are received. However, the use of batching causes updates to be applied in batches of 32 KB each; this can result in higher throughput and less CPU usage, particularly where individual updates are relatively small.

**Note**
Batching works on a per-epoch basis; updates belonging to more than one transaction can be sent as part of the same batch.
All outstanding updates are applied when the end of an epoch is reached, even if the updates total less than 32 KB.

Batching can be turned on and off at runtime. To activate it at runtime, you can use either of these two statements:

```
SET GLOBAL slave_allow_batching = 1;
SET GLOBAL slave_allow_batching = ON;
```

If a particular batch causes problems (such as a statement whose effects do not appear to be replicated correctly), batching can be deactivated using either of the following statements:

```
SET GLOBAL slave_allow_batching = 0;
SET GLOBAL slave_allow_batching = OFF;
```

You can check whether batching is currently being used by means of an appropriate `SHOW VARIABLES` statement, like this one:

```
mysql> SHOW VARIABLES LIKE 'slave%';
+----------------------------+-------+
| Variable_name              | Value |
+----------------------------+-------+
| slave_allow_batching       | ON    |
| slave_compressed_protocol  | OFF   |
| slave_load_tmpdir          | /tmp  |
| slave_net_timeout          | 3600  |
| slave_skip_errors          | OFF   |
| slave_transaction_retries  | 10    |
+----------------------------+-------+
6 rows in set (0.00 sec)
```

### 18.7.7 Using Two Replication Channels for NDB Cluster Replication

In a more complete example scenario, we envision two replication channels to provide redundancy and thereby guard against possible failure of a single replication channel. This requires a total of four replication servers, two source servers on the source cluster and two replica servers on the replica cluster. For purposes of the discussion that follows, we assume that unique identifiers are assigned as shown here:

<table>
<thead>
<tr>
<th>Server ID</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Source - primary replication channel (S)</td>
</tr>
<tr>
<td>2</td>
<td>Source - secondary replication channel (S')</td>
</tr>
<tr>
<td>3</td>
<td>Replica - primary replication channel (R)</td>
</tr>
<tr>
<td>4</td>
<td>Replica - secondary replication channel (R')</td>
</tr>
</tbody>
</table>

Setting up replication with two channels is not radically different from setting up a single replication channel. First, the `mysqld` processes for the primary and secondary replication source servers must be started, followed by those for the primary and secondary replicas. The replication processes can be initiated by issuing the `START SLAVE` statement on each of the replicas. The commands and the order in which they need to be issued are shown here:

1. Start the primary replication source:

```
shell> mysqld --ndbcluster --server-id=1 \
   --log-bin &
```
Implementing Failover with NDB Cluster Replication

2. Start the secondary replication source:

```
shellS' > mysqld --ndbcluster --server-id=2 --log-bin &
```

3. Start the primary replica server:

```
shellR > mysqld --ndbcluster --server-id=3 --skip-slave-start &
```

4. Start the secondary replica server:

```
shellR' > mysqld --ndbcluster --server-id=4 --skip-slave-start &
```

5. Finally, initiate replication on the primary channel by executing the `START SLAVE` statement on the primary replica as shown here:

```
mysqlR > START SLAVE;
```

**Warning**

Only the primary channel must be started at this point. The secondary replication channel needs to be started only in the event that the primary replication channel fails, as described in Section 18.7.8, “Implementing Failover with NDB Cluster Replication”. Running multiple replication channels simultaneously can result in unwanted duplicate records being created on the replicas.

As mentioned previously, it is not necessary to enable binary logging on the replicas.

### 18.7.8 Implementing Failover with NDB Cluster Replication

In the event that the primary Cluster replication process fails, it is possible to switch over to the secondary replication channel. The following procedure describes the steps required to accomplish this.

1. Obtain the time of the most recent global checkpoint (GCP). That is, you need to determine the most recent epoch from the `ndb_apply_status` table on the replica cluster, which can be found using the following query:

```
mysqlR' > SELECT @latest:=MAX(epoch) -> FROM mysql.ndb_apply_status;
```

In a circular replication topology, with a source and a replica running on each host, when you are using `ndb_log_apply_status=1`, NDB Cluster epochs are written in the replicas’ binary logs. This means that the `ndb_apply_status` table contains information for the replica on this host as well as for any other host which acts as a replica of the replication source server running on this host.

In this case, you need to determine the latest epoch on this replica to the exclusion of any epochs from any other replicas in this replica’s binary log that were not listed in the `IGNORE_SERVER_IDS` options of the `CHANGE MASTER TO` statement used to set up this replica. The reason for excluding such epochs is that rows in the `mysql.ndb_apply_status` table whose server IDs have a match in the `IGNORE_SERVER_IDS` list from the `CHANGE MASTER TO` statement used to prepare this replicas's source are also considered to be from local servers, in addition to those having the replica's own server ID. You can retrieve this list as `Replicate_Ignore_Server_Ids` from the output of `SHOW SLAVE STATUS`. We assume that you have obtained this list and are substituting it for `ignore_server_ids` in the query shown here, which like the previous version of the query, selects the greatest epoch into a variable named `@latest`:
Implementing Failover with NDB Cluster Replication

```sql
mysql\r\n-> SELECT @latest:=MAX(epoch)
     -> FROM mysql.ndb_apply_status
     -> WHERE server_id NOT IN (ignore_server_ids);
```

In some cases, it may be simpler or more efficient (or both) to use a list of the server IDs to be included and `server_id IN server_id_list` in the `WHERE` condition of the preceding query.

2. Using the information obtained from the query shown in Step 1, obtain the corresponding records from the `ndb_binlog_index` table on the source cluster.

You can use the following query to obtain the needed records from the `ndb_binlog_index` table on the source:

```sql
mysql\r\nS'-> SELECT
     -> @file:=SUBSTRING_INDEX(next_file, '/', -1),
     -> @pos:=next_position
     -> FROM mysql.ndb_binlog_index
     -> WHERE epoch >= @latest
     -> ORDER BY epoch ASC LIMIT 1;
```

These are the records saved on the source since the failure of the primary replication channel. We have employed a user variable `@latest` here to represent the value obtained in Step 1. Of course, it is not possible for one `mysqld` instance to access user variables set on another server instance directly. These values must be “plugged in” to the second query manually or by an application.

**Important**

You must ensure that the replica `mysqld` is started with `--slave-skip-errors=ddl_exist_errors` before executing `START SLAVE`. Otherwise, replication may stop with duplicate DDL errors.

3. Now it is possible to synchronize the secondary channel by running the following query on the secondary replica server:

```sql
mysqlR'-> CHANGE MASTER TO
     -> MASTER_LOG_FILE='@file',
     -> MASTER_LOG_POS=@pos;
```

Again we have employed user variables (in this case `@file` and `@pos`) to represent the values obtained in Step 2 and applied in Step 3; in practice these values must be inserted manually or using an application that can access both of the servers involved.

**Note**

`@file` is a string value such as `'~/var/log/mysql/replication-source-bin.00001'`, and so must be quoted when used in SQL or application code. However, the value represented by `@pos` must *not* be quoted. Although MySQL normally attempts to convert strings to numbers, this case is an exception.

4. You can now initiate replication on the secondary channel by issuing the appropriate statement on the secondary replica `mysqld`:

```sql
mysqlR'-> START SLAVE;
```

Once the secondary replication channel is active, you can investigate the failure of the primary and effect repairs. The precise actions required to do this depend upon the reasons for which the primary channel failed.
Warning

The secondary replication channel is to be started only if and when the primary replication channel has failed. Running multiple replication channels simultaneously can result in unwanted duplicate records being created on the replicas.

If the failure is limited to a single server, it should in theory be possible to replicate from $S$ to $R'$, or from $S'$ to $R$.

### 18.7.9 NDB Cluster Backups With NDB Cluster Replication

This section discusses making backups and restoring from them using NDB Cluster replication. We assume that the replication servers have already been configured as covered previously (see Section 18.7.5, “Preparing the NDB Cluster for Replication”, and the sections immediately following). This having been done, the procedure for making a backup and then restoring from it is as follows:

1. There are two different methods by which the backup may be started.

   - **Method A.** This method requires that the cluster backup process was previously enabled on the source server, prior to starting the replication process. This can be done by including the following line in a `[mysql_cluster]` section in the `my.cnf` file, where `management_host` is the IP address or host name of the NDB management server for the source cluster, and `port` is the management server's port number:

     ```
     ndb-connectstring=management_host[:port]
     ```

   - **Method B.** If the `my.cnf` file does not specify where to find the management host, you can start the backup process by passing this information to the NDB management client as part of the `START BACKUP` command. This can be done as shown here, where `management_host` and `port` are the host name and port number of the management server:

     ```
     shell> ndb_mgm management_host:port -e "START BACKUP"
     ```

     In this case, the backup can be started by executing this statement on the replication source:

     ```
     shell> ndb_mgm -e "START BACKUP"
     ```

   - **Method B.** If the `my.cnf` file does not specify where to find the management host, you can start the backup process by passing this information to the NDB management client as part of the `START BACKUP` command. This can be done as shown here, where `management_host` and `port` are the host name and port number of the management server:

     ```
     shell> ndb_mgm management_host:port -e "START BACKUP"
     ```

     In this case, the backup can be started by executing this statement on the replication source:

     ```
     shell> ndb_mgm -e "START BACKUP"
     ```

2. Copy the cluster backup files to the replica that is being brought on line. Each system running an ndbd process for the source cluster has cluster backup files located on it, and all of these files must be copied to the replica to ensure a successful restore. The backup files can be copied into any directory on the computer where the replica’s management host resides, as long as the MySQL and NDB binaries have read permissions in that directory. In this case, we assume that these files have been copied into the directory `/var/BACKUPS/BACKUP-1`.

   While it is not necessary that the replica cluster have the same number of ndbd processes (data nodes) as the source, it is highly recommended this number be the same. It is necessary that the
replica be started with the `--skip-slave-start` option, to prevent premature startup of the replication process.

3. Create any databases on the replica cluster that are present on the source cluster and that are to be replicated.

   ! Important
   A CREATE DATABASE (or CREATE SCHEMA) statement corresponding to each database to be replicated must be executed on each SQL node in the replica cluster.

4. Reset the replica cluster using this statement in the `mysql` client:

   ```
   mysql> RESET SLAVE;
   ```

5. You can now start the cluster restoration process on the replica using the `ndb_restore` command for each backup file in turn. For the first of these, it is necessary to include the `-m` option to restore the cluster metadata, as shown here:

   ```
   shell> ndb_restore -c replica_host:port -n node-id \
       -b backup-id -m -r dir
   ```

dir is the path to the directory where the backup files have been placed on the replica. For the `ndb_restore` commands corresponding to the remaining backup files, the `-m` option should not be used.

For restoring from a source cluster with four data nodes (as shown in the figure in Section 18.7, “NDB Cluster Replication”) where the backup files have been copied to the directory `/var/BACKUPS/BACKUP-1`, the proper sequence of commands to be executed on the replica might look like this:

```
shell> ndb_restore -c replica-host:1186 -n 2 -b 1 -m \
   -r ./var/BACKUPS/BACKUP-1
shell> ndb_restore -c replica-host:1186 -n 3 -b 1 \
   -r ./var/BACKUPS/BACKUP-1
shell> ndb_restore -c replica-host:1186 -n 4 -b 1 \
   -r ./var/BACKUPS/BACKUP-1
shell> ndb_restore -c replica-host:1186 -n 5 -b 1 -e \
   -r ./var/BACKUPS/BACKUP-1
```

! Important
The `-e` (or `--restore-epoch`) option in the final invocation of `ndb_restore` in this example is required to make sure that the epoch is written to the replica's `mysql.ndb_apply_status` table. Without this information, the replica cannot synchronize properly with the source. (See Section 18.5.22, “ndb_restore — Restore an NDB Cluster Backup”.)

6. Now you need to obtain the most recent epoch from the `ndb_apply_status` table on the replica (as discussed in Section 18.7.8, “Implementing Failover with NDB Cluster Replication”):

   ```
   mysql> SELECT @latest:=MAX(epoch) \
       FROM mysql.ndb_apply_status;
   ```

7. Using `@latest` as the epoch value obtained in the previous step, you can obtain the correct starting position `@pos` in the correct binary log file `@file` from the `mysql.ndb_binlog_index` table on the source. The query shown here gets these from the `next_position` and `next_file` columns from the last epoch applied before the logical restore position:

   ```
   mysql> SELECT
   ```
In the event that there is currently no replication traffic, you can get similar information by running `SHOW MASTER STATUS` on the source and using the value shown in the `Position` column of the output for the file whose name has the suffix with the greatest value for all files shown in the `File` column. In this case, you must determine which file this is and supply the name in the next step manually or by parsing the output with a script.

8. Using the values obtained in the previous step, you can now issue the appropriate `CHANGE MASTER TO` statement in the replica's `mysql` client:

```
mysql>
CHANGE MASTER TO
-> MASTER_LOG_FILE='@file',
-> MASTER_LOG_POS=@pos;
```

9. Now that the replica knows from what point in which binary log file to start reading data from the source, you can cause the replica to begin replicating with this statement:

```
mysql>
START SLAVE;
```

To perform a backup and restore on a second replication channel, it is necessary only to repeat these steps, substituting the host names and IDs of the secondary source and replica for those of the primary source and replica servers where appropriate, and running the preceding statements on them.

For additional information on performing Cluster backups and restoring Cluster from backups, see Section 18.6.8, “Online Backup of NDB Cluster”.

### 18.7.9.1 NDB Cluster Replication: Automating Synchronization of the Replica to the Source Binary Log

It is possible to automate much of the process described in the previous section (see Section 18.7.9, “NDB Cluster Backups With NDB Cluster Replication”). The following Perl script `reset-replica.pl` serves as an example of how you can do this.

```
#!/usr/bin/perl -w

# file: reset-replica.pl

}
# end reset-replica.pl
```

18.7.9.2 Point-In-Time Recovery Using NDB Cluster Replication

Point-in-time recovery—that is, recovery of data changes made since a given point in time—is performed after restoring a full backup that returns the server to its state when the backup was made. Performing point-in-time recovery of NDB Cluster tables with NDB Cluster and NDB Cluster Replication can be accomplished using a native NDB data backup (taken by issuing `CREATE BACKUP` in the `ndb_mgm` client) and restoring the `ndb_binlog_index` table (from a dump made using `mysqldump`).

To perform point-in-time recovery of NDB Cluster, it is necessary to follow the steps shown here:

1. Back up all NDB databases in the cluster, using the `START BACKUP` command in the `ndb_mgm` client (see Section 18.6.8, “Online Backup of NDB Cluster”).

2. At some later point, prior to restoring the cluster, make a backup of the `mysql.ndb_binlog_index` table. It is probably simplest to use `mysqldump` for this task. Also back up the binary log files at this time.
   
   This backup should be updated regularly—perhaps even hourly—depending on your needs.

3. *(Catastrophic failure or error occurs.)*

4. Locate the last known good backup.

5. Clear the data node file systems (using `ndbd --initial` or `ndbmtd --initial`).

```
# Note
NDB Cluster Disk Data tablespace and log files are not removed by --initial. You must delete these manually.
```

6. Use `DROP TABLE` or `TRUNCATE TABLE` with the `mysql.ndb_binlog_index` table.

7. Execute `ndb_restore`, restoring all data. You must include the `--restore-epoch` option when you run `ndb_restore`, so that the `ndb_apply_status` table is populated correctly. (See Section 18.5.22, “ndb_restore — Restore an NDB Cluster Backup”, for more information.)

8. Restore the `ndb_binlog_index` table from the output of `mysqldump` and restore the binary log files from backup, if necessary.

9. Find the epoch applied most recently—that is, the maximum `epoch` column value in the `ndb_apply_status` table—as the user variable `@LATEST_EPOCH` (emphasized):
SELECT @LATEST_EPOCH:=MAX(epoch)
FROM mysql.ndb_apply_status;

10. Find the latest binary log file (@FIRST_FILE) and position (Position column value) within this file that correspond to @LATEST_EPOCH in the ndb_binlog_index table:

```
SELECT Position, @FIRST_FILE:=File
FROM mysql.ndb_binlog_index
WHERE epoch > @LATEST_EPOCH ORDER BY epoch ASC LIMIT 1;
```

11. Using `mysqlbinlog`, replay the binary log events from the given file and position up to the point of the failure. (See Section 4.6.8, “mysqlbinlog — Utility for Processing Binary Log Files”.)

See also Section 7.5, “Point-in-Time (Incremental) Recovery Using the Binary Log”, for more information about the binary log, replication, and incremental recovery.

### 18.7.10 NDB Cluster Replication: Bidirectional and Circular Replication

It is possible to use NDB Cluster for bidirectional replication between two clusters, as well as for circular replication between any number of clusters.

**Circular replication example.** In the next few paragraphs we consider the example of a replication setup involving three NDB Clusters numbered 1, 2, and 3, in which Cluster 1 acts as the replication source for Cluster 2, Cluster 2 acts as the source for Cluster 3, and Cluster 3 acts as the source for Cluster 1. Each cluster has two SQL nodes, with SQL nodes A and B belonging to Cluster 1, SQL nodes C and D belonging to Cluster 2, and SQL nodes E and F belonging to Cluster 3.

Circular replication using these clusters is supported as long as the following conditions are met:

- The SQL nodes on all sources and replicas are the same.
- All SQL nodes acting as sources and replicas are started with the `log_slave_updates` system variable enabled.

This type of circular replication setup is shown in the following diagram:
In this scenario, SQL node A in Cluster 1 replicates to SQL node C in Cluster 2; SQL node C replicates to SQL node E in Cluster 3; SQL node E replicates to SQL node A. In other words, the replication line (indicated by the curved arrows in the diagram) directly connects all SQL nodes used as replication sources and replicas.

It is also possible to set up circular replication in such a way that not all source SQL nodes are also replicas, as shown here:
In this case, different SQL nodes in each cluster are used as replication sources and replicas. You must *not* start any of the SQL nodes with the `log_slave_updates` system variable enabled. This type of circular replication scheme for NDB Cluster, in which the line of replication (again indicated by the curved arrows in the diagram) is discontinuous, should be possible, but it should be noted that it has not yet been thoroughly tested and must therefore still be considered experimental.

**Using NDB-native backup and restore to initialize a replica cluster.** When setting up circular replication, it is possible to initialize the replica cluster by using the management client `START BACKUP` command on one NDB Cluster to create a backup and then applying this backup on another NDB Cluster using `ndb_restore`. This does not automatically create binary logs on the second NDB Cluster's SQL
node acting as the replica; in order to cause the binary logs to be created, you must issue a `SHOW TABLES` statement on that SQL node; this should be done prior to running `START SLAVE`. This is a known issue.

**Multi-source failover example.** In this section, we discuss failover in a multi-source NDB Cluster replication setup with three NDB Clusters having server IDs 1, 2, and 3. In this scenario, Cluster 1 replicates to Clusters 2 and 3; Cluster 2 also replicates to Cluster 3. This relationship is shown here:

**Figure 18.29 NDB Cluster Multi-Master Replication With 3 Sources**

In other words, data replicates from Cluster 1 to Cluster 3 through 2 different routes: directly, and by way of Cluster 2.

Not all MySQL servers taking part in multi-source replication must act as both source and replica, and a given NDB Cluster might use different SQL nodes for different replication channels. Such a case is shown here:

**Figure 18.30 NDB Cluster Multi-Source Replication, With MySQL Servers**

MySQL servers acting as replicas must be run with the `log_slave_updates` system variable enabled. Which `mysqld` processes require this option is also shown in the preceding diagram.
Using the `log_slave_updates` system variable has no effect on servers not being run as replicas.

The need for failover arises when one of the replicating clusters goes down. In this example, we consider the case where Cluster 1 is lost to service, and so Cluster 3 loses 2 sources of updates from Cluster 1. Because replication between NDB Clusters is asynchronous, there is no guarantee that Cluster 3’s updates originating directly from Cluster 1 are more recent than those received through Cluster 2. You can handle this by ensuring that Cluster 3 catches up to Cluster 2 with regard to updates from Cluster 1. In terms of MySQL servers, this means that you need to replicate any outstanding updates from MySQL server C to server F.

On server C, perform the following queries:

```sql
mysqlC> SELECT @latest:=MAX(epoch)
     -> FROM mysql.ndb_apply_status
     -> WHERE server_id=1;

mysqlC> SELECT
     -> @file:=SUBSTRING_INDEX(File, '/', -1),
     -> @pos:=Position
     -> FROM mysql.ndb_binlog_index
     -> WHERE orig_epoch >= @latest
     -> AND orig_server_id = 1
     -> ORDER BY epoch ASC LIMIT 1;
```

You can improve the performance of this query, and thus likely speed up failover times significantly, by adding the appropriate index to the `ndb_binlog_index` table. See Section 18.7.4, “NDB Cluster Replication Schema and Tables”, for more information.

Copy over the values for `@file` and `@pos` manually from server C to server F (or have your application perform the equivalent). Then, on server F, execute the following `CHANGE MASTER TO` statement:

```sql
mysqlF> CHANGE MASTER TO
     -> MASTER_HOST = 'serverC'
     -> MASTER_LOG_FILE='@file',
     -> MASTER_LOG_POS=@pos;
```

Once this has been done, you can issue a `START SLAVE` statement on MySQL server F; this causes any missing updates originating from server B to be replicated to server F.

The `CHANGE MASTER TO` statement also supports an `IGNORE_SERVER_IDS` option which takes a comma-separated list of server IDs and causes events originating from the corresponding servers to be ignored. For more information, see Section 13.4.2.1, “CHANGE MASTER TO Statement”, and Section 13.7.5.35, “SHOW SLAVE STATUS Statement”. For information about how this option interacts with the `ndb_log_apply_status` variable, see Section 18.7.8, “Implementing Failover with NDB Cluster Replication”.

### 18.7.11 NDB Cluster Replication Conflict Resolution

- **Requirements**
- **Source Column Control**
- **Conflict Resolution Control**
When using a replication setup involving multiple sources (including circular replication), it is possible that different sources may try to update the same row on the replica with different data. Conflict resolution in NDB Cluster Replication provides a means of resolving such conflicts by permitting a user-defined resolution column to be used to determine whether or not an update on a given source should be applied on the replica.

Some types of conflict resolution supported by NDB Cluster (NDB$OLD(), NDB$MAX(), NDB$MAX_DELETE_WIN()) implement this user-defined column as a “timestamp” column (although its type cannot be TIMESTAMP, as explained later in this section). These types of conflict resolution are always applied a row-by-row basis rather than a transactional basis. The epoch-based conflict resolution functions NDB$EPOCH() and NDB$EPOCH_TRANS() compare the order in which epochs are replicated (and thus these functions are transactional). Different methods can be used to compare resolution column values on the replica when conflicts occur, as explained later in this section; the method used can be set on a per-table basis.

You should also keep in mind that it is the application's responsibility to ensure that the resolution column is correctly populated with relevant values, so that the resolution function can make the appropriate choice when determining whether to apply an update.

Requirements

Preparations for conflict resolution must be made on both the source and the replica. These tasks are described in the following list:

- On the source writing the binary logs, you must determine which columns are sent (all columns or only those that have been updated). This is done for the MySQL Server as a whole by applying the mysqld startup option --ndb-log-updated-only (described later in this section) or on a per-table basis by entries in the mysql.ndb_replication table (see ndb_replication Table).

  Note

  If you are replicating tables with very large columns (such as TEXT or BLOB columns), --ndb-log-updated-only can also be useful for reducing the size of the binary logs and avoiding possible replication failures due to exceeding max_allowed_packet.

  See Section 17.4.1.19, “Replication and max_allowed_packet”, for more information about this issue.

- On the replica, you must determine which type of conflict resolution to apply (“latest timestamp wins”, “same timestamp wins”, “primary wins”, “primary wins, complete transaction”, or none). This is done using the mysql.ndb_replication system table, on a per-table basis (see ndb_replication Table).

- NDB 7.4.1 and later also supports read conflict detection, that is, detecting conflicts between reads of a given row in one cluster and updates or deletes of the same row in another cluster. This requires exclusive read locks obtained by setting ndb_log_exclusive_reads equal to 1 on the replica. All rows read by a conflicting read are logged in the exceptions table. For more information, see Read conflict detection and resolution.
When using the functions NDB$OLD(), NDB$MAX(), and NDB$MAX_DELETE_WIN() for timestamp-based conflict resolution, we often refer to the column used for determining updates as a “timestamp” column. However, the data type of this column is never TIMESTAMP; instead, its data type should be INT (INTEGER) or BIGINT. The “timestamp” column should also be UNSIGNED and NOT NULL.

The NDB$EPOCH() and NDB$EPOCH_TRANS() functions discussed later in this section work by comparing the relative order of replication epochs applied on a primary and secondary NDB Cluster, and do not make use of timestamps.

**Source Column Control**

We can see update operations in terms of “before” and “after” images—that is, the states of the table before and after the update is applied. Normally, when updating a table with a primary key, the “before” image is not of great interest; however, when we need to determine on a per-update basis whether or not to use the updated values on a replica, we need to make sure that both images are written to the source's binary log. This is done with the --ndb-log-update-as-write option for mysqld, as described later in this section.

**Important**

Whether logging of complete rows or of updated columns only is done is decided when the MySQL server is started, and cannot be changed online; you must either restart mysqld, or start a new mysqld instance with different logging options.

**Logging Full or Partial Rows.** For purposes of conflict resolution, there are two basic methods of logging rows, as determined by the setting of the --ndb-log-updated-only option for mysqld:

- Log complete rows (option set to ON)
- Log only column data that has been updated—that is, column data whose value has been set, regardless of whether or not this value was actually changed. This is the default behavior (option set to OFF).

It is usually sufficient—and more efficient—to log updated columns only; however, if you need to log full rows, you can do so by setting --ndb-log-updated-only to 0 or OFF.

**Logging Changed Data as Updates.** The setting of the MySQL Server's --ndb-log-update-as-write option determines whether logging is performed with or without the “before” image. Because conflict resolution is done in the MySQL Server's update handler, it is necessary to control logging performed by the replication source such that updates are updates and not writes; that is, such that updates are treated as changes in existing rows rather than the writing of new rows, even though these replace existing rows. This option is turned on by default; in other words, updates are treated as writes. That is, updates are by default written as write_row events in the binary log, rather than as update_row events.

To disable the option, start the source mysqld with --ndb-log-update-as-write=0 or --ndb-log-update-as-write=OFF. You must do this when replicating from NDB tables to tables using a different storage engine; see Replication from NDB to other storage engines, and Replication from NDB to a nontransactional storage engine, for more information.

**Conflict Resolution Control**

Conflict resolution is usually enabled on the server where conflicts can occur. Like logging method selection, it is enabled by entries in the mysql.ndb_replication table.

NBT_UPDATED_ONLY_MINIMAL and NBT_UPDATED_FULL_MINIMAL can be used with NDB$EPOCH(), NDB$EPOCH2(), and NDB$EPOCH_TRANS(), because these do not require “before” values of columns.
which are not primary keys. Conflict resolution algorithms requiring the old values, such as \texttt{NDB\$MAX()} and \texttt{NDB\$OLD()}, do not work correctly with these binlog\_type values.

### Conflict Resolution Functions

The next few paragraphs provide detailed information about the functions which can be used for conflict detection and resolution with NDB Replication.

**\texttt{NDB\$OLD(column\_name)}.** If the value of \texttt{column\_name} is the same on both the source and the replica, then the update is applied; otherwise, the update is not applied on the replica and an exception is written to the log. This is illustrated by the following pseudocode:

```plaintext
if (source\_old\_column\_value == replica\_current\_column\_value)
    apply\_update();
else
    log\_exception();
```

This function can be used for “same value wins” conflict resolution. This type of conflict resolution ensures that updates are not applied on the replica from the wrong source.

![Important]

The column value from the source’s “before” image is used by this function.

**\texttt{NDB\$MAX(column\_name)}.** If the “timestamp” column value for a given row coming from the source is higher than that on the replica, it is applied; otherwise it is not applied on the replica. This is illustrated by the following pseudocode:

```plaintext
if (source\_new\_column\_value > replica\_current\_column\_value)
    apply\_update();
```

This function can be used for “greatest timestamp wins” conflict resolution. This type of conflict resolution ensures that, in the event of a conflict, the version of the row that was most recently updated is the version that persists.

![Important]

The column value from the source's “after” image is used by this function.

**\texttt{NDB\$MAX\_DELETE\_WIN()}.** This is a variation on \texttt{NDB\$MAX()}. Due to the fact that no timestamp is available for a delete operation, a delete using \texttt{NDB\$MAX()} is in fact processed as \texttt{NDB\$OLD}, but for some use cases, this is not optimal. For \texttt{NDB\$MAX\_DELETE\_WIN()}, if the “timestamp” column value for a given row adding or updating an existing row coming from the source is higher than that on the replica, it is applied. However, delete operations are treated as always having the higher value. This is illustrated by the following pseudocode:

```plaintext
if ( (source\_new\_column\_value > replica\_current\_column\_value)
     ||
     operation\_type == "delete")
    apply\_update();
```

This function can be used for “greatest timestamp, delete wins” conflict resolution. This type of conflict resolution ensures that, in the event of a conflict, the version of the row that was deleted or (otherwise) most recently updated is the version that persists.

![Note]

As with \texttt{NDB\$MAX()}, the column value from the source’s “after” image is the value used by this function.
**NDB$EPOCH().** The **NDB$EPOCH()** function tracks the order in which replicated epochs are applied on a replica cluster relative to changes originating on the replica. This relative ordering is used to determine whether changes originating on the replica are concurrent with any changes that originate locally, and are therefore potentially in conflict.

Most of what follows in the description of **NDB$EPOCH()** also applies to **NDB$EPOCH_TRANS()**. Any exceptions are noted in the text.

**NDB$EPOCH()** is asymmetric, operating on one NDB Cluster in a bidirectional replication configuration (sometimes referred to as “active-active” replication). We refer here to cluster on which it operates as the primary, and the other as the secondary. The replica on the primary is responsible for detecting and handling conflicts, while the replica on the secondary is not involved in any conflict detection or handling.

When the replica on the primary detects conflicts, it injects events into its own binary log to compensate for these; this ensures that the secondary NDB Cluster eventually realigns itself with the primary and so keeps the primary and secondary from diverging. This compensation and realignment mechanism requires that the primary NDB Cluster always wins any conflicts with the secondary—that is, that the primary's changes are always used rather than those from the secondary in event of a conflict. This “primary always wins” rule has the following implications:

- Operations that change data, once committed on the primary, are fully persistent and are not undone or rolled back by conflict detection and resolution.

- Data read from the primary is fully consistent. Any changes committed on the Primary (locally or from the replica) are not reverted later.

- Operations that change data on the secondary may later be reverted if the primary determines that they are in conflict.

- Individual rows read on the secondary are self-consistent at all times, each row always reflecting either a state committed by the secondary, or one committed by the primary.

- Sets of rows read on the secondary may not necessarily be consistent at a given single point in time. For **NDB$EPOCH_TRANS()**, this is a transient state; for **NDB$EPOCH()**, it can be a persistent state.

- Assuming a period of sufficient length without any conflicts, all data on the secondary NDB Cluster (eventually) becomes consistent with the primary's data.

**NDB$EPOCH()** and **NDB$EPOCH_TRANS()** do not require any user schema modifications, or application changes to provide conflict detection. However, careful thought must be given to the schema used, and the access patterns used, to verify that the complete system behaves within specified limits.

Each of the **NDB$EPOCH()** and **NDB$EPOCH_TRANS()** functions can take an optional parameter; this is the number of bits to use to represent the lower 32 bits of the epoch, and should be set to no less than the value calculated as shown here:

\[
\text{CEIL} \left( \log_2 \left( \frac{\text{TimeBetweenGlobalCheckpoints}}{\text{TimeBetweenEpochs}} \right) \right), 1
\]

For the default values of these configuration parameters (2000 and 100 milliseconds, respectively), this gives a value of 5 bits, so the default value (6) should be sufficient, unless other values are used for **TimeBetweenGlobalCheckpoints**, **TimeBetweenEpochs**, or both. A value that is too small can result in false positives, while one that is too large could lead to excessive wasted space in the database.

Both **NDB$EPOCH()** and **NDB$EPOCH_TRANS()** insert entries for conflicting rows into the relevant exceptions tables, provided that these tables have been defined according to the same exceptions table schema rules as described elsewhere in this section (see **NDB$OLD(column_name)**). You must create any exceptions table before creating the data table with which it is to be used.
As with the other conflict detection functions discussed in this section, \texttt{NDB$EPOCH()} and \texttt{NDB$EPOCH\_TRANS()} are activated by including relevant entries in the \texttt{mysql.ndb\_replication} table (see \texttt{ndb\_replication Table}). The roles of the primary and secondary NDB Clusters in this scenario are fully determined by \texttt{mysql.ndb\_replication} table entries.

Because the conflict detection algorithms employed by \texttt{NDB$EPOCH()} and \texttt{NDB$EPOCH\_TRANS()} are asymmetric, you must use different values for the \texttt{server\_id} entries of the primary and secondary replicas.

Prior to NDB 7.3.6, conflicts between \texttt{DELETE} operations were handled like those for \texttt{UPDATE} operations, and within the same epoch were considered in conflict. In NDB 7.3.6 and later, a conflict between \texttt{DELETE} operations alone is not sufficient to trigger a conflict using \texttt{NDB$EPOCH()} or \texttt{NDB$EPOCH\_TRANS()}, and the relative placement within epochs does not matter. (Bug \#18459944)

For more information, see Limitations on \texttt{NDB$EPOCH()}.

\textbf{NDB$EPOCH\_TRANS()}. \texttt{NDB$EPOCH\_TRANS()} extends the \texttt{NDB$EPOCH()} function. Conflicts are detected and handled in the same way using the “primary wins all” rule (see \texttt{NDB$EPOCH()}) but with the extra condition that any other rows updated in the same transaction in which the conflict occurred are also regarded as being in conflict. In other words, where \texttt{NDB$EPOCH()} realigns individual conflicting rows on the secondary, \texttt{NDB$EPOCH\_TRANS()} realigns conflicting transactions.

In addition, any transactions which are detectably dependent on a conflicting transaction are also regarded as being in conflict, these dependencies being determined by the contents of the secondary cluster's binary log. Since the binary log contains only data modification operations (inserts, updates, and deletes), only overlapping data modifications are used to determine dependencies between transactions.

\texttt{NDB$EPOCH\_TRANS()} is subject to the same conditions and limitations as \texttt{NDB$EPOCH()}, and in addition requires that Version 2 binary log row events are used (\texttt{log\_bin\_use\_v1\_row\_events} equal to 0), which adds a storage overhead of 2 bytes per event in the binary log. In addition, all transaction IDs must be recorded in the secondary's binary log (\texttt{--ndb\_log\_transaction\_id} option), which adds a further variable overhead (up to 13 bytes per row).

See \texttt{NDB$EPOCH()}.

\textbf{NDB$EPOCH2()}. The \texttt{NDB$EPOCH2()} function, added in NDB 7.4.2, is similar to \texttt{NDB$EPOCH()}, except that \texttt{NDB$EPOCH2()} provides for delete-delete handling with a bidirectional replication topology. In this scenario, primary and secondary roles are assigned to the two sources by setting the \texttt{ndb\_slave\_conflict\_role} system variable to the appropriate value on each source (usually one each of \texttt{PRIMARY, SECONDARY}). When this is done, modifications made by the secondary are reflected by the primary back to the secondary which then conditionally applies them.

\textbf{NDB$EPOCH2\_TRANS()}. In NDB 7.4.2 and later, \texttt{NDB$EPOCH2\_TRANS()} extends the \texttt{NDB$EPOCH2()} function. Conflicts are detected and handled in the same way, and assigning primary and secondary roles to the replicating clusters, but with the extra condition that any other rows updated in the same transaction in which the conflict occurred are also regarded as being in conflict. That is, \texttt{NDB$EPOCH2()} realigns individual conflicting rows on the secondary, while \texttt{NDB$EPOCH\_TRANS()} realigns conflicting transactions.

Where \texttt{NDB$EPOCH()} and \texttt{NDB$EPOCH\_TRANS()} use metadata that is specified per row, per last modified epoch, to determine on the primary whether an incoming replicated row change from the secondary is concurrent with a locally committed change; concurrent changes are regarded as conflicting, with subsequent exceptions table updates and realignment of the secondary. A problem arises when a row is deleted on the primary so there is no longer any last-modified epoch available to determine whether any replicated operations conflict, which means that conflicting delete operationss are not detected. This can...
result in divergence, an example being a delete on one cluster which is concurrent with a delete and insert on the other; this why delete operations can be routed to only one cluster when using **NDB$EPOCH()** and **NDB$EPOCH_TRANS()**.

**NDB$EPOCH2()** bypasses the issue just described—storing information about deleted rows on the PRIMARY—by ignoring any delete-delete conflict, and by avoiding any potential resultant divergence as well. This is accomplished by reflecting any operation successfully applied on and replicated from the secondary back to the secondary. On its return to the secondary, it can be used to reapply an operation on the secondary which was deleted by an operation originating from the primary.

When using **NDB$EPOCH2()**, you should keep in mind that the secondary applies the delete from the primary, removing the new row until it is restored by a reflected operation. In theory, the subsequent insert or update on the secondary conflicts with the delete from the primary, but in this case, we choose to ignore this and allow the secondary to “win”, in the interest of preventing divergence between the clusters. In other words, after a delete, the primary does not detect conflicts, and instead adopts the secondary’s following changes immediately. Because of this, the secondary’s state can revisit multiple previous committed states as it progresses to a final (stable) state, and some of these may be visible.

You should also be aware that reflecting all operations from the secondary back to the primary increases the size of the primary’s logbinary log, as well as demands on bandwidth, CPU usage, and disk I/O.

Application of reflected operations on the secondary depends on the state of the target row on the secondary. Whether or not reflected changes are applied on the secondary can be tracked by checking the **Ndb_conflict_reflected_op_prepare_count** and **Ndb_conflict_reflected_op_discard_count** status variables, both added in NDB 7.4.2. The number of changes applied is simply the difference between these two values (note that **Ndb_conflict_reflected_op_prepare_count** is always greater than or equal to **Ndb_conflict_reflected_op_discard_count**).

Events are applied if and only if both of the following conditions are true:

- The existence of the row—that is, whether or not it exists—is in accordance with the type of event. For delete and update operations, the row must already exist. For insert operations, the row must not exist.
- The row was last modified by the primary. It is possible that the modification was accomplished through the execution of a reflected operation.

If both of these conditions are not met, the reflected operation is discarded by the secondary.

**Limitations on NDB$EPOCH().** The following limitations currently apply when using **NDB$EPOCH()** to perform conflict detection:

- Conflicts are detected using NDB Cluster epoch boundaries, with granularity proportional to **TimeBetweenEpochs** (default: 100 milliseconds). The minimum conflict window is the minimum time during which concurrent updates to the same data on both clusters always report a conflict. This is always a nonzero length of time, and is roughly proportional to \(2 \times (\text{latency} + \text{queueing} + \text{TimeBetweenEpochs})\). This implies that—assuming the default for **TimeBetweenEpochs** and ignoring any latency between clusters (as well as any queuing delays)—the minimum conflict window size is approximately 200 milliseconds. This minimum window should be considered when looking at expected application “race” patterns.

- Additional storage is required for tables using the **NDB$EPOCH()** and **NDB$EPOCH_TRANS()** functions; from 1 to 32 bits extra space per row is required, depending on the value passed to the function.

- Conflicts between delete operations may result in divergence between the primary and secondary. When a row is deleted on both clusters concurrently, the conflict can be detected, but is not recorded, since the
row is deleted. This means that further conflicts during the propagation of any subsequent realignment operations are not detected, which can lead to divergence.

Deletes should be externally serialized, or routed to one cluster only. Alternatively, a separate row should be updated transactionally with such deletes and any inserts that follow them, so that conflicts can be tracked across row deletes. This may require changes in applications.

- Only two NDB Clusters in a bi-directional “active-active” configuration are currently supported when using NDB$EPOCH() or NDB$EPOCH_TRANS() for conflict detection.
- Tables having BLOB or TEXT columns are not currently supported with NDB$EPOCH() or NDB$EPOCH_TRANS().

Conflict Resolution Exceptions Table

To use the NDB$OLD() conflict resolution function, it is also necessary to create an exceptions table corresponding to each NDB table for which this type of conflict resolution is to be employed. This is also true when using NDB$EPOCH() or NDB$EPOCH_TRANS(). The name of this table is that of the table for which conflict resolution is to be applied, with the string $EX appended. (For example, if the name of the original table is mytable, the name of the corresponding exceptions table name should be mytable$EX.)

Prior to NDB 7.4.1, the syntax for creating the exceptions table is as shown here:

```
CREATE TABLE original_table$EX (  
  server_id INT UNSIGNED,  
  source_server_id INT UNSIGNED,  
  source_epoch BIGINT UNSIGNED,  
  count INT UNSIGNED,  
  original_table_pk_columns,  
  [additional_columns,]  
  PRIMARY KEY(server_id, source_server_id, source_epoch, count)  
) ENGINE=NDB;
```

NDB 7.4.1 and later supports an extended exceptions table definition that includes optional columns providing information about an exception's type, cause, and originating transaction. In these versions, the syntax for creating the exceptions table is as shown here:

```
CREATE TABLE original_table$EX (  
  [NDB$]server_id INT UNSIGNED,  
  [NDB$]source_server_id INT UNSIGNED,  
  [NDB$]source_epoch BIGINT UNSIGNED,  
  [NDB$]count INT UNSIGNED,  
  [NDB$]op_type ENUM('WRITE_ROW', 'UPDATE_ROW', 'DELETE_ROW', 'REFRESH_ROW', 'READ_ROW') NOT NULL,  
  [NDB$]cft_cause ENUM('ROW_DOES_NOT_EXIST', 'ROW_ALREADY_EXISTS', 'DATA_IN_CONFLICT', 'TRANS_IN_CONFLICT') NOT NULL,  
  [NDB$]orig_transid BIGINT UNSIGNED NOT NULL,  
  original_table_pk_columns,  
  [orig_table_column|orig_table_column$OLD|orig_table_column$NEW,]  
  [additional_columns,]  
) ENGINE=NDB;
```

The first four columns are required. The names of the first four columns and the columns matching the original table's primary key columns are not critical; however, we suggest for reasons of clarity
and consistency, that you use the names shown here for the `server_id`, `source_server_id`, `source_epoch`, and `count` columns, and that you use the same names as in the original table for the columns matching those in the original table's primary key.

Starting with NDB 7.4.1, if the exceptions table uses one or more of the optional columns `NDB$OP_TYPE`, `NDB$CFT_CAUSE`, or `NDB$ORIG_TRANSID` discussed later in this section, then each of the required columns must also be named using the prefix `NDB$`. If desired, you can use the `NDB$` prefix to name the required columns even if you do not define any optional columns, but in this case, all four of the required columns must be named using the prefix.

Following these columns, the columns making up the original table's primary key should be copied in the order in which they are used to define the primary key of the original table. The data types for the columns duplicating the primary key columns of the original table should be the same as (or larger than) those of the original columns. In NDB Cluster 7.3 and earlier, the exceptions table's primary key must be reproduced column for column. Beginning with NDB 7.4.1, a subset of the primary key columns may be used instead.

Regardless of the NDB Cluster version employed, the exceptions table must use the `NDB` storage engine. (An example that uses `NDB$OLD()` with an exceptions table is shown later in this section.)

Additional columns may optionally be defined following the copied primary key columns, but not before any of them; any such extra columns cannot be `NOT NULL`. In NDB 7.4.1 and later, support is provided for three additional, predefined optional columns `NDB$OP_TYPE`, `NDB$CFT_CAUSE`, and `NDB$ORIG_TRANSID`, which are described in the next few paragraphs.

`NDB$OP_TYPE`: This column can be used to obtain the type of operation causing the conflict. If you use this column, define it as shown here:

```
NDB$OP_TYPE ENUM('WRITE_ROW', 'UPDATE_ROW', 'DELETE_ROW', 'REFRESH_ROW', 'READ_ROW') NOT NULL
```

The `WRITE_ROW`, `UPDATE_ROW`, and `DELETE_ROW` operation types represent user-initiated operations. `REFRESH_ROW` operations are operations generated by conflict resolution in compensating transactions sent back to the originating cluster from the cluster that detected the conflict. `READ_ROW` operations are user-initiated read tracking operations defined with exclusive row locks.

`NDB$CFT_CAUSE`: You can define an optional column `NDB$CFT_CAUSE` which provides the cause of the registered conflict. This column, if used, is defined as shown here:

```
NDB$CFT_CAUSE ENUM('ROW_DOES_NOT_EXIST', 'ROW_ALREADY_EXISTS', 'DATA_IN_CONFLICT', 'TRANS_IN_CONFLICT') NOT NULL
```

`ROW_DOES_NOT_EXIST` can be reported as the cause for `UPDATE_ROW` and `WRITE_ROW` operations; `ROW_ALREADY_EXISTS` can be reported for `WRITE_ROW` events. `DATA_IN_CONFLICT` is reported when a row-based conflict function detects a conflict; `TRANS_IN_CONFLICT` is reported when a transactional conflict function rejects all of the operations belonging to a complete transaction.

`NDB$ORIG_TRANSID`: The `NDB$ORIG_TRANSID` column, if used, contains the ID of the originating transaction. This column should be defined as follows:

```
NDB$ORIG_TRANSID BIGINT UNSIGNED NOT NULL
```

`NDB$ORIG_TRANSID` is a 64-bit value generated by `NDB`. This value can be used to correlate multiple exceptions table entries belonging to the same conflicting transaction from the same or different exceptions tables.

In NDB 7.4.1 and later, additional reference columns which are not part of the original table's primary key can be named `colname$OLD` or `colname$NEW`. `colname$OLD` references old values in update and delete operations—that is, operations containing `DELETE_ROW` events. `colname$NEW` can be used
to reference new values in insert and update operations—in other words, operations using `WRITE_ROW` events, `UPDATE_ROW` events, or both types of events. Where a conflicting operation does not supply a value for a given reference column that is not a primary key, the exceptions table row contains either `NULL`, or a defined default value for that column.

**Important**

The `mysql.ndb_replication` table is read when a data table is set up for replication, so the row corresponding to a table to be replicated must be inserted into `mysql.ndb_replication` *before* the table to be replicated is created.

### Conflict Detection Status Variables

Several status variables can be used to monitor conflict detection. You can see how many rows have been found in conflict by `NDB$EPOCH()` since this replica was last restarted from the current value of the `Ndb_conflict_fn_epoch` system status variable.

- `Ndb_conflict_fn_epoch_trans` provides the number of rows that have been found directly in conflict by `NDB$EPOCH_TRANS()`. `Ndb_conflict_fn_epoch2` and `Ndb_conflict_fn_epoch2_trans`, both added in NDB 7.4.2, show the number of rows found in conflict by `NDB$EPOCH2()` and `NDB$EPOCH2_TRANS()`, respectively. The number of rows actually realigned, including those affected due to their membership in or dependency on the same transactions as other conflicting rows, is given by `Ndb_conflict_trans_row_reject_count`.

Another server status variable `Ndb_conflict_fn_max` provides a count of the number of times that a row was not applied on the current SQL node due to “greatest timestamp wins” conflict resolution since the last time that `mysqld` was started.

The number of times that a row was not applied as the result of “same timestamp wins” conflict resolution on a given `mysqld` since the last time it was restarted is given by the global status variable `Ndb_conflict_fn_old`. In addition to incrementing `Ndb_conflict_fn_old`, the primary key of the row that was not used is inserted into an *exceptions table*, as explained elsewhere in this section.

See also NDB Cluster Status Variables.

### Examples

The following examples assume that you have already a working NDB Cluster replication setup, as described in Section 18.7.5, “Preparing the NDB Cluster for Replication”, and Section 18.7.6, “Starting NDB Cluster Replication (Single Replication Channel)”.

**NDB$MAX() example.** Suppose you wish to enable “greatest timestamp wins” conflict resolution on table `test.t1`, using column `mycol` as the “timestamp”. This can be done using the following steps:

1. Make sure that you have started the source `mysqld` with `--ndb-log-update-as-write=OFF`.
2. On the source, perform this `INSERT` statement:

```sql
INSERT INTO mysql.ndb_replication
VALUES ('test', 't1', 0, NULL, 'NDB$MAX(mycol)');
```

Inserting a 0 into the `server_id` indicates that all SQL nodes accessing this table should use conflict resolution. If you want to use conflict resolution on a specific `mysqld` only, use the actual server ID.

Inserting `NULL` into the `binlog_type` column has the same effect as inserting 0 (`NBT_DEFAULT`); the server default is used.

3. Create the `test.t1` table:
CREATE TABLE test.t1 (  
  columns  
  mycol INT UNSIGNED,  
  columns  
) ENGINE=NDB;

Now, when updates are performed on this table, conflict resolution is applied, and the version of the row having the greatest value for mycol is written to the replica.

Note
Other binlog_type options—such as NBT_UPDATED_ONLY_USE_UPDATE should be used to control logging on the source using the ndb_replication table rather than by using command-line options.

NDB$OLD() example. Suppose an NDB table such as the one defined here is being replicated, and you wish to enable “same timestamp wins” conflict resolution for updates to this table:

CREATE TABLE test.t2 (  
  a INT UNSIGNED NOT NULL,  
  b CHAR(25) NOT NULL,  
  columns,  
  mycol INT UNSIGNED NOT NULL,  
  columns,  
  PRIMARY KEY pk (a, b)  
) ENGINE=NDB;

The following steps are required, in the order shown:

1. First—and prior to creating test.t2—you must insert a row into the mysql.ndb_replication table, as shown here:

```sql
INSERT INTO mysql.ndb_replication  
VALUES ('test', 't2', 0, NULL, 'NDB$OLD(mycol)');
```

Possible values for the binlog_type column are shown earlier in this section. The value 'NDB$OLD(mycol)' should be inserted into the conflict_fn column.

2. Create an appropriate exceptions table for test.t2. The table creation statement shown here includes all required columns; any additional columns must be declared following these columns, and before the definition of the table’s primary key.

```sql
CREATE TABLE test.t2$EX (  
  server_id INT UNSIGNED,  
  source_server_id INT UNSIGNED,  
  source_epoch BIGINT UNSIGNED,  
  count INT UNSIGNED,  
  a INT UNSIGNED NOT NULL,  
  b CHAR(25) NOT NULL,  
  [additional_columns,]  
  PRIMARY KEY(server_id, source_server_id, source_epoch, count)  
) ENGINE=NDB;
```

In NDB 7.4.1 and later, we can include additional columns for information about the type, cause, and originating transaction ID for a given conflict. We are also not required to supply matching columns for all primary key columns in the original table. In these versions, you can create the exceptions table like this:

```sql
CREATE TABLE test.t2$EX (  
```

3127
NDB Cluster Replication Conflict Resolution

NDB\$server_id INT UNSIGNED,
NDB\$source_server_id INT UNSIGNED,
NDB\$source_epoch BIGINT UNSIGNED,
NDB\$count INT UNSIGNED,
a INT UNSIGNED NOT NULL,
NDB\$OP_TYPE ENUM('WRITE_ROW', 'UPDATE_ROW', 'DELETE_ROW',
  'REFRESH_ROW', 'READ_ROW') NOT NULL,
NDB\$CFT_CAUSE ENUM('ROW_DOES_NOT_EXIST', 'ROW_ALREADY_EXISTS',
  'DATA_IN_CONFLICT', 'TRANS_IN_CONFLICT') NOT NULL,
NDB\$ORIG_TRANSID BIGINT UNSIGNED NOT NULL,
[additional_columns,]
PRIMARY KEY(NDB\$server_id, NDB\$source_server_id, NDB\$source_epoch, NDB\$count)
} ENGINE=NDB;

Note
The NDB\$ prefix is required for the four required columns since we included at least one of the columns NDB\$OP_TYPE, NDB\$CFT_CAUSE, or NDB\$ORIG_TRANSID in the table definition.

3. Create the table test.t2 as shown previously.

These steps must be followed for every table for which you wish to perform conflict resolution using NDB $OLD(). For each such table, there must be a corresponding row in mysql.ndb_replication, and there must be an exceptions table in the same database as the table being replicated.

Read conflict detection and resolution. NDB 7.4.1 and later supports tracking of read operations, which makes it possible in circular replication setups to manage conflicts between reads of a given row in one cluster and updates or deletes of the same row in another. This example uses employee and department tables to model a scenario in which an employee is moved from one department to another on the source cluster (which we refer to hereafter as cluster A) while the replica cluster (hereafter B) updates the employee count of the employee's former department in an interleaved transaction.

The data tables have been created using the following SQL statements:

# Employee table
CREATE TABLE employee (  
id INT PRIMARY KEY,
  name VARCHAR(2000),
  dept INT NOT NULL
) ENGINE=NDB;

# Department table
CREATE TABLE department (  
id INT PRIMARY KEY,
  name VARCHAR(2000),
  members INT
) ENGINE=NDB;

The contents of the two tables include the rows shown in the (partial) output of the following SELECT statements:

mysql> SELECT id, name, dept FROM employee;
+----------+--------+-----+
| id      | name   | dept |
|---------+--------+-----|
| ...     |        +-----+
| 998     | Mike   | 3    |
| 999     | Joe    | 3    |
| 1000    | Mary   | 3    |

3128
We assume that we are already using an exceptions table that includes the four required columns (and these are used for this table’s primary key), the optional columns for operation type and cause, and the original table’s primary key column, created using the SQL statement shown here:

```sql
CREATE TABLE employee$EX
(
  NDB$server_id INT UNSIGNED,
  NDB$source_server_id INT UNSIGNED,
  NDB$source_epoch BIGINT UNSIGNED,
  NDB$count INT UNSIGNED,
  NDB$OP_TYPE ENUM( 'WRITE_ROW','UPDATE_ROW', 'DELETE_ROW', 'REFRESH_ROW','READ_ROW') NOT NULL,
  NDB$CFT_CAUSE ENUM( 'ROW_DOES_NOT_EXIST', 'ROW_ALREADY_EXISTS', 'DATA_IN_CONFLICT', 'TRANS_IN_CONFLICT') NOT NULL,
  id INT NOT NULL,
  PRIMARY KEY(NDB$server_id, NDB$source_server_id, NDB$source_epoch, NDB$count)
)   ENGINE=NDB;
```

Suppose there occur the two simultaneous transactions on the two clusters. On cluster A, we create a new department, then move employee number 999 into that department, using the following SQL statements:

```sql
BEGIN;
  INSERT  INTO department VALUES (4, "New project", 1);
  UPDATE  employee SET dept = 4 WHERE id = 999;
COMMIT;
```

At the same time, on cluster B, another transaction reads from employee, as shown here:

```sql
BEGIN;
  SELECT name FROM employee WHERE id = 999;
  UPDATE department SET members = members - 1 WHERE id = 3;
  commit;
```

The conflicting transactions are not normally detected by the conflict resolution mechanism, since the conflict is between a read (SELECT) and an update operation. Beginning with NDB 7.4.1, you can circumvent this issue by executing `SET ndb_log_exclusive_reads = 1` on the replica cluster. Acquiring exclusive read locks in this way causes any rows read on the source to be flagged as needing conflict resolution on the replica cluster. If we enable exclusive reads in this way prior to the logging of these transactions, the read on cluster B is tracked and sent to cluster A for resolution; the conflict on the employee row is subsequently detected and the transaction on cluster B is aborted.

The conflict is registered in the exceptions table (on cluster A) as a READ_ROW operation (see Conflict Resolution Exceptions Table, for a description of operation types), as shown here:

```sql
mysql> SELECT id, NDB$OP_TYPE, NDB$CFT_CAUSE FROM employee$EX;
+-------+-------------+-------------------+
<table>
<thead>
<tr>
<th>id</th>
<th>NDB$OP_TYPE</th>
<th>NDB$CFT_CAUSE</th>
</tr>
</thead>
<tbody>
<tr>
<td>3129</td>
<td>READ.Row</td>
<td>READ_ROW</td>
</tr>
</tbody>
</table>
```
Any existing rows found in the read operation are flagged. This means that multiple rows resulting from the same conflict may be logged in the exception table, as shown by examining the effects a conflict between an update on cluster A and a read of multiple rows on cluster B from the same table in simultaneous transactions. The transaction executed on cluster A is shown here:

```sql
BEGIN;
  INSERT INTO department VALUES (4, "New project", 0);
  UPDATE employee SET dept = 4 WHERE dept = 3;
  SELECT COUNT(*) INTO @count FROM employee WHERE dept = 4;
  UPDATE department SET members = @count WHERE id = 4;
COMMIT;
```

Concurrently a transaction containing the statements shown here runs on cluster B:

```sql
SET ndb_log_exclusive_reads = 1;  # Must be set if not already enabled
...
BEGIN;
  SELECT COUNT(*) INTO @count FROM employee WHERE dept = 3 FOR UPDATE;
  UPDATE department SET members = @count WHERE id = 3;
COMMIT;
```

In this case, all three rows matching the `WHERE` condition in the second transaction's `SELECT` are read, and are thus flagged in the exceptions table, as shown here:

```sql
mysql> SELECT id, NDB$OP_TYPE, NDB$CFT_CAUSE FROM employee$EX;
```

<table>
<thead>
<tr>
<th>id</th>
<th>NDB$OP_TYPE</th>
<th>NDB$CFT_CAUSE</th>
</tr>
</thead>
<tbody>
<tr>
<td>998</td>
<td>READ_ROW</td>
<td>TRANS_IN_CONFLICT</td>
</tr>
<tr>
<td>999</td>
<td>READ_ROW</td>
<td>TRANS_IN_CONFLICT</td>
</tr>
<tr>
<td>1000</td>
<td>READ_ROW</td>
<td>TRANS_IN_CONFLICT</td>
</tr>
<tr>
<td>...</td>
<td>-------------</td>
<td>-------------------</td>
</tr>
</tbody>
</table>

Read tracking is performed on the basis of existing rows only. A read based on a given condition track conflicts only of any rows that are found and not of any rows that are inserted in an interleaved transaction. This is similar to how exclusive row locking is performed in a single instance of NDB Cluster.

18.8 NDB Cluster Release Notes

Changes in NDB Cluster releases are documented separately from this reference manual; you can find release notes for the changes in each NDB Cluster 7.4 release at NDB Cluster 7.4 Release Notes, and for NDB Cluster 7.3 releases at NDB Cluster 7.3 Release Notes.

You can obtain release notes for older versions of NDB Cluster from NDB Cluster Release Notes.

This chapter discusses MySQL's implementation of user-defined partitioning. You can determine whether your MySQL Server supports partitioning by checking the output of the SHOW PLUGINS statement, like this:

```
mysql> SHOW PLUGINS;
+-----------+----------+----------------+---------+---------+
| Name      | Status   | Type           | Library | License |
|-----------+----------+----------------+---------+---------+
| binlog    | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| partition | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| ARCHIVE   | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| BLACKHOLE | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| CSV       | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| FEDERATED | DISABLED | STORAGE ENGINE | NULL    | GPL     |
| MEMORY    | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| InnoDB    | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| MRG_MYISAM| ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| MyISAM    | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| ndbcluster| DISABLED | STORAGE ENGINE | NULL    | GPL     |
+-----------+----------+----------------+---------+---------+
11 rows in set (0.00 sec)
```

You can also check the INFORMATION_SCHEMA.PLUGINS table with a query similar to this one:

```
INFORMATION_SCHEMA.PLUGINS
```

Note

Previous versions of MySQL had the have_partitioning variable, which was deprecated and removed in MySQL 5.6.1.
In either case, if you do not see the partition plugin listed with the value ACTIVE for the Status column in the output (shown in bold text in each of the examples just given), then your version of MySQL was not built with partitioning support.

MySQL 5.6 Community binaries provided by Oracle include partitioning support. For information about partitioning support offered in MySQL Enterprise Edition binaries, see Chapter 24, MySQL Enterprise Edition.

To enable partitioning if you are compiling MySQL 5.6 from source, the build must be configured with the -DWITH_PARTITION_STORAGE_ENGINE option. For more information, see Section 2.9, “Installing MySQL from Source”.

If your MySQL binary is built with partitioning support, nothing further needs to be done to enable it (for example, no special entries are required in your my.cnf file).

If you want to disable partitioning support, you can start the MySQL Server with the --skip-partition option. When partitioning support is disabled, you can see any existing partitioned tables and drop them (although doing this is not advised), but you cannot otherwise manipulate them or access their data.

MySQL supports several types of partitioning as well as subpartitioning; see Section 19.2, “Partitioning Types”, and Section 19.2.6, “Subpartitioning”.

Section 19.3.4, “Maintenance of Partitions”, discusses table maintenance commands for use with partitioned tables.

The PARTITIONS table in the INFORMATION_SCHEMA database provides information about partitions and partitioned tables. See Section 21.3.14, “The INFORMATION_SCHEMA PARTITIONS Table”, for more information; for some examples of queries against this table, see Section 19.2.7, “How MySQL Partitioning Handles NULL”.

For known issues with partitioning in MySQL 5.6, see Section 19.6, “Restrictions and Limitations on Partitioning”. 
Overview of Partitioning in MySQL

You may also find the following resources to be useful when working with partitioned tables.

**Additional Resources.** Other sources of information about user-defined partitioning in MySQL include the following:

- **MySQL Partitioning Forum**
  
  This is the official discussion forum for those interested in or experimenting with MySQL Partitioning technology. It features announcements and updates from MySQL developers and others. It is monitored by members of the Partitioning Development and Documentation Teams.

- **Mikael Ronström’s Blog**
  
  MySQL Partitioning Architect and Lead Developer Mikael Ronström frequently posts articles here concerning his work with MySQL Partitioning and NDB Cluster.

- **PlanetMySQL**
  
  A MySQL news site featuring MySQL-related blogs, which should be of interest to anyone using my MySQL. We encourage you to check here for links to blogs kept by those working with MySQL Partitioning, or to have your own blog added to those covered.

MySQL 5.6 binaries are available from [https://dev.mysql.com/downloads/mysql/5.6.html](https://dev.mysql.com/downloads/mysql/5.6.html). However, for the latest partitioning bugfixes and feature additions, you can obtain the source from our GitHub repository. To enable partitioning, the build must be configured with the `-DWITH_PARTITION_STORAGE_ENGINE` option. For more information about building MySQL, see Section 2.9, “Installing MySQL from Source”. If you have problems compiling a partitioning-enabled MySQL 5.6 build, check the MySQL Partitioning Forum and ask for assistance there if you do not find a solution to your problem already posted.

### 19.1 Overview of Partitioning in MySQL

This section provides a conceptual overview of partitioning in MySQL 5.6.

For information on partitioning restrictions and feature limitations, see Section 19.6, “Restrictions and Limitations on Partitioning”.

The SQL standard does not provide much in the way of guidance regarding the physical aspects of data storage. The SQL language itself is intended to work independently of any data structures or media underlying the schemas, tables, rows, or columns with which it works. Nonetheless, most advanced database management systems have evolved some means of determining the physical location to be used for storing specific pieces of data in terms of the file system, hardware or even both. In MySQL, the InnoDB storage engine has long supported the notion of a tablespace, and the MySQL Server, even prior to the introduction of partitioning, could be configured to employ different physical directories for storing different databases (see Section 8.12.3, “Using Symbolic Links”, for an explanation of how this is done).

**Partitioning** takes this notion a step further, by enabling you to distribute portions of individual tables across a file system according to rules which you can set largely as needed. In effect, different portions of a table are stored as separate tables in different locations. The user-selected rule by which the division of data is accomplished is known as a **partitioning function**, which in MySQL can be the modulus, simple matching against a set of ranges or value lists, an internal hashing function, or a linear hashing function. The function is selected according to the partitioning type specified by the user, and takes as its parameter the value of a user-supplied expression. This expression can be a column value, a function acting on one or more column values, or a set of one or more column values, depending on the type of partitioning that is used.

In the case of **RANGE, LIST**, and **LINEAR HASH** partitioning, the value of the partitioning column is passed to the partitioning function, which returns an integer value representing the number of the partition in which
that particular record should be stored. This function must be nonconstant and nonrandom. It may not contain any queries, but may use an SQL expression that is valid in MySQL, as long as that expression returns either \texttt{NULL} or an integer \texttt{intval} such that
\[ -\text{MAXVALUE} \leq intval \leq \text{MAXVALUE} \]

(\texttt{MAXVALUE} is used to represent the least upper bound for the type of integer in question. \texttt{-MAXVALUE} represents the greatest lower bound.)

For \texttt{[LINEAR] KEY}, \texttt{RANGE COLUMNS}, and \texttt{LIST COLUMNS} partitioning, the partitioning expression consists of a list of one or more columns.

For \texttt{[LINEAR] KEY} partitioning, the partitioning function is supplied by MySQL.

For more information about permitted partitioning column types and partitioning functions, see Section 19.2, “Partitioning Types”, as well as Section 13.1.17, “CREATE TABLE Statement”, which provides partitioning syntax descriptions and additional examples. For information about restrictions on partitioning functions, see Section 19.6.3, “Partitioning Limitations Relating to Functions”.

This is known as \textit{horizontal partitioning}—that is, different rows of a table may be assigned to different physical partitions. MySQL 5.6 does not support \textit{vertical partitioning}, in which different columns of a table are assigned to different physical partitions. There are no plans at this time to introduce vertical partitioning into MySQL.

For information about determining whether your MySQL Server binary supports user-defined partitioning, see Chapter 19, Partitioning.

For creating partitioned tables, you can use most storage engines that are supported by your MySQL server; the MySQL partitioning engine runs in a separate layer and can interact with any of these. In MySQL 5.6, all partitions of the same partitioned table must use the same storage engine; for example, you cannot use \texttt{MyISAM} for one partition and \texttt{InnoDB} for another. However, there is nothing preventing you from using different storage engines for different partitioned tables on the same MySQL server or even in the same database.

MySQL partitioning cannot be used with the \texttt{MERGE}, \texttt{CSV}, or \texttt{FEDERATED} storage engines.

Partitioning by \texttt{KEY} or \texttt{LINEAR KEY} is possible with \texttt{NDB}, but other types of user-defined partitioning are not supported for tables using this storage engine. In addition, an \texttt{NDB} table that employs user-defined partitioning must have an explicit primary key, and any columns referenced in the table’s partitioning expression must be part of the primary key. However, if no columns are listed in the \texttt{PARTITION BY KEY} or \texttt{PARTITION BY LINEAR KEY} clause of the \texttt{CREATE TABLE} or \texttt{ALTER TABLE} statement used to create or modify a user-partitioned \texttt{NDB} table, then the table is not required to have an explicit primary key. For more information, see Section 18.2.7.1, “Noncompliance with SQL Syntax in NDB Cluster”.

To employ a particular storage engine for a partitioned table, it is necessary only to use the \texttt{[STORAGE] ENGINE} option just as you would for a nonpartitioned table. However, you should keep in mind that \texttt{[STORAGE] ENGINE} (and other table options) need to be listed \textit{before} any partitioning options are used in an \texttt{CREATE TABLE} statement. This example shows how to create a table that is partitioned by hash into 6 partitions and which uses the \texttt{InnoDB} storage engine:

\begin{verbatim}
CREATE TABLE ti (id INT, amount DECIMAL(7,2), tr_date DATE) ENGINE=INNODB
PARTITION BY HASH( MONTH(tr_date) ) PARTITIONS 6;
\end{verbatim}

Each \texttt{PARTITION} clause can include a \texttt{[STORAGE] ENGINE} option, but in MySQL 5.6 this has no effect.
Partitioning applies to all data and indexes of a table; you cannot partition only the data and not the indexes, or vice versa, nor can you partition only a portion of the table.

Data and indexes for each partition can be assigned to a specific directory using the `DATA DIRECTORY` and `INDEX DIRECTORY` options for the `PARTITION` clause of the `CREATE TABLE` statement used to create the partitioned table.

`DATA DIRECTORY` and `INDEX DIRECTORY` are not supported for individual partitions or subpartitions of `MyISAM` tables on Windows.

Only the `DATA DIRECTORY` option is supported for individual partitions and subpartitions of `InnoDB` tables.

All columns used in the table's partitioning expression must be part of every unique key that the table may have, including any primary key. This means that a table such as this one, created by the following SQL statement, cannot be partitioned:

```sql
CREATE TABLE tnp (
    id INT NOT NULL AUTO_INCREMENT,
    ref BIGINT NOT NULL,
    name VARCHAR(255),
    PRIMARY KEY pk (id),
    UNIQUE KEY uk (name)
);
```

Because the keys `pk` and `uk` have no columns in common, there are no columns available for use in a partitioning expression. Possible workarounds in this situation include adding the `name` column to the table's primary key, adding the `id` column to `uk`, or simply removing the unique key altogether. See Section 19.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”, for more information.

In addition, `MAX_ROWS` and `MIN_ROWS` can be used to determine the maximum and minimum numbers of rows, respectively, that can be stored in each partition. The `MAX_ROWS` option can be useful for causing NDB Cluster tables to be created with extra partitions, thus allowing for greater storage of hash indexes. See the documentation for the `DataMemory` data node configuration parameter, as well as Section 18.2.2, “NDB Cluster Nodes, Node Groups, Fragment Replicas, and Partitions”, for more information.

Some advantages of partitioning are listed here:

- Partitioning makes it possible to store more data in one table than can be held on a single disk or file system partition.
- Data that loses its usefulness can often be easily removed from a partitioned table by dropping the partition (or partitions) containing only that data. Conversely, the process of adding new data can in some cases be greatly facilitated by adding one or more new partitions for storing specifically that data.
- Some queries can be greatly optimized in virtue of the fact that data satisfying a given `WHERE` clause can be stored only on one or more partitions, which automatically excludes any remaining partitions from the search. Because partitions can be altered after a partitioned table has been created, you can reorganize your data to enhance frequent queries that may not have been often used when the partitioning scheme was first set up. This ability to exclude non-matching partitions (and thus any rows they contain) is often referred to as **partition pruning**. For more information, see Section 19.4, “Partition Pruning”.

In addition, MySQL 5.6 supports explicit partition selection for queries. For example, `SELECT * FROM t PARTITION (p0,p1) WHERE c < 5` selects only those rows in partitions `p0` and `p1` that match the `WHERE` condition. In this case, MySQL does not check any other partitions of table `t`; this can greatly speed up queries when you already know which partition or partitions you wish to examine.
Partition selection is also supported for the data modification statements `DELETE`, `INSERT`, `REPLACE`, `UPDATE`, and `LOAD DATA`, `LOAD XML`. See the descriptions of these statements for more information and examples.

### 19.2 Partitioning Types

This section discusses the types of partitioning which are available in MySQL 5.6. These include the types listed here:

- **RANGE partitioning.** This type of partitioning assigns rows to partitions based on column values falling within a given range. See Section 19.2.1, "RANGE Partitioning". For information about an extension to this type, `RANGE COLUMNS`, see Section 19.2.3.1, "RANGE COLUMNS partitioning".

- **LIST partitioning.** Similar to partitioning by `RANGE`, except that the partition is selected based on columns matching one of a set of discrete values. See Section 19.2.2, "LIST Partitioning". For information about an extension to this type, `LIST COLUMNS`, see Section 19.2.3.2, "LIST COLUMNS partitioning".

- **HASH partitioning.** With this type of partitioning, a partition is selected based on the value returned by a user-defined expression that operates on column values in rows to be inserted into the table. The function may consist of any expression valid in MySQL that yields a nonnegative integer value. An extension to this type, `LINEAR HASH`, is also available. See Section 19.2.4, "HASH Partitioning".

- **KEY partitioning.** This type of partitioning is similar to partitioning by `HASH`, except that only one or more columns to be evaluated are supplied, and the MySQL server provides its own hashing function. These columns can contain other than integer values, since the hashing function supplied by MySQL guarantees an integer result regardless of the column data type. An extension to this type, `LINEAR KEY`, is also available. See Section 19.2.5, "KEY Partitioning".

A very common use of database partitioning is to segregate data by date. Some database systems support explicit date partitioning, which MySQL does not implement in 5.6. However, it is not difficult in MySQL to create partitioning schemes based on `DATE`, `TIME`, or `DATETIME` columns, or based on expressions making use of such columns.

When partitioning by `KEY` or `LINEAR KEY`, you can use a `DATE`, `TIME`, or `DATETIME` column as the partitioning column without performing any modification of the column value. For example, this table creation statement is perfectly valid in MySQL:

```sql
CREATE TABLE members (  
    firstname VARCHAR(25) NOT NULL,  
    lastname VARCHAR(25) NOT NULL,  
    username VARCHAR(16) NOT NULL,  
    email VARCHAR(35),  
    joined DATE NOT NULL  
)  
PARTITION BY KEY(joined)  
PARTITIONS 6;
```

In MySQL 5.6, it is also possible to use a `DATE` or `DATETIME` column as the partitioning column using `RANGE COLUMNS` and `LIST COLUMNS` partitioning.

MySQL's other partitioning types, however, require a partitioning expression that yields an integer value or `NULL`. If you wish to use date-based partitioning by `RANGE`, `LIST`, `HASH`, or `LINEAR HASH`, you can simply employ a function that operates on a `DATE`, `TIME`, or `DATETIME` column and returns such a value, as shown here:

```sql
CREATE TABLE members (  
    firstname VARCHAR(25) NOT NULL,  
    joined DATE NOT NULL
)  
PARTITION BY RANGE(joined)
```
Partitioning Types

```sql
lastname VARCHAR(25) NOT NULL,
username VARCHAR(16) NOT NULL,
email VARCHAR(35),
joined DATE NOT NULL
)
PARTITION BY RANGE( YEAR(joined) ) (  
    PARTITION p0 VALUES LESS THAN (1960),
    PARTITION p1 VALUES LESS THAN (1970),
    PARTITION p2 VALUES LESS THAN (1980),
    PARTITION p3 VALUES LESS THAN (1990),
    PARTITION p4 VALUES LESS THAN MAXVALUE
);
```

Additional examples of partitioning using dates may be found in the following sections of this chapter:

- Section 19.2.1, “RANGE Partitioning”
- Section 19.2.4, “HASH Partitioning”
- Section 19.2.4.1, “LINEAR HASH Partitioning”

For more complex examples of date-based partitioning, see the following sections:

- Section 19.4, “Partition Pruning”
- Section 19.2.6, “Subpartitioning”

MySQL partitioning is optimized for use with the `TO_DAYS()`, `YEAR()`, and `TO_SECONDS()` functions. However, you can use other date and time functions that return an integer or `NULL`, such as `WEEKDAY()`, `DAYOFYEAR()`, or `MONTH()`. See Section 12.7, “Date and Time Functions”, for more information about such functions.

It is important to remember—regardless of the type of partitioning that you use—that partitions are always numbered automatically and in sequence when created, starting with 0. When a new row is inserted into a partitioned table, it is these partition numbers that are used in identifying the correct partition. For example, if your table uses 4 partitions, these partitions are numbered 0, 1, 2, and 3. For the `RANGE` and `LIST` partitioning types, it is necessary to ensure that there is a partition defined for each partition number. For `HASH` partitioning, the user-supplied expression must evaluate to an integer value greater than 0. For `KEY` partitioning, this issue is taken care of automatically by the hashing function which the MySQL server employs internally.

Names of partitions generally follow the rules governing other MySQL identifiers, such as those for tables and databases. However, partition names are not case-sensitive. For example, the following `CREATE TABLE` statement fails as shown:

```sql
mysql> CREATE TABLE t2 (val INT)
    -> PARTITION BY LIST(val)(
    ->  PARTITION mypart VALUES IN (1,3,5),
    ->  PARTITION MyPart VALUES IN (2,4,6)
    -> );
ERROR 1488 (HY000): Duplicate partition name mypart
```

Failure occurs because MySQL sees no difference between the partition names `mypart` and `MyPart`.

When you specify the number of partitions for the table, this must be expressed as a positive, nonzero integer literal with no leading zeros, and may not be an expression such as `0.8E+01` or `6-2`, even if it evaluates to an integer value. Decimal fractions are not permitted.

In the sections that follow, we do not necessarily provide all possible forms for the syntax that can be used for creating each partition type; this information may be found in Section 13.1.17, “CREATE TABLE Statement”.
19.2.1 RANGE Partitioning

A table that is partitioned by range is partitioned in such a way that each partition contains rows for which the partitioning expression value lies within a given range. Ranges should be contiguous but not overlapping, and are defined using the VALUES LESS THAN operator. For the next few examples, suppose that you are creating a table such as the following to hold personnel records for a chain of 20 video stores, numbered 1 through 20:

```sql
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT NOT NULL,
  store_id INT NOT NULL
);
```

**Note**

The `employees` table used here has no primary or unique keys. While the examples work as shown for purposes of the present discussion, you should keep in mind that tables are extremely likely in practice to have primary keys, unique keys, or both, and that allowable choices for partitioning columns depend on the columns used for these keys, if any are present. For a discussion of these issues, see Section 19.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”.

This table can be partitioned by range in a number of ways, depending on your needs. One way would be to use the `store_id` column. For instance, you might decide to partition the table 4 ways by adding a PARTITION BY RANGE clause as shown here:

```sql
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT NOT NULL,
  store_id INT NOT NULL
)
PARTITION BY RANGE (store_id) (
  PARTITION p0 VALUES LESS THAN (6),
  PARTITION p1 VALUES LESS THAN (11),
  PARTITION p2 VALUES LESS THAN (16),
  PARTITION p3 VALUES LESS THAN (21)
);
```

In this partitioning scheme, all rows corresponding to employees working at stores 1 through 5 are stored in partition `p0`, to those employed at stores 6 through 10 are stored in partition `p1`, and so on. Each partition is defined in order, from lowest to highest. This is a requirement of the PARTITION BY RANGE syntax; you can think of it as being analogous to a series of if ... elseif ... statements in C or Java in this regard.

It is easy to determine that a new row containing the data (72, 'Mitchell', 'Wilson', '1998-06-25', NULL, 13) is inserted into partition `p2`, but what happens when your chain adds a 21\textsuperscript{st} store? Under this scheme, there is no rule that covers a row whose `store_id` is greater than 20, so an error results because the server does not know where to place it. You can keep this from occurring by using a "catchall" VALUES LESS THAN clause in the CREATE TABLE statement that provides for all values greater than the highest value explicitly named:

```sql
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT NOT NULL,
  store_id INT NOT NULL
)
PARTITION BY RANGE (store_id) (
  PARTITION p0 VALUES LESS THAN (6),
  PARTITION p1 VALUES LESS THAN (11),
  PARTITION p2 VALUES LESS THAN (16),
  PARTITION p3 VALUES LESS THAN (21),
  PARTITION default VALUES LESS THAN (21) DEFAULT TableRow
);
```
RANGE Partitioning

```sql
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT NOT NULL,
    store_id INT NOT NULL
)
PARTITION BY RANGE (store_id) (
    PARTITION p0 VALUES LESS THAN (6),
    PARTITION p1 VALUES LESS THAN (11),
    PARTITION p2 VALUES LESS THAN (16),
    PARTITION p3 VALUES LESS THAN MAXVALUE
);
```

**Note**

Another way to avoid an error when no matching value is found is to use the `IGNORE` keyword as part of the `INSERT` statement. For an example, see Section 19.2.2, "LIST Partitioning". Also see Section 13.2.5, "INSERT Statement", for general information about `IGNORE`.

`MAXVALUE` represents an integer value that is always greater than the largest possible integer value (in mathematical language, it serves as a least upper bound). Now, any rows whose `store_id` column value is greater than or equal to 16 (the highest value defined) are stored in partition `p3`. At some point in the future—when the number of stores has increased to 25, 30, or more—you can use an `ALTER TABLE` statement to add new partitions for stores 21-25, 26-30, and so on (see Section 19.3, "Partition Management", for details of how to do this).

In much the same fashion, you could partition the table based on employee job codes—that is, based on ranges of `job_code` column values. For example—assuming that two-digit job codes are used for regular (in-store) workers, three-digit codes are used for office and support personnel, and four-digit codes are used for management positions—you could create the partitioned table using the following statement:

```sql
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT NOT NULL,
    store_id INT NOT NULL
)
PARTITION BY RANGE (job_code) (
    PARTITION p0 VALUES LESS THAN (100),
    PARTITION p1 VALUES LESS THAN (1000),
    PARTITION p2 VALUES LESS THAN (10000)
);
```

In this instance, all rows relating to in-store workers would be stored in partition `p0`, those relating to office and support staff in `p1`, and those relating to managers in partition `p2`.

It is also possible to use an expression in `VALUES LESS THAN` clauses. However, MySQL must be able to evaluate the expression's return value as part of a `LESS THAN (<)` comparison.

Rather than splitting up the table data according to store number, you can use an expression based on one of the two `DATE` columns instead. For example, let us suppose that you wish to partition based on the year that each employee left the company; that is, the value of `YEAR(separated)`. An example of a `CREATE TABLE` statement that implements such a partitioning scheme is shown here:

```sql
CREATE TABLE employees {
    id INT NOT NULL,
    ...;
```
RANGE Partitioning

```sql
CREATE TABLE employees (
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT,
    store_id INT
) PARTITION BY RANGE ( YEAR(separated) ) {
    PARTITION p0 VALUES LESS THAN (1991),
    PARTITION p1 VALUES LESS THAN (1996),
    PARTITION p2 VALUES LESS THAN (2001),
    PARTITION p3 VALUES LESS THAN MAXVALUE
};
```

In this scheme, for all employees who left before 1991, the rows are stored in partition `p0`; for those who left in the years 1991 through 1995, in `p1`; for those who left in the years 1996 through 2000, in `p2`; and for any workers who left after the year 2000, in `p3`.

It is also possible to partition a table by `RANGE`, based on the value of a `TIMESTAMP` column, using the `UNIX_TIMESTAMP()` function, as shown in this example:

```sql
CREATE TABLE quarterly_report_status (
    report_id INT NOT NULL,
    report_status VARCHAR(20) NOT NULL,
    report_updated TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP
) PARTITION BY RANGE ( UNIX_TIMESTAMP(report_updated) ) {
    PARTITION p0 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-01-01 00:00:00') ),
    PARTITION p1 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-04-01 00:00:00') ),
    PARTITION p2 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-07-01 00:00:00') ),
    PARTITION p3 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-10-01 00:00:00') ),
    PARTITION p4 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-01-01 00:00:00') ),
    PARTITION p5 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-04-01 00:00:00') ),
    PARTITION p6 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-07-01 00:00:00') ),
    PARTITION p7 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-10-01 00:00:00') ),
    PARTITION p8 VALUES LESS THAN ( UNIX_TIMESTAMP('2010-01-01 00:00:00') ),
    PARTITION p9 VALUES LESS THAN (MAXVALUE)
};
```

Any other expressions involving `TIMESTAMP` values are not permitted. (See Bug #42849.)

Range partitioning is particularly useful when one or more of the following conditions is true:

- You want or need to delete “old” data. If you are using the partitioning scheme shown previously for the `employees` table, you can simply use `ALTER TABLE employees DROP PARTITION p0;` to delete all rows relating to employees who stopped working for the firm prior to 1991. (See Section 13.1.7, “ALTER TABLE Statement”, and Section 19.3, “Partition Management”, for more information.) For a table with a great many rows, this can be much more efficient than running a `DELETE` query such as `DELETE FROM employees WHERE YEAR(separated) <= 1990;`.

- You want to use a column containing date or time values, or containing values arising from some other series.

- You frequently run queries that depend directly on the column used for partitioning the table. For example, when executing a query such as `EXPLAIN PARTITIONS SELECT COUNT(*) FROM employees WHERE separated BETWEEN '2000-01-01' AND '2000-12-31' GROUP BY store_id;`, MySQL can quickly determine that only partition `p2` needs to be scanned because the remaining partitions cannot contain any records satisfying the `WHERE` clause. See Section 19.4, “Partition Pruning”, for more information about how this is accomplished.

A variant on this type of partitioning is `RANGE COLUMNS` partitioning. Partitioning by `RANGE COLUMNS` makes it possible to employ multiple columns for defining partitioning ranges that apply both to placement
RANGE Partitioning

of rows in partitions and for determining the inclusion or exclusion of specific partitions when performing
partition pruning. See Section 19.2.3.1, “RANGE COLUMNS partitioning”, for more information.

Partitioning schemes based on time intervals. If you wish to implement a partitioning scheme based
on ranges or intervals of time in MySQL 5.6, you have two options:

1. Partition the table by RANGE, and for the partitioning expression, employ a function operating on a
DATE, TIME, or DATETIME column and returning an integer value, as shown here:

```sql
CREATE TABLE members (  firstname VARCHAR(25) NOT NULL,  lastname VARCHAR(25) NOT NULL,  username VARCHAR(16) NOT NULL,  email VARCHAR(35),  joined DATE NOT NULL ) PARTITION BY RANGE( YEAR(joined) ) (  PARTITION p0 VALUES LESS THAN (1960),  PARTITION p1 VALUES LESS THAN (1970),  PARTITION p2 VALUES LESS THAN (1980),  PARTITION p3 VALUES LESS THAN (1990),  PARTITION p4 VALUES LESS THAN MAXVALUE );
```

In MySQL 5.6, it is also possible to partition a table by RANGE based on the value of a TIMESTAMP
column, using the UNIX_TIMESTAMP() function, as shown in this example:

```sql
CREATE TABLE quarterly_report_status (  report_id INT NOT NULL,  report_status VARCHAR(20) NOT NULL,  report_updated TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP ) PARTITION BY RANGE ( UNIX_TIMESTAMP(report_updated) ) (  PARTITION p0 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-01-01 00:00:00') ),  PARTITION p1 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-04-01 00:00:00') ),  PARTITION p2 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-07-01 00:00:00') ),  PARTITION p3 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-10-01 00:00:00') ),  PARTITION p4 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-01-01 00:00:00') ),  PARTITION p5 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-04-01 00:00:00') ),  PARTITION p6 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-07-01 00:00:00') ),  PARTITION p7 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-10-01 00:00:00') ),  PARTITION p8 VALUES LESS THAN ( UNIX_TIMESTAMP('2010-01-01 00:00:00') ),  PARTITION p9 VALUES LESS THAN (MAXVALUE) );
```

In MySQL 5.6, any other expressions involving TIMESTAMP values are not permitted. (See Bug
#42849.)

---

Note

It is also possible in MySQL 5.6 to use

`UNIX_TIMESTAMP(timestamp_column)`

as a partitioning expression for
tables that are partitioned by LIST. However, it is usually not practical to do so.

2. Partition the table by RANGE COLUMNS, using a DATE or DATETIME column as the partitioning column.
For example, the `members` table could be defined using the `joined` column directly, as shown here:

```sql
CREATE TABLE members (  firstname VARCHAR(25) NOT NULL,  lastname VARCHAR(25) NOT NULL,  username VARCHAR(16) NOT NULL,  email VARCHAR(35),  joined DATE NOT NULL
```
PARTITION BY RANGE COLUMNS(joined) {
  PARTITION p0 VALUES LESS THAN ('1960-01-01'),
  PARTITION p1 VALUES LESS THAN ('1970-01-01'),
  PARTITION p2 VALUES LESS THAN ('1980-01-01'),
  PARTITION p3 VALUES LESS THAN ('1990-01-01'),
  PARTITION p4 VALUES LESS THAN MAXVALUE
};

Note
The use of partitioning columns employing date or time types other than DATE or DATETIME is not supported with RANGE COLUMNS.

19.2.2 LIST Partitioning

List partitioning in MySQL is similar to range partitioning in many ways. As in partitioning by RANGE, each partition must be explicitly defined. The chief difference between the two types of partitioning is that, in list partitioning, each partition is defined and selected based on the membership of a column value in one of a set of value lists, rather than in one of a set of contiguous ranges of values. This is done by using PARTITION BY LIST(expr) where expr is a column value or an expression based on a column value and returning an integer value, and then defining each partition by means of a VALUES IN (value_list), where value_list is a comma-separated list of integers.

Note
In MySQL 5.6, it is possible to match against only a list of integers (and possibly NULL—see Section 19.2.7, “How MySQL Partitioning Handles NULL”) when partitioning by LIST.

However, other column types may be used in value lists when employing LIST COLUMN partitioning, which is described later in this section.

Unlike the case with partitions defined by range, list partitions do not need to be declared in any particular order. For more detailed syntactical information, see Section 13.1.17, “CREATE TABLE Statement”.

For the examples that follow, we assume that the basic definition of the table to be partitioned is provided by the CREATE TABLE statement shown here:

```
CREATE TABLE employees {
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT,
  store_id INT
};
```

(This is the same table used as a basis for the examples in Section 19.2.1, “RANGE Partitioning”.)

Suppose that there are 20 video stores distributed among 4 franchises as shown in the following table.

<table>
<thead>
<tr>
<th>Region</th>
<th>Store ID Numbers</th>
</tr>
</thead>
<tbody>
<tr>
<td>North</td>
<td>3, 5, 6, 9, 17</td>
</tr>
<tr>
<td>East</td>
<td>1, 2, 10, 11, 19, 20</td>
</tr>
<tr>
<td>West</td>
<td>4, 12, 13, 14, 18</td>
</tr>
<tr>
<td>Central</td>
<td>7, 8, 15, 16</td>
</tr>
</tbody>
</table>
LIST Partitioning

To partition this table in such a way that rows for stores belonging to the same region are stored in the same partition, you could use the `CREATE TABLE` statement shown here:

```sql
CREATE TABLE employees (  id INT NOT NULL,  fname VARCHAR(30),  lname VARCHAR(30),  hired DATE NOT NULL DEFAULT '1970-01-01',  separated DATE NOT NULL DEFAULT '9999-12-31',  job_code INT,  store_id INT )  PARTITION BY LIST(store_id) (    PARTITION pNorth VALUES IN (3,5,6,9,17),    PARTITION pEast VALUES IN (1,2,10,11,19,20),    PARTITION pWest VALUES IN (4,12,13,14,18),    PARTITION pCentral VALUES IN (7,8,15,16) );
```

This makes it easy to add or drop employee records relating to specific regions to or from the table. For instance, suppose that all stores in the West region are sold to another company. In MySQL 5.6, all rows relating to employees working at stores in that region can be deleted with the query `ALTER TABLE employees TRUNCATE PARTITION pWest`, which can be executed much more efficiently than the equivalent `DELETE` statement `DELETE FROM employees WHERE store_id IN (4,12,13,14,18);`. (Using `ALTER TABLE employees DROP PARTITION pWest` would also delete all of these rows, but would also remove the partition `pWest` from the definition of the table; you would need to use an `ALTER TABLE ... ADD PARTITION` statement to restore the table's original partitioning scheme.)

As with `RANGE` partitioning, it is possible to combine `LIST` partitioning with partitioning by hash or key to produce a composite partitioning (subpartitioning). See Section 19.2.6, "Subpartitioning".

Unlike the case with `RANGE` partitioning, there is no "catch-all" such as `MAXVALUE`; all expected values for the partitioning expression should be covered in `PARTITION ... VALUES IN (...)` clauses. An `INSERT` statement containing an unmatched partitioning column value fails with an error, as shown in this example:

```sql
mysql> CREATE TABLE h2 (  -> c1 INT,  -> c2 INT  -> )  -> PARTITION BY LIST(c1) (  -> PARTITION p0 VALUES IN (1, 4, 7),  -> PARTITION p1 VALUES IN (2, 5, 8)  -> );
Query OK, 0 rows affected (0.11 sec)

mysql> INSERT INTO h2 VALUES (3, 5);
ERROR 1525 (HY000): Table has no partition for value 3
```

When inserting multiple rows using a single `INSERT` statement the behavior depends on whether the table uses a transactional storage engine. For an InnoDB table, the statement is considered a single transaction, so the presence of any unmatched values causes the statement to fail completely, and no rows are inserted. For a table using a nontransactional storage engine such as MyISAM, any rows coming before the row containing the unmatched value are inserted, but any coming after it are not.

You can cause this type of error to be ignored by using the `IGNORE` keyword. If you do so, rows containing unmatched partitioning column values are not inserted, but any rows with matching values are inserted, and no errors are reported:

```sql
mysql> TRUNCATE h2;
Query OK, 1 row affected (0.00 sec)
```
MySQL 5.6 provides support for `LIST COLUMNS` partitioning. This is a variant of `LIST` partitioning that enables you to use columns of types other than integer types for partitioning columns, as well as to use multiple columns as partitioning keys. For more information, see Section 19.2.3.2, “LIST COLUMNS partitioning”.

### 19.2.3 COLUMNS Partitioning

The next two sections discuss `COLUMNS partitioning`, which are variants on `RANGE` and `LIST` partitioning. `COLUMNS` partitioning enables the use of multiple columns in partitioning keys. All of these columns are taken into account both for the purpose of placing rows in partitions and for the determination of which partitions are to be checked for matching rows in partition pruning.

In addition, both `RANGE COLUMNS` partitioning and `LIST COLUMNS` partitioning support the use of non-integer columns for defining value ranges or list members. The permitted data types are shown in the following list:

- All integer types: `TINYINT`, `SMALLINT`, `MEDIUMINT`, `INT` (`INTEGER`), and `BIGINT`. (This is the same as with partitioning by `RANGE` and `LIST`.)
  - Other numeric data types (such as `DECIMAL` or `FLOAT`) are not supported as partitioning columns.
- `DATE` and `DATETIME`.
  - Columns using other data types relating to dates or times are not supported as partitioning columns.
- The following string types: `CHAR`, `VARCHAR`, `BINARY`, and `VARBINARY`.
  - `TEXT` and `BLOB` columns are not supported as partitioning columns.

The discussions of `RANGE COLUMNS` and `LIST COLUMNS` partitioning in the next two sections assume that you are already familiar with partitioning based on ranges and lists as supported in MySQL 5.1 and later; for more information about these, see Section 19.2.1, “RANGE Partitioning”, and Section 19.2.2, “LIST Partitioning”, respectively.

### 19.2.3.1 RANGE COLUMNS partitioning

Range columns partitioning is similar to range partitioning, but enables you to define partitions using ranges based on multiple column values. In addition, you can define the ranges using columns of types other than integer types.

`RANGE COLUMNS` partitioning differs significantly from `RANGE` partitioning in the following ways:

- `RANGE COLUMNS` does not accept expressions, only names of columns.
**COLUMNS Partitioning**

- **RANGE COLUMNS** accepts a list of one or more columns.

  **RANGE COLUMNS** partitions are based on comparisons between *tuples* (lists of column values) rather than comparisons between scalar values. Placement of rows in **RANGE COLUMNS** partitions is also based on comparisons between tuples; this is discussed further later in this section.

- **RANGE COLUMNS** partitioning columns are not restricted to integer columns; string, **DATE** and **DATETIME** columns can also be used as partitioning columns. (See Section 19.2.3, “COLUMNS Partitioning”, for details.)

The basic syntax for creating a table partitioned by **RANGE COLUMNS** is shown here:

```sql
CREATE TABLE table_name
PARTITION BY RANGE COLUMNS(column_list) (  
    PARTITION partition_name VALUES LESS THAN (value_list)[,  
    PARTITION partition_name VALUES LESS THAN (value_list)][,  
    ...]
)

column_list:
    column_name[, column_name][, ...]

value_list:
    value[, value][, ...]
```

**Note**

Not all **CREATE TABLE** options that can be used when creating partitioned tables are shown here. For complete information, see Section 13.1.17, “**CREATE TABLE** Statement”.

In the syntax just shown, **column_list** is a list of one or more columns (sometimes called a *partitioning column list*), and **value_list** is a list of values (that is, it is a *partition definition value list*). A **value_list** must be supplied for each partition definition, and each **value_list** must have the same number of values as the **column_list** has columns. Generally speaking, if you use \( N \) columns in the **COLUMNS** clause, then each **VALUES LESS THAN** clause must also be supplied with a list of \( N \) values.

The elements in the partitioning column list and in the value list defining each partition must occur in the same order. In addition, each element in the value list must be of the same data type as the corresponding element in the column list. However, the order of the column names in the partitioning column list and the value lists does not have to be the same as the order of the table column definitions in the main part of the **CREATE TABLE** statement. As with table partitioned by **RANGE**, you can use **MAXVALUE** to represent a value such that any legal value inserted into a given column is always less than this value. Here is an example of a **CREATE TABLE** statement that helps to illustrate all of these points:

```sql
mysql> CREATE TABLE rcx (  
    -> a INT,  
    -> b INT,  
    -> c CHAR(3),  
    -> d INT  
    -> )  
    -> PARTITION BY RANGE COLUMNS(a,d,c) (  
    -> PARTITION p0 VALUES LESS THAN (5,10,'ggg'),  
    -> PARTITION p1 VALUES LESS THAN (10,20,'mmm'),  
    -> PARTITION p2 VALUES LESS THAN (15,30,'sss'),  
    -> PARTITION p3 VALUES LESS THAN (MAXVALUE,MAXVALUE,MAXVALUE)  
    -> );  
Query OK, 0 rows affected (0.15 sec)
```

Table **rcx** contains the columns **a**, **b**, **c**, **d**. The partitioning column list supplied to the **COLUMNS** clause uses 3 of these columns, in the order **a**, **d**, **c**. Each value list used to define a partition contains 3 values in
the same order; that is, each value list tuple has the form `(INT, INT, CHAR(3))`, which corresponds to the data types used by columns `a`, `d`, and `c` (in that order).

Placement of rows into partitions is determined by comparing the tuple from a row to be inserted that matches the column list in the `COLUMNS` clause with the tuples used in the `VALUES LESS THAN` clauses to define partitions of the table. Because we are comparing tuples (that is, lists or sets of values) rather than scalar values, the semantics of `VALUES LESS THAN` as used with `RANGE COLUMNS` partitions differs somewhat from the case with simple `RANGE` partitions. In `RANGE` partitioning, a row generating an expression value that is equal to a limiting value in a `VALUES LESS THAN` is never placed in the corresponding partition; however, when using `RANGE COLUMNS` partitioning, it is sometimes possible for a row whose partitioning column list's first element is equal in value to the that of the first element in a `VALUES LESS THAN` value list to be placed in the corresponding partition.

Consider the `RANGE` partitioned table created by this statement:

```sql
CREATE TABLE r1 (
    a INT,
    b INT
)
PARTITION BY RANGE (a) {
    PARTITION p0 VALUES LESS THAN (5),
    PARTITION p1 VALUES LESS THAN (MAXVALUE)
};
```

If we insert 3 rows into this table such that the column value for `a` is 5 for each row, all 3 rows are stored in partition `p1` because the `a` column value is in each case not less than 5, as we can see by executing the proper query against the `INFORMATION_SCHEMA.PARTITIONS` table:

```sql
mysql> INSERT INTO r1 VALUES (5,10), (5,11), (5,12);
Query OK, 3 rows affected (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 0

mysql> SELECT PARTITION_NAME, TABLE_ROWS
    => FROM INFORMATION_SCHEMA.PARTITIONS
    => WHERE TABLE_NAME = 'r1';
+----------------+------------+
| PARTITION_NAME | TABLE_ROWS |
|----------------+------------|
| p0             |          0 |
| p1             |          3 |
+----------------+------------+
2 rows in set (0.00 sec)
```

Now consider a similar table `rc1` that uses `RANGE COLUMNS` partitioning with both columns `a` and `b` referenced in the `COLUMNS` clause, created as shown here:

```sql
CREATE TABLE rc1 (
    a INT,
    b INT
)
PARTITION BY RANGE COLUMNS(a, b) {
    PARTITION p0 VALUES LESS THAN (5, 12),
    PARTITION p3 VALUES LESS THAN (MAXVALUE, MAXVALUE)
};
```

If we insert exactly the same rows into `rc1` as we just inserted into `r1`, the distribution of the rows is quite different:

```sql
mysql> INSERT INTO rc1 VALUES (5,10), (5,11), (5,12);
Query OK, 3 rows affected (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 0

mysql> SELECT PARTITION_NAME, TABLE_ROWS
    => FROM INFORMATION_SCHEMA.PARTITIONS
    => WHERE TABLE_NAME = 'rc1';
+----------------+------------+
| PARTITION_NAME | TABLE_ROWS |
|----------------+------------|
| p0             |          0 |
| p1             |          3 |
| p3             |          0 |
| p4             |          0 |
| p5             |          0 |
+----------------+------------+
5 rows in set (0.00 sec)
```
This is because we are comparing rows rather than scalar values. We can compare the row values inserted with the limiting row value from the VALUES THAN LESS THAN clause used to define partition p0 in table rcl, like this:

```sql
SELECT (5,10) < (5,12), (5,11) < (5,12), (5,12) < (5,12);
```

The 2 tuples (5,10) and (5,11) evaluate as less than (5,12), so they are stored in partition p0. Since 5 is not less than 5 and 12 is not less than 12, (5,12) is considered not less than (5,12), and is stored in partition p1.

The SELECT statement in the preceding example could also have been written using explicit row constructors, like this:

```sql
SELECT ROW(5,10) < ROW(5,12), ROW(5,11) < ROW(5,12), ROW(5,12) < ROW(5,12);
```

For more information about the use of row constructors in MySQL, see Section 13.2.10.5, “Row Subqueries”.

For a table partitioned by RANGE COLUMNS using only a single partitioning column, the storing of rows in partitions is the same as that of an equivalent table that is partitioned by RANGE. The following CREATE TABLE statement creates a table partitioned by RANGE COLUMNS using 1 partitioning column:

```sql
CREATE TABLE rx (  
a INT,
b INT
);  
PARTITION BY RANGE COLUMNS (a) (  
    PARTITION p0 VALUES LESS THAN (5),  
    PARTITION p1 VALUES LESS THAN (MAXVALUE)
);
```

If we insert the rows (5,10), (5,11), and (5,12) into this table, we can see that their placement is the same as it is for the table rcl we created and populated earlier:
It is also possible to create tables partitioned by `RANGE COLUMNS` where limiting values for one or more columns are repeated in successive partition definitions. You can do this as long as the tuples of column values used to define the partitions are strictly increasing. For example, each of the following `CREATE TABLE` statements is valid:

```sql
CREATE TABLE rc2 (a INT, b INT)
PARTITION BY RANGE COLUMNS(a,b) (PARTITION p0 VALUES LESS THAN (0,10),
   PARTITION p1 VALUES LESS THAN (10,20),
   PARTITION p2 VALUES LESS THAN (10,30),
   PARTITION p3 VALUES LESS THAN (MAXVALUE,MAXVALUE));
CREATE TABLE rc3 (a INT, b INT)
PARTITION BY RANGE COLUMNS(a,b) (PARTITION p0 VALUES LESS THAN (0,10),
   PARTITION p1 VALUES LESS THAN (10,20),
   PARTITION p2 VALUES LESS THAN (10,30),
   PARTITION p3 VALUES LESS THAN (10,35),
   PARTITION p4 VALUES LESS THAN (20,40),
   PARTITION p5 VALUES LESS THAN (MAXVALUE,MAXVALUE));
CREATE TABLE rc4 (a INT, b INT, c INT)
PARTITION BY RANGE COLUMNS(a,b,c) (PARTITION p0 VALUES LESS THAN (0,25,50),
   PARTITION p1 VALUES LESS THAN (10,20,100),
   PARTITION p2 VALUES LESS THAN (10,30,50),
   PARTITION p3 VALUES LESS THAN (MAXVALUE,MAXVALUE,MAXVALUE));
```

The following statement also succeeds, even though it might appear at first glance that it would not, since the limiting value of column `b` is 25 for partition `p0` and 20 for partition `p1`, and the limiting value of column `c` is 100 for partition `p1` and 50 for partition `p2`:

```sql
CREATE TABLE rc4 (a INT, b INT, c INT)
PARTITION BY RANGE COLUMNS(a,b,c) (PARTITION p0 VALUES LESS THAN (0,25,50),
   PARTITION p1 VALUES LESS THAN (10,20,100),
   PARTITION p2 VALUES LESS THAN (10,30,50),
   PARTITION p3 VALUES LESS THAN (MAXVALUE,MAXVALUE,MAXVALUE));
```

When designing tables partitioned by `RANGE COLUMNS`, you can always test successive partition definitions by comparing the desired tuples using the `mysql` client, like this:

```sql
mysql> SELECT (0,25,50) < (10,20,100), (10,20,100) < (10,30,50);
+-------------------------+--------------------------+
| (0,25,50) < (10,20,100) | (10,20,100) < (10,30,50) |
|                        |                          |
+-------------------------+--------------------------+
|                       1 |                        1 |
+-------------------------+--------------------------+
1 row in set (0.00 sec)
```

If a `CREATE TABLE` statement contains partition definitions that are not in strictly increasing order, it fails with an error, as shown in this example:

```sql
mysql> CREATE TABLE ref (a INT, b INT, c INT
```
When you get such an error, you can deduce which partition definitions are invalid by making “less than” comparisons between their column lists. In this case, the problem is with the definition of partition p2 because the tuple used to define it is not less than the tuple used to define partition p3, as shown here:

```sql
mysql> SELECT (0,25,50) < (20,20,100), (20,20,100) < (10,30,50);
```

```
+-------------------------+--------------------------+
| (0,25,50) < (20,20,100) | (20,20,100) < (10,30,50) |
+-------------------------+--------------------------+
|                       1 |                        0 |
+-------------------------+--------------------------+
1 row in set (0.00 sec)
```

It is also possible for MAXVALUE to appear for the same column in more than one VALUES LESS THAN clause when using RANGE COLUMNS. However, the limiting values for individual columns in successive partition definitions should otherwise be increasing, there should be no more than one partition defined where MAXVALUE is used as the upper limit for all column values, and this partition definition should appear last in the list of PARTITION ... VALUES LESS THAN clauses. In addition, you cannot use MAXVALUE as the limiting value for the first column in more than one partition definition.

As stated previously, it is also possible with RANGE COLUMNS partitioning to use non-integer columns as partitioning columns. (See Section 19.2.3, “COLUMNS Partitioning”, for a complete listing of these.) Consider a table named employees (which is not partitioned), created using the following statement:

```sql
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT NOT NULL,
  store_id INT NOT NULL
);
```

Using RANGE COLUMNS partitioning, you can create a version of this table that stores each row in one of four partitions based on the employee's last name, like this:

```sql
CREATE TABLE employees_by_lname (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT NOT NULL,
  store_id INT NOT NULL
)
PARTITION BY RANGE COLUMNS (lname) {
  PARTITION p0 VALUES LESS THAN ('g'),
  PARTITION p1 VALUES LESS THAN ('m'),
  PARTITION p2 VALUES LESS THAN ('t'),
  PARTITION p3 VALUES LESS THAN (MAXVALUE)
};
```

Alternatively, you could cause the employees table as created previously to be partitioned using this scheme by executing the following ALTER TABLE statement:
COLUMNS Partitioning

```sql
ALTER TABLE employees PARTITION BY RANGE COLUMNS (lname) {
    PARTITION p0 VALUES LESS THAN ('g'),
    PARTITION p1 VALUES LESS THAN ('m'),
    PARTITION p2 VALUES LESS THAN ('t'),
    PARTITION p3 VALUES LESS THAN (MAXVALUE)
};
```

**Note**

Because different character sets and collations have different sort orders, the character sets and collations in use may effect which partition of a table partitioned by `RANGE COLUMNS` a given row is stored in when using string columns as partitioning columns. In addition, changing the character set or collation for a given database, table, or column after such a table is created may cause changes in how rows are distributed. For example, when using a case-sensitive collation, 'and' sorts before 'Andersen', but when using a collation that is case-insensitive, the reverse is true.

For information about how MySQL handles character sets and collations, see Chapter 10, Character Sets, Collations, Unicode.

Similarly, you can cause the `employees` table to be partitioned in such a way that each row is stored in one of several partitions based on the decade in which the corresponding employee was hired using the `ALTER TABLE` statement shown here:

```sql
ALTER TABLE employees PARTITION BY RANGE COLUMNS (hired) {
    PARTITION p0 VALUES LESS THAN ('1970-01-01'),
    PARTITION p1 VALUES LESS THAN ('1980-01-01'),
    PARTITION p2 VALUES LESS THAN ('1990-01-01'),
    PARTITION p3 VALUES LESS THAN ('2000-01-01'),
    PARTITION p4 VALUES LESS THAN ('2010-01-01'),
    PARTITION p5 VALUES LESS THAN (MAXVALUE)
};
```

See Section 13.1.17, “CREATE TABLE Statement”, for additional information about `PARTITION BY RANGE COLUMNS` syntax.

### 19.2.3.2 LIST COLUMNS partitioning

MySQL 5.6 provides support for `LIST COLUMNS` partitioning. This is a variant of `LIST` partitioning that enables the use of multiple columns as partition keys, and for columns of data types other than integer types to be used as partitioning columns; you can use string types, `DATE`, and `DATETIME` columns. (For more information about permitted data types for `COLUMNS` partitioning columns, see Section 19.2.3, “COLUMNS Partitioning”.)

Suppose that you have a business that has customers in 12 cities which, for sales and marketing purposes, you organize into 4 regions of 3 cities each as shown in the following table:

<table>
<thead>
<tr>
<th>Region</th>
<th>Cities</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Oskarshamn, Högsby, Mönsterås</td>
</tr>
<tr>
<td>2</td>
<td>Vimmerby, Hultsfred, Västervik</td>
</tr>
<tr>
<td>3</td>
<td>Nässjö, Eksjö, Vetlanda</td>
</tr>
<tr>
<td>4</td>
<td>Uppvidinge, Alvesta, Växjo</td>
</tr>
</tbody>
</table>

With `LIST COLUMNS` partitioning, you can create a table for customer data that assigns a row to any of 4 partitions corresponding to these regions based on the name of the city where a customer resides, as shown here:
CREATE TABLE customers_1 (  
    first_name VARCHAR(25),  
    last_name VARCHAR(25),  
    street_1 VARCHAR(30),  
    street_2 VARCHAR(30),  
    city VARCHAR(15),  
    renewal DATE  
)  
PARTITION BY LIST COLUMNS(city) (  
    PARTITION pRegion_1 VALUES IN('Oskarshamn', 'Högsby', 'Mönsterås'),  
    PARTITION pRegion_2 VALUES IN('Vimmerby', 'Hultsfred', 'Västervik'),  
    PARTITION pRegion_3 VALUES IN('Nässjö', 'Eksjö', 'Vetlanda'),  
    PARTITION pRegion_4 VALUES IN('Uppvidinge', 'Alvesta', 'Växjö')  
);  

As with partitioning by `RANGE COLUMNS`, you do not need to use expressions in the `COLUMNS()` clause to convert column values into integers. (In fact, the use of expressions other than column names is not permitted with `COLUMNS()`.)

It is also possible to use `DATE` and `DATETIME` columns, as shown in the following example that uses the same name and columns as the `customers_1` table shown previously, but employs `LIST COLUMNS` partitioning based on the `renewal` column to store rows in one of 4 partitions depending on the week in February 2010 the customer's account is scheduled to renew:

CREATE TABLE customers_2 (  
    first_name VARCHAR(25),  
    last_name VARCHAR(25),  
    street_1 VARCHAR(30),  
    street_2 VARCHAR(30),  
    city VARCHAR(15),  
    renewal DATE  
)  
PARTITION BY LIST COLUMNS(renewal) (  
    PARTITION pWeek_1 VALUES IN('2010-02-01', '2010-02-02', '2010-02-03', '2010-02-04', '2010-02-05', '2010-02-06', '2010-02-07'),  
    PARTITION pWeek_2 VALUES IN('2010-02-08', '2010-02-09', '2010-02-10', '2010-02-11', '2010-02-12', '2010-02-13', '2010-02-14'),  
    PARTITION pWeek_3 VALUES IN('2010-02-15', '2010-02-16', '2010-02-17', '2010-02-18', '2010-02-19', '2010-02-20', '2010-02-21'),  
    PARTITION pWeek_4 VALUES IN('2010-02-22', '2010-02-23', '2010-02-24', '2010-02-25', '2010-02-26', '2010-02-27', '2010-02-28')  
);  

This works, but becomes cumbersome to define and maintain if the number of dates involved grows very large; in such cases, it is usually more practical to employ `RANGE` or `RANGE COLUMNS` partitioning instead. In this case, since the column we wish to use as the partitioning key is a `DATE` column, we use `RANGE COLUMNS` partitioning, as shown here:

CREATE TABLE customers_3 (  
    first_name VARCHAR(25),  
    last_name VARCHAR(25),  
    street_1 VARCHAR(30),  
    street_2 VARCHAR(30),  
    city VARCHAR(15),  
    renewal DATE  
)  
PARTITION BY RANGE COLUMNS(renewal) (  
    PARTITION pWeek_1 VALUES LESS THAN('2010-02-09'),  
    PARTITION pWeek_2 VALUES LESS THAN('2010-02-15'),  
    PARTITION pWeek_3 VALUES LESS THAN('2010-02-22'),  
    PARTITION pWeek_4 VALUES LESS THAN('2010-03-01')  
);  

See Section 19.2.3.1, “RANGE COLUMNS partitioning”, for more information.
In addition (as with RANGE COLUMNS partitioning), you can use multiple columns in the \texttt{COLUMNS()} clause.

See Section 13.1.17, "CREATE TABLE Statement", for additional information about \texttt{PARTITION BY LIST COLUMNS()} syntax.

### 19.2.4 HASH Partitioning

Partitioning by \texttt{HASH} is used primarily to ensure an even distribution of data among a predetermined number of partitions. With range or list partitioning, you must specify explicitly into which partition a given column value or set of column values is to be stored; with hash partitioning, MySQL takes care of this for you, and you need only specify a column value or expression based on a column value to be hashed and the number of partitions into which the partitioned table is to be divided.

To partition a table using \texttt{HASH} partitioning, it is necessary to append to the \texttt{CREATE TABLE} statement a \texttt{PARTITION BY HASH (expr)} clause, where \texttt{expr} is an expression that returns an integer. This can simply be the name of a column whose type is one of MySQL's integer types. In addition, you most likely want to follow this with \texttt{PARTITIONS num}, where \texttt{num} is a positive integer representing the number of partitions into which the table is to be divided.

**Note**

For simplicity, the tables in the examples that follow do not use any keys. You should be aware that, if a table has any unique keys, every column used in the partitioning expression for this table must be part of every unique key, including the primary key. See Section 19.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”, for more information.

The following statement creates a table that uses hashing on the \texttt{store_id} column and is divided into 4 partitions:

```sql
CREATE TABLE employees (  
  id INT NOT NULL,  
  fname VARCHAR(30),  
  lname VARCHAR(30),  
  hired DATE NOT NULL DEFAULT '1970-01-01',  
  separated DATE NOT NULL DEFAULT '9999-12-31',  
  job_code INT,  
  store_id INT  
)  
PARTITION BY HASH(store_id)  
PARTITIONS 4;
```

If you do not include a \texttt{PARTITIONS} clause, the number of partitions defaults to 1.

Using the \texttt{PARTITIONS} keyword without a number following it results in a syntax error.

You can also use an SQL expression that returns an integer for \texttt{expr}. For instance, you might want to partition based on the year in which an employee was hired. This can be done as shown here:

```sql
CREATE TABLE employees (  
  id INT NOT NULL,  
  fname VARCHAR(30),  
  lname VARCHAR(30),  
  hired DATE NOT NULL DEFAULT '1970-01-01',  
  separated DATE NOT NULL DEFAULT '9999-12-31',  
  job_code INT,  
  store_id INT  
)  
PARTITION BY HASH( YEAR(hired) )  
PARTITIONS 4;
```
**expr** must return a nonconstant, nonrandom integer value (in other words, it should be varying but deterministic), and must not contain any prohibited constructs as described in Section 19.6, “Restrictions and Limitations on Partitioning”. You should also keep in mind that this expression is evaluated each time a row is inserted or updated (or possibly deleted); this means that very complex expressions may give rise to performance issues, particularly when performing operations (such as batch inserts) that affect a great many rows at one time.

The most efficient hashing function is one which operates upon a single table column and whose value increases or decreases consistently with the column value, as this allows for “pruning” on ranges of partitions. That is, the more closely that the expression varies with the value of the column on which it is based, the more efficiently MySQL can use the expression for hash partitioning.

For example, where \( \text{date\_col} \) is a column of type \( \text{DATE} \), then the expression \( \text{TO\_DAYS} (\text{date\_col}) \) is said to vary directly with the value of \( \text{date\_col} \), because for every change in the value of \( \text{date\_col} \), the value of the expression changes in a consistent manner. The variance of the expression \( \text{YEAR} (\text{date\_col}) \) with respect to \( \text{date\_col} \) is not quite as direct as that of \( \text{TO\_DAYS} (\text{date\_col}) \), because not every possible change in \( \text{date\_col} \) produces an equivalent change in \( \text{YEAR} (\text{date\_col}) \). Even so, \( \text{YEAR} (\text{date\_col}) \) is a good candidate for a hashing function, because it varies directly with a portion of \( \text{date\_col} \) and there is no possible change in \( \text{date\_col} \) that produces a disproportionate change in \( \text{YEAR} (\text{date\_col}) \).

By way of contrast, suppose that you have a column named \( \text{int\_col} \) whose type is \( \text{INT} \). Now consider the expression \( \text{POW} (5-\text{int\_col}, 3) + 6 \). This would be a poor choice for a hashing function because a change in the value of \( \text{int\_col} \) is not guaranteed to produce a proportional change in the value of the expression. Changing the value of \( \text{int\_col} \) by a given amount can produce widely differing changes in the value of the expression. For example, changing \( \text{int\_col} \) from 5 to 6 produces a change of -1 in the value of the expression, but changing the value of \( \text{int\_col} \) from 6 to 7 produces a change of -7 in the expression value.

In other words, the more closely the graph of the column value versus the value of the expression follows a straight line as traced by the equation \( y=cx \) where \( c \) is some nonzero constant, the better the expression is suited to hashing. This has to do with the fact that the more nonlinear an expression is, the more uneven the distribution of data among the partitions it tends to produce.

In theory, pruning is also possible for expressions involving more than one column value, but determining which of such expressions are suitable can be quite difficult and time-consuming. For this reason, the use of hashing expressions involving multiple columns is not particularly recommended.

When **PARTITION BY HASH** is used, MySQL determines which partition of \( \text{num} \) partitions to use based on the modulus of the result of the expression. In other words, for a given expression \( \text{expr} \), the partition in which the record is stored is partition number \( N \), where \( N = \text{MOD} (\text{expr}, \text{num}) \). Suppose that table \( t1 \) is defined as follows, so that it has 4 partitions:

```sql
CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATE)
PARTITION BY HASH( YEAR(col3) )
PARTITIONS 4;
```

If you insert a record into \( t1 \) whose \( \text{col3} \) value is ‘2005-09-15’, then the partition in which it is stored is determined as follows:

```sql
MOD(YEAR('2005-09-15'),4)
= MOD(2005,4)
= 1
```

MySQL 5.6 also supports a variant of **HASH** partitioning known as *linear hashing* which employs a more complex algorithm for determining the placement of new rows inserted into the partitioned table. See Section 19.2.4.1, “LINEAR HASH Partitioning”, for a description of this algorithm.
HASH Partitioning

The user-supplied expression is evaluated each time a record is inserted or updated. It may also—depending on the circumstances—be evaluated when records are deleted.

19.2.4.1 LINEAR HASH Partitioning

MySQL also supports linear hashing, which differs from regular hashing in that linear hashing utilizes a linear powers-of-two algorithm whereas regular hashing employs the modulus of the hashing function's value.

Syntactically, the only difference between linear-hash partitioning and regular hashing is the addition of the LINEAR keyword in the PARTITION BY clause, as shown here:

```sql
CREATE TABLE employees (  
id INT NOT NULL,  
fname VARCHAR(30),  
lname VARCHAR(30),  
hired DATE NOT NULL DEFAULT '1970-01-01',  
separated DATE NOT NULL DEFAULT '9999-12-31',  
job_code INT,  
store_id INT  
)  
PARTITION BY LINEAR HASH( YEAR(hired) )  
PARTITIONS 4;
```

Given an expression $expr$, the partition in which the record is stored when linear hashing is used is partition number $N$ from among $num$ partitions, where $N$ is derived according to the following algorithm:

1. Find the next power of 2 greater than $num$. We call this value $V$; it can be calculated as:

   $$V = \text{POWER}(2, \text{CEILING} (\log_2(num)))$$

   (Suppose that $num$ is 13. Then $\log_2(13)$ is 3.7004397181411. $\text{CEILING}(3.7004397181411)$ is 4, and $V = \text{POWER}(2, 4)$, which is 16.)

2. Set $N = F(column\_list) \& (V - 1)$.

3. While $N >= num$:
   
   • Set $V = V/2$
   
   • Set $N = N \& (V - 1)$

Suppose that the table $t1$, using linear hash partitioning and having 6 partitions, is created using this statement:

```sql
CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATE)  
PARTITION BY LINEAR HASH( YEAR(col3) )  
PARTITIONS 6;
```

Now assume that you want to insert two records into $t1$ having the $col3$ column values '2003-04-14' and '1998-10-19'. The partition number for the first of these is determined as follows:

```sql
V = \text{POWER}(2, \text{CEILING} (\log_2(6))) = 8
N = \text{YEAR}('2003-04-14') \& (8 - 1)  
    = 2003 \& 7  
    = 3
(3 >= 6 is FALSE: record stored in partition #3)
```

The number of the partition where the second record is stored is calculated as shown here:

```sql
V = 8
```
The advantage in partitioning by linear hash is that the adding, dropping, merging, and splitting of partitions is made much faster, which can be beneficial when dealing with tables containing extremely large amounts (terabytes) of data. The disadvantage is that data is less likely to be evenly distributed between partitions as compared with the distribution obtained using regular hash partitioning.

19.2.5 KEY Partitioning

Partitioning by key is similar to partitioning by hash, except that where hash partitioning employs a user-defined expression, the hashing function for key partitioning is supplied by the MySQL server. NDB Cluster uses MD5() for this purpose; for tables using other storage engines, the server employs its own internal hashing function which is based on the same algorithm as PASSWORD().

The syntax rules for CREATE TABLE ... PARTITION BY KEY are similar to those for creating a table that is partitioned by hash. The major differences are listed here:

- **KEY** is used rather than **HASH**.
- **KEY** takes only a list of zero or more column names. Any columns used as the partitioning key must comprise part or all of the table's primary key, if the table has one. Where no column name is specified as the partitioning key, the table's primary key is used, if there is one. For example, the following CREATE TABLE statement is valid in MySQL 5.6:

```sql
CREATE TABLE k1 (  
    id INT NOT NULL PRIMARY KEY,  
    name VARCHAR(20)  
)  
PARTITION BY KEY()  
PARTITIONS 2;
```

If there is no primary key but there is a unique key, then the unique key is used for the partitioning key:

```sql
CREATE TABLE k1 (  
    id INT NOT NULL,  
    name VARCHAR(20),  
    UNIQUE KEY (id)  
)  
PARTITION BY KEY()  
PARTITIONS 2;
```

However, if the unique key column were not defined as **NOT NULL**, then the previous statement would fail.

In both of these cases, the partitioning key is the **id** column, even though it is not shown in the output of SHOW CREATE TABLE or in the PARTITION_EXPRESSION column of the INFORMATION_SCHEMA.PARTITIONS table.

Unlike the case with other partitioning types, columns used for partitioning by **KEY** are not restricted to integer or **NULL** values. For example, the following CREATE TABLE statement is valid:
CREATE TABLE tm1 (  
  s1 CHAR(32) PRIMARY KEY  
)  
PARTITION BY KEY(s1)  
PARTITIONS 10;

The preceding statement would not be valid, were a different partitioning type to be specified. (In this case, simply using PARTITION BY KEY() would also be valid and have the same effect as PARTITION BY KEY(s1), since s1 is the table's primary key.)

For additional information about this issue, see Section 19.6, “Restrictions and Limitations on Partitioning”.

Columns with index prefixes are not supported in partitioning keys. This means that CHAR, VARCHAR, BINARY, and VARBINARY columns can be used in a partitioning key, as long as they do not employ prefixes; because a prefix must be specified for BLOB and TEXT columns in index definitions, it is not possible to use columns of these two types in partitioning keys. In MySQL 5.6, columns using prefixes are permitted when creating, altering, or upgrading partitioned tables, even though they are not included in the table's partitioning key. This is a known issue in MySQL 5.6 which is addressed in MySQL 8.0, where this permissive behavior is deprecated, and the server displays appropriate warnings or errors when attempting to use such columns in these cases. See Column index prefixes not supported for key partitioning, for more information and examples.

Note

Tables using the NDB storage engine are implicitly partitioned by KEY, using the table's primary key as the partitioning key (as with other MySQL storage engines). In the event that the NDB Cluster table has no explicit primary key, the “hidden” primary key generated by the NDB storage engine for each NDB Cluster table is used as the partitioning key.

If you define an explicit partitioning scheme for an NDB table, the table must have an explicit primary key, and any columns used in the partitioning expression must be part of this key. However, if the table uses an “empty” partitioning expression—that is, PARTITION BY KEY() with no column references—then no explicit primary key is required.

You can observe this partitioning using the ndb_desc utility (with the -p option).

Important

For a key-partitioned table, you cannot execute an ALTER TABLE DROP PRIMARY KEY, as doing so generates the error ERROR 1466 (HY000): Field in list of fields for partition function not found in table. This is not an issue for NDB Cluster tables which are partitioned by KEY; in such cases, the table is reorganized using the “hidden” primary key as the table’s new partitioning key. See Chapter 18, MySQL NDB Cluster 7.3 and NDB Cluster 7.4.

It is also possible to partition a table by linear key. Here is a simple example:

CREATE TABLE tk (  
  col1 INT NOT NULL,  
  col2 CHAR(3),  
  col3 DATE  
)
PARTITION BY LINEAR KEY (col1) PARTITIONS 3;

Using **LINEAR** has the same effect on **KEY** partitioning as it does on **HASH** partitioning, with the partition number being derived using a powers-of-two algorithm rather than modulo arithmetic. See Section 19.2.4.1, “**LINEAR HASH Partitioning**”, for a description of this algorithm and its implications.

### 19.2.6 Subpartitioning

Subpartitioning—also known as **composite partitioning**—is the further division of each partition in a partitioned table. Consider the following **CREATE TABLE** statement:

```sql
CREATE TABLE ts (id INT, purchased DATE)
    PARTITION BY RANGE( YEAR(purchased) )
    SUBPARTITION BY HASH( TO_DAYS(purchased) )
    SUBPARTITIONS 2 (  
        PARTITION p0 VALUES LESS THAN (1990),  
        PARTITION p1 VALUES LESS THAN (2000),  
        PARTITION p2 VALUES LESS THAN MAXVALUE
    );
```

Table **ts** has 3 **RANGE** partitions. Each of these partitions—**p0**, **p1**, and **p2**—is further divided into 2 subpartitions. In effect, the entire table is divided into $3 \times 2 = 6$ partitions. However, due to the action of the **PARTITION BY RANGE** clause, the first 2 of these store only those records with a value less than 1990 in the **purchased** column.

In MySQL 5.6, it is possible to subpartition tables that are partitioned by **RANGE** or **LIST**. Subpartitions may use either **HASH** or **KEY** partitioning. This is also known as **composite partitioning**.

---

**Note**

**SUBPARTITION BY HASH** and **SUBPARTITION BY KEY** generally follow the same syntax rules as **PARTITION BY HASH** and **PARTITION BY KEY**, respectively. An exception to this is that **SUBPARTITION BY KEY** (unlike **PARTITION BY KEY**) does not currently support a default column, so the column used for this purpose must be specified, even if the table has an explicit primary key. This is a known issue which we are working to address; see Issues with subpartitions, for more information and an example.

It is also possible to define subpartitions explicitly using **SUBPARTITION** clauses to specify options for individual subpartitions. For example, a more verbose fashion of creating the same table **ts** as shown in the previous example would be:

```sql
CREATE TABLE ts (id INT, purchased DATE)
    PARTITION BY RANGE( YEAR(purchased) )
    SUBPARTITION BY HASH( TO_DAYS(purchased) ) {  
        PARTITION p0 VALUES LESS THAN (1990) {  
            SUBPARTITION s0,  
            SUBPARTITION s1
        },  
        PARTITION p1 VALUES LESS THAN (2000) {  
            SUBPARTITION s2,  
            SUBPARTITION s3
        },  
        PARTITION p2 VALUES LESS THAN MAXVALUE {  
            SUBPARTITION s4,  
            SUBPARTITION s5
        }
    );
```
Some syntactical items of note are listed here:

- Each partition must have the same number of subpartitions.

- If you explicitly define any subpartitions using `SUBPARTITION` on any partition of a partitioned table, you must define them all. In other words, the following statement fails:

```sql
CREATE TABLE ts (id INT, purchased DATE)
PARTITION BY RANGE( YEAR(purchased) )
SUBPARTITION BY HASH( TO_DAYS(purchased) ) (  
    PARTITION p0 VALUES LESS THAN (1990) (  
        SUBPARTITION s0,  
        SUBPARTITION s1  
    ),  
    PARTITION p1 VALUES LESS THAN (2000),  
    PARTITION p2 VALUES LESS THAN MAXVALUE (  
        SUBPARTITION s2,  
        SUBPARTITION s3  
    )
);
```

This statement would still fail even if it included a `SUBPARTITIONS 2` clause.

- Each `SUBPARTITION` clause must include (at a minimum) a name for the subpartition. Otherwise, you may set any desired option for the subpartition or allow it to assume its default setting for that option.

- Subpartition names must be unique across the entire table. For example, the following `CREATE TABLE` statement is valid in MySQL 5.6:

```sql
CREATE TABLE ts (id INT, purchased DATE)
PARTITION BY RANGE( YEAR(purchased) )
SUBPARTITION BY HASH( TO_DAYS(purchased) ) (  
    PARTITION p0 VALUES LESS THAN (1990) (  
        SUBPARTITION s0,  
        SUBPARTITION s1  
    ),  
    PARTITION p1 VALUES LESS THAN (2000) (  
        SUBPARTITION s2,  
        SUBPARTITION s3  
    ),  
    PARTITION p2 VALUES LESS THAN MAXVALUE (  
        SUBPARTITION s4,  
        SUBPARTITION s5  
    )
);
```

Subpartitions can be used with especially large MyISAM tables to distribute data and indexes across many disks. Suppose that you have 6 disks mounted as `/disk0`, `/disk1`, `/disk2`, and so on. Now consider the following example:

```sql
CREATE TABLE ts (id INT, purchased DATE)
ENGINE = MYISAM
PARTITION BY RANGE( YEAR(purchased) )
SUBPARTITION BY HASH( TO_DAYS(purchased) ) (  
    PARTITION p0 VALUES LESS THAN (1990) (  
        SUBPARTITION s0  
    ),  
    PARTITION p1 VALUES LESS THAN (2000) (  
        SUBPARTITION s2  
    ),  
    PARTITION p2 VALUES LESS THAN MAXVALUE (  
        SUBPARTITION s4  
    )
);
```
In this case, a separate disk is used for the data and for the indexes of each RANGE. Many other variations are possible; another example might be:

```sql
CREATE TABLE ts (id INT, purchased DATE) ENGINE = MYISAM PARTITION BY RANGE(YEAR(purchased)) ( PARTITION p0 VALUES LESS THAN (1990) ( SUBPARTITION s0a DATA DIRECTORY = '/disk0' INDEX DIRECTORY = '/disk1', SUBPARTITION s0b DATA DIRECTORY = '/disk2' INDEX DIRECTORY = '/disk3' ), PARTITION p1 VALUES LESS THAN (2000) ( SUBPARTITION s1a DATA DIRECTORY = '/disk4/data' INDEX DIRECTORY = '/disk4/idx', SUBPARTITION s1b DATA DIRECTORY = '/disk5/data' INDEX DIRECTORY = '/disk5/idx' ), PARTITION p2 VALUES LESS THAN MAXVALUE ( SUBPARTITION s2a, SUBPARTITION s2b )
);```

Here, the storage is as follows:

- Rows with `purchased` dates from before 1990 take up a vast amount of space, so are split up 4 ways, with a separate disk dedicated to the data and to the indexes for each of the two subpartitions (`s0a` and `s0b`) making up partition `p0`. In other words:
  - The data for subpartition `s0a` is stored on `/disk0`.
  - The indexes for subpartition `s0a` are stored on `/disk1`.
  - The data for subpartition `s0b` is stored on `/disk2`.
  - The indexes for subpartition `s0b` are stored on `/disk3`.

- Rows containing dates ranging from 1990 to 1999 (partition `p1`) do not require as much room as those from before 1990. These are split between 2 disks (`/disk4` and `/disk5`) rather than 4 disks as with the legacy records stored in `p0`:
  - Data and indexes belonging to `p1`'s first subpartition (`s1a`) are stored on `/disk4`—the data in `/disk4/data`, and the indexes in `/disk4/idx`. 

Hence, subpartitioning can be a useful strategy to optimize storage and query performance for specific date ranges.
How MySQL Partitioning Handles NULL

- Data and indexes belonging to \( p1 \)'s second subpartition (\( s1b \)) are stored on /disk5—the data in /disk5/data, and the indexes in /disk5/idx.
- Rows reflecting dates from the year 2000 to the present (partition \( p2 \)) do not take up as much space as required by either of the two previous ranges. Currently, it is sufficient to store all of these in the default location.

In future, when the number of purchases for the decade beginning with the year 2000 grows to a point where the default location no longer provides sufficient space, the corresponding rows can be moved using an \texttt{ALTER TABLE ... REORGANIZE PARTITION} statement. See Section 19.3, “Partition Management”, for an explanation of how this can be done.

The \texttt{DATA DIRECTORY} and \texttt{INDEX DIRECTORY} options are not permitted in partition definitions when the \texttt{NO_DIR_IN_CREATE} server SQL mode is in effect. In MySQL 5.6, these options are also not permitted when defining subpartitions (Bug #42954).

19.2.7 How MySQL Partitioning Handles NULL

Partitioning in MySQL does nothing to disallow \texttt{NULL} as the value of a partitioning expression, whether it is a column value or the value of a user-supplied expression. Even though it is permitted to use \texttt{NULL} as the value of an expression that must otherwise yield an integer, it is important to keep in mind that \texttt{NULL} is not a number. MySQL’s partitioning implementation treats \texttt{NULL} as being less than any non-\texttt{NULL} value, just as \texttt{ORDER BY} does.

This means that treatment of \texttt{NULL} varies between partitioning of different types, and may produce behavior which you do not expect if you are not prepared for it. This being the case, we discuss in this section how each MySQL partitioning type handles \texttt{NULL} values when determining the partition in which a row should be stored, and provide examples for each.

Handling of NULL with RANGE partitioning. If you insert a row into a table partitioned by \texttt{RANGE} such that the column value used to determine the partition is \texttt{NULL}, the row is inserted into the lowest partition. Consider these two tables in a database named \( p \), created as follows:

```sql
mysql> CREATE TABLE t1 (  
  -> c1 INT,  
  -> c2 VARCHAR(20)  
  -> )  
  -> PARTITION BY RANGE(c1) (  
  -> PARTITION p0 VALUES LESS THAN (0),  
  -> PARTITION p1 VALUES LESS THAN (10),  
  -> PARTITION p2 VALUES LESS THAN MAXVALUE  
  -> );  
Query OK, 0 rows affected (0.09 sec)
```

```sql
mysql> CREATE TABLE t2 (  
  -> c1 INT,  
  -> c2 VARCHAR(20)  
  -> )  
  -> PARTITION BY RANGE(c1) (  
  -> PARTITION p0 VALUES LESS THAN (-5),  
  -> PARTITION p1 VALUES LESS THAN (0),  
  -> PARTITION p2 VALUES LESS THAN (10),  
  -> PARTITION p3 VALUES LESS THAN MAXVALUE  
  -> );  
Query OK, 0 rows affected (0.09 sec)
```

You can see the partitions created by these two \texttt{CREATE TABLE} statements using the following query against the \texttt{PARTITIONS} table in the \texttt{INFORMATION_SCHEMA} database:

```sql
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
```
How MySQL Partitioning Handles NULL

(For more information about this table, see Section 21.3.14, “The INFORMATION_SCHEMA PARTITIONS Table”.) Now let us populate each of these tables with a single row containing a NULL in the column used as the partitioning key, and verify that the rows were inserted using a pair of SELECT statements:

```sql
mysql> INSERT INTO t1 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO t2 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM t1;
+------+--------+
| id   | name   |
+------+--------+
| NULL | mothra |
+------+--------+
1 row in set (0.00 sec)

mysql> SELECT * FROM t2;
+------+--------+
| id   | name   |
+------+--------+
| NULL | mothra |
+------+--------+
1 row in set (0.00 sec)
```

You can see which partitions are used to store the inserted rows by rerunning the previous query against INFORMATION_SCHEMA.PARTITIONS and inspecting the output:

```sql
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
    > FROM INFORMATION_SCHEMA.PARTITIONS
    > WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME LIKE 't_';
```

You can also demonstrate that these rows were stored in the lowest partition of each table by dropping these partitions, and then re-running the SELECT statements:

```sql
mysql> ALTER TABLE t1 DROP PARTITION p0;
Query OK, 0 rows affected (0.16 sec)
```
NULL is also treated in this way for partitioning expressions that use SQL functions. Suppose that we define a table using a `CREATE TABLE` statement such as this one:

```sql
CREATE TABLE tndate (
    id INT,
    dt DATE
) PARTITION BY RANGE( YEAR(dt) ) (
    PARTITION p0 VALUES LESS THAN (1990),
    PARTITION p1 VALUES LESS THAN (2000),
    PARTITION p2 VALUES LESS THAN MAXVALUE
);
```

As with other MySQL functions, `YEAR(NULL)` returns NULL. A row with a `dt` column value of NULL is treated as though the partitioning expression evaluated to a value less than any other value, and so is inserted into partition `p0`.

**Handling of NULL with LIST partitioning.** A table that is partitioned by `LIST` admits NULL values if and only if one of its partitions is defined using that value-list that contains NULL. The converse of this is that a table partitioned by `LIST` which does not explicitly use NULL in a value list rejects rows resulting in a NULL value for the partitioning expression, as shown in this example:

```sql
mysql> CREATE TABLE ts1 (
    ->     c1 INT,
    ->     c2 VARCHAR(20)
    -> ) PARTITION BY LIST(c1) (
    ->     PARTITION p0 VALUES IN (0, 3, 6),
    ->     PARTITION p1 VALUES IN (1, 4, 7),
    ->     PARTITION p2 VALUES IN (2, 5, 8)
    -> );
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO ts1 VALUES (9, 'mothra');
ERROR 1504 (HY000): Table has no partition for value 9

mysql> INSERT INTO ts1 VALUES (NULL, 'mothra');
ERROR 1504 (HY000): Table has no partition for value NULL
```

Only rows having a `c1` value between 0 and 8 inclusive can be inserted into `ts1`. NULL falls outside this range, just like the number 9. We can create tables `ts2` and `ts3` having value lists containing NULL, as shown here:

```sql
mysql> CREATE TABLE ts2 (
    ->     c1 INT,
    ->     c2 VARCHAR(20)
    -> ) PARTITION BY LIST(c1) (
    ->     PARTITION p0 VALUES IN (0, 3, 6),
    ->     PARTITION p1 VALUES IN (1, 4, 7),
    ->     PARTITION p2 VALUES IN (2, 5, 8),
    ->     PARTITION p3 VALUES IN (NULL)
```
When defining value lists for partitioning, you can (and should) treat `NULL` just as you would any other value. For example, both `VALUES IN (NULL)` and `VALUES IN (1, 4, 7, NULL)` are valid, as are `VALUES IN (1, NULL, 4, 7), VALUES IN (NULL, 1, 4, 7)`, and so on. You can insert a row having `NULL` for column `c1` into each of the tables `ts2` and `ts3`:

```
mysql> INSERT INTO ts2 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO ts3 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)
```

By issuing the appropriate query against `INFORMATION_SCHEMA.PARTITIONS`, you can determine which partitions were used to store the rows just inserted (we assume, as in the previous examples, that the partitioned tables were created in the `p` database):

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
FROM INFORMATION_SCHEMA.PARTITIONS
WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME LIKE 'ts_';
```

```
+------------+----------------+------------+----------------+-------------+
| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
|------------+----------------+------------+----------------+-------------+
| ts2        | p0             |          0 |              0 |           0 |
| ts2        | p1             |          0 |              0 |           0 |
| ts2        | p2             |          0 |              0 |           0 |
| ts2        | p3             |          0 |              0 |           0 |
| ts3        | p0             |          0 |              0 |           0 |
| ts3        | p1             |          0 |              0 |           0 |
| ts3        | p2             |          0 |              0 |           0 |
+------------+----------------+------------+----------------+-------------+
7 rows in set (0.01 sec)
```

As shown earlier in this section, you can also verify which partitions were used for storing the rows by deleting these partitions and then performing a `SELECT`.

**Handling of NULL with HASH and KEY partitioning.** `NULL` is handled somewhat differently for tables partitioned by `HASH` or `KEY`. In these cases, any partition expression that yields a `NULL` value is treated as though its return value were zero. We can verify this behavior by examining the effects on the file system of creating a table partitioned by `HASH` and populating it with a record containing appropriate values. Suppose that you have a table `th` (also in the `p` database) created using the following statement:

```
mysql> CREATE TABLE th (c1 INT, c2 VARCHAR(20));
Query OK, 0 rows affected (0.00 sec)
```

The partitions belonging to this table can be viewed using the query shown here:
Notice that `TABLE_ROWS` for each partition is 0. Now insert two rows into `th` whose `c1` column values are `NULL` and 0, and verify that these rows were inserted, as shown here:

```
mysql> INSERT INTO th VALUES (NULL, 'mothra'), (0, 'gigan');
Query OK, 1 row affected (0.00 sec)
```

```
mysql> SELECT * FROM th;
+------+---------+
| c1   | c2      |
+------+---------+
| NULL | mothra  |
| 0    | gigan   |
+------+---------+
```

Recall that for any integer \( N \), the value of `NULL MOD N` is always `NULL`. For tables that are partitioned by `HASH` or `KEY`, this result is treated for determining the correct partition as 0. Checking the `INFORMATION_SCHEMA.PARTITIONS` table once again, we can see that both rows were inserted into partition `p0`:

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
  > FROM INFORMATION_SCHEMA.PARTITIONS
  > WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME = 'th';
```

```
+------------+----------------+------------+----------------+-------------+
| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
+------------+----------------+------------+----------------+-------------+
| th         | p0             |          2 |             20 |          20 |
| th         | p1             |          0 |              0 |           0 |
+------------+----------------+------------+----------------+-------------+
```

If you repeat this example using `PARTITION BY KEY` in place of `PARTITION BY HASH` in the definition of the table, you can verify easily that `NULL` is also treated like 0 for this type of partitioning.

### 19.3 Partition Management

MySQL 5.6 provides a number of ways to modify partitioned tables. It is possible to add, drop, redefine, merge, or split existing partitions. All of these actions can be carried out using the partitioning extensions to the `ALTER TABLE` statement. There are also ways to obtain information about partitioned tables and partitions. We discuss these topics in the sections that follow.

- For information about partition management in tables partitioned by `RANGE` or `LIST`, see Section 19.3.1, “Management of RANGE and LIST Partitions”.
- For a discussion of managing `HASH` and `KEY` partitions, see Section 19.3.2, “Management of HASH and KEY Partitions”.
- See Section 19.3.5, “Obtaining Information About Partitions”, for a discussion of mechanisms provided in MySQL 5.6 for obtaining information about partitioned tables and partitions.
Management of RANGE and LIST Partitions

• For a discussion of performing maintenance operations on partitions, see Section 19.3.4, “Maintenance of Partitions”.

Note

In MySQL 5.6, all partitions of a partitioned table must have the same number of subpartitions, and it is not possible to change the subpartitioning once the table has been created.

To change a table's partitioning scheme, it is necessary only to use the `ALTER TABLE` statement with a `partition_options` clause. This clause has the same syntax as that as used with `CREATE TABLE` for creating a partitioned table, and always begins with the keywords `PARTITION BY`. Suppose that you have a table partitioned by range using the following `CREATE TABLE` statement:

```
CREATE TABLE trb3 (id INT, name VARCHAR(50), purchased DATE)
  PARTITION BY RANGE( YEAR(purchased) ) {
    PARTITION p0 VALUES LESS THAN (1990),
    PARTITION p1 VALUES LESS THAN (1995),
    PARTITION p2 VALUES LESS THAN (2000),
    PARTITION p3 VALUES LESS THAN (2005)
  };
```

To repartition this table so that it is partitioned by key into two partitions using the `id` column value as the basis for the key, you can use this statement:

```
ALTER TABLE trb3 PARTITION BY KEY(id) PARTITIONS 2;
```

This has the same effect on the structure of the table as dropping the table and re-creating it using `CREATE TABLE trb3 PARTITION BY KEY(id) PARTITIONS 2;`.

```
ALTER TABLE ... ENGINE = ... changes only the storage engine used by the table, and leaves the table's partitioning scheme intact. Use `ALTER TABLE ... REMOVE PARTITIONING` to remove a table's partitioning. See Section 13.1.7, “ALTER TABLE Statement”.
```

Important

Only a single `PARTITION BY, ADD PARTITION, DROP PARTITION, REORGANIZE PARTITION, or COALESCE PARTITION` clause can be used in a given `ALTER TABLE` statement. If you (for example) wish to drop a partition and reorganize a table's remaining partitions, you must do so in two separate `ALTER TABLE` statements (one using `DROP PARTITION` and then a second one using `REORGANIZE PARTITION`).

In MySQL 5.6, it is possible to delete all rows from one or more selected partitions using `ALTER TABLE ... TRUNCATE PARTITION`.

19.3.1 Management of RANGE and LIST Partitions

Adding and dropping of range and list partitions are handled in a similar fashion, so we discuss the management of both sorts of partitioning in this section. For information about working with tables that are partitioned by hash or key, see Section 19.3.2, “Management of HASH and KEY Partitions”.

Dropping a partition from a table that is partitioned by either `RANGE` or by `LIST` can be accomplished using the `ALTER TABLE` statement with the `DROP PARTITION` option. Suppose that you have created a table that is partitioned by range and then populated with 10 records using the following `CREATE TABLE` and `INSERT` statements:

```
mysql> CREATE TABLE tr (id INT, name VARCHAR(50), purchased DATE)
```
Management of RANGE and LIST Partitions

```sql
-> PARTITION BY RANGE( YEAR(purchased) ) (  
-> PARTITION p0 VALUES LESS THAN (1990),  
-> PARTITION p1 VALUES LESS THAN (1995),  
-> PARTITION p2 VALUES LESS THAN (2000),  
-> PARTITION p3 VALUES LESS THAN (2005),  
-> PARTITION p4 VALUES LESS THAN (2010),  
-> PARTITION p5 VALUES LESS THAN (2015)  
-> );
```

Query OK, 0 rows affected (0.28 sec)

```sql
mysql> INSERT INTO tr VALUES  
-> (1, 'desk organiser', '2003-10-15'),  
-> (2, 'alarm clock', '1997-11-05'),  
-> (3, 'chair', '2009-03-10'),  
-> (4, 'bookcase', '1989-01-10'),  
-> (5, 'exercise bike', '2014-05-09'),  
-> (6, 'sofa', '1987-06-05'),  
-> (7, 'espresso maker', '2011-11-22'),  
-> (8, 'aquarium', '1992-08-04'),  
-> (9, 'study desk', '2006-09-16'),  
-> (10, 'lava lamp', '1998-12-25');
```

Query OK, 10 rows affected (0.05 sec)

Records: 10  Duplicates: 0  Warnings: 0

You can see which items should have been inserted into partition `p2` as shown here:

```sql
mysql> SELECT * FROM tr  
-> WHERE purchased BETWEEN '1995-01-01' AND '1999-12-31';
```

<table>
<thead>
<tr>
<th>id</th>
<th>name</th>
<th>purchased</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>alarm clock</td>
<td>1997-11-05</td>
</tr>
<tr>
<td>10</td>
<td>lava lamp</td>
<td>1998-12-25</td>
</tr>
</tbody>
</table>

2 rows in set (0.00 sec)

You can also get this information using partition selection, as shown here:

```sql
mysql> SELECT * FROM tr PARTITION (p2);
```

<table>
<thead>
<tr>
<th>id</th>
<th>name</th>
<th>purchased</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>alarm clock</td>
<td>1997-11-05</td>
</tr>
<tr>
<td>10</td>
<td>lava lamp</td>
<td>1998-12-25</td>
</tr>
</tbody>
</table>

2 rows in set (0.00 sec)

See Section 19.5, “Partition Selection”, for more information.

To drop the partition named `p2`, execute the following command:

```sql
mysql> ALTER TABLE tr DROP PARTITION p2;
```

Query OK, 0 rows affected (0.03 sec)

---

**Note**

The NDBCLUSTER storage engine does not support `ALTER TABLE ... DROP PARTITION`. It does, however, support the other partitioning-related extensions to `ALTER TABLE` that are described in this chapter.

It is very important to remember that, when you drop a partition, you also delete all the data that was stored in that partition. You can see that this is the case by re-running the previous `SELECT` query:

```sql
mysql> SELECT * FROM tr WHERE purchased
```
Because of this, you must have the **DROP** privilege for a table before you can execute **ALTER TABLE ... DROP PARTITION** on that table.

If you wish to drop all data from all partitions while preserving the table definition and its partitioning scheme, use the **TRUNCATE TABLE** statement. (See Section 13.1.33, “TRUNCATE TABLE Statement”.)

If you intend to change the partitioning of a table *without* losing data, use **ALTER TABLE ... REORGANIZE PARTITION** instead. See below or in Section 13.1.7, “ALTER TABLE Statement”, for information about **REORGANIZE PARTITION**.

If you now execute a **SHOW CREATE TABLE** statement, you can see how the partitioning makeup of the table has been changed:

```
SHOW CREATE TABLE tr
```

```
CREATE TABLE tr
(`id` int(11) DEFAULT NULL,
 `name` varchar(50) DEFAULT NULL,
 `purchased` date DEFAULT NULL)
ENGINE=InnoDB DEFAULT CHARSET=latin1
/*!50100 PARTITION BY RANGE ( YEAR(purchased))
(PARTITION p0 VALUES LESS THAN (1990) ENGINE = InnoDB,
 PARTITION p1 VALUES LESS THAN (1995) ENGINE = InnoDB,
 PARTITION p3 VALUES LESS THAN (2005) ENGINE = InnoDB,
 PARTITION p4 VALUES LESS THAN (2010) ENGINE = InnoDB,
 PARTITION p5 VALUES LESS THAN (2015) ENGINE = InnoDB) */
```

When you insert new rows into the changed table with `purchased` column values between '1995-01-01' and '2004-12-31' inclusive, those rows are stored in partition `p3`. You can verify this as follows:

```
INSERT INTO tr VALUES (11, 'pencil holder', '1995-07-12');
```

```
SELECT * FROM tr WHERE purchased BETWEEN '1995-01-01' AND '2004-12-31';
```

```
+-----+---------------+------------+
<table>
<thead>
<tr>
<th>id</th>
<th>name</th>
<th>purchased</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>desk organiser</td>
<td>2003-10-15</td>
</tr>
<tr>
<td>11</td>
<td>pencil holder</td>
<td>1995-07-12</td>
</tr>
</tbody>
</table>
+-----+---------------+------------+
```

```
ALTER TABLE tr DROP PARTITION p3;
```

```
SELECT * FROM tr WHERE purchased BETWEEN '1995-01-01' AND '2004-12-31';
```

```
Empty set (0.00 sec)
```

The number of rows dropped from the table as a result of **ALTER TABLE ... DROP PARTITION** is not reported by the server as it would be by the equivalent **DELETE** query.

Dropping **LIST** partitions uses exactly the same **ALTER TABLE ... DROP PARTITION** syntax as used for dropping **RANGE** partitions. However, there is one important difference in the effect this has on your use of the table afterward: You can no longer insert into the table any rows having any of the values that
were included in the value list defining the deleted partition. (See Section 19.2.2, "LIST Partitioning", for an example.)

To add a new range or list partition to a previously partitioned table, use the `ALTER TABLE ... ADD PARTITION` statement. For tables which are partitioned by RANGE, this can be used to add a new range to the end of the list of existing partitions. Suppose that you have a partitioned table containing membership data for your organization, which is defined as follows:

```
CREATE TABLE members (  
id INT,  
fname VARCHAR(25),  
lname VARCHAR(25),  
dob DATE
)
PARTITION BY RANGE( YEAR(dob) ) (  
  PARTITION p0 VALUES LESS THAN (1980),  
  PARTITION p1 VALUES LESS THAN (1990),  
  PARTITION p2 VALUES LESS THAN (2000)
);
```

Suppose further that the minimum age for members is 16. As the calendar approaches the end of 2015, you realize that you are soon likely to be admitting members who were born in 2000 (and later). You can modify the `members` table to accommodate new members born in the years 2000 to 2010 as shown here:

```
ALTER TABLE members ADD PARTITION (PARTITION p3 VALUES LESS THAN (2010));
```

With tables that are partitioned by range, you can use `ADD PARTITION` to add new partitions to the high end of the partitions list only. Trying to add a new partition in this manner between or before existing partitions results in an error as shown here:

```
mysql> ALTER TABLE members
    > ADD PARTITION (PARTITION n VALUES LESS THAN (1970));
ERROR 1463 (HY000): VALUES LESS THAN value must be strictly increasing for each partition
```

You can work around this problem by reorganizing the first partition into two new ones that split the range between them, like this:

```
ALTER TABLE members
REORGANIZE PARTITION p0 INTO (  
  PARTITION n0 VALUES LESS THAN (1970),  
  PARTITION n1 VALUES LESS THAN (1980)
);
```

Using `SHOW CREATE TABLE` you can see that the `ALTER TABLE` statement has had the desired effect:

```
mysql> SHOW CREATE TABLE members\G
*************************** 1. row ***************************
Table: members
Create Table: CREATE TABLE `members` (  
  `id` int(11) DEFAULT NULL,  
  `fname` varchar(25) DEFAULT NULL,  
  `lname` varchar(25) DEFAULT NULL,  
  `dob` date DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
/*150100 PARTITION BY RANGE ( YEAR(dob))  
(PARTITION n0 VALUES LESS THAN (1970) ENGINE = InnoDB,  
PARTITION n1 VALUES LESS THAN (1980) ENGINE = InnoDB,  
PARTITION p1 VALUES LESS THAN (1990) ENGINE = InnoDB,  
PARTITION p2 VALUES LESS THAN (2000) ENGINE = InnoDB,  
PARTITION p3 VALUES LESS THAN (2010) ENGINE = InnoDB) */
1 row in set (0.00 sec)
```
Management of RANGE and LIST Partitions

See also Section 13.1.7.1, “ALTER TABLE Partition Operations”.

You can also use `ALTER TABLE ... ADD PARTITION` to add new partitions to a table that is partitioned by `LIST`. Suppose a table `tt` is defined using the following `CREATE TABLE` statement:

```sql
CREATE TABLE tt (
    id INT,
    data INT
) PARTITION BY LIST(data) (
    PARTITION p0 VALUES IN (5, 10, 15),
    PARTITION p1 VALUES IN (6, 12, 18)
);
```

You can add a new partition in which to store rows having the `data` column values 7, 14, and 21 as shown:

```sql
ALTER TABLE tt ADD PARTITION (PARTITION p2 VALUES IN (7, 14, 21));
```

Keep in mind that you **cannot** add a new `LIST` partition encompassing any values that are already included in the value list of an existing partition. If you attempt to do so, an error results:

```sql
mysql> ALTER TABLE tt ADD PARTITION (PARTITION np VALUES IN (4, 8, 12));
ERROR 1465 (HY000): Multiple definition of same constant »
in list partitioning
```

Because any rows with the `data` column value 12 have already been assigned to partition `p1`, you cannot create a new partition on table `tt` that includes 12 in its value list. To accomplish this, you could drop `p1`, and add `np` and then a new `p1` with a modified definition. However, as discussed earlier, this would result in the loss of all data stored in `p1` — and it is often the case that this is not what you really want to do. Another solution might appear to be to make a copy of the table with the new partitioning and to copy the data into it using `CREATE TABLE ... SELECT ...`, then drop the old table and rename the new one, but this could be very time-consuming when dealing with a large amounts of data. This also might not be feasible in situations where high availability is a requirement.

You can add multiple partitions in a single `ALTER TABLE ... ADD PARTITION` statement as shown here:

```sql
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(50) NOT NULL,
    lname VARCHAR(50) NOT NULL,
    hired DATE NOT NULL
) PARTITION BY RANGE( YEAR(hired) ) (
    PARTITION p1 VALUES LESS THAN (1991),
    PARTITION p2 VALUES LESS THAN (1996),
    PARTITION p3 VALUES LESS THAN (2001),
    PARTITION p4 VALUES LESS THAN (2005)
);
```

```sql
ALTER TABLE employees ADD PARTITION (
    PARTITION p5 VALUES LESS THAN (2010),
    PARTITION p6 VALUES LESS THAN MAXVALUE
);
```

Fortunately, MySQL’s partitioning implementation provides ways to redefine partitions without losing data. Let us look first at a couple of simple examples involving `RANGE` partitioning. Recall the `members` table which is now defined as shown here:

```sql
mysql> SHOW CREATE TABLE members\G
*************************** 1. row ***************************
3169
```
Management of RANGE and LIST Partitions

Table: members

Create Table: `CREATE TABLE `members` ( `id` int(11) DEFAULT NULL, `fname` varchar(25) DEFAULT NULL, `lname` varchar(25) DEFAULT NULL, `dob` date DEFAULT NULL ) ENGINE=InnoDB DEFAULT CHARSET=latin1 /*!50100 PARTITION BY RANGE ( YEAR(dob)) (PARTITION n0 VALUES LESS THAN (1970) ENGINE = InnoDB, PARTITION n1 VALUES LESS THAN (1980) ENGINE = InnoDB, PARTITION p1 VALUES LESS THAN (1990) ENGINE = InnoDB, PARTITION p2 VALUES LESS THAN (2000) ENGINE = InnoDB, PARTITION p3 VALUES LESS THAN (2010) ENGINE = InnoDB) */ 1 row in set (0.00 sec)

Suppose that you would like to move all rows representing members born before 1960 into a separate partition. As we have already seen, this cannot be done using `ALTER TABLE ... ADD PARTITION`. However, you can use another partition-related extension to `ALTER TABLE` to accomplish this:

```
ALTER TABLE members REORGANIZE PARTITION n0 INTO ( PARTITION s0 VALUES LESS THAN (1960), PARTITION s1 VALUES LESS THAN (1970) );
```

In effect, this command splits partition `p0` into two new partitions `s0` and `s1`. It also moves the data that was stored in `p0` into the new partitions according to the rules embodied in the two `PARTITION ... VALUES ...` clauses, so that `s0` contains only those records for which `YEAR(dob)` is less than 1960 and `s1` contains those rows in which `YEAR(dob)` is greater than or equal to 1960 but less than 1970.

A `REORGANIZE PARTITION` clause may also be used for merging adjacent partitions. You can reverse the effect of the previous statement on the `members` table as shown here:

```
ALTER TABLE members REORGANIZE PARTITION s0,s1 INTO ( PARTITION p0 VALUES LESS THAN (1970) );
```

No data is lost in splitting or merging partitions using `REORGANIZE PARTITION`. In executing the above statement, MySQL moves all of the records that were stored in partitions `s0` and `s1` into partition `p0`.

The general syntax for `REORGANIZE PARTITION` is shown here:

```
ALTER TABLE tbl_name REORGANIZE PARTITION partition_list INTO (partition_definitions);
```

Here, `tbl_name` is the name of the partitioned table, and `partition_list` is a comma-separated list of names of one or more existing partitions to be changed. `partition_definitions` is a comma-separated list of new partition definitions, which follow the same rules as for the `partition_definitions` list used in `CREATE TABLE`. You are not limited to merging several partitions into one, or to splitting one partition into many, when using `REORGANIZE PARTITION`. For example, you can reorganize all four partitions of the `members` table into two, like this:

```
ALTER TABLE members REORGANIZE PARTITION p0,p1,p2,p3 INTO ( PARTITION m0 VALUES LESS THAN (1980), PARTITION m1 VALUES LESS THAN (2000) );
```

You can also use `REORGANIZE PARTITION` with tables that are partitioned by `LIST`. Let us return to the problem of adding a new partition to the list-partitioned `tt` table and failing because the new partition had a value that was already present in the value-list of one of the existing partitions. We can handle this by adding a partition that contains only nonconflicting values, and then reorganizing the new partition and the existing one so that the value which was stored in the existing one is now moved to the new one:
Here are some key points to keep in mind when using `ALTER TABLE ... REORGANIZE PARTITION` to repartition tables that are partitioned by `RANGE` or `LIST`:

- The `PARTITION` options used to determine the new partitioning scheme are subject to the same rules as those used with a `CREATE TABLE` statement.

  A new `RANGE` partitioning scheme cannot have any overlapping ranges; a new `LIST` partitioning scheme cannot have any overlapping sets of values.

- The combination of partitions in the `partition_definitions` list should account for the same range or set of values overall as the combined partitions named in the `partition_list`.

  For example, partitions `p1` and `p2` together cover the years 1980 through 1999 in the `members` table used as an example in this section. Any reorganization of these two partitions should cover the same range of years overall.

- For tables partitioned by `RANGE`, you can reorganize only adjacent partitions; you cannot skip range partitions.

  For instance, you could not reorganize the example `members` table using a statement beginning with `ALTER TABLE members REORGANIZE PARTITION p0,p2 INTO ...` because `p0` covers the years prior to 1970 and `p2` the years from 1990 through 1999 inclusive, so these are not adjacent partitions. (You cannot skip partition `p1` in this case.)

- You cannot use `REORGANIZE PARTITION` to change the type of partitioning used by the table (for example, you cannot change `RANGE` partitions to `HASH` partitions or the reverse). You also cannot use this statement to change the partitioning expression or column. To accomplish either of these tasks without dropping and re-creating the table, you can use `ALTER TABLE ... PARTITION BY ...`, as shown here:

  ```
  ALTER TABLE tt ADD PARTITION (PARTITION np VALUES IN (4, 8));
  ALTER TABLE tt REORGANIZE PARTITION p1,np INTO {
    PARTITION p1 VALUES IN (6, 18),
    PARTITION np VALUES in (4, 8, 12)
  };
  ```

19.3.2 Management of HASH and KEY Partitions

Tables which are partitioned by hash or by key are very similar to one another with regard to making changes in a partitioning setup, and both differ in a number of ways from tables which have been partitioned by range or list. For that reason, this section addresses the modification of tables partitioned by hash or by key only. For a discussion of adding and dropping of partitions of tables that are partitioned by range or list, see Section 19.3.1, “Management of RANGE and LIST Partitions”.

You cannot drop partitions from tables that are partitioned by `HASH` or `KEY` in the same way that you can from tables that are partitioned by `RANGE` or `LIST`. However, you can merge `HASH` or `KEY` partitions using the `ALTER TABLE ... COALESCE PARTITION` statement. Suppose that you have a table containing data about clients, which is divided into twelve partitions. The `clients` table is defined as shown here:
Exchanging Partitions and Subpartitions with Tables

Exchanging Partitions and Subpartitions with Tables

To reduce the number of partitions from twelve to eight, execute the following `ALTER TABLE` command:

```
mysql> ALTER TABLE clients COALESCE PARTITION 4;
Query OK, 0 rows affected (0.02 sec)
```

`COALESCE` works equally well with tables that are partitioned by `HASH`, `KEY`, `LINEAR HASH`, or `LINEAR KEY`. Here is an example similar to the previous one, differing only in that the table is partitioned by `LINEAR KEY`:

```
mysql> CREATE TABLE clients_lk (
->     id INT,
->     fname VARCHAR(30),
->     lname VARCHAR(30),
->     signed DATE
-> )
-> PARTITION BY LINEAR KEY(signed)
-> PARTITIONS 12;
Query OK, 0 rows affected (0.03 sec)
```

```
mysql> ALTER TABLE clients_lk COALESCE PARTITION 4;
Query OK, 0 rows affected (0.06 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

The number following `COALESCE PARTITION` is the number of partitions to merge into the remainder—in other words, it is the number of partitions to remove from the table.

If you attempt to remove more partitions than the table has, the result is an error like the one shown:

```
mysql> ALTER TABLE clients COALESCE PARTITION 18;
ERROR 1478 (HY000): Cannot remove all partitions, use DROP TABLE instead
```

To increase the number of partitions for the `clients` table from 12 to 18, use `ALTER TABLE ... ADD PARTITION` as shown here:

```
ALTER TABLE clients ADD PARTITION PARTITIONS 6;
```

### 19.3.3 Exchanging Partitions and Subpartitions with Tables

In MySQL 5.6, it is possible to exchange a table partition or subpartition with a table using `ALTER TABLE pt EXCHANGE PARTITION p WITH TABLE nt`, where `pt` is the partitioned table and `p` is the partition or subpartition of `pt` to be exchanged with unpartitioned table `nt`, provided that the following statements are true:

1. Table `nt` is not itself partitioned.
2. Table `nt` is not a temporary table.
3. The structures of tables `pt` and `nt` are otherwise identical.
4. Table `nt` contains no foreign key references, and no other table has any foreign keys that refer to `nt`.
5. There are no rows in `nt` that lie outside the boundaries of the partition definition for `p`.
6. Both tables must use the same character set and collation.
7. For `InnoDB` tables, both tables must use the same row format. To determine the row format of an `InnoDB` table, query `INFORMATION_SCHEMA.INNODB_SYS_TABLES`. 

3172
8. Any partition-level \texttt{MAX\_ROWS} setting for \(p\) must be the same as the table-level \texttt{MAX\_ROWS} value set for \(nt\). The setting for any partition-level \texttt{MIN\_ROWS} setting for \(p\) must also be the same any table-level \texttt{MIN\_ROWS} value set for \(nt\).

   This is true in either case whether not \(pt\) has an explicit table-level \texttt{MAX\_ROWS} or \texttt{MIN\_ROWS} option in effect.

9. The \texttt{AVG\_ROW\_LENGTH} cannot differ between the two tables \(pt\) and \(nt\).

10. \(pt\) does not have any partitions that use the \texttt{DATA\_DIRECTORY} option.

11. \texttt{INDEX\_DIRECTORY} cannot differ between the table and the partition to be exchanged with it.

12. No table or partition \texttt{TABLESPACE} options can be used in either of the tables.

   In addition to the \texttt{ALTER}, \texttt{INSERT}, and \texttt{CREATE} privileges usually required for \texttt{ALTER TABLE} statements, you must have the \texttt{DROP} privilege to perform \texttt{ALTER TABLE ... EXCHANGE PARTITION}.

   You should also be aware of the following effects of \texttt{ALTER TABLE ... EXCHANGE PARTITION}:

   - Executing \texttt{ALTER TABLE ... EXCHANGE PARTITION} does not invoke any triggers on either the partitioned table or the table to be exchanged.

   - Any \texttt{AUTO\_INCREMENT} columns in the exchanged table are reset.

   - The \texttt{IGNORE} keyword has no effect when used with \texttt{ALTER TABLE ... EXCHANGE PARTITION}.

   The complete syntax of the \texttt{ALTER TABLE ... EXCHANGE PARTITION} statement is shown here, where \(pt\) is the partitioned table, \(p\) is the partition or subpartition to be exchanged, and \(nt\) is the nonpartitioned table to be exchanged with \(p\):

\begin{verbatim}
ALTER TABLE pt
  EXCHANGE PARTITION p
WITH TABLE nt;
\end{verbatim}

One and only one partition or subpartition may be exchanged with one and only one nonpartitioned table in a single \texttt{ALTER TABLE EXCHANGE PARTITION} statement. To exchange multiple partitions or subpartitions, use multiple \texttt{ALTER TABLE EXCHANGE PARTITION} statements. \texttt{EXCHANGE PARTITION} may not be combined with other \texttt{ALTER TABLE} options. The partitioning and (if applicable) subpartitioning used by the partitioned table may be of any type or types supported in MySQL 5.6.

### Exchanging a Partition with a Nonpartitioned Table

Suppose that a partitioned table \(e\) has been created and populated using the following SQL statements:

\begin{verbatim}
CREATE TABLE e (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30)
)
PARTITION BY RANGE (id) {
  PARTITION p0 VALUES LESS THAN (50),
  PARTITION p1 VALUES LESS THAN (100),
  PARTITION p2 VALUES LESS THAN (150),
  PARTITION p3 VALUES LESS THAN (MAXVALUE)
};

INSERT INTO e VALUES
  (1669, "Jim", "Smith"),
  (337, "Mary", "Jones"),
  (16, "Frank", "White"),
  (2005, "Linda", "Black");
\end{verbatim}
Now we create a nonpartitioned copy of `e` named `e2`. This can be done using the `mysql` client as shown here:

```
mysql> CREATE TABLE e2 LIKE e;
Query OK, 0 rows affected (1.34 sec)
mysql> ALTER TABLE e2 REMOVE PARTITIONING;
Query OK, 0 rows affected (0.90 sec)
```

You can see which partitions in table `e` contain rows by querying the `INFORMATION_SCHEMA.PARTITIONS` table, like this:

```
mysql> SELECT PARTITION_NAME, TABLE_ROWS
  ->   FROM INFORMATION_SCHEMA.PARTITIONS
  ->   WHERE TABLE_NAME = 'e';
+------------+-----+
| PARTITION_NAME | TABLE_ROWS |
+------------+-----+
| p0         | 1   |
| p1         | 0   |
| p2         | 0   |
| p3         | 3   |
+------------+-----+
4 rows in set (0.00 sec)
```

**Note**

For partitioned InnoDB tables, the row count given in the `TABLE_ROWS` column of the `INFORMATION_SCHEMA.PARTITIONS` table is only an estimated value used in SQL optimization, and is not always exact.

To exchange partition `p0` in table `e` with table `e2`, you can use the `ALTER TABLE` statement shown here:

```
mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e2;
Query OK, 0 rows affected (0.28 sec)
```

More precisely, the statement just issued causes any rows found in the partition to be swapped with those found in the table. You can observe how this has happened by querying the `INFORMATION_SCHEMA.PARTITIONS` table, as before. The table row that was previously found in partition `p0` is no longer present:

```
mysql> SELECT PARTITION_NAME, TABLE_ROWS
  ->   FROM INFORMATION_SCHEMA.PARTITIONS
  ->   WHERE TABLE_NAME = 'e';
+------------+-----+
| PARTITION_NAME | TABLE_ROWS |
+------------+-----+
| p0         | 0   |
| p1         | 0   |
| p2         | 0   |
| p3         | 3   |
+------------+-----+
4 rows in set (0.00 sec)
```

If you query table `e2`, you can see that the “missing” row can now be found there:

```
mysql> SELECT * FROM e2;
+----+-------+-------+
| id | fname | lname |
+----+-------+-------+
| 16 | Frank | White |
+----+-------+-------+
1 row in set (0.00 sec)
```
Exchanging Partitions and Subpartitions with Tables

The table to be exchanged with the partition does not necessarily have to be empty. To demonstrate this, we first insert a new row into table e, making sure that this row is stored in partition p0 by choosing an id column value that is less than 50, and verifying this afterward by querying the PARTITIONS table:

```
mysql> INSERT INTO e VALUES (41, "Michael", "Green");
Query OK, 1 row affected (0.05 sec)
```

```
mysql> SELECT PARTITION_NAME, TABLE_ROWS
-> FROM INFORMATION_SCHEMA.PARTITIONS
-> WHERE TABLE_NAME = 'e';
+----------------+------------+
| PARTITION_NAME | TABLE_ROWS |
|----------------+------------|
| p0             |          1 |
| p1             |          0 |
| p2             |          0 |
| p3             |          3 |
+----------------+------------+
4 rows in set (0.00 sec)
```

Now we once again exchange partition p0 with table e2 using the same ALTER TABLE statement as previously:

```
mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e2;
Query OK, 0 rows affected (0.28 sec)
```

The output of the following queries shows that the table row that was stored in partition p0 and the table row that was stored in table e2, prior to issuing the ALTER TABLE statement, have now switched places:

```
mysql> SELECT * FROM e;
+------+-------+-------+
<table>
<thead>
<tr>
<th>id</th>
<th>fname</th>
<th>lname</th>
</tr>
</thead>
<tbody>
<tr>
<td>16</td>
<td>Frank</td>
<td>White</td>
</tr>
<tr>
<td>1669</td>
<td>Jim</td>
<td>Smith</td>
</tr>
<tr>
<td>337</td>
<td>Mary</td>
<td>Jones</td>
</tr>
<tr>
<td>2005</td>
<td>Linda</td>
<td>Black</td>
</tr>
</tbody>
</table>
+------+-------+-------+
4 rows in set (0.00 sec)
```

```
mysql> SELECT PARTITION_NAME, TABLE_ROWS
-> FROM INFORMATION_SCHEMA.PARTITIONS
-> WHERE TABLE_NAME = 'e';
+----------------+------------+
| PARTITION_NAME | TABLE_ROWS |
|----------------+------------|
| p0             |          1 |
| p1             |          0 |
| p2             |          0 |
| p3             |          3 |
+----------------+------------+
4 rows in set (0.00 sec)
```

```
mysql> SELECT * FROM e2;
+----+---------+-------+
<table>
<thead>
<tr>
<th>id</th>
<th>fname</th>
<th>lname</th>
</tr>
</thead>
<tbody>
<tr>
<td>41</td>
<td>Michael</td>
<td>Green</td>
</tr>
</tbody>
</table>
+----+---------+-------+
1 row in set (0.00 sec)
```

Non-Matching Rows

You should keep in mind that any rows found in the nonpartitioned table prior to issuing the ALTER TABLE ... EXCHANGE PARTITION statement must meet the conditions required for them to be stored
Exchanging Partitions and Subpartitions with Tables

in the target partition; otherwise, the statement fails. To see how this occurs, first insert a row into `e2` that is outside the boundaries of the partition definition for partition `p0` of table `e`. For example, insert a row with an `id` column value that is too large; then, try to exchange the table with the partition again:

```sql
mysql> INSERT INTO e2 VALUES (51, "Ellen", "McDonald");
Query OK, 1 row affected (0.08 sec)

mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e2;
ERROR 1707 (HY000): Found row that does not match the partition
```

The `IGNORE` keyword is accepted, but has no effect when used with `EXCHANGE PARTITION`, as shown here:

```sql
mysql> ALTER IGNORE TABLE e EXCHANGE PARTITION p0 WITH TABLE e2;
ERROR 1707 (HY000): Found row that does not match the partition
```

Exchanging a Subpartition with a Nonpartitioned Table

You can also exchange a subpartition of a subpartitioned table (see Section 19.2.6, “Subpartitioning”) with a nonpartitioned table using an `ALTER TABLE ... EXCHANGE PARTITION` statement. In the following example, we first create a table `es` that is partitioned by `RANGE` and subpartitioned by `KEY`, populate this table as we did table `e`, and then create an empty, nonpartitioned copy `es2` of the table, as shown here:

```sql
mysql> CREATE TABLE es (-> id INT NOT NULL,-> fname VARCHAR(30),-> lname VARCHAR(30)->)
-> PARTITION BY RANGE (id)
-> SUBPARTITION BY KEY (lname)
-> SUBPARTITIONS 2 (-> PARTITION p0 VALUES LESS THAN (50),-> PARTITION p1 VALUES LESS THAN (100),-> PARTITION p2 VALUES LESS THAN (150),-> PARTITION p3 VALUES LESS THAN (MAXVALUE) ->);
Query OK, 0 rows affected (2.76 sec)

mysql> INSERT INTO es VALUES
-> (1669, "Jim", "Smith"),
-> (337, "Mary", "Jones"),
-> (16, "Frank", "White"),
-> (2005, "Linda", "Black");
Query OK, 4 rows affected (0.04 sec)
Records: 4  Duplicates: 0  Warnings: 0

mysql> CREATE TABLE es2 LIKE es;
Query OK, 0 rows affected (1.27 sec)

mysql> ALTER TABLE es2 REMOVE PARTITIONING;
Query OK, 0 rows affected (0.70 sec)
Records: 0  Duplicates: 0  Warnings: 0

Although we did not explicitly name any of the subpartitions when creating table `es`, we can obtain generated names for these by including the `SUBPARTITION_NAME` of the `PARTITIONS` table from `INFORMATION_SCHEMA` when selecting from that table, as shown here:

```sql
mysql> SELECT PARTITION_NAME, SUBPARTITION_NAME, TABLE_ROWS
-> FROM INFORMATION_SCHEMA.PARTITIONS
-> WHERE TABLE_NAME = 'es';
```

```sql
<table>
<thead>
<tr>
<th>PARTITION_NAME</th>
<th>SUBPARTITION_NAME</th>
<th>TABLE_ROWS</th>
</tr>
</thead>
<tbody>
<tr>
<td>p0</td>
<td>p0sp0</td>
<td>1</td>
</tr>
</tbody>
</table>
```
The following `ALTER TABLE` statement exchanges subpartition `p3sp0` table `es` with the nonpartitioned table `es2`:

```sql
mysql> ALTER TABLE es EXCHANGE PARTITION p3sp0 WITH TABLE es2;
Query OK, 0 rows affected (0.29 sec)
```

You can verify that the rows were exchanged by issuing the following queries:

```sql
mysql> SELECT PARTITION_NAME, SUBPARTITION_NAME, TABLE_ROWS
            FROM INFORMATION_SCHEMA.PARTITIONS
            WHERE TABLE_NAME = 'es';
```

If a table is subpartitioned, you can exchange only a subpartition of the table—not an entire partition—with an unpartitioned table, as shown here:

```sql
mysql> ALTER TABLE es EXCHANGE PARTITION p3 WITH TABLE es2;
ERROR 1704 (HY000): Subpartitioned table, use subpartition instead of partition
```

The comparison of table structures used by MySQL is very strict. The number, order, names, and types of columns and indexes of the partitioned table and the nonpartitioned table must match exactly. In addition, both tables must use the same storage engine:

```sql
mysql> CREATE TABLE es3 LIKE e;
Query OK, 0 rows affected (1.31 sec)
mysql> ALTER TABLE es3 REMOVE PARTITIONING;
Query OK, 0 rows affected (0.53 sec)
Records: 0  Duplicates: 0  Warnings: 0
mysql> SHOW CREATE TABLE es3\G
*************************** 1. row ***************************
Table: es3
Create Table: CREATE TABLE 'es3' {
```
19.3.4 Maintenance of Partitions

A number of table and partition maintenance tasks can be carried out using SQL statements intended for such purposes on partitioned tables in MySQL 5.6.

Table maintenance of partitioned tables can be accomplished using the statements `CHECK TABLE`, `OPTIMIZE TABLE`, `ANALYZE TABLE`, and `REPAIR TABLE`, which are supported for partitioned tables.

You can use a number of extensions to `ALTER TABLE` for performing operations of this type on one or more partitions directly, as described in the following list:

- **Rebuilding partitions.** Rebuilds the partition; this has the same effect as dropping all records stored in the partition, then reinserting them. This can be useful for purposes of defragmentation.

  Example:

  ```
  ALTER TABLE t1 REBUILD PARTITION p0, p1;
  ```

- **Optimizing partitions.** If you have deleted a large number of rows from a partition or if you have made many changes to a partitioned table with variable-length rows (that is, having `VARCHAR`, `BLOB`, or `TEXT` columns), you can use `ALTER TABLE ... OPTIMIZE PARTITION` to reclaim any unused space and to defragment the partition data file.

  Example:

  ```
  ALTER TABLE t1 OPTIMIZE PARTITION p0, p1;
  ```

  Using `OPTIMIZE PARTITION` on a given partition is equivalent to running `CHECK PARTITION`, `ANALYZE PARTITION`, and `REPAIR PARTITION` on that partition.

  Some MySQL storage engines, including `InnoDB`, do not support per-partition optimization; in these cases, `ALTER TABLE ... OPTIMIZE PARTITION` rebuilds the entire table. In MySQL 5.6.9 and later, running this statement on such a table causes the entire table to rebuilt and analyzed, and an appropriate warning to be issued. (Bug #11751825, Bug #42822) Use `ALTER TABLE ... REBUILD PARTITION` and `ALTER TABLE ... ANALYZE PARTITION` instead, to avoid this issue.

- **Analyzing partitions.** This reads and stores the key distributions for partitions.

  Example:

  ```
  ALTER TABLE t1 ANALYZE PARTITION p3;
  ```

- **Repairing partitions.** This repairs corrupted partitions.

  Example:

  ```
  ALTER TABLE t1 REPAIR PARTITION p0,p1;
  ```
• **Checking partitions.** You can check partitions for errors in much the same way that you can use `CHECK TABLE` with nonpartitioned tables.

**Example:**

```
ALTER TABLE trb3 CHECK PARTITION p1;
```

This command tells you if the data or indexes in partition `p1` of table `t1` are corrupted. If this is the case, use `ALTER TABLE ... REPAIR PARTITION` to repair the partition.

Each of the statements in the list just shown also supports the keyword `ALL` in place of the list of partition names. Using `ALL` causes the statement to act on all partitions in the table.

The use of `mysqlcheck` and `myisamchk` is not supported with partitioned tables.

In MySQL 5.6, you can also truncate partitions using `ALTER TABLE ... TRUNCATE PARTITION`. This statement can be used to delete all rows from one or more partitions in much the same way that `TRUNCATE TABLE` deletes all rows from a table.

```
ALTER TABLE ... TRUNCATE PARTITION ALL truncates all partitions in the table.
```

`ANALYZE, CHECK, OPTIMIZE, REBUILD, REPAIR, and TRUNCATE` operations are not supported for subpartitions.

### 19.3.5 Obtaining Information About Partitions

This section discusses obtaining information about existing partitions, which can be done in a number of ways. Methods of obtaining such information include the following:

- Using the `SHOW CREATE TABLE` statement to view the partitioning clauses used in creating a partitioned table.
- Using the `SHOW TABLE STATUS` statement to determine whether a table is partitioned.
- Querying the `INFORMATION_SCHEMA.PARTITIONS` table.
- Using the statement `EXPLAIN PARTITIONS SELECT` to see which partitions are used by a given `SELECT`.

As discussed elsewhere in this chapter, `SHOW CREATE TABLE` includes in its output the `PARTITION BY` clause used to create a partitioned table. For example:

```
mysql> SHOW CREATE TABLE trb3"G
*************************** 1. row ***************************
Table: trb3
Create Table: CREATE TABLE `trb3` (  `id` int(11) default NULL,  `name` varchar(50) default NULL,  `purchased` date default NULL ) ENGINE=MyISAM DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```

The output from `SHOW TABLE STATUS` for partitioned tables is the same as that for nonpartitioned tables, except that the `Create_options` column contains the string `partitioned`. The `Engine` column
Obtaining Information About Partitions

contains the name of the storage engine used by all partitions of the table. (See Section 13.7.5.37, “SHOW TABLE STATUS Statement”, for more information about this statement.)

You can also obtain information about partitions from INFORMATION_SCHEMA, which contains a PARTITIONS table. See Section 21.3.14, “The INFORMATION_SCHEMA PARTITIONS Table”.

It is possible to determine which partitions of a partitioned table are involved in a given SELECT query using EXPLAIN PARTITIONS. The PARTITIONS keyword adds a partitions column to the output of EXPLAIN listing the partitions from which records would be matched by the query.

Suppose that you have a table trb1 created and populated as follows:

```sql
CREATE TABLE trb1 (id INT, name VARCHAR(50), purchased DATE)
    PARTITION BY RANGE(id)
    {
        PARTITION p0 VALUES LESS THAN (3),
        PARTITION p1 VALUES LESS THAN (7),
        PARTITION p2 VALUES LESS THAN (9),
        PARTITION p3 VALUES LESS THAN (11)
    }
;
INSERT INTO trb1 VALUES
    (1, 'desk organiser', '2003-10-15'),
    (2, 'CD player', '1993-11-05'),
    (3, 'TV set', '1996-03-10'),
    (4, 'bookcase', '1982-01-10'),
    (5, 'exercise bike', '2004-05-09'),
    (6, 'sofa', '1987-06-05'),
    (7, 'popcorn maker', '2001-11-22'),
    (8, 'aquarium', '1992-08-04'),
    (9, 'study desk', '1984-09-16'),
    (10, 'lava lamp', '1998-12-25');
```

You can see which partitions are used in a query such as SELECT * FROM trb1, as shown here:

```sql
mysql> EXPLAIN PARTITIONS SELECT * FROM trb1
*************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: trb1
partitions: p0,p1,p2,p3
type: ALL
possible_keys: NULL
key: NULL
key_len: NULL
ref: NULL
rows: 10
Extra: Using filesort
```

In this case, all four partitions are searched. However, when a limiting condition making use of the partitioning key is added to the query, you can see that only those partitions containing matching values are scanned, as shown here:

```sql
mysql> EXPLAIN PARTITIONS SELECT * FROM trb1 WHERE id < 5
*************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: trb1
partitions: p0,p1
key: NULL
key_len: NULL
ref: NULL
rows: 10
```
**Extra: Using where**

**EXPLAIN PARTITIONS** provides information about keys used and possible keys, just as with the standard **EXPLAIN SELECT** statement:

```sql
mysql> ALTER TABLE trb1 ADD PRIMARY KEY (id);
Query OK, 10 rows affected (0.03 sec)
Records: 10  Duplicates: 0  Warnings: 0

mysql> EXPLAIN PARTITIONS SELECT * FROM trb1 WHERE id < 5\G
*************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: trb1
partitions: p0,p1
type: range
possible_keys: PRIMARY
key: PRIMARY
key_len: 4
ref: NULL
rows: 7
Extra: Using where
```

You should take note of the following restrictions and limitations on **EXPLAIN PARTITIONS**:

- You cannot use the **PARTITIONS** and **EXTENDED** keywords together in the same **EXPLAIN ... SELECT** statement. Attempting to do so produces a syntax error.

- If **EXPLAIN PARTITIONS** is used to examine a query against a nonpartitioned table, no error is produced, but the value of the **partitions** column is always **NULL**.

The **rows** column of **EXPLAIN PARTITIONS** output displays the total number of rows in the table.

See also Section 13.8.2, “EXPLAIN Statement”.

### 19.4 Partition Pruning

This section discusses an optimization known as **partition pruning**. The core concept behind partition pruning is relatively simple, and can be described as “Do not scan partitions where there can be no matching values”. Suppose that you have a partitioned table `t1` defined by this statement:

```sql
CREATE TABLE t1 (
    fname VARCHAR(50) NOT NULL,
    lname VARCHAR(50) NOT NULL,
    region_code TINYINT UNSIGNED NOT NULL,
    dob DATE NOT NULL
) PARTITION BY RANGE( region_code ) (
    PARTITION p0 VALUES LESS THAN (64),
    PARTITION p1 VALUES LESS THAN (128),
    PARTITION p2 VALUES LESS THAN (192),
    PARTITION p3 VALUES LESS THAN MAXVALUE
);
```

Consider the case where you wish to obtain results from a **SELECT** statement such as this one:

```sql
SELECT fname, lname, region_code, dob
FROM t1
WHERE region_code > 125 AND region_code < 130;
```

It is easy to see that none of the rows which ought to be returned are in either of the partitions `p0` or `p3`; that is, we need to search only in partitions `p1` and `p2` to find matching rows. By doing so, it is possible to expend much less time and effort in finding matching rows than would be required to scan all partitions in
Partition Pruning

the table. This “cutting away” of unneeded partitions is known as pruning. When the optimizer can make use of partition pruning in performing this query, execution of the query can be an order of magnitude faster than the same query against a nonpartitioned table containing the same column definitions and data.

Note

When pruning is performed on a partitioned MyISAM table, all partitions are opened, whether or not they are examined, due to the design of the MyISAM storage engine. This means that you must have a sufficient number of file descriptors available to cover all partitions of the table. See MyISAM and partition file descriptor usage. This limitation does not apply to partitioned tables using other MySQL storage engines such as InnoDB.

The optimizer can perform pruning whenever a WHERE condition can be reduced to either one of the following two cases:

- \( \text{partition}_\text{column} = \text{constant} \)
- \( \text{partition}_\text{column} \in (\text{constant}_1, \text{constant}_2, \ldots, \text{constant}_N) \)

In the first case, the optimizer simply evaluates the partitioning expression for the value given, determines which partition contains that value, and scans only this partition. In many cases, the equal sign can be replaced with another arithmetic comparison, including <, >, <=, >=, and <>. Some queries using BETWEEN in the WHERE clause can also take advantage of partition pruning. See the examples later in this section.

In the second case, the optimizer evaluates the partitioning expression for each value in the list, creates a list of matching partitions, and then scans only the partitions in this partition list.

MySQL can apply partition pruning to SELECT, DELETE, and UPDATE statements. An INSERT statement also accesses only one partition per inserted row; this is true even for a table that is partitioned by HASH or KEY although this is not currently shown in the output of EXPLAIN.

Pruning can also be applied to short ranges, which the optimizer can convert into equivalent lists of values. For instance, in the previous example, the WHERE clause can be converted to WHERE region_code IN (126, 127, 128, 129). Then the optimizer can determine that the first two values in the list are found in partition p1, the remaining two values in partition p2, and that the other partitions contain no relevant values and so do not need to be searched for matching rows.

In MySQL 5.6, the optimizer can also perform pruning for WHERE conditions that involve comparisons of the preceding types on multiple columns for tables that use RANGE_COLUMNS or LIST_COLUMNS partitioning.

This type of optimization can be applied whenever the partitioning expression consists of an equality or a range which can be reduced to a set of equalities, or when the partitioning expression represents an increasing or decreasing relationship. Pruning can also be applied for tables partitioned on a DATE or DATETIME column when the partitioning expression uses the YEAR() or TO_DAYS() function. In addition, in MySQL 5.6, pruning can be applied for such tables when the partitioning expression uses the TO_SECONDS() function.

Suppose that table t2, defined as shown here, is partitioned on a DATE column:

```sql
CREATE TABLE t2 (
    fname VARCHAR(50) NOT NULL,
    lname VARCHAR(50) NOT NULL,
    region_code TINYINT UNSIGNED NOT NULL,
    dob DATE NOT NULL
) PARTITION BY RANGE( YEAR(dob) ) (  
    PARTITION d0 VALUES LESS THAN (1970),
```
Partition Pruning

PARTITION d1 VALUES LESS THAN (1975),
PARTITION d2 VALUES LESS THAN (1980),
PARTITION d3 VALUES LESS THAN (1985),
PARTITION d4 VALUES LESS THAN (1990),
PARTITION d5 VALUES LESS THAN (2000),
PARTITION d6 VALUES LESS THAN (2005),
PARTITION d7 VALUES LESS THAN MAXVALUE
);

The following statements using \( t_2 \) can make use of partition pruning:

```sql
SELECT * FROM t2 WHERE dob = '1982-06-23';
UPDATE t2 SET region_code = 8 WHERE dob BETWEEN '1991-02-15' AND '1997-04-25';
DELETE FROM t2 WHERE dob >= '1984-06-21' AND dob <= '1999-06-21'
```

In the case of the last statement, the optimizer can also act as follows:

1. Find the partition containing the low end of the range.
   
   `YEAR('1984-06-21')` yields the value 1984, which is found in partition \( d_3 \).

2. Find the partition containing the high end of the range.
   
   `YEAR('1999-06-21')` evaluates to 1999, which is found in partition \( d_5 \).

3. Scan only these two partitions and any partitions that may lie between them.

   In this case, this means that only partitions \( d_3, d_4, \) and \( d_5 \) are scanned. The remaining partitions may be safely ignored (and are ignored).

**Important**

Invalid `DATE` and `DATETIME` values referenced in the `WHERE` condition of a statement against a partitioned table are treated as `NULL`. This means that a query such as `SELECT * FROM partitioned_table WHERE date_column < '2008-12-00'` does not return any values (see Bug #40972).

So far, we have looked only at examples using `RANGE` partitioning, but pruning can be applied with other partitioning types as well.

Consider a table that is partitioned by `LIST`, where the partitioning expression is increasing or decreasing, such as the table \( t_3 \) shown here. (In this example, we assume for the sake of brevity that the `region_code` column is limited to values between 1 and 10 inclusive.)

```sql
CREATE TABLE t3 (  
    fname VARCHAR(50) NOT NULL,  
    lname VARCHAR(50) NOT NULL,  
    region_code TINYINT UNSIGNED NOT NULL,  
    dob DATE NOT NULL  
)  
PARTITION BY LIST(region_code) (  
    PARTITION r0 VALUES IN (1, 3),  
    PARTITION r1 VALUES IN (2, 5, 8),  
    PARTITION r2 VALUES IN (4, 9),  
    PARTITION r3 VALUES IN (6, 7, 10)  
);

For a statement such as `SELECT * FROM t3 WHERE region_code BETWEEN 1 AND 3`, the optimizer determines in which partitions the values 1, 2, and 3 are found (\( r_0 \) and \( r_1 \)) and skips the remaining ones (\( r_2 \) and \( r_3 \)).
For tables that are partitioned by `HASH` or `[LINEAR] KEY`, partition pruning is also possible in cases in which the `WHERE` clause uses a simple `=` relation against a column used in the partitioning expression. Consider a table created like this:

```sql
CREATE TABLE t4 (
    fname VARCHAR(50) NOT NULL,
    lname VARCHAR(50) NOT NULL,
    region_code TINYINT UNSIGNED NOT NULL,
    dob DATE NOT NULL
) PARTITION BY KEY(region_code)
PARTITIONS 8;
```

A statement that compares a column value with a constant can be pruned:

```
UPDATE t4 WHERE region_code = 7;
```

Pruning can also be employed for short ranges, because the optimizer can turn such conditions into `IN` relations. For example, using the same table `t4` as defined previously, queries such as these can be pruned:

```sql
SELECT * FROM t4 WHERE region_code > 2 AND region_code < 6;
SELECT * FROM t4 WHERE region_code BETWEEN 3 AND 5;
```

In both these cases, the `WHERE` clause is transformed by the optimizer into `WHERE region_code IN (3, 4, 5)`.

**Important**

This optimization is used only if the range size is smaller than the number of partitions. Consider this statement:

```sql
DELETE FROM t4 WHERE region_code BETWEEN 4 AND 12;
```

The range in the `WHERE` clause covers 9 values (4, 5, 6, 7, 8, 9, 10, 11, 12), but `t4` has only 8 partitions. This means that the `DELETE` cannot be pruned.

When a table is partitioned by `HASH` or `[LINEAR] KEY`, pruning can be used only on integer columns. For example, this statement cannot use pruning because `dob` is a `DATE` column:

```sql
SELECT * FROM t4 WHERE dob >= '2001-04-14' AND dob <= '2005-10-15';
```

However, if the table stores year values in an `INT` column, then a query having `WHERE year_col >= 2001 AND year_col <= 2005` can be pruned.

In MySQL 5.6.8 and later, partition pruning is disabled for all tables using a storage engine that provides automatic partitioning, such as the `NDB` storage engine used by NDB Cluster. (Bug #14672885) Beginning with MySQL 5.6.10, such tables can be pruned if they are explicitly partitioned. (Bug #14827952)

### 19.5 Partition Selection

MySQL 5.6 supports explicit selection of partitions and subpartitions that, when executing a statement, should be checked for rows matching a given `WHERE` condition. Partition selection is similar to partition pruning, in that only specific partitions are checked for matches, but differs in two key respects:

1. The partitions to be checked are specified by the issuer of the statement, unlike partition pruning, which is automatic.
2. Whereas partition pruning applies only to queries, explicit selection of partitions is supported for both queries and a number of DML statements.

SQL statements supporting explicit partition selection are listed here:

- SELECT
- DELETE
- INSERT
- REPLACE
- UPDATE
- LOAD DATA.
- LOAD XML.

The remainder of this section discusses explicit partition selection as it applies generally to the statements just listed, and provides some examples.

Explicit partition selection is implemented using a PARTITION option. For all supported statements, this option uses the syntax shown here:

```
PARTITION (partition_names)
partition_names:
    partition_name, ...
```

This option always follows the name of the table to which the partition or partitions belong. `partition_names` is a comma-separated list of partitions or subpartitions to be used. Each name in this list must be the name of an existing partition or subpartition of the specified table; if any of the partitions or subpartitions are not found, the statement fails with an error (`partition 'partition_name' doesn't exist`). Partitions and subpartitions named in `partition_names` may be listed in any order, and may overlap.

When the PARTITION option is used, only the partitions and subpartitions listed are checked for matching rows. This option can be used in a SELECT statement to determine which rows belong to a given partition. Consider a partitioned table named `employees`, created and populated using the statements shown here:

```
SET @SQL_MODE = '';

CREATE TABLE employees  (
    id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    fname VARCHAR(25) NOT NULL,
    lname VARCHAR(25) NOT NULL,
    store_id INT NOT NULL,
    department_id INT NOT NULL
) PARTITION BY RANGE(id)  {
    PARTITION p0 VALUES LESS THAN (5),
    PARTITION p1 VALUES LESS THAN (10),
    PARTITION p2 VALUES LESS THAN (15),
    PARTITION p3 VALUES LESS THAN MAXVALUE
};

INSERT INTO employees VALUES
('', 'Bob', 'Taylor', 3, 2), ('', 'Frank', 'Williams', 1, 2),
('', 'Ellen', 'Johnson', 3, 4), ('', 'Jim', 'Smith', 2, 4),
('', 'Mary', 'Jones', 1, 1), ('', 'Linda', 'Black', 2, 3),
```
You can see which rows are stored in partition \texttt{p1} like this:

```
mysql> SELECT * FROM employees PARTITION (p1);
```

The result is the same as obtained by the query `SELECT * FROM employees WHERE id BETWEEN 5 AND 9`.

To obtain rows from multiple partitions, supply their names as a comma-delimited list. For example, `SELECT * FROM employees PARTITION (p1, p2)` returns all rows from partitions \texttt{p1} and \texttt{p2} while excluding rows from the remaining partitions.

Any valid query against a partitioned table can be rewritten with a PARTITION option to restrict the result to one or more desired partitions. You can use WHERE conditions, ORDER BY and LIMIT options, and so on. You can also use aggregate functions with HAVING and GROUP BY options. Each of the following queries produces a valid result when run on the \texttt{employees} table as previously defined:

```
mysql> SELECT * FROM employees PARTITION (p0, p2) WHERE lname LIKE 'S%';
```

```
mysql> SELECT id, CONCAT(fname, ' ', lname) AS name FROM employees PARTITION (p0) ORDER BY lname;
```

```
mysql> SELECT store_id, COUNT(department_id) AS c FROM employees PARTITION (p1, p2, p3) GROUP BY store_id HAVING c > 4;
```

```
| c | store_id |
|---+----------|
| 5 | 2        |
| 5 | 3        |
```
Partition Selection

Statements using partition selection can be employed with tables using any of the partitioning types supported in MySQL 5.6. When a table is created using \texttt{[LINEAR] HASH} or \texttt{[LINEAR] KEY} partitioning and the names of the partitions are not specified, MySQL automatically names the partitions $p_0, p_1, p_2, \ldots, p_{N-1}$, where $N$ is the number of partitions. For subpartitions not explicitly named, MySQL assigns automatically to the subpartitions in each partition $p_X$ the names $p_{Xsp0}, p_{Xsp1}, p_{Xsp2}, \ldots, p_{XspM-1}$, where $M$ is the number of subpartitions. When executing against this table a \texttt{SELECT} (or other SQL statement for which explicit partition selection is allowed), you can use these generated names in a \texttt{PARTITION} option, as shown here:

```sql
mysql> CREATE TABLE employees_sub (
  -> id INT NOT NULL AUTO_INCREMENT,
  -> fname VARCHAR(25) NOT NULL,
  -> lname VARCHAR(25) NOT NULL,
  -> store_id INT NOT NULL,
  -> department_id INT NOT NULL,
  -> PRIMARY KEY pk (id, lname)
  -> )
  -> PARTITION BY RANGE(id)
  -> SUBPARTITION BY KEY (lname)
  -> SUBPARTITIONS 2 (
  -> PARTITION p0 VALUES LESS THAN (5),
  -> PARTITION p1 VALUES LESS THAN (10),
  -> PARTITION p2 VALUES LESS THAN (15),
  -> PARTITION p3 VALUES LESS THAN MAXVALUE
  -> );
```

You may also use a \texttt{PARTITION} option in the \texttt{SELECT} portion of an \texttt{INSERT ... SELECT} statement, as shown here:

```sql
mysql> CREATE TABLE employees_copy LIKE employees;
Query OK, 0 rows affected (0.28 sec)

mysql> INSERT INTO employees_copy
  -> SELECT * FROM employees PARTITION (p2);
Query OK, 5 rows affected (0.04 sec)
Records: 5  Duplicates: 0  Warnings: 0

mysql> SELECT * FROM employees_copy;
+----+--------+----------+----------+---------------+
<table>
<thead>
<tr>
<th>id</th>
<th>fname</th>
<th>lname</th>
<th>store_id</th>
<th>department_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>Lou</td>
<td>Waters</td>
<td>2</td>
<td>4</td>
</tr>
<tr>
<td>11</td>
<td>Jill</td>
<td>Stone</td>
<td>1</td>
<td>4</td>
</tr>
<tr>
<td>12</td>
<td>Roger</td>
<td>White</td>
<td>3</td>
<td>2</td>
</tr>
<tr>
<td>13</td>
<td>Howard</td>
<td>Andrews</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>14</td>
<td>Fred</td>
<td>Goldberg</td>
<td>3</td>
<td>3</td>
</tr>
</tbody>
</table>
+----+--------+----------+----------+---------------+
```

You may also use a \texttt{PARTITION} option in the \texttt{SELECT} portion of an \texttt{INSERT ... SELECT} statement, as shown here:

```sql
mysql> CREATE TABLE employees_copy LIKE employees;
Query OK, 0 rows affected (0.28 sec)

mysql> INSERT INTO employees_copy
  -> SELECT * FROM employees PARTITION (p2);
Query OK, 5 rows affected (0.04 sec)
Records: 5  Duplicates: 0  Warnings: 0

mysql> SELECT * FROM employees_copy;
+----+--------+----------+----------+---------------+
<table>
<thead>
<tr>
<th>id</th>
<th>fname</th>
<th>lname</th>
<th>store_id</th>
<th>department_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>Lou</td>
<td>Waters</td>
<td>2</td>
<td>4</td>
</tr>
<tr>
<td>11</td>
<td>Jill</td>
<td>Stone</td>
<td>1</td>
<td>4</td>
</tr>
<tr>
<td>12</td>
<td>Roger</td>
<td>White</td>
<td>3</td>
<td>2</td>
</tr>
<tr>
<td>13</td>
<td>Howard</td>
<td>Andrews</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>14</td>
<td>Fred</td>
<td>Goldberg</td>
<td>3</td>
<td>3</td>
</tr>
</tbody>
</table>
+----+--------+----------+----------+---------------+
```
Partition selection can also be used with joins. Suppose we create and populate two tables using the statements shown here:

```sql
CREATE TABLE stores (  
id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,  
city VARCHAR(30) NOT NULL  
)  
PARTITION BY HASH(id)  
PARTITIONS 2;
```

```sql
INSERT INTO stores VALUES  
('', 'Nambucca'), ('', 'Uranga'),  
('', 'Bellingen'), ('', 'Grafton');
```

```sql
CREATE TABLE departments  
(id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,  
name VARCHAR(30) NOT NULL  
)  
PARTITION BY KEY(id)  
PARTITIONS 2;
```

```sql
INSERT INTO departments VALUES  
('', 'Sales'), ('', 'Customer Service'),  
('', 'Delivery'), ('', 'Accounting');
```

You can explicitly select partitions (or subpartitions, or both) from any or all of the tables in a join. (The PARTITION option used to select partitions from a given table immediately follows the name of the table, before all other options, including any table alias.) For example, the following query gets the name, employee ID, department, and city of all employees who work in the Sales or Delivery department (partition p1 of the departments table) at the stores in either of the cities of Nambucca and Bellingen (partition p0 of the stores table):

```sql
mysql> SELECT  
>     e.id AS 'Employee ID', CONCAT(e.fname, ' ', e.lname) AS Name,  
>     s.city AS City, d.name AS department  
> FROM employees AS e  
>     JOIN stores PARTITION (p1) AS s ON e.store_id=s.id  
>     JOIN departments PARTITION (p0) AS d ON e.department_id=d.id  
> ORDER BY e.lname;
```

```plaintext
+-------------+---------------+-----------+------------+
<table>
<thead>
<tr>
<th>Employee ID</th>
<th>Name</th>
<th>City</th>
<th>department</th>
</tr>
</thead>
<tbody>
<tr>
<td>14</td>
<td>Fred Goldberg</td>
<td>Bellingen</td>
<td>Delivery</td>
</tr>
<tr>
<td>5</td>
<td>Mary Jones</td>
<td>Nambucca</td>
<td>Sales</td>
</tr>
<tr>
<td>17</td>
<td>Mark Morgan</td>
<td>Bellingen</td>
<td>Delivery</td>
</tr>
<tr>
<td>9</td>
<td>Andy Smith</td>
<td>Nambucca</td>
<td>Delivery</td>
</tr>
<tr>
<td>8</td>
<td>June Wilson</td>
<td>Bellingen</td>
<td>Sales</td>
</tr>
</tbody>
</table>
+-------------+---------------+-----------+------------+
```

For general information about joins in MySQL, see Section 13.2.9.2, “JOIN Clause”.

When the PARTITION option is used with DELETE statements, only those partitions (and subpartitions, if any) listed with the option are checked for rows to be deleted. Any other partitions are ignored, as shown here:

```sql
mysql> SELECT * FROM employees WHERE fname LIKE 'j%';
```

```plaintext
+----+-------+--------+----------+---------------+
<table>
<thead>
<tr>
<th>id</th>
<th>fname</th>
<th>lname</th>
<th>store_id</th>
<th>department_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>Jim</td>
<td>Smith</td>
<td>2</td>
<td>4</td>
</tr>
<tr>
<td>8</td>
<td>June</td>
<td>Wilson</td>
<td>3</td>
<td>1</td>
</tr>
<tr>
<td>11</td>
<td>Jill</td>
<td>Stone</td>
<td>1</td>
<td>4</td>
</tr>
</tbody>
</table>
+----+-------+--------+----------+---------------+
```

5 rows in set (0.00 sec)
Partition Selection

Only the two rows in partitions p0 and p1 matching the WHERE condition were deleted. As you can see from the result when the SELECT is run a second time, there remains a row in the table matching the WHERE condition, but residing in a different partition (p2).

**UPDATE** statements using explicit partition selection behave in the same way; only rows in the partitions referenced by the PARTITION option are considered when determining the rows to be updated, as can be seen by executing the following statements:

```sql
mysql> UPDATE employees PARTITION (p0) 
  -> SET store_id = 2 WHERE fname = 'Jill';
Query OK, 0 rows affected (0.00 sec)
Rows matched: 0  Changed: 0  Warnings: 0

mysql> SELECT * FROM employees WHERE fname = 'Jill';
+----+-------+-------+----------+---------------+
<table>
<thead>
<tr>
<th>id</th>
<th>fname</th>
<th>lname</th>
<th>store_id</th>
<th>department_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>Jill</td>
<td>Stone</td>
<td>1</td>
<td>4</td>
</tr>
</tbody>
</table>
+----+-------+-------+----------+---------------+
1 row in set (0.00 sec)

mysql> UPDATE employees PARTITION (p2) 
  -> SET store_id = 2 WHERE fname = 'Jill';
Query OK, 1 row affected (0.09 sec)
Rows matched: 1  Changed: 1  Warnings: 0

mysql> SELECT * FROM employees WHERE fname = 'Jill';
+----+-------+-------+----------+---------------+
<table>
<thead>
<tr>
<th>id</th>
<th>fname</th>
<th>lname</th>
<th>store_id</th>
<th>department_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>Jill</td>
<td>Stone</td>
<td>2</td>
<td>4</td>
</tr>
</tbody>
</table>
+----+-------+-------+----------+---------------+
1 row in set (0.00 sec)
```

In the same way, when **PARTITION** is used with **DELETE**, only rows in the partition or partitions named in the partition list are checked for deletion.

For statements that insert rows, the behavior differs in that failure to find a suitable partition causes the statement to fail. This is true for both **INSERT** and **REPLACE** statements, as shown here:

```sql
mysql> INSERT INTO employees PARTITION (p2) VALUES (20, 'Jan', 'Jones', 1, 3);
ERROR 1729 (HY000): Found a row not matching the given partition set

mysql> INSERT INTO employees PARTITION (p3) VALUES (20, 'Jan', 'Jones', 1, 3);
Query OK, 1 row affected (0.07 sec)

mysql> REPLACE INTO employees PARTITION (p0) VALUES (20, 'Jan', 'Jones', 3, 2);
ERROR 1729 (HY000): Found a row not matching the given partition set

mysql> REPLACE INTO employees PARTITION (p3) VALUES (20, 'Jan', 'Jones', 3, 2);
Query OK, 2 rows affected (0.09 sec)
```
Restrictions and Limitations on Partitioning

For statements that write multiple rows to a partitioned table that uses the InnoDB storage engine:
If any row in the list following VALUES cannot be written to one of the partitions specified in the partition_names list, the entire statement fails and no rows are written. This is shown for INSERT statements in the following example, reusing the employees table created previously:

```sql
mysql> ALTER TABLE employees
>    ->    REORGANIZE PARTITION p3 INTO (
>    ->    PARTITION p3 VALUES LESS THAN (20),
>    ->    PARTITION p4 VALUES LESS THAN (25),
>    ->    PARTITION p5 VALUES LESS THAN MAXVALUE
>    ->    );
Query OK, 6 rows affected (2.09 sec)
Records: 6  Duplicates: 0  Warnings: 0

mysql> SHOW CREATE TABLE employees\G
*************************** 1. row ****************************
Table: employees
Create Table: CREATE TABLE `employees` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `fname` varchar(25) NOT NULL,
  `lname` varchar(25) NOT NULL,
  `store_id` int(11) NOT NULL,
  `department_id` int(11) NOT NULL,
  PRIMARY KEY (`id`) ) ENGINE=InnoDB AUTO_INCREMENT=27 DEFAULT CHARSET=latin1
/*!50100 PARTITION BY RANGE (id)
(PARTITION p0 VALUES LESS THAN (5) ENGINE = InnoDB,
PARTITION p1 VALUES LESS THAN (10) ENGINE = InnoDB,
PARTITION p2 VALUES LESS THAN (15) ENGINE = InnoDB,
PARTITION p3 VALUES LESS THAN (20) ENGINE = InnoDB,
PARTITION p4 VALUES LESS THAN (25) ENGINE = InnoDB,
PARTITION p5 VALUES LESS THAN MAXVALUE ENGINE = InnoDB) */
1 row in set (0.00 sec)

mysql> INSERT INTO employees PARTITION (p3, p4) VALUES
>    ->    (24, 'Tim', 'Greene', 3, 1),  (26, 'Linda', 'Mills', 2, 1);
ERROR 1729 (HY000): Found a row not matching the given partition set

mysql> INSERT INTO employees PARTITION (p3, p4, p5) VALUES
>    ->    (24, 'Tim', 'Greene', 3, 1),  (26, 'Linda', 'Mills', 2, 1);
Query OK, 2 rows affected (0.06 sec)
Records: 2  Duplicates: 0  Warnings: 0
```

The preceding is true for both INSERT statements and REPLACE statements that write multiple rows.

In MySQL 5.6.10 and later, partition selection is disabled for tables employing a storage engine that supplies automatic partitioning, such as NDB. (Bug #14827952)

19.6 Restrictions and Limitations on Partitioning

This section discusses current restrictions and limitations on MySQL partitioning support.

Prohibited constructs. The following constructs are not permitted in partitioning expressions:

- Stored procedures, stored functions, loadable functions, or plugins.
- Declared variables or user variables.

For a list of SQL functions which are permitted in partitioning expressions, see Section 19.6.3, “Partitioning Limitations Relating to Functions”.

Arithmetic and logical operators. Use of the arithmetic operators +, -, and * is permitted in partitioning expressions. However, the result must be an integer value or NULL (except in the case of
Restrictions and Limitations on Partitioning

**Restrictions and Limitations on Partitioning**

- **[LINEAR] KEY** partitioning, as discussed elsewhere in this chapter; see Section 19.2, “Partitioning Types”, for more information).

- The **DIV** operator is also supported, and the **/** operator is not permitted. (Bug #30188, Bug #33182)

- The bit operators |, &, ^, <<, >>, and ~ are not permitted in partitioning expressions.

**HANDLER** statements. In MySQL 5.6, the **HANDLER** statement is not supported with partitioned tables.

**Server SQL mode.** Tables employing user-defined partitioning do not preserve the SQL mode in effect at the time that they were created. As discussed in Section 5.1.10, “Server SQL Modes”, the results of many MySQL functions and operators may change according to the server SQL mode. Therefore, a change in the SQL mode at any time after the creation of partitioned tables may lead to major changes in the behavior of such tables, and could easily lead to corruption or loss of data. For these reasons, it is strongly recommended that you never change the server SQL mode after creating partitioned tables.

**Examples.** The following examples illustrate some changes in behavior of partitioned tables due to a change in the server SQL mode:

1. **Error handling.** Suppose that you create a partitioned table whose partitioning expression is one such as **column DIV 0** or **column MOD 0**, as shown here:

   ```sql
   mysql> CREATE TABLE tn (c1 INT)
   -> PARTITION BY LIST(1 DIV c1) {
   -> PARTITION p0 VALUES IN (NULL),
   -> PARTITION p1 VALUES IN (1)
   ->);
   Query OK, 0 rows affected (0.05 sec)
   
   mysql> SELECT @@sql_mode;
   +------------+
   | @@sql_mode |
   +------------+
   |            |
   +------------+
   1 row in set (0.00 sec)
   
   mysql> INSERT INTO tn VALUES (NULL), (0), (1);
   Query OK, 3 rows affected (0.00 sec)
   Records: 3  Duplicates: 0  Warnings: 0
   
   However, changing the server SQL mode to treat division by zero as an error and to enforce strict error handling causes the same **INSERT** statement to fail, as shown here:
   
   ```sql
   mysql> SET sql_mode='STRICT_ALL_TABLES,ERROR_FOR_DIVISION_BY_ZERO';
   Query OK, 0 rows affected (0.00 sec)
   
   mysql> INSERT INTO tn VALUES (NULL), (0), (1);
   ERROR 1365 (22012): Division by 0
   ```

2. **Table accessibility.** Sometimes a change in the server SQL mode can make partitioned tables unusable. The following **CREATE TABLE** statement can be executed successfully only if the **NO_UNSIGNED_SUBTRACTION** mode is in effect:

   ```sql
   mysql> SELECT @@sql_mode;
   +------------+
   | @@sql_mode |
   +------------+
   | NO_UNSIGNED_SUBTRACTION |
   +------------+
   1 row in set (0.00 sec)
   
   mysql> SELECT * FROM tn;  # Error: Division by 0
   ```
Restrictions and Limitations on Partitioning

If you remove the **NO_UNSIGNED_SUBTRACTION** server SQL mode after creating `tu`, you may no longer be able to access this table:

```
mysql> SET sql_mode='';
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> SELECT * FROM tu;
ERROR 1563 (HY000): Partition constant is out of partition function domain
```

```
mysql> INSERT INTO tu VALUES (20);
ERROR 1563 (HY000): Partition constant is out of partition function domain
```

Server SQL modes also impact replication of partitioned tables. Differing SQL modes on source and replica can lead to partitioning expressions being evaluated differently; this can cause the distribution of data among partitions to be different in the source's and replica's copies of a given table, and may even cause inserts into partitioned tables that succeed on the source to fail on the replica. For best results, you should always use the same server SQL mode on the source and on the replica.

**Performance considerations.** Some effects of partitioning operations on performance are given in the following list:

- **File system operations.** Partitioning and repartitioning operations (such as `ALTER TABLE` with `PARTITION BY ...`, `REORGANIZE PARTITION`, or `REMOVE PARTITIONING`) depend on file system operations for their implementation. This means that the speed of these operations is affected by such factors as file system type and characteristics, disk speed, swap space, file handling efficiency of the operating system, and MySQL server options and variables that relate to file handling. In particular, you should make sure that `large_files_support` is enabled and that `open_files_limit` is set properly. For partitioned tables using the **MyISAM** storage engine, increasing
myisam_max_sort_file_size may improve performance; partitioning and repartitioning operations involving InnoDB tables may be made more efficient by enabling innodb_file_per_table.

See also Maximum number of partitions.

**MyISAM and partition file descriptor usage.**

For a partitioned MyISAM table, MySQL uses 2 file descriptors for each partition, for each such table that is open. This means that you need many more file descriptors to perform operations on a partitioned MyISAM table than on a table which is identical to it except that the latter table is not partitioned, particularly when performing ALTER TABLE operations.

Assume a MyISAM table t with 100 partitions, such as the table created by this SQL statement:

```sql
CREATE TABLE t (c1 VARCHAR(50))
PARTITION BY KEY (c1) PARTITIONS 100
ENGINE=MYISAM;
```

**Note**

For brevity, we use KEY partitioning for the table shown in this example, but file descriptor usage as described here applies to all partitioned MyISAM tables, regardless of the type of partitioning that is employed. Partitioned tables using other storage engines such as InnoDB are not affected by this issue.

Now assume that you wish to repartition t so that it has 101 partitions, using the statement shown here:

```sql
ALTER TABLE t PARTITION BY KEY (c1) PARTITIONS 101;
```

To process this ALTER TABLE statement, MySQL uses 402 file descriptors—that is, two for each of the 100 original partitions, plus two for each of the 101 new partitions. This is because all partitions (old and new) must be opened concurrently during the reorganization of the table data. It is recommended that, if you expect to perform such operations, you should make sure that the open_files_limit system variable is not set too low to accommodate them.

**ALGORITHM and ALTER TABLE.** Partitioned tables do not support ALTER TABLE statements with ALGORITHM=DEFAULT, ALGORITHM=INPLACE, or ALGORITHM=COPY. See Section 13.1.7.1, “ALTER TABLE Partition Operations”.

**Table locks.** Generally, the process executing a partitioning operation on a table takes a write lock on the table. Reads from such tables are relatively unaffected; pending INSERT and UPDATE operations are performed as soon as the partitioning operation has completed. For InnoDB-specific information related to this limitation, see Partitioning Operations.

LOCK is not supported for ALTER TABLE statements on partitioned tables.

**Storage engine.** Partitioning operations, queries, and update operations generally tend to be faster with MyISAM tables than with InnoDB or NDB tables.

**Indexes; partition pruning.** As with nonpartitioned tables, proper use of indexes can speed up queries on partitioned tables significantly. In addition, designing partitioned tables and queries on these tables to take advantage of partition pruning can improve performance dramatically. See Section 19.4, “Partition Pruning”, for more information.

Index condition pushdown is not supported for partitioned tables. See Section 8.2.1.5, “Index Condition Pushdown Optimization”.

**Performance with LOAD DATA.** In MySQL 5.6, LOAD DATA uses buffering to improve performance. You should be aware that the buffer uses 130 KB memory per partition to achieve this.
Restrictions and Limitations on Partitioning

**Maximum number of partitions.**
Prior to MySQL 5.6.7, the maximum possible number of partitions for a given table not using the NDB storage engine was 1024. Beginning with MySQL 5.6.7, this limit is increased to 8192 partitions. Regardless of the MySQL Server version, this maximum includes subpartitions.

The maximum possible number of user-defined partitions for a table using the NDB storage engine is determined according to the version of the NDB Cluster software being used, the number of data nodes, and other factors. See NDB and user-defined partitioning, for more information.

If, when creating tables with a large number of partitions (but less than the maximum), you encounter an error message such as `Got error ... from storage engine: Out of resources when opening file`, you may be able to address the issue by increasing the value of the `open_files_limit` system variable. However, this is dependent on the operating system, and may not be possible or advisable on all platforms; see Section B.3.2.17, “File Not Found and Similar Errors”, for more information. In some cases, using large numbers (hundreds) of partitions may also not be advisable due to other concerns, so using more partitions does not automatically lead to better results.

See also File system operations.

**Query cache not supported.**
The query cache is not supported for partitioned tables. Beginning with MySQL 5.6.5, the query cache is automatically disabled for queries involving partitioned tables, and cannot be enabled for such queries. (Bug #53775)

**Per-partition key caches.**
In MySQL 5.6, key caches are supported for partitioned MyISAM tables, using the `CACHE INDEX` and `LOAD INDEX INTO CACHE` statements. Key caches may be defined for one, several, or all partitions, and indexes for one, several, or all partitions may be preloaded into key caches.

**Foreign keys not supported for partitioned InnoDB tables.**
Partitioned tables using the InnoDB storage engine do not support foreign keys. More specifically, this means that the following two statements are true:

1. No definition of an InnoDB table employing user-defined partitioning may contain foreign key references; no InnoDB table whose definition contains foreign key references may be partitioned.

2. No InnoDB table definition may contain a foreign key reference to a user-partitioned table; no InnoDB table with user-defined partitioning may contain columns referenced by foreign keys.

The scope of the restrictions just listed includes all tables that use the InnoDB storage engine. CREATE TABLE and ALTER TABLE statements that would result in tables violating these restrictions are not allowed.

**ALTER TABLE ... ORDER BY.** An ALTER TABLE ... ORDER BY column statement run against a partitioned table causes ordering of rows only within each partition.

**Effects on REPLACE statements by modification of primary keys.** It can be desirable in some cases (see Section 19.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”) to modify a table’s primary key. Be aware that, if your application uses REPLACE statements and you do this, the results of these statements can be drastically altered. See Section 13.2.8, “REPLACE Statement”, for more information and an example.

**FULLTEXT indexes.**
Partitioned tables do not support FULLTEXT indexes or searches, even for partitioned tables employing the InnoDB or MyISAM storage engine.

**Spatial columns.** Columns with spatial data types such as POINT or GEOMETRY cannot be used in partitioned tables.
Restrictions and Limitations on Partitioning

Temporary tables.
Temporary tables cannot be partitioned. (Bug #17497)

Log tables. It is not possible to partition the log tables; an \texttt{ALTER TABLE \ldots PARTITION BY \ldots} statement on such a table fails with an error.

Data type of partitioning key.
A partitioning key must be either an integer column or an expression that resolves to an integer. Expressions employing \texttt{ENUM} columns cannot be used. The column or expression value may also be \texttt{NULL}. (See Section 19.2.7, “How MySQL Partitioning Handles NULL”.)

There are two exceptions to this restriction:

1. When partitioning by [\texttt{LINEAR] KEY}, it is possible to use columns of any valid MySQL data type other than \texttt{TEXT} or \texttt{BLOB} as partitioning keys, because MySQL’s internal key-hashing functions produce the correct data type from these types. For example, the following two \texttt{CREATE TABLE} statements are valid:

   ```sql
   CREATE TABLE tkc (c1 CHAR)
   PARTITION BY KEY(c1)
   PARTITIONS 4;
   
   CREATE TABLE tke
   ( c1 ENUM('red', 'orange', 'yellow', 'green', 'blue', 'indigo', 'violet') )
   PARTITION BY LINEAR KEY(c1)
   PARTITIONS 6;
   ```

2. When partitioning by \texttt{RANGE COLUMNS} or \texttt{LIST COLUMNS}, it is possible to use string, \texttt{DATE}, and \texttt{DATETIME} columns. For example, each of the following \texttt{CREATE TABLE} statements is valid:

   ```sql
   CREATE TABLE rc (c1 INT, c2 DATE)
   PARTITION BY RANGE COLUMNS(c2) (  
   PARTITION p0 VALUES LESS THAN('1990-01-01'),  
   PARTITION p1 VALUES LESS THAN('1995-01-01'),  
   PARTITION p2 VALUES LESS THAN('2000-01-01'),  
   PARTITION p3 VALUES LESS THAN('2005-01-01'),  
   PARTITION p4 VALUES LESS THAN(MAXVALUE)
   );
   
   CREATE TABLE lc (c1 INT, c2 CHAR(1))
   PARTITION BY LIST COLUMNS(c2) (  
   PARTITION p0 VALUES IN('a', 'd', 'g', 'j', 'm', 'p', 's', 'v', 'y'),  
   PARTITION p1 VALUES IN('b', 'e', 'h', 'k', 'n', 'q', 't', 'w', 'z'),  
   PARTITION p2 VALUES IN('c', 'f', 'i', 'l', 'o', 'r', 'u', 'x', NULL)
   );
   ```

Neither of the preceding exceptions applies to \texttt{BLOB} or \texttt{TEXT} column types.

Subqueries.
A partitioning key may not be a subquery, even if that subquery resolves to an integer value or \texttt{NULL}.

Column index prefixes not supported for key partitioning. When creating a table that is partitioned by key, any columns in the partitioning key which use column prefixes are ignored by the table’s partitioning function. Consider the following \texttt{CREATE TABLE} statement, which has three \texttt{VARCHAR} columns, and whose primary key uses all three columns and specifies prefixes for two of them:

```sql
CREATE TABLE t1 (  
   a VARCHAR(10000),
   b VARCHAR(25),
   c VARCHAR(10),
   PRIMARY KEY (a(10), b, c(2))
) PARTITION BY KEY() PARTITIONS 2;
```
Restrictions and Limitations on Partitioning

This statement is accepted, but the resulting table is actually created as if you had issued the following statement, using only the primary key column which does not include a prefix (column b) for the partitioning key:

```sql
CREATE TABLE t1 (  
  a VARCHAR(10000),  
  b VARCHAR(25),  
  c VARCHAR(10),  
  PRIMARY KEY (a(10), b, c(2))  
) PARTITION BY KEY(b) PARTITIONS 2;
```

No warning is issued or any other indication provided that this has occurred, except in the event that all columns specified for the partitioning key use prefixes, in which case the statement fails with the error message shown here:

```sql
mysql> CREATE TABLE t2 (  
  a VARCHAR(10000),  
  b VARCHAR(25),  
  c VARCHAR(10),  
  PRIMARY KEY (a(10), b(5), c(2))  
) PARTITION BY KEY() PARTITIONS 2;  
ERROR 1503 (HY000): A PRIMARY KEY must include all columns in the table's partitioning function
```

This also occurs when altering or upgrading such tables, and includes cases in which the columns used in the partitioning function are defined implicitly as those in the table’s primary key by employing an empty `PARTITION BY KEY()` clause.

This is a known issue which is addressed in MySQL 8.0 by deprecating the permissive behavior; in MYSQL 8.0, if any columns using prefixes are included in a table’s partitioning function, the server logs an appropriate warning for each such column, or raises a descriptive error if necessary. (Allowing the use of columns with prefixes in partitioning keys is subject to removal altogether in a future version of MySQL.)

For general information about partitioning tables by key, see Section 19.2.5, “KEY Partitioning”.

Issues with subpartitions.
Subpartitions must use `HASH` or `KEY` partitioning. Only `RANGE` and `LIST` partitions may be subpartitioned; `HASH` and `KEY` partitions cannot be subpartitioned.

`SUBPARTITION BY KEY` requires that the subpartitioning column or columns be specified explicitly, unlike the case with `PARTITION BY KEY`, where it can be omitted (in which case the table’s primary key column is used by default). Consider the table created by this statement:

```sql
CREATE TABLE ts (  
  id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,  
  name VARCHAR(30)  
);  
```

You can create a table having the same columns, partitioned by `KEY`, using a statement such as this one:

```sql
CREATE TABLE ts (  
  id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,  
  name VARCHAR(30)  
) PARTITION BY KEY() PARTITIONS 4;
```

The previous statement is treated as though it had been written like this, with the table’s primary key column used as the partitioning column:

```sql
CREATE TABLE ts (  
  id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,  
  name VARCHAR(30)  
)
```
Restrictions and Limitations on Partitioning

```sql
CREATE TABLE ts (    id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,    name VARCHAR(30) )    PARTITION BY KEY(id)    PARTITIONS 4;
```

However, the following statement that attempts to create a subpartitioned table using the default column as the subpartitioning column fails, and the column must be specified for the statement to succeed, as shown here:

```sql
mysql> CREATE TABLE ts (    -> id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,    -> name VARCHAR(30)    -> )    -> PARTITION BY RANGE(id)    -> SUBPARTITION BY KEY()    -> SUBPARTITIONS 4    -> {    -> -> PARTITION p0 VALUES LESS THAN (100),    -> -> PARTITION p1 VALUES LESS THAN (MAXVALUE)    -> -> });
ERROR 1064 (42000): You have an error in your SQL syntax; check the manual that corresponds to your MySQL server version for the right syntax to use near ')
```

```sql
mysql> CREATE TABLE ts (    -> id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,    -> name VARCHAR(30)    -> )    -> PARTITION BY RANGE(id)    -> SUBPARTITION BY KEY(id)    -> SUBPARTITIONS 4    -> {    -> -> PARTITION p0 VALUES LESS THAN (100),    -> -> PARTITION p1 VALUES LESS THAN (MAXVALUE)    -> -> };
Query OK, 0 rows affected (0.07 sec)
```

This is a known issue (see Bug #51470).

**DELAYED option not supported.** Use of `INSERT DELAYED` to insert rows into a partitioned table is not supported. Attempting to do so fails with an error.

**DATA DIRECTORY and INDEX DIRECTORY options.** `DATA DIRECTORY` and `INDEX DIRECTORY` are subject to the following restrictions when used with partitioned tables:

- Table-level `DATA DIRECTORY` and `INDEX DIRECTORY` options are ignored (see Bug #32091).

- On Windows, the `DATA DIRECTORY` and `INDEX DIRECTORY` options are not supported for individual partitions or subpartitions of MyISAM tables (Bug #30459). However, you can use `DATA DIRECTORY` for individual partitions or subpartitions of InnoDB tables.

**Repairing and rebuilding partitioned tables.** The statements `CHECK TABLE`, `OPTIMIZE TABLE`, `ANALYZE TABLE`, and `REPAIR TABLE` are supported for partitioned tables.

In addition, you can use `ALTER TABLE ... REBUILD PARTITION` to rebuild one or more partitions of a partitioned table; `ALTER TABLE ... REORGANIZE PARTITION` also causes partitions to be rebuilt. See Section 13.1.7, “ALTER TABLE Statement”, for more information about these two statements.

`mysqlcheck`, `myisamchk`, and `myisampack` are not supported with partitioned tables.

**FOR EXPORT option (FLUSH TABLES).** The `FLUSH TABLES` statement's `FOR EXPORT` option is not supported for partitioned InnoDB tables in MySQL 5.6.16 and earlier. (Bug #16943907)
19.6.1 Partitioning Keys, Primary Keys, and Unique Keys

This section discusses the relationship of partitioning keys with primary keys and unique keys. The rule governing this relationship can be expressed as follows: All columns used in the partitioning expression for a partitioned table must be part of every unique key that the table may have.

In other words, every unique key on the table must use every column in the table's partitioning expression. (This also includes the table's primary key, since it is by definition a unique key. This particular case is discussed later in this section.) For example, each of the following table creation statements is invalid:

```
CREATE TABLE t1 (  
  col1 INT NOT NULL,  
  col2 DATE NOT NULL,  
  col3 INT NOT NULL,  
  col4 INT NOT NULL,  
  UNIQUE KEY (col1, col2)  
)  
PARTITION BY HASH(col3)  
PARTITIONS 4;
```

```
CREATE TABLE t2 (  
  col1 INT NOT NULL,  
  col2 DATE NOT NULL,  
  col3 INT NOT NULL,  
  col4 INT NOT NULL,  
  UNIQUE KEY (col1),  
  UNIQUE KEY (col3)  
)  
PARTITION BY HASH(col1 + col3)  
PARTITIONS 4;
```

In each case, the proposed table would have at least one unique key that does not include all columns used in the partitioning expression.

Each of the following statements is valid, and represents one way in which the corresponding invalid table creation statement could be made to work:

```
CREATE TABLE t1 (  
  col1 INT NOT NULL,  
  col2 DATE NOT NULL,  
  col3 INT NOT NULL,  
  col4 INT NOT NULL,  
  UNIQUE KEY (col1, col2, col3)  
)  
PARTITION BY HASH(col3)  
PARTITIONS 4;
```

```
CREATE TABLE t2 (  
  col1 INT NOT NULL,  
  col2 DATE NOT NULL,  
  col3 INT NOT NULL,  
  col4 INT NOT NULL,  
  UNIQUE KEY (col1, col3)  
)  
PARTITION BY HASH(col1 + col3)  
PARTITIONS 4;
```

This example shows the error produced in such cases:

```
mysql> CREATE TABLE t3 (  
->  col1 INT NOT NULL,  
->  col2 DATE NOT NULL,  
->  col3 INT NOT NULL,  
->  col4 INT NOT NULL,  
3198
```
Partitioning Keys, Primary Keys, and Unique Keys

The `CREATE TABLE` statement fails because both `col1` and `col3` are included in the proposed partitioning key, but neither of these columns is part of both of unique keys on the table. This shows one possible fix for the invalid table definition:

```sql
mysql> CREATE TABLE t3 (  
  -> col1 INT NOT NULL,  
  -> col2 DATE NOT NULL,  
  -> col3 INT NOT NULL,  
  -> col4 INT NOT NULL,  
  -> UNIQUE KEY (col1, col2, col3),  
  -> UNIQUE KEY (col3)  
  -> )  
  -> PARTITION BY HASH(col3)  
  -> PARTITIONS 4;  
Query OK, 0 rows affected (0.05 sec)
```

In this case, the proposed partitioning key `col3` is part of both unique keys, and the table creation statement succeeds.

The following table cannot be partitioned at all, because there is no way to include in a partitioning key any columns that belong to both unique keys:

```sql
CREATE TABLE t4 (  
  col1 INT NOT NULL,  
  col2 INT NOT NULL,  
  col3 INT NOT NULL,  
  col4 INT NOT NULL,  
  UNIQUE KEY (col1, col3),  
  UNIQUE KEY (col2, col4)  
);  
```

Since every primary key is by definition a unique key, this restriction also includes the table's primary key, if it has one. For example, the next two statements are invalid:

```sql
CREATE TABLE t5 (  
  col1 INT NOT NULL,  
  col2 DATE NOT NULL,  
  col3 INT NOT NULL,  
  col4 INT NOT NULL,  
  PRIMARY KEY(col1, col2)  
)  
PARTITION BY HASH(col3)  
PARTITIONS 4;  
CREATE TABLE t6 (  
  col1 INT NOT NULL,  
  col2 DATE NOT NULL,  
  col3 INT NOT NULL,  
  col4 INT NOT NULL,  
  PRIMARY KEY(col1, col3),  
  UNIQUE KEY(col2)  
)  
PARTITION BY HASH( YEAR(col2) )  
PARTITIONS 4;  
```

In both cases, the primary key does not include all columns referenced in the partitioning expression. However, both of the next two statements are valid:
Partitioning Keys, Primary Keys, and Unique Keys

CREATE TABLE t7 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    PRIMARY KEY(col1, col2)
) PARTITION BY HASH(col1 + YEAR(col2)) PARTITIONS 4;

CREATE TABLE t8 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    PRIMARY KEY(col1, col2, col4),
    UNIQUE KEY(col2, col1)
) PARTITION BY HASH(col1 + YEAR(col2)) PARTITIONS 4;

If a table has no unique keys—this includes having no primary key—then this restriction does not apply, and you may use any column or columns in the partitioning expression as long as the column type is compatible with the partitioning type.

For the same reason, you cannot later add a unique key to a partitioned table unless the key includes all columns used by the table’s partitioning expression. Consider the partitioned table created as shown here:

```sql
mysql> CREATE TABLE t_no_pk (c1 INT, c2 INT) PARTITION BY RANGE(c1) (PARTITION p0 VALUES LESS THAN (10), PARTITION p1 VALUES LESS THAN (20), PARTITION p2 VALUES LESS THAN (30), PARTITION p3 VALUES LESS THAN (40));
Query OK, 0 rows affected (0.12 sec)
```

It is possible to add a primary key to `t_no_pk` using either of these `ALTER TABLE` statements:

```sql
# possible PK
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c1);
Query OK, 0 rows affected (0.13 sec)
Records: 0  Duplicates: 0  Warnings: 0

# drop this PK
mysql> ALTER TABLE t_no_pk DROP PRIMARY KEY;
Query OK, 0 rows affected (0.10 sec)
Records: 0  Duplicates: 0  Warnings: 0

# use another possible PK
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c1, c2);
Query OK, 0 rows affected (0.12 sec)
Records: 0  Duplicates: 0  Warnings: 0

# drop this PK
mysql> ALTER TABLE t_no_pk DROP PRIMARY KEY;
Query OK, 0 rows affected (0.09 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

However, the next statement fails, because `c1` is part of the partitioning key, but is not part of the proposed primary key:

```sql
# fails with error 1503
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c2);
ERROR 1503 (HY000): A PRIMARY KEY must include all columns in the table’s partitioning function
```
Since $t_{no_p_k}$ has only $c_1$ in its partitioning expression, attempting to adding a unique key on $c_2$ alone fails. However, you can add a unique key that uses both $c_1$ and $c_2$.

These rules also apply to existing nonpartitioned tables that you wish to partition using `ALTER TABLE ... PARTITION BY`. Consider a table $np_{pk}$ created as shown here:

```sql
mysql> CREATE TABLE np_{pk} (
    -> id INT NOT NULL AUTO_INCREMENT,
    -> name VARCHAR(50),
    -> added DATE,
    -> PRIMARY KEY (id)
    -> );
Query OK, 0 rows affected (0.08 sec)
```

The following `ALTER TABLE` statement fails with an error, because the `added` column is not part of any unique key in the table:

```sql
mysql> ALTER TABLE np_{pk} 
    -> PARTITION BY HASH( TO_DAYS(added) ) 
    -> PARTITIONS 4;
```

ERROR 1503 (HY000): A PRIMARY KEY must include all columns in the table's partitioning function

However, this statement using the `id` column for the partitioning column is valid, as shown here:

```sql
mysql> ALTER TABLE np_{pk} 
    -> PARTITION BY HASH(id) 
    -> PARTITIONS 4;
Query OK, 0 rows affected (0.11 sec)
```

In the case of $np_{pk}$, the only column that may be used as part of a partitioning expression is $id$; if you wish to partition this table using any other column or columns in the partitioning expression, you must first modify the table, either by adding the desired column or columns to the primary key, or by dropping the primary key altogether.

### 19.6.2 Partitioning Limitations Relating to Storage Engines

The following limitations apply to the use of storage engines with user-defined partitioning of tables.

**MERGE storage engine.** User-defined partitioning and the `MERGE` storage engine are not compatible. Tables using the `MERGE` storage engine cannot be partitioned. Partitioned tables cannot be merged.

**FEDERATED storage engine.** Partitioning of `FEDERATED` tables is not supported; it is not possible to create partitioned `FEDERATED` tables.

**CSV storage engine.** Partitioned tables using the `CSV` storage engine are not supported; it is not possible to create partitioned `CSV` tables.

**InnoDB storage engine.** InnoDB foreign keys and MySQL partitioning are not compatible. Partitioned InnoDB tables cannot have foreign key references, nor can they have columns referenced by foreign keys. InnoDB tables which have or which are referenced by foreign keys cannot be partitioned.

InnoDB does not support the use of multiple disks for subpartitions. (This is currently supported only by MyISAM.)

In addition, `ALTER TABLE ... OPTIMIZE PARTITION` does not work correctly with partitioned tables that use the InnoDB storage engine. Use `ALTER TABLE ... REBUILD PARTITION` and `ALTER TABLE ... ANALYZE PARTITION`, instead, for such tables. For more information, see Section 13.1.7.1, “ALTER TABLE Partition Operations”.

3201
Partitioning Limitations Relating to Functions

**User-defined partitioning and the NDB storage engine (NDB Cluster).** Partitioning by **KEY** (including **LINEAR KEY**) is the only type of partitioning supported for the **NDB** storage engine. It is not possible under normal circumstances in MySQL NDB Cluster 7.4 to create an NDB Cluster table using any partitioning type other than **LINEAR**, and attempting to do so fails with an error.

*Exception (not for production):* It is possible to override this restriction by setting the **new** system variable on NDB Cluster SQL nodes to **ON**. If you choose to do this, you should be aware that tables using partitioning types other than **LINEAR KEY** are not supported in production. *In such cases, you can create and use tables with partitioning types other than **KEY** or **LINEAR KEY**, but you do this entirely at your own risk.*

The maximum number of partitions that can be defined for an **NDB** table depends on the number of data nodes and node groups in the cluster, the version of the NDB Cluster software in use, and other factors. See NDB and user-defined partitioning, for more information.

The maximum amount of fixed-size data that can be stored per partition in an **NDB** table is 16 GB.

**CREATE TABLE** and **ALTER TABLE** statements that would cause a user-partitioned **NDB** table not to meet either or both of the following two requirements are not permitted, and fail with an error:

1. The table must have an explicit primary key.
2. All columns listed in the table’s partitioning expression must be part of the primary key.

*Exception.* If a user-partitioned **NDB** table is created using an empty column-list (that is, using **PARTITION BY KEY()** or **PARTITION BY LINEAR KEY()**), then no explicit primary key is required.

**Upgrading partitioned tables.** When performing an upgrade, tables which are partitioned by **KEY** and which use any storage engine other than **NDB** must be dumped and reloaded.

**Same storage engine for all partitions.** All partitions of a partitioned table must use the same storage engine and it must be the same storage engine used by the table as a whole. In addition, if one does not specify an engine on the table level, then one must do either of the following when creating or altering a partitioned table:

- Do not specify any engine for any partition or subpartition
- Specify the engine for all partitions or subpartitions

### 19.6.3 Partitioning Limitations Relating to Functions

This section discusses limitations in MySQL Partitioning relating specifically to functions used in partitioning expressions.

Only the MySQL functions shown in the following list are allowed in partitioning expressions:

- **ABS()**
- **CEILING()** (see **CEILING()** and **FLOOR()**)
- **DATEDIFF()**
- **DAY()**
- **DAYOFMONTH()**
- **DAYOFWEEK()**
Partitioning and Locking

- `DAYOFYEAR()`
- `EXTRACT()` (see `EXTRACT()` function with WEEK specifier)
- `FLOOR()` (see `CEILING()` and `FLOOR()`)
- `HOUR()`
- `MICROSECOND()`
- `MINUTE()`
- `MOD()`
- `MONTH()`
- `QUARTER()`
- `SECOND()`
- `TIME_TO_SEC()`
- `TO_DAYS()`
- `UNIX_TIMESTAMP()` (with `TIMESTAMP` columns)
- `WEEKDAY()`
- `YEAR()`
- `YEARWEEK()`

In MySQL 5.6, range optimization can be used for the `TO_DAYS()`, `TO_SECONDS()`, and `YEAR()` functions. In addition, beginning with MySQL 5.6.3, `UNIX_TIMESTAMP()` is treated as monotonic in partitioning expressions. See Section 19.4, “Partition Pruning”, for more information.

**CEILING() and FLOOR().** Each of these functions returns an integer only if it is passed an argument of an exact numeric type, such as one of the `INT` types or `DECIMAL`. This means, for example, that the following `CREATE TABLE` statement fails with an error, as shown here:

```sql
mysql> CREATE TABLE t (c FLOAT) PARTITION BY LIST( FLOOR(c) ) (-> PARTITION p0 VALUES IN (1,3,5), -> PARTITION p1 VALUES IN (2,4,6) -> );
ERROR 1490 (HY000): The PARTITION function returns the wrong type
```

**EXTRACT() function with WEEK specifier.** The value returned by the `EXTRACT()` function, when used as `EXTRACT(WEEK FROM col)`, depends on the value of the `default_week_format` system variable. For this reason, beginning with MySQL 5.6.2, `EXTRACT()` is no longer permitted as a partitioning function when it specifies the unit as `WEEK`. (Bug #54483)

See Section 12.6.2, “Mathematical Functions”, for more information about the return types of these functions, as well as Section 11.1, “Numeric Data Types”.

### 19.6.4 Partitioning and Locking

In MySQL 5.6.5 and earlier, for storage engines such as `MyISAM` that actually execute table-level locks when executing DML or DDL statements, such a statement affecting a partitioned table imposed a lock.
Partitioning and Locking

on the table as a whole; that is, all partitions were locked until the statement was finished. MySQL 5.6.6 implements partition lock pruning, which eliminates unneeded locks in many cases. In MySQL 5.6.6 and later, most statements reading from or updating a partitioned MyISAM table cause only the effected partitions to be locked. For example, prior to MySQL 5.6.6, a SELECT from a partitioned MyISAM table caused a lock on the entire table; in MySQL 5.6.6 and later, only those partitions actually containing rows that satisfy the SELECT statement's WHERE condition are locked. This has the effect of increasing the speed and efficiency of concurrent operations on partitioned MyISAM tables. This improvement becomes particularly noticeable when working with MyISAM tables that have many (32 or more) partitions.

This change in behavior does not have any impact on statements affecting partitioned tables using storage engines such as InnoDB, that employ row-level locking and do not actually perform (or need to perform) the locks prior to partition pruning.

The next few paragraphs discuss the effects of partition lock pruning for various MySQL statements on tables using storage engines that employ table-level locks.

Effects on DML statements

SELECT statements (including those containing unions or joins) now lock only those partitions that actually need to be read. This also applies to SELECT ... PARTITION.

An UPDATE prunes locks only for tables on which no partitioning columns are updated.

REPLACE and INSERT now lock only those partitions having rows to be inserted or replaced. However, if an AUTO_INCREMENT value is generated for any partitioning column then all partitions are locked.

INSERT ... ON DUPLICATE KEY UPDATE is pruned as long as no partitioning column is updated.

INSERT ... SELECT now locks only those partitions in the source table that need to be read, although all partitions in the target table are locked.

Note

INSERT DELAYED is not supported for partitioned tables.

Locks imposed by LOAD DATA statements on partitioned tables cannot be pruned.

The presence of BEFORE INSERT or BEFORE UPDATE triggers using any partitioning column of a partitioned table means that locks on INSERT and UPDATE statements updating this table cannot be pruned, since the trigger can alter its values: A BEFORE INSERT trigger on any of the table's partitioning columns means that locks set by INSERT or REPLACE cannot be pruned, since the BEFORE INSERT trigger may change a row's partitioning columns before the row is inserted, forcing the row into a different partition than it would be otherwise. A BEFORE UPDATE trigger on a partitioning column means that locks imposed by UPDATE or INSERT ... ON DUPLICATE KEY UPDATE cannot be pruned.

Affected DDL statements

CREATE VIEW no longer causes any locks.

ALTER TABLE ... EXCHANGE PARTITION now prunes locks; only the exchanged table and the exchanged partition are locked.

ALTER TABLE ... TRUNCATE PARTITION now prunes locks; only the partitions to be emptied are locked.

ALTER TABLE statements still take metadata locks on the table level.
Other statements

`LOCK TABLES` cannot prune partition locks.

`CALL stored_procedure(expr)` supports lock pruning, but evaluating `expr` does not.

`DO` and `SET` statements do not support partitioning lock pruning.

This chapter discusses stored database objects that are defined in terms of SQL code that is stored on the server for later execution.

Stored objects include these object types:

- Stored procedure: An object created with `CREATE PROCEDURE` and invoked using the `CALL` statement. A procedure does not have a return value but can modify its parameters for later inspection by the caller. It can also generate result sets to be returned to the client program.

- Stored function: An object created with `CREATE FUNCTION` and used much like a built-in function. You invoke it in an expression and it returns a value during expression evaluation.

- Trigger: An object created with `CREATE TRIGGER` that is associated with a table. A trigger is activated when a particular event occurs for the table, such as an insert or update.

- Event: An object created with `CREATE EVENT` and invoked by the server according to schedule.

- View: An object created with `CREATE VIEW` that when referenced produces a result set. A view acts as a virtual table.

Terminology used in this document reflects the stored object hierarchy:

- Stored routines include stored procedures and functions.
Defining Stored Programs

- Stored programs include stored routines, triggers, and events.
- Stored objects include stored programs and views.

This chapter describes how to use stored objects. The following sections provide additional information about SQL syntax for statements related to these objects, and about object processing:

- For each object type, there are `CREATE`, `ALTER`, and `DROP` statements that control which objects exist and how they are defined. See Section 13.1, “Data Definition Statements”.

- The `CALL` statement is used to invoke stored procedures. See Section 13.2.1, “CALL Statement”.

- Stored program definitions include a body that may use compound statements, loops, conditionals, and declared variables. See Section 13.6, “Compound Statements”.

- Metadata changes to objects referred to by stored programs are detected and cause automatic reparsing of the affected statements when the program is next executed. For more information, see Section 8.10.4, “Caching of Prepared Statements and Stored Programs”.

20.1 Defining Stored Programs

Each stored program contains a body that consists of an SQL statement. This statement may be a compound statement made up of several statements separated by semicolon (`;`) characters. For example, the following stored procedure has a body made up of a `BEGIN ... END` block that contains a `SET` statement and a `REPEAT` loop that itself contains another `SET` statement:

```sql
CREATE PROCEDURE dorepeat(p1 INT)
BEGIN
  SET @x = 0;
  REPEAT SET @x = @x + 1; UNTIL @x > p1 END REPEAT;
END;
```

If you use the `mysql` client program to define a stored program containing semicolon characters, a problem arises. By default, `mysql` itself recognizes the semicolon as a statement delimiter, so you must redefine the delimiter temporarily to cause `mysql` to pass the entire stored program definition to the server.

To redefine the `mysql` delimiter, use the `delimiter` command. The following example shows how to do this for the `dorepeat()` procedure just shown. The delimiter is changed to `//` to enable the entire definition to be passed to the server as a single statement, and then restored to `;` before invoking the procedure. This enables the `;` delimiter used in the procedure body to be passed through to the server rather than being interpreted by `mysql` itself.

```sql
mysql> delimiter //
mysql> CREATE PROCEDURE dorepeat(p1 INT)
    
    -> BEGIN
    -> SET @x = 0;
    -> REPEAT SET @x = @x + 1; UNTIL @x > p1 END REPEAT;
    -> END
    -> //

Query OK, 0 rows affected (0.00 sec)

mysql> delimiter ;
mysql> CALL dorepeat(1000);
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @x;
+------+
<table>
<thead>
<tr>
<th>@x</th>
</tr>
</thead>
<tbody>
<tr>
<td>3208</td>
</tr>
</tbody>
</table>
```
You can redefine the delimiter to a string other than `//`, and the delimiter can consist of a single character or multiple characters. You should avoid the use of the backslash (`\`) character because that is the escape character for MySQL.

The following is an example of a function that takes a parameter, performs an operation using an SQL function, and returns the result. In this case, it is unnecessary to use `delimiter` because the function definition contains no internal `;` statement delimiters:

```
mysql> CREATE FUNCTION hello (s CHAR(20))
mysql> RETURNS CHAR(50) DETERMINISTIC
-> RETURN CONCAT('Hello, ',s,'!');
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> SELECT hello('world');
+----------------+
| hello('world') |
+----------------+
| Hello, world!  |
+----------------+
1 row in set (0.00 sec)
```

### 20.2 Using Stored Routines

MySQL supports stored routines (procedures and functions). A stored routine is a set of SQL statements that can be stored in the server. Once this has been done, clients don't need to keep reissuing the individual statements but can refer to the stored routine instead.

Stored routines require the `proc` table in the `mysql` database. This table is created during the MySQL installation procedure. If you are upgrading to MySQL 5.6 from an earlier version, be sure to update your grant tables to make sure that the `proc` table exists. See Section 4.4.7, "mysql_upgrade — Check and Upgrade MySQL Tables".

Stored routines can be particularly useful in certain situations:

- When multiple client applications are written in different languages or work on different platforms, but need to perform the same database operations.

- When security is paramount. Banks, for example, use stored procedures and functions for all common operations. This provides a consistent and secure environment, and routines can ensure that each operation is properly logged. In such a setup, applications and users would have no access to the database tables directly, but can only execute specific stored routines.

Stored routines can provide improved performance because less information needs to be sent between the server and the client. The tradeoff is that this does increase the load on the database server because more of the work is done on the server side and less is done on the client (application) side. Consider this if many client machines (such as Web servers) are serviced by only one or a few database servers.

Stored routines also enable you to have libraries of functions in the database server. This is a feature shared by modern application languages that enable such design internally (for example, by using classes). Using these client application language features is beneficial for the programmer even outside the scope of database use.

MySQL follows the SQL:2003 syntax for stored routines, which is also used by IBM's DB2. All syntax described here is supported and any limitations and extensions are documented where appropriate.
Additional Resources

- You may find the Stored Procedures User Forum of use when working with stored procedures and functions.

- For answers to some commonly asked questions regarding stored routines in MySQL, see Section A.4, "MySQL 5.6 FAQ: Stored Procedures and Functions".

- There are some restrictions on the use of stored routines. See Section 20.8, “Restrictions on Stored Programs”.

- Binary logging for stored routines takes place as described in Section 20.7, “Stored Program Binary Logging”.

20.2.1 Stored Routine Syntax

A stored routine is either a procedure or a function. Stored routines are created with the `CREATE PROCEDURE` and `CREATE FUNCTION` statements (see Section 13.1.15, "CREATE PROCEDURE and CREATE FUNCTION Statements"). A procedure is invoked using a `CALL` statement (see Section 13.2.1, "CALL Statement"), and can only pass back values using output variables. A function can be called from inside a statement just like any other function (that is, by invoking the function's name), and can return a scalar value. The body of a stored routine can use compound statements (see Section 13.6, “Compound Statements”).

Stored routines can be dropped with the `DROP PROCEDURE` and `DROP FUNCTION` statements (see Section 13.1.26, “DROP PROCEDURE and DROP FUNCTION Statements”), and altered with the `ALTER PROCEDURE` and `ALTER FUNCTION` statements (see Section 13.1.5, “ALTER PROCEDURE Statement”).

A stored procedure or function is associated with a particular database. This has several implications:

- When the routine is invoked, an implicit `USE db_name` is performed (and undone when the routine terminates). `USE` statements within stored routines are not permitted.

- You can qualify routine names with the database name. This can be used to refer to a routine that is not in the current database. For example, to invoke a stored procedure `p` or function `f` that is associated with the `test` database, you can say `CALL test.p()` or `test.f()`.

- When a database is dropped, all stored routines associated with it are dropped as well.

Stored functions cannot be recursive.

Recursion in stored procedures is permitted but disabled by default. To enable recursion, set the `max_sp_recursion_depth` server system variable to a value greater than zero. Stored procedure recursion increases the demand on thread stack space. If you increase the value of `max_sp_recursion_depth`, it may be necessary to increase thread stack size by increasing the value of `thread_stack` at server startup. See Section 5.1.7, “Server System Variables”, for more information.

MySQL supports a very useful extension that enables the use of regular `SELECT` statements (that is, without using cursors or local variables) inside a stored procedure. The result set of such a query is simply sent directly to the client. Multiple `SELECT` statements generate multiple result sets, so the client must use a MySQL client library that supports multiple result sets. This means the client must use a client library from a version of MySQL at least as recent as 4.1. The client should also specify the `CLIENT_MULTI_RESULTS` option when it connects. For C programs, this can be done with the `mysql_real_connect()` C API function. See `mysql_real_connect()`, and Multiple Statement Execution Support.
20.2.2 Stored Routines and MySQL Privileges

The MySQL grant system takes stored routines into account as follows:

- **The `CREATE ROUTINE` privilege is needed to create stored routines.**

- **The `ALTER ROUTINE` privilege is needed to alter or drop stored routines.** This privilege is granted automatically to the creator of a routine if necessary, and dropped from the creator when the routine is dropped.

- **The `EXECUTE` privilege is required to execute stored routines.** However, this privilege is granted automatically to the creator of a routine if necessary (and dropped from the creator when the routine is dropped). Also, the default `SQL SECURITY` characteristic for a routine is `DEFINER`, which enables users who have access to the database with which the routine is associated to execute the routine.

- **If the `automatic_sp_privileges` system variable is 0, the `EXECUTE` and `ALTER ROUTINE` privileges are not automatically granted to and dropped from the routine creator.**

- **The creator of a routine is the account used to execute the `CREATE` statement for it.** This might not be the same as the account named as the `DEFINER` in the routine definition.

The server manipulates the `mysql.proc` table in response to statements that create, alter, or drop stored routines. It is not supported that the server notices manual manipulation of this table.

20.2.3 Stored Routine Metadata

To obtain metadata about stored routines:

- Query the `ROUTINES` table of the `INFORMATION_SCHEMA` database. See Section 21.3.19, “The `INFORMATION_SCHEMA ROUTINES` Table”.

- Use the `SHOW CREATE PROCEDURE` and `SHOW CREATE FUNCTION` statements to see routine definitions. See Section 13.7.5.11, “SHOW CREATE PROCEDURE Statement”.

- Use the `SHOW PROCEDURE STATUS` and `SHOW FUNCTION STATUS` statements to see routine characteristics. See Section 13.7.5.29, “SHOW PROCEDURE STATUS Statement”.

- Use the `SHOW PROCEDURE CODE` and `SHOW FUNCTION CODE` statements to see a representation of the internal implementation of the routine. See Section 13.7.5.28, “SHOW PROCEDURE CODE Statement”.

20.2.4 Stored Procedures, Functions, Triggers, and `LAST_INSERT_ID()`

Within the body of a stored routine (procedure or function) or a trigger, the value of `LAST_INSERT_ID()` changes the same way as for statements executed outside the body of these kinds of objects (see Section 12.16, “Information Functions”). The effect of a stored routine or trigger upon the value of `LAST_INSERT_ID()` that is seen by following statements depends on the kind of routine:

- If a stored procedure executes statements that change the value of `LAST_INSERT_ID()`, the changed value is seen by statements that follow the procedure call.

- For stored functions and triggers that change the value, the value is restored when the function or trigger ends, so following statements do not see a changed value.

20.3 Using Triggers
A trigger is a named database object that is associated with a table, and that activates when a particular event occurs for the table. Some uses for triggers are to perform checks of values to be inserted into a table or to perform calculations on values involved in an update.

A trigger is defined to activate when a statement inserts, updates, or deletes rows in the associated table. These row operations are trigger events. For example, rows can be inserted by `INSERT` or `LOAD DATA` statements, and an insert trigger activates for each inserted row. A trigger can be set to activate either before or after the trigger event. For example, you can have a trigger activate before each row that is inserted into a table or after each row that is updated.

**Important**

MySQL triggers activate only for changes made to tables by SQL statements. This includes changes to base tables that underlie updatable views. Triggers do not activate for changes to tables made by APIs that do not transmit SQL statements to the MySQL Server. This means that triggers are not activated by updates made using the NDB API.

Triggers are not activated by changes in `INFORMATION_SCHEMA` or `performance_schema` tables. Those tables are actually views and triggers are not permitted on views.

The following sections describe the syntax for creating and dropping triggers, show some examples of how to use them, and indicate how to obtain trigger metadata.

### Additional Resources

- You may find the Triggers User Forum of use when working with triggers.
- For answers to commonly asked questions regarding triggers in MySQL, see Section A.5, “MySQL 5.6 FAQ: Triggers”.
- There are some restrictions on the use of triggers; see Section 20.8, “Restrictions on Stored Programs”.
- Binary logging for triggers takes place as described in Section 20.7, “Stored Program Binary Logging”.

#### 20.3.1 Trigger Syntax and Examples

To create a trigger or drop a trigger, use the `CREATE TRIGGER` or `DROP TRIGGER` statement, described in Section 13.1.19, “CREATE TRIGGER Statement”, and Section 13.1.30, “DROP TRIGGER Statement”.

Here is a simple example that associates a trigger with a table, to activate for `INSERT` operations. The trigger acts as an accumulator, summing the values inserted into one of the columns of the table.

```sql
mysql> CREATE TABLE account (acct_num INT, amount DECIMAL(10,2));
Query OK, 0 rows affected (0.03 sec)

mysql> CREATE TRIGGER ins_sum BEFORE INSERT ON account
    FOR EACH ROW SET @sum = @sum + NEW.amount;
Query OK, 0 rows affected (0.01 sec)
```

The `CREATE TRIGGER` statement creates a trigger named `ins_sum` that is associated with the `account` table. It also includes clauses that specify the trigger action time, the triggering event, and what to do when the trigger activates:

- The keyword `BEFORE` indicates the trigger action time. In this case, the trigger activates before each row inserted into the table. The other permitted keyword here is `AFTER`.
Trigger Syntax and Examples

- The keyword `INSERT` indicates the trigger event; that is, the type of operation that activates the trigger. In the example, `INSERT` operations cause trigger activation. You can also create triggers for `DELETE` and `UPDATE` operations.

- The statement following `FOR EACH ROW` defines the trigger body; that is, the statement to execute each time the trigger activates, which occurs once for each row affected by the triggering event. In the example, the trigger body is a simple `SET` that accumulates into a user variable the values inserted into the `amount` column. The statement refers to the column as `NEW.amount` which means "the value of the amount column to be inserted into the new row."

To use the trigger, set the accumulator variable to zero, execute an `INSERT` statement, and then see what value the variable has afterward:

```sql
mysql> SET @sum = 0;
mysql> INSERT INTO account VALUES(137,14.98),(141,1937.50),(97,-100.00);
mysql> SELECT @sum AS 'Total amount inserted';
+-----------------------+
<table>
<thead>
<tr>
<th>Total amount inserted</th>
</tr>
</thead>
<tbody>
<tr>
<td>1852.48</td>
</tr>
</tbody>
</table>
+-----------------------+
```

In this case, the value of `@sum` after the `INSERT` statement has executed is `14.98 + 1937.50 - 100`, or `1852.48`.

To destroy the trigger, use a `DROP TRIGGER` statement. You must specify the schema name if the trigger is not in the default schema:

```sql
mysql> DROP TRIGGER test.ins_sum;
```

If you drop a table, any triggers for the table are also dropped.

Trigger names exist in the schema namespace, meaning that all triggers must have unique names within a schema. Triggers in different schemas can have the same name.

In addition to the requirement that trigger names be unique for a schema, there are other limitations on the types of triggers you can create. In particular, there cannot be multiple triggers for a given table that have the same trigger event and action time. For example, you cannot have two `BEFORE UPDATE` triggers for a table. To work around this, you can define a trigger that executes multiple statements by using the `BEGIN ... END` compound statement construct after `FOR EACH ROW`. (An example appears later in this section.)

Within the trigger body, the `OLD` and `NEW` keywords enable you to access columns in the rows affected by a trigger. `OLD` and `NEW` are MySQL extensions to triggers; they are not case-sensitive.

In an `INSERT` trigger, only `NEW.col_name` can be used; there is no old row. In a `DELETE` trigger, only `OLD.col_name` can be used; there is no new row. In an `UPDATE` trigger, you can use `OLD.col_name` to refer to the columns of a row before it is updated and `NEW.col_name` to refer to the columns of the row after it is updated.

A column named with `OLD` is read only. You can refer to it (if you have the `SELECT` privilege), but not modify it. You can refer to a column named with `NEW` if you have the `SELECT` privilege for it. In a `BEFORE` trigger, you can also change its value with `SET NEW.col_name = value` if you have the `UPDATE` privilege for it. This means you can use a trigger to modify the values to be inserted into a new row or used to update a row. (Such a `SET` statement has no effect in an `AFTER` trigger because the row change will have already occurred.)

In a `BEFORE` trigger, the `NEW` value for an `AUTO_INCREMENT` column is 0, not the sequence number that is generated automatically when the new row actually is inserted.
By using the `BEGIN ... END` construct, you can define a trigger that executes multiple statements. Within the `BEGIN` block, you also can use other syntax that is permitted within stored routines such as conditionals and loops. However, just as for stored routines, if you use the `mysql` program to define a trigger that executes multiple statements, it is necessary to redefine the `mysql` statement delimiter so that you can use the `;` statement delimiter within the trigger definition. The following example illustrates these points. It defines an `UPDATE` trigger that checks the new value to be used for updating each row, and modifies the value to be within the range from 0 to 100. This must be a `BEFORE` trigger because the value must be checked before it is used to update the row:

```sql
mysql> delimiter //
mysql> CREATE TRIGGER upd_check BEFORE UPDATE ON account
    -> FOR EACH ROW
    -> BEGIN
    -> IF NEW.amount < 0 THEN
    ->  SET NEW.amount = 0;
    -> ELSEIF NEW.amount > 100 THEN
    ->  SET NEW.amount = 100;
    -> END IF;
    -> END; //
mysql> delimiter ;
```

It can be easier to define a stored procedure separately and then invoke it from the trigger using a simple `CALL` statement. This is also advantageous if you want to execute the same code from within several triggers.

There are limitations on what can appear in statements that a trigger executes when activated:

- The trigger cannot use the `CALL` statement to invoke stored procedures that return data to the client or that use dynamic SQL. (Stored procedures are permitted to return data to the trigger through `OUT` or `INOUT` parameters.)

- The trigger cannot use statements that explicitly or implicitly begin or end a transaction, such as `START TRANSACTION`, `COMMIT`, or `ROLLBACK`. (`ROLLBACK` to `SAVEPOINT` is permitted because it does not end a transaction.).

See also Section 20.8, “Restrictions on Stored Programs”.

MySQL handles errors during trigger execution as follows:

- If a `BEFORE` trigger fails, the operation on the corresponding row is not performed.

- A `BEFORE` trigger is activated by the attempt to insert or modify the row, regardless of whether the attempt subsequently succeeds.

- An `AFTER` trigger is executed only if any `BEFORE` triggers and the row operation execute successfully.

- An error during either a `BEFORE` or `AFTER` trigger results in failure of the entire statement that caused trigger invocation.

- For transactional tables, failure of a statement should cause rollback of all changes performed by the statement. Failure of a trigger causes the statement to fail, so trigger failure also causes rollback. For nontransactional tables, such rollback cannot be done, so although the statement fails, any changes performed prior to the point of the error remain in effect.

Triggers can contain direct references to tables by name, such as the trigger named `testref` shown in this example:

```sql
CREATE TABLE test1(a1 INT);
CREATE TABLE test2(a2 INT);
```
CREATE TABLE test3(a3 INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
CREATE TABLE test4(
a4 INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
b4 INT DEFAULT 0
);

CREATE TRIGGER testref BEFORE INSERT ON test1
FOR EACH ROW
BEGIN
    INSERT INTO test2 SET a2 = NEW.a1;
    DELETE FROM test3 WHERE a3 = NEW.a1;
    UPDATE test4 SET b4 = b4 + 1 WHERE a4 = NEW.a1;
END;

INSERT INTO test3 (a3) VALUES
(NULL), (NULL), (NULL), (NULL), (NULL),
(NULL), (NULL), (NULL), (NULL), (NULL);

INSERT INTO test4 (a4) VALUES
(0), (0), (0), (0), (0), (0), (0), (0), (0), (0);

Suppose that you insert the following values into table test1 as shown here:

mysql> INSERT INTO test1 VALUES
    (1), (3), (1), (7), (1), (8), (4), (4);
Query OK, 8 rows affected (0.01 sec)
Records: 8  Duplicates: 0  Warnings: 0

As a result, the four tables contain the following data:

mysql> SELECT * FROM test1;
+------+
| a1   |
+------+
| 1    |
| 3    |
| 1    |
| 7    |
| 1    |
| 8    |
| 4    |
| 4    |
+------+
8 rows in set (0.00 sec)

mysql> SELECT * FROM test2;
+------+
| a2   |
+------+
| 1    |
| 3    |
| 1    |
| 7    |
| 1    |
| 8    |
| 4    |
| 4    |
+------+
8 rows in set (0.00 sec)

mysql> SELECT * FROM test3;
+----+
| a3 |
+----+
| 3215
+----+

mysql> SELECT * FROM test4;
+----+
| a4 |
+----+
| 0  |
| 0  |
| 0  |
| 0  |
| 0  |
| 0  |
| 0  |
| 0  |
| 0  |
+----+
20.3.2 Trigger Metadata

To obtain metadata about triggers:

- Query the TRIGGERS table of the INFORMATION_SCHEMA database. See Section 21.3.27, “The INFORMATION_SCHEMA TRIGGERS Table”.
- Use the SHOW CREATE TRIGGER statement. See Section 13.7.5.13, “SHOW CREATE TRIGGER Statement”.
- Use the SHOW TRIGGERS statement. See Section 13.7.5.39, “SHOW TRIGGERS Statement”.

20.4 Using the Event Scheduler

The MySQL Event Scheduler manages the scheduling and execution of events, that is, tasks that run according to a schedule. The following discussion covers the Event Scheduler and is divided into the following sections:

- Section 20.4.1, “Event Scheduler Overview”, provides an introduction to and conceptual overview of MySQL Events.
- Section 20.4.3, “Event Syntax”, discusses the SQL statements for creating, altering, and dropping MySQL Events.
- Section 20.4.4, “Event Metadata”, shows how to obtain information about events and how this information is stored by the MySQL Server.
- Section 20.4.6, “The Event Scheduler and MySQL Privileges”, discusses the privileges required to work with events and the ramifications that events have with regard to privileges when executing.

Stored routines require the event table in the mysql database. This table is created during the MySQL 5.6 installation procedure. If you are upgrading to MySQL 5.6 from an earlier version, be sure to update your grant tables to make sure that the event table exists. See Section 2.11, “Upgrading MySQL”.

3216
20.4.1 Event Scheduler Overview

MySQL Events are tasks that run according to a schedule. Therefore, we sometimes refer to them as scheduled events. When you create an event, you are creating a named database object containing one or more SQL statements to be executed at one or more regular intervals, beginning and ending at a specific date and time. Conceptually, this is similar to the idea of the Unix `crontab` (also known as a “cron job”) or the Windows Task Scheduler.

Scheduled tasks of this type are also sometimes known as “temporal triggers”, implying that these are objects that are triggered by the passage of time. While this is essentially correct, we prefer to use the term events to avoid confusion with triggers of the type discussed in Section 20.3, “Using Triggers”. Events should more specifically not be confused with “temporary triggers”. Whereas a trigger is a database object whose statements are executed in response to a specific type of event that occurs on a given table, a (scheduled) event is an object whose statements are executed in response to the passage of a specified time interval.

While there is no provision in the SQL Standard for event scheduling, there are precedents in other database systems, and you may notice some similarities between these implementations and that found in the MySQL Server.

MySQL Events have the following major features and properties:

• In MySQL, an event is uniquely identified by its name and the schema to which it is assigned.

• An event performs a specific action according to a schedule. This action consists of an SQL statement, which can be a compound statement in a BEGIN ... END block if desired (see Section 13.6, “Compound Statements”). An event's timing can be either one-time or recurrent. A one-time event executes one time only. A recurrent event repeats its action at a regular interval, and the schedule for a recurring event can be assigned a specific start day and time, end day and time, both, or neither. (By default, a recurring event's schedule begins as soon as it is created, and continues indefinitely, until it is disabled or dropped.)

If a repeating event does not terminate within its scheduling interval, the result may be multiple instances of the event executing simultaneously. If this is undesirable, you should institute a mechanism to prevent simultaneous instances. For example, you could use the `GET_LOCK()` function, or row or table locking.

• Users can create, modify, and drop scheduled events using SQL statements intended for these purposes. Syntactically invalid event creation and modification statements fail with an appropriate error message. A user may include statements in an event’s action which require privileges that the user does not actually have. The event creation or modification statement succeeds but the event’s action fails. See Section 20.4.6, “The Event Scheduler and MySQL Privileges” for details.

• Many of the properties of an event can be set or modified using SQL statements. These properties include the event’s name, timing, persistence (that is, whether it is preserved following the expiration of its schedule), status (enabled or disabled), action to be performed, and the schema to which it is assigned. See Section 13.1.2, “ALTER EVENT Statement”.

The default definer of an event is the user who created the event, unless the event has been altered, in which case the definer is the user who issued the last `ALTER EVENT` statement affecting that event. An
event can be modified by any user having the EVENT privilege on the database for which the event is defined. See Section 20.4.6, “The Event Scheduler and MySQL Privileges”.

- An event’s action statement may include most SQL statements permitted within stored routines. For restrictions, see Section 20.8, “Restrictions on Stored Programs”.

20.4.2 Event Scheduler Configuration

Events are executed by a special event scheduler thread; when we refer to the Event Scheduler, we actually refer to this thread. When running, the event scheduler thread and its current state can be seen by users having the PROCESS privilege in the output of SHOW PROCESSLIST, as shown in the discussion that follows.

The global event_scheduler system variable determines whether the Event Scheduler is enabled and running on the server. It has one of the following values, which affect event scheduling as described:

- **OFF**: The Event Scheduler is stopped. The event scheduler thread does not run, is not shown in the output of SHOW PROCESSLIST, and no scheduled events execute. OFF is the default event_scheduler value.

  When the Event Scheduler is stopped (event_scheduler is OFF), it can be started by setting the value of event_scheduler to ON. (See next item.)

- **ON**: The Event Scheduler is started; the event scheduler thread runs and executes all scheduled events.

  When the Event Scheduler is ON, the event scheduler thread is listed in the output of SHOW PROCESSLIST as a daemon process, and its state is represented as shown here:

  ```
  mysql> SHOW PROCESSLIST\G
  ********************* 1. row *********************
  Id: 1
  User: root
  Host: localhost
  db: NULL
  Command: Query
  Time: 0
  State: NULL
  Info: show processlist
  ********************* 2. row *********************
  Id: 2
  User: event_scheduler
  Host: localhost
  db: NULL
  Command: Daemon
  Time: 3
  State: Waiting for next activation
  Info: NULL
  2 rows in set (0.00 sec)
  ```

  Event scheduling can be stopped by setting the value of event_scheduler to OFF.

- **DISABLED**: This value renders the Event Scheduler nonoperational. When the Event Scheduler is DISABLED, the event scheduler thread does not run (and so does not appear in the output of SHOW PROCESSLIST). In addition, the Event Scheduler state cannot be changed at runtime.

  If the Event Scheduler status has not been set to DISABLED, event_scheduler can be toggled between ON and OFF (using SET). It is also possible to use 0 for OFF, and 1 for ON when setting this variable. Thus, any of the following 4 statements can be used in the mysql client to turn on the Event Scheduler:

  ```
  SET GLOBAL event_scheduler = ON;
  ```
SET @@GLOBAL.event_scheduler = ON;
SET GLOBAL event_scheduler = 1;
SET @@GLOBAL.event_scheduler = 1;

Similarly, any of these 4 statements can be used to turn off the Event Scheduler:

SET GLOBAL event_scheduler = OFF;
SET @@GLOBAL.event_scheduler = OFF;
SET GLOBAL event_scheduler = 0;
SET @@GLOBAL.event_scheduler = 0;

Although ON and OFF have numeric equivalents, the value displayed for event_scheduler by SELECT or SHOW VARIABLES is always one of OFF, ON, or DISABLED. DISABLED has no numeric equivalent. For this reason, ON and OFF are usually preferred over 1 and 0 when setting this variable.

Attempting to set event_scheduler without specifying it as a global variable causes an error:

mysql< SET @@event_scheduler = OFF;
ERROR 1229 (HY000): Variable 'event_scheduler' is a GLOBAL variable and should be set with SET GLOBAL

Important

It is possible to set the Event Scheduler to DISABLED only at server startup. If event_scheduler is ON or OFF, you cannot set it to DISABLED at runtime. Also, if the Event Scheduler is set to DISABLED at startup, you cannot change the value of event_scheduler at runtime.

To disable the event scheduler, use one of the following two methods:

• As a command-line option when starting the server:

  --event-scheduler=DISABLED

• In the server configuration file (my.cnf, or my.ini on Windows systems), include the line where it is read by the server (for example, in a [mysqld] section):

  event_scheduler=DISABLED

To enable the Event Scheduler, restart the server without the --event-scheduler=DISABLED command-line option, or after removing or commenting out the line containing event_scheduler=DISABLED in the server configuration file, as appropriate. Alternatively, you can use ON (or 1) or OFF (or 0) in place of the DISABLED value when starting the server.

Note

You can issue event-manipulation statements when event_scheduler is set to DISABLED. No warnings or errors are generated in such cases (provided that the statements are themselves valid). However, scheduled events cannot execute until this variable is set to ON (or 1). Once this has been done, the event scheduler thread executes all events whose scheduling conditions are satisfied.

Starting the MySQL server with the --skip-grant-tables option causes event_scheduler to be set to DISABLED, overriding any other value set either on the command line or in the my.cnf or my.ini file (Bug #26807).

For SQL statements used to create, alter, and drop events, see Section 20.4.3, “Event Syntax”.

MySQL provides an EVENTS table in the INFORMATION_SCHEMA database. This table can be queried to obtain information about scheduled events which have been defined on the server. See Section 20.4.4,
20.4.3 Event Syntax

MySQL provides several SQL statements for working with scheduled events:

- New events are defined using the `CREATE EVENT` statement. See Section 13.1.11, “CREATE EVENT Statement”.

- The definition of an existing event can be changed by means of the `ALTER EVENT` statement. See Section 13.1.2, “ALTER EVENT Statement”.

- When a scheduled event is no longer wanted or needed, it can be deleted from the server by its definer using the `DROP EVENT` statement. See Section 13.1.22, “DROP EVENT Statement”. Whether an event persists past the end of its schedule also depends on its `ON COMPLETION` clause, if it has one. See Section 13.1.11, “CREATE EVENT Statement”.

An event can be dropped by any user having the `EVENT` privilege for the database on which the event is defined. See Section 20.4.6, “The Event Scheduler and MySQL Privileges”.

20.4.4 Event Metadata

To obtain metadata about events:

- Query the `event` table of the `mysql` database.

- Query the `EVENTS` table of the `INFORMATION_SCHEMA` database. See Section 21.3.8, “The INFORMATION_SCHEMA EVENTS Table”.

- Use the `SHOW CREATE EVENT` statement. See Section 13.7.5.9, “SHOW CREATE EVENT Statement”.

- Use the `SHOW EVENTS` statement. See Section 13.7.5.19, “SHOW EVENTS Statement”.

Event Scheduler Time Representation

Each session in MySQL has a session time zone (STZ). This is the session `time_zone` value that is initialized from the server’s global `time_zone` value when the session begins but may be changed during the session.

The session time zone that is current when a `CREATE EVENT` or `ALTER EVENT` statement executes is used to interpret times specified in the event definition. This becomes the event time zone (ETZ); that is, the time zone that is used for event scheduling and is in effect within the event as it executes.

For representation of event information in the `mysql.event` table, the `execute_at`, `starts`, and `ends` times are converted to UTC and stored along with the event time zone. This enables event execution to proceed as defined regardless of any subsequent changes to the server time zone or daylight saving time effects. The `last_executed` time is also stored in UTC.

If you select information from `mysql.event`, the times just mentioned are retrieved as UTC values. These times can also be obtained by selecting from the `INFORMATION_SCHEMA.EVENTS` table or from `SHOW EVENTS`, but they are reported as ETZ values. Other times available from these sources indicate when...
an event was created or last altered; these are displayed as STZ values. The following table summarizes
representation of event times.

<table>
<thead>
<tr>
<th>Value</th>
<th>mysql.event</th>
<th>INFORMATION_SCHEMA.EVENTS</th>
<th>EVENTSEVENTS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execute at</td>
<td>UTC</td>
<td>ETZ</td>
<td>ETZ</td>
</tr>
<tr>
<td>Starts</td>
<td>UTC</td>
<td>ETZ</td>
<td>ETZ</td>
</tr>
<tr>
<td>Ends</td>
<td>UTC</td>
<td>ETZ</td>
<td>ETZ</td>
</tr>
<tr>
<td>Last executed</td>
<td>UTC</td>
<td>ETZ</td>
<td>n/a</td>
</tr>
<tr>
<td>Created</td>
<td>STZ</td>
<td>STZ</td>
<td>n/a</td>
</tr>
<tr>
<td>Last altered</td>
<td>STZ</td>
<td>STZ</td>
<td>n/a</td>
</tr>
</tbody>
</table>

20.4.5 Event Scheduler Status

The Event Scheduler writes information about event execution that terminates with an error or warning to
the MySQL Server's error log. See Section 20.4.6, "The Event Scheduler and MySQL Privileges" for an
eample.

To obtain information about the state of the Event Scheduler for debugging and troubleshooting purposes,
run `mysqladmin debug` (see Section 4.5.2, "mysqladmin — A MySQL Server Administration Program");
after running this command, the server's error log contains output relating to the Event Scheduler, similar to
what is shown here:

```
Events status:
LLA = Last Locked At  LUA = Last Unlocked At
WOC = Waiting On Condition  DL = Data Locked

Event scheduler status:
State : INITIALIZED
Thread id : 0
LLA : n/a:0
LUA : n/a:0
WOC : NO
Workers : 0
Executed : 0
Data locked: NO

Event queue status:
Element count : 0
Data locked : NO
Attempting lock : NO
LLA : init_queue:95
LUA : init_queue:103
WOC : NO
Next activation : never
```

In statements that occur as part of events executed by the Event Scheduler, diagnostics messages (not
only errors, but also warnings) are written to the error log, and, on Windows, to the application event log.
For frequently executed events, it is possible for this to result in many logged messages. For example,
for `SELECT ... INTO var_list` statements, if the query returns no rows, a warning with error code
1329 occurs (No data), and the variable values remain unchanged. If the query returns multiple rows,
error 1172 occurs (Result consisted of more than one row). For either condition, you can avoid
having the warnings be logged by declaring a condition handler; see Section 13.6.7.2, "DECLARE ...
HANDLER Statement". For statements that may retrieve multiple rows, another strategy is to use LIMIT 1
to limit the result set to a single row.

20.4.6 The Event Scheduler and MySQL Privileges
The Event Scheduler and MySQL Privileges

To enable or disable the execution of scheduled events, it is necessary to set the value of the global `event_scheduler` system variable. This requires privileges sufficient to set global system variables. See Section 5.1.8.1, “System Variable Privileges”.

The `EVENT` privilege governs the creation, modification, and deletion of events. This privilege can be bestowed using `GRANT`. For example, this `GRANT` statement confers the `EVENT` privilege for the schema named `myschema` on the user `jon@ghidora`:

```
GRANT EVENT ON myschema.* TO jon@ghidora;
```

(We assume that this user account already exists, and that we wish for it to remain unchanged otherwise.)

To grant this same user the `EVENT` privilege on all schemas, use the following statement:

```
GRANT EVENT ON *.* TO jon@ghidora;
```

The `EVENT` privilege has global or schema-level scope. Therefore, trying to grant it on a single table results in an error as shown:

```
mysql> GRANT EVENT ON myschema.mytable TO jon@ghidora;
ERROR 1144 (42000): Illegal GRANT/REVOKE command; please consult the manual to see which privileges can be used
```

It is important to understand that an event is executed with the privileges of its definer, and that it cannot perform any actions for which its definer does not have the requisite privileges. For example, suppose that `jon@ghidora` has the `EVENT` privilege for `myschema`. Suppose also that this user has the `SELECT` privilege for `myschema`, but no other privileges for this schema. It is possible for `jon@ghidora` to create a new event such as this one:

```sql
CREATE EVENT e_store_ts
  ON SCHEDULE EVERY 10 SECOND
  DO
    INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP());
```

The user waits for a minute or so, and then performs a `SELECT * FROM mytable;` query, expecting to see several new rows in the table. Instead, the table is empty. Since the user does not have the `INSERT` privilege for the table in question, the event has no effect.

If you inspect the MySQL error log (`hostname.err`), you can see that the event is executing, but the action it is attempting to perform fails, as indicated by `RetCode=0`:

```
060209 22:39:44 [Note]     EVEX EXECUTED event newdb.e  [EXPR:10]. RetCode=0
060209 22:39:54 [Note]     EVEX EXECUTING event newdb.e [EXPR:10]
060209 22:39:54 [Note]     EVEX EXECUTED event newdb.e  [EXPR:10]. RetCode=0
060209 22:40:04 [Note]     EVEX EXECUTING event newdb.e [EXPR:10]
060209 22:40:04 [Note]     EVEX EXECUTED event newdb.e  [EXPR:10]. RetCode=0
```

Since this user very likely does not have access to the error log, it is possible to verify whether the event's action statement is valid by executing it directly:

```
mysql> INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP());
ERROR 1142 (42000): INSERT command denied to user 'jon'@'ghidora' for table 'mytable'
```

Inspection of the `INFORMATION_SCHEMA.EVENTS` table shows that `e_store_ts` exists and is enabled, but its `LAST_EXECUTED` column is `NULL`:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.EVENTS
    > WHERE EVENT_NAME='e_store_ts'
```

3222
To rescind the \texttt{EVENT} privilege, use the \texttt{REVOKE} statement. In this example, the \texttt{EVENT} privilege on the schema \texttt{myschema} is removed from the \texttt{jon@ghidora} user account:

\begin{verbatim}
REVOKE EVENT ON myschema.* FROM jon@ghidora;
\end{verbatim}

\textbf{Important}

Revoking the \texttt{EVENT} privilege from a user does not delete or disable any events that may have been created by that user.

An event is not migrated or dropped as a result of renaming or dropping the user who created it.

Suppose that the user \texttt{jon@ghidora} has been granted the \texttt{EVENT} and \texttt{INSERT} privileges on the \texttt{myschema} schema. This user then creates the following event:

\begin{verbatim}
CREATE EVENT e_insert
ON SCHEDULE
  EVERY 7 SECOND
DO
  INSERT INTO myschema.mytable;
\end{verbatim}

After this event has been created, \texttt{root} revokes the \texttt{EVENT} privilege for \texttt{jon@ghidora}. However, \texttt{e_insert} continues to execute, inserting a new row into \texttt{mytable} each seven seconds. The same would be true if \texttt{root} had issued either of these statements:

\begin{itemize}
  \item \texttt{DROP USER jon@ghidora;}
  \item \texttt{RENAME USER jon@ghidora TO someotherguy@ghidora;}
\end{itemize}

You can verify that this is true by examining the \texttt{mysql.event} table (discussed later in this section) or the \texttt{INFORMATION_SCHEMA.EVENTS} table (see Section 21.3.8, “The INFORMATION_SCHEMA EVENTS Table”) before and after issuing a \texttt{DROP USER} or \texttt{RENAME USER} statement.

Event definitions are stored in the \texttt{mysql.event} table. To drop an event created by another user account, the MySQL \texttt{root} user (or another user with the necessary privileges) can delete rows from this table. For example, to remove the event \texttt{e_insert} shown previously, \texttt{root} can use the following statement:

\begin{verbatim}
DELETE FROM mysql.event
  WHERE db = 'myschema';
\end{verbatim}
It is very important to match the event name and database schema name when deleting rows from the `mysql.event` table. This is because different events of the same name can exist in different schemas.

Users' `EVENT` privileges are stored in the `Event_priv` columns of the `mysql.user` and `mysql.db` tables. In both cases, this column holds one of the values 'Y' or 'N'. 'N' is the default. `mysql.user.Event_priv` is set to 'Y' for a given user only if that user has the global `EVENT` privilege (that is, if the privilege was bestowed using `GRANT EVENT ON *.*`). For a schema-level `EVENT` privilege, `GRANT` creates a row in `mysql.db` and sets that row's `Db` column to the name of the schema, the `User` column to the name of the user, and the `Event_priv` column to 'Y'. There should never be any need to manipulate these tables directly, since the `GRANT EVENT` and `REVOKE EVENT` statements perform the required operations on them.

Five status variables provide counts of event-related operations (but not of statements executed by events; see Section 20.8, “Restrictions on Stored Programs”). These are:

- `Com_create_event`: The number of `CREATE EVENT` statements executed since the last server restart.
- `Com_alter_event`: The number of `ALTER EVENT` statements executed since the last server restart.
- `Com_drop_event`: The number of `DROP EVENT` statements executed since the last server restart.
- `Com_show_create_event`: The number of `SHOW CREATE EVENT` statements executed since the last server restart.
- `Com_show_events`: The number of `SHOW EVENTS` statements executed since the last server restart.

You can view current values for all of these at one time by running the statement `SHOW STATUS LIKE '%event%';`.

### 20.5 Using Views

MySQL supports views, including updatable views. Views are stored queries that when invoked produce a result set. A view acts as a virtual table.

To use views if you have upgraded to MySQL 5.6 from an older release that did not support views, you should upgrade your grant tables so that they contain the view-related privileges. See Section 4.4.7, “mysql_upgrade — Check and Upgrade MySQL Tables”.

The following discussion describes the syntax for creating and dropping views, and shows some examples of how to use them.

### Additional Resources

- You may find the Views User Forum of use when working with views.
- For answers to some commonly asked questions regarding views in MySQL, see Section A.6, “MySQL 5.6 FAQ: Views”.
- There are some restrictions on the use of views; see Section 20.9, “Restrictions on Views”.

### 20.5.1 View Syntax

The `CREATE VIEW` statement creates a new view (see Section 13.1.20, “CREATE VIEW Statement”). To alter the definition of a view or drop a view, use `ALTER VIEW` (see Section 13.1.9, “ALTER VIEW Statement”), or `DROP VIEW` (see Section 13.1.31, “DROP VIEW Statement”).
A view can be created from many kinds of `SELECT` statements. It can refer to base tables or other views. It can use joins, `UNION`, and subqueries. The `SELECT` need not even refer to any tables. The following example defines a view that selects two columns from another table, as well as an expression calculated from those columns:

```
mysql> CREATE TABLE t (qty INT, price INT);
mysql> INSERT INTO t VALUES(3, 50), (5, 60);
mysql> CREATE VIEW v AS SELECT qty, price, qty*price AS value FROM t;
mysql> SELECT * FROM v;
+----+----+-----+
| qty| price| value|
+----+----+-----+
|    3|    50|   150|
|    5|    60|   300|
+----+----+-----+
mysql> SELECT * FROM v WHERE qty = 5;
+----+----+-----+
| qty| price| value|
+----+----+-----+
|    5|    60|   300|
+----+----+-----+
```

### 20.5.2 View Processing Algorithms

The optional `ALGORITHM` clause for `CREATE VIEW` or `ALTER VIEW` is a MySQL extension to standard SQL. It affects how MySQL processes the view. `ALGORITHM` takes three values: `MERGE`, `TEMPTABLE`, or `UNDEFINED`.

- For `MERGE`, the text of a statement that refers to the view and the view definition are merged such that parts of the view definition replace corresponding parts of the statement.
- For `TEMPTABLE`, the results from the view are retrieved into a temporary table, which then is used to execute the statement.
- For `UNDEFINED`, MySQL chooses which algorithm to use. It prefers `MERGE` over `TEMPTABLE` if possible, because `MERGE` is usually more efficient and because a view cannot be updatable if a temporary table is used.
- If no `ALGORITHM` clause is present, `UNDEFINED` is the default algorithm.

A reason to specify `TEMPTABLE` explicitly is that locks can be released on underlying tables after the temporary table has been created and before it is used to finish processing the statement. This might result in quicker lock release than the `MERGE` algorithm so that other clients that use the view are not blocked as long.

A view algorithm can be `UNDEFINED` for three reasons:

- No `ALGORITHM` clause is present in the `CREATE VIEW` statement.
- The `CREATE VIEW` statement has an explicit `ALGORITHM = UNDEFINED` clause.
- `ALGORITHM = MERGE` is specified for a view that can be processed only with a temporary table. In this case, MySQL generates a warning and sets the algorithm to `UNDEFINED`.

As mentioned earlier, `MERGE` is handled by merging corresponding parts of a view definition into the statement that refers to the view. The following examples briefly illustrate how the `MERGE` algorithm works. The examples assume that there is a view `v_merge` that has this definition:

```
CREATE ALGORITHM = MERGE VIEW v_merge (vc1, vc2) AS
```
SELECT c1, c2 FROM t WHERE c3 > 100;

Example 1: Suppose that we issue this statement:

SELECT * FROM v_merge;

MySQL handles the statement as follows:

- `v_merge` becomes `t`
- `*` becomes `vc1, vc2`, which corresponds to `c1, c2`
- The view `WHERE` clause is added

The resulting statement to be executed becomes:

SELECT c1, c2 FROM t WHERE c3 > 100;

Example 2: Suppose that we issue this statement:

SELECT * FROM v_merge WHERE vc1 < 100;

This statement is handled similarly to the previous one, except that `vc1 < 100` becomes `c1 < 100` and the view `WHERE` clause is added to the statement using an `AND` connective (and parentheses are added to make sure the parts of the clause are executed with correct precedence). The resulting statement to be executed becomes:

SELECT c1, c2 FROM t WHERE (c3 > 100) AND (c1 < 100);

Effectively, the statement to be executed has a `WHERE` clause of this form:

`WHERE (select WHERE) AND (view WHERE)`

If the `MERGE` algorithm cannot be used, a temporary table must be used instead. `MERGE` cannot be used if the view contains any of the following constructs:

- Aggregate functions (`SUM()`, `MIN()`, `MAX()`, `COUNT()`, and so forth)
- `DISTINCT`
- `GROUP BY`
- `HAVING`
- `LIMIT`
- `UNION` or `UNION ALL`
- Subquery in the select list
- Assignment to user variables
- Refers only to literal values (in this case, there is no underlying table)

### 20.5.3 Updatable and Insertable Views

Some views are updatable and references to them can be used to specify tables to be updated in data change statements. That is, you can use them in statements such as `UPDATE`, `DELETE`, or `INSERT` to update the contents of the underlying table.
For a view to be updatable, there must be a one-to-one relationship between the rows in the view and the rows in the underlying table. There are also certain other constructs that make a view nonupdatable. To be more specific, a view is not updatable if it contains any of the following:

- Aggregate functions (SUM(), MIN(), MAX(), COUNT(), and so forth)
- DISTINCT
- GROUP BY
- HAVING
- UNION or UNION ALL
- Subquery in the select list
- Certain joins (see additional join discussion later in this section)
- Reference to nonupdatable view in the FROM clause
- Subquery in the WHERE clause that refers to a table in the FROM clause
- Refers only to literal values (in this case, there is no underlying table to update)
- ALGORITHM = TEMPTABLE (use of a temporary table always makes a view nonupdatable)
- Multiple references to any column of a base table

It is sometimes possible for a multiple-table view to be updatable, assuming that it can be processed with the MERGE algorithm. For this to work, the view must use an inner join (not an outer join or a UNION). Also, only a single table in the view definition can be updated, so the SET clause must name only columns from one of the tables in the view. Views that use UNION ALL are not permitted even though they might be theoretically updatable.

With respect to insertability (being updatable with INSERT statements), an updatable view is insertable if it also satisfies these additional requirements for the view columns:

- There must be no duplicate view column names.
- The view must contain all columns in the base table that do not have a default value.
- The view columns must be simple column references. They must not be expressions, such as these:

```
3.14159
col1 + 3
UPPER(col2)
col3 / col4
(subquery)
```

MySQL sets a flag, called the view updatability flag, at CREATE VIEW time. The flag is set to YES (true) if UPDATE and DELETE (and similar operations) are legal for the view. Otherwise, the flag is set to NO (false). The IS_UPDATABLE column in the INFORMATION_SCHEMA.VIEWS table displays the status of this flag. It means that the server always knows whether a view is updatable.

If a view is not updatable, statements such UPDATE, DELETE, and INSERT are illegal and are rejected. (Even if a view is updatable, it might not be possible to insert into it, as described elsewhere in this section.)

The updatability of views may be affected by the value of the updatable_views_with_limit system variable. See Section 5.1.7, “Server System Variables”.
Earlier discussion in this section pointed out that a view is not insertable if not all columns are simple column references (for example, if it contains columns that are expressions or composite expressions). Although such a view is not insertable, it can be updatable if you update only columns that are not expressions. Consider this view:

```
CREATE VIEW v AS SELECT col1, 1 AS col2 FROM t;
```

This view is not insertable because `col2` is an expression. But it is updatable if the update does not try to update `col2`. This update is permissible:

```
UPDATE v SET col1 = 0;
```

This update is not permissible because it attempts to update an expression column:

```
UPDATE v SET col2 = 0;
```

For a multiple-table updatable view, `INSERT` can work if it inserts into a single table. `DELETE` is not supported.

`INSERT DELAYED` is not supported for views.

If a table contains an `AUTO_INCREMENT` column, inserting into an insertable view on the table that does not include the `AUTO_INCREMENT` column does not change the value of `LAST_INSERT_ID()`, because the side effects of inserting default values into columns not part of the view should not be visible.

### 20.5.4 The View WITH CHECK OPTION Clause

The `WITH CHECK OPTION` clause can be given for an updatable view to prevent inserts to rows for which the `WHERE` clause in the `select_statement` is not true. It also prevents updates to rows for which the `WHERE` clause is true but the update would cause it to be not true (in other words, it prevents visible rows from being updated to nonvisible rows).

In a `WITH CHECK OPTION` clause for an updatable view, the `LOCAL` and `CASCADED` keywords determine the scope of check testing when the view is defined in terms of another view. When neither keyword is given, the default is `CASCADED`. The `LOCAL` keyword restricts the `CHECK OPTION` only to the view being defined. `CASCADED` causes the checks for underlying views to be evaluated as well.

Consider the definitions for the following table and set of views:

```
CREATE TABLE t1 (a INT);
CREATE VIEW v1 AS SELECT * FROM t1 WHERE a < 2 WITH CHECK OPTION;
CREATE VIEW v2 AS SELECT * FROM v1 WHERE a > 0 WITH LOCAL CHECK OPTION;
CREATE VIEW v3 AS SELECT * FROM v1 WHERE a > 0 WITH CASCADED CHECK OPTION;
```

Here the `v2` and `v3` views are defined in terms of another view, `v1`. `v2` has a `LOCAL` check option, so inserts are tested only against the `v2` check. `v3` has a `CASCADED` check option, so inserts are tested not only against its own check, but against those of underlying views. The following statements illustrate these differences:

```
mysql> INSERT INTO v2 VALUES (2);
Query OK, 1 row affected (0.00 sec)
mysql> INSERT INTO v3 VALUES (2);
ERROR 1369 (HY000): CHECK OPTION failed 'test.v3'
```

### 20.5.5 View Metadata
To obtain metadata about views:

- Query the `VIEWS` table of the `INFORMATION_SCHEMA` database. See Section 21.3.29, “The INFORMATION_SCHEMA VIEWS Table”.
- Use the `SHOW CREATE VIEW` statement. See Section 13.7.5.14, “SHOW CREATE VIEW Statement”.

## 20.6 Stored Object Access Control

Stored programs (procedures, functions, triggers, and events) and views are defined prior to use and, when referenced, execute within a security context that determines their privileges. The privileges applicable to execution of a stored object are controlled by its `DEFINER` attribute and `SQL SECURITY` characteristic.

### The `DEFINER` Attribute

A stored object definition can include a `DEFINER` attribute that names a MySQL account. If a definition omits the `DEFINER` attribute, the default object definer is the user who creates it.

The following rules determine which accounts you can specify as the `DEFINER` attribute for a stored object:

- If you have the `SUPER` privilege, you can specify any account as the `DEFINER` attribute. If the account does not exist, a warning is generated.
- Otherwise, the only permitted account is your own, specified either literally or as `CURRENT_USER` or `CURRENT_USER()`. You cannot set the definer to any other account.

Creating a stored object with a nonexistent `DEFINER` account creates an orphan object, which may have negative consequences; see Orphan Stored Objects.

### The `SQL SECURITY` Characteristic

For stored routines (procedures and functions) and views, the object definition can include an `SQL SECURITY` characteristic with a value of `DEFINER` or `INVOKER` to specify whether the object executes in definer or invoker context. If the definition omits the `SQL SECURITY` characteristic, the default is definer context.

Triggers and events have no `SQL SECURITY` characteristic and always execute in definer context. The server invokes these objects automatically as necessary, so there is no invoking user.

Definer and invoker security contexts differ as follows:

- A stored object that executes in definer security context executes with the privileges of the account named by its `DEFINER` attribute. These privileges may be entirely different from those of the invoking
Examples

The invoker must have appropriate privileges to reference the object (for example, `EXECUTE` to call a stored procedure or `SELECT` to select from a view), but during object execution, the invoker's privileges are ignored and only the `DEFINER` account privileges matter. If the `DEFINER` account has few privileges, the object is correspondingly limited in the operations it can perform. If the `DEFINER` account is highly privileged (such as an administrative account), the object can perform powerful operations *no matter who invokes it.*

- A stored routine or view that executes in invoker security context can perform only operations for which the invoker has privileges. The `DEFINER` attribute has no effect on object execution.

**Examples**

Consider the following stored procedure, which is declared with `SQL SECURITY DEFINER` to execute in definer security context:

```sql
CREATE DEFINER = 'admin'@'localhost' PROCEDURE p1()
SQL SECURITY DEFINER
BEGIN
  UPDATE t1 SET counter = counter + 1;
END;
```

Any user who has the `EXECUTE` privilege for `p1` can invoke it with a `CALL` statement. However, when `p1` executes, it does so in definer security context and thus executes with the privileges of `'admin'@'localhost'`, the account named as its `DEFINER` attribute. This account must have the `EXECUTE` privilege for `p1` as well as the `UPDATE` privilege for the table `t1` referenced within the object body. Otherwise, the procedure fails.

Now consider this stored procedure, which is identical to `p1` except that its `SQL SECURITY` characteristic is `INVOKER`:

```sql
CREATE DEFINER = 'admin'@'localhost' PROCEDURE p2()
SQL SECURITY INVOKER
BEGIN
  UPDATE t1 SET counter = counter + 1;
END;
```

Unlike `p1`, `p2` executes in invoker security context and thus with the privileges of the invoking user regardless of the `DEFINER` attribute value. `p2` fails if the invoker lacks the `EXECUTE` privilege for `p2` or the `UPDATE` privilege for the table `t1`.

**Orphan Stored Objects**

An orphan stored object is one for which its `DEFINER` attribute names a nonexistent account:

- An orphan stored object can be created by specifying a nonexistent `DEFINER` account at object-creation time.

- An existing stored object can become orphaned through execution of a `DROP USER` statement that drops the object `DEFINER` account, or a `RENAME USER` statement that renames the object `DEFINER` account.

An orphan stored object may be problematic in these ways:

- Because the `DEFINER` account does not exist, the object may not work as expected if it executes in definer security context:

- For a stored routine, an error occurs at routine execution time if the `SQL SECURITY` value is `DEFINER` but the definer account does not exist.
Orphan Stored Objects

- For a trigger, it is not a good idea for trigger activation to occur until the account actually does exist. Otherwise, the behavior with respect to privilege checking is undefined.

- For an event, an error occurs at event execution time if the account does not exist.

- For a view, an error occurs when the view is referenced if the SQL SECURITY value is DEFINER but the definer account does not exist.

- The object may present a security risk if the nonexistent DEFINER account is subsequently re-created for a purpose unrelated to the object. In this case, the account “adopts” the object and, with the appropriate privileges, is able to execute it even if that is not intended.

To obtain information about the accounts used as stored object definers in a MySQL installation, query the INFORMATION_SCHEMA.

This query identifies which INFORMATION_SCHEMA tables describe objects that have a DEFINER attribute:

```sql
mysql> SELECT TABLE_SCHEMA, TABLE_NAME FROM INFORMATION_SCHEMA.COLUMNS
WHERE COLUMN_NAME = 'DEFINER';
```

<table>
<thead>
<tr>
<th>TABLE_SCHEMA</th>
<th>TABLE_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>information_schema</td>
<td>EVENTS</td>
</tr>
<tr>
<td>information_schema</td>
<td>ROUTINES</td>
</tr>
<tr>
<td>information_schema</td>
<td>TRIGGERS</td>
</tr>
<tr>
<td>information_schema</td>
<td>VIEWS</td>
</tr>
</tbody>
</table>
```

The result tells you which tables to query to discover which stored object DEFINER values exist and which objects have a particular DEFINER value:

- To identify which DEFINER values exist in each table, use these queries:

  ```sql
  SELECT DISTINCT DEFINER FROM INFORMATION_SCHEMA.EVENTS;
  SELECT DISTINCT DEFINER FROM INFORMATION_SCHEMA.ROUTINES;
  SELECT DISTINCT DEFINER FROM INFORMATION_SCHEMA.TRIGGERS;
  SELECT DISTINCT DEFINER FROM INFORMATION_SCHEMA.VIEWS;
  ```

The query results are significant for any account displayed as follows:

- If the account exists, dropping or renaming it causes stored objects to become orphaned. If you plan to drop or rename the account, consider first dropping its associated stored objects or redefining them to have a different definer.

- If the account does not exist, creating it causes it to adopt currently orphaned stored objects. If you plan to create the account, consider whether the orphaned objects should be associated with it. If not, redefine them to have a different definer.

To redefine an object with a different definer, you can use ALTER EVENT or ALTER VIEW to directly modify the DEFINER account of events and views. For stored procedures and functions and for triggers, you must drop the object and re-create it with a different DEFINER account.

- To identify which objects have a given DEFINER account, use these queries, substituting the account of interest for user_name@host_name:

  ```sql
  SELECT EVENT_SCHEMA, EVENT_NAME FROM INFORMATION_SCHEMA.EVENTS
  WHERE DEFINER = 'user_name@host_name';
  SELECT ROUTINE_SCHEMA, ROUTINE_NAME, ROUTINE_TYPE
  FROM INFORMATION_SCHEMA.ROUTINES
  WHERE DEFINER = 'user_name@host_name';
  ```
For the `ROUTINES` table, the query includes the `ROUTINE_TYPE` column so that output rows distinguish whether the `DEFINER` is for a stored procedure or stored function.

If the account you are searching for does not exist, any objects displayed by those queries are orphan objects.

Risk-Minimization Guidelines

To minimize the risk potential for stored object creation and use, follow these guidelines:

- Do not create orphan stored objects; that is, objects for which the `DEFINER` attribute names a nonexistent account. Do not cause stored objects to become orphaned by dropping or renaming an account named by the `DEFINER` attribute of any existing object.

- For a stored routine or view, use `SQL SECURITY INVOKER` in the object definition when possible so that it can be used only by users with permissions appropriate for the operations performed by the object.

- If you create definer-context stored objects while using an account that has the `SUPER` privilege, specify an explicit `DEFINER` attribute that names an account possessing only the privileges required for the operations performed by the object. Specify a highly privileged `DEFINER` account only when absolutely necessary.

- Administrators can prevent users from creating stored objects that specify highly privileged `DEFINER` accounts by not granting them the `SUPER` privilege.

- Definer-context objects should be written keeping in mind that they may be able to access data for which the invoking user has no privileges. In some cases, you can prevent references to these objects by not granting unauthorized users particular privileges:
  - A stored routine cannot be referenced by a user who does not have the `EXECUTE` privilege for it.
  - A view cannot be referenced by a user who does not have the appropriate privilege for it (`SELECT` to select from it, `INSERT` to insert into it, and so forth).

However, no such control exists for triggers and events because they always execute in definer context. The server invokes these objects automatically as necessary, and users do not reference them directly:

- A trigger is activated by access to the table with which it is associated, even ordinary table accesses by users with no special privileges.

- An event is executed by the server on a scheduled basis.

In both cases, if the `DEFINER` account is highly privileged, the object may be able to perform sensitive or dangerous operations. This remains true if the privileges needed to create the object are revoked from the account of the user who created it. Administrators should be especially careful about granting users object-creation privileges.

20.7 Stored Program Binary Logging

The binary log contains information about SQL statements that modify database contents. This information is stored in the form of "events" that describe the modifications. (Binary log events differ from scheduled event stored objects.) The binary log has two important purposes:
For replication, the binary log is used on source replication servers as a record of the statements to be sent to replica servers. The source sends the events contained in its binary log to its replicas, which execute those events to make the same data changes that were made on the source. See Section 17.2, “Replication Implementation”.

Certain data recovery operations require use of the binary log. After a backup file has been restored, the events in the binary log that were recorded after the backup was made are re-executed. These events bring databases up to date from the point of the backup. See Section 7.3.2, “Using Backups for Recovery”.

However, if logging occurs at the statement level, there are certain binary logging issues with respect to stored programs (stored procedures and functions, triggers, and events):

- In some cases, a statement might affect different sets of rows on source and replica.
- Replicated statements executed on a replica are processed by the replica SQL thread, which has full privileges. It is possible for a procedure to follow different execution paths on source and replica servers, so a user can write a routine containing a dangerous statement that executes only on the replica where it is processed by a thread that has full privileges.
- If a stored program that modifies data is nondeterministic, it is not repeatable. This can result in different data on source and replica, or cause restored data to differ from the original data.

This section describes how MySQL handles binary logging for stored programs. It states the current conditions that the implementation places on the use of stored programs, and what you can do to avoid logging problems. It also provides additional information about the reasons for these conditions.

In general, the issues described here result when binary logging occurs at the SQL statement level (statement-based binary logging). If you use row-based binary logging, the log contains changes made to individual rows as a result of executing SQL statements. When routines or triggers execute, row changes are logged, not the statements that make the changes. For stored procedures, this means that the CALL statement is not logged. For stored functions, row changes made within the function are logged, not the function invocation. For triggers, row changes made by the trigger are logged. On the replica side, only the row changes are seen, not the stored program invocation.

Mixed format binary logging (binlog_format=MIXED) uses statement-based binary logging, except for cases where only row-based binary logging is guaranteed to lead to proper results. With mixed format, when a stored function, stored procedure, trigger, event, or prepared statement contains anything that is not safe for statement-based binary logging, the entire statement is marked as unsafe and logged in row format. The statements used to create and drop procedures, functions, triggers, and events are always safe, and are logged in statement format. For more information about row-based, mixed, and statement-based logging, and how safe and unsafe statements are determined, see Section 17.1.2, “Replication Formats”.

Unless noted otherwise, the remarks here assume that binary logging is enabled on the server (see Section 5.4.4, “The Binary Log”). If the binary log is not enabled, replication is not possible, nor is the binary log available for data recovery.

The conditions on the use of stored functions in MySQL can be summarized as follows. These conditions do not apply to stored procedures or Event Scheduler events and they do not apply unless binary logging is enabled.

- To create or alter a stored function, you must have the SUPER privilege, in addition to the CREATE ROUTINE or ALTER ROUTINE privilege that is normally required. (Depending on the DEFINER value in the function definition, SUPER might be required regardless of whether binary logging is enabled. See Section 13.1.15, “CREATE PROCEDURE and CREATE FUNCTION Statements”.)
• When you create a stored function, you must declare either that it is deterministic or that it does not modify data. Otherwise, it may be unsafe for data recovery or replication.

By default, for a CREATE FUNCTION statement to be accepted, at least one of DETERMINISTIC, NO SQL, or READS SQL DATA must be specified explicitly. Otherwise an error occurs:

```
ERROR 1418 (HY000): This function has none of DETERMINISTIC, NO SQL, or READS SQL DATA in its declaration and binary logging is enabled
(you *might* want to use the less safe log_bin_trust_function_creators variable)
```

This function is deterministic (and does not modify data), so it is safe:

```
CREATE FUNCTION f1(i INT)
RETURNS INT
DETERMINISTIC
READS SQL DATA
BEGIN
  RETURN i;
END;
```

This function uses UUID(), which is not deterministic, so the function also is not deterministic and is not safe:

```
CREATE FUNCTION f2()
RETURNS CHAR(36) CHARACTER SET utf8
BEGIN
  RETURN UUID();
END;
```

This function modifies data, so it may not be safe:

```
CREATE FUNCTION f3(p_id INT)
RETURNS INT
BEGIN
  UPDATE t SET modtime = NOW() WHERE id = p_id;
  RETURN ROW_COUNT();
END;
```

Assessment of the nature of a function is based on the “honesty” of the creator. MySQL does not check that a function declared DETERMINISTIC is free of statements that produce nondeterministic results.

• When you attempt to execute a stored function, if binlog_format=STATEMENT is set, the DETERMINISTIC keyword must be specified in the function definition. If this is not the case, an error is generated and the function does not run, unless log_bin_trust_function_creators=1 is specified to override this check (see below). For recursive function calls, the DETERMINISTIC keyword is required on the outermost call only. If row-based or mixed binary logging is in use, the statement is accepted and replicated even if the function was defined without the DETERMINISTIC keyword.

• Because MySQL does not check if a function really is deterministic at creation time, the invocation of a stored function with the DETERMINISTIC keyword might carry out an action that is unsafe for statement-based logging, or invoke a function or procedure containing unsafe statements. If this occurs when binlog_format=STATEMENT is set, a warning message is issued. If row-based or mixed binary logging is in use, no warning is issued, and the statement is replicated in row-based format.

• To relax the preceding conditions on function creation (that you must have the SUPER privilege and that a function must be declared deterministic or to not modify data), set the global log_bin_trust_function_creators system variable to 1. By default, this variable has a value of 0, but you can change it like this:

```
mysql> SET GLOBAL log_bin_trust_function_creators = 1;
```
You can also set this variable at server startup.

If binary logging is not enabled, `log_bin_trust_function_creators` does not apply. `SUPER` is not required for function creation unless, as described previously, the `DEFINER` value in the function definition requires it.

- For information about built-in functions that may be unsafe for replication (and thus cause stored functions that use them to be unsafe as well), see Section 17.4.1, “Replication Features and Issues”.

Triggers are similar to stored functions, so the preceding remarks regarding functions also apply to triggers with the following exception: `CREATE TRIGGER` does not have an optional `DETERMINISTIC` characteristic, so triggers are assumed to be always deterministic. However, this assumption might be invalid in some cases. For example, the `UUID()` function is nondeterministic (and does not replicate). Be careful about using such functions in triggers.

Triggers can update tables, so error messages similar to those for stored functions occur with `CREATE TRIGGER` if you do not have the required privileges. On the replica side, the replica uses the trigger `DEFINER` attribute to determine which user is considered to be the creator of the trigger.

The rest of this section provides additional detail about the logging implementation and its implications. You need not read it unless you are interested in the background on the rationale for the current logging-related conditions on stored routine use. This discussion applies only for statement-based logging, and not for row-based logging, with the exception of the first item: `CREATE` and `DROP` statements are logged as statements regardless of the logging mode.

- The server writes `CREATE EVENT`, `CREATE PROCEDURE`, `CREATE FUNCTION`, `ALTER EVENT`, `ALTER PROCEDURE`, `ALTER FUNCTION`, `DROP EVENT`, `DROP PROCEDURE`, and `DROP FUNCTION` statements to the binary log.
- A stored function invocation is logged as a `SELECT` statement if the function changes data and occurs within a statement that would not otherwise be logged. This prevents nonreplication of data changes that result from use of stored functions in nonlogged statements. For example, `SELECT` statements are not written to the binary log, but a `SELECT` might invoke a stored function that makes changes. To handle this, a `SELECT func_name()` statement is written to the binary log when the given function makes a change. Suppose that the following statements are executed on the source server:

```sql
CREATE FUNCTION f1(a INT) RETURNS INT
BEGIN
    IF (a < 3) THEN
        INSERT INTO t2 VALUES (a);
    END IF;
    RETURN 0;
END;

CREATE TABLE t1 (a INT);
INSERT INTO t1 VALUES (1),(2),(3);
SELECT f1(a) FROM t1;
```

When the `SELECT` statement executes, the function `f1()` is invoked three times. Two of those invocations insert a row, and MySQL logs a `SELECT` statement for each of them. That is, MySQL writes the following statements to the binary log:

```sql
SELECT f1(1);
SELECT f1(2);
```

The server also logs a `SELECT` statement for a stored function invocation when the function invokes a stored procedure that causes an error. In this case, the server writes the `SELECT` statement to the log.
along with the expected error code. On the replica, if the same error occurs, that is the expected result and replication continues. Otherwise, replication stops.

- Logging stored function invocations rather than the statements executed by a function has a security implication for replication, which arises from two factors:

  - It is possible for a function to follow different execution paths on source and replica servers.
  
  - Statements executed on a replica are processed by the replica SQL thread which has full privileges.

The implication is that although a user must have the **CREATE ROUTINE** privilege to create a function, the user can write a function containing a dangerous statement that executes only on the replica where it is processed by a thread that has full privileges. For example, if the source and replica servers have server ID values of 1 and 2, respectively, a user on the source server could create and invoke an unsafe function `unsafe_func()` as follows:

```sql
mysql> delimiter //
mysql> CREATE FUNCTION unsafe_func () RETURNS INT
   -> BEGIN
   -> IF @@server_id=2 THEN dangerous_statement; END IF;
   -> RETURN 1;
   -> END;
   -> //
mysql> delimiter ;
mysql> INSERT INTO t VALUES(unsafe_func());
```

The **CREATE FUNCTION** and **INSERT** statements are written to the binary log, so the replica executes them. Because the replica SQL thread has full privileges, it executes the dangerous statement. Thus, the function invocation has different effects on the source and replica and is not replication-safe.

To guard against this danger for servers that have binary logging enabled, stored function creators must have the **SUPER** privilege, in addition to the usual **CREATE ROUTINE** privilege that is required. Similarly, to use **ALTER FUNCTION**, you must have the **SUPER** privilege in addition to the **ALTER ROUTINE** privilege. Without the **SUPER** privilege, an error occurs:

```sql
ERROR 1419 (HY000): You do not have the SUPER privilege and binary logging is enabled (you *might* want to use the less safe log_bin_trust_function_creators variable)
```

If you do not want to require function creators to have the **SUPER** privilege (for example, if all users with the **CREATE ROUTINE** privilege on your system are experienced application developers), set the global `log_bin_trust_function_creators` system variable to 1. You can also set this variable at server startup. If binary logging is not enabled, `log_bin_trust_function_creators` does not apply. **SUPER** is not required for function creation unless, as described previously, the **DEFINER** value in the function definition requires it.

- If a function that performs updates is nondeterministic, it is not repeatable. This can have two undesirable effects:

  - It makes a replica different from the source.
  
  - Restored data is different from the original data.

To deal with these problems, MySQL enforces the following requirement: On a source server, creation and alteration of a function is refused unless you declare the function to be deterministic or to not modify data. Two sets of function characteristics apply here:

- The **DETERMINISTIC** and **NOT DETERMINISTIC** characteristics indicate whether a function always produces the same result for given inputs. The default is **NOT DETERMINISTIC** if neither
characteristic is given. To declare that a function is deterministic, you must specify `DETERMINISTIC` explicitly.

- The `CONTAINS SQL`, `NO SQL`, `READS SQL DATA`, and `MODIFIES SQL DATA` characteristics provide information about whether the function reads or writes data. Either `NO SQL` or `READS SQL DATA` indicates that a function does not change data, but you must specify one of these explicitly because the default is `CONTAINS SQL` if no characteristic is given.

By default, for a `CREATE FUNCTION` statement to be accepted, at least one of `DETERMINISTIC`, `NO SQL`, or `READS SQL DATA` must be specified explicitly. Otherwise an error occurs:

```
ERROR 1418 (HY000): This function has none of DETERMINISTIC, NO SQL, or READS SQL DATA in its declaration and binary logging is enabled
(you *might* want to use the less safe log_bin_trust_function_creators variable)
```

If you set `log_bin_trust_function_creators` to 1, the requirement that functions be deterministic or not modify data is dropped.

- Stored procedure calls are logged at the statement level rather than at the `CALL` level. That is, the server does not log the `CALL` statement, it logs those statements within the procedure that actually execute. As a result, the same changes that occur on the source server are observed on replicas. This prevents problems that could result from a procedure having different execution paths on different machines.

In general, statements executed within a stored procedure are written to the binary log using the same rules that would apply were the statements to be executed in standalone fashion. Some special care is taken when logging procedure statements because statement execution within procedures is not quite the same as in nonprocedure context:

- A statement to be logged might contain references to local procedure variables. These variables do not exist outside of stored procedure context, so a statement that refers to such a variable cannot be logged literally. Instead, each reference to a local variable is replaced by this construct for logging purposes:

  ```
  NAME_CONST(var_name, var_value)
  ```

  `var_name` is the local variable name, and `var_value` is a constant indicating the value that the variable has at the time the statement is logged. `NAME_CONST()` has a value of `var_value`, and a “name” of `var_name`. Thus, if you invoke this function directly, you get a result like this:

```
mysql> SELECT NAME_CONST('myname', 14);
+--------+
<table>
<thead>
<tr>
<th>myname</th>
</tr>
</thead>
<tbody>
<tr>
<td>14</td>
</tr>
</tbody>
</table>
+--------+
```

`NAME_CONST()` enables a logged standalone statement to be executed on a replica with the same effect as the original statement that was executed on the source within a stored procedure.

The use of `NAME_CONST()` can result in a problem for `CREATE TABLE ... SELECT` statements when the source column expressions refer to local variables. Converting these references to `NAME_CONST()` expressions can result in column names that are different on the source and replica...
Restrictions on Stored Programs

servers, or names that are too long to be legal column identifiers. A workaround is to supply aliases for
columns that refer to local variables. Consider this statement when \texttt{myvar} has a value of 1:

\begin{verbatim}
CREATE TABLE t1 SELECT myvar;
\end{verbatim}

That is rewritten as follows:

\begin{verbatim}
CREATE TABLE t1 SELECT NAME_CONST(myvar, 1);
\end{verbatim}

To ensure that the source and replica tables have the same column names, write the statement like
this:

\begin{verbatim}
CREATE TABLE t1 SELECT myvar \textbf{AS myvar};
\end{verbatim}

The rewritten statement becomes:

\begin{verbatim}
CREATE TABLE t1 SELECT NAME_CONST(myvar, 1) \textbf{AS myvar};
\end{verbatim}

• A statement to be logged might contain references to user-defined variables. To handle this, MySQL
writes a \texttt{SET} statement to the binary log to make sure that the variable exists on the replica with the
same value as on the source. For example, if a statement refers to a variable \texttt{@my\_var}, that statement
is preceded in the binary log by the following statement, where \texttt{value} is the value of \texttt{@my\_var} on the
source:

\begin{verbatim}
SET @my\_var = \texttt{value};
\end{verbatim}

• Procedure calls can occur within a committed or rolled-back transaction. Transactional context is
accounted for so that the transactional aspects of procedure execution are replicated correctly. That is,
the server logs those statements within the procedure that actually execute and modify data, and also
logs \texttt{BEGIN}, \texttt{COMMIT}, and \texttt{ROLLBACK} statements as necessary. For example, if a procedure updates
only transactional tables and is executed within a transaction that is rolled back, those updates are not
logged. If the procedure occurs within a committed transaction, \texttt{BEGIN} and \texttt{COMMIT} statements are
logged with the updates. For a procedure that executes within a rolled-back transaction, its statements
are logged using the same rules that would apply if the statements were executed in standalone
fashion:

• Updates to transactional tables are not logged.

• Updates to nontransactional tables are logged because rollback does not cancel them.

• Updates to a mix of transactional and nontransactional tables are logged surrounded by \texttt{BEGIN} and
\texttt{ROLLBACK} so that replicas make the same changes and rollbacks as on the source.

• A stored procedure call is \textit{not} written to the binary log at the statement level if the procedure is invoked
from within a stored function. In that case, the only thing logged is the statement that invokes the
function (if it occurs within a statement that is logged) or a \texttt{DO} statement (if it occurs within a statement
that is not logged). For this reason, care should be exercised in the use of stored functions that invoke a
procedure, even if the procedure is otherwise safe in itself.

\section*{20.8 Restrictions on Stored Programs}

• \textbf{SQL Statements Not Permitted in Stored Routines}

• \textbf{Restrictions for Stored Functions}

• \textbf{Restrictions for Triggers}

• \textbf{Name Conflicts within Stored Routines}
SQL Statements Not Permitted in Stored Routines

- Replication Considerations
- Debugging Considerations
- Unsupported Syntax from the SQL:2003 Standard
- Stored Routine Concurrency Considerations
- Event Scheduler Restrictions
- Stored Programs in NDB Cluster

These restrictions apply to the features described in Chapter 20, *Stored Objects*.

Some of the restrictions noted here apply to all stored routines; that is, both to stored procedures and stored functions. There are also some restrictions specific to stored functions but not to stored procedures.

The restrictions for stored functions also apply to triggers. There are also some restrictions specific to triggers.

The restrictions for stored procedures also apply to the DO clause of Event Scheduler event definitions. There are also some restrictions specific to events.

**SQL Statements Not Permitted in Stored Routines**

Stored routines cannot contain arbitrary SQL statements. The following statements are not permitted:

- The locking statements `LOCK TABLES` and `UNLOCK TABLES`.
- `ALTER VIEW`.
- `LOAD DATA` and `LOAD XML`.
- SQL prepared statements (`PREPARE`, `EXECUTE`, `DEALLOCATE PREPARE`) can be used in stored procedures, but not stored functions or triggers. Thus, stored functions and triggers cannot use dynamic SQL (where you construct statements as strings and then execute them).
- Generally, statements not permitted in SQL prepared statements are also not permitted in stored programs. For a list of statements supported as prepared statements, see Section 13.5, “Prepared Statements”. Exceptions are `SIGNAL`, `RESIGNAL`, and `GET DIAGNOSTICS`, which are not permissible as prepared statements but are permitted in stored programs.
- Because local variables are in scope only during stored program execution, references to them are not permitted in prepared statements created within a stored program. Prepared statement scope is the current session, not the stored program, so the statement could be executed after the program ends, at which point the variables would no longer be in scope. For example, `SELECT ... INTO local_var` cannot be used as a prepared statement. This restriction also applies to stored procedure and function parameters. See Section 13.5.1, “PREPARE Statement”.
- Inserts cannot be delayed. `INSERT DELAYED` syntax is accepted, but the statement is handled as a normal `INSERT`.
- Within all stored programs (stored procedures and functions, triggers, and events), the parser treats `BEGIN [WORK]` as the beginning of a `BEGIN ... END` block. To begin a transaction in this context, use `START TRANSACTION` instead.

**Restrictions for Stored Functions**

The following additional statements or operations are not permitted within stored functions. They are permitted within stored procedures, except stored procedures that are invoked from within a stored function.
or trigger. For example, if you use FLUSH in a stored procedure, that stored procedure cannot be called from a stored function or trigger.

- Statements that perform explicit or implicit commit or rollback. Support for these statements is not required by the SQL standard, which states that each DBMS vendor may decide whether to permit them.

- Statements that return a result set. This includes SELECT statements that do not have an INTO var_list clause and other statements such as SHOW, EXPLAIN, and CHECK TABLE. A function can process a result set either with SELECT ... INTO var_list or by using a cursor and FETCH statements. See Section 13.2.9.1, “SELECT ... INTO Statement”, and Section 13.6.6, “Cursors”.

- FLUSH statements.

- Stored functions cannot be used recursively.

- A stored function or trigger cannot modify a table that is already being used (for reading or writing) by the statement that invoked the function or trigger.

- If you refer to a temporary table multiple times in a stored function under different aliases, a Can't reopen table: 'tbl_name' error occurs, even if the references occur in different statements within the function.

- HANDLER ... READ statements that invoke stored functions can cause replication errors and are disallowed.

Restrictions for Triggers

For triggers, the following additional restrictions apply:

- Triggers are not activated by foreign key actions.

- When using row-based replication, triggers on the replica are not activated by statements originating on the source. The triggers on the replica are activated when using statement-based replication. For more information, see Section 17.4.1.33, “Replication and Triggers”.

- The RETURN statement is not permitted in triggers, which cannot return a value. To exit a trigger immediately, use the LEAVE statement.

- Triggers are not permitted on tables in the mysql database. Nor are they permitted on INFORMATION_SCHEMA or performance_schema tables. Those tables are actually views and triggers are not permitted on views.

- The trigger cache does not detect when metadata of the underlying objects has changed. If a trigger uses a table and the table has changed since the trigger was loaded into the cache, the trigger operates using the outdated metadata.

Name Conflicts within Stored Routines

The same identifier might be used for a routine parameter, a local variable, and a table column. Also, the same local variable name can be used in nested blocks. For example:

```sql
CREATE PROCEDURE p (i INT)
BEGIN
  DECLARE i INT DEFAULT 0;
  SELECT i FROM t;
BEGIN
  DECLARE i INT DEFAULT 1;
  SELECT i FROM t;
```
In such cases, the identifier is ambiguous and the following precedence rules apply:

- A local variable takes precedence over a routine parameter or table column.
- A routine parameter takes precedence over a table column.
- A local variable in an inner block takes precedence over a local variable in an outer block.

The behavior that variables take precedence over table columns is nonstandard.

**Replication Considerations**

Use of stored routines can cause replication problems. This issue is discussed further in Section 20.7, “Stored Program Binary Logging”.

The `--replicate-wild-do-table=db_name.tbl_name` option applies to tables, views, and triggers. It does not apply to stored procedures and functions, or events. To filter statements operating on the latter objects, use one or more of the `--replicate-*-db` options.

**Debugging Considerations**

There are no stored routine debugging facilities.

**Unsupported Syntax from the SQL:2003 Standard**

The MySQL stored routine syntax is based on the SQL:2003 standard. The following items from that standard are not currently supported:

- `UNDO` handlers
- `FOR` loops

**Stored Routine Concurrency Considerations**

To prevent problems of interaction between sessions, when a client issues a statement, the server uses a snapshot of routines and triggers available for execution of the statement. That is, the server calculates a list of procedures, functions, and triggers that may be used during execution of the statement, loads them, and then proceeds to execute the statement. While the statement executes, it does not see changes to routines performed by other sessions.

For maximum concurrency, stored functions should minimize their side-effects; in particular, updating a table within a stored function can reduce concurrent operations on that table. A stored function acquires table locks before executing, to avoid inconsistency in the binary log due to mismatch of the order in which statements execute and when they appear in the log. When statement-based binary logging is used, statements that invoke a function are recorded rather than the statements executed within the function. Consequently, stored functions that update the same underlying tables do not execute in parallel. In contrast, stored procedures do not acquire table-level locks. All statements executed within stored procedures are written to the binary log, even for statement-based binary logging. See Section 20.7, “Stored Program Binary Logging”.

**Event Scheduler Restrictions**

The following limitations are specific to the Event Scheduler:
• Event names are handled in case-insensitive fashion. For example, you cannot have two events in the same database with the names `anEvent` and `AnEvent`.

• An event may not be created, altered, or dropped from within a stored program, if the event name is specified by means of a variable. An event also may not create, alter, or drop stored routines or triggers.

• DDL statements on events are prohibited while a `LOCK TABLES` statement is in effect.

• Event timings using the intervals `YEAR`, `QUARTER`, `MONTH`, and `YEAR_MONTH` are resolved in months; those using any other interval are resolved in seconds. There is no way to cause events scheduled to occur at the same second to execute in a given order. In addition—due to rounding, the nature of threaded applications, and the fact that a nonzero length of time is required to create events and to signal their execution—events may be delayed by as much as 1 or 2 seconds. However, the time shown in the `INFORMATION_SCHEMA.EVENTS` table’s `LAST_EXECUTED` column or the `mysql.event` table’s `last_executed` column is always accurate to within one second of the actual event execution time. (See also Bug #16522.)

• Each execution of the statements contained in the body of an event takes place in a new connection; thus, these statements have no effect in a given user session on the server’s statement counts such as `Com_select` and `Com_insert` that are displayed by `SHOW STATUS`. However, such counts are updated in the global scope. (Bug #16422)

• Events do not support times later than the end of the Unix Epoch; this is approximately the beginning of the year 2038. Such dates are specifically not permitted by the Event Scheduler. (Bug #16396)

• References to stored functions, loadable functions, and tables in the `ON SCHEDULE` clauses of `CREATE EVENT` and `ALTER EVENT` statements are not supported. These sorts of references are not permitted. (See Bug #22830 for more information.)

**Stored Programs in NDB Cluster**

While stored procedures, stored functions, triggers, and scheduled events are all supported by tables using the `NDB` storage engine, you must keep in mind that these do not propagate automatically between MySQL Servers acting as Cluster SQL nodes. This is because of the following:

• Stored routine definitions are kept in tables in the `mysql` system database using the `MyISAM` storage engine, and so do not participate in clustering.

• The `.TRN` and `.TRG` files containing trigger definitions are not read by the `NDB` storage engine, and are not copied between Cluster nodes.

Any stored routine or trigger that interacts with NDB Cluster tables must be re-created by running the appropriate `CREATE PROCEDURE`, `CREATE FUNCTION`, or `CREATE TRIGGER` statements on each MySQL Server that participates in the cluster where you wish to use the stored routine or trigger. Similarly, any changes to existing stored routines or triggers must be carried out explicitly on all Cluster SQL nodes, using the appropriate `ALTER` or `DROP` statements on each MySQL Server accessing the cluster.

**Warning**

Do not attempt to work around the issue described in the first item mentioned previously by converting any `mysql` database tables to use the `NDB` storage engine. *Altering the system tables in the `mysql` database is not supported* and is very likely to produce undesirable results.

**20.9 Restrictions on Views**
Restrictions on Views

The maximum number of tables that can be referenced in the definition of a view is 61.

View processing is not optimized:

- It is not possible to create an index on a view.
- Indexes can be used for views processed using the merge algorithm. However, a view that is processed with the temptable algorithm is unable to take advantage of indexes on its underlying tables (although indexes can be used during generation of the temporary tables).

Subqueries cannot be used in the `FROM` clause of a view.

There is a general principle that you cannot modify a table and select from the same table in a subquery. See Section 13.2.10.12, “Restrictions on Subqueries”.

The same principle also applies if you select from a view that selects from the table, if the view selects from the table in a subquery and the view is evaluated using the merge algorithm. Example:

```sql
CREATE VIEW v1 AS
SELECT * FROM t2 WHERE EXISTS (SELECT 1 FROM t1 WHERE t1.a = t2.a);
UPDATE t1, v2 SET t1.a = 1 WHERE t1.b = v2.b;
```

If the view is evaluated using a temporary table, you can select from the table in the view subquery and still modify that table in the outer query. In this case the view is stored in a temporary table and thus you are not really selecting from the table in a subquery and modifying it “at the same time.” (This is another reason you might wish to force MySQL to use the temptable algorithm by specifying `ALGORITHM = TEMPTABLE` in the view definition.)

You can use `DROP TABLE` or `ALTER TABLE` to drop or alter a table that is used in a view definition. No warning results from the `DROP` or `ALTER` operation, even though this invalidates the view. Instead, an error occurs later, when the view is used. `CHECK TABLE` can be used to check for views that have been invalidated by `DROP` or `ALTER` operations.

Before MySQL 5.6.5, a view definition is “frozen” by certain statements. If a statement prepared by `PREPARE` refers to a view, the view definition seen each time the statement is executed later is the definition of the view at the time it was prepared. This is true even if the view definition is changed after the statement is prepared and before it is executed. In the following example, the result returned by the `EXECUTE` statement is a random number, not the current date and time:

```sql
CREATE VIEW v AS SELECT RAND();
PREPARE s FROM 'SELECT * FROM v';
ALTER VIEW v AS SELECT NOW();
EXECUTE s;
```

With regard to view updatability, the overall goal for views is that if any view is theoretically updatable, it should be updatable in practice. MySQL as quickly as possible. Many theoretically updatable views can be updated now, but limitations still exist. For details, see Section 20.5.3, “Updatable and Insertable Views”.

There exists a shortcoming with the current implementation of views. If a user is granted the basic privileges necessary to create a view (the `CREATE VIEW` and `SELECT` privileges), that user cannot call `SHOW CREATE VIEW` on that object unless the user is also granted the `SHOW VIEW` privilege.

That shortcoming can lead to problems backing up a database with `mysqldump`, which may fail due to insufficient privileges. This problem is described in Bug #22062.

The workaround to the problem is for the administrator to manually grant the `SHOW VIEW` privilege to users who are granted `CREATE VIEW`, since MySQL doesn't grant it implicitly when views are created.
Views do not have indexes, so index hints do not apply. Use of index hints when selecting from a view is not permitted.

`SHOW CREATE VIEW` displays view definitions using an `AS alias_name` clause for each column. If a column is created from an expression, the default alias is the expression text, which can be quite long. Aliases for column names in `CREATE VIEW` statements are checked against the maximum column length of 64 characters (not the maximum alias length of 256 characters). As a result, views created from the output of `SHOW CREATE VIEW` fail if any column alias exceeds 64 characters. This can cause problems in the following circumstances for views with too-long aliases:

- View definitions fail to replicate to newer replicas that enforce the column-length restriction.
- Dump files created with `mysqldump` cannot be loaded into servers that enforce the column-length restriction.

A workaround for either problem is to modify each problematic view definition to use aliases that provide shorter column names. Then the view replicates properly, and can be dumped and reloaded without causing an error. To modify the definition, drop and create the view again with `DROP VIEW` and `CREATE VIEW`, or replace the definition with `CREATE OR REPLACE VIEW`.

For problems that occur when reloading view definitions in dump files, another workaround is to edit the dump file to modify its `CREATE VIEW` statements. However, this does not change the original view definitions, which may cause problems for subsequent dump operations.

21.1 Introduction

**INFORMATION_SCHEMA** provides access to database metadata, information about the MySQL server such as the name of a database or table, the data type of a column, or access privileges. Other terms that are sometimes used for this information are *data dictionary* and *system catalog*.

- INFORMATION_SCHEMA Usage Notes
- Character Set Considerations
- INFORMATION_SCHEMA as Alternative to SHOW Statements
- INFORMATION_SCHEMA and Privileges
- Performance Considerations
- Standards Considerations
INFORMATION_SCHEMA Usage Notes

INFORMATION_SCHEMA is a database within each MySQL instance, the place that stores information about all the other databases that the MySQL server maintains. The INFORMATION_SCHEMA database contains several read-only tables. They are actually views, not base tables, so there are no files associated with them, and you cannot set triggers on them. Also, there is no database directory with that name.

Although you can select INFORMATION_SCHEMA as the default database with a USE statement, you can only read the contents of tables, not perform INSERT, UPDATE, or DELETE operations on them.

Here is an example of a statement that retrieves information from INFORMATION_SCHEMA:

```sql
mysql> SELECT table_name, table_type, engine
    FROM information_schema.tables
    WHERE table_schema = 'db5'
    ORDER BY table_name;
```

```
+------------+------------+--------+
| table_name | table_type | engine |
+------------+------------+--------+
| fk         | BASE TABLE | InnoDB |
| fk2        | BASE TABLE | InnoDB |
| goto       | BASE TABLE | MyISAM |
| into       | BASE TABLE | MyISAM |
| k          | BASE TABLE | MyISAM |
| kurs       | BASE TABLE | MyISAM |
| loop       | BASE TABLE | MyISAM |
| pk         | BASE TABLE | InnoDB |
| t          | BASE TABLE | MyISAM |
| t2         | BASE TABLE | MyISAM |
| t3         | BASE TABLE | MyISAM |
| t7         | BASE TABLE | MyISAM |
| tables     | BASE TABLE | MyISAM |
| v          | VIEW       | NULL   |
| v2         | VIEW       | NULL   |
| v3         | VIEW       | NULL   |
| v56        | VIEW       | NULL   |
+------------+------------+--------+
17 rows in set (0.01 sec)
```

Explanation: The statement requests a list of all the tables in database db5, showing just three pieces of information: the name of the table, its type, and its storage engine.

Character Set Considerations

The definition for character columns (for example, TABLES.TABLE_NAME) is generally VARCHAR(N) CHARACTER SET utf8 where N is at least 64. MySQL uses the default collation for this character set (utf8_general_ci) for all searches, sorts, comparisons, and other string operations on such columns.

Because some MySQL objects are represented as files, searches in INFORMATION_SCHEMA string columns can be affected by file system case sensitivity. For more information, see Section 10.8.7, “Using Collation in INFORMATION_SCHEMA Searches”.

INFORMATION_SCHEMA as Alternative to SHOW Statements

The SELECT ... FROM INFORMATION_SCHEMA statement is intended as a more consistent way to provide access to the information provided by the various SHOW statements that MySQL supports (SHOW DATABASES, SHOW TABLES, and so forth). Using SELECT has these advantages, compared to SHOW:
INFORMATION_SCHEMA and Privileges

- It conforms to Codd's rules, because all access is done on tables.
- You can use the familiar syntax of the `SELECT` statement, and only need to learn some table and column names.
- The implementor need not worry about adding keywords.
- You can filter, sort, concatenate, and transform the results from INFORMATION_SCHEMA queries into whatever format your application needs, such as a data structure or a text representation to parse.
- This technique is more interoperable with other database systems. For example, Oracle Database users are familiar with querying tables in the Oracle data dictionary.

Because `SHOW` is familiar and widely used, the `SHOW` statements remain as an alternative. In fact, along with the implementation of INFORMATION_SCHEMA, there are enhancements to `SHOW` as described in Section 21.9, “Extensions to SHOW Statements”.

INFORMATION_SCHEMA and Privileges

For most INFORMATION_SCHEMA tables, each MySQL user has the right to access them, but can see only the rows in the tables that correspond to objects for which the user has the proper access privileges. In some cases (for example, the ROUTINE_DEFINITION column in the INFORMATION_SCHEMA ROUTINES table), users who have insufficient privileges see `NULL`. Some tables have different privilege requirements; for these, the requirements are mentioned in the applicable table descriptions. For example, InnoDB tables (tables with names that begin with `INNODB_`) require the `PROCESS` privilege.

The same privileges apply to selecting information from INFORMATION_SCHEMA and viewing the same information through `SHOW` statements. In either case, you must have some privilege on an object to see information about it.

Performance Considerations

INFORMATION_SCHEMA queries that search for information from more than one database might take a long time and impact performance. To check the efficiency of a query, you can use `EXPLAIN`. For information about using `EXPLAIN` output to tune INFORMATION_SCHEMA queries, see Section 8.2.3, “Optimizing INFORMATION_SCHEMA Queries”.

Standards Considerations

The implementation for the INFORMATION_SCHEMA table structures in MySQL follows the ANSI/ISO SQL:2003 standard Part 11 Schemata. Our intent is approximate compliance with SQL:2003 core feature F021 Basic information schema.

Users of SQL Server 2000 (which also follows the standard) may notice a strong similarity. However, MySQL has omitted many columns that are not relevant for our implementation, and added columns that are MySQL-specific. One such added column is the ENGINE column in the INFORMATION_SCHEMA TABLES table.

Although other DBMSs use a variety of names, like `syscat` or `system`, the standard name is INFORMATION_SCHEMA.

To avoid using any name that is reserved in the standard or in DB2, SQL Server, or Oracle, we changed the names of some columns marked “MySQL extension”. (For example, we changed `COLLATION` to `TABLE_COLLATION` in the TABLES table.) See the list of reserved words near the end of this article: https://web.archive.org/web/20070428032454/http://www.dbazine.com/db2/db2-disarticles/gulutzan5.
Conventions in the INFORMATION_SCHEMA Reference Sections

The following sections describe each of the tables and columns in INFORMATION_SCHEMA. For each column, there are three pieces of information:

- "INFORMATION_SCHEMA Name" indicates the name for the column in the INFORMATION_SCHEMA table. This corresponds to the standard SQL name unless the “Remarks” field says “MySQL extension.”
- “SHOW Name” indicates the equivalent field name in the closest SHOW statement, if there is one.
- “Remarks” provides additional information where applicable. If this field is NULL, it means that the value of the column is always NULL. If this field says “MySQL extension,” the column is a MySQL extension to standard SQL.

Many sections indicate what SHOW statement is equivalent to a SELECT that retrieves information from INFORMATION_SCHEMA. For SHOW statements that display information for the default database if you omit a FROM db_name clause, you can often select information for the default database by adding an AND TABLE_SCHEMA = SCHEMA() condition to the WHERE clause of a query that retrieves information from an INFORMATION_SCHEMA table.

Related Information

These sections discuss additional INFORMATION_SCHEMA-related topics:

- information about INFORMATION_SCHEMA tables specific to the InnoDB storage engine: Section 21.4, "INFORMATION_SCHEMA InnoDB Tables"
- information about INFORMATION_SCHEMA tables specific to the NDB storage engine (NDB Cluster): Section 21.5, “INFORMATION_SCHEMA NDB Cluster Tables”
- information about INFORMATION_SCHEMA tables specific to the thread pool plugin: Section 21.6, “INFORMATION_SCHEMA Thread Pool Tables”
- information about INFORMATION_SCHEMA tables specific to the CONNECTION_CONTROL plugin: Section 21.7, “INFORMATION_SCHEMA Connection-Control Tables”
- Answers to questions that are often asked concerning the INFORMATION_SCHEMA database: Section A.7, “MySQL 5.6 FAQ: INFORMATION_SCHEMA”
- INFORMATION_SCHEMA queries and the optimizer: Section 8.2.3, “Optimizing INFORMATION_SCHEMA Queries”
- The effect of collation on INFORMATION_SCHEMA comparisons: Section 10.8.7, “Using Collation in INFORMATION_SCHEMA Searches”
- As of MySQL 5.6.49, you must have the PROCESS privilege to query this table.

21.2 INFORMATION_SCHEMA Table Reference

The following table summarizes all available INFORMATION_SCHEMA tables. For greater detail, see the individual table descriptions.

Table 21.1 INFORMATION_SCHEMA Tables

21.3 INFORMATION_SCHEMA General Tables

The following sections describe what may be denoted as the “general” set of INFORMATION_SCHEMA tables. These are the tables not associated with particular storage engines, components, or plugins.

21.3.1 INFORMATION_SCHEMA General Table Reference

The following table summarizes INFORMATION_SCHEMA general tables. For greater detail, see the individual table descriptions.

<table>
<thead>
<tr>
<th>Table Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHARACTER_SETS</td>
<td>Available character sets</td>
</tr>
<tr>
<td>COLLATION_CHARACTER_SET_APPLICABILITY</td>
<td>Character set applicable to each collation</td>
</tr>
<tr>
<td>COLLATIONS</td>
<td>Collations for each character set</td>
</tr>
<tr>
<td>COLUMN_PRIVILEGES</td>
<td>Privileges defined on columns</td>
</tr>
<tr>
<td>COLUMNS</td>

<tr>
<td>EVENTS</td>
<td>Event Manager events</td>
</tr>
<tr>
<td>FILES</td>
<td>Files that store tablespace data</td>
</tr>
<tr>
<td>GLOBAL_STATUS</td>
<td>Global status variables</td>
</tr>
</tbody>
</table>
21.3.2 The INFORMATION_SCHEMA CHARACTER_SETS Table

The CHARACTER_SETS table provides information about available character sets.

The CHARACTER_SETS table has these columns:

- **CHARACTER_SET_NAME**
  The character set name.

- **DEFAULT_COLLATE_NAME**
  The default collation for the character set.

- **DESCRIPTION**
  A description of the character set.

- **MAXLEN**
  The maximum number of bytes required to store one character.
The INFORMATION_SCHEMA COLLATIONS Table

Notes

Character set information is also available from the SHOW CHARACTER SET statement. See Section 13.7.5.4, “SHOW CHARACTER SET Statement”. The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.CHARACTER_SETS
   WHERE CHARACTER_SET_NAME LIKE 'wild'
SHOW CHARACTER SET
   LIKE 'wild'
```

21.3.3 The INFORMATION_SCHEMA COLLATIONS Table

The COLLATIONS table provides information about collations for each character set.

The COLLATIONS table has these columns:

- **COLLATION_NAME**
  - The collation name.
- **CHARACTER_SET_NAME**
  - The name of the character set with which the collation is associated.
- **ID**
  - The collation ID.
- **IS_DEFAULT**
  - Whether the collation is the default for its character set.
- **IS_COMPILED**
  - Whether the character set is compiled into the server.
- **SORTLEN**
  - This is related to the amount of memory required to sort strings expressed in the character set.

Notes

Collation information is also available from the SHOW COLLATION statement. See Section 13.7.5.5, “SHOW COLLATION Statement”. The following statements are equivalent:

```
SELECT COLLATION_NAME FROM INFORMATION_SCHEMA.COLLATIONS
   WHERE COLLATION_NAME LIKE 'wild'
SHOW COLLATION
   LIKE 'wild'
```

21.3.4 The INFORMATION_SCHEMA COLLATION_CHARACTER_SET_APPLICABILITY Table

The COLLATION_CHARACTER_SET_APPLICABILITY table indicates what character set is applicable for what collation.

The COLLATION CHARACTER SET APPLICABILITY table has these columns:
The INFORMATION_SCHEMA COLUMNS Table

- **COLLATION_NAME**
  The collation name.

- **CHARACTER_SET_NAME**
  The name of the character set with which the collation is associated.

**Notes**

The **COLLATION_CHARACTER_SET_APPLICABILITY** columns are equivalent to the first two columns displayed by the `SHOW COLLATION` statement.

**21.3.5 The INFORMATION_SCHEMA COLUMNS Table**

The **COLUMNS** table provides information about columns in tables.

The **COLUMNS** table has these columns:

- **TABLE_CATALOG**
  The name of the catalog to which the table containing the column belongs. This value is always def.

- **TABLE_SCHEMA**
  The name of the schema (database) to which the table containing the column belongs.

- **TABLE_NAME**
  The name of the table containing the column.

- **COLUMN_NAME**
  The name of the column.

- **ORDINAL_POSITION**
  The position of the column within the table. **ORDINAL_POSITION** is necessary because you might want to say `ORDER BY ORDINAL_POSITION`. Unlike `SHOW COLUMNS`, `SELECT` from the **COLUMNS** table does not have automatic ordering.

- **COLUMN_DEFAULT**
  The default value for the column. This is **NULL** if the column has an explicit default of **NULL**, or if the column definition includes no **DEFAULT** clause.

- **IS_NULLABLE**
  The column nullability. The value is **YES** if **NULL** values can be stored in the column, **NO** if not.

- **DATA_TYPE**
  The column data type.
  
  The **DATA_TYPE** value is the type name only with no other information. The **COLUMN_TYPE** value contains the type name and possibly other information such as the precision or length.

- **CHARACTER_MAXIMUM_LENGTH**
The INFORMATION_SCHEMA COLUMNS Table

For string columns, the maximum length in characters.

- **CHARACTER_OCTET_LENGTH**
  For string columns, the maximum length in bytes.

- **NUMERIC_PRECISION**
  For numeric columns, the numeric precision.

- **NUMERIC_SCALE**
  For numeric columns, the numeric scale.

- **DATETIME_PRECISION**
  For temporal columns, the fractional seconds precision.

- **CHARACTER_SET_NAME**
  For character string columns, the character set name.

- **COLLATION_NAME**
  For character string columns, the collation name.

- **COLUMN_TYPE**
  The column data type.

  The DATA_TYPE value is the type name only with no other information. The COLUMN_TYPE value contains the type name and possibly other information such as the precision or length.

- **COLUMN_KEY**
  Whether the column is indexed:

  - If COLUMN_KEY is empty, the column either is not indexed or is indexed only as a secondary column in a multiple-column, nonunique index.

  - If COLUMN_KEY is PRI, the column is a PRIMARY KEY or is one of the columns in a multiple-column PRIMARY KEY.

  - If COLUMN_KEY is UNI, the column is the first column of a UNIQUE index. (A UNIQUE index permits multiple NULL values, but you can tell whether the column permits NULL by checking the Null column.)

  - If COLUMN_KEY is MUL, the column is the first column of a nonunique index in which multiple occurrences of a given value are permitted within the column.

  If more than one of the COLUMN_KEY values applies to a given column of a table, COLUMN_KEY displays the one with the highest priority, in the order PRI, UNI, MUL.

  A UNIQUE index may be displayed as PRI if it cannot contain NULL values and there is no PRIMARY KEY in the table. A UNIQUE index may display as MUL if several columns form a composite UNIQUE index; although the combination of the columns is unique, each column can still hold multiple occurrences of a given value.
• **EXTRA**

Any additional information that is available about a given column. The value is nonempty in these cases: `auto_increment` for columns that have the `AUTO_INCREMENT` attribute; `on update CURRENT_TIMESTAMP` for `TIMESTAMP` or `DATETIME` columns that have the `ON UPDATE CURRENT_TIMESTAMP` attribute.

• **PRIVILEGES**

The privileges you have for the column.

• **COLUMN_COMMENT**

Any comment included in the column definition.

**Notes**

• In `SHOW COLUMNS`, the `Type` display includes values from several different `COLUMNS` columns.

• **CHARACTER_OCTET_LENGTH** should be the same as **CHARACTER_MAXIMUM_LENGTH**, except for multibyte character sets.

• **CHARACTER_SET_NAME** can be derived from **COLLATION_NAME**. For example, if you say `SHOW FULL COLUMNS FROM t`, and you see in the **COLLATION_NAME** column a value of `latin1_swedish_ci`, the character set is what is before the first underscore: `latin1`.

Column information is also available from the `SHOW COLUMNS` statement. See Section 13.7.5.6, “SHOW COLUMNS Statement”. The following statements are nearly equivalent:

```sql
SELECT COLUMN_NAME, DATA_TYPE, IS_NULLABLE, COLUMN_DEFAULT
FROM INFORMATION_SCHEMA.COLUMNS
WHERE table_name = 'tbl_name'
[AND table_schema = 'db_name']
[AND column_name LIKE 'wild']

SHOW COLUMNS
FROM tbl_name
[FROM db_name]
[LIKE 'wild']
```

### 21.3.6 The INFORMATION_SCHEMA COLUMN_PRIVILEGES Table

The **COLUMN_PRIVILEGES** table provides information about column privileges. It takes its values from the `mysql.columns_priv` system table.

The **COLUMN_PRIVILEGES** table has these columns:

• **GRANTEE**

  The name of the account to which the privilege is granted, in `'user_name'@'host_name'` format.

• **TABLE_CATALOG**

  The name of the catalog to which the table containing the column belongs. This value is always `def`.

• **TABLE_SCHEMA**

  The name of the schema (database) to which the table containing the column belongs.

• **TABLE_NAME**
The INFORMATION_SCHEMA ENGINES Table

The name of the table containing the column.

- **COLUMN_NAME**
  
The name of the column.

- **PRIVILEGE_TYPE**
  
The privilege granted. The value can be any privilege that can be granted at the column level; see Section 13.7.1.4, "GRANT Statement". Each row lists a single privilege, so there is one row per column privilege held by the grantee.

  In the output from `SHOW FULL COLUMNS`, the privileges are all in one column and in lowercase, for example, `select, insert, update, references`. In `COLUMN_PRIVILEGES`, there is one privilege per row, in uppercase.

- **IS_GRANTABLE**
  
  `YES` if the user has the `GRANT OPTION` privilege, `NO` otherwise. The output does not list `GRANT OPTION` as a separate row with `PRIVILEGE_TYPE='GRANT OPTION'`.

Notes

- **COLUMN_PRIVILEGES** is a nonstandard INFORMATION_SCHEMA table.

  The following statements are *not* equivalent:

  ```sql
  SELECT ... FROM INFORMATION_SCHEMA.COLUMN_PRIVILEGES
  SHOW GRANTS ...
  ```

21.3.7 The INFORMATION_SCHEMA ENGINES Table

The **ENGINES** table provides information about storage engines. This is particularly useful for checking whether a storage engine is supported, or to see what the default engine is.

The **ENGINES** table has these columns:

- **ENGINE**
  
The name of the storage engine.

- **SUPPORT**
  
The server's level of support for the storage engine, as shown in the following table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>YES</td>
<td>The engine is supported and is active</td>
</tr>
<tr>
<td>DEFAULT</td>
<td>Like <strong>YES</strong>, plus this is the default engine</td>
</tr>
<tr>
<td>NO</td>
<td>The engine is not supported</td>
</tr>
<tr>
<td>DISABLED</td>
<td>The engine is supported but has been disabled</td>
</tr>
</tbody>
</table>

A value of **NO** means that the server was compiled without support for the engine, so it cannot be enabled at runtime.
A value of **DISABLED** occurs either because the server was started with an option that disables the engine, or because not all options required to enable it were given. In the latter case, the error log should contain a reason indicating why the option is disabled. See Section 5.4.2, “The Error Log”.

You might also see **DISABLED** for a storage engine if the server was compiled to support it, but was started with a `--skip-engine_name` option. For the **NDB** storage engine, **DISABLED** means the server was compiled with support for NDB Cluster, but was not started with the `--ndbcluster` option.

All MySQL servers support **MyISAM** tables. It is not possible to disable **MyISAM**.

- **COMMENT**
  A brief description of the storage engine.

- **TRANSACTIONS**
  Whether the storage engine supports transactions.

- **XA**
  Whether the storage engine supports XA transactions.

- **SAVEPOINTS**
  Whether the storage engine supports savepoints.

### Notes

- **ENGINES** is a nonstandard **INFORMATION_SCHEMA** table.

Storage engine information is also available from the **SHOW ENGINES** statement. See Section 13.7.5.17, “SHOW ENGINES Statement”. The following statements are equivalent:

```sql
SELECT * FROM INFORMATION_SCHEMA.ENGINES
SHOW ENGINES
```

### 21.3.8 The **INFORMATION_SCHEMA EVENTS** Table

The **EVENTS** table provides information about Event Manager events, which are discussed in Section 20.4, “Using the Event Scheduler”.

The **EVENTS** table has these columns:

- **EVENT_CATALOG**
  The name of the catalog to which the event belongs. This value is always **def**.

- **EVENT_SCHEMA**
  The name of the schema (database) to which the event belongs.

- **EVENT_NAME**
  The name of the event.

- **DEFINER**
The account named in the \texttt{DEFINER} clause (often the user who created the event), in \texttt{'user_name'@'host_name'} format.

- \textbf{TIME\_ZONE}

  The event time zone, which is the time zone used for scheduling the event and that is in effect within the event as it executes. The default value is \texttt{SYSTEM}.

- \textbf{EVENT\_BODY}

  The language used for the statements in the event's \texttt{DO} clause. The value is always \texttt{SQL}.

- \textbf{EVENT\_DEFINITION}

  The text of the SQL statement making up the event's \texttt{DO} clause; in other words, the statement executed by this event.

- \textbf{EVENT\_TYPE}

  The event repetition type, either \texttt{ONE\ TIME} (transient) or \texttt{RECURRING} (repeating).

- \textbf{EXECUTE\_AT}

  For a one-time event, this is the \texttt{DATETIME} value specified in the \texttt{AT} clause of the \texttt{CREATE EVENT} statement used to create the event, or of the last \texttt{ALTER EVENT} statement that modified the event. The value shown in this column reflects the addition or subtraction of any \texttt{INTERVAL} value included in the event's \texttt{AT} clause. For example, if an event is created using \texttt{ON SCHEDULE AT CURRENT\_TIMESTAMP + '1:6' DAY\_HOUR}, and the event was created at 2018-02-09 14:05:30, the value shown in this column would be '2018-02-10 20:05:30'. If the event's timing is determined by an \texttt{EVERY} clause instead of an \texttt{AT} clause (that is, if the event is recurring), the value of this column is \texttt{NULL}.

- \textbf{INTERVAL\_VALUE}

  For a recurring event, the number of intervals to wait between event executions. For a transient event, the value is always \texttt{NULL}.

- \textbf{INTERVAL\_FIELD}

  The time units used for the interval which a recurring event waits before repeating. For a transient event, the value is always \texttt{NULL}.

- \textbf{SQL\_MODE}

  The SQL mode in effect when the event was created or altered, and under which the event executes. For the permitted values, see \textsection 5.1.10, "Server SQL Modes".

- \textbf{STARTS}

  The start date and time for a recurring event. This is displayed as a \texttt{DATETIME} value, and is \texttt{NULL} if no start date and time are defined for the event. For a transient event, this column is always \texttt{NULL}. For a recurring event whose definition includes a \texttt{STARTS} clause, this column contains the corresponding \texttt{DATETIME} value. As with the \texttt{EXECUTE\_AT} column, this value resolves any expressions used. If there is no \texttt{STARTS} clause affecting the timing of the event, this column is \texttt{NULL}. 

3260
The INFORMATION_SCHEMA EVENTS Table

• **ENDS**

For a recurring event whose definition includes a `ENDS` clause, this column contains the corresponding `DATETIME` value. As with the `EXECUTE_AT` column, this value resolves any expressions used. If there is no `ENDS` clause affecting the timing of the event, this column is `NULL`.

• **STATUS**

The event status. One of `ENABLED`, `DISABLED`, or `SLAVESIDE_DISABLED`. `SLAVESIDE_DISABLED` indicates that the creation of the event occurred on another MySQL server acting as a replication source and replicated to the current MySQL server which is acting as a replica, but the event is not presently being executed on the replica. For more information, see Section 17.4.1.16, “Replication of Invoked Features”. information.

• **ON_COMPLETION**

One of the two values `PRESERVE` or `NOT PRESERVE`.

• **CREATED**

The date and time when the event was created. This is a `TIMESTAMP` value.

• **LAST_ALTERED**

The date and time when the event was last modified. This is a `TIMESTAMP` value. If the event has not been modified since its creation, this value is the same as the `CREATED` value.

• **LAST_EXECUTED**

The date and time when the event last executed. This is a `DATETIME` value. If the event has never executed, this column is `NULL`.

`LAST_EXECUTED` indicates when the event started. As a result, the `ENDS` column is never less than `LAST_EXECUTED`.

• **EVENT_COMMENT**

The text of the comment, if the event has one. If not, this value is empty.

• **ORIGINATOR**

The server ID of the MySQL server on which the event was created; used in replication. This value may be updated by `ALTER EVENT` to the server ID of the server on which that statement occurs, if executed on a replication source. The default value is 0.

• **CHARACTER_SET_CLIENT**

The session value of the `character_set_client` system variable when the event was created.

• **COLLATION_CONNECTION**

The session value of the `collation_connection` system variable when the event was created.

• **DATABASE_COLLATION**

The collation of the database with which the event is associated.
Notes

- **EVENTS** is a nonstandard INFORMATION_SCHEMA table.
- Times in the **EVENTS** table are displayed using the event time zone, the current session time zone, or UTC, as described in Section 20.4.4, “Event Metadata”.
- For more information about **SLAVESIDE_DISABLED** and the **ORIGINATOR** column, see Section 17.4.1.16, “Replication of Invoked Features”.

Example

Suppose that the user `'jon'@'ghidora' creates an event named **e_daily**, and then modifies it a few minutes later using an **ALTER EVENT** statement, as shown here:

```
DELIMITER |

CREATE EVENT e_daily
ON SCHEDULE
EVERY 1 DAY
COMMENT 'Saves total number of sessions then clears the table each day'
DO
BEGIN
    INSERT INTO site_activity.totals (time, total)
    SELECT CURRENT_TIMESTAMP, COUNT(*)
    FROM site_activity.sessions;
    DELETE FROM site_activity.sessions;
END |
DELIMITER ;

ALTER EVENT e_daily
ENABLE;
```

(Note that comments can span multiple lines.)

This user can then run the following **SELECT** statement, and obtain the output shown:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.EVENTS
WHERE EVENT_NAME = 'e_daily'
AND EVENT_SCHEMA = 'myschema'\G
*************************** 1. row ***************************
EVENT_CATALOG: def
EVENT_SCHEMA: myschema
EVENT_NAME: e_daily
DEFINER: jon@ghidora
TIME_ZONE: SYSTEM
EVENT_BODY: SQL
EVENT_DEFINITION: BEGIN
    INSERT INTO site_activity.totals (time, total)
    SELECT CURRENT_TIMESTAMP, COUNT(*)
    FROM site_activity.sessions;
    DELETE FROM site_activity.sessions;
END
EVENT_TYPE: RECURRING
EXECUTE_AT: NULL
INTERVAL_VALUE: 1
INTERVAL_FIELD: DAY
SQL_MODE: NO_ENGINE_SUBSTITUTION
STARTS: 2018-08-08 11:06:34
ENDS: NULL
STATUS: ENABLED
ON_COMPLETION: NOT PRESERVE
CREATED: 2018-08-08 11:06:34
LAST_ALTERED: 2018-08-08 11:06:34
```

3262
The INFORMATION_SCHEMA GLOBAL_STATUS and SESSION_STATUS Tables

Event information is also available from the SHOW EVENTS statement. See Section 13.7.5.19, “SHOW EVENTS Statement”. The following statements are equivalent:

```
SELECT
  EVENT_SCHEMA, EVENT_NAME, DEFINER, TIME_ZONE, EVENT_TYPE, EXECUTE_AT,
  INTERVAL_VALUE, INTERVAL_FIELD, STARTS, ENDS, STATUS, ORIGINATOR,
  CHARACTER_SET_CLIENT, COLLATION_CONNECTION, DATABASE_COLLATION
FROM INFORMATION_SCHEMA.EVENTS
WHERE table_schema = 'db_name'
  AND column_name LIKE 'wild'
```

SHOW EVENTS
[FROM 'db_name']
[LIKE 'wild']

21.3.9 The INFORMATION_SCHEMA GLOBAL_STATUS and SESSION_STATUS Tables

The GLOBAL_STATUS and SESSION_STATUS tables provide information about server status variables. Their contents correspond to the information produced by the SHOW GLOBAL STATUS and SHOW SESSION STATUS statements (see Section 13.7.5.36, “SHOW STATUS Statement”).

Notes

- The VARIABLE_VALUE column for each of these tables is defined as VARCHAR(1024).

21.3.10 The INFORMATION_SCHEMA GLOBAL_VARIABLES and SESSION_VARIABLES Tables

The GLOBAL_VARIABLES and SESSION_VARIABLES tables provide information about server status variables. Their contents correspond to the information produced by the SHOW GLOBAL VARIABLES and SHOW SESSION VARIABLES statements (see Section 13.7.5.40, “SHOW VARIABLES Statement”).

Notes

- The VARIABLE_VALUE column for each of these tables is defined as VARCHAR(1024). For variables with very long values that are not completely displayed, use SELECT as a workaround. For example:

  ```
  SELECT @@GLOBAL.innodb_data_file_path;
  ```

21.3.11 The INFORMATION_SCHEMA KEY_COLUMN_USAGE Table

The KEY_COLUMN_USAGE table describes which key columns have constraints.

The KEY_COLUMN_USAGE table has these columns:

- CONSTRAINT_CATALOG

  The name of the catalog to which the constraint belongs. This value is always def.

- CONSTRAINT_SCHEMA
The name of the schema (database) to which the constraint belongs.

- **CONSTRAINT_NAME**
  The name of the constraint.

- **TABLE_CATALOG**
  The name of the catalog to which the table belongs. This value is always `def`.

- **TABLE_SCHEMA**
  The name of the schema (database) to which the table belongs.

- **TABLE_NAME**
  The name of the table that has the constraint.

- **COLUMN_NAME**
  The name of the column that has the constraint.
  If the constraint is a foreign key, then this is the column of the foreign key, not the column that the foreign key references.

- **ORDINAL_POSITION**
  The column's position within the constraint, not the column's position within the table. Column positions are numbered beginning with 1.

- **POSITION_IN_UNIQUE_CONSTRAINT**
  `NULL` for unique and primary-key constraints. For foreign-key constraints, this column is the ordinal position in key of the table that is being referenced.

- **REFERENCED_TABLE_SCHEMA**
  The name of the schema (database) referenced by the constraint.

- **REFERENCED_TABLE_NAME**
  The name of the table referenced by the constraint.

- **REFERENCED_COLUMN_NAME**
  The name of the column referenced by the constraint.

Suppose that there are two tables name `t1` and `t3` that have the following definitions:

```sql
CREATE TABLE t1
(
  s1 INT,
  s2 INT,
  s3 INT,
  PRIMARY KEY(s3)
) ENGINE=InnoDB;

CREATE TABLE t3
(
  s1 INT,
```
For those two tables, the `KEY_COLUMN_USAGE` table has two rows:

- One row with `CONSTRAINT_NAME = 'PRIMARY', TABLE_NAME = 't1', COLUMN_NAME = 's3', ORDINAL_POSITION = 1, POSITION_IN_UNIQUE_CONSTRAINT = NULL.
- One row with `CONSTRAINT_NAME = 'CO', TABLE_NAME = 't3', COLUMN_NAME = 's2', ORDINAL_POSITION = 1, POSITION_IN_UNIQUE_CONSTRAINT = 1.

### 21.3.12 The INFORMATION_SCHEMA OPTIMIZER_TRACE Table

The `OPTIMIZER_TRACE` table provides information produced by the optimizer tracing capability for traced statements. To enable tracking, use the `optimizer_trace` system variable. For details, see MySQL Internals: Tracing the Optimizer.

The `OPTIMIZER_TRACE` table has these columns:

- **QUERY**
  
  The text of the traced statement.

- **TRACE**
  
  The trace, in JSON format.

- **MISSING_BYTES_BEYOND_MAX_MEM_SIZE**

  Each remembered trace is a string that is extended as optimization progresses and appends data to it. The `optimizer_trace_max_mem_size` variable sets a limit on the total amount of memory used by all currently remembered traces. If this limit is reached, the current trace is not extended (and thus is incomplete), and the `MISSING_BYTES_BEYOND_MAX_MEM_SIZE` column shows the number of bytes missing from the trace.

- **INSUFFICIENT_PRIVILEGES**

  If a traced query uses views or stored routines that have `SQL SECURITY` with a value of `DEFINER`, it may be that a user other than the definer is denied from seeing the trace of the query. In that case, the trace is shown as empty and `INSUFFICIENT_PRIVILEGES` has a value of 1. Otherwise, the value is 0.

### 21.3.13 The INFORMATION_SCHEMA PARAMETERS Table

The `PARAMETERS` table provides information about parameters for stored routines (stored procedures and stored functions), and about return values for stored functions. The `PARAMETERS` table does not include built-in (native) functions or loadable functions. Parameter information is similar to the contents of the `param_list` column in the `mysql.proc` table.

The `PARAMETERS` table has these columns:

- **SPECIFIC_CATALOG**

  The name of the catalog to which the routine containing the parameter belongs. This value is always `def`.

- **SPECIFIC_SCHEMA**
The INFORMATION_SCHEMA PARAMETERS Table

The name of the schema (database) to which the routine containing the parameter belongs.

- **SPECIFIC_NAME**
  The name of the routine containing the parameter.

- **ORDINAL_POSITION**
  For successive parameters of a stored procedure or function, the **ORDINAL_POSITION** values are 1, 2, 3, and so forth. For a stored function, there is also a row that applies to the function return value (as described by the **RETURNS** clause). The return value is not a true parameter, so the row that describes it has these unique characteristics:
  - The **ORDINAL_POSITION** value is 0.
  - The **PARAMETER_NAME** and **PARAMETER_MODE** values are **NULL** because the return value has no name and the mode does not apply.

- **PARAMETER_MODE**
  The mode of the parameter. This value is one of **IN**, **OUT**, or **INOUT**. For a stored function return value, this value is **NULL**.

- **PARAMETER_NAME**
  The name of the parameter. For a stored function return value, this value is **NULL**.

- **DATA_TYPE**
  The parameter data type.
  The **DATA_TYPE** value is the type name only with no other information. The **DTD_IDENTIFIER** value contains the type name and possibly other information such as the precision or length.

- **CHARACTER_MAXIMUM_LENGTH**
  For string parameters, the maximum length in characters.

- **CHARACTER_OCTET_LENGTH**
  For string parameters, the maximum length in bytes.

- **NUMERIC_PRECISION**
  For numeric parameters, the numeric precision.

- **NUMERIC_SCALE**
  For numeric parameters, the numeric scale.

- **DATETIME_PRECISION**
  For temporal parameters, the fractional seconds precision.

- **CHARACTER_SET_NAME**
  For character string parameters, the character set name.

- **COLLATION_NAME**
For character string parameters, the collation name.

- **DTD_IDENTIFIER**
  
The parameter data type.
  
The `DATA_TYPE` value is the type name only with no other information. The `DTD_IDENTIFIER` value contains the type name and possibly other information such as the precision or length.

- **ROUTINE_TYPE**
  
  `PROCEDURE` for stored procedures, `FUNCTION` for stored functions.

### 21.3.14 The INFORMATION_SCHEMA PARTITIONS Table

The `PARTITIONS` table provides information about table partitions. Each row in this table corresponds to an individual partition or subpartition of a partitioned table. For more information about partitioning tables, see Chapter 19, *Partitioning*.

The `PARTITIONS` table has these columns:

- **TABLE_CATALOG**
  
The name of the catalog to which the table belongs. This value is always `def`.

- **TABLE_SCHEMA**
  
The name of the database to which the table belongs.

- **TABLE_NAME**
  
The name of the table containing the partition.

- **PARTITION_NAME**
  
The name of the partition.

- **SUBPARTITION_NAME**
  
  If the `PARTITIONS` table row represents a subpartition, the name of subpartition; otherwise `NULL`.

- **PARTITION_ORDINAL_POSITION**
  
  All partitions are indexed in the same order as they are defined, with 1 being the number assigned to the first partition. The indexing can change as partitions are added, dropped, and reorganized; the number shown is this column reflects the current order, taking into account any indexing changes.

- **SUBPARTITION_ORDINAL_POSITION**
  
  Subpartitions within a given partition are also indexed and reindexed in the same manner as partitions are indexed within a table.

- **PARTITION_METHOD**
  
  One of the values `RANGE`, `LIST`, `HASH`, `LINEAR_HASH`, `KEY`, or `LINEAR_KEY`; that is, one of the available partitioning types as discussed in Section 19.2, “Partitioning Types”.

- **SUBPARTITION_METHOD**
The INFORMATION_SCHEMA PARTITIONS Table

One of the values HASH, LINEAR HASH, KEY, or LINEAR KEY; that is, one of the available subpartitioning types as discussed in Section 19.2.6, “Subpartitioning”.

- **PARTITION_EXPRESSION**

  The expression for the partitioning function used in the CREATE TABLE or ALTER TABLE statement that created the table’s current partitioning scheme.

  For example, consider a partitioned table created in the test database using this statement:

  ```sql
  CREATE TABLE tp (
    c1 INT,
    c2 INT,
    c3 VARCHAR(25)
  )
  PARTITION BY HASH(c1 + c2)
  PARTITIONS 4;
  ```

  The PARTITION_EXPRESSION column in a PARTITIONS table row for a partition from this table displays c1 + c2, as shown here:

  ```sql
  mysql> SELECT DISTINCT PARTITION_EXPRESSION
  FROM INFORMATION_SCHEMA.PARTITIONS
  WHERE TABLE_NAME='tp' AND TABLE_SCHEMA='test';
  +----------------------+
  | PARTITION_EXPRESSION |
  +----------------------+
  | c1 + c2              |
  +----------------------+
  ```

- **SUBPARTITION_EXPRESSION**

  This works in the same fashion for the subpartitioning expression that defines the subpartitioning for a table as PARTITION_EXPRESSION does for the partitioning expression used to define a table’s partitioning.

  If the table has no subpartitions, this column is NULL.

- **PARTITION_DESCRIPTION**

  This column is used for RANGE and LIST partitions. For a RANGE partition, it contains the value set in the partition’s VALUES LESS THAN clause, which can be either an integer or MAXVALUE. For a LIST partition, this column contains the values defined in the partition’s VALUES IN clause, which is a list of comma-separated integer values.

  For partitions whose PARTITION_METHOD is other than RANGE or LIST, this column is always NULL.

- **TABLE_ROWS**

  The number of table rows in the partition.

  For partitioned InnoDB tables, the row count given in the TABLE_ROWS column is only an estimated value used in SQL optimization, and may not always be exact.

  For NDB tables, you can also obtain this information using the ndb_desc utility.

- **AVG_ROW_LENGTH**

  The average length of the rows stored in this partition or subpartition, in bytes. This is the same as DATA_LENGTH divided by TABLE_ROWS.
For **NDB** tables, you can also obtain this information using the `ndb_desc` utility.

- **DATA_LENGTH**
  The total length of all rows stored in this partition or subpartition, in bytes; that is, the total number of bytes stored in the partition or subpartition.
  For **NDB** tables, you can also obtain this information using the `ndb_desc` utility.

- **MAX_DATA_LENGTH**
  The maximum number of bytes that can be stored in this partition or subpartition.
  For **NDB** tables, you can also obtain this information using the `ndb_desc` utility.

- **INDEX_LENGTH**
  The length of the index file for this partition or subpartition, in bytes.
  For partitions of **NDB** tables, whether the tables use implicit or explicit partitioning, the **INDEX_LENGTH** column value is always 0. However, you can obtain equivalent information using the `ndb_desc` utility.

- **DATA_FREE**
  The number of bytes allocated to the partition or subpartition but not used.
  For **NDB** tables, you can also obtain this information using the `ndb_desc` utility.

- **CREATE_TIME**
  The time that the partition or subpartition was created.
  Prior to MySQL 5.6.25, for partitioned **InnoDB** tables, this column was always NULL. The correct creation time is shown in MySQL 5.6.25 and later. (Bug #17299181, Bug #69990)

- **UPDATE_TIME**
  The time that the partition or subpartition was last modified.
  For partitioned **InnoDB** tables, the value is always NULL.

- **CHECK_TIME**
  The last time that the table to which this partition or subpartition belongs was checked.
  For partitioned **InnoDB** tables, this column is always NULL.

- **CHECKSUM**
  The checksum value, if any; otherwise NULL.

- **PARTITION_COMMENT**
  The text of the comment, if the partition has one. If not, this value is empty.
  The maximum length for a partition comment is defined as 1024 characters, and the display width of the **PARTITIONCOMMENT** column is also 1024, characters to match this limit.

- **NODEGROUP**
The INFORMATION_SCHEMA PLUGINS Table

The PLUGIN table provides information about server plugins.

The PLUGIN table has these columns:

- **PLUGIN_NAME**
  The name used to refer to the plugin in statements such as INSTALL PLUGIN and UNINSTALL PLUGIN.

- **PLUGIN_VERSION**
  The version from the plugin's general type descriptor.

- **PLUGIN_STATUS**
  The plugin status, one of ACTIVE, INACTIVE, DISABLED, or DELETED.

- **PLUGIN_TYPE**
  The type of plugin, such as STORAGE ENGINE, INFORMATION_SCHEMA, or AUTHENTICATION.

- **PLUGIN_TYPE_VERSION**
The version from the plugin's type-specific descriptor.

- **PLUGIN_LIBRARY**
  
  The name of the plugin shared library file. This is the name used to refer to the plugin file in statements such as `INSTALL PLUGIN` and `UNINSTALL PLUGIN`. This file is located in the directory named by the `plugin_dir` system variable. If the library name is `NULL`, the plugin is compiled in and cannot be uninstalled with `UNINSTALL PLUGIN`.

- **PLUGIN_LIBRARY_VERSION**
  
  The plugin API interface version.

- **PLUGIN_AUTHOR**
  
  The plugin author.

- **PLUGIN_DESCRIPTION**
  
  A short description of the plugin.

- **PLUGIN_LICENSE**
  
  How the plugin is licensed (for example, GPL).

- **LOAD_OPTION**
  
  How the plugin was loaded. The value is OFF, ON, FORCE, or FORCE_PLUS_PERMANENT. See Section 5.5.1, “Installing and Uninstalling Plugins”.

**Notes**

- **PLUGINS** is a nonstandard INFORMATION_SCHEMA table.

- For plugins installed with `INSTALL PLUGIN`, the PLUGIN_NAME and PLUGIN_LIBRARY values are also registered in the `mysql.plugin` table.

- For information about plugin data structures that form the basis of the information in the PLUGINS table, see The MySQL Plugin API.

Plugin information is also available from the SHOW PLUGINS statement. See Section 13.7.5.26, “SHOW PLUGINS Statement”. These statements are equivalent:

```sql
SELECT
  PLUGIN_NAME, PLUGIN_STATUS, PLUGIN_TYPE,
  PLUGIN_LIBRARY, PLUGIN_LICENSE
FROM INFORMATION_SCHEMA.PLUGINS;
SHOW PLUGINS;
```

### 21.3.16 The INFORMATION_SCHEMA PROCESSLIST Table

The MySQL process list indicates the operations currently being performed by the set of threads executing within the server. The PROCESSLIST table is one source of process information. For a comparison of this table with other sources, see Sources of Process Information.

The PROCESSLIST table has these columns:

- **ID**

---

3271
The connection identifier. This is the same value displayed in the `Id` column of the `SHOW PROCESSLIST` statement, displayed in the `PROCESSLIST_ID` column of the Performance Schema `threads` table, and returned by the `CONNECTION_ID()` function within the thread.

- **USER**
  The MySQL user who issued the statement. A value of `system user` refers to a nonclient thread spawned by the server to handle tasks internally, for example, a delayed-row handler thread or an I/O or SQL thread used on replica hosts. For `system user`, there is no host specified in the `Host` column. `unauthenticated user` refers to a thread that has become associated with a client connection but for which authentication of the client user has not yet occurred. `event_scheduler` refers to the thread that monitors scheduled events (see Section 20.4, "Using the Event Scheduler").

- **HOST**
  The host name of the client issuing the statement (except for `system user`, for which there is no host). The host name for TCP/IP connections is reported in `host_name:client_port` format to make it easier to determine which client is doing what.

- **DB**
  The default database for the thread, or `NULL` if none has been selected.

- **COMMAND**
  The type of command the thread is executing on behalf of the client, or `Sleep` if the session is idle. For descriptions of thread commands, see Section 8.14, "Examining Server Thread (Process) Information". The value of this column corresponds to the `COM_` commands of the client/server protocol and `Com_` status variables. See Section 5.1.9, “Server Status Variables”.

- **TIME**
  The time in seconds that the thread has been in its current state. For a replica SQL thread, the value is the number of seconds between the timestamp of the last replicated event and the real time of the replica host. See Section 17.2.1, “Replication Threads”.

- **STATE**
  An action, event, or state that indicates what the thread is doing. For descriptions of `STATE` values, see Section 8.14, “Examining Server Thread (Process) Information”.

  Most states correspond to very quick operations. If a thread stays in a given state for many seconds, there might be a problem that needs to be investigated.

- **INFO**
  The statement the thread is executing, or `NULL` if it is executing no statement. The statement might be the one sent to the server, or an innermost statement if the statement executes other statements. For example, if a `CALL` statement executes a stored procedure that is executing a `SELECT` statement, the `INFO` value shows the `SELECT` statement.

**Notes**

- `PROCESSLIST` is a nonstandard `INFORMATION_SCHEMA` table.

- Like the output from the `SHOW PROCESSLIST` statement, the `PROCESSLIST` table provides information about all threads, even those belonging to other users, if you have the `PROCESS` privilege. Otherwise
(without the `PROCESS` privilege), nonanonymous users have access to information about their own threads but not threads for other users, and anonymous users have no access to thread information.

- If an SQL statement refers to the `PROCESSLIST` table, MySQL populates the entire table once, when statement execution begins, so there is read consistency during the statement. There is no read consistency for a multi-statement transaction.

The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.PROCESSLIST
SHOW FULL PROCESSLIST
```

### 21.3.17 The INFORMATION_SCHEMA PROFILING Table

The `PROFILING` table provides statement profiling information. Its contents correspond to the information produced by the `SHOW PROFILE` and `SHOW PROFILES` statements (see Section 13.7.5.31, “SHOW PROFILE Statement”). The table is empty unless the `profiling` session variable is set to 1.

The `PROFILING` table has these columns:

- **QUERY_ID**
  A numeric statement identifier.

- **SEQ**
  A sequence number indicating the display order for rows with the same `QUERY_ID` value.

- **STATE**
  The profiling state to which the row measurements apply.

- **DURATION**
  How long statement execution remained in the given state, in seconds.

- **CPU_USER, CPU_SYSTEM**
  User and system CPU use, in seconds.

- **CONTEXT_VOLUNTARY, CONTEXT_INVOLUNTARY**
  How many voluntary and involuntary context switches occurred.

- **BLOCK_OPS_IN, BLOCK_OPS_OUT**
  The number of block input and output operations.

- **MESSAGES_SENT, MESSAGES_RECEIVED**
  The number of communication messages sent and received.

- **PAGE_FAULTS_MAJOR, PAGE_FAULTS_MINOR**
  The number of major and minor page faults.

- **SWAPS**
  How many swaps occurred.
The INFORMATION_SCHEMA REFERENTIAL_CONSTRAINTS Table

- **SOURCE_FUNCTION, SOURCE_FILE, and SOURCE_LINE**
  Information indicating where in the source code the profiled state executes.

### Notes

- **PROFILING** is a nonstandard INFORMATION_SCHEMA table.

Profiling information is also available from the `SHOW PROFILE` and `SHOW PROFILES` statements. See Section 13.7.5.31, “SHOW PROFILE Statement”. For example, the following queries are equivalent:

```
SHOW PROFILE FOR QUERY 2;
SELECT STATE, FORMAT(DURATION, 6) AS DURATION
FROM INFORMATION_SCHEMA.PROFILING
WHERE QUERY_ID = 2 ORDER BY SEQ;
```

### 21.3.18 The INFORMATION_SCHEMA REFERENTIAL_CONSTRAINTS Table

The REFERENTIAL_CONSTRAINTS table provides information about foreign keys.

The REFERENTIAL_CONSTRAINTS table has these columns:

- **CONSTRAINT_CATALOG**
  The name of the catalog to which the constraint belongs. This value is always `def`.

- **CONSTRAINT_SCHEMA**
  The name of the schema (database) to which the constraint belongs.

- **CONSTRAINT_NAME**
  The name of the constraint.

- **UNIQUE_CONSTRAINT_CATALOG**
  The name of the catalog containing the unique constraint that the constraint references. This value is always `def`.

- **UNIQUE_CONSTRAINT_SCHEMA**
  The name of the schema (database) containing the unique constraint that the constraint references.

- **UNIQUE_CONSTRAINT_NAME**
  The name of the unique constraint that the constraint references.

- **MATCH_OPTION**
  The value of the constraint MATCH attribute. The only valid value at this time is `NONE`.

- **UPDATE_RULE**
  The value of the constraint ON UPDATE attribute. The possible values are `CASCADE`, `SET NULL`, `SET DEFAULT`, `RESTRICT`, `NO ACTION`.

- **DELETE_RULE**
The value of the constraint ON DELETE attribute. The possible values are CASCADE, SET NULL, SET DEFAULT, RESTRICT, NO ACTION.

- **TABLE_NAME**
  - The name of the table. This value is the same as in the TABLE_CONSTRAINTS table.

- **REFERENCED_TABLE_NAME**
  - The name of the table referenced by the constraint.

### 21.3.19 The INFORMATION_SCHEMA ROUTINES Table

The ROUTINES table provides information about stored routines (stored procedures and stored functions). The ROUTINES table does not include built-in (native) functions or loadable functions.

The column named “mysql.proc Name” indicates the mysql.proc table column that corresponds to the INFORMATION_SCHEMA ROUTINES table column, if any.

The ROUTINES table has these columns:

- **SPECIFIC_NAME**
  - The name of the routine.

- **ROUTINE_CATALOG**
  - The name of the catalog to which the routine belongs. This value is always def.

- **ROUTINE_SCHEMA**
  - The name of the schema (database) to which the routine belongs.

- **ROUTINE_NAME**
  - The name of the routine.

- **ROUTINE_TYPE**
  - PROCEDURE for stored procedures, FUNCTION for stored functions.

- **DATA_TYPE**
  - If the routine is a stored function, the return value data type. If the routine is a stored procedure, this value is empty.

  The DATA_TYPE value is the type name only with no other information. The DTD_IDENTIFIER value contains the type name and possibly other information such as the precision or length.

- **CHARACTER_MAXIMUM_LENGTH**
  - For stored function string return values, the maximum length in characters. If the routine is a stored procedure, this value is NULL.

- **CHARACTER_OCTET_LENGTH**
  - For stored function string return values, the maximum length in bytes. If the routine is a stored procedure, this value is NULL.
• **NUMERIC_PRECISION**
  For stored function numeric return values, the numeric precision. If the routine is a stored procedure, this value is `NULL`.

• **NUMERIC_SCALE**
  For stored function numeric return values, the numeric scale. If the routine is a stored procedure, this value is `NULL`.

• **DATETIME_PRECISION**
  For stored function temporal return values, the fractional seconds precision. If the routine is a stored procedure, this value is `NULL`.

• **CHARACTER_SET_NAME**
  For stored function character string return values, the character set name. If the routine is a stored procedure, this value is `NULL`.

• **COLLATION_NAME**
  For stored function character string return values, the collation name. If the routine is a stored procedure, this value is `NULL`.

• **DTD_IDENTIFIER**
  If the routine is a stored function, the return value data type. If the routine is a stored procedure, this value is empty.
  
  The **DATA_TYPE** value is the type name only with no other information. The **DTD_IDENTIFIER** value contains the type name and possibly other information such as the precision or length.

• **ROUTINE_BODY**
  The language used for the routine definition. This value is always `SQL`.

• **ROUTINE_DEFINITION**
  The text of the SQL statement executed by the routine.

• **EXTERNAL_NAME**
  This value is always `NULL`.

• **EXTERNAL_LANGUAGE**
  The language of the stored routine. MySQL calculates **EXTERNAL_LANGUAGE** thus:
  
  • If `mysql.proc.language='SQL'`, **EXTERNAL_LANGUAGE** is `NULL`.
  • Otherwise, **EXTERNAL_LANGUAGE** is what is in `mysql.proc.language`. However, we do not have external languages yet, so it is always `NULL`.

• **PARAMETER_STYLE**
  This value is always `SQL`.

• **IS_DETERMINISTIC**
The INFORMATION_SCHEMA ROUTINES Table

YES or NO, depending on whether the routine is defined with the DETERMINISTIC characteristic.

- **SQL_DATA_ACCESS**
  The data access characteristic for the routine. The value is one of CONTAINS SQL, NO SQL, READS SQL DATA, or MODIFIES SQL DATA.

- **SQL_PATH**
  This value is always NULL.

- **SECURITY_TYPE**
  The routine SQL SECURITY characteristic. The value is one of DEFINER or INVOKER.

- **CREATED**
  The date and time when the routine was created. This is a TIMESTAMP value.

- **LAST_ALTERED**
  The date and time when the routine was last modified. This is a TIMESTAMP value. If the routine has not been modified since its creation, this value is the same as the CREATED value.

- **SQL_MODE**
  The SQL mode in effect when the routine was created or altered, and under which the routine executes. For the permitted values, see Section 5.1.10, “Server SQL Modes”.

- **ROUTINE_COMMENT**
  The text of the comment, if the routine has one. If not, this value is empty.

- **DEFINER**
  The account named in the DEFINER clause (often the user who created the routine), in 'user_name'@'host_name' format.

- **CHARACTER_SET_CLIENT**
  The session value of the character_set_client system variable when the routine was created.

- **COLLATION_CONNECTION**
  The session value of the collation_connection system variable when the routine was created.

- **DATABASE_COLLATION**
  The collation of the database with which the routine is associated.

**Notes**

- To see information about a routine, you must be the user named in the routine DEFINER clause or have SELECT access to the mysql.proc table. If you do not have privileges for the routine itself, the value displayed for the ROUTINE_DEFINITION column is NULL.

- Information about stored function return values is also available in the PARAMETERS table. The return value row for a stored function can be identified as the row that has an ORDINAL_POSITION value of 0.
21.3.20 The INFORMATION_SCHEMA SCHEMATA Table

A schema is a database, so the SCHEMATA table provides information about databases. The SCHEMATA table has these columns:

- CATALOG_NAME
  The name of the catalog to which the schema belongs. This value is always def.
- SCHEMA_NAME
  The name of the schema.
- DEFAULT_CHARACTER_SET_NAME
  The schema default character set.
- DEFAULT_COLLATION_NAME
  The schema default collation.
- SQL_PATH
  This value is always NULL.

Schema names are also available from the SHOW DATABASES statement. See Section 13.7.5.15, “SHOW DATABASES Statement”. The following statements are equivalent:

```sql
SELECT SCHEMA_NAME AS 'Database'
FROM INFORMATION_SCHEMA.SCHEMATA
[WHERE SCHEMA_NAME LIKE 'wild']
SHOW DATABASES
[LIKE 'wild']
```

You see only those databases for which you have some kind of privilege, unless you have the global SHOW DATABASES privilege.

Caution

Because a global privilege is considered a privilege for all databases, any global privilege enables a user to see all database names with SHOW DATABASES or by examining the INFORMATION_SCHEMA SCHEMATA table.

21.3.21 The INFORMATION_SCHEMA SCHEMA_PRIVILEGES Table

The SCHEMA_PRIVILEGES table provides information about schema (database) privileges. It takes its values from the mysql.db system table. The SCHEMA_PRIVILEGES table has these columns:

- GRANTEE
  The name of the account to which the privilege is granted, in 'user_name'@'host_name' format.
- TABLE_CATALOG
  The name of the catalog to which the schema belongs. This value is always def.
The name of the schema.

- PRIVILEGE_TYPE
  The privilege granted. The value can be any privilege that can be granted at the schema level; see Section 13.7.1.4, "GRANT Statement". Each row lists a single privilege, so there is one row per schema privilege held by the grantee.

- IS_GRANTABLE
  YES if the user has the GRANT OPTION privilege, NO otherwise. The output does not list GRANT OPTION as a separate row with PRIVILEGE_TYPE='GRANT OPTION'.

Notes

- SCHEMA_PRIVILEGES is a nonstandard INFORMATION_SCHEMA table.

The following statements are not equivalent:

```
SELECT ... FROM INFORMATION_SCHEMA.SCHEMA_PRIVILEGES
SHOW GRANTS ...
```

21.3.22 The INFORMATION_SCHEMA STATISTICS Table

The STATISTICS table provides information about table indexes.

The STATISTICS table has these columns:

- TABLE_CATALOG
  The name of the catalog to which the table containing the index belongs. This value is always def.

- TABLE_SCHEMA
  The name of the schema (database) to which the table containing the index belongs.

- TABLE_NAME
  The name of the table containing the index.

- NON_UNIQUE
  0 if the index cannot contain duplicates, 1 if it can.

- INDEX_SCHEMA
  The name of the schema (database) to which the index belongs.

- INDEX_NAME
  The name of the index. If the index is the primary key, the name is always PRIMARY.

- SEQ_IN_INDEX
  The column sequence number in the index, starting with 1.

- COLUMN_NAME
  The column name. See also the description for the EXPRESSION column.
The INFORMATION_SCHEMA STATISTICS Table

- **COLLATION**
  How the column is sorted in the index. This can have values A (ascending), D (descending), or NULL (not sorted).

- **CARDINALITY**
  An estimate of the number of unique values in the index. To update this number, run `ANALYZE TABLE` or (for MyISAM tables) `myisamchk -a`.

  **CARDINALITY** is counted based on statistics stored as integers, so the value is not necessarily exact even for small tables. The higher the cardinality, the greater the chance that MySQL uses the index when doing joins.

- **SUB_PART**
  The index prefix. That is, the number of indexed characters if the column is only partly indexed, NULL if the entire column is indexed.

  **Note**
  Prefix limits are measured in bytes. However, prefix lengths for index specifications in `CREATE TABLE`, `ALTER TABLE`, and `CREATE INDEX` statements are interpreted as number of characters for nonbinary string types (CHAR, VARCHAR, TEXT) and number of bytes for binary string types (BINARY, VARBINARY, BLOB). Take this into account when specifying a prefix length for a nonbinary string column that uses a multibyte character set.

  For additional information about index prefixes, see Section 8.3.4, “Column Indexes”, and Section 13.1.13, “CREATE INDEX Statement”.

- **PACKED**
  Indicates how the key is packed. NULL if it is not.

- **NULLABLE**
  Contains YES if the column may contain NULL values and '' if not.

- **INDEX_TYPE**
  The index method used (BTREE, FULLTEXT, HASH, RTREE).

- **COMMENT**
  Information about the index not described in its own column, such as disabled if the index is disabled.

- **INDEX_COMMENT**
  Any comment provided for the index with a COMMENT attribute when the index was created.

**Notes**

- There is no standard INFORMATION_SCHEMA table for indexes. The MySQL column list is similar to what SQL Server 2000 returns for `sp_statistics`, except that QUALIFIER and OWNER are replaced with CATALOG and SCHEMA, respectively.

  Information about table indexes is also available from the SHOW INDEX statement. See Section 13.7.5.23, “SHOW INDEX Statement”. The following statements are equivalent:
21.3.23 The INFORMATION_SCHEMA TABLES Table

The TABLES table provides information about tables in databases.

The TABLES table has these columns:

- **TABLE_CATALOG**
  The name of the catalog to which the table belongs. This value is always default.

- **TABLE_SCHEMA**
  The name of the schema (database) to which the table belongs.

- **TABLE_NAME**
  The name of the table.

- **TABLE_TYPE**
  BASE TABLE for a table, VIEW for a view, or SYSTEM VIEW for an INFORMATION_SCHEMA table.

The TABLES table does not list TEMPORARY tables.

- **ENGINE**

  For partitioned tables, ENGINE shows the name of the storage engine used by all partitions.

- **VERSION**
  The version number of the table's .frm file.

- **ROW_FORMAT**
  The row-storage format (Fixed, Dynamic, Compressed, Redundant, Compact). For MyISAM tables, Dynamic corresponds to what myisamchk -dvv reports as Packed. InnoDB table format is either Redundant or Compact when using the Antelope file format, or Compressed or Dynamic when using the Barracuda file format.

- **TABLE_ROWS**
  The number of rows. Some storage engines, such as MyISAM, store the exact count. For other storage engines, such as InnoDB, this value is an approximation, and may vary from the actual value by as much as 40% to 50%. In such cases, use SELECT COUNT(*) to obtain an accurate count.

  TABLE_ROWS is NULL for INFORMATION_SCHEMA tables.

  For InnoDB tables, the row count is only a rough estimate used in SQL optimization. (This is also true if the InnoDB table is partitioned.)
The INFORMATION_SCHEMA TABLES Table

- **AVG_ROW_LENGTH**
  
The average row length.
  
  Refer to the notes at the end of this section for related information.

- **DATA_LENGTH**

  For **MyISAM**, **DATA_LENGTH** is the length of the data file, in bytes.

  For **InnoDB**, **DATA_LENGTH** is the approximate amount of space allocated for the clustered index, in bytes. Specifically, it is the clustered index size, in pages, multiplied by the **InnoDB** page size.

  Refer to the notes at the end of this section for information regarding other storage engines.

- **MAX_DATA_LENGTH**

  For **MyISAM**, **MAX_DATA_LENGTH** is maximum length of the data file. This is the total number of bytes of data that can be stored in the table, given the data pointer size used.

  Unused for **InnoDB**.

  Refer to the notes at the end of this section for information regarding other storage engines.

- **INDEX_LENGTH**

  For **MyISAM**, **INDEX_LENGTH** is the length of the index file, in bytes.

  For **InnoDB**, **INDEX_LENGTH** is the approximate amount of space allocated for non-clustered indexes, in bytes. Specifically, it is the sum of non-clustered index sizes, in pages, multiplied by the **InnoDB** page size.

  Refer to the notes at the end of this section for information regarding other storage engines.

- **DATA_FREE**

  The number of allocated but unused bytes.

  **InnoDB** tables report the free space of the tablespace to which the table belongs. For a table located in the shared tablespace, this is the free space of the shared tablespace. If you are using multiple tablespaces and the table has its own tablespace, the free space is for only that table. Free space means the number of bytes in completely free extents minus a safety margin. Even if free space displays as 0, it may be possible to insert rows as long as new extents need not be allocated.

  For **NDB Cluster**, **DATA_FREE** shows the space allocated on disk for, but not used by, a Disk Data table or fragment on disk. (In-memory data resource usage is reported by the **DATA_LENGTH** column.)

  For partitioned tables, this value is only an estimate and may not be absolutely correct. A more accurate method of obtaining this information in such cases is to query the INFORMATION_SCHEMA PARTITIONS table, as shown in this example:

  ```sql
  SELECT SUM(DATA_FREE)
  FROM INFORMATION_SCHEMA.PARTITIONS
  WHERE TABLE_SCHEMA = 'mydb'
  AND TABLE_NAME   = 'mytable';
  ```

  For more information, see Section 21.3.14, “The INFORMATION_SCHEMA PARTITIONS Table”.

- **AUTO_INCREMENT**

  3282
The INFORMATION_SCHEMA TABLES Table

The next AUTO_INCREMENT value.

- **CREATE_TIME**

  When the table was created.

  Prior to MySQL 5.6.25, for partitioned InnoDB tables, the CREATE_TIME column shows NULL. This column shows the correct table creation time for such tables in MySQL 5.6.25 and later. (Bug #17299181, Bug #69990)

- **UPDATE_TIME**

  When the data file was last updated. For some storage engines, this value is NULL. For example, InnoDB stores multiple tables in its system tablespace and the data file timestamp does not apply. Even with file-per-table mode with each InnoDB table in a separate .ibd file, change buffering can delay the write to the data file, so the file modification time is different from the time of the last insert, update, or delete. For MyISAM, the data file timestamp is used; however, on Windows the timestamp is not updated by updates, so the value is inaccurate.

  For partitioned InnoDB tables, UPDATE_TIME is always NULL.

- **CHECK_TIME**

  When the table was last checked. Not all storage engines update this time, in which case, the value is always NULL.

  For partitioned InnoDB tables, CHECK_TIME is always NULL.

- **TABLE_COLLATION**

  The table default collation. The output does not explicitly list the table default character set, but the collation name begins with the character set name.

- **CHECKSUM**

  The live checksum value, if any.

- **CREATE_OPTIONS**

  Extra options used with CREATE TABLE.

  CREATE_OPTIONS shows partitioned for partitioned tables.

  When creating a table with strict mode disabled, the storage engine's default row format is used if the specified row format is not supported. The actual row format of the table is reported in the ROW_FORMAT column. CREATE_OPTIONS shows the row format that was specified in the CREATE TABLE statement.

  When altering the storage engine of a table, table options that are not applicable to the new storage engine are retained in the table definition to enable reverting the table with its previously defined options to the original storage engine, if necessary. The CREATE_OPTIONS column may show retained options.

- **TABLE_COMMENT**

  The comment used when creating the table (or information as to why MySQL could not access the table information).
The INFORMATION_SCHEMA TABLESPACES Table

Notes

- For NDB tables, the output of this statement shows appropriate values for the \texttt{AVG\_ROW\_LENGTH} and \texttt{DATA\_LENGTH} columns, with the exception that \texttt{BLOB} columns are not taken into account.

- For NDB tables, \texttt{DATA\_LENGTH} includes data stored in main memory only; the \texttt{MAX\_DATA\_LENGTH} and \texttt{DATA\_FREE} columns apply to Disk Data.

- For NDB Cluster Disk Data tables, \texttt{MAX\_DATA\_LENGTH} shows the space allocated for the disk part of a Disk Data table or fragment. (In-memory data resource usage is reported by the \texttt{DATA\_LENGTH} column.)

- For MEMORY tables, the \texttt{DATA\_LENGTH}, \texttt{MAX\_DATA\_LENGTH}, and \texttt{INDEX\_LENGTH} values approximate the actual amount of allocated memory. The allocation algorithm reserves memory in large amounts to reduce the number of allocation operations.

- For views, all \texttt{TABLES} columns are \texttt{NULL} except that \texttt{TABLE\_NAME} indicates the view name and \texttt{TABLE\_COMMENT} says \texttt{VIEW}.

Table information is also available from the \texttt{SHOW TABLE STATUS} and \texttt{SHOW TABLES} statements. See Section 13.7.5.37, "SHOW TABLE STATUS Statement", and Section 13.7.5.38, "SHOW TABLES Statement". The following statements are equivalent:

```
SELECT
  TABLE\_NAME, ENGINE, VERSION, ROW\_FORMAT, TABLE\_ROWS, AVG\_ROW\_LENGTH,
  DATA\_LENGTH, MAX\_DATA\_LENGTH, INDEX\_LENGTH, DATA\_FREE, AUTO\_INCREMENT,
  CREATE\_TIME, UPDATE\_TIME, CHECK\_TIME, TABLE\_COLLATION, CHECKSUM,
  CREATE\_OPTIONS, TABLE\_COMMENT
FROM INFORMATION\_SCHEMA\_TABLES
WHERE table\_schema = 'db\_name'
  [AND table\_name LIKE 'wild']
SHOW TABLE STATUS
FROM db\_name
  [LIKE 'wild']
```

The following statements are equivalent:

```
SELECT
  TABLE\_NAME, TABLE\_TYPE
FROM INFORMATION\_SCHEMA\_TABLES
WHERE table\_schema = 'db\_name'
  [AND table\_name LIKE 'wild']
SHOW FULL TABLES
FROM db\_name
  [LIKE 'wild']
```

21.3.24 The INFORMATION_SCHEMA TABLESPACES Table

This table is unused. Other \texttt{INFORMATION\_SCHEMA} tables may provide related information:

- For NDB, the \texttt{INFORMATION\_SCHEMA FILES} table provides tablespace-related information.

- For InnoDB, the \texttt{INFORMATION\_SCHEMA INNODB\_SYS\_TABLESPACES} and \texttt{INNODB\_SYS\_DATAFILES} tables provide tablespace metadata.

21.3.25 The INFORMATION_SCHEMA TABLE\_CONSTRAINTS Table

The \texttt{TABLE\_CONSTRAINTS} table describes which tables have constraints.
The INFORMATION_SCHEMA TABLE_CONSTRAINTS Table has these columns:

- **CONSTRAINT_CATALOG**
  The name of the catalog to which the constraint belongs. This value is always `def`.

- **CONSTRAINT_SCHEMA**
  The name of the schema (database) to which the constraint belongs.

- **TABLE_SCHEMA**
  The name of the schema (database) to which the table belongs.

- **TABLE_NAME**
  The name of the table.

- **CONSTRAINT_TYPE**
  The type of constraint. The value can be `UNIQUE`, `PRIMARY KEY`, `FOREIGN KEY`, or `CHECK`. This is a `CHAR` (not `ENUM`) column. The `CHECK` value is not available until MySQL supports `CHECK`.

  The `UNIQUE` and `PRIMARY KEY` information is about the same as what you get from the `Key_name` column in the output from `SHOW INDEX` when the `Non_unique` column is `0`.

21.3.26 The INFORMATION_SCHEMA TABLE_PRIVILEGES Table

The INFORMATION_SCHEMA TABLE_PRIVILEGES table has these columns:

- **GRANTEE**
  The name of the account to which the privilege is granted, in `'user_name'@'host_name'` format.

- **TABLE_CATALOG**
  The name of the catalog to which the table belongs. This value is always `def`.

- **TABLE_SCHEMA**
  The name of the schema (database) to which the table belongs.

- **TABLE_NAME**
  The name of the table.

- **PRIVILEGE_TYPE**
  The privilege granted. The value can be any privilege that can be granted at the table level; see Section 13.7.1.4, “GRANT Statement”. Each row lists a single privilege, so there is one row per table privilege held by the grantee.

- **IS_GRANTABLE**
  `YES` if the user has the `GRANT OPTION` privilege, `NO` otherwise. The output does not list `GRANT OPTION` as a separate row with `PRIVILEGE_TYPE='GRANT OPTION'`. 
Notes

- **TABLE_PRIVILEGES** is a nonstandard INFORMATION_SCHEMA table.

The following statements are *not* equivalent:

```
SELECT ... FROM INFORMATION_SCHEMA.TAB... LE_PRIVILEGES
SHOW GRANTS ...
```

### 21.3.27 The INFORMATION_SCHEMA TRIGGERS Table

The **TRIGGERS** table provides information about triggers. To see information about a table’s triggers, you must have the **TRIGGER** privilege for the table.

The **TRIGGERS** table has these columns:

- **TRIGGER_CATALOG**
  The name of the catalog to which the trigger belongs. This value is always `def`.

- **TRIGGER_SCHEMA**
  The name of the schema (database) to which the trigger belongs.

- **TRIGGER_NAME**
  The name of the trigger.

- **EVENT_MANIPULATION**
  The trigger event. This is the type of operation on the associated table for which the trigger activates. The value is `INSERT` (a row was inserted), `DELETE` (a row was deleted), or `UPDATE` (a row was modified).

- **EVENT_OBJECT_CATALOG**, **EVENT_OBJECT_SCHEMA**, and **EVENT_OBJECT_TABLE**
  As noted in Section 20.3, "Using Triggers", every trigger is associated with exactly one table. These columns indicate the catalog and schema (database) in which this table occurs, and the table name, respectively. The **EVENT_OBJECT_CATALOG** value is always `def`.

- **ACTION_ORDER**
  The ordinal position of the trigger's action within the list of all similar triggers on the same table. This value is always `0` because it is not possible to have more than one trigger with the same **EVENT_MANIPULATION** and **ACTION_TIMING** on the same table.

- **ACTION_CONDITION**
  This value is always `NULL`.

- **ACTION_STATEMENT**
  The trigger body; that is, the statement executed when the trigger activates. This text uses UTF-8 encoding.

- **ACTION_ORIENTATION**
  This value is always `ROW`.
The INFORMATION_SCHEMA TRIGGERS Table

• **ACTION_TIMING**
  Whether the trigger activates before or after the triggering event. The value is **BEFORE** or **AFTER**.

• **ACTION_REFERENCE_OLD_TABLE**
  This value is always **NULL**.

• **ACTION_REFERENCE_NEW_TABLE**
  This value is always **NULL**.

• **ACTION_REFERENCE_OLD_ROW** and **ACTION_REFERENCE_NEW_ROW**
  The old and new column identifiers, respectively. The **ACTION_REFERENCE_OLD_ROW** value is always **OLD** and the **ACTION_REFERENCE_NEW_ROW** value is always **NEW**.

• **CREATED**
  This value is always **NULL**.

• **SQL_MODE**
  The SQL mode in effect when the trigger was created, and under which the trigger executes. For the permitted values, see Section 5.1.10, “Server SQL Modes”.

• **DEFINER**
  The account named in the **DEFINER** clause (often the user who created the trigger), in **'user_name'@'host_name'** format.

• **CHARACTER_SET_CLIENT**
  The session value of the **character_set_client** system variable when the trigger was created.

• **COLLATION_CONNECTION**
  The session value of the **collation_connection** system variable when the trigger was created.

• **DATABASE_COLLATION**
  The collation of the database with which the trigger is associated.

Example

The following example uses the **ins_sum** trigger defined in Section 20.3, “Using Triggers”:

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.TRIGGERS
    WHERE TRIGGER_SCHEMA='test' AND TRIGGER_NAME='ins_sum'
G
+----------------+-----------------------------------------------------------------------+
| TRIGGER_CATALOG | def                                                                   |
| TRIGGER_SCHEMA  | test                                                                  |
| TRIGGER_NAME    | ins_sum                                                              |
| EVENT_MANIPULATION | INSERT                                                                 |
| EVENT_OBJECT_CATALOG | def                                                                  |
| EVENT_OBJECT_SCHEMA | test                                                                  |
| EVENT_OBJECT_TABLE | account                                                              |
| ACTION_ORDER    | 0                                                                    |
| ACTION_CONDITION | NULL                                                                 |
| ACTION_STATEMENT | SET @sum = @sum + NEW.amount                                          |
| ACTION_ORIENTATION | ROW                                                                  |
```
The INFORMATION_SCHEMA USER_PRIVILEGES Table

The USER_PRIVILEGES table provides information about global privileges. It takes its values from the mysql.user system table.

The USER_PRIVILEGES table has these columns:

- **GRANTEE**
  The name of the account to which the privilege is granted, in 'user_name'@'host_name' format.

- **TABLE_CATALOG**
  The name of the catalog. This value is always def.

- **PRIVILEGE_TYPE**
  The privilege granted. The value can be any privilege that can be granted at the global level; see Section 13.7.1.4, “GRANT Statement”. Each row lists a single privilege, so there is one row per global privilege held by the grantee.

- **IS_GRANTABLE**
  YES if the user has the GRANT OPTION privilege, NO otherwise. The output does not list GRANT OPTION as a separate row with PRIVILEGE_TYPE='GRANT OPTION'.

Notes

- USER_PRIVILEGES is a nonstandard INFORMATION_SCHEMA table.

The following statements are not equivalent:

```
SELECT ... FROM INFORMATION_SCHEMA.USER_PRIVILEGES
SHOW GRANTS ...
```

21.3.29 The INFORMATION_SCHEMA VIEWS Table

The VIEWS table provides information about views in databases. You must have the SHOW VIEW privilege to access this table.

The VIEWS table has these columns:

- **TABLE_CATALOG**
  The name of the catalog to which the view belongs. This value is always def.
The INFORMATION_SCHEMA VIEWS Table

- **TABLE_SCHEMA**
  The name of the schema (database) to which the view belongs.

- **TABLE_NAME**
  The name of the view.

- **VIEW_DEFINITION**
  The *SELECT* statement that provides the definition of the view. This column has most of what you see in the *Create Table* column that *SHOW CREATE VIEW* produces. Skip the words before *SELECT* and skip the words *WITH CHECK OPTION*. Suppose that the original statement was:

  ```sql
  CREATE VIEW v AS
  SELECT s2, s1 FROM t
  WHERE s1 > 5
  ORDER BY s1
  WITH CHECK OPTION;
  ```

  Then the view definition looks like this:

  ```sql
  SELECT s2, s1 FROM t WHERE s1 > 5 ORDER BY s1
  ```

- **CHECK_OPTION**
  The value of the *CHECK_OPTION* attribute. The value is one of *NONE*, *CASCADE*, or *LOCAL*.

- **IS_UPDATABLE**
  MySQL sets a flag, called the view updatability flag, at *CREATE VIEW* time. The flag is set to *YES* (true) if *UPDATE* and *DELETE* (and similar operations) are legal for the view. Otherwise, the flag is set to *NO* (false). The *IS_UPDATABLE* column in the *VIEWS* table displays the status of this flag. It means that the server always knows whether a view is updatable.

  If a view is not updatable, statements such *UPDATE*, *DELETE*, and *INSERT* are illegal and are rejected. (Even if a view is updatable, it might not be possible to insert into it; for details, refer to Section 20.5.3, “Updatable and Insertable Views”.)

- **DEFINER**
  The account of the user who created the view, in *'user_name'@'host_name'* format.

- **SECURITY_TYPE**
  The view *SQL SECURITY* characteristic. The value is one of *DEFINER* or *INVOKER*.

- **CHARACTER_SET_CLIENT**
  The session value of the *character_set_client* system variable when the view was created.

- **COLLATION_CONNECTION**
  The session value of the *collation_connection* system variable when the view was created.

**Notes**

MySQL permits different *sql_mode* settings to tell the server the type of SQL syntax to support. For example, you might use the *ANSI* SQL mode to ensure MySQL correctly interprets the standard SQL concatenation operator, the double bar (*||*), in your queries. If you then create a view that concatenates...
items, you might worry that changing the `sql_mode` setting to a value different from `ANSI` could cause the view to become invalid. But this is not the case. No matter how you write out a view definition, MySQL always stores it the same way, in a canonical form. Here is an example that shows how the server changes a double bar concatenation operator to a `CONCAT()` function:

```sql
mysql> SET sql_mode = 'ANSI';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE VIEW test.v AS SELECT 'a' || 'b' as col1;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT VIEW_DEFINITION FROM INFORMATION_SCHEMA.VIEWS
    > WHERE TABLE_SCHEMA = 'test' AND TABLE_NAME = 'v';
+----------------------------------+
| VIEW_DEFINITION                  |
+----------------------------------+
| select concat('a','b') AS 'col1' |
+----------------------------------+
1 row in set (0.00 sec)
```

The advantage of storing a view definition in canonical form is that changes made later to the value of `sql_mode` do not affect the results from the view. However, an additional consequence is that comments prior to `SELECT` are stripped from the definition by the server.

# 21.4 INFORMATION_SCHEMA InnoDB Tables

This section provides table definitions for `INFORMATION_SCHEMA` InnoDB tables. For related information and examples, see Section 14.15, “InnoDB INFORMATION_SCHEMA Tables”.

`INFORMATION_SCHEMA` InnoDB tables can be used to monitor ongoing InnoDB activity, to detect inefficiencies before they turn into issues, or to troubleshoot performance and capacity issues. As your database becomes bigger and busier, running up against the limits of your hardware capacity, you monitor and tune these aspects to keep the database running smoothly.

## 21.4.1 INFORMATION_SCHEMA InnoDB Table Reference

The following table summarizes `INFORMATION_SCHEMA` InnoDB tables. For greater detail, see the individual table descriptions.

<table>
<thead>
<tr>
<th>Table Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>INNODB_BUFFER_PAGE</td>
<td>Pages in InnoDB buffer pool</td>
</tr>
<tr>
<td>INNODB_BUFFER_PAGE_LRU</td>
<td>LRU ordering of pages in InnoDB buffer pool</td>
</tr>
<tr>
<td>INNODB_BUFFER_POOL_STATS</td>
<td>InnoDB buffer pool statistics</td>
</tr>
<tr>
<td>INNODB_CMP</td>
<td>Status for operations related to compressed InnoDB</td>
</tr>
<tr>
<td></td>
<td>tables</td>
</tr>
<tr>
<td>INNODB_CMP_PER_INDEX</td>
<td>Status for operations related to compressed InnoDB</td>
</tr>
<tr>
<td></td>
<td>tables and indexes</td>
</tr>
<tr>
<td>INNODB_CMP_PER_INDEX_RESET</td>
<td>Status for operations related to compressed InnoDB</td>
</tr>
<tr>
<td></td>
<td>tables and indexes</td>
</tr>
<tr>
<td>INNODB_CMP_RESET</td>
<td>Status for operations related to compressed InnoDB</td>
</tr>
<tr>
<td></td>
<td>tables</td>
</tr>
<tr>
<td>INNODB_CMPMEM</td>
<td>Status for compressed pages within InnoDB buffer pool</td>
</tr>
</tbody>
</table>
### The INFORMATION_SCHEMA INNODB_BUFFER_PAGE Table

<table>
<thead>
<tr>
<th>Table Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>INNODB_CMPMEM_RESET</td>
<td>Status for compressed pages within InnoDB buffer pool</td>
</tr>
<tr>
<td>INNODB_FT_BEING_DELETED</td>
<td>Snapshot of INNODB_FT_DELETED table</td>
</tr>
<tr>
<td>INNODB_FT_CONFIG</td>
<td>Metadata for InnoDB table FULLTEXT index and associated processing</td>
</tr>
<tr>
<td>INNODB_FT_DEFAULT_STOPWORD</td>
<td>Default list of stopwords for InnoDB FULLTEXT indexes</td>
</tr>
<tr>
<td>INNODB_FT_DELETED</td>
<td>Rows deleted from InnoDB table FULLTEXT index</td>
</tr>
<tr>
<td>INNODB_FT_INDEX_CACHE</td>
<td>Token information for newly inserted rows in InnoDB FULLTEXT index</td>
</tr>
<tr>
<td>INNODB_FT_INDEX_TABLE</td>
<td>Inverted index information for processing text searches against InnoDB table FULLTEXT index</td>
</tr>
<tr>
<td>INNODB_LOCK_WAITS</td>
<td>InnoDB transaction lock-wait information</td>
</tr>
<tr>
<td>INNODB_LOCKS</td>
<td>InnoDB transaction lock information</td>
</tr>
<tr>
<td>INNODB_METRICS</td>

<tr>
<td>INNODB_SYS_TABLESPACES</td>
<td>InnoDB file-per-table, general, and undo tablespace metadata</td>
</tr>
<tr>
<td>INNODB_SYS_TABLESTATS</td>
<td>InnoDB table low-level status information</td>
</tr>
<tr>
<td>INNODB_TRX</td>
<td>Active InnoDB transaction information</td>
</tr>
</tbody>
</table>

#### 21.4.2 The INFORMATION_SCHEMA INNODB_BUFFER_PAGE Table

The **INNODB_BUFFER_PAGE** table provides information about each page in the InnoDB buffer pool.

For related usage information and examples, see [Section 14.15.5, “InnoDB INFORMATION_SCHEMA Buffer Pool Tables”](#).

**Warning**

Querying the **INNODB_BUFFER_PAGE** table can affect performance. Do not query this table on a production system unless you are aware of the performance impact and have determined it to be acceptable. To avoid impacting performance on a production system, reproduce the issue you want to investigate and query buffer pool statistics on a test instance.

The **INNODB_BUFFER_PAGE** table has these columns:

- **POOL_ID**
The buffer pool ID. This is an identifier to distinguish between multiple buffer pool instances.

- **BLOCK_ID**
  
  The buffer pool block ID.

- **SPACE**
  
  The tablespace ID; the same value as `INNODB_SYS_TABLES.SPACE`.

- **PAGE_NUMBER**
  
  The page number.

- **PAGE_TYPE**
  
  The page type. The following table shows the permitted values.

  **Table 21.4 INNODB_BUFFER_PAGE.PAGE_TYPE Values**

<table>
<thead>
<tr>
<th>Page Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALLOCATED</td>
<td>Freshly allocated page</td>
</tr>
<tr>
<td>BLOB</td>
<td>Uncompressed BLOB page</td>
</tr>
<tr>
<td>COMPRESSED_BLOB2</td>
<td>Subsequent comp BLOB page</td>
</tr>
<tr>
<td>COMPRESSED_BLOB</td>
<td>First compressed BLOB page</td>
</tr>
<tr>
<td>EXTENT_DESCRIPTOR</td>
<td>Extent descriptor page</td>
</tr>
<tr>
<td>FILE_SPACE_HEADER</td>
<td>File space header</td>
</tr>
<tr>
<td>IBUF_BITMAP</td>
<td>Insert buffer bitmap</td>
</tr>
<tr>
<td>IBUF_FREE_LIST</td>
<td>Insert buffer free list</td>
</tr>
<tr>
<td>IBUF_INDEX</td>
<td>Insert buffer index</td>
</tr>
<tr>
<td>INDEX</td>
<td>B-tree node</td>
</tr>
<tr>
<td>INODE</td>
<td>Index node</td>
</tr>
<tr>
<td>SYSTEM</td>
<td>System page</td>
</tr>
<tr>
<td>TRX_SYSTEM</td>
<td>Transaction system data</td>
</tr>
<tr>
<td>UNDO_LOG</td>
<td>Undo log page</td>
</tr>
<tr>
<td>UNKNOWN</td>
<td>Unknown</td>
</tr>
</tbody>
</table>

- **FLUSH_TYPE**
  
  The flush type.

- **FIX_COUNT**
  
  The number of threads using this block within the buffer pool. When zero, the block is eligible to be evicted.

- **IS_HASHED**
  
  Whether a hash index has been built on this page.

- **NEWEST_MODIFICATION**
The INFORMATION_SCHEMA INNODB_BUFFER_PAGE Table

The Log Sequence Number of the youngest modification.

- **OLDEST_MODIFICATION**
  The Log Sequence Number of the oldest modification.

- **ACCESS_TIME**
  An abstract number used to judge the first access time of the page.

- **TABLE_NAME**
  The name of the table the page belongs to. This column is applicable only to pages with a `PAGE_TYPE` value of `INDEX`.

- **INDEX_NAME**
  The name of the index the page belongs to. This can be the name of a clustered index or a secondary index. This column is applicable only to pages with a `PAGE_TYPE` value of `INDEX`.

- **NUMBER_RECORDS**
  The number of records within the page.

- **DATA_SIZE**
  The sum of the sizes of the records. This column is applicable only to pages with a `PAGE_TYPE` value of `INDEX`.

- **COMPRESSED_SIZE**
  The compressed page size. `NULL` for pages that are not compressed.

- **PAGE_STATE**
  The page state. The following table shows the permitted values.

  **Table 21.5 INNODB_BUFFER_PAGE.PAGE_STATE Values**

<table>
<thead>
<tr>
<th>Page State</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FILE_PAGE</td>
<td>A buffered file page</td>
</tr>
<tr>
<td>MEMORY</td>
<td>Contains a main memory object</td>
</tr>
<tr>
<td>NOT_USED</td>
<td>In the free list</td>
</tr>
<tr>
<td>NULL</td>
<td>Clean compressed pages, compressed pages in the flush list, pages used as buffer pool watch sentinels</td>
</tr>
<tr>
<td>READY_FOR_USE</td>
<td>A free page</td>
</tr>
<tr>
<td>REMOVE_HASH</td>
<td>Hash index should be removed before placing in the free list</td>
</tr>
</tbody>
</table>

- **IO_FIX**
  Whether any I/O is pending for this page: `IO_NONE` = no pending I/O, `IO_READ` = read pending, `IO_WRITE` = write pending.

- **IS_OLD**
The INFORMATION_SCHEMA INNODB_BUFFER_PAGE_LRU Table

Whether the block is in the sublist of old blocks in the LRU list.

- **FREE_PAGE_CLOCK**

The value of the freed_page_clock counter when the block was the last placed at the head of the LRU list. The freed_page_clock counter tracks the number of blocks removed from the end of the LRU list.

**Example**

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE LIMIT 1;
*************************** 1. row ***************************
POOL_ID: 0
BLOCK_ID: 0
SPACE: 97
PAGE_NUMBER: 2473
PAGE_TYPE: INDEX
FLUSH_TYPE: 1
FIX_COUNT: 0
IS_HASHED: YES
NEWEST_MODIFICATION: 733855581
OLDEST_MODIFICATION: 0
ACCESS_TIME: 3378385672
TABLE_NAME: `employees`.`salaries`
INDEX_NAME: PRIMARY
NUMBER_RECORDS: 468
DATA_SIZE: 14976
COMPRESSED_SIZE: 0
PAGE_STATE: FILE_PAGE
IO_FIX: IO_NONE
IS_OLD: YES
FREE_PAGE_CLOCK: 66
```

**Notes**

- This table is useful primarily for expert-level performance monitoring, or when developing performance-related extensions for MySQL.
- You must have the `PROCESS` privilege to query this table.
- Use the `INFORMATION_SCHEMA COLUMNS` table or the `SHOW COLUMNS` statement to view additional information about the columns of this table, including data types and default values.
- When tables, table rows, partitions, or indexes are deleted, associated pages remain in the buffer pool until space is required for other data. The `INNODB_BUFFER_PAGE` table reports information about these pages until they are evicted from the buffer pool. For more information about how the InnoDB manages buffer pool data, see Section 14.5.1, "Buffer Pool".

**21.4.3 The INFORMATION_SCHEMA INNODB_BUFFER_PAGE_LRU Table**

The `INNODB_BUFFER_PAGE_LRU` table provides information about the pages in the InnoDB buffer pool; in particular, how they are ordered in the LRU list that determines which pages to evict from the buffer pool when it becomes full.

The `INNODB_BUFFER_PAGE_LRU` table has the same columns as the `INNODB_BUFFER_PAGE` table, except that the `INNODB_BUFFER_PAGE_LRU` table has `LRU_POSITION` and `COMPRESSED` columns instead of `BLOCK_ID` and `PAGE_STATE` columns.

For related usage information and examples, see Section 14.15.5, "InnoDB INFORMATION_SCHEMA Buffer Pool Tables".
Warning
Querying the INNODB_BUFFER_PAGE_LRU table can affect performance. Do not query this table on a production system unless you are aware of the performance impact and have determined it to be acceptable. To avoid impacting performance on a production system, reproduce the issue you want to investigate and query buffer pool statistics on a test instance.

The INNODB_BUFFER_PAGE_LRU table has these columns:

- **POOL_ID**
The buffer pool ID. This is an identifier to distinguish between multiple buffer pool instances.

- **LRU_POSITION**
The position of the page in the LRU list.

- **SPACE**
The tablespace ID; the same value as INNODB_SYS_TABLES.SPACE.

- **PAGE_NUMBER**
The page number.

- **PAGE_TYPE**
The page type. The following table shows the permitted values.

<table>
<thead>
<tr>
<th>Page Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALLOCATED</td>
<td>Freshly allocated page</td>
</tr>
<tr>
<td>BLOB</td>
<td>Uncompressed BLOB page</td>
</tr>
<tr>
<td>COMPRESSED_BLOB2</td>
<td>Subsequent comp BLOB page</td>
</tr>
<tr>
<td>COMPRESSED_BLOB</td>
<td>First compressed BLOB page</td>
</tr>
<tr>
<td>EXTENT_DESCRIPTOR</td>
<td>Extent descriptor page</td>
</tr>
<tr>
<td>FILE_SPACE_HEADER</td>
<td>File space header</td>
</tr>

</tr>
</tbody>
</table>

- **FLUSH_TYPE**
The flush type.
The INFORMATION_SCHEMA INNODB_BUFFER_PAGE_LRU Table

- **FIX_COUNT**
  The number of threads using this block within the buffer pool. When zero, the block is eligible to be evicted.

- **IS_HASHED**
  Whether a hash index has been built on this page.

- **NEWEST_MODIFICATION**
  The Log Sequence Number of the youngest modification.

- **OLDEST_MODIFICATION**
  The Log Sequence Number of the oldest modification.

- **ACCESS_TIME**
  An abstract number used to judge the first access time of the page.

- **TABLE_NAME**
  The name of the table the page belongs to. This column is applicable only to pages with a `PAGE_TYPE` value of `INDEX`.

- **INDEX_NAME**
  The name of the index the page belongs to. This can be the name of a clustered index or a secondary index. This column is applicable only to pages with a `PAGE_TYPE` value of `INDEX`.

- **NUMBER_RECORDS**
  The number of records within the page.

- **DATA_SIZE**
  The sum of the sizes of the records. This column is applicable only to pages with a `PAGE_TYPE` value of `INDEX`.

- **COMPRESSED_SIZE**
  The compressed page size. NULL for pages that are not compressed.

- **COMPRESSED**
  Whether the page is compressed.

- **IO_FIX**
  Whether any I/O is pending for this page: `IO_NONE` = no pending I/O, `IO_READ` = read pending, `IO_WRITE` = write pending.

- **IS_OLD**
  Whether the block is in the sublist of old blocks in the LRU list.
• **FREE_PAGE_CLOCK**

The value of the freed_page_clock counter when the block was the last placed at the head of the LRU list. The freed_page_clock counter tracks the number of blocks removed from the end of the LRU list.

**Example**

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE_LRU LIMIT 1;
```

```
The idea of making pages in the buffer pool “young” or “not young” refers to transferring them between the sublists at the head and tail of the buffer pool data structure. Pages made “young” take longer to age out of the buffer pool, while pages made “not young” are moved much closer to the point of eviction.

For related usage information and examples, see Section 14.15.5, “InnoDB INFORMATION_SCHEMA Buffer Pool Tables”.

The `INNODB_BUFFER_POOL_STATS` table has these columns:

- **POOL_ID**
  - The buffer pool ID. This is an identifier to distinguish between multiple buffer pool instances.

- **POOL_SIZE**
  - The InnoDB buffer pool size in pages.

- **FREE_BUFFERS**
  - The number of free pages in the InnoDB buffer pool.

- **DATABASE_PAGES**
  - The number of pages in the InnoDB buffer pool containing data. This number includes both dirty and clean pages.

- **OLD_DATABASE_PAGES**
  - The number of pages in the old buffer pool sublist.

- **MODIFIED_DATABASE_PAGES**
  - The number of modified (dirty) database pages.

- **PENDING_DECOMPRESS**
  - The number of pages pending decompression.

- **PENDING_READS**
  - The number of pending reads.

- **PENDING_FLUSH_LRU**
  - The number of pages pending flush in the LRU.

- **PENDING_FLUSH_LIST**
  - The number of pages pending flush in the flush list.

- **PAGES_MADE_YOUNG**
  - The number of pages made young.

- **PAGES_NOT_MADE_YOUNG**
  - The number of pages not made young.

- **PAGES_MADE_YOUNG_RATE**
The number of pages made young per second (pages made young since the last printout / time elapsed).

- **PAGES_MADE_NOT_YOUNG_RATE**
  The number of pages not made per second (pages not made young since the last printout / time elapsed).

- **NUMBER_PAGES_READ**
  The number of pages read.

- **NUMBER_PAGES_CREATED**
  The number of pages created.

- **NUMBER_PAGES_WRITTEN**
  The number of pages written.

- **PAGES_READ_RATE**
  The number of pages read per second (pages read since the last printout / time elapsed).

- **PAGES_CREATE_RATE**
  The number of pages created per second (pages created since the last printout / time elapsed).

- **PAGES_WRITTEN_RATE**
  The number of pages written per second (pages written since the last printout / time elapsed).

- **NUMBER_PAGES_GET**
  The number of logical read requests.

- **HIT_RATE**
  The buffer pool hit rate.

- **YOUNG_MAKE_PER_THOUSAND_GETS**
  The number of pages made young per thousand gets.

- **NOT_YOUNG_MAKE_PER_THOUSAND_GETS**
  The number of pages not made young per thousand gets.

- **NUMBER_PAGES_READ_AHEAD**
  The number of pages read ahead.

- **NUMBER_READ_AHEAD_EVICTED**
  The number of pages read into the InnoDB buffer pool by the read-ahead background thread that were subsequently evicted without having been accessed by queries.

- **READ_AHEAD_RATE**
  The read-ahead rate per second (pages read ahead since the last printout / time elapsed).
The INFORMATION_SCHEMA INNODB_BUFFER_POOL_STATS Table

- **READ_AHEAD_EVICTED_RATE**
  The number of read-ahead pages evicted without access per second (read-ahead pages not accessed since the last printout / time elapsed).

- **LRU_IO_TOTAL**
  Total LRU I/O.

- **LRU_IO_CURRENT**
  LRU I/O for the current interval.

- **UNCOMPRESS_TOTAL**
  The total number of pages decompressed.

- **UNCOMPRESS_CURRENT**
  The number of pages decompressed in the current interval.

**Example**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_BUFFER_POOL_STATS;
*************************** 1. row ***************************
POOL_ID: 0
POOL_SIZE: 8192
FREE_BUFFERS: 1
DATABASE_PAGES: 8085
OLD_DATABASE_PAGES: 2964
MODIFIED_DATABASE_PAGES: 0
PENDING_DECOMPRESS: 0
PENDING_READS: 0
PENDING_FLUSH_LRU: 0
PENDING_FLUSH_LIST: 0
PAGES_MADE_YOUNG: 22821
PAGES_MADE_YOUNG_RATE: 357.62602199870594
PAGES_MADE_NOT_YOUNG_RATE: 0
NUMBER_PAGES_READ: 2389
NUMBER_PAGES_CREATED: 12385
NUMBER_PAGES_WRITTEN: 13111
PAGES_READ_RATE: 0
PAGES_CREATE_RATE: 0
PAGES_WRITTEN_RATE: 0
NUMBER_PAGES_GET: 33322210
HIT_RATE: 1000
YOUNG_MAKE_PER_THOUSAND_GETS: 18
NOT_YOUNG_MAKE_PER_THOUSAND_GETS: 0
NUMBER_PAGES_READ_AHEAD: 2024
NUMBER_READ_AHEAD_EVICTED: 0
READ_AHEAD_RATE: 0
READ_AHEAD_EVICTED_RATE: 0
LRU_IO_TOTAL: 0
LRU_IO_CURRENT: 0
UNCOMPRESS_TOTAL: 0
UNCOMPRESS_CURRENT: 0
```

**Notes**

- This table is useful primarily for expert-level performance monitoring, or when developing performance-related extensions for MySQL.
- You must have the `PROCESS` privilege to query this table.
The INFORMATION_SCHEMA INNODB_CMP and INNODB_CMP_RESET Tables

- Use the INFORMATION_SCHEMA COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of this table, including data types and default values.

21.4.5 The INFORMATION_SCHEMA INNODB_CMP and INNODB_CMP_RESET Tables

The INNODB_CMP and INNODB_CMP_RESET tables provide status information on operations related to compressed InnoDB tables.

The INNODB_CMP and INNODB_CMP_RESET tables have these columns:

- **PAGE_SIZE**
  The compressed page size in bytes.

- **COMPRESS_OPS**
  The number of times a B-tree page of size PAGE_SIZE has been compressed. Pages are compressed whenever an empty page is created or the space for the uncompressed modification log runs out.

- **COMPRESS_OPS_OK**
  The number of times a B-tree page of size PAGE_SIZE has been successfully compressed. This count should never exceed COMPRESS_OPS.

- **COMPRESS_TIME**
  The total time in seconds used for attempts to compress B-tree pages of size PAGE_SIZE.

- **UNCOMPRESS_OPS**
  The number of times a B-tree page of size PAGE_SIZE has been uncompressed. B-tree pages are uncompressed whenever compression fails or at first access when the uncompressed page does not exist in the buffer pool.

- **UNCOMPRESS_TIME**
  The total time in seconds used for uncompressing B-tree pages of the size PAGE_SIZE.

Example

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_CMP;
+------------------+
| page_size | compress_ops | compress_ops_ok | compress_time | uncompress_ops | uncompress_time |
+------------------+
| 1024           | 0            | 0               | 0             | 0             | 0              |
| 2048           | 0            | 0               | 0             | 0             | 0              |
| 4096           | 0            | 0               | 0             | 0             | 0              |
+------------------+
```

3301
The INFORMATION_SCHEMA INNODB_CMPMEM and INNODB_CMPMEM_RESET Tables

The INNODB_CMPMEM and INNODB_CMPMEM_RESET tables provide status information on compressed pages within the InnoDB buffer pool.

The INNODB_CMPMEM and INNODB_CMPMEM_RESET tables have these columns:

• PAGE_SIZE
  The block size in bytes. Each record of this table describes blocks of this size.

• BUFFER_POOL_INSTANCE
  A unique identifier for the buffer pool instance.

• PAGES_USED
  The number of blocks of size PAGE_SIZE that are currently in use.

• PAGES_FREE
  The number of blocks of size PAGE_SIZE that are currently available for allocation. This column shows the external fragmentation in the memory pool. Ideally, these numbers should be at most 1.

• RELOCATION_OPS
  The number of times a block of size PAGE_SIZE has been relocated. The buddy system can relocate the allocated "buddy neighbor" of a freed block when it tries to form a bigger freed block. Reading from the INNODB_CMPMEM_RESET table resets this count.

Notes

• Use these tables to measure the effectiveness of InnoDB table compression in your database.

• You must have the PROCESS privilege to query this table.

• Use the INFORMATION_SCHEMA COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of this table, including data types and default values.

• For usage information, see Section 14.9.4, “Monitoring InnoDB Table Compression at Runtime” and Section 14.15.1.3, “Using the Compression Information Schema Tables”. For general information about InnoDB table compression, see Section 14.9, “InnoDB Table Compression”.

21.4.6 The INFORMATION_SCHEMA INNODB_CMPMEM and INNODB_CMPMEM_RESET Tables

uncompress_ops: 0
uncompress_time: 0

*************************** 4. row ***************************
page_size: 8192
compress_ops: 86955
compress_ops_ok: 81182
compress_time: 27
uncompress_ops: 26828
uncompress_time: 5

*************************** 5. row ***************************
page_size: 16384
compress_ops: 0
compress_ops_ok: 0
compress_time: 0
uncompress_ops: 0
uncompress_time: 0
• **RELOCATION_TIME**

The total time in microseconds used for relocating blocks of size `PAGE_SIZE`. Reading from the table `INNODB_CMPMEM_RESET` resets this count.

**Example**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_CMPMEM\G
*************************** 1. row ***************************
    page_size: 1024
   buffer_pool_instance: 0
        pages_used: 0
        pages_free: 0
   relocation_ops: 0
relocation_time: 0
*************************** 2. row ***************************
    page_size: 2048
   buffer_pool_instance: 0
        pages_used: 0
        pages_free: 0
   relocation_ops: 0
relocation_time: 0
*************************** 3. row ***************************
    page_size: 4096
   buffer_pool_instance: 0
        pages_used: 0
        pages_free: 0
   relocation_ops: 0
relocation_time: 0
*************************** 4. row ***************************
    page_size: 8192
   buffer_pool_instance: 0
        pages_used: 0
        pages_free: 0
   relocation_ops: 0
relocation_time: 0
*************************** 5. row ***************************
    page_size: 16384
   buffer_pool_instance: 0
        pages_used: 0
        pages_free: 0
   relocation_ops: 0
relocation_time: 0
```

**Notes**

- Use these tables to measure the effectiveness of InnoDB table compression in your database.
- You must have the `PROCESS` privilege to query this table.
- Use the `INFORMATION_SCHEMA.COLUMNS` table or the `SHOW COLUMNS` statement to view additional information about the columns of this table, including data types and default values.
- For usage information, see Section 14.9.4, “Monitoring InnoDB Table Compression at Runtime” and Section 14.15.1.3, “Using the Compression Information Schema Tables”. For general information about InnoDB table compression, see Section 14.9, “InnoDB Table Compression”.

**21.4.7 The INFORMATION_SCHEMA INNODB_CMP_PER_INDEX and INNODB_CMP_PER_INDEX_RESET Tables**

The `INNODB_CMP_PER_INDEX` and `INNODB_CMP_PER_INDEX_RESET` tables provide status information on operations related to compressed InnoDB tables and indexes, with separate statistics for each
The INFORMATION_SCHEMA INNODB_CMP_PER_INDEX and INNODB_CMP_PER_INDEX_RESET Tables

The combination of database, table, and index, to help you evaluate the performance and usefulness of compression for specific tables.

For a compressed InnoDB table, both the table data and all the secondary indexes are compressed. In this context, the table data is treated as just another index, one that happens to contain all the columns: the clustered index.

The INNODB_CMP_PER_INDEX and INNODB_CMP_PER_INDEX_RESET tables have these columns:

- **DATABASE_NAME**
  The schema (database) containing the applicable table.

- **TABLE_NAME**
  The table to monitor for compression statistics.

- **INDEX_NAME**
  The index to monitor for compression statistics.

- **COMPRESS_OPS**
  The number of compression operations attempted. Pages are compressed whenever an empty page is created or the space for the uncompressed modification log runs out.

- **COMPRESS_OPS_OK**
  The number of successful compression operations. Subtract from the COMPRESS_OPS value to get the number of compression failures. Divide by the COMPRESS_OPS value to get the percentage of compression failures.

- **COMPRESS_TIME**
  The total time in seconds used for compressing data in this index.

- **UNCOMPRESS_OPS**
  The number of uncompression operations performed. Compressed InnoDB pages are uncompressed whenever compression fails, or the first time a compressed page is accessed in the buffer pool and the uncompressed page does not exist.

- **UNCOMPRESS_TIME**
  The total time in seconds used for uncompressing data in this index.

Example

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_CMP_PER_INDEX\G
*************************** 1. row ***************************
  database_name: employees  
  table_name: salaries     
  index_name: PRIMARY      
  compress_ops: 0          
  compress_ops_ok: 0       
  compress_time: 0         
  uncompress_ops: 23451    
  uncompress_time: 4       
*************************** 2. row ***************************
  database_name: employees  
  table_name: salaries
```

3304
The INFORMATION_SCHEMA INNODB_FT_BEING_DELETED Table

<table>
<thead>
<tr>
<th>index_name: emp_no</th>
</tr>
</thead>
<tbody>
<tr>
<td>compress_ops: 0</td>
</tr>
<tr>
<td>compress_ops_ok: 0</td>
</tr>
<tr>
<td>compress_time: 0</td>
</tr>
<tr>
<td>uncompress_ops: 1597</td>
</tr>
<tr>
<td>uncompress_time: 0</td>
</tr>
</tbody>
</table>

Notes

- Use these tables to measure the effectiveness of InnoDB table compression for specific tables, indexes, or both.
- You must have the PROCESS privilege to query these tables.
- Use the INFORMATION_SCHEMA COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of these tables, including data types and default values.
- Because collecting separate measurements for every index imposes substantial performance overhead, INNODB_CMP_PER_INDEX and INNODB_CMP_PER_INDEX_RESET statistics are not gathered by default. You must enable the innodb_cmp_per_index_enabled system variable before performing the operations on compressed tables that you want to monitor.
- For usage information, see Section 14.9.4, “Monitoring InnoDB Table Compression at Runtime” and Section 14.15.1.3, “Using the Compression Information Schema Tables”. For general information about InnoDB table compression, see Section 14.9, “InnoDB Table Compression”.

21.4.8 The INFORMATION_SCHEMA INNODB_FT_BEING_DELETED Table

The INNODB_FT_BEING_DELETED table provides a snapshot of the INNODB_FT_DELETED table: it is used only during an OPTIMIZE TABLE maintenance operation. When OPTIMIZE TABLE is run, the INNODB_FT_BEING_DELETED table is emptied, and DOC_ID values are removed from the INNODB_FT_DELETED table. Because the contents of INNODB_FT_BEING_DELETED typically have a short lifetime, this table has limited utility for monitoring or debugging. For information about running OPTIMIZE TABLE on tables with FULLTEXT indexes, see Section 12.10.6, “Fine-Tuning MySQL Full-Text Search”.

This table is empty initially. Before querying it, set the value of the innodb_ft_aux_table system variable to the name (including the database name) of the table that contains the FULLTEXT index; for example test/articles. The output appears similar to the example provided for the INNODB_FT_DELETED table.

For related usage information and examples, see Section 14.15.4, “InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables”.

The INNODB_FT_BEING_DELETED table has these columns:

- DOC_ID
  
  The document ID of the row that is in the process of being deleted. This value might reflect the value of an ID column that you defined for the underlying table, or it can be a sequence value generated by InnoDB when the table contains no suitable column. This value is used when you do text searches, to skip rows in the INNODB_FT_INDEX_TABLE table before data for deleted rows is physically removed from the FULLTEXT index by an OPTIMIZE TABLE statement. For more information, see Optimizing InnoDB Full-Text Indexes.

Notes

- You must have the PROCESS privilege to query this table.
21.4.9 The INFORMATION_SCHEMA INNODB_FT_CONFIG Table

The INFORMATION_SCHEMA INNODB_FT_CONFIG table provides metadata about the FULLTEXT index and associated processing for an InnoDB table.

This table is empty initially. Before querying it, set the value of the innodb_ft_aux_table system variable to the name (including the database name) of the table that contains the FULLTEXT index; for example test/articles.

For related usage information and examples, see Section 14.15.4, “InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables”.

The INFORMATION_SCHEMA INNODB_FT_CONFIG table has these columns:

- **KEY**
  
The name designating an item of metadata for an InnoDB table containing a FULLTEXT index.

  The values for this column might change, depending on the needs for performance tuning and debugging for InnoDB full-text processing. The key names and their meanings include:

  - **optimize_checkpoint_limit**: The number of seconds after which an OPTIMIZE TABLE run stops.
  - **synced_doc_id**: The next DOC_ID to be issued.
  - **stopword_table_name**: The database/table name for a user-defined stopword table. The VALUE column is empty if there is no user-defined stopword table.
  - **use_stopword**: Indicates whether a stopword table is used, which is defined when the FULLTEXT index is created.

- **VALUE**
  
The value associated with the corresponding KEY column, reflecting some limit or current value for an aspect of a FULLTEXT index for an InnoDB table.

**Example**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_CONFIG;
+---------------------------+-------------------+
<table>
<thead>
<tr>
<th>KEY</th>
<th>VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>optimize_checkpoint_limit</td>
<td>180</td>
</tr>
<tr>
<td>synced_doc_id</td>
<td>0</td>
</tr>
<tr>
<td>stopword_table_name</td>
<td>test/my_stopwords</td>
</tr>
<tr>
<td>use_stopword</td>
<td>1</td>
</tr>
</tbody>
</table>
+---------------------------+-------------------+
```

**Notes**

- This table is intended only for internal configuration. It is not intended for statistical information purposes.
The INFORMATION_SCHEMA INNODB_FT_DEFAULT_STOPWORD Table

- You must have the PROCESS privilege to query this table.
- Use the INFORMATION_SCHEMA COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of this table, including data types and default values.
- For more information about InnoDB FULLTEXT search, see Section 14.6.2.3, “InnoDB Full-Text Indexes”, and Section 12.10, “Full-Text Search Functions”.

21.4.10 The INFORMATION_SCHEMA INNODB_FT_DEFAULT_STOPWORD Table

The INNODB_FT_DEFAULT_STOPWORD table holds a list of stopwords that are used by default when creating a FULLTEXT index on InnoDB tables. For information about the default InnoDB stopword list and how to define your own stopword lists, see Section 12.10.4, “Full-Text Stopwords”.

For related usage information and examples, see Section 14.15.4, “InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables”.

The INNODB_FT_DEFAULT_STOPWORD table has these columns:

- **value**

  A word that is used by default as a stopword for FULLTEXT indexes on InnoDB tables. This is not used if you override the default stopword processing with either the innodb_ft_server_stopword_table or the innodb_ft_user_stopword_table system variable.

Example

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_DEFAULT_STOPWORD;
```

<table>
<thead>
<tr>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
</tr>
<tr>
<td>about</td>
</tr>
<tr>
<td>an</td>
</tr>
<tr>
<td>are</td>
</tr>
<tr>
<td>as</td>
</tr>
<tr>
<td>at</td>
</tr>
<tr>
<td>be</td>
</tr>
<tr>
<td>by</td>
</tr>
<tr>
<td>com</td>
</tr>
<tr>
<td>de</td>
</tr>
<tr>
<td>en</td>
</tr>
<tr>
<td>for</td>
</tr>
<tr>
<td>from</td>
</tr>
<tr>
<td>how</td>
</tr>
<tr>
<td>i</td>
</tr>
<tr>
<td>in</td>
</tr>
<tr>
<td>is</td>
</tr>
<tr>
<td>it</td>
</tr>
<tr>
<td>la</td>
</tr>
<tr>
<td>of</td>
</tr>
<tr>
<td>or</td>
</tr>
<tr>
<td>that</td>
</tr>
<tr>
<td>the</td>
</tr>
<tr>
<td>this</td>
</tr>
<tr>
<td>to</td>
</tr>
<tr>
<td>was</td>
</tr>
<tr>
<td>what</td>
</tr>
<tr>
<td>when</td>
</tr>
<tr>
<td>where</td>
</tr>
</tbody>
</table>
```

3307
The INFORMATION_SCHEMA INNODB_FT_DELETED Table

The INNODB_FT_DELETED table stores rows that are deleted from the FULLTEXT index for an InnoDB table. To avoid expensive index reorganization during DML operations for an InnoDB FULLTEXT index, the information about newly deleted words is stored separately, filtered out of search results when you do a text search, and removed from the main search index only when you issue an OPTIMIZE TABLE statement for the InnoDB table. For more information, see Optimizing InnoDB Full-Text Indexes.

This table is empty initially. Before querying it, set the value of the innodb_ft_aux_table system variable to the name (including the database name) of the table that contains the FULLTEXT index; for example test/articles.

For related usage information and examples, see Section 14.15.4, “InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables”.

The INNODB_FT_DELETED table has these columns:

- **DOC_ID**

  The document ID of the newly deleted row. This value might reflect the value of an ID column that you defined for the underlying table, or it can be a sequence value generated by InnoDB when the table contains no suitable column. This value is used when you do text searches, to skip rows in the INNODB_FT_INDEX_TABLE table before data for deleted rows is physically removed from the FULLTEXT index by an OPTIMIZE_TABLE statement. For more information, see Optimizing InnoDB Full-Text Indexes.

Example

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_DELETED;
+--------+
<table>
<thead>
<tr>
<th>DOC_ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>6</td>
</tr>
<tr>
<td>7</td>
</tr>
<tr>
<td>8</td>
</tr>
</tbody>
</table>
+--------+
```

Notes

- You must have the PROCESS privilege to query this table.
The INFORMATION_SCHEMA INNODB_FT_INDEX_CACHE Table

- Use the INFORMATION_SCHEMA COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of this table, including data types and default values.

- For more information about InnoDB FULLTEXT search, see Section 14.6.2.3, “InnoDB Full-Text Indexes”, and Section 12.10, “Full-Text Search Functions”.

21.4.12 The INFORMATION_SCHEMA INNODB_FT_INDEX_CACHE Table

The INNODB_FT_INDEX_CACHE table provides token information about newly inserted rows in a FULLTEXT index. To avoid expensive index reorganization during DML operations, the information about newly indexed words is stored separately, and combined with the main search index only when OPTIMIZE TABLE is run, when the server is shut down, or when the cache size exceeds a limit defined by the innodb_ft_cache_size or innodb_ft_total_cache_size system variable.

This table is empty initially. Before querying it, set the value of the innodb_ft_aux_table system variable to the name (including the database name) of the table that contains the FULLTEXT index; for example test/articles.

For related usage information and examples, see Section 14.15.4, “InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables”.

The INNODB_FT_INDEX_CACHE table has these columns:

- **WORD**
  A word extracted from the text of a newly inserted row.

- **FIRST_DOC_ID**
  The first document ID in which this word appears in the FULLTEXT index.

- **LAST_DOC_ID**
  The last document ID in which this word appears in the FULLTEXT index.

- **DOC_COUNT**
  The number of rows in which this word appears in the FULLTEXT index. The same word can occur several times within the cache table, once for each combination of DOC_ID and POSITION values.

- **DOC_ID**
  The document ID of the newly inserted row. This value might reflect the value of an ID column that you defined for the underlying table, or it can be a sequence value generated by InnoDB when the table contains no suitable column.

- **POSITION**
  The position of this particular instance of the word within the relevant document identified by the DOC_ID value. The value does not represent an absolute position; it is an offset added to the POSITION of the previous instance of that word.

Notes

- This table is empty initially. Before querying it, set the value of the innodb_ft_aux_table system variable to the name (including the database name) of the table that contains the FULLTEXT index; for example test/articles. The following example demonstrates how to use the
The `INFORMATION_SCHEMA INNODB_FT_INDEX_TABLE` Table

The `INNODB_FT_INDEX_TABLE` table provides information about the inverted index used to process text searches against the `FULLTEXT` index of an `InnoDB` table.

This table is empty initially. Before querying it, set the value of the `innodb_ft_aux_table` system variable to the name (including the database name) of the table that contains the `FULLTEXT` index; for example `test/articles`.

For related usage information and examples, see Section 14.15.4, “InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables”.

The `INNODB_FT_INDEX_TABLE` table has these columns:

- **WORD**
  A word extracted from the text of the columns that are part of a `FULLTEXT`.

- **FIRST_DOC_ID**
  The first document ID in which this word appears in the `FULLTEXT` index.
The INFORMATION_SCHEMA INNODB_FT_INDEX_TABLE Table

- **LAST_DOC_ID**
  
  The last document ID in which this word appears in the `FULLTEXT` index.

- **DOC_COUNT**
  
  The number of rows in which this word appears in the `FULLTEXT` index. The same word can occur several times within the cache table, once for each combination of `DOC_ID` and `POSITION` values.

- **DOC_ID**
  
  The document ID of the row containing the word. This value might reflect the value of an ID column that you defined for the underlying table, or it can be a sequence value generated by `InnoDB` when the table contains no suitable column.

- **POSITION**
  
  The position of this particular instance of the word within the relevant document identified by the `DOC_ID` value.

**Notes**

- This table is empty initially. Before querying it, set the value of the `innodb_ft_aux_table` system variable to the name (including the database name) of the table that contains the `FULLTEXT` index; for example `test/articles`. The following example demonstrates how to use the `innodb_ft_aux_table` system variable to show information about a `FULLTEXT` index for a specified table. Before information for newly inserted rows appears in `INNODB_FT_INDEX_TABLE`, the `FULLTEXT` index cache must be flushed to disk. This is accomplished by running an `OPTIMIZE TABLE` operation on the indexed table with the `innodb_optimize_fulltext_only` system variable enabled. (The example disables that variable again at the end because it is intended to be enabled only temporarily.)

```sql
mysql> USE test;
mysql> CREATE TABLE articles (
    
id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
  title VARCHAR(200),
    body TEXT,
  FULLTEXT (title,body)
) ENGINE=InnoDB;

mysql> INSERT INTO articles (title,body) VALUES 
  ('MySQL Tutorial','DBMS stands for DataBase ...'),
  ('How To Use MySQL Well','After you went through a ...'),
  ('Optimizing MySQL','In this tutorial we show ...'),
  ('1001 MySQL Tricks','1. Never run mysqld as root. 2. ...'),
  ('MySQL vs. YourSQL','In the following database comparison ...'),
  ('MySQL Security','When configured properly, MySQL ...');

mysql> SET GLOBAL innodb_optimize_fulltext_only=ON;

mysql> OPTIMIZE TABLE articles;

+---------------+----------+----------+----------+
| Table         | Op       | Msg_type | Msg_text |
+---------------+----------+----------+----------+
| test.articles | optimize | status   | OK       |
+---------------+----------+----------+----------+

mysql> SET GLOBAL innodb_ft_aux_table = 'test/articles';

mysql> SELECT WORD, DOC_COUNT, DOC_ID, POSITION
  FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_TABLE LIMIT 5;
```

You must have the `PROCESS` privilege to query this table.

Use the `INFORMATION_SCHEMA COLUMNS` table or the `SHOW COLUMNS` statement to view additional information about the columns of this table, including data types and default values.

For more information about InnoDB Full-Text search, see Section 14.6.2.3, “InnoDB Full-Text Indexes”, and Section 12.10, “Full-Text Search Functions”.

21.4.14 The INFORMATION_SCHEMA INNODB_LOCKS Table

The `INNODB_LOCKS` table provides information about each lock that an InnoDB transaction has requested but not yet acquired, and each lock that a transaction holds that is blocking another transaction.

The `INNODB_LOCKS` table has these columns:

- **LOCK_ID**
  A unique lock ID number, internal to InnoDB. Treat it as an opaque string. Although `LOCK_ID` currently contains `TRX_ID`, the format of the data in `LOCK_ID` is subject to change at any time. Do not write applications that parse the `LOCK_ID` value.

- **LOCK_TRX_ID**
  The ID of the transaction holding the lock. To obtain details about the transaction, join this column with the `TRX_ID` column of the `INNODB_TRX` table.

- **LOCK_MODE**
  How the lock is requested. Permitted lock mode descriptors are `S`, `X`, `IS`, `IX`, `GAP`, `AUTO_INC`, and `UNKNOWN`. Lock mode descriptors may be used in combination to identify particular lock modes. For information about InnoDB lock modes, see Section 14.7.1, “InnoDB Locking”.

- **LOCK_TYPE**
  The type of lock. Permitted values are `RECORD` for a row-level lock, `TABLE` for a table-level lock.

- **LOCK_TABLE**
  The name of the table that has been locked or contains locked records.

- **LOCK_INDEX**
  The name of the index, if `LOCK_TYPE` is `RECORD`; otherwise `NULL`.

- **LOCK_SPACE**
  The tablespace ID of the locked record, if `LOCK_TYPE` is `RECORD`; otherwise `NULL`.

- **LOCK_PAGE**
  The page ID of the locked record.
The page number of the locked record, if `LOCK_TYPE` is `RECORD`; otherwise `NULL`.

- **LOCK_REC**

  The heap number of the locked record within the page, if `LOCK_TYPE` is `RECORD`; otherwise `NULL`.

- **LOCK_DATA**

  The data associated with the lock, if any. A value is shown if the `LOCK_TYPE` is `RECORD`, otherwise the value is `NULL`. Primary key values of the locked record are shown for a lock placed on the primary key index. Secondary index values of the locked record are shown for a lock placed on a unique secondary index. Secondary index values are shown with primary key values appended if the secondary index is not unique. If there is no primary key, `LOCK_DATA` shows either the key values of a selected unique index or the unique InnoDB internal row ID number, according to the rules governing InnoDB clustered index use (see Section 14.6.2.1, “Clustered and Secondary Indexes”). `LOCK_DATA` reports “supremum pseudo-record” for a lock taken on a supremum pseudo-record. If the page containing the locked record is not in the buffer pool because it was written to disk while the lock was held, InnoDB does not fetch the page from disk. Instead, `LOCK_DATA` reports `NULL`.

**Example**

```mysql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_LOCKS
*************************** 1. row ***************************
lock_id: 3723:72:3:2
lock_trx_id: 3723
lock_mode: X
lock_type: RECORD
lock_table: `mysql`.`t`
lock_index: PRIMARY
lock_space: 72
lock_page: 3
lock_rec: 2
lock_data: 1, 9
*************************** 2. row ***************************
lock_id: 3722:72:3:2
lock_trx_id: 3722
lock_mode: S
lock_type: RECORD
lock_table: `mysql`.`t`
lock_index: PRIMARY
lock_space: 72
lock_page: 3
lock_rec: 2
lock_data: 1, 9
```

**Notes**

- Use this table to help diagnose performance problems that occur during times of heavy concurrent load. Its contents are updated as described in Section 14.15.2.3, “Persistence and Consistency of InnoDB Transaction and Locking Information”.

- You must have the `PROCESS` privilege to query this table.

- Use the `INFORMATION_SCHEMA.COLUMNS` table or the `SHOW COLUMNS` statement to view additional information about the columns of this table, including data types and default values.

- For usage information, see Section 14.15.2.1, “Using InnoDB Transaction and Locking Information”.

**21.4.15 The INFORMATION_SCHEMA INNODB_LOCK_WAITS Table**
The **INNODB_LOCK_WAITS** table contains one or more rows for each blocked InnoDB transaction, indicating the lock it has requested and any locks that are blocking that request.

The **INNODB_LOCK_WAITS** table has these columns:

- **REQUESTING_TRX_ID**
  
  The ID of the requesting (blocked) transaction.

- **REQUESTED_LOCK_ID**
  
  The ID of the lock for which a transaction is waiting. To obtain details about the lock, join this column with the **LOCK_ID** column of the **INNODB_LOCKS** table.

- **BLOCKING_TRX_ID**
  
  The ID of the blocking transaction.

- **BLOCKING_LOCK_ID**
  
  The ID of a lock held by a transaction blocking another transaction from proceeding. To obtain details about the lock, join this column with the **LOCK_ID** column of the **INNODB_LOCKS** table.

**Example**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_LOCK_WAITS;
*************************** 1. row ***************************
requesting_trx_id: 3396
requested_lock_id: 3396:91:3:2
blocking_trx_id: 3395
blocking_lock_id: 3395:91:3:2
```

**Notes**

- Use this table to help diagnose performance problems that occur during times of heavy concurrent load. Its contents are updated as described in Section 14.15.2.3, “Persistence and Consistency of InnoDB Transaction and Locking Information”.
- You must have the **PROCESS** privilege to query this table.
- Use the **INFORMATION_SCHEMA COLUMNS** table or the **SHOW COLUMNS** statement to view additional information about the columns of this table, including data types and default values.
- For usage information, see Section 14.15.2.1, “Using InnoDB Transaction and Locking Information”.

### 21.4.16 The INFORMATION_SCHEMA INNODB_METRICS Table

The **INNODB_METRICS** table provides a wide variety of InnoDB performance information, complementing the specific focus areas of the Performance Schema tables for InnoDB. With simple queries, you can check the overall health of the system. With more detailed queries, you can diagnose issues such as performance bottlenecks, resource shortages, and application issues.

Each monitor represents a point within the InnoDB source code that is instrumented to gather counter information. Each counter can be started, stopped, and reset. You can also perform these actions for a group of counters using their common module name.

By default, relatively little data is collected. To start, stop, and reset counters, set one of the system variables `innodb_monitor_enable`, `innodb_monitor_disable`, `innodb_monitor_reset`, or
The INFORMATION_SCHEMA INNODB_METRICS Table

innodb_monitor_reset_all, using the name of the counter, the name of the module, a wildcard match for such a name using the “%” character, or the special keyword all.

For usage information, see Section 14.15.6, “InnoDB INFORMATION_SCHEMA Metrics Table”.

The INNODB_METRICS table has these columns:

- **NAME**
  A unique name for the counter.

- **SUBSYSTEM**
  The aspect of InnoDB that the metric applies to.

- **COUNT**
  The value since the counter was enabled.

- **MAX_COUNT**
  The maximum value since the counter was enabled.

- **MIN_COUNT**
  The minimum value since the counter was enabled.

- **AVG_COUNT**
  The average value since the counter was enabled.

- **COUNT_RESET**
  The counter value since it was last reset. (The _RESET columns act like the lap counter on a stopwatch: you can measure the activity during some time interval, while the cumulative figures are still available in COUNT, MAX_COUNT, and so on.)

- **MAX_COUNT_RESET**
  The maximum counter value since it was last reset.

- **MIN_COUNT_RESET**
  The minimum counter value since it was last reset.

- **AVG_COUNT_RESET**
  The average counter value since it was last reset.

- **TIME_ENABLED**
  The timestamp of the last start.

- **TIME_DISABLED**
  The timestamp of the last stop.

- **TIME_ELAPSED**
  The elapsed time in seconds since the counter started.
The INFORMATION_SCHEMA INNODB_SYS_COLUMNS Table

- **TIME_RESET**
  The timestamp of the last reset.

- **STATUS**
  Whether the counter is still running (enabled) or stopped (disabled).

- **TYPE**
  Whether the item is a cumulative counter, or measures the current value of some resource.

- **COMMENT**
  The counter description.

**Example**

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME='dml Inserts'\G
*************************** 1. row ***************************
   NAME: dml Inserts
  SUBSYSTEM: dml
    COUNT: 3
    MAX_COUNT: 3
      MIN_COUNT: NULL
      AVG_COUNT: 0.046153846153846156
      COUNT_RESET: 3
      MAX_COUNT_RESET: 3
      MIN_COUNT_RESET: NULL
      AVG_COUNT_RESET: NULL
 TIME_ENABLED: 2014-12-04 14:18:28
TIME_DISABLED: NULL
 TIME_ELAPSED: 65
       TIME_RESET: NULL
        STATUS: enabled
         TYPE: status_counter
       COMMENT: Number of rows inserted
```

**Notes**

- You must have the **PROCESS** privilege to query this table.

- Use the **INFORMATION_SCHEMA COLUMNS** table or the **SHOW COLUMNS** statement to view additional information about the columns of this table, including data types and default values.

**21.4.17 The INFORMATION_SCHEMA INNODB_SYS_COLUMNS Table**

The **INNODB_SYS_COLUMNS** table provides metadata about InnoDB table columns, equivalent to the information from the **SYS_COLUMNS** table in the InnoDB data dictionary.

For related usage information and examples, see Section 14.15.3, “InnoDB INFORMATION_SCHEMA System Tables”.

The **INNODB_SYS_COLUMNS** table has these columns:

- **TABLE_ID**
  An identifier representing the table associated with the column; the same value as **INNODB_SYS_TABLES.TABLE_ID**.
The INFORMATION_SCHEMA INNODB_SYS_DATAFILES Table

- **NAME**
  The name of the column. These names can be uppercase or lowercase depending on the lower_case_table_names setting. There are no special system-reserved names for columns.

- **POS**
  The ordinal position of the column within the table, starting from 0 and incrementing sequentially. When a column is dropped, the remaining columns are reordered so that the sequence has no gaps.

- **MTYPE**
  Stands for “main type”. A numeric identifier for the column type. 1 = VARCHAR, 2 = CHAR, 3 = FIXBINARY, 4 = BINARY, 5 = BLOB, 6 = INT, 7 = SYS_CHILD, 8 = SYS, 9 = FLOAT, 10 = DOUBLE, 11 = DECIMAL, 12 = VARMYSQL, 13 = MYSQL.

- **PRTYPE**
  The InnoDB "precise type", a binary value with bits representing MySQL data type, character set code, and nullability.

- **LEN**
  The column length, for example 4 for INT and 8 for BIGINT. For character columns in multibyte character sets, this length value is the maximum length in bytes needed to represent a definition such as VARCHAR(N); that is, it might be 2*N, 3*N, and so on depending on the character encoding.

**Example**

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_COLUMNS where TABLE_ID = 71\G
*************************** 1. row ***************************
TABLE_ID: 71
  NAME: col1
  POS: 0
  MTYPE: 6
  PRTYPE: 1027
  LEN: 4
*************************** 2. row ***************************
TABLE_ID: 71
  NAME: col2
  POS: 1
  MTYPE: 2
  PRTYPE: 524542
  LEN: 10
*************************** 3. row ***************************
TABLE_ID: 71
  NAME: col3
  POS: 2
  MTYPE: 1
  PRTYPE: 524303
  LEN: 10
```

**Notes**

- You must have the PROCESS privilege to query this table.

- Use the INFORMATION_SCHEMA COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of this table, including data types and default values.

21.4.18 The INFORMATION_SCHEMA INNODB_SYS_DATAFILES Table
The `INNODB_SYS_DATAFILES` table provides data file path information for InnoDB tablespaces, equivalent to the information in the `SYS_DATAFILES` table in the InnoDB data dictionary.

For related usage information and examples, see Section 14.15.3, “InnoDB INFORMATION_SCHEMA System Tables”.

The `INNODB_SYS_DATAFILES` table has these columns:

- **SPACE**
  The tablespace ID.

- **PATH**
  The tablespace data file path. If a file-per-table tablespace is created in a location outside the MySQL data directory, the path value is a fully qualified directory path. Otherwise, the path is relative to the data directory.

**Example**

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_DATAFILES WHERE SPACE = 57\G
*************************** 1. row ***************************
SPACE: 57
PATH: ./test/t1.ibd
```

**Notes**

- You must have the `PROCESS` privilege to query this table.
- Use the `INFORMATION_SCHEMA COLUMNS` table or the `SHOW COLUMNS` statement to view additional information about the columns of this table, including data types and default values.

### 21.4.19 The INFORMATION_SCHEMA INNODB_SYS_FIELDS Table

The `INNODB_SYS_FIELDS` table provides metadata about the key columns (fields) of InnoDB indexes, equivalent to the information from the `SYS_FIELDS` table in the InnoDB data dictionary.

For related usage information and examples, see Section 14.15.3, “InnoDB INFORMATION_SCHEMA System Tables”.

The `INNODB_SYS_FIELDS` table has these columns:

- **INDEX_ID**
  An identifier for the index associated with this key field; the same value as `INNODB_SYS_INDEXES.INDEX_ID`.

- **NAME**
  The name of the original column from the table; the same value as `INNODB_SYS_COLUMNS.NAME`.

- **POS**
  The ordinal position of the key field within the index, starting from 0 and incrementing sequentially. When a column is dropped, the remaining columns are reordered so that the sequence has no gaps.

**Example**

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_FIELDS WHERE INDEX_ID = 117\G
*************************** 1. row ***************************
3318
```
The INFORMATION_SCHEMA INNODB_SYS_FOREIGN Table

INDEX_ID: 117
NAME: col1
POS: 0

Notes

• You must have the PROCESS privilege to query this table.

• Use the INFORMATION_SCHEMA COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of this table, including data types and default values.

21.4.20 The INFORMATION_SCHEMA INNODB_SYS_FOREIGN Table

The INNODB_SYS_FOREIGN table provides metadata about InnoDB foreign keys, equivalent to the information from the SYS_FOREIGN table in the InnoDB data dictionary.

For related usage information and examples, see Section 14.15.3, “InnoDB INFORMATION_SCHEMA System Tables”.

The INNODB_SYS_FOREIGN table has these columns:

• ID
  The name (not a numeric value) of the foreign key index, preceded by the schema (database) name (for example, test/products_fk).

• FOR_NAME
  The name of the child table in this foreign key relationship.

• REF_NAME
  The name of the parent table in this foreign key relationship.

• N_COLS
  The number of columns in the foreign key index.

• TYPE
  A collection of bit flags with information about the foreign key column, ORed together. 0 = ON DELETE/UPDATE RESTRICT, 1 = ON DELETE CASCADE, 2 = ON DELETE SET NULL, 4 = ON UPDATE CASCADE, 8 = ON UPDATE SET NULL, 16 = ON DELETE NO ACTION, 32 = ON UPDATE NO ACTION.

Example

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_FOREIGN\G
*************************** 1. row ***************************
ID: test/fk1
FOR_NAME: test/child
REF_NAME: test/parent
N_COLS: 1
TYPE: 1

Notes

• You must have the PROCESS privilege to query this table.

• Use the INFORMATION_SCHEMA COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of this table, including data types and default values.
21.4.21 The INFORMATION_SCHEMA INNODB_SYS_FOREIGN_COLS Table

The `INNODB_SYS_FOREIGN_COLS` table provides status information about the columns of InnoDB foreign keys, equivalent to the information from the `SYS_FOREIGN_COLS` table in the InnoDB data dictionary.

For related usage information and examples, see Section 14.15.3, “InnoDB INFORMATION_SCHEMA System Tables”.

The `INNODB_SYS_FOREIGN_COLS` table has these columns:

- **ID**
  The foreign key index associated with this index key field, using the same value as `INNODB_SYS_FOREIGN.ID`.

- **FOR_COL_NAME**
  The name of the associated column in the child table.

- **REF_COL_NAME**
  The name of the associated column in the parent table.

- **POS**
  The ordinal position of this key field within the foreign key index, starting from 0.

Example

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_FOREIGN_COLS WHERE ID = 'test/fk1'
```

```
+---+------------------+------------------+
| ID | FOR_COL_NAME     | REF_COL_NAME     |
+---+------------------+------------------+
| test/fk1 | parent_id | id |
+---+------------------+------------------+
```

Notes

- You must have the `PROCESS` privilege to query this table.
- Use the `INFORMATION_SCHEMA.COLUMNS` table or the `SHOW COLUMNS` statement to view additional information about the columns of this table, including data types and default values.

21.4.22 The INFORMATION_SCHEMA INNODB_SYS_INDEXES Table

The `INNODB_SYS_INDEXES` table provides metadata about InnoDB indexes, equivalent to the information in the internal `SYS_INDEXES` table in the InnoDB data dictionary.

For related usage information and examples, see Section 14.15.3, “InnoDB INFORMATION_SCHEMA System Tables”.

The `INNODB_SYS_INDEXES` table has these columns:

- **INDEX_ID**
  An identifier for the index. Index identifiers are unique across all the databases in an instance.

- **NAME**
The name of the index. Most indexes created implicitly by InnoDB have consistent names but the index names are not necessarily unique. Examples: PRIMARY for a primary key index, GEN_CLUST_INDEX for the index representing a primary key when one is not specified, and ID_IND, FOR_IND, and REF_IND for foreign key constraints.

- **TABLE_ID**

An identifier representing the table associated with the index; the same value as INNODB_SYS_TABLES.TABLE_ID.

- **TYPE**

A numeric value derived from bit-level information that identifies the index type. 0 = nonunique secondary index; 1 = automatically generated clustered index (GEN_CLUST_INDEX); 2 = unique nonclustered index; 3 = clustered index; 32 = full-text index

- **N_FIELDS**

The number of columns in the index key. For GEN_CLUST_INDEX indexes, this value is 0 because the index is created using an artificial value rather than a real table column.

- **PAGE_NO**

The root page number of the index B-tree. For full-text indexes, the PAGE_NO column is unused and set to -1 (FIL_NULL) because the full-text index is laid out in several B-trees (auxiliary tables).

- **SPACE**

An identifier for the tablespace where the index resides. 0 means the InnoDB system tablespace. Any other number represents a table created with a separate .ibd file in file-per-table mode. This identifier stays the same after a TRUNCATE TABLE statement. Because all indexes for a table reside in the same tablespace as the table, this value is not necessarily unique.

**Example**

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_INDEXES WHERE TABLE_ID = 74
*************************** 1. row ***************************
INDEX_ID: 116
   NAME: GEN_CLUST_INDEX
TABLE_ID: 74
    TYPE: 1
  N_FIELDS: 0
  PAGE_NO: 3
   SPACE: 60
*************************** 2. row ***************************
INDEX_ID: 117
   NAME: i1
TABLE_ID: 74
    TYPE: 0
  N_FIELDS: 1
  PAGE_NO: 4
   SPACE: 60
```

**Notes**

- You must have the PROCESS privilege to query this table.

- Use the INFORMATION_SCHEMA_COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of this table, including data types and default values.
The **INNODB_SYS_TABLES** table provides metadata about InnoDB tables, equivalent to the information from the **SYS_TABLES** table in the InnoDB data dictionary.

For related usage information and examples, see [Section 14.15.3, “InnoDB INFORMATION_SCHEMA System Tables”](#).

The **INNODB_SYS_TABLES** table has these columns:

- **TABLE_ID**
  - An identifier for the InnoDB table. This value is unique across all databases in the instance.

- **NAME**
  - The name of the table, preceded by the schema (database) name where appropriate (for example, `test/t1`). Names of databases and user tables are in the same case as they were originally defined, possibly influenced by the `lower_case_table_names` setting.

- **FLAG**
  - A numeric value that represents bit-level information about table format and storage characteristics.

- **N_COLS**
  - The number of columns in the table. The number reported includes three hidden columns that are created by InnoDB (DB_ROW_ID, DB_TRX_ID, and DB_ROLL_PTR).

- **SPACE**
  - An identifier for the tablespace where the table resides. 0 means the InnoDB system tablespace. Any other number represents a table created in file-per-table mode with a separate .ibd file. This identifier stays the same after a **TRUNCATE TABLE** statement. Other than the zero value, this identifier is unique for tables across all the databases in the instance.

- **FILE_FORMAT**
  - The table’s file format (Antelope or Barracuda).

- **ROW_FORMAT**
  - The table’s row format (Compact, Redundant, Dynamic, or Compressed).

- **ZIP_PAGE_SIZE**
  - The zip page size. Applies only to tables with a row format of Compressed.

**Example**

```sql
code
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE TABLE_ID = 74
+------------------+
<table>
<thead>
<tr>
<th>TABLE_ID</th>
<th>NAME</th>
<th>FLAG</th>
<th>N_COLS</th>
<th>SPACE</th>
<th>FILE_FORMAT</th>
<th>ROW_FORMAT</th>
<th>ZIP_PAGE_SIZE</th>
</tr>
</thead>
<tbody>
<tr>
<td>74</td>
<td>test/t1</td>
<td>1</td>
<td>6</td>
<td>60</td>
<td>Antelope</td>
<td>Compact</td>
<td></td>
</tr>
</tbody>
</table>
```

---

3322
The INFORMATION_SCHEMA INNODB_SYS_TABLESPACES Table

Notes

• You must have the PROCESS privilege to query this table.

• Use the INFORMATION_SCHEMA COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of this table, including data types and default values.

21.4.24 The INFORMATION_SCHEMA INNODB_SYS_TABLESPACES Table

The INNODB_SYS_TABLESPACES table provides metadata about InnoDB tablespaces, equivalent to the information in the SYS_TABLESPACES table in the InnoDB data dictionary.

For related usage information and examples, see Section 14.15.3, “InnoDB INFORMATION_SCHEMA System Tables”.

The INNODB_SYS_TABLESPACES table has these columns:

• SPACE
  The tablespace ID.

• NAME
  The schema (database) and table name.

• FLAG
  A numeric value that represents bit-level information about tablespace format and storage characteristics.

• FILE_FORMAT
  The tablespace file format (for example, Antelope or Barracuda). The data in this field is interpreted from the tablespace flags information that resides in the .ibd file. For more information about InnoDB file formats, see Section 14.10, “InnoDB File-Format Management”.

• ROW_FORMAT
  The tablespace row format (Compact or Redundant, Dynamic, or Compressed). The data in this column is interpreted from the tablespace flags information that resides in the .ibd file.

• PAGE_SIZE
  The tablespace page size. The data in this column is interpreted from the tablespace flags information that resides in the .ibd file.

• ZIP_PAGE_SIZE
  The tablespace zip page size. The data in this column is interpreted from the tablespace flags information that resides in the .ibd file.

Example

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES WHERE SPACE = 57\G
*************************** 1. row ***************************
SPACE: 57
The INFORMATION_SCHEMA INNODB_SYS_TABLESTATS View

| NAME: test/t1 |
| FILE_FORMAT: Antelope |
| ROW_FORMAT: Compact or Redundant |
| PAGE_SIZE: 16384 |
| ZIP_PAGE_SIZE: 0 |

Notes

- You must have the PROCESS privilege to query this table.
- Use the INFORMATION_SCHEMA COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of this table, including data types and default values.
- Because tablespace flags are always zero for all Antelope file formats (unlike table flags), there is no way to determine from this flag integer if the tablespace row format is Redundant or Compact. As a result, the possible values for the ROW_FORMAT field are “Compact or Redundant”, “Compressed”, or “Dynamic.”

21.4.25 The INFORMATION_SCHEMA INNODB_SYS_TABLESTATS View

The INNODB_SYS_TABLESTATS table provides a view of low-level status information about InnoDB tables. This data is used by the MySQL optimizer to calculate which index to use when querying an InnoDB table. This information is derived from in-memory data structures rather than data stored on disk. There is no corresponding internal InnoDB system table.

InnoDB tables are represented in this view if they have been opened since the last server restart and have not aged out of the table cache. Tables for which persistent stats are available are always represented in this view.

Table statistics are updated only for DELETE or UPDATE operations that modify indexed columns. Statistics are not updated by operations that modify only nonindexed columns.

ANALYZE TABLE clears table statistics and sets the STATS_INITIALIZED column to Uninitialized. Statistics are collected again the next time the table is accessed.

For related usage information and examples, see Section 14.15.3, “InnoDB INFORMATION_SCHEMA System Tables”.

The INNODB_SYS_TABLESTATS table has these columns:

- **TABLE_ID**
  An identifier representing the table for which statistics are available; the same value as INNODB_SYS_TABLES.TABLE_ID.

- **NAME**
  The name of the table; the same value as INNODB_SYS_TABLES.NAME.

- **STATS_INITIALIZED**
  The value is Initialized if the statistics are already collected, Uninitialized if not.

- **NUM_ROWS**
  The current estimated number of rows in the table. Updated after each DML operation. The value could be imprecise if uncommitted transactions are inserting into or deleting from the table.
The INFORMATION_SCHEMA INNODB_TRX Table

- **CLUST_INDEX_SIZE**
  
The number of pages on disk that store the clustered index, which holds the InnoDB table data in primary key order. This value might be null if no statistics are collected yet for the table.

- **OTHER_INDEX_SIZE**
  
The number of pages on disk that store all secondary indexes for the table. This value might be null if no statistics are collected yet for the table.

- **MODIFIED_COUNTER**
  
The number of rows modified by DML operations, such as `INSERT`, `UPDATE`, `DELETE`, and also cascade operations from foreign keys. This column is reset each time table statistics are recalculated.

- **AUTOINC**
  
The next number to be issued for any auto-increment-based operation. The rate at which the `AUTOINC` value changes depends on how many times auto-increment numbers have been requested and how many numbers are granted per request.

- **REF_COUNT**
  
When this counter reaches zero, the table metadata can be evicted from the table cache.

**Example**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLESTATS where TABLE_ID = 71;
*************************** 1. row ***************************
TABLE_ID: 71
NAME: test/t1
STATS_INITIALIZED: Initialized
NUM_ROWS: 1
CLUST_INDEX_SIZE: 1
OTHER_INDEX_SIZE: 0
MODIFIED_COUNTER: 1
AUTOINC: 0
REF_COUNT: 1
```

**Notes**

- This table is useful primarily for expert-level performance monitoring, or when developing performance-related extensions for MySQL.
- You must have the `PROCESS` privilege to query this table.
- Use the `INFORMATION_SCHEMA COLUMNS` table or the `SHOW COLUMNS` statement to view additional information about the columns of this table, including data types and default values.

### 21.4.26 The INFORMATION_SCHEMA INNODB_TRX Table

The **INNODB_TRX** table provides information about every transaction currently executing inside InnoDB, including whether the transaction is waiting for a lock, when the transaction started, and the SQL statement the transaction is executing, if any.

For usage information, see Section 14.15.2.1, “Using InnoDB Transaction and Locking Information”.

The **INNODB_TRX** table has these columns:
The INFORMATION_SCHEMA INNODB_TRX Table

- **TRX_ID**
  A unique transaction ID number, internal to InnoDB. (Starting in MySQL 5.6, these IDs are not created for transactions that are read only and nonlocking. For details, see Section 8.5.3, "Optimizing InnoDB Read-Only Transactions".)

- **TRX_WEIGHT**
  The weight of a transaction, reflecting (but not necessarily the exact count of) the number of rows altered and the number of rows locked by the transaction. To resolve a deadlock, InnoDB selects the transaction with the smallest weight as the “victim” to roll back. Transactions that have changed nontransactional tables are considered heavier than others, regardless of the number of altered and locked rows.

- **TRX_STATE**
  The transaction execution state. Permitted values are **RUNNING**, LOCK WAIT, ROLLING BACK, and COMMITTING.

- **TRX_STARTED**
  The transaction start time.

- **TRX_REQUESTED_LOCK_ID**
  The ID of the lock the transaction is currently waiting for, if TRX_STATE is LOCK WAIT; otherwise NULL. To obtain details about the lock, join this column with the LOCK_ID column of the INNODB_LOCKS table.

- **TRX_WAIT_STARTED**
  The time when the transaction started waiting on the lock, if TRX_STATE is LOCK WAIT; otherwise NULL.

- **TRX_MYSQL_THREAD_ID**
  The MySQL thread ID. To obtain details about the thread, join this column with the ID column of the INFORMATION_SCHEMA PROCESSLIST table, but see Section 14.15.2.3, "Persistence and Consistency of InnoDB Transaction and Locking Information".

- **TRX_QUERY**
  The SQL statement that is being executed by the transaction.

- **TRX_OPERATION_STATE**
  The transaction's current operation, if any; otherwise NULL.

- **TRX_TABLES_IN_USE**
  The number of InnoDB tables used while processing the current SQL statement of this transaction.

- **TRX_TABLES_LOCKED**
  The number of InnoDB tables that the current SQL statement has row locks on. (Because these are row locks, not table locks, the tables can usually still be read from and written to by multiple transactions, despite some rows being locked.)

- **TRX_LOCK_STRUCTS**
The number of locks reserved by the transaction.

- **TRX_LOCK_MEMORY_BYTES**
  The total size taken up by the lock structures of this transaction in memory.

- **TRX_ROWS_LOCKED**
  The approximate number of rows locked by this transaction. The value might include delete-marked rows that are physically present but not visible to the transaction.

- **TRX_ROWS_MODIFIED**
  The number of modified and inserted rows in this transaction.

- **TRX_CONCURRENCY_TICKETS**
  A value indicating how much work the current transaction can do before being swapped out, as specified by the `innodb_concurrency_tickets` system variable.

- **TRX_ISOLATION_LEVEL**
  The isolation level of the current transaction.

- **TRX_UNIQUE_CHECKS**
  Whether unique checks are turned on or off for the current transaction. For example, they might be turned off during a bulk data load.

- **TRX_FOREIGN_KEY_CHECKS**
  Whether foreign key checks are turned on or off for the current transaction. For example, they might be turned off during a bulk data load.

- **TRX_LAST_FOREIGN_KEY_ERROR**
  The detailed error message for the last foreign key error, if any; otherwise `NULL`.

- **TRX_ADAPTIVE_HASH_LATCHED**
  Whether the adaptive hash index is locked by the current transaction. (Only a single transaction at a time can modify the adaptive hash index.)

- **TRX_ADAPTIVE_HASH_TIMEOUT**
  Whether to relinquish the search latch immediately for the adaptive hash index, or reserve it across calls from MySQL. When there is no adaptive hash index contention, this value remains zero and statements reserve the latch until they finish. During times of contention, it counts down to zero, and statements release the latch immediately after each row lookup.

- **TRX_IS_READONLY**
  A value of 1 indicates the transaction is read only.

- **TRX_AUTOCOMMIT_NON_LOCKING**
  A value of 1 indicates the transaction is a `SELECT` statement that does not use the `FOR UPDATE` or `LOCK IN SHARED MODE` clauses, and is executing with `autocommit` enabled so that the transaction...
contains only this one statement. When this column and TRX_IS_READ_ONLY are both 1, InnoDB optimizes the transaction to reduce the overhead associated with transactions that change table data.

Example

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TRX;
```

```
+---------+-----------------+-----------------+------------------+
|        |                 |                 |                  |
|        |                 |                 |                  |
| trx_id | 3298            | trx_state       | RUNNING          |
|        | trx_started     | 2014-11-19 13:54:39 |                  |
|        | trx_requested_lock_id | NULL             |                  |
|        | trx_wait_started | NULL            |                  |
|        | trx_weight      | 316436          |                  |
|        | trx_mysql_thread_id | 2               |                  |
|        | trx_query       | DELETE FROM employees.salaries WHERE salary > 65000 |                  |
|        | trx_operation_state | updating or deleting |                  |
|        | trx_tables_in_use | 1               |                  |
|        | trx_tables_locked | 1               |                  |
|        | trx_lock_structs | 1621            |                  |
|        | trx_lock_memory_bytes | 243240         |                  |
|        | trx_rows_locked | 759343          |                  |
|        | trx_rows_modified | 314815          |                  |
|        | trx_concurrency_tickets | 0             |                  |
|        | trx_isolation_level | REPEATABLE READ |                  |
|        | trx_unique_checks | 0               |                  |
|        | trx_foreign_key_checks | 0         |                  |
|        | trx_last_foreign_key_error | NULL |                  |
|        | trx_adaptive_hash_latched | 0       |                  |
|        | trx_adaptive_hash_timeout | 100000 |                  |
|        | trx_is_read_only | 0               |                  |
|        | trx_autocommit_non_locking | 0    |                  |
+---------+-----------------+-----------------+------------------+
```

Notes

- Use this table to help diagnose performance problems that occur during times of heavy concurrent load. Its contents are updated as described in Section 14.15.2.3, “Persistence and Consistency of InnoDB Transaction and Locking Information”.
- You must have the PROCESS privilege to query this table.
- Use the INFORMATION_SCHEMA COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of this table, including data types and default values.

21.5 INFORMATION_SCHEMA NDB Cluster Tables

The following sections provide information about INFORMATION_SCHEMA tables which are specific to NDB Cluster. (The FILES table is available in standard MySQL 5.6 but is not used there.) The ndb_transid_mysql_connection_map table is implemented as an INFORMATION_SCHEMA plugin available only in NDB Cluster binaries or source, and does not exist in MySQL Server 5.6.

Additional statistical and other data about NDB Cluster transactions, operations, threads, blocks, and other aspects of performance can be obtained from the tables in the ndbinfo database. For information about these tables, see Section 18.6.14, “ndbinfo: The NDB Cluster Information Database”.

21.5.1 The INFORMATION_SCHEMA FILES Table

The FILES table provides information about the files in which MySQL NDB Disk Data tables are stored. The FILES table has these columns:

- FILE_ID
A file identifier. **FILE_ID** column values are auto-generated.

- **FILE_NAME**
  
The name of an **UNDO** log file created by **CREATE LOGFILE GROUP** or **ALTER LOGFILE GROUP**, or of a data file created by **CREATE TABLESPACE** or **ALTER TABLESPACE**.

- **FILE_TYPE**
  
  One of the values **UNDO LOG**, **DATAFILE**, or **TABLESPACE**.

- **TABLESPACE_NAME**
  
  The name of the tablespace with which the file is associated.

- **TABLE_CATALOG**
  
  This value is always empty.

- **TABLE_SCHEMA**
  
  This value is always **NULL**.

- **TABLE_NAME**
  
  The name of the Disk Data table with which the file is associated, if any.

- **LOGFILE_GROUP_NAME**
  
  The name of the log file group to which the log file or data file belongs.

- **LOGFILE_GROUP_NUMBER**
  
  For an **UNDO** log file, the auto-generated ID number of the log file group to which the log file belongs.

- **ENGINE**
  
  For an NDB Cluster Disk Data log file or data file, this value always **NDB** or **NDBCLUSTER**.

- **FULLTEXT_KEYS**
  
  For an NDB Cluster Disk Data log file or data file, this value is always empty.

- **DELETED_ROWS**
  
  This value is always **NULL**.

- **UPDATE_COUNT**
  
  This value is always **NULL**.

- **FREE_EXTENTS**
  
  The number of extents which have not yet been used by the file.

- **TOTAL_EXTENTS**
  
  The total number of extents allocated to the file.
The INFORMATION_SCHEMA FILES Table

- **EXTENT_SIZE**
  The size of an extent for the file in bytes.

- **INITIAL_SIZE**
  The size of the file in bytes. This is the same value that was used in the INITIAL_SIZE clause of the CREATE LOGFILE GROUP, ALTER LOGFILE GROUP, CREATE TABLESPACE, or ALTER TABLESPACE statement used to create the file.

- **MAXIMUM_SIZE**
  For NDB Cluster Disk Data files, this value is always the same as the INITIAL_SIZE value.

- **AUTOEXTEND_SIZE**
  For NDB Cluster Disk Data files, this value is always empty.

- **CREATION_TIME**
  The date and time when the file was created.

- **LAST_UPDATE_TIME**
  The date and time when the file was last modified.

- **LAST_ACCESS_TIME**
  The date and time when the file was last accessed by the server.

- **RECOVER_TIME**
  For NDB Cluster Disk Data files, this value is always 0.

- **TRANSACTION_COUNTER**
  For NDB Cluster Disk Data files, this value is always 0.

- **VERSION**
  For NDB Cluster Disk Data files, this value is always NULL.

- **ROW_FORMAT**
  For NDB Cluster Disk Data files, this value is always NULL.

- **TABLE_ROWS**
  For NDB Cluster Disk Data files, this value is always NULL.

- **AVG_ROW_LENGTH**
  For NDB Cluster Disk Data files, this value is always NULL.

- **DATA_LENGTH**
  For NDB Cluster Disk Data files, this value is always NULL.

- **MAX_DATA_LENGTH**
For NDB Cluster Disk Data files, this value is always **NULL**.

**INDEX_LENGTH**

For NDB Cluster Disk Data files, this value is always **NULL**.

**DATA_FREE**

For NDB Cluster Disk Data files, this value is always **NULL**.

**CREATE_TIME**

For NDB Cluster Disk Data files, this value is always **NULL**.

**UPDATE_TIME**

For NDB Cluster Disk Data files, this value is always **NULL**.

**CHECK_TIME**

For NDB Cluster Disk Data files, this value is always **NULL**.

**CHECKSUM**

For NDB Cluster Disk Data files, this value is always **NULL**.

**STATUS**

For NDB Cluster Disk Data files, this value is always **NORMAL**.

**EXTRA**

For NDB Cluster Disk Data files, the **EXTRA** column shows which data node the file belongs to (each data node having its own copy), as well as the size of its undo buffer. Suppose that you use this statement on an NDB Cluster with four data nodes:

```sql
CREATE LOGFILE GROUP mygroup
  ADD UNDOFILE 'new_undo.dat'
  INITIAL_SIZE 2G
ENGINE NDB;
```

After running the **CREATE LOGFILE GROUP** statement successfully, you should see a result similar to the one shown here for this query against the **FILES** table:

```sql
mysql> SELECT LOGFILE_GROUP_NAME, FILE_TYPE, EXTRA
FROM INFORMATION_SCHEMA.FILES
WHERE FILE_NAME = 'new_undo.dat';
```

<table>
<thead>
<tr>
<th>LOGFILE_GROUP_NAME</th>
<th>FILE_TYPE</th>
<th>EXTRA</th>
</tr>
</thead>
<tbody>
<tr>
<td>mygroup</td>
<td>UNDO LOG</td>
<td>CLUSTER_NODE=5;UNDO_BUFFER_SIZE=8388608</td>
</tr>
<tr>
<td>mygroup</td>
<td>UNDO LOG</td>
<td>CLUSTER_NODE=6;UNDO_BUFFER_SIZE=8388608</td>
</tr>
<tr>
<td>mygroup</td>
<td>UNDO LOG</td>
<td>CLUSTER_NODE=7;UNDO_BUFFER_SIZE=8388608</td>
</tr>
<tr>
<td>mygroup</td>
<td>UNDO LOG</td>
<td>CLUSTER_NODE=8;UNDO_BUFFER_SIZE=8388608</td>
</tr>
</tbody>
</table>

**Notes**

- The **FILES** table is a nonstandard **INFORMATION_SCHEMA** table.
NDB Notes

• This table provides information about Disk Data files only; you cannot use it for determining disk space allocation or availability for individual NDB tables. However, it is possible to see how much space is allocated for each NDB table having data stored on disk—as well as how much remains available for storage of data on disk for that table—using ndb_desc. For more information, see Section 18.5.10, "ndb_desc — Describe NDB Tables".

• The CREATION_TIME, LAST_UPDATE_TIME, and LAST_ACCESSED values are as reported by the operating system, and are not supplied by the NDB storage engine. Where no value is provided by the operating system, these columns display 0000-00-00 00:00:00.

• The difference between the TOTAL_EXTENTS and FREE_EXTENTS columns is the number of extents currently in use by the file:

```sql
SELECT TOTAL_EXTENTS - FREE_EXTENTS AS extents_used
FROM INFORMATION_SCHEMA.FILES
WHERE FILE_NAME = 'myfile.dat';
```

To approximate the amount of disk space in use by the file, multiply that difference by the value of the EXTENT_SIZE column, which gives the size of an extent for the file in bytes:

```sql
SELECT (TOTAL_EXTENTS - FREE_EXTENTS) * EXTENT_SIZE AS bytes_used
FROM INFORMATION_SCHEMA.FILES
WHERE FILE_NAME = 'myfile.dat';
```

Similarly, you can estimate the amount of space that remains available in a given file by multiplying FREE_EXTENTS by EXTENT_SIZE:

```sql
SELECT FREE_EXTENTS * EXTENT_SIZE AS bytes_free
FROM INFORMATION_SCHEMA.FILES
WHERE FILE_NAME = 'myfile.dat';
```

Important

The byte values produced by the preceding queries are approximations only, and their precision is inversely proportional to the value of EXTENT_SIZE. That is, the larger EXTENT_SIZE becomes, the less accurate the approximations are.

It is also important to remember that once an extent is used, it cannot be freed again without dropping the data file of which it is a part. This means that deletes from a Disk Data table do not release disk space.

The extent size can be set in a CREATE TABLESPACE statement. For more information, see Section 13.1.18, “CREATE TABLESPACE Statement”.

• An additional row is present in the FILES table following the creation of a logfile group. This row has NULL for the value of the FILE_NAME column. For this row, the value of the FILE_ID column is always 0, that of the FILE_TYPE column is always UNDO_LOG, and that of the STATUS column is always NORMAL. The value of the ENGINE column is always NDBCLUSTER.

The FREE_EXTENTS column in this row shows the total number of free extents available to all undo files belonging to a given log file group whose name and number are shown in the LOGFILE_GROUP_NAME and LOGFILE_GROUP_NUMBER columns, respectively.

Suppose there are no existing log file groups on your NDB Cluster, and you create one using the following statement:

```sql
mysql> CREATE LOGFILE GROUP lg1
```
The INFORMATION_SCHEMA FILES Table

ADD UNDOFILE 'undofile.dat'
INITIAL_SIZE = 16M
UNDO_BUFFER_SIZE = 1M
ENGINE = NDB;

You can now see this NULL row when you query the FILES table:

```
mysql> SELECT DISTINCT
       FILE_NAME AS File,
       FREE_EXTENTS AS Free,
       TOTAL_EXTENTS AS Total,
       EXTENT_SIZE AS Size,
       INITIAL_SIZE AS Initial
       FROM INFORMATION_SCHEMA.FILES;
```

```
+--------------+---------+---------+------+----------+
<table>
<thead>
<tr>
<th>File</th>
<th>Free</th>
<th>Total</th>
<th>Size</th>
<th>Initial</th>
</tr>
</thead>
<tbody>
<tr>
<td>undofile.dat</td>
<td>NULL</td>
<td>4194304</td>
<td>4</td>
<td>16777216</td>
</tr>
<tr>
<td>NULL</td>
<td>4184068</td>
<td>NULL</td>
<td>4</td>
<td>NULL</td>
</tr>
</tbody>
</table>
+--------------+---------+---------+------|----------+
```

The total number of free extents available for undo logging is always somewhat less than the sum of the TOTAL_EXTENTS column values for all undo files in the log file group due to overhead required for maintaining the undo files. This can be seen by adding a second undo file to the log file group, then repeating the previous query against the FILES table:

```
mysql> ALTER LOGFILE GROUP lg1
       ADD UNDOFILE 'undofile02.dat'
       INITIAL_SIZE = 4M
       ENGINE = NDB;

mysql> SELECT DISTINCT
       FILE_NAME AS File,
       FREE_EXTENTS AS Free,
       TOTAL_EXTENTS AS Total,
       EXTENT_SIZE AS Size,
       INITIAL_SIZE AS Initial
       FROM INFORMATION_SCHEMA.FILES;
```

```
+----------------+---------+---------+------+----------+
<table>
<thead>
<tr>
<th>File</th>
<th>Free</th>
<th>Total</th>
<th>Size</th>
<th>Initial</th>
</tr>
</thead>
<tbody>
<tr>
<td>undofile.dat</td>
<td>NULL</td>
<td>4194304</td>
<td>4</td>
<td>16777216</td>
</tr>
<tr>
<td>undofile02.dat</td>
<td>NULL</td>
<td>1048576</td>
<td>4</td>
<td>4194304</td>
</tr>
<tr>
<td>NULL</td>
<td>5223944</td>
<td>NULL</td>
<td>4</td>
<td>NULL</td>
</tr>
</tbody>
</table>
+----------------+---------+---------+------|----------+
```

The amount of free space in bytes which is available for undo logging by Disk Data tables using this log file group can be approximated by multiplying the number of free extents by the initial size:

```
mysql> SELECT
       FREE_EXTENTS AS 'Free Extents',
       FREE_EXTENTS * EXTENT_SIZE AS 'Free Bytes'
       FROM INFORMATION_SCHEMA.FILES
       WHERE LOGFILE_GROUP_NAME = 'lg1'
       AND FILE_NAME IS NULL;
```

```
+-----------------+-------------+
<table>
<thead>
<tr>
<th>Free Extents</th>
<th>Free Bytes</th>
</tr>
</thead>
<tbody>
<tr>
<td>5223944</td>
<td>20895776</td>
</tr>
</tbody>
</table>
+-----------------+-------------+
```
If you create an NDB Cluster Disk Data table and then insert some rows into it, you can see approximately how much space remains for undo logging afterward, for example:

```sql
mysql> CREATE TABLESPACE ts1
    ADD DATAFILE 'data1.dat'
    USE LOGFILE GROUP lg1
    INITIAL_SIZE 512M
    ENGINE = NDB;

mysql> CREATE TABLE dd (
    c1 INT NOT NULL PRIMARY KEY,
    c2 INT,
    c3 DATE
) TABLESPACE ts1 STORAGE DISK
    ENGINE = NDB;

mysql> INSERT INTO dd VALUES
    (NULL, 1234567890, '2007-02-02'),
    (NULL, 1126789005, '2007-02-03'),
    (NULL, 1357924680, '2007-02-04'),
    (NULL, 1642097531, '2007-02-05');

mysql> SELECT
    FREE_EXTENTS AS 'Free Extents',
    FREE_EXTENTS * EXTENT_SIZE AS 'Free Bytes'
FROM INFORMATION_SCHEMA.FILES
    WHERE LOGFILE_GROUP_NAME = 'lg1'
    AND FILE_NAME IS NULL;
```

```
+--------------+------------+
<table>
<thead>
<tr>
<th>Free Extents</th>
<th>Free Bytes</th>
</tr>
</thead>
<tbody>
<tr>
<td>5207565</td>
<td>20830260</td>
</tr>
</tbody>
</table>
+--------------+------------+
```

- An additional row is present in the FILES table for any NDB Cluster tablespace, whether or not any data files are associated with the tablespace. This row has NULL for the value of the FILE_NAME column. For this row, the value of the FILE_ID column is always 0, that of the FILE_TYPE column is always TABLESPACE, and that of the STATUS column is always NORMAL. The value of the ENGINE column is always NDBCLUSTER.
- For additional information, and examples of creating and dropping NDB Cluster Disk Data objects, see Section 18.6.10, “NDB Cluster Disk Data Tables”.

### 21.5.2 The INFORMATION_SCHEMA ndb_transid_mysql_connection_map Table

The ndb_transid_mysql_connection_map table provides a mapping between NDB transactions, NDB transaction coordinators, and MySQL Servers attached to an NDB Cluster as API nodes. This information is used when populating the server_operations and server_transactions tables of the ndbinfo NDB Cluster information database.

The ndb_transid_mysql_connection_map table has these columns:

- `mysql_connection_id`
- `node_id`

The MySQL server connection ID.
INFORMATION_SCHEMA Thread Pool Tables

The transaction coordinator node ID.

- `ndb_transid`

The NDB transaction ID.

Notes

The `mysql_connection_id` value is the same as the connection or session ID shown in the output of `SHOW PROCESSLIST`.

There are no `SHOW` statements associated with this table.

This is a nonstandard table, specific to NDB Cluster. It is implemented as an `INFORMATION_SCHEMA` plugin; you can verify that it is supported by checking the output of `SHOW PLUGINS`. If `ndb_transid_mysql_connection_map` support is enabled, the output from this statement includes a plugin having this name, of type `INFORMATION_SCHEMA`, and having status `ACTIVE`, as shown here (using emphasized text):

```
mysql> SHOW PLUGINS;
+----------------------------------+--------+--------------------+---------+---------+
<table>

The plugin is enabled by default. You can disable it (or force the server not to run unless the plugin starts) by starting the server with the `--ndb-transid-mysql-connection-map` option. If the plugin is disabled, the status is shown by `SHOW PLUGINS` as `DISABLED`. The plugin cannot be enabled or disabled at runtime.

Although the names of this table and its columns are displayed using lowercase, you can use uppercase or lowercase when referring to them in SQL statements.

For this table to be created, the MySQL Server must be a binary supplied with the NDB Cluster distribution, or one built from the NDB Cluster sources with NDB storage engine support enabled. It is not available in the standard MySQL 5.6 Server.

21.6 INFORMATION_SCHEMA Thread Pool Tables
The following sections describe the INFORMATION_SCHEMA tables associated with the thread pool plugin (see Section 5.5.3, “MySQL Enterprise Thread Pool”). They provide information about thread pool operation:

- **TP_THREAD_GROUP_STATE**: Information about thread pool thread group states
- **TP_THREAD_GROUP_STATS**: Thread group statistics
- **TP_THREAD_STATE**: Information about thread pool thread states

Rows in these tables represent snapshots in time. In the case of TP_THREAD_STATE, all rows for a thread group comprise a snapshot in time. Thus, the MySQL server holds the mutex of the thread group while producing the snapshot. But it does not hold mutexes on all thread groups at the same time, to prevent a statement against TP_THREAD_STATE from blocking the entire MySQL server.

The thread pool INFORMATION_SCHEMA tables are implemented by individual plugins and the decision whether to load one can be made independently of the others (see Section 5.5.3.2, “Thread Pool Installation”). However, the content of all the tables depends on the thread pool plugin being enabled. If a table plugin is enabled but the thread pool plugin is not, the table becomes visible and can be accessed but is empty.

### 21.6.1 INFORMATION_SCHEMA Thread Pool Table Reference

The following table summarizes INFORMATION_SCHEMA thread pool tables. For greater detail, see the individual table descriptions.

<table>
<thead>
<tr>
<th>Table Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TP_THREAD_GROUP_STATE</td>
<td>Thread pool thread group states</td>
</tr>
<tr>
<td>TP_THREAD_GROUP_STATS</td>
<td>Thread pool thread group statistics</td>
</tr>
<tr>
<td>TP_THREAD_STATE</td>
<td>Thread pool thread information</td>
</tr>
</tbody>
</table>

### 21.6.2 The INFORMATION_SCHEMA TP_THREAD_GROUP_STATE Table

The TP_THREAD_GROUP_STATE table has one row per thread group in the thread pool. Each row provides information about the current state of a group.

The TP_THREAD_GROUP_STATE table has these columns:

- **TP_GROUP_ID**
  
  The thread group ID. This is a unique key within the table.

- **CONSUMER_THREADS**
  
  The number of consumer threads. There is at most one thread ready to start executing if the active threads become stalled or blocked.

- **RESERVE_THREADS**
  
  The number of threads in the reserved state. This means that they are not started until there is a need to wake a new thread and there is no consumer thread. This is where most threads end up when the thread group has created more threads than needed for normal operation. Often a thread group needs additional threads for a short while and then does not need them again for a while. In this case, they go
The INFORMATION_SCHEMA TP_THREAD_GROUP_STATE Table

into the reserved state and remain until needed again. They take up some extra memory resources, but no extra computing resources.

• CONNECT_THREAD_COUNT

The number of threads that are processing or waiting to process connection initialization and authentication. There can be a maximum of four connection threads per thread group; these threads expire after a period of inactivity.

This column was added in MySQL 5.6.36.

• CONNECTION_COUNT

The number of connections using this thread group.

• QUEUED_QUERIES

The number of statements waiting in the high-priority queue.

• QUEUED_TRANSACTIONS

The number of statements waiting in the low-priority queue. These are the initial statements for transactions that have not started, so they also represent queued transactions.

• STALL_LIMIT

The value of the thread_pool_stall_limit system variable for the thread group. This is the same value for all thread groups.

• PRIORITIZE_TIMER

The value of the thread_pool_prio_kickup_timer system variable for the thread group. This is the same value for all thread groups.

• ALGORITHM

The value of the thread_pool_algorithm system variable for the thread group. This is the same value for all thread groups.

• THREAD_COUNT

The number of threads started in the thread pool as part of this thread group.

• ACTIVE_THREAD_COUNT

The number of threads active in executing statements.

• STALLED_THREAD_COUNT

The number of stalled statements in the thread group. A stalled statement could be executing, but from a thread pool perspective it is stalled and making no progress. A long-running statement quickly ends up in this category.

• WAITING_THREAD_NUMBER

If there is a thread handling the polling of statements in the thread group, this specifies the thread number within this thread group. It is possible that this thread could be executing a statement.

• OLDEST_QUEUED
The INFORMATION_SCHEMA TP_THREAD_GROUP_STATS Table

How long in milliseconds the oldest queued statement has been waiting for execution.

- **MAX_THREAD_IDS_IN_GROUP**

  The maximum thread ID of the threads in the group. This is the same as $\text{MAX(TP_THREAD_NUMBER)}$ for the threads when selected from the TP_THREAD_STATE table. That is, these two queries are equivalent:

  ```sql
  SELECT TP_GROUP_ID, MAX_THREAD_IDS_IN_GROUP
  FROM TP_THREAD_GROUP_STATE;
  
  SELECT TP_GROUP_ID, MAX(TP_THREAD_NUMBER)
  FROM TP_THREAD_STATE GROUP BY TP_GROUP_ID;
  ```

21.6.3 The INFORMATION_SCHEMA TP_THREAD_GROUP_STATS Table

The TP_THREAD_GROUP_STATS table reports statistics per thread group. There is one row per group.

The TP_THREAD_GROUP_STATS table has these columns:

- **TP_GROUP_ID**
  The thread group ID. This is a unique key within the table.

- **CONNECTIONS_STARTED**
  The number of connections started.

- **CONNECTIONS_CLOSED**
  The number of connections closed.

- **QUERIES_EXECUTED**
  The number of statements executed. This number is incremented when a statement starts executing, not when it finishes.

- **QUERIES_QUEUED**
  The number of statements received that were queued for execution. This does not count statements that the thread group was able to begin executing immediately without queuing, which can happen under the conditions described in Section 5.5.3.3, “Thread Pool Operation”.

- **THREADS_STARTED**
  The number of threads started.

- **PRIO_KICKUPS**
  The number of statements that have been moved from low-priority queue to high-priority queue based on the value of the thread_pool_prio_kickup_timer system variable. If this number increases quickly, consider increasing the value of that variable. A quickly increasing counter means that the priority system is not keeping transactions from starting too early. For InnoDB, this most likely means deteriorating performance due to too many concurrent transactions.

- **STALLED_QUERIES_EXECUTED**
  The number of statements that have become defined as stalled due to executing for longer than the value of the thread_pool_stall_limit system variable.
The INFORMATION_SCHEMA TP_THREAD_GROUP_STATS Table

- **BECOME_CONSUMER_THREAD**
  The number of times thread have been assigned the consumer thread role.

- **BECOME_RESERVE_THREAD**
  The number of times threads have been assigned the reserve thread role.

- **BECOME_WAITING_THREAD**
  The number of times threads have been assigned the waiter thread role. When statements are queued, this happens very often, even in normal operation, so rapid increases in this value are normal in the case of a highly loaded system where statements are queued up.

- **WAKE_THREAD_STALL_CHECKER**
  The number of times the stall check thread decided to wake or create a thread to possibly handle some statements or take care of the waiter thread role.

- **SLEEP_WAITS**
  The number of \texttt{THD\_WAIT\_SLEEP} waits. These occur when threads go to sleep; for example, by calling the \texttt{SLEEP()} function.

- **DISK_IO_WAITS**
  The number of \texttt{THD\_WAIT\_DISKIO} waits. These occur when threads perform disk I/O that is likely to not hit the file system cache. Such waits occur when the buffer pool reads and writes data to disk, not for normal reads from and writes to files.

- **ROW_LOCK_WAITS**
  The number of \texttt{THD\_WAIT\_ROW\_LOCK} waits for release of a row lock by another transaction.

- **GLOBAL_LOCK_WAITS**
  The number of \texttt{THD\_WAIT\_GLOBAL\_LOCK} waits for a global lock to be released.

- **META_DATA_LOCK_WAITS**
  The number of \texttt{THD\_WAIT\_META\_DATA\_LOCK} waits for a metadata lock to be released.

- **TABLE_LOCK_WAITS**
  The number of \texttt{THD\_WAIT\_TABLE\_LOCK} waits for a table to be unlocked that the statement needs to access.

- **USER_LOCK_WAITS**
  The number of \texttt{THD\_WAIT\_USER\_LOCK} waits for a special lock constructed by the user thread.

- **BINLOG_WAITS**
  The number of \texttt{THD\_WAIT\_BINLOG\_WAITS} waits for the binary log to become free.

- **GROUP_COMMIT_WAITS**
  The number of \texttt{THD\_WAIT\_GROUP\_COMMIT} waits. These occur when a group commit must wait for the other parties to complete their part of a transaction.
The INFORMATION_SCHEMA TP_THREAD_STATE Table

- **FSIZE_WAIT**
  The number of **THD_WAIT_SYNC** waits for a file sync operation.

### 21.6.4 The INFORMATION_SCHEMA TP_THREAD_STATE Table

The **TP_THREAD_STATE** table has one row per thread created by the thread pool to handle connections.

The **TP_THREAD_STATE** table has these columns:

- **TP_GROUP_ID**
  The thread group ID.

- **TP_THREAD_NUMBER**
  The ID of the thread within its thread group. **TP_GROUP_ID** and **TP_THREAD_NUMBER** together provide a unique key within the table.

- **PROCESS_COUNT**
  The 10ms interval in which the statement that uses this thread is currently executing. 0 means no statement is executing, 1 means it is in the first 10ms, and so forth.

- **WAIT_TYPE**
  The type of wait for the thread. **NULL** means the thread is not blocked. Otherwise, the thread is blocked by a call to **thd_wait_begin()** and the value specifies the type of wait. The **xxx_WAIT** columns of the **TP_THREAD_GROUP_STATS** table accumulate counts for each wait type.

The **WAIT_TYPE** value is a string that describes the type of wait, as shown in the following table.

<table>
<thead>
<tr>
<th>Wait Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>THD_WAIT_SLEEP</td>
<td>Waiting for sleep</td>
</tr>
<tr>
<td>THD_WAIT_DISKIO</td>
<td>Waiting for Disk IO</td>
</tr>
<tr>
<td>THD_WAIT_ROW_LOCK</td>
<td>Waiting for row lock</td>
</tr>
<tr>
<td>THD_WAIT_GLOBAL_LOCK</td>
<td>Waiting for global lock</td>
</tr>
<tr>
<td>THD_WAIT_META_DATA_LOCK</td>
<td>Waiting for metadata lock</td>
</tr>
<tr>
<td>THD_WAIT_TABLE_LOCK</td>
<td>Waiting for table lock</td>
</tr>
<tr>
<td>THD_WAIT_USER_LOCK</td>
<td>Waiting for user lock</td>
</tr>
<tr>
<td>THD_WAIT_BINLOG</td>
<td>Waiting for binlog</td>
</tr>
<tr>
<td>THD_WAIT_GROUP_COMMIT</td>
<td>Waiting for group commit</td>
</tr>
<tr>
<td>THD_WAIT_SYNC</td>
<td>Waiting for fsync</td>
</tr>
</tbody>
</table>

### 21.7 INFORMATION_SCHEMA Connection-Control Tables

The following sections describe the **INFORMATION_SCHEMA** tables associated with the **CONNECTION_CONTROL** plugin.

### 21.7.1 INFORMATION_SCHEMA Connection-Control Table Reference
21.7.2 The INFORMATION_SCHEMA CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS Table

This table provides information about the current number of consecutive failed connection attempts per account (user/host combination). The table was added in MySQL 5.6.35.

CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS has these columns:

- **USERHOST**
  The user/host combination indicating an account that has failed connection attempts, in 'user_name'@'host_name' format.

- **FAILED_ATTEMPTS**
  The current number of consecutive failed connection attempts for the USERHOST value. This counts all failed attempts, regardless of whether they were delayed. The number of attempts for which the server added a delay to its response is the difference between the FAILED_ATTEMPTS value and the connection_control_failed_connections_threshold system variable value.

Notes

- The CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS plugin must be activated for this table to be available, and the CONNECTION_CONTROL plugin must be activated or the table contents are always empty. See Section 6.4.2, “The Connection-Control Plugins”.

- The table contains rows only for accounts that have had one or more consecutive failed connection attempts without a subsequent successful attempt. When an account connects successfully, its failed-connection count is reset to zero and the server removes any row corresponding to the account.

- Assigning a value to the connection_control_failed_connections_threshold system variable at runtime resets all accumulated failed-connection counters to zero, which causes the table to become empty.

---

21.8 INFORMATION_SCHEMA MySQL Enterprise Firewall Tables

The following sections describe the INFORMATION_SCHEMA tables associated with MySQL Enterprise Firewall (see Section 6.4.5, “MySQL Enterprise Firewall”). They provide views into the firewall in-memory data cache. These tables are available only if the appropriate firewall plugins are enabled.

21.8.1 INFORMATION_SCHEMA Firewall Table Reference

The following table summarizes INFORMATION_SCHEMA firewall tables. For greater detail, see the individual table descriptions.
21.8.2 The INFORMATION_SCHEMA MYSQL_FIREWALL_USERS Table

The MYSQL_FIREWALL_USERS table provides a view into the in-memory data cache for MySQL Enterprise Firewall. It lists names and operational modes of registered firewall account profiles. It is used in conjunction with the mysql.firewall_users system table that provides persistent storage of firewall data; see MySQL Enterprise Firewall Tables.

The MYSQL_FIREWALL_USERS table has these columns:

- **USERHOST**
  The account profile name. Each account name has the format `user_name@host_name`.

- **MODE**
  The current operational mode for the profile. Permitted mode values are OFF, DETECTING (as of MySQL 5.6.26), PROTECTING, RECORDING, and RESET. For details about their meanings, see Firewall Concepts.

21.8.3 The INFORMATION_SCHEMA MYSQL_FIREWALL_WHITELIST Table

The MYSQL_FIREWALL_WHITELIST table provides a view into the in-memory data cache for MySQL Enterprise Firewall. It lists allowlist rules of registered firewall account profiles. It is used in conjunction with the mysql.firewall_whitelist system table that provides persistent storage of firewall data; see MySQL Enterprise Firewall Tables.

The MYSQL_FIREWALL_WHITELIST table has these columns:

- **USERHOST**
  The account profile name. Each account name has the format `user_name@host_name`.

- **RULE**
  A normalized statement indicating an acceptable statement pattern for the profile. A profile allowlist is the union of its rules.

21.9 Extensions to SHOW Statements

Some extensions to SHOW statements accompany the implementation of INFORMATION_SCHEMA:

- **SHOW** can be used to get information about the structure of INFORMATION_SCHEMA itself.
- Several SHOW statements accept a WHERE clause that provides more flexibility in specifying which rows to display.

INFORMATION_SCHEMA is an information database, so its name is included in the output from SHOW DATABASES. Similarly, SHOW TABLES can be used with INFORMATION_SCHEMA to obtain a list of its tables:
Extensions to SHOW Statements

SHOW TABLES FROM INFORMATION_SCHEMA;

+---------------------------------------+
| Tables_in_INFORMATION_SCHEMA          |
+---------------------------------------+
| CHARACTER_SETS                       |
| COLLATIONS                            |
| COLLATION_CHARACTER_SET_APPLICABILITY |
| COLUMNS                               |
| COLUMN_PRIVILEGES                     |
| ENGINES                               |
| EVENTS                                |
| FILES                                 |
| GLOBAL_STATUS                         |
| GLOBAL_VARIABLES                      |
| KEY_COLUMN_USAGE                      |
| PARTITIONS                            |
| PLUGINS                               |
| PROCESSTLIST                          |
| REFERENTIAL_CONSTRAINTS               |
| ROUTINES                              |
| SCHEMATA                              |
| SCHEMA_PRIVILEGES                     |
| SESSION_STATUS                        |
| SESSION_VARIABLES                     |
| STATISTICS                             |
| TABLES                                |
| TABLE_CONSTRAINTS                     |
| TABLE/Resources                       |
| TRIGGER                               |
| USER_PRIVILEGES                       |
| VIEWS                                 |
+---------------------------------------+

SHOW COLUMNS and DESCRIBE can display information about the columns in individual INFORMATION_SCHEMA tables.

SHOW statements that accept a LIKE clause to limit the rows displayed also permit a WHERE clause that specifies more general conditions that selected rows must satisfy:

SHOW CHARACTER SET
SHOW COLLATION
SHOW COLUMNS
SHOW DATABASES
SHOW FUNCTION STATUS
SHOW INDEX
SHOW OPEN TABLES
SHOW PROCEDURE STATUS
SHOW STATUS
SHOW TABLE STATUS
SHOW TABLES
SHOW TRIGGERS
SHOW VARIABLES

The WHERE clause, if present, is evaluated against the column names displayed by the SHOW statement. For example, the SHOW CHARACTER SET statement produces these output columns:

mysql> SHOW CHARACTER SET;

+----------+-----------------------------+---------------------+--------+
| Charset  | Description                 | Default collation   | Maxlen |
+----------+-----------------------------+---------------------+--------+
| big5     | Big5 Traditional Chinese   | big5_chinese_ci     |      2 |
| dec8     | DEC West European           | dec8_swedish_ci     |      1 |
| cp850    | DOS West European           | cp850_general_ci    |      1 |
| hp8      | HP West European            | hp8_english_ci      |      1 |
| koi8r    | KOI8-R Relcom Russian       | koi8r_general_ci    |      1 |
| latin1   | cp1252 West European        | latin1_swedish_ci   |      1 |
+----------+-----------------------------+---------------------+--------+
To use a `WHERE` clause with `SHOW CHARACTER SET`, you would refer to those column names. As an example, the following statement displays information about character sets for which the default collation contains the string 'japanese':

```
mysql> SHOW CHARACTER SET WHERE `Default collation` LIKE '%japanese%';
+---------+---------------------------+---------------------+--------+
|Charset  | Description               | Default collation   | Maxlen |
+---------+---------------------------+---------------------+--------+
| ujis    | EUC-JP Japanese           | ujis_japanese_ci    |      3 |
| sjis    | Shift-JIS Japanese        | sjis_japanese_ci    |      2 |
| cp932   | SJIS for Windows Japanese | cp932_japanese_ci   |      2 |
| eucjpms | UJIS for Windows Japanese | eucjpms_japanese_ci |      3 |
+---------+---------------------------+---------------------+--------+
```

This statement displays the multibyte character sets:

```
mysql> SHOW CHARACTER SET WHERE Maxlen > 1;
+---------+---------------------------+---------------------+--------+
|Charset  | Description               | Default collation   | Maxlen |
+---------+---------------------------+---------------------+--------+
| big5    | Big5 Traditional Chinese  | big5_chinese_ci     |      2 |
| ujis    | EUC-JP Japanese           | ujis_japanese_ci    |      3 |
| sjis    | Shift-JIS Japanese        | sjis_japanese_ci    |      2 |
| euckr   | EUC-KR Korean             | euckr_korean_ci     |      2 |
| gb2312  | GB2312 Simplified Chinese | gb2312_chinese_ci   |      2 |
| gbk     | GBK Simplified Chinese    | gbk_chinese_ci      |      2 |
| utf8    | UTF-8 Unicode             | utf8_general_ci     |      3 |
| ucs2    | UCS-2 Unicode             | ucs2_general_ci     |      2 |
| cp932   | SJIS for Windows Japanese | cp932_japanese_ci   |      2 |
| eucjpms | UJIS for Windows Japanese | eucjpms_japanese_ci |      3 |
+---------+---------------------------+---------------------+--------+
```

The MySQL Performance Schema is a feature for monitoring MySQL Server execution at a low level. The Performance Schema has these characteristics:

- The Performance Schema provides a way to inspect internal execution of the server at runtime. It is implemented using the PERFORMANCE_SCHEMA storage engine and the performance_schema database. The Performance Schema focuses primarily on performance data. This differs from INFORMATION_SCHEMA, which serves for inspection of metadata.
The Performance Schema monitors server events. An “event” is anything the server does that takes time and has been instrumented so that timing information can be collected. In general, an event could be a function call, a wait for the operating system, a stage of an SQL statement execution such as parsing or sorting, or an entire statement or group of statements. Event collection provides access to information about synchronization calls (such as for mutexes) file and table I/O, table locks, and so forth for the server and for several storage engines.

Performance Schema events are distinct from events written to the server's binary log (which describe data modifications) and Event Scheduler events (which are a type of stored program).

Performance Schema events are specific to a given instance of the MySQL Server. Performance Schema tables are considered local to the server, and changes to them are not replicated or written to the binary log.

Current events are available, as well as event histories and summaries. This enables you to determine how many times instrumented activities were performed and how much time they took. Event information is available to show the activities of specific threads, or activity associated with particular objects such as a mutex or file.

The `PERFORMANCE_SCHEMA` storage engine collects event data using “instrumentation points” in server source code.

Collected events are stored in tables in the `performance_schema` database. These tables can be queried using `SELECT` statements like other tables.

Performance Schema configuration can be modified dynamically by updating tables in the `performance_schema` database through SQL statements. Configuration changes affect data collection immediately.

Tables in the Performance Schema are in-memory tables that use no persistent on-disk storage. The contents are repopulated beginning at server startup and discarded at server shutdown.

Monitoring is available on all platforms supported by MySQL.

Some limitations might apply: The types of timers might vary per platform. Instruments that apply to storage engines might not be implemented for all storage engines. Instrumentation of each third-party engine is the responsibility of the engine maintainer. See also Section 22.19, “Restrictions on Performance Schema”.

Data collection is implemented by modifying the server source code to add instrumentation. There are no separate threads associated with the Performance Schema, unlike other features such as replication or the Event Scheduler.

The Performance Schema is intended to provide access to useful information about server execution while having minimal impact on server performance. The implementation follows these design goals:

- Activating the Performance Schema causes no changes in server behavior. For example, it does not cause thread scheduling to change, and it does not cause query execution plans (as shown by `EXPLAIN`) to change.

- No memory allocation is done beyond that which occurs during server startup. By using early allocation of structures with a fixed size, it is never necessary to resize or reallocate them, which is critical for achieving good runtime performance.

- Server monitoring occurs continuously and unobtrusively with very little overhead. Activating the Performance Schema does not make the server unusable.

- The parser is unchanged. There are no new keywords or statements.
• Execution of server code proceeds normally even if the Performance Schema fails internally.

• When there is a choice between performing processing during event collection initially or during event retrieval later, priority is given to making collection faster. This is because collection is ongoing whereas retrieval is on demand and might never happen at all.

• It is easy to add new instrumentation points.

• Instrumentation is versioned. If the instrumentation implementation changes, previously instrumented code should continue to work. This benefits developers of third-party plugins because it is not necessary to upgrade each plugin to stay synchronized with the latest Performance Schema changes.

Note

The MySQL sys schema is a set of objects that provides convenient access to data collected by the Performance Schema. In MySQL 5.7, the sys schema is installed by default. For MySQL 5.6, you can obtain it from the schema development website at https://github.com/mysql/mysql-sys. For usage instructions, see MySQL sys Schema.

22.1 Performance Schema Quick Start

This section briefly introduces the Performance Schema with examples that show how to use it. For additional examples, see Section 22.18, “Using the Performance Schema to Diagnose Problems”.

For the Performance Schema to be available, support for it must have been configured when MySQL was built. You can verify whether this is the case by checking the server's help output. If the Performance Schema is available, the output includes several variables with names that begin with performance_schema:

```
$> mysql --verbose --help
...
   --performance_schema Enable the performance schema.
   --performance_schema_events_waits_history_long_size=# Number of rows in events_waits_history_long.
...
```

If such variables do not appear in the output, your server has not been built to support the Performance Schema. In this case, see Section 22.2, “Performance Schema Build Configuration”.

Assuming that the Performance Schema is available, it is enabled by default. To enable or disable it explicitly, start the server with the performance_schema variable set to an appropriate value. For example, use these lines in your my.cnf file:

```
[mysqld]
performance_schema=ON
```

When the server starts, it sees performance_schema and attempts to initialize the Performance Schema. To verify successful initialization, use this statement:

```
mysql> SHOW VARIABLES LIKE 'performance_schema';
+-----------------+-------+
| Variable_name   | Value |
+-----------------+-------+
| performance_schema | ON    |
```

A value of ON means that the Performance Schema initialized successfully and is ready for use. A value of OFF means that some error occurred. Check the server error log for information about what went wrong.
The Performance Schema is implemented as a storage engine. If this engine is available (which you should already have checked earlier), you should see it listed with a SUPPORT value of YES in the output from the INFORMATION_SCHEMA.ENGINES table or the SHOW ENGINES statement:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.ENGINES
      WHERE ENGINE='PERFORMANCE_SCHEMA'
G
*************************** 1. row ***************************
 ENGINE: PERFORMANCE_SCHEMA
 SUPPORT: YES
 COMMENT: Performance Schema
 TRANSACTIONS: NO
XA: NO
SAVEPOINTS: NO
```

```
mysql> SHOW ENGINES
G
...
   Engine: PERFORMANCE_SCHEMA
   Support: YES
   Comment: Performance Schema
   Transactions: NO
    XA: NO
    Savepoints: NO
...
```

The PERFORMANCE_SCHEMA storage engine operates on tables in the performance_schema database. You can make performance_schema the default database so that references to its tables need not be qualified with the database name:

```
mysql> USE performance_schema;
```

Performance Schema tables are stored in the performance_schema database. Information about the structure of this database and its tables can be obtained, as for any other database, by selecting from the INFORMATION_SCHEMA database or by using SHOW statements. For example, use either of these statements to see what Performance Schema tables exist:

```
mysql> SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
      WHERE TABLE_SCHEMA = 'performance_schema';
```

```
+-------------------+
| TABLE_NAME         |
+-------------------+
| accounts          |
| cond_instances    |
| events_stages_current |
| events_stages_history |
| events_stages_history_long |
| events_stages_summary_by_account_by_event_name |
| events_stages_summary_by_host_by_event_name |
| events_stages_summary_by_thread_by_event_name |
| events_stages_summary_by_user_by_event_name |
| events_stages_summary_global_by_event_name |
| events_statements_current |
| events_statements_history |
| events_statements_history_long |
| file_instances    |
| file_summary_by_event_name |
| file_summary_by_instance |
| host_cache        |
| hosts             |
| mutex_instances   |
| objects_summary_global_by_type |
| performance_timers |
| rwlock_instances  |
| session_account_connect_attrs |
| session_connect_attrs |
+-------------------+```
The number of Performance Schema tables increases over time as implementation of additional instrumentation proceeds.

The name of the `performance_schema` database is lowercase, as are the names of tables within it. Queries should specify the names in lowercase.

To see the structure of individual tables, use `SHOW CREATE TABLE`:

```
mysql> SHOW CREATE TABLE performance_schema.setup_consumers;
```

```
Table: setup_consumers
Create Table: CREATE TABLE `setup_consumers` (
  `NAME` varchar(64) NOT NULL,
  `ENABLED` enum('YES','NO') NOT NULL
) ENGINE=PERFORMANCE_SCHEMA DEFAULT CHARSET=utf8
```

Table structure is also available by selecting from tables such as `INFORMATION_SCHEMA.COLUMNS` or by using statements such as `SHOW COLUMNS`.

Tables in the `performance_schema` database can be grouped according to the type of information in them: Current events, event histories and summaries, object instances, and setup (configuration) information. The following examples illustrate a few uses for these tables. For detailed information about the tables in each group, see Section 22.12, “Performance Schema Table Descriptions”.

Initially, not all instruments and consumers are enabled, so the performance schema does not collect all events. To turn all of these on and enable event timing, execute two statements (the row counts may differ depending on MySQL version):

```
mysql> UPDATE performance_schema.setup_instruments
    
SET ENABLED = 'YES', TIMED = 'YES';
Query OK, 338 rows affected (0.12 sec)

mysql> UPDATE performance_schema.setup_consumers
    
SET ENABLED = 'YES';
Query OK, 8 rows affected (0.00 sec)
```

To see what the server is doing at the moment, examine the `events_waits_current` table. It contains one row per thread showing each thread's most recent monitored event:
This event indicates that thread 0 was waiting for 86,526 picoseconds to acquire a lock on \texttt{THR\_LOCK::mutex}, a mutex in the \texttt{mysys} subsystem. The first few columns provide the following information:

- The ID columns indicate which thread the event comes from and the event number.
- \texttt{EVENT\_NAME} indicates what was instrumented and \texttt{SOURCE} indicates which source file contains the instrumented code.
- The timer columns show when the event started and stopped and how long it took. If an event is still in progress, the \texttt{TIMER\_END} and \texttt{TIMER\_WAIT} values are \texttt{NULL}. Timer values are approximate and expressed in picoseconds. For information about timers and event time collection, see Section 22.4.1, “Performance Schema Event Timing”.

The history tables contain the same kind of rows as the current-events table but have more rows and show what the server has been doing “recently” rather than “currently.” The \texttt{events\_waits\_history} and \texttt{events\_waits\_history\_long} tables contain the most recent 10 events per thread and most recent 10,000 events, respectively. For example, to see information for recent events produced by thread 13, do this:

```
mysql> SELECT EVENT_ID, EVENT_NAME, TIMER_WAIT
    FROM performance_schema.events_waits_history
    WHERE THREAD_ID = 13
    ORDER BY EVENT_ID;
```

As new events are added to a history table, older events are discarded if the table is full.
Summary tables provide aggregated information for all events over time. The tables in this group summarize event data in different ways. To see which instruments have been executed the most times or have taken the most wait time, sort the `events_waits_summary_global_by_event_name` table on the `COUNT_STAR` or `SUM_TIMER_WAIT` column, which correspond to a `COUNT(*)` or `SUM(TIMER_WAIT)` value, respectively, calculated over all events:

```sql
mysql> SELECT EVENT_NAME, COUNT_STAR
FROM performance_schema.events_waits_summary_global_by_event_name
ORDER BY COUNT_STAR DESC LIMIT 10;
```

<table>
<thead>
<tr>
<th>EVENT_NAME</th>
<th>COUNT_STAR</th>
</tr>
</thead>
<tbody>
<tr>
<td>wait/synch/mutex/mysys/THR_LOCK_malloc</td>
<td>6419</td>
</tr>
<tr>
<td>wait/io/file/sql/FRM</td>
<td>452</td>
</tr>
<tr>
<td>wait/synch/mutex/sql/LOCK_plugin</td>
<td>337</td>
</tr>
<tr>
<td>wait/synch/mutex/mysys/THR_LOCK_open</td>
<td>187</td>
</tr>
<tr>
<td>wait/synch/mutex/mysys/LOCK_alarm</td>
<td>147</td>
</tr>
<tr>
<td>wait/synch/mutex/sql/THD::LOCK_thd_data</td>
<td>115</td>
</tr>
<tr>
<td>wait/io/file/mysam/kfile</td>
<td>102</td>
</tr>
<tr>
<td>wait/synch/mutex/sql/LOCK_global_system_variables</td>
<td>89</td>
</tr>
<tr>
<td>wait/synch/mutex/mysys/THR_LOCK::mutex</td>
<td>89</td>
</tr>
<tr>
<td>wait/synch/mutex/sql/LOCK_open</td>
<td>88</td>
</tr>
</tbody>
</table>

```sql
mysql> SELECT EVENT_NAME, SUM_TIMER_WAIT
FROM performance_schema.events_waits_summary_global_by_event_name
ORDER BY SUM_TIMER_WAIT DESC LIMIT 10;
```

<table>
<thead>
<tr>
<th>EVENT_NAME</th>
<th>SUM_TIMER_WAIT</th>
</tr>
</thead>
<tbody>
<tr>
<td>wait/io/file/sql/MYSQL_LOG</td>
<td>1599816582</td>
</tr>
<tr>
<td>wait/synch/mutex/mysys/THR_LOCK_malloc</td>
<td>1530083250</td>
</tr>
<tr>
<td>wait/io/file/sql/binlog_index</td>
<td>1385291934</td>
</tr>
<tr>
<td>wait/synch/mutex/mysys/THR_LOCK_malloc</td>
<td>1385291934</td>
</tr>
<tr>
<td>wait/io/file/sql/FRM</td>
<td>1292823243</td>
</tr>
<tr>
<td>wait/io/file/mysam/kfile</td>
<td>411193611</td>
</tr>
<tr>
<td>wait/io/file/mysam/dfile</td>
<td>322401645</td>
</tr>
<tr>
<td>wait/synch/mutex/mysys/LOCK_alarm</td>
<td>145126935</td>
</tr>
<tr>
<td>wait/io/file/sql/casetest</td>
<td>104324715</td>
</tr>
<tr>
<td>wait/synch/mutex/sql/LOCK_plugin</td>
<td>86027823</td>
</tr>
<tr>
<td>wait/io/file/sql/pid</td>
<td>72591750</td>
</tr>
</tbody>
</table>

These results show that the `THR_LOCK_malloc` mutex is “hot,” both in terms of how often it is used and amount of time that threads wait attempting to acquire it.

**Note**

The `THR_LOCK_malloc` mutex is used only in debug builds. In production builds it is not hot because it is nonexistent.

Instance tables document what types of objects are instrumented. An instrumented object, when used by the server, produces an event. These tables provide event names and explanatory notes or status information. For example, the `file_instances` table lists instances of instruments for file I/O operations and their associated files:

```sql
mysql> SELECT *
FROM performance_schema.file_instances\G
```

<table>
<thead>
<tr>
<th>FILE_NAME</th>
<th>EVENT_NAME</th>
<th>OPEN_COUNT</th>
</tr>
</thead>
<tbody>
<tr>
<td>/opt/mysql-log/60500/binlog.000007</td>
<td>wait/io/file/sql/binlog</td>
<td>0</td>
</tr>
<tr>
<td>/opt/mysql-log/60500/data/mysql/tables_priv.MYI</td>
<td>wait/io/file/mysql/tables_priv.MYI</td>
<td>0</td>
</tr>
</tbody>
</table>

3351
Setup tables are used to configure and display monitoring characteristics. For example, `setup_instruments` lists the set of instruments for which events can be collected and shows which of them are enabled:

```sql
SELECT * FROM performance_schema.setup_instruments;
```

<table>
<thead>
<tr>
<th>NAME</th>
<th>ENABLED</th>
<th>TIMED</th>
</tr>
</thead>
<tbody>
<tr>
<td>stage/sql/end</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>stage/sql/executing</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>stage/sql/init</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>stage/sql/insert</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>statement/sql/load</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>statement/sql/grant</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>statement/sql/check</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>statement/sql/flush</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>wait/synch/mutex/sql/LOCK_global_read_lock</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>wait/synch/mutex/sql/LOCK_global_system_variables</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>wait/synch/mutex/sql/LOCK_lock_db</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>wait/synch/mutex/sql/LOCK_manager</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>wait/synch/rwlock/sql/LOCK_grant</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>wait/synch/rwlock/sql/LOGGER::LOCK_logger</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>wait/synch/rwlock/sql/LOCK_sys_init_connect</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>wait/synch/rwlock/sql/LOCK_sys_init_slave</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>wait/io/file/sql/binlog</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>wait/io/file/sql/binlog_index</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>wait/io/file/sql/casetest</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>wait/io/file/sql/dbopt</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

To understand how to interpret instrument names, see Section 22.6, “Performance Schema Instrument Naming Conventions”.

To control whether events are collected for an instrument, set its `ENABLED` value to `YES` or `NO`. For example:

```sql
UPDATE performance_schema.setup_instruments
SET ENABLED = 'NO'
WHERE NAME = 'wait/synch/mutex/sql/LOCK_mysql_create_db';
```

The Performance Schema uses collected events to update tables in the `performance_schema` database, which act as “consumers” of event information. The `setup_consumers` table lists the available consumers and which are enabled:

```sql
SELECT * FROM performance_schema.setup_consumers;
```

<table>
<thead>
<tr>
<th>NAME</th>
<th>ENABLED</th>
</tr>
</thead>
<tbody>
<tr>
<td>events_stages_current</td>
<td>NO</td>
</tr>
<tr>
<td>events_stages_history</td>
<td>NO</td>
</tr>
<tr>
<td>events_stages_history_long</td>
<td>NO</td>
</tr>
<tr>
<td>events_stages_history_long</td>
<td>NO</td>
</tr>
<tr>
<td>events_statements_current</td>
<td>YES</td>
</tr>
</tbody>
</table>
To control whether the Performance Schema maintains a consumer as a destination for event information, set its **ENABLED** value.

For more information about the setup tables and how to use them to control event collection, see [Section 22.4.2, “Performance Schema Event Filtering”](#).

There are some miscellaneous tables that do not fall into any of the previous groups. For example, `performance_timers` lists the available event timers and their characteristics. For information about timers, see [Section 22.4.1, “Performance Schema Event Timing”](#).

## 22.2 Performance Schema Build Configuration

For the Performance Schema to be available, it must be configured into the MySQL server at build time. Binary MySQL distributions provided by Oracle Corporation are configured to support the Performance Schema. If you use a binary MySQL distribution from another provider, check with the provider whether the distribution has been appropriately configured.

If you build MySQL from a source distribution, enable the Performance Schema by running `CMake` with the `WITH_PERFSCHEMA_STORAGE_ENGINE` option enabled:

```
$> cmake . -DWITH_PERFSCHEMA_STORAGE_ENGINE=1
```

Configuring MySQL with the `--WITHOUT_PERFSCHEMA_STORAGE_ENGINE=1` option prevents inclusion of the Performance Schema, so if you want it included, do not use this option. See [Section 2.9.7, “MySQL Source-Configuration Options”](#).

If you install MySQL over a previous installation that was configured without the Performance Schema (or with an older version of the Performance Schema that has missing or out-of-date tables). One indication of this issue is the presence of messages such as the following in the error log:

```
[ERROR] Native table 'performance_schema'.'events_waits_history'
has the wrong structure
[ERROR] Native table 'performance_schema'.'events_waits_history_long'
has the wrong structure
...
```

To correct that problem, perform the MySQL upgrade procedure. See [Section 2.11, “Upgrading MySQL”](#).

To verify whether a server was built with Performance Schema support, check its help output. If the Performance Schema is available, the output includes several variables with names that begin with `performance_schema`:

```
$> mysql --verbose --help
...
--performance_schema
    Enable the performance schema.
    --performance_schema_events_waits_history_long_size=#
        Number of rows in events_waits_history_long.
...
```
You can also connect to the server and look for a line that names the `PERFORMANCE_SCHEMA` storage engine in the output from `SHOW ENGINES`:

```
mysql> SHOW ENGINES\G
... Engine: PERFORMANCE_SCHEMA
Support: YES
Comment: Performance Schema
Transactions: NO
XA: NO
Savepoints: NO
...
```

If the Performance Schema was not configured into the server at build time, no row for `PERFORMANCE_SCHEMA` appears in the output from `SHOW ENGINES`. You might see `performance_schema` listed in the output from `SHOW DATABASES`, but it contains no tables and you cannot use it.

A line for `PERFORMANCE_SCHEMA` in the `SHOW ENGINES` output means that the Performance Schema is available, not that it is enabled. To enable it, you must do so at server startup, as described in the next section.

## 22.3 Performance Schema Startup Configuration

To use the MySQL Performance Schema, it must be enabled at server startup to enable event collection to occur.

Assuming that the Performance Schema is available, it is enabled by default. To enable or disable it explicitly, start the server with the `performance_schema` variable set to an appropriate value. For example, use these lines in your `my.cnf` file:

```
[mysqld]
performance_schema=ON
```

If the server is unable to allocate any internal buffer during Performance Schema initialization, the Performance Schema disables itself and sets `performance_schema` to `OFF`, and the server runs without instrumentation.

The Performance Schema also permits instrument and consumer configuration at server startup.

To control an instrument at server startup, use an option of this form:

```
--performance-schema-instrument='instrument_name=value'
```

Here, `instrument_name` is an instrument name such as `wait/synch/mutex/sql/LOCK_open`, and `value` is one of these values:

- **OFF**, **FALSE**, or **0**: Disable the instrument
- **ON**, **TRUE**, or **1**: Enable and time the instrument
- **COUNTED**: Enable and count (rather than time) the instrument

Each `--performance-schema-instrument` option can specify only one instrument name, but multiple instances of the option can be given to configure multiple instruments. In addition, patterns are permitted in instrument names to configure instruments that match the pattern. To configure all condition synchronization instruments as enabled and counted, use this option:
Performance Schema Startup Configuration

To disable all instruments, use this option:

```bash
--performance-schema-instrument='%=OFF'
```

Longer instrument name strings take precedence over shorter pattern names, regardless of order. For information about specifying patterns to select instruments, see Section 22.4.9, “Naming Instruments or Consumers for Filtering Operations”.

An unrecognized instrument name is ignored. It is possible that a plugin installed later may create the instrument, at which time the name is recognized and configured.

To control a consumer at server startup, use an option of this form:

```bash
--performance-schema-consumer-consumer_name=value
```

Here, `consumer_name` is a consumer name such as `events_waits_history`, and `value` is one of these values:

- OFF, FALSE, or 0: Do not collect events for the consumer
- ON, TRUE, or 1: Collect events for the consumer

For example, to enable the `events_waits_history` consumer, use this option:

```bash
--performance-schema-consumer-events-waits-history=ON
```

The permitted consumer names can be found by examining the `setup_consumers` table. Patterns are not permitted. Consumer names in the `setup_consumers` table use underscores, but for consumers set at startup, dashes and underscores within the name are equivalent.

The Performance Schema includes several system variables that provide configuration information:

```sql
mysql> SHOW VARIABLES LIKE 'perf%';
+------------------------+---------+
| Variable_name          | Value   |
+------------------------+---------+
| performance_schema     | ON      |
| performance_schema_accounts_size | 100     |
| performance_schema_digests_size  | 200     |
| performance_schema_events_stages_history_long_size | 10000   |
| performance_schema_events_stages_history_size      | 10      |
| performance_schema_events_statements_history_long_size | 10000   |
| performance_schema_events_statements_history_size      | 10      |
| performance_schema_events_waits_history_long_size    | 10000   |
| performance_schema_events_waits_history_size         | 10      |
| performance_schema_hosts_size                       | 100     |
| performance_schema_max_cond_classes                  | 80      |
| performance_schema_max_cond_instances                | 1000    |
+------------------------+---------+
```

The `performance_schema` variable is ON or OFF to indicate whether the Performance Schema is enabled or disabled. The other variables indicate table sizes (number of rows) or memory allocation values.

**Note**

With the Performance Schema enabled, the number of Performance Schema instances affects the server memory footprint, perhaps to a large extent. It may be
necessary to tune the values of Performance Schema system variables to find the number of instances that balances insufficient instrumentation against excessive memory consumption.

To change the value of Performance Schema system variables, set them at server startup. For example, put the following lines in a `my.cnf` file to change the sizes of the history tables for wait events:

```sql
[mysqld]
performance_schema
performance_schema_events_waits_history_size=20
performance_schema_events_waits_history_long_size=15000
```

The Performance Schema automatically sizes the values of several of its parameters at server startup if they are not set explicitly. For example, it sizes the parameters that control the sizes of the events waits tables this way. To see which parameters are autosized under this policy, use `mysqld --verbose --help` and look for those with a default value of −1, or see Section 22.15, “Performance Schema System Variables”.

For each autosized parameter that is not set at server startup, the Performance Schema determines how to set its value based on the value of the following system values, which are considered as “hints” about how you have configured your MySQL server:

- `max_connections`
- `open_files_limit`
- `table_definition_cache`
- `table_open_cache`

To override autosizing for a given parameter, set it to a value other than −1 at startup. In this case, the Performance Schema assigns it the specified value.

At runtime, `SHOW VARIABLES` displays the actual values that autosized parameters were set to.

If the Performance Schema is disabled, its autosized parameters remain set to −1 and `SHOW VARIABLES` displays −1.

### 22.4 Performance Schema Runtime Configuration

Specific Performance Schema features can be enabled at runtime to control which types of event collection occur.

Performance Schema setup tables contain information about monitoring configuration:

```sql
mysql> SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
WHERE TABLE_SCHEMA = 'performance_schema'
AND TABLE_NAME LIKE 'setup%';
```

You can examine the contents of these tables to obtain information about Performance Schema monitoring characteristics. If you have the `UPDATE` privilege, you can change Performance Schema operation by modifying setup tables to affect how monitoring occurs. For additional details about these tables, see Section 22.12.2, “Performance Schema Setup Tables”.

3356
Performance Schema Event Timing

To see which event timers are selected, query the `setup_timers` tables:

```sql
mysql> SELECT * FROM performance_schema.setup_timers;
+-----------+-------------+
| NAME      | TIMER_NAME  |
|-----------+-------------|
| idle      | MICROSECOND |
| wait      | CYCLE       |
| stage     | NANOSECOND  |
| statement | NANOSECOND  |
+-----------+-------------+
```

The `NAME` value indicates the type of instrument to which the timer applies, and `TIMER_NAME` indicates which timer applies to those instruments. The timer applies to instruments where their name begins with an element matching the `NAME` value.

To change the timer, update the `NAME` value. For example, to use the `NANOSECOND` timer for the `wait` timer:

```sql
mysql> UPDATE performance_schema.setup_timers
    > SET TIMER_NAME = 'NANOSECOND'
    > WHERE NAME = 'wait';

mysql> SELECT * FROM performance_schema.setup_timers;
+-----------+-------------+
| NAME      | TIMER_NAME  |
|-----------+-------------|
| idle      | MICROSECOND |
| wait      | NANOSECOND  |
| stage     | NANOSECOND  |
| statement | NANOSECOND  |
+-----------+-------------+
```

For discussion of timers, see Section 22.4.1, “Performance Schema Event Timing”.

The `setup_instruments` and `setup_consumers` tables list the instruments for which events can be collected and the types of consumers for which event information actually is collected, respectively. Other setup tables enable further modification of the monitoring configuration. Section 22.4.2, “Performance Schema Event Filtering”, discusses how you can modify these tables to affect event collection.

If there are Performance Schema configuration changes that must be made at runtime using SQL statements and you would like these changes to take effect each time the server starts, put the statements in a file and start the server with the `init_file` system variable set to name the file. This strategy can also be useful if you have multiple monitoring configurations, each tailored to produce a different kind of monitoring, such as casual server health monitoring, incident investigation, application behavior troubleshooting, and so forth. Put the statements for each monitoring configuration into their own file and specify the appropriate file as the `init_file` value when you start the server.

### 22.4.1 Performance Schema Event Timing

Events are collected by means of instrumentation added to the server source code. Instruments time events, which is how the Performance Schema provides an idea of how long events take. It is also possible to configure instruments not to collect timing information. This section discusses the available timers and their characteristics, and how timing values are represented in events.

#### Performance Schema Timers

Two Performance Schema tables provide timer information:

- `performance_timers` lists the available timers and their characteristics.
• **setup_timers** indicates which timers are used for which instruments.

Each timer row in **setup_timers** must refer to one of the timers listed in **performance_timers**.

Timers vary in precision and amount of overhead. To see what timers are available and their characteristics, check the **performance_timers** table:

```sql
mysql> SELECT * FROM performance_schema.performance_timers;
+-------------+-----------------+------------------+----------------+
<table>
<thead>
<tr>
<th>TIMER_NAME</th>
<th>TIMER_FREQUENCY</th>
<th>TIMER_RESOLUTION</th>
<th>TIMER_OVERHEAD</th>
</tr>
</thead>
<tbody>
<tr>
<td>CYCLE</td>
<td>2389029850</td>
<td>1</td>
<td>72</td>
</tr>
<tr>
<td>NANOSECOND</td>
<td>1000000000</td>
<td>1</td>
<td>112</td>
</tr>
<tr>
<td>MICROSECOND</td>

+-------------+-----------------+------------------|----------------+
```

If the values associated with a given timer name are **NULL**, that timer is not supported on your platform. The rows that do not contain **NULL** indicate which timers you can use in **setup_timers**.

The columns have these meanings:

- The **TIMER_NAME** column shows the names of the available timers. **CYCLE** refers to the timer that is based on the CPU (processor) cycle counter. The timers in **setup_timers** that you can use are those that do not have **NULL** in the other columns. If the values associated with a given timer name are **NULL**, that timer is not supported on your platform.

- **TIMER_FREQUENCY** indicates the number of timer units per second. For a cycle timer, the frequency is generally related to the CPU speed. The value shown was obtained on a system with a 2.4GHz processor. The other timers are based on fixed fractions of seconds. For **TICK**, the frequency may vary by platform (for example, some use 100 ticks/second, others 1000 ticks/second).

- **TIMER_RESOLUTION** indicates the number of timer units by which timer values increase at a time. If a timer has a resolution of 10, its value increases by 10 each time.

- **TIMER_OVERHEAD** is the minimal number of cycles of overhead to obtain one timing with the given timer. The overhead per event is twice the value displayed because the timer is invoked at the beginning and end of the event.

To see which timers are in effect or to change timers, access the **setup_timers** table:

```sql
mysql> SELECT * FROM performance_schema.setup_timers;
+-----------+-------------+
| NAME      | TIMER_NAME  |
+-----------+-------------+
| idle      | MICROSECOND |
| wait      | CYCLE       |
| stage     | NANOSECOND  |
| statement | NANOSECOND  |
+-----------+-------------+

mysql> UPDATE performance_schema.setup_timers
    SET TIMER_NAME = 'MICROSECOND'
    WHERE NAME = 'idle';

mysql> SELECT * FROM performance_schema.setup_timers;
+-----------+-------------+
| NAME      | TIMER_NAME  |
| idle      | MICROSECOND |
| wait      | CYCLE       |
+-----------+-------------+
```
By default, the Performance Schema uses the best timer available for each instrument type, but you can select a different one.

To time wait events, the most important criterion is to reduce overhead, at the possible expense of the timer accuracy, so using the CYCLE timer is the best.

The time a statement (or stage) takes to execute is in general orders of magnitude larger than the time it takes to execute a single wait. To time statements, the most important criterion is to have an accurate measure, which is not affected by changes in processor frequency, so using a timer which is not based on cycles is the best. The default timer for statements is NANOSECOND. The extra “overhead” compared to the CYCLE timer is not significant, because the overhead caused by calling a timer twice (once when the statement starts, once when it ends) is orders of magnitude less compared to the CPU time used to execute the statement itself. Using the CYCLE timer has no benefit here, only drawbacks.

The precision offered by the cycle counter depends on processor speed. If the processor runs at 1 GHz (one billion cycles/second) or higher, the cycle counter delivers sub-nanosecond precision. Using the cycle counter is much cheaper than getting the actual time of day. For example, the standard gettimeofday() function can take hundreds of cycles, which is an unacceptable overhead for data gathering that may occur thousands or millions of times per second.

Cycle counters also have disadvantages:

- End users expect to see timings in wall-clock units, such as fractions of a second. Converting from cycles to fractions of seconds can be expensive. For this reason, the conversion is a quick and fairly rough multiplication operation.

- Processor cycle rate might change, such as when a laptop goes into power-saving mode or when a CPU slows down to reduce heat generation. If a processor's cycle rate fluctuates, conversion from cycles to real-time units is subject to error.

- Cycle counters might be unreliable or unavailable depending on the processor or the operating system. For example, on Pentiums, the instruction is RDTSC (an assembly-language rather than a C instruction) and it is theoretically possible for the operating system to prevent user-mode programs from using it.

- Some processor details related to out-of-order execution or multiprocessor synchronization might cause the counter to seem fast or slow by up to 1000 cycles.

MySQL works with cycle counters on x386 (Windows, macOS, Linux, Solaris, and other Unix flavors), PowerPC, and IA-64.

**Performance Schema Timer Representation in Events**

Rows in Performance Schema tables that store current events and historical events have three columns to represent timing information: TIMER_START and TIMER_END indicate when an event started and finished, and TIMER_WAIT indicates event duration.

The setup_instruments table has an ENABLED column to indicate the instruments for which to collect events. The table also has a TIMED column to indicate which instruments are timed. If an instrument is not enabled, it produces no events. If an enabled instrument is not timed, events produced by the instrument have NULL for the TIMER_START, TIMER_END, and TIMER_WAIT timer values. This in turn causes those values to be ignored when calculating aggregate time values in summary tables (sum, minimum, maximum, and average).
Internally, times within events are stored in units given by the timer in effect when event timing begins. For display when events are retrieved from Performance Schema tables, times are shown in picoseconds (trillionths of a second) to normalize them to a standard unit, regardless of which timer is selected.

Modifications to the `setup_timers` table affect monitoring immediately. Events already in progress may use the original timer for the begin time and the new timer for the end time. To avoid unpredictable results after you make timer changes, use `TRUNCATE TABLE` to reset Performance Schema statistics.

The timer baseline ("time zero") occurs at Performance Schema initialization during server startup. `TIMER_START` and `TIMER_END` values in events represent picoseconds since the baseline. `TIMER_WAIT` values are durations in picoseconds.

Picosecond values in events are approximate. Their accuracy is subject to the usual forms of error associated with conversion from one unit to another. If the `CYCLE` timer is used and the processor rate varies, there might be drift. For these reasons, it is not reasonable to look at the `TIMER_START` value for an event as an accurate measure of time elapsed since server startup. On the other hand, it is reasonable to use `TIMER_START` or `TIMER_WAIT` values in `ORDER BY` clauses to order events by start time or duration.

The choice of picoseconds in events rather than a value such as microseconds has a performance basis. One implementation goal was to show results in a uniform time unit, regardless of the timer. In an ideal world this time unit would look like a wall-clock unit and be reasonably precise; in other words, microseconds. But to convert cycles or nanoseconds to microseconds, it would be necessary to perform a division for every instrumentation. Division is expensive on many platforms. Multiplication is not expensive, so that is what is used. Therefore, the time unit is an integer multiple of the highest possible `TIMER_FREQUENCY` value, using a multiplier large enough to ensure that there is no major precision loss. The result is that the time unit is "picoseconds." This precision is spurious, but the decision enables overhead to be minimized.

Before MySQL 5.6.26, while a wait, stage, or statement event is executing, the respective current-event tables display the event with `TIMER_START` populated, but with `TIMER_END` and `TIMER_WAIT` set to `NULL`:

- `events_waits_current`
- `events_stages_current`
- `events_statements_current`

As of MySQL 5.6.26, current-event timing provides more information. To make it possible to determine how long a not-yet-completed event has been running, the timer columns are set as follows:

- `TIMER_START` is populated.
- `TIMER_END` is populated with the current timer value.
- `TIMER_WAIT` is populated with the time elapsed so far (`TIMER_END - TIMER_START`).

Events that have not yet completed have an `END_EVENT_ID` value of `NULL`. To assess time elapsed so far for an event, use the `TIMER_WAIT` column. Therefore, to identify events that have not yet completed and have taken longer than `N` picoseconds thus far, monitoring applications can use this expression in queries:

```
WHERE END_EVENT_ID IS NULL AND TIMER_WAIT > N
```

Event identification as just described assumes that the corresponding instruments have `ENABLED` and `TIMED` set to `YES` and that the relevant consumers are enabled.

### 22.4.2 Performance Schema Event Filtering
Performance Schema Event Filtering

Events are processed in a producer/consumer fashion:

- Instrumented code is the source for events and produces events to be collected. The setup_instruments table lists the instruments for which events can be collected, whether they are enabled, and (for enabled instruments) whether to collect timing information:

```
mysql> SELECT * FROM performance_schema.setup_instruments;
+---------------------------------------------------+---------+-------+
| NAME                                              | ENABLED | TIMED |
+---------------------------------------------------+---------+-------+
| wait/synch/mutex/sql/LOCK_global_read_lock        | YES     | YES   |
| wait/synch/mutex/sql/LOCK_global_system_variables | YES     | YES   |
| wait/synch/mutex/sql/LOCK_lock_db                 | YES     | YES   |
| wait/synch/mutex/sql/LOCK_manager                 | YES     | YES   |
| ...                                                |         |       |
```

The setup_instruments table provides the most basic form of control over event production. To further refine event production based on the type of object or thread being monitored, other tables may be used as described in Section 22.4.3, “Event Pre-Filtering”.

- Performance Schema tables are the destinations for events and consume events. The setup_consumers table lists the types of consumers to which event information can be sent and whether they are enabled:

```
mysql> SELECT * FROM performance_schema.setup_consumers;
+--------------------------------+---------+
| NAME                           | ENABLED |
+--------------------------------+---------+
| events_stages_current          | NO      |
| events_stages_history          | NO      |
| events_stages_history_long     | NO      |
| events_statements_current      | YES     |
| events_statements_history      | NO      |
| events_statements_history_long | NO      |
| events_waits_current           | NO      |
| events_waits_history           | NO      |
| events_waits_history_long      | NO      |
| global_instrumentation         | YES     |
| thread_instrumentation         | YES     |
| statements_digest              | YES     |
+--------------------------------+---------+
```

Filtering can be done at different stages of performance monitoring:

- **Pre-filtering.** This is done by modifying Performance Schema configuration so that only certain types of events are collected from producers, and collected events update only certain consumers. To do this, enable or disable instruments or consumers. Pre-filtering is done by the Performance Schema and has a global effect that applies to all users.

Reasons to use pre-filtering:

- To reduce overhead. Performance Schema overhead should be minimal even with all instruments enabled, but perhaps you want to reduce it further. Or you do not care about timing events and want to disable the timing code to eliminate timing overhead.

- To avoid filling the current-events or history tables with events in which you have no interest. Pre-filtering leaves more “room” in these tables for instances of rows for enabled instrument types. If you enable only file instruments with pre-filtering, no rows are collected for nonfile instruments. With post-filtering, nonfile events are collected, leaving fewer rows for file events.
Event Pre-Filtering

- To avoid maintaining some kinds of event tables. If you disable a consumer, the server does not spend time maintaining destinations for that consumer. For example, if you do not care about event histories, you can disable the history table consumers to improve performance.

- **Post-filtering.** This involves the use of `WHERE` clauses in queries that select information from Performance Schema tables, to specify which of the available events you want to see. Post-filtering is performed on a per-user basis because individual users select which of the available events are of interest.

  Reasons to use post-filtering:

  - To avoid making decisions for individual users about which event information is of interest.
  - To use the Performance Schema to investigate a performance issue when the restrictions to impose using pre-filtering are not known in advance.

The following sections provide more detail about pre-filtering and provide guidelines for naming instruments or consumers in filtering operations. For information about writing queries to retrieve information (post-filtering), see Section 22.5, “Performance Schema Queries”.

### 22.4.3 Event Pre-Filtering

Pre-filtering is done by the Performance Schema and has a global effect that applies to all users. Pre-filtering can be applied to either the producer or consumer stage of event processing:

- To configure pre-filtering at the producer stage, several tables can be used:
  - `setup_instruments` indicates which instruments are available. An instrument disabled in this table produces no events regardless of the contents of the other production-related setup tables. An instrument enabled in this table is permitted to produce events, subject to the contents of the other tables.
  - `setup_objects` controls whether the Performance Schema monitors particular table objects.
  - `threads` indicates whether monitoring is enabled for each server thread.
  - `setup_actors` determines the initial monitoring state for new foreground threads.

- To configure pre-filtering at the consumer stage, modify the `setup_consumers` table. This determines the destinations to which events are sent. `setup_consumers` also implicitly affects event production. If a given event is not sent to any destination (is not consumed), the Performance Schema does not produce it.

  Modifications to any of these tables affect monitoring immediately, with some exceptions:

  - Modifications to some instruments in the `setup_instruments` table are effective only at server startup; changing them at runtime has no effect. This affects primarily mutexes, conditions, and rwlocks in the server, although there may be other instruments for which this is true.

  - Modifications to the `setup_actors` table affect only foreground threads created subsequent to the modification, not existing threads.

When you change the monitoring configuration, the Performance Schema does not flush the history tables. Events already collected remain in the current-events and history tables until displaced by newer events. If you disable instruments, you might need to wait a while before events for them are displaced by newer events of interest. Alternatively, use `TRUNCATE TABLE` to empty the history tables.
After making instrumentation changes, you might want to truncate the summary tables. Generally, the effect is to reset the summary columns to 0 or NULL, not to remove rows. This enables you to clear collected values and restart aggregation. That might be useful, for example, after you have made a runtime configuration change. Exceptions to this truncation behavior are noted in individual summary table sections.

The following sections describe how to use specific tables to control Performance Schema pre-filtering.

### 22.4.4 Pre-Filtering by Instrument

The `setup_instruments` table lists the available instruments:

```sql
mysql> SELECT * FROM performance_schema.setup_instruments;
+------------------------+---------+-------+
| NAME                   | ENABLED | TIMED |
+------------------------+---------+-------+
| stage/sql/end          | NO      | NO    |
| stage/sql/executing    | NO      | NO    |
| stage/sql/init         | NO      | NO    |
| stage/sql/insert       | NO      | NO    |
| ...                    |         |       |
| statement/sql/load     | YES     | YES   |
| statement/sql/grant    | YES     | YES   |
| statement/sql/check    | YES     | YES   |
| statement/sql/flush    | YES     | YES   |
| ...                    |         |       |
| wait/synch/mutex/sql/LOCK_global_read_lock | YES | YES |
| wait/synch/mutex/sql/LOCK_global_system_variables | YES | YES |
| wait/synch/mutex/sql/LOCK_lock_db | YES | YES |
| wait/synch/mutex/sql/LOCK_manager | YES | YES |
| ...                    |         |       |
| wait/synch/rwlock/sql/LOCK_grant | YES | YES |
| wait/synch/rwlock/sql/LOCK_logger | YES | YES |
| wait/synch/rwlock/sql/LOCK_sys_init_connect | YES | YES |
| wait/synch/rwlock/sql/LOCK_sys_init_slave | YES | YES |
| ...                    |         |       |
| wait/io/file/sql/binlog | YES | YES |
| wait/io/file/sql/binlog_index | YES | YES |
| wait/io/file/sql/casetest | YES | YES |
| wait/io/file/sql/dbopt | YES | YES |
| ...                    |         |       |
```

To control whether an instrument is enabled, set its `ENABLED` column to `YES` or `NO`. To configure whether to collect timing information for an enabled instrument, set its `TIMED` value to `YES` or `NO`. Setting the `TIMED` column affects Performance Schema table contents as described in Section 22.4.1, “Performance Schema Event Timing”.

Modifications to most `setup_instruments` rows affect monitoring immediately. For some instruments, modifications are effective only at server startup; changing them at runtime has no effect. This affects primarily mutexes, conditions, and rwlocks in the server, although there may be other instruments for which this is true.

The `setup_instruments` table provides the most basic form of control over event production. To further refine event production based on the type of object or thread being monitored, other tables may be used as described in Section 22.4.3, “Event Pre-Filtering”.

The following examples demonstrate possible operations on the `setup_instruments` table. These changes, like other pre-filtering operations, affect all users. Some of these queries use the `LIKE` operator and a pattern match instrument names. For additional information about specifying patterns to select instruments, see Section 22.4.9, “Naming Instruments or Consumers for Filtering Operations”. 

---

3363
Pre-Filtering by Object

- Disable all instruments:

  ```sql
  UPDATE performance_schema.setup_instruments
  SET ENABLED = 'NO';
  
  Now no events are collected.
  ```

- Disable all file instruments, adding them to the current set of disabled instruments:

  ```sql
  UPDATE performance_schema.setup_instruments
  SET ENABLED = 'NO'
  WHERE NAME LIKE 'wait/io/file/%%';
  ```

- Disable only file instruments, enable all other instruments:

  ```sql
  UPDATE performance_schema.setup_instruments
  SET ENABLED = IF(NAME LIKE 'wait/io/file/%%', 'NO', 'YES');
  ```

- Enable all but those instruments in the `mysys` library:

  ```sql
  UPDATE performance_schema.setup_instruments
  SET ENABLED = CASE WHEN NAME LIKE '%/mysys/%%' THEN 'YES' ELSE 'NO' END;
  ```

- Disable a specific instrument:

  ```sql
  UPDATE performance_schema.setup_instruments
  SET ENABLED = 'NO'
  WHERE NAME = 'wait/synch/mutex/mysys/TMPDIR_mutex';
  ```

- To toggle the state of an instrument, “flip” its `ENABLED` value:

  ```sql
  UPDATE performance_schema.setup_instruments
  SET ENABLED = IF(ENABLED = 'YES', 'NO', 'YES')
  WHERE NAME = 'wait/synch/mutex/mysys/TMPDIR_mutex';
  ```

- Disable timing for all events:

  ```sql
  UPDATE performance_schema.setup_instruments
  SET TIMED = 'NO';
  ```

### 22.4.5 Pre-Filtering by Object

The `setup_objects` table controls whether the Performance Schema monitors particular table objects.

The initial `setup_objects` contents look like this:

```sql
mysql> SELECT * FROM performance_schema.setup_objects;
+-------------+--------------------+-------------+---------+-------+
| OBJECT_TYPE | OBJECT_SCHEMA      | OBJECT_NAME | ENABLED | TIMED |
|-------------+--------------------+-------------+---------+-------+
| TABLE       | mysql              | %           | NO      | NO    |
| TABLE       | performance_schema | %           | NO      | NO    |
| TABLE       | information_schema | %           | NO      | NO    |
| TABLE       | %                  | %           | YES     | YES   |
+-------------+--------------------+-------------+---------+-------+
```

Modifications to the `setup_objects` table affect object monitoring immediately.

The `OBJECT_TYPE` column indicates the type of object to which a row applies. `TABLE` filtering affects table I/O events (`wait/io/table/sql/handler` instrument) and table lock events (`wait/lock/table/sql/handler` instrument).

The `OBJECT_SCHEMA` and `OBJECT_NAME` columns should contain a literal schema or table name, or `'%'` to match any name.
Pre-Filtering by Object

The **ENABLED** column indicates whether matching objects are monitored, and **TIMED** indicates whether to collect timing information. Setting the **TIMED** column affects Performance Schema table contents as described in Section 22.4.1, "Performance Schema Event Timing".

The effect of the default object configuration is to instrument all tables except those in the **mysql**, **INFORMATION_SCHEMA**, and **performance_schema** databases. (Tables in the **INFORMATION_SCHEMA** database are not instrumented regardless of the contents of **setup_objects**; the row for **information_schema.%** simply makes this default explicit.)

When the Performance Schema checks for a match in **setup_objects**, it tries to find more specific matches first. For rows that match a given **OBJECT_TYPE**, the Performance Schema checks rows in this order:

- Rows with **OBJECT_SCHEMA='literal'** and **OBJECT_NAME='literal'**.
- Rows with **OBJECT_SCHEMA='literal'** and **OBJECT_NAME='%'.**
- Rows with **OBJECT_SCHEMA='%'** and **OBJECT_NAME='%'**.

For example, with a table `db1.t1`, the Performance Schema looks in **TABLE** rows for a match for 'db1' and 't1', then for 'db1' and '%', then for '%' and '%'. The order in which matching occurs matters because different matching **setup_objects** rows can have different **ENABLED** and **TIMED** values.

For table-related events, the Performance Schema combines the contents of **setup_objects** with **setup_instruments** to determine whether to enable instruments and whether to time enabled instruments:

- For tables that match a row in **setup_objects**, table instruments produce events only if **ENABLED** is **YES** in both **setup_instruments** and **setup_objects**.
- The **TIMED** values in the two tables are combined, so that timing information is collected only when both values are **YES**.

Suppose that **setup_objects** contains the following **TABLE** rows that apply to **db1**, **db2**, and **db3**:

<table>
<thead>
<tr>
<th><strong>OBJECT_TYPE</strong></th>
<th><strong>OBJECT_SCHEMA</strong></th>
<th><strong>OBJECT_NAME</strong></th>
<th><strong>ENABLED</strong></th>
<th><strong>TIMED</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLE</td>
<td>db1</td>
<td>t1</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>TABLE</td>
<td>db1</td>
<td>t2</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>TABLE</td>
<td>db2</td>
<td>%</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>TABLE</td>
<td>db3</td>
<td>%</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>TABLE</td>
<td>%</td>
<td>%</td>
<td>YES</td>
<td>YES</td>
</tr>
</tbody>
</table>

If a table-related instrument in **setup_instruments** has an **ENABLED** value of **NO**, events for the object are not monitored. If the **ENABLED** value is **YES**, event monitoring occurs according to the **ENABLED** value in the relevant **setup_objects** row:

- **db1.t1** events are monitored
- **db1.t2** events are not monitored
- **db2.t3** events are monitored
- **db3.t4** events are not monitored
- **db4.t5** events are monitored
Similar logic applies for combining the TIMED columns from the setup_instruments and setup_objects tables to determine whether to collect event timing information.

If a persistent table and a temporary table have the same name, matching against setup_objects rows occurs the same way for both. It is not possible to enable monitoring for one table but not the other. However, each table is instrumented separately.

**22.4.6 Pre-Filtering by Thread**

The threads table contains a row for each server thread. Each row contains information about a thread and indicates whether monitoring is enabled for it. For the Performance Schema to monitor a thread, these things must be true:

- The thread_instrumentation consumer in the setup_consumers table must be YES.
- The threads.INSTRUMENTED column must be YES.
- Monitoring occurs only for those thread events produced from instruments that are enabled in the setup_instruments table.

The INSTRUMENTED column in the threads table indicates the monitoring state for each thread. For foreground threads (resulting from client connections), the initial INSTRUMENTED value is determined by whether the user account associated with the thread matches any row in the setup_actors table.

For background threads, there is no associated user. INSTRUMENTED is YES by default and setup_actors is not consulted.

The initial setup_actors contents look like this:

```
mysql> SELECT * FROM performance_schema.setup_actors;
+--------+--------+--------+
| HOST   | USER   | ROLE   |
|--------+--------+--------|
| %      | %      | %      |
```

The HOST and USER columns should contain a literal host or user name, or '%' to match any name.

The Performance Schema uses the HOST and USER columns to match each new foreground thread. (ROLE is unused.) The INSTRUMENTED value for the thread becomes YES if any row matches, NO otherwise. This enables instrumenting to be applied selectively per host, user, or combination of host and user.

By default, monitoring is enabled for all new foreground threads because the setup_actors table initially contains a row with '%' for both HOST and USER. To perform more limited matching such as to enable monitoring only for some foreground threads, you must delete this row because it matches any connection.

Suppose that you modify setup_actors as follows:

```
TRUNCATE TABLE performance_schema.setup_actors;
```

Now setup_actors is empty and there are no rows that could match incoming connections. Consequently, the Performance Schema sets the INSTRUMENTED column to NO for all new foreground threads.

Suppose that you further modify setup_actors:

```
INSERT INTO performance_schema.setup_actors
(HOST,USER,ROLE) VALUES('localhost','joe','%');
```
INSERT INTO performance_schema.setup_actors
(HOST,USER,ROLE) VALUES('%','sam','%');

Now the Performance Schema determines how to set the \textit{INSTRUMENTED} value for new connection threads as follows:

- If \textit{joe} connects from the local host, the connection matches the first inserted row.
- If \textit{joe} connects from any other host, there is no match.
- If \textit{sam} connects from any host, the connection matches the second inserted row.
- For any other connection, there is no match.

Modifications to the \textit{setup_actors} table affect only foreground threads created subsequent to the modification, not existing threads. To affect existing threads, modify the \textit{INSTRUMENTED} column of \textit{threads} table rows.

\textbf{22.4.7 Pre-Filtering by Consumer}

The \textit{setup_consumers} table lists the available consumer types and which are enabled:

```sql
mysql> SELECT * FROM performance_schema.setup_consumers;
```

<table>
<thead>
<tr>
<th>NAME</th>
<th>ENABLED</th>
</tr>
</thead>
<tbody>
<tr>
<td>events_stages_current</td>
<td>NO</td>
</tr>
<tr>
<td>events_stages_history</td>
<td>NO</td>
</tr>
<tr>
<td>events_stages_history_long</td>
<td>NO</td>
</tr>
<tr>
<td>events_statements_current</td>
<td>YES</td>
</tr>
<tr>
<td>events_statements_history</td>
<td>NO</td>
</tr>
<tr>
<td>events_statements_history_long</td>
<td>NO</td>
</tr>
<tr>
<td>events_waits_current</td>
<td>NO</td>
</tr>
<tr>
<td>events_waits_history</td>
<td>NO</td>
</tr>
<tr>
<td>events_waits_history_long</td>
<td>NO</td>
</tr>
<tr>
<td>global_instrumentation</td>
<td>YES</td>
</tr>
<tr>
<td>thread_instrumentation</td>
<td>YES</td>
</tr>
<tr>
<td>statements_digest</td>
<td>YES</td>
</tr>
</tbody>
</table>

Modify the \textit{setup_consumers} table to affect pre-filtering at the consumer stage and determine the destinations to which events are sent. To enable or disable a consumer, set its \textit{ENABLED} value to \textit{YES} or \textit{NO}.

Modifications to the \textit{setup_consumers} table affect monitoring immediately.

If you disable a consumer, the server does not spend time maintaining destinations for that consumer. For example, if you do not care about historical event information, disable the history consumers:

```sql
UPDATE performance_schema.setup_consumers
SET ENABLED = 'NO'
WHERE NAME LIKE '%history%';
```

The consumer settings in the \textit{setup_consumers} table form a hierarchy from higher levels to lower. The following principles apply:

- Destinations associated with a consumer receive no events unless the Performance Schema checks the consumer and the consumer is enabled.
- A consumer is checked only if all consumers it depends on (if any) are enabled.
Pre-Filtering by Consumer

- If a consumer is not checked, or is checked but is disabled, other consumers that depend on it are not checked.

- Dependent consumers may have their own dependent consumers.

- If an event would not be sent to any destination, the Performance Schema does not produce it.

The following lists describe the available consumer values. For discussion of several representative consumer configurations and their effect on instrumentation, see Section 22.4.8, “Example Consumer Configurations”.

- Global and Thread Consumers
- Wait Event Consumers
- Stage Event Consumers
- Statement Event Consumers
- Statement Digest Consumer

Global and Thread Consumers

- `global_instrumentation` is the highest level consumer. If `global_instrumentation` is NO, it disables global instrumentation. All other settings are lower level and are not checked; it does not matter what they are set to. No global or per thread information is maintained and no individual events are collected in the current-events or event-history tables. If `global_instrumentation` is YES, the Performance Schema maintains information for global states and also checks the `thread_instrumentation` consumer.

- `thread_instrumentation` is checked only if `global_instrumentation` is YES. Otherwise, if `thread_instrumentation` is NO, it disables thread-specific instrumentation and all lower-level settings are ignored. No information is maintained per thread and no individual events are collected in the current-events or event-history tables. If `thread_instrumentation` is YES, the Performance Schema maintains thread-specific information and also checks `events_xxx_current` consumers.

Wait Event Consumers

These consumers require both `global_instrumentation` and `thread_instrumentation` to be YES or they are not checked. If checked, they act as follows:

- `events_waits_current`, if NO, disables collection of individual wait events in the `events_waits_current` table. If YES, it enables wait event collection and the Performance Schema checks the `events_waits_history` and `events_waits_history_long` consumers.

- `events_waits_history` is not checked if `event_waits_current` is NO. Otherwise, an `events_waits_history` value of NO or YES disables or enables collection of wait events in the `events_waits_history` table.

- `events_waits_history_long` is not checked if `event_waits_current` is NO. Otherwise, an `events_waits_history_long` value of NO or YES disables or enables collection of wait events in the `events_waits_history_long` table.

Stage Event Consumers

These consumers require both `global_instrumentation` and `thread_instrumentation` to be YES or they are not checked. If checked, they act as follows:
Example Consumer Configurations

- `events_stages_current`, if NO, disables collection of individual stage events in the `events_stages_current` table. If YES, it enables stage event collection and the Performance Schema checks the `events_stages_history` and `events_stages_history_long` consumers.

- `events_stages_history` is not checked if `event_stages_current` is NO. Otherwise, an `events_stages_history` value of NO or YES disables or enables collection of stage events in the `events_stages_history` table.

- `events_stages_history_long` is not checked if `event_stages_current` is NO. Otherwise, an `events_stages_history_long` value of NO or YES disables or enables collection of stage events in the `events_stages_history_long` table.

**Statement Event Consumers**

These consumers require both `global_instrumentation` and `thread_instrumentation` to be YES or they are not checked. If checked, they act as follows:

- `events_statements_current`, if NO, disables collection of individual statement events in the `events_statements_current` table. If YES, it enables statement event collection and the Performance Schema checks the `events_statements_history` and `events_statements_history_long` consumers.

- `events_statements_history` is not checked if `events_statements_current` is NO. Otherwise, an `events_statements_history` value of NO or YES disables or enables collection of statement events in the `events_statements_history` table.

- `events_statements_history_long` is not checked if `events_statements_current` is NO. Otherwise, an `events_statements_history_long` value of NO or YES disables or enables collection of statement events in the `events_statements_history_long` table.

**Statement Digest Consumer**

The `statements_digest` consumer requires `global_instrumentation` to be YES or it is not checked. There is no dependency on the statement event consumers, so you can obtain statistics per digest without having to collect statistics in `events_statements_current`, which is advantageous in terms of overhead. Conversely, you can get detailed statements in `events_statements_current` without digests (the `DIGEST` and `DIGEST_TEXT` columns are NULL).

For more information about statement digesting, see Section 22.10, “Performance Schema Statement Digests”.

### 22.4.8 Example Consumer Configurations

The consumer settings in the `setup_consumers` table form a hierarchy from higher levels to lower. The following discussion describes how consumers work, showing specific configurations and their effects as consumer settings are enabled progressively from high to low. The consumer values shown are representative. The general principles described here apply to other consumer values that may be available.

The configuration descriptions occur in order of increasing functionality and overhead. If you do not need the information provided by enabling lower-level settings, disable them and the Performance Schema executes less code on your behalf and you have less information to sift through.

The `setup_consumers` table contains the following hierarchy of values:
Example Consumer Configurations

```
thread_instrumentation
events_waits_current
  events_waits_history
  events_waits_history_long
events_stages_current
  events_stages_history
  events_stages_history_long
events_statements_current
  events_statements_history
  events_statements_history_long
statements_digest
```

Note

In the consumer hierarchy, the consumers for waits, stages, and statements are all at the same level. This differs from the event nesting hierarchy, for which wait events nest within stage events, which nest within statement events.

If a given consumer setting is `NO`, the Performance Schema disables the instrumentation associated with the consumer and ignores all lower-level settings. If a given setting is `YES`, the Performance Schema enables the instrumentation associated with it and checks the settings at the next lowest level. For a description of the rules for each consumer, see Section 22.4.7, “Pre-Filtering by Consumer”.

For example, if `global_instrumentation` is enabled, `thread_instrumentation` is checked. If `thread_instrumentation` is enabled, the `events_xxx_current` consumers are checked. If of these `events_waits_current` is enabled, `events_waits_history` and `events_waits_history_long` are checked.

Each of the following configuration descriptions indicates which setup elements the Performance Schema checks and which output tables it maintains (that is, for which tables it collects information).

- No Instrumentation
- Global Instrumentation Only
- Global and Thread Instrumentation Only
- Global, Thread, and Current-Event Instrumentation
- Global, Thread, Current-Event, and Event-History instrumentation

**No Instrumentation**

Server configuration state:

```
mysql> SELECT * FROM performance_schema.setup_consumers;
+---------------------------+---------+
| NAME                      | ENABLED |
+---------------------------+---------+
| global_instrumentation    | NO      |
| ...                       |         |
```

In this configuration, nothing is instrumented.

Setup elements checked:

- Table `setup_consumers`, consumer `global_instrumentation`

Output tables maintained:
Example Consumer Configurations

- None

Global Instrumentation Only

Server configuration state:

```sql
mysql> SELECT * FROM performance_schema.setup_consumers;
+---------------------------+---------+
| NAME                      | ENABLED |
+---------------------------+---------+
| global_instrumentation    | YES     |
| thread_instrumentation    | NO      |
...                        
+---------------------------+---------+
```

In this configuration, instrumentation is maintained only for global states. Per-thread instrumentation is disabled.

Additional setup elements checked, relative to the preceding configuration:

- Table `setup_consumers`, consumer `thread_instrumentation`
- Table `setup_instruments`
- Table `setup_objects`
- Table `setup_timers`

Additional output tables maintained, relative to the preceding configuration:

- `mutex_instances`
- `rwlock_instances`
- `cond_instances`
- `file_instances`
- `users`
- `hosts`
- `accounts`
- `socket_summary_by_event_name`
- `file_summary_by_instance`
- `file_summary_by_event_name`
- `objects_summary_global_by_type`
- `table_lock_waits_summary_by_table`
- `table_io_waits_summary_by_index_usage`
- `table_io_waits_summary_by_table`
- `events_waits_summary_by_instance`
Example Consumer Configurations

- `events_waits_summary_global_by_event_name`
- `events_stages_summary_global_by_event_name`
- `events_statements_summary_global_by_event_name`

**Global and Thread Instrumentation Only**

Server configuration state:

```
mysql> SELECT * FROM performance_schema.setup_consumers;
+--------------------------------+---------+
| NAME                           | ENABLED |
+--------------------------------+---------+
| global_instrumentation         | YES     |
| thread_instrumentation         | YES     |
| events_waits_current           | NO      |
| events_waits_history           | NO      |
| events_waits_history_long      | NO      |
| events_stages_current          | YES     |
| events_stages_history          | NO      |
| events_stages_history_long     | NO      |
| events_statements_current      | YES     |
| events_statements_history      | NO      |
| events_statements_history_long | NO      |
+--------------------------------+---------+
```

In this configuration, instrumentation is maintained globally and per thread. No individual events are collected in the current-events or event-history tables.

Additional setup elements checked, relative to the preceding configuration:

- Table `setup_consumers`, consumers `events_xxx_current`, where `xxx` is `waits`, `stages`, `statements`
- Table `setup_actors`
- Column `threads.instrumented`

Additional output tables maintained, relative to the preceding configuration:

- `events_xxx_summary_by_yyy_by_event_name`, where `xxx` is `waits`, `stages`, `statements`; and `yyy` is `thread`, `user`, `host`, `account`

**Global, Thread, and Current-Event Instrumentation**

Server configuration state:

```
mysql> SELECT * FROM performance_schema.setup_consumers;
+--------------------------------+---------+
| NAME                           | ENABLED |
+--------------------------------+---------+
| global_instrumentation         | YES     |
| thread_instrumentation         | YES     |
| events_waits_current           | YES     |
| events_waits_history           | NO      |
| events_waits_history_long      | NO      |
| events_stages_current          | YES     |
| events_stages_history          | NO      |
| events_stages_history_long     | NO      |
| events_statements_current      | YES     |
| events_statements_history      | NO      |
| events_statements_history_long | NO      |
+--------------------------------+---------+
```
Example Consumer Configurations

In this configuration, instrumentation is maintained globally and per thread. Individual events are collected in the current-events table, but not in the event-history tables.

Additional setup elements checked, relative to the preceding configuration:

- Consumers `events_xxx_history`, where `xxx` is `waits, stages, statements`
- Consumers `events_xxx_history_long`, where `xxx` is `waits, stages, statements`

Additional output tables maintained, relative to the preceding configuration:

- `events_xxx_current`, where `xxx` is `waits, stages, statements`

Global, Thread, Current-Event, and Event-History instrumentation

The preceding configuration collects no event history because the `events_xxx_history` and `events_xxx_history_long` consumers are disabled. Those consumers can be enabled separately or together to collect event history per thread, globally, or both.

This configuration collects event history per thread, but not globally:

```
mysql> SELECT * FROM performance_schema.setup_consumers;
+--------------------------------+---------+
| NAME                           | ENABLED |
+--------------------------------+---------+
| global_instrumentation         | YES     |
| thread_instrumentation         | YES     |
| events_waits_current           | YES     |
| events_waits_history           | NO      |
| events_waits_history_long      | YES     |
| events_stages_current          | YES     |
| events_stages_history          | NO      |
| events_stages_history_long     | YES     |
| events_statements_current      | YES     |
| events_statements_history      | NO      |
| events_statements_history_long | YES     |
| events_statements_history_long | NO      |
| ...                            |         |
```

Event-history tables maintained for this configuration:

- `events_xxx_history`, where `xxx` is `waits, stages, statements`

This configuration collects event history globally, but not per thread:

```
mysql> SELECT * FROM performance_schema.setup_consumers;
+--------------------------------+---------+
| NAME                           | ENABLED |
+--------------------------------+---------+
| global_instrumentation         | YES     |
| thread_instrumentation         | YES     |
| events_waits_current           | YES     |
| events_waits_history           | NO      |
| events_waits_history_long      | YES     |
| events_stages_current          | YES     |
| events_stages_history          | NO      |
| events_stages_history_long     | YES     |
| events_statements_current      | YES     |
| events_statements_history      | NO      |
| events_statements_history_long | YES     |
| events_statements_history_long | YES     |
| ...                            |         |
```

Event-history tables maintained for this configuration:

- `events_xxx_history_long`, where `xxx` is `waits, stages, statements`

This configuration collects event history per thread and globally:

```sql
mysql> SELECT * FROM performance_schema.setup_consumers;
```

<table>
<thead>
<tr>
<th>NAME</th>
<th>ENABLED</th>
</tr>
</thead>
<tbody>
<tr>
<td>global_instrumentation</td>
<td>YES</td>
</tr>
<tr>
<td>thread_instrumentation</td>
<td>YES</td>
</tr>
<tr>
<td>events_waits_current</td>
<td>YES</td>
</tr>
<tr>
<td>events_waits_history</td>
<td>YES</td>
</tr>
<tr>
<td>events_waits_history_long</td>
<td>YES</td>
</tr>
<tr>
<td>events_stages_current</td>
<td>YES</td>
</tr>
<tr>
<td>events_stages_history</td>
<td>YES</td>
</tr>
<tr>
<td>events_stages_history_long</td>
<td>YES</td>
</tr>
<tr>
<td>events_statements_current</td>
<td>YES</td>
</tr>
<tr>
<td>events_statements_history</td>
<td>YES</td>
</tr>
<tr>
<td>events_statements_history_long</td>
<td>YES</td>
</tr>
<tr>
<td>...</td>
<td></td>
</tr>
</tbody>
</table>

Event-history tables maintained for this configuration:

- `events_xxx_history`, where `xxx` is `waits, stages, statements`
- `events_xxx_history_long`, where `xxx` is `waits, stages, statements`

### 22.4.9 Naming Instruments or Consumers for Filtering Operations

Names given for filtering operations can be as specific or general as required. To indicate a single instrument or consumer, specify its name in full:

```sql
UPDATE performance_schema.setup_instruments
SET ENABLED = 'NO'
WHERE NAME = 'wait/synch/mutex/myisammrg/MYRG_INFO::mutex';
```

```sql
UPDATE performance_schema.setup_consumers
SET ENABLED = 'NO'
WHERE NAME = 'events_waits_current';
```

To specify a group of instruments or consumers, use a pattern that matches the group members:

```sql
UPDATE performance_schema.setup_instruments
SET ENABLED = 'NO'
WHERE NAME LIKE 'wait/synch/mutex/%';
```

```sql
UPDATE performance_schema.setup_consumers
SET ENABLED = 'NO'
WHERE NAME LIKE '%history%';
```

If you use a pattern, it should be chosen so that it matches all the items of interest and no others. For example, to select all file I/O instruments, it is better to use a pattern that includes the entire instrument name prefix:

```sql
... WHERE NAME LIKE 'wait/io/file/%';
```

The pattern `'/file/%'` matches other instruments that have an element of `'/file/'` anywhere in the name. Even less suitable is the pattern `'/file%'` because it matches instruments with `file` anywhere in the name, such as `wait/synch/mutex/sql/LOCK_des_key_file`. 
Determining What Is Instrumented

To check which instrument or consumer names a pattern matches, perform a simple test:

```sql
SELECT NAME FROM performance_schema.setup_instruments
WHERE NAME LIKE 'pattern';

SELECT NAME FROM performance_schema.setup_consumers
WHERE NAME LIKE 'pattern';
```

For information about the types of names that are supported, see Section 22.6, “Performance Schema Instrument Naming Conventions”.

### 22.4.10 Determining What Is Instrumented

It is always possible to determine what instruments the Performance Schema includes by checking the `setup_instruments` table. For example, to see what file-related events are instrumented for the InnoDB storage engine, use this query:

```sql
mysql> SELECT * FROM performance_schema.setup_instruments
    WHERE NAME LIKE 'wait/io/file/innodb/%';
```

<table>
<thead>
<tr>
<th>NAME</th>
<th>ENABLED</th>
<th>TIMED</th>
</tr>
</thead>
<tbody>
<tr>
<td>wait/io/file/innodb/innodb_data_file</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>wait/io/file/innodb/innodb_log_file</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>wait/io/file/innodb/innodb_temp_file</td>
<td>YES</td>
<td>YES</td>
</tr>
</tbody>
</table>

An exhaustive description of precisely what is instrumented is not given in this documentation, for several reasons:

- What is instrumented is the server code. Changes to this code occur often, which also affects the set of instruments.

- It is not practical to list all the instruments because there are hundreds of them.

- As described earlier, it is possible to find out by querying the `setup_instruments` table. This information is always up to date for your version of MySQL, also includes instrumentation for instrumented plugins you might have installed that are not part of the core server, and can be used by automated tools.

### 22.5 Performance Schema Queries

Pre-filtering limits which event information is collected and is independent of any particular user. By contrast, post-filtering is performed by individual users through the use of queries with appropriate `WHERE` clauses that restrict what event information to select from the events available after pre-filtering has been applied.

In Section 22.4.3, “Event Pre-Filtering”, an example showed how to pre-filter for file instruments. If the event tables contain both file and nonfile information, post-filtering is another way to see information only for file events. Add a `WHERE` clause to queries to restrict event selection appropriately:

```sql
mysql> SELECT THREAD_ID, NUMBER_OF_BYTES
    FROM performance_schema.events_waits_history
    WHERE EVENT_NAME LIKE 'wait/io/file/%'
    AND NUMBER_OF_BYTES IS NOT NULL;
```

<table>
<thead>
<tr>
<th>THREAD_ID</th>
<th>NUMBER_OF_BYTES</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>66</td>
</tr>
</tbody>
</table>
22.6 Performance Schema Instrument Naming Conventions

An instrument name consists of a sequence of elements separated by '/' characters. Example names:

- `wait/io/file/myisam/log`
- `wait/io/file/mysys/charset`
- `wait/lock/table/sql/handler`
- `wait/synch/cond/mysys/COND_alarm`
- `wait/synch/cond/sql/BINLOG::update_cond`
- `wait/synch/mutex/mysys/BITMAP_mutex`
- `wait/synch/rwlock/sql/BINLOG::update_cond`
- `wait/synch/mutex/sql/LOCK_delete`
- `wait/synch/mutex/sql/mysys/COND_alarm`
- `wait/synch/mutex/sql/mysys/BITMAP_mutex`
- `wait/synch/mutex/sql/COND_alarm`
- `wait/synch/mutex/sql/mysys/LOCK_delete`
- `wait/synch/mutex/sql/mysys/BINLOG::update_cond`
- `wait/synch/mutex/sql/mysys/BINLOG::LOCK_delete`
- `stage/sql/closing tables`
- `stage/sql/Sorting result`
- `statement/com/Execute`
- `statement/com/Query`
- `statement/sql/create_table`
- `statement/sql/lock_tables`

The instrument name space has a tree-like structure. The elements of an instrument name from left to right provide a progression from more general to more specific. The number of elements a name has depends on the type of instrument.

The interpretation of a given element in a name depends on the elements to the left of it. For example, `myisam` appears in both of the following names, but `myisam` in the first name is related to file I/O, whereas in the second it is related to a synchronization instrument:

- `wait/io/file/myisam/log`
- `wait/synch/cond/myisam/MI_SORT_INFO::cond`

Instrument names consist of a prefix with a structure defined by the Performance Schema implementation and a suffix defined by the developer implementing the instrument code. The top-level element of an instrument prefix indicates the type of instrument. This element also determines which event timer in the `setup_timers` table applies to the instrument. For the prefix part of instrument names, the top level indicates the type of instrument.

The suffix part of instrument names comes from the code for the instruments themselves. Suffixes may include levels such as these:

- A name for the major element (a server module such as `myisam`, `innodb`, `mysys`, or `sql`) or a plugin name.
- The name of a variable in the code, in the form `XXX` (a global variable) or `CCC::MMM` (a member `MMM` in class `CCC`). Examples: `COND_thread_cache`, `THR_LOCK_myisam`, `BINLOG::LOCK_index`.

- Top-Level Instrument Elements
- Idle Instrument Elements
- Stage Instrument Elements
- Statement Instrument Elements
- Wait Instrument Elements
Top-Level Instrument Elements

- **idle**: An instrumented idle event. This instrument has no further elements.
- **stage**: An instrumented stage event.
- **statement**: An instrumented statement event.
- **wait**: An instrumented wait event.

Idle Instrument Elements

The *idle* instrument is used for idle events, which The Performance Schema generates as discussed in the description of the `socket_instances.STATE` column in Section 22.12.3.5, “The socket_instances Table”.

Stage Instrument Elements

Stage instruments have names of the form `stage/code_area/stage_name`, where `code_area` is a value such as `sql` or `myisam`, and `stage_name` indicates the stage of statement processing, such as `Sorting result` or `Sending data`. Stages correspond to the thread states displayed by `SHOW PROCESSLIST` or that are visible in the `INFORMATION_SCHEMA.PROCESSLIST` table.

Statement Instrument Elements

- **statement/abstract/***: An abstract instrument for statement operations. Abstract instruments are used during the early stages of statement classification before the exact statement type is known, then changed to a more specific statement instrument when the type is known. For a description of this process, see Section 22.12.6, “Performance Schema Statement Event Tables”.
- **statement/com**: An instrumented command operation. These have names corresponding to `COM_`xxx` operations (see the `mysql_com.h` header file and `sql/sql_parse.cc`. For example, the `statement/com/Connect` and `statement/com/Init DB` instruments correspond to the `COM_CONNECT` and `COM_INIT_DB` commands.
- **statement/sql**: An instrumented SQL statement operation. For example, the `statement/sql/create_db` and `statement/sql/select` instruments are used for `CREATE DATABASE` and `SELECT` statements.

Wait Instrument Elements

- **wait/io**
  An instrumented I/O operation.
- **wait/io/file**
  An instrumented file I/O operation. For files, the wait is the time waiting for the file operation to complete (for example, a call to `fwrite()`). Due to caching, the physical file I/O on the disk might not happen within this call.
- **wait/io/socket**
  An instrumented socket operation. Socket instruments have names of the form `wait/io/socket/sql/socket_type`. The server has a listening socket for each network protocol that it supports. The instruments associated with listening sockets for TCP/IP or Unix socket file connections have a
socket_type value of server_tcpip_socket or server_unix_socket, respectively. When a listening socket detects a connection, the server transfers the connection to a new socket managed by a separate thread. The instrument for the new connection thread has a socket_type value of client_connection.

- **wait/io/table**

An instrumented table I/O operation. These include row-level accesses to persistent base tables or temporary tables. Operations that affect rows are fetch, insert, update, and delete. For a view, waits are associated with base tables referenced by the view.

Unlike most waits, a table I/O wait can include other waits. For example, table I/O might include file I/O or memory operations. Thus, events_waits_current for a table I/O wait usually has two rows. For more information, see Section 22.8, “Performance Schema Atom and Molecule Events”.

Some row operations might cause multiple table I/O waits. For example, an insert might activate a trigger that causes an update.

- **wait/lock**

An instrumented lock operation.

- **wait/lock/table**

An instrumented table lock operation.

- **wait/synch**

An instrumented synchronization object. For synchronization objects, the TIMER_WAIT time includes the amount of time blocked while attempting to acquire a lock on the object, if any.

- **wait/synch/cond**

A condition is used by one thread to signal to other threads that something they were waiting for has happened. If a single thread was waiting for a condition, it can wake up and proceed with its execution. If several threads were waiting, they can all wake up and compete for the resource for which they were waiting.

- **wait/synch/mutex**

A mutual exclusion object used to permit access to a resource (such as a section of executable code) while preventing other threads from accessing the resource.

- **wait/synch/rwlock**

A read/write lock object used to lock a specific variable for access while preventing its use by other threads. A shared read lock can be acquired simultaneously by multiple threads. An exclusive write lock can be acquired by only one thread at a time.

### 22.7 Performance Schema Status Monitoring

There are several status variables associated with the Performance Schema:

```
mysql> SHOW STATUS LIKE 'perf%';
+-----------------------------------------------+-------+
| Variable_name                                 | Value |
+-----------------------------------------------+-------+
| Performance_schema_accounts_lost              | 0     |
+-----------------------------------------------+-------+
```
The Performance Schema status variables provide information about instrumentation that could not be loaded or created due to memory constraints. Names for these variables have several forms:

- `Performance_schema_xxx_classes_lost` indicates how many instruments of type `xxx` could not be loaded.
- `Performance_schema_xxx_instances_lost` indicates how many instances of object type `xxx` could not be created.
- `Performance_schema_xxx_handles_lost` indicates how many instances of object type `xxx` could not be opened.
- `Performance_schema_locker_lost` indicates how many events are “lost” or not recorded.

For example, if a mutex is instrumented in the server source but the server cannot allocate memory for the instrumentation at runtime, it increments `Performance_schema_mutex_classes_lost`. The mutex still functions as a synchronization object (that is, the server continues to function normally), but performance data for it is not collected. If the instrument can be allocated, it can be used for initializing instrumented mutex instances. For a singleton mutex such as a global mutex, there is only one instance. Other mutexes have an instance per connection, or per page in various caches and data buffers, so the number of instances varies over time. Increasing the maximum number of connections or the maximum size of some buffers increases the maximum number of instances that might be allocated at once. If the server cannot create a given instrumented mutex instance, it increments `Performance_schema_mutex_instances_lost`.

Suppose that the following conditions hold:

- The server was started with the `--performance_schema_max_mutex_classes=200` option and thus has room for 200 mutex instruments.
- 150 mutex instruments have been loaded already.
- The plugin named `plugin_a` contains 40 mutex instruments.
- The plugin named `plugin_b` contains 20 mutex instruments.

The server allocates mutex instruments for the plugins depending on how many they need and how many are available, as illustrated by the following sequence of statements:
INSTALL PLUGIN plugin_a

The server now has 150+40 = 190 mutex instruments.

UNINSTALL PLUGIN plugin_a;

The server still has 190 instruments. All the historical data generated by the plugin code is still available, but new events for the instruments are not collected.

INSTALL PLUGIN plugin_a;

The server detects that the 40 instruments are already defined, so no new instruments are created, and previously assigned internal memory buffers are reused. The server still has 190 instruments.

INSTALL PLUGIN plugin_b;

The server has room for 200-190 = 10 instruments (in this case, mutex classes), and sees that the plugin contains 20 new instruments. 10 instruments are loaded, and 10 are discarded or “lost.” The Performance_schema_mutex_classes_lost indicates the number of instruments (mutex classes) lost:

```
mysql> SHOW STATUS LIKE "perf%mutex_classes_lost";
+---------------------------------------+-------+
| Variable_name                        | Value |
+---------------------------------------+-------+
| Performance_schema_mutex_classes_lost | 10    |
+---------------------------------------+-------+
```

The instrumentation still works and collects (partial) data for plugin_b.

When the server cannot create a mutex instrument, these results occur:

- No row for the instrument is inserted into the setup_instruments table.
- Performance_schema_mutex_classes_lost increases by 1.
- Performance_schema_mutex_instances_lost does not change. (When the mutex instrument is not created, it cannot be used to create instrumented mutex instances later.)

The pattern just described applies to all types of instruments, not just mutexes.

A value of Performance_schema_mutex_classes_lost greater than 0 can happen in two cases:

- To save a few bytes of memory, you start the server with --performance_schema_max_mutex_classes=N, where N is less than the default value. The default value is chosen to be sufficient to load all the plugins provided in the MySQL distribution, but this can be reduced if some plugins are never loaded. For example, you might choose not to load some of the storage engines in the distribution.

- You load a third-party plugin that is instrumented for the Performance Schema but do not allow for the plugin's instrumentation memory requirements when you start the server. Because it comes from a third party, the instrument memory consumption of this engine is not accounted for in the default value chosen for performance_schema_max_mutex_classes.

If the server has insufficient resources for the plugin’s instruments and you do not explicitly allocate more using --performance_schema_max_mutex_classes=N, loading the plugin leads to starvation of instruments.

If the value chosen for performance_schema_max_mutex_classes is too small, no error is reported in the error log and there is no failure at runtime. However, the content of the tables in the
Performance Schema Status Monitoring

performance_schema database misses events. The Performance_schema_mutex_classes_lost status variable is the only visible sign to indicate that some events were dropped internally due to failure to create instruments.

If an instrument is not lost, it is known to the Performance Schema, and is used when instrumenting instances. For example, wait/synch/mutex/sql/LOCK_delete is the name of a mutex instrument in the setup_instruments table. This single instrument is used when creating a mutex in the code (in THD::LOCK_delete) however many instances of the mutex are needed as the server runs. In this case, LOCK_delete is a mutex that is per connection (THD), so if a server has 1000 connections, there are 1000 threads, and 1000 instrumented LOCK_delete mutex instances (THD::LOCK_delete).

If the server does not have room for all these 1000 instrumented mutexes (instances), some mutexes are created with instrumentation, and some are created without instrumentation. If the server can create only 800 instances, 200 instances are lost. The server continues to run, but increments Performance_schema_mutex_instances_lost by 200 to indicate that instances could not be created.

A value of Performance_schema_mutex_instances_lost greater than 0 can happen when the code initializes more mutexes at runtime than were allocated for --performance_schema_max_mutex_instances=N.

The bottom line is that if SHOW STATUS LIKE 'perf%' says that nothing was lost (all values are zero), the Performance Schema data is accurate and can be relied upon. If something was lost, the data is incomplete, and the Performance Schema could not record everything given the insufficient amount of memory it was given to use. In this case, the specific Performance_schema_xxx_lost variable indicates the problem area.

It might be appropriate in some cases to cause deliberate instrument starvation. For example, if you do not care about performance data for file I/O, you can start the server with all Performance Schema parameters related to file I/O set to 0. No memory is allocated for file-related classes, instances, or handles, and all file events are lost.

Use SHOW ENGINE PERFORMANCE_SCHEMA STATUS to inspect the internal operation of the Performance Schema code:

```
mysql> SHOW ENGINE PERFORMANCE_SCHEMA STATUS\G
...
*************** 3. row ***************
  Type: performance_schema
  Name: events_waits_history.row_size
  Status: 76
*************** 4. row ***************
  Type: performance_schema
  Name: events_waits_history.row_count
  Status: 10000
*************** 5. row ***************
  Type: performance_schema
  Name: events_waits_history.memory
  Status: 760000
... *************** 57. row ***************
  Type: performance_schema
  Name: performance_schema.memory
  Status: 26459600
...
```

This statement is intended to help the DBA understand the effects that different Performance Schema options have on memory requirements. For a description of the field meanings, see Section 13.7.5.16, “SHOW ENGINE Statement”.

3381
22.8 Performance Schema Atom and Molecule Events

For a table I/O event, there are usually two rows in `events_waits_current`, not one. For example, a row fetch might result in rows like this:

<table>
<thead>
<tr>
<th>Row#</th>
<th>EVENT_NAME</th>
<th>TIMER_START</th>
<th>TIMER_END</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>wait/io/file/myisam/dfile</td>
<td>10001</td>
<td>10002</td>
</tr>
<tr>
<td>2</td>
<td>wait/io/table/sql/handler</td>
<td>10000</td>
<td>NULL</td>
</tr>
</tbody>
</table>

The row fetch causes a file read. In the example, the table I/O fetch started before the file I/O event but has not finished (its `TIMER_END` value is `NULL`). The file I/O event is “nested” within the table I/O event.

This occurs because, unlike other “atomic” wait events such as for mutexes or file I/O, table I/O events are “molecular” and include (overlap with) other events. In `events_waits_current`, the table I/O event usually has two rows:

- One row for the most recent table I/O wait event
- One row for the most recent wait event of any kind

Usually, but not always, the “of any kind” wait event differs from the table I/O event. As each subsidiary event completes, it disappears from `events_waits_current`. At this point, and until the next subsidiary event begins, the table I/O wait is also the most recent wait of any kind.

22.9 Performance Schema Tables for Current and Historical Events

For wait, stage, and statement events, the Performance Schema can monitor and store current events. In addition, when events end, the Performance Schema can store them in history tables. For each event type, the Performance Schema uses three tables for storing current and historical events. The tables have names of the following forms, where `xxx` indicates the event type (`waits`, `stages`, `statements`):

- `events_xxx_current`: The “current events” table stores the current monitored event for each thread (one row per thread).
- `events_xxx_history`: The “recent history” table stores the most recent events that have ended per thread (up to a maximum number of rows per thread).
- `events_xxx_history_long`: The “long history” table stores the most recent events that have ended globally (across all threads, up to a maximum number of rows per table).

The `_current` table for each event type contains one row per thread, so there is no system variable for configuring its maximum size. The Performance Schema autosizes the history tables, or the sizes can be configured explicitly at server startup using table-specific system variables, as indicated in the sections that describe the individual history tables. Typical autosized values are 10 rows per thread for `_history` tables, and 10,000 rows total for `_history_long` tables.

For each event type, the `_current`, `_history`, and `_history_long` tables have the same columns.

The `_current` tables show what is currently happening within the server. When a current event ends, it is removed from its `_current` table.

The `_history` and `_history_long` tables show what has happened in the recent past. When the history tables become full, old events are discarded as new events are added. Rows expire from the `_history` and `_history_long` tables in different ways because the tables serve different purposes:

- `_history` is meant to investigate individual threads, independently of the global server load.
• \_history\_long is meant to investigate the server globally, not each thread.

The difference between the two types of history tables relates to the data retention policy. Both tables contain the same data when an event is first seen. However, data within each table expires differently over time, so that data might be preserved for a longer or shorter time in each table:

• For \_history, when the table contains the maximum number of rows for a given thread, the oldest thread row is discarded when a new row for that thread is added.

• For \_history\_long, when the table becomes full, the oldest row is discarded when a new row is added, regardless of which thread generated either row.

When a thread ends, all its rows are discarded from the \_history table but not from the \_history\_long table.

The following example illustrates the differences in how events are added to and discarded from the two types of history tables. The principles apply equally to all event types. The example is based on these assumptions:

• The Performance Schema is configured to retain 10 rows per thread in the \_history table and 10,000 rows total in the \_history\_long table.

• Thread A generates 1 event per second.

• Thread B generates 100 events per second.

• No other threads are running.

After 5 seconds of execution:

• A and B have generated 5 and 500 events, respectively.

• \_history contains 5 rows for A and 10 rows for B. Because storage per thread is limited to 10 rows, no rows have been discarded for A, whereas 490 rows have been discarded for B.

• \_history\_long contains 5 rows for A and 500 rows for B. Because the table has a maximum size of 10,000 rows, no rows have been discarded for either thread.

After 5 minutes (300 seconds) of execution:

• A and B have generated 300 and 30,000 events, respectively.

• \_history contains 10 rows for A and 10 rows for B. Because storage per thread is limited to 10 rows, 290 rows have been discarded for A, whereas 29,990 rows have been discarded for B. Rows for A include data up to 10 seconds old, whereas rows for B include data up to only .1 seconds old.

• \_history\_long contains 10,000 rows. Because A and B together generate 101 events per second, the table contains data up to approximately 10,000/101 = 99 seconds old, with a mix of rows approximately 100 to 1 from B as opposed to A.

22.10 Performance Schema Statement Digests

The MySQL server is capable of maintaining statement digest information. The digesting process converts each SQL statement to normalized form (the statement digest) and computes an MD5 hash value (the digest hash value) from the normalized result. Normalization permits statements that are similar to be grouped and summarized to expose information about the types of statements the server is executing and how often they occur. This section describes how statement digesting occurs and how it can be useful.
As of 5.6.24, digesting occurs in the parser regardless of whether the Performance Schema is available, so that other server components such as MySQL Enterprise Firewall have access to statement digests. Before MySQL 5.6.24, statement digesting was a function of the Performance Schema.

- Statement Digest General Concepts
- Statement Digests in the Performance Schema
- Statement Digest Memory Use

**Statement Digest General Concepts**

When the parser receives an SQL statement, it computes a statement digest if that digest is needed, which is true if any of the following conditions are true:

- Performance Schema digest instrumentation is enabled
- MySQL Enterprise Firewall is enabled

The `max_digest_length` system variable value determines the maximum number of bytes available per session for computation of normalized statement digests. Once that amount of space is used during digest computation, truncation occurs: no further tokens from a parsed statement are collected or figure into its digest value. Statements that differ only after that many bytes of parsed tokens produce the same normalized statement digest and are considered identical if compared or if aggregated for digest statistics.

**Warning**

Setting the `max_digest_length` system variable to zero disables digest production, which also disables server functionality that requires digests.

After the normalized statement has been computed, an MD5 hash value is computed from it. In addition:

- If MySQL Enterprise Firewall is enabled, it is called and the digest as computed is available to it.
- If the Performance Schema has digest instrumentation enabled, it makes a copy of the normalized statement digest, allocating a maximum of `performance_schema_max_digest_length` bytes for it. Consequently, if `performance_schema_max_digest_length` is less than `max_digest_length`, the copy is truncated relative to the original. The copy of the normalized statement digest is stored in the appropriate Performance Schema tables, along with the MD5 hash value computed from the original normalized statement. (If the Performance Schema truncates its copy of the normalized statement digest relative to the original, it does not recompute the MD5 hash value.)

In MySQL 5.6.24 and 5.6.25, `performance_schema_max_digest_length` is not available and `max_digest_length` applies to all digest computation. Before MySQL 5.6.24, neither `max_digest_length` nor `performance_schema_max_digest_length` are available and a fixed maximum of 1024 bytes applies to all digest computation.

Statement normalization transforms the statement text to a more standardized digest string representation that preserves the general statement structure while removing information not essential to the structure:

- Object identifiers such as database and table names are preserved.
- Literal values are converted to parameter markers. A normalized statement does not retain information such as names, passwords, dates, and so forth.
- Comments are removed and whitespace is adjusted.
Consider these statements:

<table>
<thead>
<tr>
<th>SQL Statement</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>SELECT * FROM orders WHERE customer_id=10 AND quantity&gt;20</code></td>
</tr>
<tr>
<td><code>SELECT * FROM orders WHERE customer_id = 20 AND quantity &gt; 100</code></td>
</tr>
</tbody>
</table>

To normalize these statements, the parser replaces data values by `?` and adjusts whitespace. Both statements yield the same normalized form and thus are considered “the same”:

<table>
<thead>
<tr>
<th>SQL Statement</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>SELECT * FROM orders WHERE customer_id = ? AND quantity &gt; ?</code></td>
</tr>
</tbody>
</table>

The normalized statement contains less information but is still representative of the original statement. Other similar statements that have different data values have the same normalized form.

Now consider these statements:

<table>
<thead>
<tr>
<th>SQL Statement</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>SELECT * FROM customers WHERE customer_id = 1000</code></td>
</tr>
<tr>
<td><code>SELECT * FROM orders WHERE customer_id = 1000</code></td>
</tr>
</tbody>
</table>

In this case, the normalized statements differ because the object identifiers differ:

<table>
<thead>
<tr>
<th>SQL Statement</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>SELECT * FROM customers WHERE customer_id = ?</code></td>
</tr>
<tr>
<td><code>SELECT * FROM orders WHERE customer_id = ?</code></td>
</tr>
</tbody>
</table>

If normalization produces a statement that exceeds the space available in the digest buffer (as determined by `max_digest_length`), truncation occurs and the text ends with “...”. Long normalized statements that differ only in the part that occurs following the “...” are considered the same. Consider these statements:

<table>
<thead>
<tr>
<th>SQL Statement</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>SELECT * FROM mytable WHERE cola = 10 AND colb = 20</code></td>
</tr>
<tr>
<td><code>SELECT * FROM mytable WHERE cola = 10 AND colc = 20</code></td>
</tr>
</tbody>
</table>

If the cutoff happens to be right after the `AND`, both statements have this normalized form:

<table>
<thead>
<tr>
<th>SQL Statement</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>SELECT * FROM mytable WHERE cola = ? AND ...</code></td>
</tr>
</tbody>
</table>

In this case, the difference in the second column name is lost and both statements are considered the same.

**Statement Digests in the Performance Schema**

In the Performance Schema, statement digesting involves these elements:

- A `statements_digest` consumer in the `setup_consumers` table controls whether the Performance Schema maintains digest information. See `Statement Digest Consumer`.

- The statement event tables (`events_statements_current`, `events_statements_history`, and `events_statements_history_long`) have columns for storing normalized statement digests and the corresponding digest MD5 hash values:
  - `DIGEST_TEXT` is the text of the normalized statement digest. This is a copy of the original normalized statement that was computed to a maximum of `max_digest_length` bytes, further truncated as necessary to `performance_schema_max_digest_length` bytes.
  - `DIGEST` is the digest MD5 hash value computed from the original normalized statement.

See `Section 22.12.6, “Performance Schema Statement Event Tables”`.

- The `events_statements_summary_by_digest` summary table provides aggregated statement digest information. This table aggregates information for statements per `SCHEMA_NAME` and `DIGEST`
The Performance Schema uses MD5 hash values for aggregation because they are fast to compute and have a favorable statistical distribution that minimizes collisions. See Section 22.12.9.3, “Statement Summary Tables”.

The statement event tables also have an SQL column that contains the original SQL statement. The maximum space available for statement display is 1024 bytes.

The performance_schema_max_digest_length system variable determines the maximum number of bytes available per statement for digest value storage in the Performance Schema. However, the display length of statement digests may be longer than the available buffer size due to internal encoding of statement elements such as keywords and literal values. Consequently, values selected from the DIGEST column of statement event tables may appear to exceed the performance_schema_max_digest_length value.

The events_statements_summary_by_digest summary table provides a profile of the statements executed by the server. It shows what kinds of statements an application is executing and how often. An application developer can use this information together with other information in the table to assess the application’s performance characteristics. For example, table columns that show wait times, lock times, or index use may highlight types of queries that are inefficient. This gives the developer insight into which parts of the application need attention.

The events_statements_summary_by_digest summary table has a fixed size. By default the Performance Schema estimates the size to use at startup. To specify the table size explicitly, set the performance_schema_digests_size system variable at server startup. If the table becomes full, the Performance Schema groups statements that have SCHEMA_NAME and DIGEST values not matching existing values in the table in a special row with SCHEMA_NAME and DIGEST set to NULL. This permits all statements to be counted. However, if the special row accounts for a significant percentage of the statements executed, it might be desirable to increase the summary table size by increasing performance_schema_digests_size.

Statement Digest Memory Use

For applications that generate very long statements that differ only at the end, increasing max_digest_length enables computation of digests that distinguish statements that would otherwise aggregate to the same digest. Conversely, decreasing max_digest_length causes the server to devote less memory to digest storage but increases the likelihood of longer statements aggregating to the same digest. Administrators should keep in mind that larger values result in correspondingly increased memory requirements, particularly for workloads that involve large numbers of simultaneous sessions (the server allocates max_digest_length bytes per session).

As described previously, normalized statement digests as computed by the parser are constrained to a maximum of max_digest_length bytes, whereas normalized statement digests stored in the Performance Schema use performance_schema_max_digest_length bytes. The following memory-use considerations apply regarding the relative values of max_digest_length and performance_schema_max_digest_length:

- If max_digest_length is less than performance_schema_max_digest_length:
  - Server components other than the Performance Schema use normalized statement digests that take up to max_digest_length bytes.
  - The Performance Schema does not further truncate normalized statement digests that it stores, but allocates more memory than max_digest_length bytes per digest, which is unnecessary.

- If max_digest_length equals performance_schema_max_digest_length:
• Server components other than the Performance Schema use normalized statement digests that take up to \texttt{max\_digest\_length} bytes.

• The Performance Schema does not further truncate normalized statement digests that it stores, and allocates the same amount of memory as \texttt{max\_digest\_length} bytes per digest.

• If \texttt{max\_digest\_length} is greater than \texttt{performance\_schema\_max\_digest\_length}:
  • Server components other than the Performance Schema use normalized statement digests that take up to \texttt{max\_digest\_length} bytes.
  • The Performance Schema further truncates normalized statement digests that it stores, and allocates less memory than \texttt{max\_digest\_length} bytes per digest.

Because the Performance Schema statement event tables might store many digests, setting \texttt{performance\_schema\_max\_digest\_length} smaller than \texttt{max\_digest\_length} enables administrators to balance these factors:

• The need to have long normalized statement digests available for server components outside the Performance Schema

• Many concurrent sessions, each of which allocates digest-computation memory

• The need to limit memory consumption by the Performance Schema statement event tables when storing many statement digests

The \texttt{performance\_schema\_max\_digest\_length} setting is not per session, it is per statement, and a session can store multiple statements in the \texttt{events\_statements\_history} table. A typical number of statements in this table is 10 per session, so each session consumes 10 times the memory indicated by the \texttt{performance\_schema\_max\_digest\_length} value, for this table alone.

There are also many statements (and digests) collected globally, most notably in the \texttt{events\_statements\_history\_long} table. Here, too, \( N \) statements stored consume \( N \) times the memory indicated by the \texttt{performance\_schema\_max\_digest\_length} value.

### 22.11 Performance Schema General Table Characteristics

The name of the \texttt{performance\_schema} database is lowercase, as are the names of tables within it. Queries should specify the names in lowercase.

Many tables in the \texttt{performance\_schema} database are read only and cannot be modified:

```
mysql> TRUNCATE TABLE performance_schema.setup_instruments;
ERROR 1683 (HY000): Invalid performance_schema usage.
```

Some of the setup tables have columns that can be modified to affect Performance Schema operation; some also permit rows to be inserted or deleted. Truncation is permitted to clear collected events, so \texttt{TRUNCATE TABLE} can be used on tables containing those kinds of information, such as tables named with a prefix of \texttt{events\_waits\_}.

Summary tables can be truncated with \texttt{TRUNCATE TABLE}. Generally, the effect is to reset the summary columns to 0 or \texttt{NULL}, not to remove rows. This enables you to clear collected values and restart aggregation. That might be useful, for example, after you have made a runtime configuration change. Exceptions to this truncation behavior are noted in individual summary table sections.

Privileges are as for other databases and tables:
• To retrieve from `performance_schema` tables, you must have the `SELECT` privilege.

• To change those columns that can be modified, you must have the `UPDATE` privilege.

• To truncate tables that can be truncated, you must have the `DROP` privilege.

Because only a limited set of privileges apply to Performance Schema tables, attempts to use `GRANT ALL` as shorthand for granting privileges at the database or table level fail with an error:

```sql
mysql> GRANT ALL ON performance_schema.*
    TO 'u1'@'localhost';
ERROR 1044 (42000): Access denied for user 'root'@'localhost'

mysql> GRANT ALL ON performance_schema.setup_instruments
    TO 'u2'@'localhost';
ERROR 1044 (42000): Access denied for user 'root'@'localhost'
```

Instead, grant exactly the desired privileges:

```sql
mysql> GRANT SELECT ON performance_schema.*
    TO 'u1'@'localhost';
Query OK, 0 rows affected (0.03 sec)

mysql> GRANT SELECT, UPDATE ON performance_schema.setup_instruments
    TO 'u2'@'localhost';
Query OK, 0 rows affected (0.02 sec)
```

### 22.12 Performance Schema Table Descriptions

Tables in the `performance_schema` database can be grouped as follows:

• Setup tables. These tables are used to configure and display monitoring characteristics.

• Current events tables. The `events_waits_current` table contains the most recent event for each thread. Other similar tables contain current events at different levels of the event hierarchy: `events_stages_current` for stage events, and `events_statements_current` for statement events.

• History tables. These tables have the same structure as the current events tables, but contain more rows. For example, for wait events, `events_waits_history` table contains the most recent 10 events per thread. `events_waits_history_long` contains the most recent 10,000 events. Other similar tables exist for stage and statement histories.

To change the sizes of the history tables, set the appropriate system variables at server startup. For example, to set the sizes of the wait event history tables, set `performance_schema_events_waits_history_size` and `performance_schema_events_waits_history_long_size`.

• Summary tables. These tables contain information aggregated over groups of events, including those that have been discarded from the history tables.

• Instance tables. These tables document what types of objects are instrumented. An instrumented object, when used by the server, produces an event. These tables provide event names and explanatory notes or status information.

• Miscellaneous tables. These do not fall into any of the other table groups.

### 22.12.1 Performance Schema Table Reference
The following table summarizes all available Performance Schema tables. For greater detail, see the individual table descriptions.

### Table 22.1 Performance Schema Tables

<table>
<thead>
<tr>

### 22.12.2 Performance Schema Setup Tables

The setup tables provide information about the current instrumentation and enable the monitoring configuration to be changed. For this reason, some columns in these tables can be changed if you have the `UPDATE` privilege.

The use of tables rather than individual variables for setup information provides a high degree of flexibility in modifying Performance Schema configuration. For example, you can use a single statement with standard SQL syntax to make multiple simultaneous configuration changes.

These setup tables are available:

- **setup_actors**: How to initialize monitoring for new foreground threads
- **setup_consumers**: The destinations to which event information can be sent and stored
- **setup_instruments**: The classes of instrumented objects for which events can be collected
- **setup_objects**: Which objects should be monitored
- **setup_timers**: The current event timer

### 22.12.2.1 The setup_actors Table

The `setup_actors` table contains information that determines whether to enable monitoring for new foreground server threads (threads associated with client connections). This table has a maximum size of 100 rows by default. To change the table size, modify the `performance_schema_setup_actors_size` system variable at server startup.
For each new foreground thread, the Performance Schema matches the user and host for the thread against the rows of the `setup_actors` table. If a row from that table matches, its `ENABLED` column value is used to set the `INSTRUMENTED` column of the `threads` table row for the thread. This enables instrumenting to be applied selectively per host, user, or account (user and host combination). If there is no match, the `INSTRUMENTED` column for the thread is set to `NO`.

For background threads, there is no associated user. `INSTRUMENTED` is `YES` by default and `setup_actors` is not consulted.

The initial contents of the `setup_actors` table match any user and host combination, so monitoring is enabled by default for all foreground threads:

```
mymysql> SELECT * FROM performance_schema.setup_actors;
+-------+-------+-------+
| HOST  | USER  | ROLE  |
| %     | %     | %     |
+-------+-------+-------+
```

For information about how to use the `setup_actors` table to affect event monitoring, see Section 22.4.6, “Pre-Filtering by Thread”.

Modifications to the `setup_actors` table affect only foreground threads created subsequent to the modification, not existing threads. To affect existing threads, modify the `INSTRUMENTED` column of `threads` table rows.

The `setup_actors` table has these columns:

- **HOST**
  - The host name. This should be a literal name, or '%' to mean “any host.”

- **USER**
  - The user name. This should be a literal name, or '%', to mean “any user.”

- **ROLE**
  - Unused.

`TRUNCATE TABLE` is permitted for the `setup_actors` table. It removes the rows.

### 22.12.2.2 The `setup_consumers` Table

The `setup_consumers` table lists the types of consumers for which event information can be stored and which are enabled:

```
mymysql> SELECT * FROM performance_schema.setup_consumers;
+-----------------+-------+
| NAME            | ENABLED |
+-----------------+-------+
| events_stages_current | NO     |
| events_stages_history  | NO     |
| events_stages_history_long | NO     |
| events_statements_current | YES    |
| events_statements_history | NO     |
| events_statements_history_long | NO     |
| events_waits_current  | NO     |
| events_waits_history  | NO     |
| events_waits_history_long | NO     |
| global_instrumentation | YES    |
```

3391
### Performance Schema Setup Tables

<table>
<thead>
<tr>
<th>thread_instrumentation</th>
<th>YES</th>
</tr>
</thead>
<tbody>
<tr>
<td>statements_digest</td>
<td>YES</td>
</tr>
</tbody>
</table>

The consumer settings in the `setup_consumers` table form a hierarchy from higher levels to lower. For detailed information about the effect of enabling different consumers, see Section 22.4.7, "Pre-Filtering by Consumer".

Modifications to the `setup_consumers` table affect monitoring immediately.

The `setup_consumers` table has these columns:

- **NAME**
  - The consumer name.

- **ENABLED**
  - Whether the consumer is enabled. The value is **YES** or **NO**. This column can be modified. If you disable a consumer, the server does not spend time adding event information to it.

**TRUNCATE TABLE** is not permitted for the `setup_consumers` table.

#### 22.12.2.3 The setup_instruments Table

The `setup_instruments` table lists classes of instrumented objects for which events can be collected:

```sql
mysql> SELECT * FROM performance_schema.setup_instruments;
```

<table>
<thead>
<tr>
<th>NAME</th>
<th>ENABLED</th>
<th>TIMED</th>
</tr>
</thead>
<tbody>
<tr>
<td>stage/sql/end</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>stage/sql/executing</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>stage/sql/init</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>stage/sql/insert</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>

</tr>
<tr>
<td>wait/synch/mutex/sql/LOCK_lock_db</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>wait/synch/mutex/sql/LOCK_manager</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>wait/synch/rwlock/sql/LOCK_grant</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>wait/synch/rwlock/sql/LOGGER::LOCK_logger</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>wait/synch/rwlock/sql/LOCK_sys_init_connect</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>wait/synch/rwlock/sql/LOCK_sys_init_slave</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>wait/io/file/sql/binlog</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>wait/io/file/sql/binlog_index</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>wait/io/file/sql/casetest</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>wait/io/file/sql/casemanager</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>wait/io/file/sql/dbopt</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
<td>...</td>
</tr>
</tbody>
</table>
```

Each instrument added to the source code provides a row for the `setup_instruments` table, even when the instrumented code is not executed. When an instrument is enabled and executed, instrumented instances are created, which are visible in the `xxx_instances` tables, such as `file_instances` or `rwlock_instances`.
Performance Schema Setup Tables

Modifications to most setup_instruments rows affect monitoring immediately. For some instruments, modifications are effective only at server startup; changing them at runtime has no effect. This affects primarily mutexes, conditions, and rwlocks in the server, although there may be other instruments for which this is true.

For more information about the role of the setup_instruments table in event filtering, see Section 22.4.3, “Event Pre-Filtering”.

The setup_instruments table has these columns:

- **NAME**
  The instrument name. Instrument names may have multiple parts and form a hierarchy, as discussed in Section 22.6, “Performance Schema Instrument Naming Conventions”. Events produced from execution of an instrument have an EVENT_NAME value that is taken from the instrument NAME value. (Events do not really have a “name,” but this provides a way to associate events with instruments.)

- **ENABLED**
  Whether the instrument is enabled. The value is YES or NO. A disabled instrument produces no events. This column can be modified, although setting ENABLED has no effect for instruments that have already been created.

- **TIMED**
  Whether the instrument is timed. The value is YES or NO. This column can be modified, although setting TIMED has no effect for instruments that have already been created.

  If an enabled instrument is not timed, the instrument code is enabled, but the timer is not. Events produced by the instrument have NULL for the TIMER_START, TIMER_END, and TIMER_WAIT timer values. This in turn causes those values to be ignored when calculating the sum, minimum, maximum, and average time values in summary tables.

TRUNCATE TABLE is not permitted for the setup_instruments table.

### 22.12.2.4 The setup_objects Table

The setup_objects table controls whether the Performance Schema monitors particular objects. This table has a maximum size of 100 rows by default. To change the table size, modify the performance_schema_setup_objects_size system variable at server startup.

The initial setup_objects contents look like this:

```
mysql> SELECT * FROM performance_schema.setup_objects;
```

```
+-------------+---------------------+-------------+---------+-------+
<table>
<thead>
<tr>
<th>OBJECT_TYPE</th>
<th>OBJECT_SCHEMA</th>
<th>OBJECT_NAME</th>
<th>ENABLED</th>
<th>TIMED</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLE</td>
<td>mysql</td>
<td>%</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>TABLE</td>
<td>performance_schema</td>
<td>%</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>TABLE</td>
<td>information_schema</td>
<td>%</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>TABLE</td>
<td>%</td>
<td>%</td>
<td>YES</td>
<td>YES</td>
</tr>
</tbody>
</table>
+-------------+---------------------+-------------+---------+-------+
```

Modifications to the setup_objects table affect object monitoring immediately.

For object types listed in setup_objects, the Performance Schema uses the table to how to monitor them. Object matching is based on the OBJECT_SCHEMA and OBJECT_NAME columns. Objects for which there is no match are not monitored.
Performance Schema Setup Tables

The effect of the default object configuration is to instrument all tables except those in the mysql, INFORMATION_SCHEMA, and performance_schema databases. (Tables in the INFORMATION_SCHEMA database are not instrumented regardless of the contents of setup_objects; the row for information_schema.% simply makes this default explicit.)

When the Performance Schema checks for a match in setup_objects, it tries to find more specific matches first. For example, with a table `db1.t1`, it looks for a match for 'db1' and 't1', then for 'db1' and '%', then for '%' and '%'. The order in which matching occurs matters because different matching setup_objects rows can have different ENABLED and TIMED values.

Rows can be inserted into or deleted from setup_objects by users with the INSERT or DELETE privilege on the table. For existing rows, only the ENABLED and TIMED columns can be modified, by users with the UPDATE privilege on the table.

For more information about the role of the setup_objects table in event filtering, see Section 22.4.3, “Event Pre-Filtering”.

The setup_objects table has these columns:

- **OBJECT_TYPE**
  The type of object to instrument. This is always 'TABLE' (base table).
  TABLE filtering affects table I/O events (wait/io/table/sql/handler instrument) and table lock events (wait/lock/table/sql/handler instrument).

- **OBJECT_SCHEMA**
  The schema that contains the object. This should be a literal name, or '%' to mean “any schema.”

- **OBJECT_NAME**
  The name of the instrumented object. This should be a literal name, or '%' to mean “any object.”

- **ENABLED**
  Whether events for the object are instrumented. The value is YES or NO. This column can be modified.

- **TIMED**
  Whether events for the object are timed. The value is YES or NO. This column can be modified.

TRUNCATE TABLE is permitted for the setup_objects table. It removes the rows.

### 22.12.2.5 The setup_timers Table

The setup_timers table shows the currently selected event timers:

```
mysql> SELECT * FROM performance_schema.setup_timers;
+-----------+-------------+
| NAME      | TIMER_NAME  |
+-----------+-------------+
| idle      | MICROSECOND |
| wait      | CYCLE       |
| stage     | NANOSECOND  |
| statement | NANOSECOND  |
+-----------+-------------+
```

The setup_timers.TIMER_NAME value can be changed to select a different timer. The value can be any of the values in the performance_timers.TIMER_NAME column. For an explanation of how event timing occurs, see Section 22.4.1, “Performance Schema Event Timing”.
Modifications to the `setup_timers` table affect monitoring immediately. Events already in progress may use the original timer for the begin time and the new timer for the end time. To avoid unpredictable results after you make timer changes, use `TRUNCATE TABLE` to reset Performance Schema statistics.

The `setup_timers` table has these columns:

- **NAME**
  The type of instrument the timer is used for.

- **TIMER_NAME**
  The timer that applies to the instrument type. This column can be modified.

`TRUNCATE TABLE` is not permitted for the `setup_timers` table.

### 22.12.3 Performance Schema Instance Tables

Instance tables document what types of objects are instrumented. They provide event names and explanatory notes or status information:

- **cond_instances**: Condition synchronization object instances
- **file_instances**: File instances
- **mutex_instances**: Mutex synchronization object instances
- **rwlock_instances**: Lock synchronization object instances
- **socket_instances**: Active connection instances

These tables list instrumented synchronization objects, files, and connections. There are three types of synchronization objects: `cond`, `mutex`, and `rwlock`. Each instance table has an `EVENT_NAME` or `NAME` column to indicate the instrument associated with each row. Instrument names may have multiple parts and form a hierarchy, as discussed in Section 22.6, “Performance Schema Instrument Naming Conventions”.

The `mutex_instances.LOCKED_BY_THREAD_ID` and `rwlock_instances.WRITE_LOCKED_BY_THREAD_ID` columns are extremely important for investigating performance bottlenecks or deadlocks. For examples of how to use them for this purpose, see Section 22.18, “Using the Performance Schema to Diagnose Problems”

#### 22.12.3.1 The cond_instances Table

The `cond_instances` table lists all the conditions seen by the Performance Schema while the server executes. A condition is a synchronization mechanism used in the code to signal that a specific event has happened, so that a thread waiting for this condition can resume work.

When a thread is waiting for something to happen, the condition name is an indication of what the thread is waiting for, but there is no immediate way to tell which other threads cause the condition to happen.

The `cond_instances` table has these columns:

- **NAME**
  The instrument name associated with the condition.

- **OBJECT_INSTANCE_BEGIN**
  The address in memory of the instrumented condition.
TRUNCATE TABLE is not permitted for the cond_instances table.

22.12.3.2 The file_instances Table

The file_instances table lists all the files seen by the Performance Schema when executing file I/O instrumentation. If a file on disk has never been opened, it is not listed in file_instances. When a file is deleted from the disk, it is also removed from the file_instances table.

The file_instances table has these columns:

- **FILE_NAME**
  The file name.

- **EVENT_NAME**
  The instrument name associated with the file.

- **OPEN_COUNT**
  The count of open handles on the file. If a file was opened and then closed, it was opened 1 time, but OPEN_COUNT is 0. To list all the files currently opened by the server, use WHERE OPEN_COUNT > 0.

TRUNCATE TABLE is not permitted for the file_instances table.

22.12.3.3 The mutex_instances Table

The mutex_instances table lists all the mutexes seen by the Performance Schema while the server executes. A mutex is a synchronization mechanism used in the code to enforce that only one thread at a given time can have access to some common resource. The resource is said to be “protected” by the mutex.

When two threads executing in the server (for example, two user sessions executing a query simultaneously) do need to access the same resource (a file, a buffer, or some piece of data), these two threads compete against each other, so that the first query to obtain a lock on the mutex causes the other query to wait until the first is done and unlocks the mutex.

The work performed while holding a mutex is said to be in a “critical section,” and multiple queries do execute this critical section in a serialized way (one at a time), which is a potential bottleneck.

The mutex_instances table has these columns:

- **NAME**
  The instrument name associated with the mutex.

- **OBJECT_INSTANCE_BEGIN**
  The address in memory of the instrumented mutex.

- **LOCKED_BY_THREAD_ID**
  When a thread currently has a mutex locked, LOCKED_BY_THREAD_ID is the THREAD_ID of the locking thread, otherwise it is NULL.

TRUNCATE TABLE is not permitted for the mutex_instances table.

For every mutex instrumented in the code, the Performance Schema provides the following information.
• The `setup_instruments` table lists the name of the instrumentation point, with the prefix `wait/synch/mutex/`.

• When some code creates a mutex, a row is added to the `mutex_instances` table. The `OBJECT_INSTANCE_BEGIN` column is a property that uniquely identifies the mutex.

• When a thread attempts to lock a mutex, the `events_waits_current` table shows a row for that thread, indicating that it is waiting on a mutex (in the `EVENT_NAME` column), and indicating which mutex is waited on (in the `OBJECT_INSTANCE_BEGIN` column).

• When a thread succeeds in locking a mutex:
  - `events_waits_current` shows that the wait on the mutex is completed (in the `TIMER_END` and `TIMER_WAIT` columns)
  - The completed wait event is added to the `events_waits_history` and `events_waits_history_long` tables
  - `mutex_instances` shows that the mutex is now owned by the thread (in the `THREAD_ID` column).

• When a thread unlocks a mutex, `mutex_instances` shows that the mutex now has no owner (the `THREAD_ID` column is NULL).

• When a mutex object is destroyed, the corresponding row is removed from `mutex_instances`.

By performing queries on both of the following tables, a monitoring application or a DBA can detect bottlenecks or deadlocks between threads that involve mutexes:

• `events_waits_current`, to see what mutex a thread is waiting for

• `mutex_instances`, to see which other thread currently owns a mutex

### 22.12.3.4 The `rwlock_instances` Table

The `rwlock_instances` table lists all the `rwlock` instances (read write locks) seen by the Performance Schema while the server executes. An `rwlock` is a synchronization mechanism used in the code to enforce that threads at a given time can have access to some common resource following certain rules. The resource is said to be “protected” by the `rwlock`. The access is either shared (many threads can have a read lock at the same time) or exclusive (only one thread can have a write lock at a given time).

Depending on how many threads are requesting a lock, and the nature of the locks requested, access can be either granted in shared mode, granted in exclusive mode, or not granted at all, waiting for other threads to finish first.

The `rwlock_instances` table has these columns:

• `NAME`  
The instrument name associated with the lock.

• `OBJECT_INSTANCE_BEGIN`  
The address in memory of the instrumented lock.

• `WRITE_LOCKED_BY_THREAD_ID`  
  When a thread currently has an `rwlock` locked in exclusive (write) mode,  
  `WRITE_LOCKED_BY_THREAD_ID` is the `THREAD_ID` of the locking thread, otherwise it is NULL.

• `READ_LOCKED_BY_COUNT`
When a thread currently has an \texttt{rwlock} locked in shared (read) mode, \texttt{READ_LOCKED_BY_COUNT} is incremented by 1. This is a counter only, so it cannot be used directly to find which thread holds a read lock, but it can be used to see whether there is a read contention on an \texttt{rwlock}, and see how many readers are currently active.

\texttt{TRUNCATE TABLE} is not permitted for the \texttt{rwlock_instances} table.

By performing queries on both of the following tables, a monitoring application or a DBA may detect some bottlenecks or deadlocks between threads that involve locks:

- \texttt{events_waits_current}, to see what \texttt{rwlock} a thread is waiting for
- \texttt{rwlock_instances}, to see which other thread currently owns an \texttt{rwlock}

There is a limitation: The \texttt{rwlock_instances} can be used only to identify the thread holding a write lock, but not the threads holding a read lock.

### 22.12.3.5 The socket_instances Table

The \texttt{socket_instances} table provides a real-time snapshot of the active connections to the MySQL server. The table contains one row per TCP/IP or Unix socket file connection. Information available in this table provides a real-time snapshot of the active connections to the server. (Additional information is available in socket summary tables, including network activity such as socket operations and number of bytes transmitted and received; see Section 22.12.9.7, “Socket Summary Tables”).

```sql
mysql> SELECT * FROM performance_schema.socket_instances\G
```

```
*************************** 1. row ***************************
EVENT_NAME: wait/io/socket/sql/server_unix_socket
OBJECT_INSTANCE_BEGIN: 4316619408
THREAD_ID: 1
SOCKET_ID: 16
IP: 
PORT: 0
STATE: ACTIVE
*************************** 2. row ***************
EVENT_NAME: wait/io/socket/sql/client_connection
OBJECT_INSTANCE_BEGIN: 4316644608
THREAD_ID: 21
SOCKET_ID: 39
IP: 127.0.0.1
PORT: 55233
STATE: ACTIVE
*************************** 3. row ***************
EVENT_NAME: wait/io/socket/sql/server_tcpip_socket
OBJECT_INSTANCE_BEGIN: 4316699040
THREAD_ID: 1
SOCKET_ID: 14
IP: 0.0.0.0
PORT: 50603
STATE: ACTIVE
```

Socket instruments have names of the form \texttt{wait/io/socket/sql/socket_type} and are used like this:

1. The server has a listening socket for each network protocol that it supports. The instruments associated with listening sockets for TCP/IP or Unix socket file connections have a \texttt{socket_type} value of \texttt{server_tcpip_socket} or \texttt{server_unix_socket}, respectively.

2. When a listening socket detects a connection, the server transfers the connection to a new socket managed by a separate thread. The instrument for the new connection thread has a \texttt{socket_type} value of \texttt{client_connection}.  

3398
3. When a connection terminates, the row in `socket_instances` corresponding to it is deleted.

The `socket_instances` table has these columns:

- **EVENT_NAME**
  The name of the `wait/io/socket/*` instrument that produced the event. This is a `NAME` value from the `setup_instruments` table. Instrument names may have multiple parts and form a hierarchy, as discussed in Section 22.6, “Performance Schema Instrument Naming Conventions”.

- **OBJECT_INSTANCE_BEGIN**
  This column uniquely identifies the socket. The value is the address of an object in memory.

- **THREAD_ID**
  The internal thread identifier assigned by the server. Each socket is managed by a single thread, so each socket can be mapped to a thread which can be mapped to a server process.

- **SOCKET_ID**
  The internal file handle assigned to the socket.

- **IP**
  The client IP address. The value may be either an IPv4 or IPv6 address, or blank to indicate a Unix socket file connection.

- **PORT**
  The TCP/IP port number, in the range from 0 to 65535.

- **STATE**
  The socket status, either IDLE or ACTIVE. Wait times for active sockets are tracked using the corresponding socket instrument. Wait times for idle sockets are tracked using the `idle` instrument.

A socket is idle if it is waiting for a request from the client. When a socket becomes idle, the event row in `socket_instances` that is tracking the socket switches from a status of ACTIVE to IDLE. The `EVENT_NAME` value remains `wait/io/socket/*`, but timing for the instrument is suspended. Instead, an event is generated in the `events_waits_current` table with an `EVENT_NAME` value of `idle`.

When the next request is received, the `idle` event terminates, the socket instance switches from IDLE to ACTIVE, and timing of the socket instrument resumes.

**TRUNCATE TABLE** is not permitted for the `socket_instances` table.

The `IP:PORT` column combination value identifies the connection. This combination value is used in the `OBJECT_NAME` column of the `events_waits_xxx` tables, to identify the connection from which socket events come:

- For the Unix domain listener socket (`server_unix_socket`), the port is 0, and the IP is `''.
- For client connections via the Unix domain listener (`client_connection`), the port is 0, and the IP is `''.
- For the TCP/IP server listener socket (`server_tcpip_socket`), the port is always the master port (for example, 3306), and the IP is always `0.0.0.0`. 

3399
• For client connections via the TCP/IP listener (`client_connection`), the port is whatever the server assigns, but never 0. The IP is the IP of the originating host (127.0.0.1 or ::1 for the local host)

### 22.12.4 Performance Schema Wait Event Tables

The Performance Schema instruments waits, which are events that take time. Within the event hierarchy, wait events nest within stage events, which nest within statement events.

These tables store wait events:

- **events_waits_current**: The current wait event for each thread.
- **events_waits_history**: The most recent wait events that have ended per thread.
- **events_waits_history_long**: The most recent wait events that have ended globally (across all threads).

The following sections describe the wait event tables. There are also summary tables that aggregate information about wait events; see Section 22.12.9.1, “Wait Event Summary Tables”.

For more information about the relationship between the three wait event tables, see Section 22.9, “Performance Schema Tables for Current and Historical Events”.

### Configuring Wait Event Collection

To control whether to collect wait events, set the state of the relevant instruments and consumers:

- The `setup_instruments` table contains instruments with names that begin with `wait`. Use these instruments to enable or disable collection of individual wait event classes.
- The `setup_consumers` table contains consumer values with names corresponding to the current and historical wait event table names. Use these consumers to filter collection of wait events.

Some wait instruments are enabled by default; others are disabled. For example:

```sql
mysql> SELECT * FROM performance_schema.setup_instruments
WHERE NAME LIKE 'wait/io/file/innodb%';
+--------------------------------------+---------+-------+
| NAME                                 | ENABLED | TIMED |
+--------------------------------------+---------+-------+
| wait/io/file/innodb/innodb_data_file | YES     | YES   |
| wait/io/file/innodb/innodb_log_file  | YES     | YES   |
| wait/io/file/innodb/innodb_temp_file | YES     | YES   |
+--------------------------------------+---------+-------+
mysql> SELECT * FROM performance_schema.setup_instruments
WHERE NAME LIKE 'wait/io/socket/%';
+----------------------------------------+---------+-------+
| NAME                                   | ENABLED | TIMED |
+----------------------------------------+---------+-------+
| wait/io/socket/sql/server_tcpip_socket | NO      | NO    |
| wait/io/socket/sql/server_unix_socket  | NO      | NO    |
| wait/io/socket/sql/client_connection   | NO      | NO    |
+----------------------------------------+---------+-------+
```

The wait consumers are disabled by default:

```sql
mysql> SELECT * FROM performance_schema.setup_consumers
WHERE NAME LIKE 'events_waits%';
```
To control wait event collection at server startup, use lines like these in your `my.cnf` file:

**Enable:**

```ini
[mysqld]
performance-schema-instrument='wait/%=ON'
performance-schema-consumer-events-waits-current=ON
performance-schema-consumer-events-waits-history=ON
performance-schema-consumer-events-waits-history-long=ON
```

**Disable:**

```ini
[mysqld]
performance-schema-instrument='wait/%=OFF'
performance-schema-consumer-events-waits-current=OFF
performance-schema-consumer-events-waits-history=OFF
performance-schema-consumer-events-waits-history-long=OFF
```

To control wait event collection at runtime, update the `setup_instruments` and `setup_consumers` tables:

**Enable:**

```sql
UPDATE performance_schema.setup_instruments
SET ENABLED = 'YES', TIMED = 'YES'
WHERE NAME LIKE 'wait/%';

UPDATE performance_schema.setup_consumers
SET ENABLED = 'YES'
WHERE NAME LIKE 'events_waits%';
```

**Disable:**

```sql
UPDATE performance_schema.setup_instruments
SET ENABLED = 'NO', TIMED = 'NO'
WHERE NAME LIKE 'wait/%';

UPDATE performance_schema.setup_consumers
SET ENABLED = 'NO'
WHERE NAME LIKE 'events_waits%';
```

To collect only specific wait events, enable only the corresponding wait instruments. To collect wait events only for specific wait event tables, enable the wait instruments but only the wait consumers corresponding to the desired tables.

The `setup_timers` table contains a row with a `NAME` value of `wait` that indicates the unit for wait event timing. The default unit is `CYCLE`:

```sql
mysql> SELECT * FROM performance_schema.setup_timers WHERE NAME = 'wait';
```

```plaintext
+-------+---------------+
<table>
<thead>
<tr>
<th>NAME</th>
<th>TIMER_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>wait</td>
<td>CYCLE</td>
</tr>
</tbody>
</table>
```
Performance Schema Wait Event Tables

To change the timing unit, modify the `TIMER_NAME` value:

```
UPDATE performance_schema.setup_timers
SET TIMER_NAME = 'NANOSECOND'
WHERE NAME = 'wait';
```

For additional information about configuring event collection, see Section 22.3, “Performance Schema Startup Configuration”, and Section 22.4, “Performance Schema Runtime Configuration”.

### 22.12.4.1 The `events_waits_current` Table

The `events_waits_current` table contains current wait events. The table stores one row per thread showing the current status of the thread's most recent monitored wait event, so there is no system variable for configuring the table size.

Of the tables that contain wait event rows, `events_waits_current` is the most fundamental. Other tables that contain wait event rows are logically derived from the current events. For example, the `events_waits_history` and `events_waits_history_long` tables are collections of the most recent wait events that have ended, up to a maximum number of rows per thread and globally across all threads, respectively.

For more information about the relationship between the three wait event tables, see Section 22.9, “Performance Schema Tables for Current and Historical Events”.

For information about configuring whether to collect wait events, see Section 22.12.4, “Performance Schema Wait Event Tables”.

The `events_waits_current` table has these columns:

- **THREAD_ID, EVENT_ID**
  
  The thread associated with the event and the thread current event number when the event starts. The `THREAD_ID` and `EVENT_ID` values taken together uniquely identify the row. No two rows have the same pair of values.

- **END_EVENT_ID**
  
  This column is set to `NULL` when the event starts and updated to the thread current event number when the event ends.

- **EVENT_NAME**
  
  The name of the instrument that produced the event. This is a `NAME` value from the `setup_instruments` table. Instrument names may have multiple parts and form a hierarchy, as discussed in Section 22.6, “Performance Schema Instrument Naming Conventions”.

- **SOURCE**
  
  The name of the source file containing the instrumented code that produced the event and the line number in the file at which the instrumentation occurs. This enables you to check the source to determine exactly what code is involved. For example, if a mutex or lock is being blocked, you can check the context in which this occurs.

- **TIMER_START, TIMER_END, TIMER_WAIT**
  
  Timing information for the event. The unit for these values is picoseconds (trillionths of a second). The `TIMER_START` and `TIMER_END` values indicate when event timing started and ended. `TIMER_WAIT` is the event elapsed time (duration).
If an event has not finished, \texttt{TIMER\_END} and \texttt{TIMER\_WAIT} are \texttt{NULL} before MySQL 5.6.26. As of 5.6.26, \texttt{TIMER\_END} is the current timer value and \texttt{TIMER\_WAIT} is the time elapsed so far (\texttt{TIMER\_END} \texttt{-} \texttt{TIMER\_START}).

If an event is produced from an instrument that has \texttt{TIMED = NO}, timing information is not collected, and \texttt{TIMER\_START}, \texttt{TIMER\_END}, and \texttt{TIMER\_WAIT} are all \texttt{NULL}.

For discussion of picoseconds as the unit for event times and factors that affect time values, see Section 22.4.1, "Performance Schema Event Timing".

• \texttt{SPINS}

For a mutex, the number of spin rounds. If the value is \texttt{NULL}, the code does not use spin rounds or spinning is not instrumented.

• \texttt{OBJECT\_SCHEMA}, \texttt{OBJECT\_NAME}, \texttt{OBJECT\_TYPE}, \texttt{OBJECT\_INSTANCE\_BEGIN}

These columns identify the object "being acted on." What that means depends on the object type.

For a synchronization object (\texttt{cond}, \texttt{mutex}, \texttt{rwlock}):

• \texttt{OBJECT\_SCHEMA}, \texttt{OBJECT\_NAME}, and \texttt{OBJECT\_TYPE} are \texttt{NULL}.

• \texttt{OBJECT\_INSTANCE\_BEGIN} is the address of the synchronization object in memory.

For a file I/O object:

• \texttt{OBJECT\_SCHEMA} is \texttt{NULL}.

• \texttt{OBJECT\_NAME} is the file name.

• \texttt{OBJECT\_TYPE} is \texttt{FILE}.

• \texttt{OBJECT\_INSTANCE\_BEGIN} is an address in memory.

For a socket object:

• \texttt{OBJECT\_NAME} is the \texttt{IP:PORT} value for the socket.

• \texttt{OBJECT\_INSTANCE\_BEGIN} is an address in memory.

For a table I/O object:

• \texttt{OBJECT\_SCHEMA} is the name of the schema that contains the table.

• \texttt{OBJECT\_NAME} is the table name.

• \texttt{OBJECT\_TYPE} is \texttt{TABLE} for a persistent base table or \texttt{TEMPORARY\_TABLE} for a temporary table.

• \texttt{OBJECT\_INSTANCE\_BEGIN} is an address in memory.

An \texttt{OBJECT\_INSTANCE\_BEGIN} value itself has no meaning, except that different values indicate different objects. \texttt{OBJECT\_INSTANCE\_BEGIN} can be used for debugging. For example, it can be used with \texttt{GROUP\_BY\_OBJECT\_INSTANCE\_BEGIN} to see whether the load on 1,000 mutexes (that protect, say, 1,000 pages or blocks of data) is spread evenly or just hitting a few bottlenecks. This can help you correlate with other sources of information if you see the same object address in a log file or another debugging or performance tool.
Performance Schema Wait Event Tables

- **INDEX_NAME**
  The name of the index used. PRIMARY indicates the table primary index. NULL means that no index was used.

- **NESTING_EVENT_ID**
  The EVENT_ID value of the event within which this event is nested.

- **NESTING_EVENT_TYPE**
  The nesting event type. The value is STATEMENT, STAGE, or WAIT.

- **OPERATION**
  The type of operation performed, such as lock, read, or write.

- **NUMBER_OF_BYTES**
  The number of bytes read or written by the operation. For table I/O waits (events for the wait/io/table/sql/handler instrument), NUMBER_OF_BYTES is NULL.

- **FLAGS**
  Reserved for future use.

**TRUNCATE TABLE** is permitted for the events_waits_current table. It removes the rows.

### 22.12.4.2 The events_waits_history Table

The events_waits_history table contains the *N* most recent wait events that have ended per thread. Wait events are not added to the table until they have ended. When the table contains the maximum number of rows for a given thread, the oldest thread row is discarded when a new row for that thread is added. When a thread ends, all its rows are discarded.

The Performance Schema autosizes the value of *N* during server startup. To set the number of rows per thread explicitly, set the performance_schema_events_waits_history_size system variable at server startup.

The events_waits_history table has the same columns as events_waits_current. See Section 22.12.4.1, “The events_waits_current Table”.

**TRUNCATE TABLE** is permitted for the events_waits_history table. It removes the rows.

For more information about the relationship between the three wait event tables, see Section 22.9, “Performance Schema Tables for Current and Historical Events”.

For information about configuring whether to collect wait events, see Section 22.12.4, “Performance Schema Wait Event Tables”.

### 22.12.4.3 The events_waits_history_long Table

The events_waits_history_long table contains *N* the most recent wait events that have ended globally, across all threads. Wait events are not added to the table until they have ended. When the table becomes full, the oldest row is discarded when a new row is added, regardless of which thread generated either row.

The Performance Schema autosizes the value of *N* during server startup. To set the table size explicitly, set the performance_schema_events_waits_history_long_size system variable at server startup.
The `events_waits_history_long` table has the same columns as `events_waits_current`. See Section 22.12.4.1, “The `events_waits_current` Table”.

`TRUNCATE TABLE` is permitted for the `events_waits_history_long` table. It removes the rows.

For more information about the relationship between the three wait event tables, see Section 22.9, “Performance Schema Tables for Current and Historical Events”.

For information about configuring whether to collect wait events, see Section 22.12.4, “Performance Schema Wait Event Tables”.

### 22.12.5 Performance Schema Stage Event Tables

The Performance Schema instruments stages, which are steps during the statement-execution process, such as parsing a statement, opening a table, or performing a `filesort` operation. Stages correspond to the thread states displayed by `SHOW PROCESSLIST` or that are visible in the `INFORMATION_SCHEMA.PROCESSLIST` table. Stages begin and end when state values change.

Within the event hierarchy, wait events nest within stage events, which nest within statement events.

These tables store stage events:

- **events_stages_current**: The current stage event for each thread.
- **events_stages_history**: The most recent stage events that have ended per thread.
- **events_stages_history_long**: The most recent stage events that have ended globally (across all threads).

The following sections describe the stage event tables. There are also summary tables that aggregate information about stage events; see Section 22.12.9.2, “Stage Summary Tables”.

For more information about the relationship between the three stage event tables, see Section 22.9, “Performance Schema Tables for Current and Historical Events”.

#### Configuring Stage Event Collection

To control whether to collect stage events, set the state of the relevant instruments and consumers:

- The `setup_instruments` table contains instruments with names that begin with `stage`. Use these instruments to enable or disable collection of individual stage event classes.

- The `setup_consumers` table contains consumer values with names corresponding to the current and historical stage event table names. Use these consumers to filter collection of stage events.

The stage instruments are disabled by default. For example:

```sql
mysql> SELECT * FROM performance_schema.setup_instruments
WHERE NAME RLIKE 'stage/sql/[a-c]';
+-----------------+---------+-------+
| NAME            | ENABLED | TIMED |
+-----------------+---------+-------+
| stage/sql/After create | NO      | NO    |
| stage/sql/allocating local table | NO      | NO    |
| stage/sql/altering table | NO      | NO    |
| stage/sql/committing alter table to storage engine | NO      | NO    |
| stage/sql/Changing master | NO      | NO    |
| stage/sql/Checking master version | NO      | NO    |
```
Performance Schema Stage Event Tables

<table>
<thead>
<tr>
<th>stage/sql/checking permissions</th>
<th>NO</th>
<th>NO</th>
</tr>
</thead>
<tbody>
<tr>
<td>stage/sql/checking privileges on cached query</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>stage/sql/checking query cache for query</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>stage/sql/cleaning up</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>stage/sql/closing tables</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>stage/sql/Connecting to master</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>stage/sql/converting HEAP to MyISAM</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>stage/sql/Copying to group table</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>stage/sql/Copying to tmp table</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>stage/sql/copy to tmp table</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>stage/sql/Creating delayed handler</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>stage/sql/Creating sort index</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>stage/sql/creating table</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>stage/sql/Creating tmp table</td>
<td>NO</td>
<td>NO</td>
</tr>
</tbody>
</table>

The stage consumers are disabled by default:

```
mysql> SELECT * 
FROM performance_schema.setup_consumers 
WHERE NAME LIKE 'events_stages%';
+----------------------------+---------+
| NAME                       | ENABLED |
+----------------------------+---------+
| events_stages_current      | NO      |
| events_stages_history      | NO      |
| events_stages_history_long | NO      |
+----------------------------+---------+
```

To control stage event collection at server startup, use lines like these in your `my.cnf` file:

- Enable:

  ```
  [mysqld]
  performance-schema-instrument='stage/%=ON'
  performance-schema-consumer-events-stages-current=ON
  performance-schema-consumer-events-stages-history=ON
  performance-schema-consumer-events-stages-history-long=ON
  ```

- Disable:

  ```
  [mysqld]
  performance-schema-instrument='stage/%=OFF'
  performance-schema-consumer-events-stages-current=OFF
  performance-schema-consumer-events-stages-history=OFF
  performance-schema-consumer-events-stages-history-long=OFF
  ```

To control stage event collection at runtime, update the `setup_instruments` and `setup_consumers` tables:

- Enable:

  ```
  UPDATE performance_schema.setup_instruments
  SET ENABLED = 'YES', TIMED = 'YES'
  WHERE NAME LIKE 'stage/%';

  UPDATE performance_schema.setup_consumers
  SET ENABLED = 'YES'
  WHERE NAME LIKE 'events_stages%';
  ```

- Disable:

  ```
  UPDATE performance_schema.setup_instruments
  SET ENABLED = 'NO', TIMED = 'NO'
  WHERE NAME LIKE 'stage/%';
  ```
To collect only specific stage events, enable only the corresponding stage instruments. To collect stage events only for specific stage event tables, enable the stage instruments but only the stage consumers corresponding to the desired tables.

The `setup_timers` table contains a row with a `NAME` value of `stage` that indicates the unit for stage event timing. The default unit is `NANOSECOND`:

```
mysql> SELECT * 
FROM performance_schema.setup_timers 
WHERE NAME = 'stage';
+-------+------------+
<table>
<thead>
<tr>
<th>NAME</th>
<th>TIMER_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>stage</td>
<td>NANOSECOND</td>
</tr>
</tbody>
</table>
+-------+------------+
```

To change the timing unit, modify the `TIMER_NAME` value:

```
UPDATE performance_schema.setup_timers 
SET TIMER_NAME = 'MICROSECOND' 
WHERE NAME = 'stage';
```

For additional information about configuring event collection, see Section 22.3, “Performance Schema Startup Configuration”, and Section 22.4, “Performance Schema Runtime Configuration”.

### 22.12.5.1 The events_stages_current Table

The `events_stages_current` table contains current stage events. The table stores one row per thread showing the current status of the thread’s most recent monitored stage event, so there is no system variable for configuring the table size.

Of the tables that contain stage event rows, `events_stages_current` is the most fundamental. Other tables that contain stage event rows are logically derived from the current events. For example, the `events_stages_history` and `events_stages_history_long` tables are collections of the most recent stage events that have ended, up to a maximum number of rows per thread and globally across all threads, respectively.

For more information about the relationship between the three stage event tables, see Section 22.9, “Performance Schema Tables for Current and Historical Events”.

For information about configuring whether to collect stage events, see Section 22.12.5, “Performance Schema Stage Event Tables”.

The `events_stages_current` table has these columns:

- **THREAD_ID, EVENT_ID**
  - The thread associated with the event and the thread current event number when the event starts. The `THREAD_ID` and `EVENT_ID` values taken together uniquely identify the row. No two rows have the same pair of values.

- **END_EVENT_ID**
  - This column is set to `NULL` when the event starts and updated to the thread current event number when the event ends.

- **EVENT_NAME**
The name of the instrument that produced the event. This is a `NAME` value from the `setup_instruments` table. Instrument names may have multiple parts and form a hierarchy, as discussed in Section 22.6, “Performance Schema Instrument Naming Conventions”.

- **SOURCE**

  The name of the source file containing the instrumented code that produced the event and the line number in the file at which the instrumentation occurs. This enables you to check the source to determine exactly what code is involved.

- **TIMER_START, TIMER_END, TIMER_WAIT**

  Timing information for the event. The unit for these values is picoseconds (trillionths of a second). The `TIMER_START` and `TIMER_END` values indicate when event timing started and ended. `TIMER_WAIT` is the event elapsed time (duration).

  If an event has not finished, `TIMER_END` and `TIMER_WAIT` are `NULL` before MySQL 5.6.26. As of 5.6.26, `TIMER_END` is the current timer value and `TIMER_WAIT` is the time elapsed so far (`TIMER_END - TIMER_START`).

  If an event is produced from an instrument that has `TIMED = NO`, timing information is not collected, and `TIMER_START`, `TIMER_END`, and `TIMER_WAIT` are all `NULL`.

  For discussion of picoseconds as the unit for event times and factors that affect time values, see Section 22.4.1, “Performance Schema Event Timing”.

- **NESTING_EVENT_ID**

  The `EVENT_ID` value of the event within which this event is nested. The nesting event for a stage event is usually a statement event.

- **NESTING_EVENT_TYPE**

  The nesting event type. The value is `STATEMENT`, `STAGE`, or `WAIT`.

  `TRUNCATE TABLE` is permitted for the `events_stages_current` table. It removes the rows.

### 22.12.5.2 The `events_stages_history` Table

The `events_stages_history` table contains the $N$ most recent stage events that have ended per thread. Stage events are not added to the table until they have ended. When the table contains the maximum number of rows for a given thread, the oldest thread row is discarded when a new row for that thread is added. When a thread ends, all its rows are discarded.

The Performance Schema autosizes the value of $N$ during server startup. To set the number of rows per thread explicitly, set the `performance_schema_events_stages_history_size` system variable at server startup.

The `events_stages_history` table has the same columns as `events_stages_current`. See Section 22.12.5.1, “The `events_stages_current` Table”.

`TRUNCATE TABLE` is permitted for the `events_stages_history` table. It removes the rows.

For more information about the relationship between the three stage event tables, see Section 22.9, “Performance Schema Tables for Current and Historical Events”.

For information about configuring whether to collect stage events, see Section 22.12.5, “Performance Schema Stage Event Tables”.
22.12.5.3 The events_stages_history_long Table

The `events_stages_history_long` table contains the $N$ most recent stage events that have ended globally, across all threads. Stage events are not added to the table until they have ended. When the table becomes full, the oldest row is discarded when a new row is added, regardless of which thread generated either row.

The Performance Schema autosizes the value of $N$ during server startup. To set the table size explicitly, set the `performance_schema_events_stages_history_long_size` system variable at server startup.

The `events_stages_history_long` table has the same columns as `events_stages_current`. See Section 22.12.5.1, “The events_stages_current Table”.

`TRUNCATE TABLE` is permitted for the `events_stages_history_long` table. It removes the rows.

For more information about the relationship between the three stage event tables, see Section 22.9, “Performance Schema Tables for Current and Historical Events”.

For information about configuring whether to collect stage events, see Section 22.12.5, “Performance Schema Stage Event Tables”.

22.12.6 Performance Schema Statement Event Tables

The Performance Schema instruments statement execution. Statement events occur at a high level of the event hierarchy: Wait events nest within stage events, which nest within statement events.

These tables store statement events:

- `events_statements_current`: The current statement event for each thread.
- `events_statements_history`: The most recent statement events that have ended per thread.
- `events_statements_history_long`: The most recent statement events that have ended globally (across all threads).

The following sections describe the statement event tables. There are also summary tables that aggregate information about statement events; see Section 22.12.9.3, “Statement Summary Tables”.

For more information about the relationship between the three `events_statements_XXX` event tables, see Section 22.9, “Performance Schema Tables for Current and Historical Events”.

- Configuring Statement Event Collection
- Statement Monitoring

Configuring Statement Event Collection

To control whether to collect statement events, set the state of the relevant instruments and consumers:

- The `setup_instruments` table contains instruments with names that begin with `statement`. Use these instruments to enable or disable collection of individual statement event classes.

- The `setup_consumers` table contains consumer values with names corresponding to the current and historical statement event table names, and the statement digest consumer. Use these consumers to filter collection of statement events and statement digesting.

The statement instruments are enabled by default, and the `events_statements_current` and `statements_digest` statement consumers are enabled by default:
To control statement event collection at server startup, use lines like these in your `my.cnf` file:

**Enable:**
```
[mysqld]
performance-schema-instrument='statement/%=ON'
performance-schema-consumer-events-statements-current=ON
performance-schema-consumer-events-statements-history=ON
performance-schema-consumer-events-statements-history-long=ON
performance-schema-consumer-statements-digest=ON
```

**Disable:**
```
[mysqld]
performance-schema-instrument='statement/%=OFF'
performance-schema-consumer-events-statements-current=OFF
performance-schema-consumer-events-statements-history=OFF
performance-schema-consumer-events-statements-history-long=OFF
performance-schema-consumer-statements-digest=OFF
```

To control statement event collection at runtime, update the `setup_instruments` and `setup_consumers` tables:

**Enable:**
```
UPDATE performance_schema.setup_instruments
SET ENABLED = 'YES', TIMED = 'YES'
WHERE NAME LIKE 'statement/%';
```
```
UPDATE performance_schema.setup_consumers
SET ENABLED = 'YES'
```
WHERE NAME LIKE '%statements%';

- Disable:

    UPDATE performance_schema.setup_instruments
    SET ENABLED = 'NO', TIMED = 'NO'
    WHERE NAME LIKE 'statement/%';

    UPDATE performance_schema.setup_consumers
    SET ENABLED = 'NO'
    WHERE NAME LIKE '%statements%';

To collect only specific statement events, enable only the corresponding statement instruments. To collect
statement events only for specific statement event tables, enable the statement instruments but only the
statement consumers corresponding to the desired tables.

The setup_timers table contains a row with a NAME value of statement that indicates the unit for
statement event timing. The default unit is NANOSECOND:

mysql> SELECT *
    FROM performance_schema.setup_timers
    WHERE NAME = 'statement';

+-----------+------------+
| NAME      | TIMER_NAME |
+-----------+------------+
| statement | NANOSECOND |
+-----------+------------+

To change the timing unit, modify the TIMER_NAME value:

    UPDATE performance_schema.setup_timers
    SET TIMER_NAME = 'MICROSECOND'
    WHERE NAME = 'statement';

For additional information about configuring event collection, see Section 22.3, “Performance Schema
Startup Configuration”, and Section 22.4, “Performance Schema Runtime Configuration”.

Statement Monitoring

Statement monitoring begins from the moment the server sees that activity is requested on a thread, to the
moment when all activity has ceased. Typically, this means from the time the server gets the first packet
from the client to the time the server has finished sending the response. Monitoring occurs only for top-
level statements. Statements within stored programs and subqueries are not seen separately.

When the Performance Schema instruments a request (server command or SQL statement), it uses
instrument names that proceed in stages from more general (or “abstract”) to more specific until it arrives
at a final instrument name.

Final instrument names correspond to server commands and SQL statements:

- Server commands correspond to the COM_XXX codes defined in the mysql_com.h header file
  and processed in sql/sql_parse.cc. Examples are COM_PING and COM.Quit. Instruments for
  commands have names that begin with statement/com, such as statement/com/Ping and
  statement/com/Quit.

- SQL statements are expressed as text, such as DELETE FROM t1 or SELECT * FROM t2.
  Instruments for SQL statements have names that begin with statement/sql, such as statement/
  sql/delete and statement/sql/select.

Some final instrument names are specific to error handling:
Performance Schema Statement Event Tables

- **statement/com>Error** accounts for messages received by the server that are out of band. It can be used to detect commands sent by clients that the server does not understand. This may be helpful for purposes such as identifying clients that are misconfigured or using a version of MySQL more recent than that of the server, or clients that are attempting to attack the server.

- **statement/sql/error** accounts for SQL statements that fail to parse. It can be used to detect malformed queries sent by clients. A query that fails to parse differs from a query that parses but fails due to an error during execution. For example, `SELECT * FROM` is malformed, and the **statement/sql/error** instrument is used. By contrast, `SELECT *` parses but fails with a No tables used error. In this case, **statement/sql/select** is used and the statement event contains information to indicate the nature of the error.

A request can be obtained from any of these sources:

- As a command or statement request from a client, which sends the request as packets
- As a statement string read from the relay log on a replica

The details for a request are not initially known and the Performance Schema proceeds from abstract to specific instrument names in a sequence that depends on the source of the request.

For a request received from a client:

1. When the server detects a new packet at the socket level, a new statement is started with an abstract instrument name of **statement/abstract/new_packet**.

2. When the server reads the packet number, it knows more about the type of request received, and the Performance Schema refines the instrument name. For example, if the request is a **COM_PING** packet, the instrument name becomes **statement/com/Ping** and that is the final name. If the request is a **COM_QUERY** packet, it is known to correspond to an SQL statement but not the particular type of statement. In this case, the instrument changes from one abstract name to a more specific but still abstract name, **statement/abstract/Query**, and the request requires further classification.

3. If the request is a statement, the statement text is read and given to the parser. After parsing, the exact statement type is known. If the request is, for example, an **INSERT** statement, the Performance Schema refines the instrument name from **statement/abstract/Query** to **statement/sql/insert**, which is the final name.

For a request read as a statement from the relay log on a replica:

1. Statements in the relay log are stored as text and are read as such. There is no network protocol, so the **statement/abstract/new_packet** instrument is not used. Instead, the initial instrument is **statement/abstract/relay_log**.

2. When the statement is parsed, the exact statement type is known. If the request is, for example, an **INSERT** statement, the Performance Schema refines the instrument name from **statement/abstract/Query** to **statement/sql/insert**, which is the final name.

The preceding description applies only for statement-based replication. For row-based replication, table I/O done on the replica as it processes row changes can be instrumented, but row events in the relay log do not appear as discrete statements.

For statistics to be collected for statements, it is not sufficient to enable only the final **statement/sql/*** instruments used for individual statement types. The abstract **statement/abstract/*** instruments must be enabled as well. This should not normally be an issue because all statement instruments are enabled by default. However, an application that enables or disables statement instruments selectively must take into account that disabling abstract instruments also disables statistics collection for the individual statement instruments. For example, to collect statistics for **INSERT** statements, **statement/sql/"
**Performance Schema Statement Event Tables**

*insert* must be enabled, but also *statement/abstract/new_packet* and *statement/abstract/Query*. Similarly, for replicated statements to be instrumented, *statement/abstract/relay_log* must be enabled.

No statistics are aggregated for abstract instruments such as *statement/abstract/Query* because no statement is ever classified with an abstract instrument as the final statement name.

The abstract instrument names in the preceding discussion are as of MySQL 5.6.15. In earlier 5.6 versions, there was some renaming before those names were settled on:

- *statement/abstract/new_packet* was *statement/com/new_packet* in MySQL 5.6.13, and *statement/com* before that.
- *statement/abstract/Query* was *statement/com/Query* before MySQL 5.6.15.
- *statement/abstract/relay_log* was *statement/rpl/relay_log* from MySQL 5.6.13 to 5.6.14 and did not exist before that.

### 22.12.6.1 The events_statements_current Table

The *events_statements_current* table contains current statement events. The table stores one row per thread showing the current status of the thread's most recent monitored statement event, so there is no system variable for configuring the table size.

Of the tables that contain statement event rows, *events_statements_current* is the most fundamental. Other tables that contain statement event rows are logically derived from the current events. For example, the *events_statements_history* and *events_statements_history_long* tables are collections of the most recent statement events that have ended, up to a maximum number of rows per thread and globally across all threads, respectively.

For more information about the relationship between the three *events_statements_***xxx*** event tables, see Section 22.9, “Performance Schema Tables for Current and Historical Events”.

For information about configuring whether to collect statement events, see Section 22.12.6, “Performance Schema Statement Event Tables”.

The *events_statements_current* table has these columns:

- **THREAD_ID, EVENT_ID**

  The thread associated with the event and the thread current event number when the event starts. The **THREAD_ID** and **EVENT_ID** values taken together uniquely identify the row. No two rows have the same pair of values.

- **END_EVENT_ID**

  This column is set to **NULL** when the event starts and updated to the thread current event number when the event ends.

- **EVENT_NAME**

  The name of the instrument from which the event was collected. This is a **NAME** value from the *setup_instruments* table. Instrument names may have multiple parts and form a hierarchy, as discussed in Section 22.6, “Performance Schema Instrument Naming Conventions”.

  For SQL statements, the **EVENT_NAME** value initially is *statement/com/Query* until the statement is parsed, then changes to a more appropriate value, as described in Section 22.12.6, “Performance Schema Statement Event Tables”.

• **SOURCE**

The name of the source file containing the instrumented code that produced the event and the line number in the file at which the instrumentation occurs. This enables you to check the source to determine exactly what code is involved.

• **TIMER_START, TIMER_END, TIMER_WAIT**

Timing information for the event. The unit for these values is picoseconds (trillionths of a second). The **TIMER_START** and **TIMER_END** values indicate when event timing started and ended. **TIMER_WAIT** is the event elapsed time (duration).

If an event has not finished, **TIMER_END** and **TIMER_WAIT** are **NULL** before MySQL 5.6.26. As of 5.6.26, **TIMER_END** is the current timer value and **TIMER_WAIT** is the time elapsed so far (**TIMER_END - TIMER_START**).

If an event is produced from an instrument that has **TIMED = NO**, timing information is not collected, and **TIMER_START**, **TIMER_END**, and **TIMER_WAIT** are all **NULL**.

For discussion of picoseconds as the unit for event times and factors that affect time values, see Section 22.4.1, “Performance Schema Event Timing”.

• **LOCK_TIME**

The time spent waiting for table locks. This value is computed in microseconds but normalized to picoseconds for easier comparison with other Performance Schema timers.

• **SQL_TEXT**

The text of the SQL statement. For a command not associated with an SQL statement, the value is **NULL**. The maximum space available for statement display is 1024 bytes.

• **DIGEST**

The statement digest MD5 value as a string of 32 hexadecimal characters, or **NULL** if the statements_digest consumer is **no**. For more information about statement digesting, see Section 22.10, “Performance Schema Statement Digests”.

• **DIGEST_TEXT**

The normalized statement digest text, or **NULL** if the statements_digest consumer is **no**. For more information about statement digesting, see Section 22.10, “Performance Schema Statement Digests”.

The **performance_schema_max_digest_length** system variable determines the maximum number of bytes available per session for digest value storage. However, the display length of statement digests may be longer than the available buffer size due to encoding of statement elements such as keywords and literal values in digest buffer. Consequently, values selected from the **DIGEST_TEXT** column of statement event tables may appear to exceed the **performance_schema_max_digest_length** value.

**performance_schema_max_digest_length** was added in MySQL 5.6.26. In MySQL 5.6.24 and 5.6.25, **performance_schema_max_digest_length** is not available and the **max_digest_length** value determines the maximum number of bytes available for digest value storage. Before MySQL 5.6.24, neither **max_digest_length** nor **performance_schema_max_digest_length** are available and a fixed maximum of 1024 bytes is available for digest value storage.

• **CURRENT_SCHEMA**
The default database for the statement, **NULL** if there is none.

- **OBJECT_SCHEMA, OBJECT_NAME, OBJECT_TYPE**
  Reserved. Always **NULL**.

- **OBJECT_INSTANCE_BEGIN**
  This column identifies the statement. The value is the address of an object in memory.

- **MYSQL_ERRNO**
  The statement error number, from the statement diagnostics area.

- **RETURNED_SQLSTATE**
  The statement SQLSTATE value, from the statement diagnostics area.

- **MESSAGE_TEXT**
  The statement error message, from the statement diagnostics area.

- **ERRORS**
  Whether an error occurred for the statement. The value is 0 if the SQLSTATE value begins with **00** (completion) or **01** (warning). The value is 1 is the SQLSTATE value is anything else.

- **WARNINGS**
  The number of warnings, from the statement diagnostics area.

- **ROWS_AFFECTED**
  The number of rows affected by the statement. For a description of the meaning of “affected,” see `mysql_affected_rows()`.

- **ROWS_SENT**
  The number of rows returned by the statement.

- **ROWS_EXAMINED**
  The number of rows examined by the server layer (not counting any processing internal to storage engines).

- **CREATED_TMP_DISK_TABLES**
  Like the `Created_tmp_disk_tables` status variable, but specific to the statement.

- **CREATED_TMP_TABLES**
  Like the `Created_tmp_tables` status variable, but specific to the statement.

- **SELECT_FULL_JOIN**
  Like the `Select_full_join` status variable, but specific to the statement.

- **SELECT_FULL_RANGE_JOIN**
Like the `Select_full_range_join` status variable, but specific to the statement.

- **SELECT_RANGE**
  Like the `Select_range` status variable, but specific to the statement.

- **SELECT_RANGE_CHECK**
  Like the `Select_range_check` status variable, but specific to the statement.

- **SELECT_SCAN**
  Like the `Select_scan` status variable, but specific to the statement.

- **SORT_MERGE_PASSES**
  Like the `Sort_merge_passes` status variable, but specific to the statement.

- **SORT_RANGE**
  Like the `Sort_range` status variable, but specific to the statement.

- **SORT_ROWS**
  Like the `Sort_rows` status variable, but specific to the statement.

- **SORT_SCAN**
  Like the `Sort_scan` status variable, but specific to the statement.

- **NO_INDEX_USED**
  1 if the statement performed a table scan without using an index, 0 otherwise.

- **NO_GOOD_INDEX_USED**
  1 if the server found no good index to use for the statement, 0 otherwise. For additional information, see the description of the `Extra` column from `EXPLAIN` output for the `Range checked for each record value` in Section 8.8.2, “EXPLAIN Output Format”.

- **NESTING_EVENT_ID, NESTING_EVENT_TYPE**
  Reserved. Always NULL.

**TRUNCATE TABLE** is permitted for the `events_statements_current` table. It removes the rows.

### 22.12.6.2 The events_statements_history Table

The `events_statements_history` table contains the $N$ most recent statement events that have ended per thread. Statement events are not added to the table until they have ended. When the table contains the maximum number of rows for a given thread, the oldest thread row is discarded when a new row for that thread is added. When a thread ends, all its rows are discarded.

The Performance Schema autosizes the value of $N$ during server startup. To set the number of rows per thread explicitly, set the `performance_schema_events_statements_history_size` system variable at server startup.

The `events_statements_history` table has the same columns as `events_statements_current`. See Section 22.12.6.1, “The events_statements_current Table”. 
TRUNCATE TABLE is permitted for the `events_statements_history` table. It removes the rows.

For more information about the relationship between the three `events_statements_xxx` event tables, see Section 22.9, "Performance Schema Tables for Current and Historical Events".

For information about configuring whether to collect statement events, see Section 22.12.6, "Performance Schema Statement Event Tables".

### 22.12.6.3 The `events_statements_history_long` Table

The `events_statements_history_long` table contains the $N$ most recent statement events that have ended globally, across all threads. Statement events are not added to the table until they have ended. When the table becomes full, the oldest row is discarded when a new row is added, regardless of which thread generated either row.

The value of $N$ is autosized at server startup. To set the table size explicitly, set the `performance_schema_events_statements_history_long_size` system variable at server startup.

The `events_statements_history_long` table has the same columns as `events_statements_current`. See Section 22.12.6.1, "The `events_statements_current` Table".

TRUNCATE TABLE is permitted for the `events_statements_history_long` table. It removes the rows.

For more information about the relationship between the three `events_statements_xxx` event tables, see Section 22.9, "Performance Schema Tables for Current and Historical Events".

For information about configuring whether to collect statement events, see Section 22.12.6, "Performance Schema Statement Event Tables".

### 22.12.7 Performance Schema Connection Tables

When a client connects to the MySQL server, it does so under a particular user name and from a particular host. The Performance Schema provides statistics about these connections, tracking them per account (user and host combination) as well as separately per user name and host name, using these tables:

- **accounts**: Connection statistics per client account
- **hosts**: Connection statistics per client host name
- **users**: Connection statistics per client user name

The meaning of "account" in the connection tables is similar to its meaning in the MySQL grant tables in the `mysql` system database, in the sense that the term refers to a combination of user and host values. They differ in that, for grant tables, the host part of an account can be a pattern, whereas for Performance Schema tables, the host value is always a specific nonpattern host name.

Each connection table has `CURRENT_CONNECTIONS` and `TOTAL_CONNECTIONS` columns to track the current and total number of connections per "tracking value" on which its statistics are based. The tables differ in what they use for the tracking value. The `accounts` table has `USER` and `HOST` columns to track connections per user and host combination. The `users` and `hosts` tables have a `USER` and `HOST` column, respectively, to track connections per user name and host name.

The Performance Schema also counts internal threads and threads for user sessions that failed to authenticate, using rows with `USER` and `HOST` column values of `NULL`.

Suppose that clients named `user1` and `user2` each connect one time from `hosta` and `hostb`. The Performance Schema tracks the connections as follows:
The **accounts** table has four rows, for the `user1/hosta`, `user1/hostb`, `user2/hosta`, and `user2/hostb` account values, each row counting one connection per account.

The **hosts** table has two rows, for `hosta` and `hostb`, each row counting two connections per host name.

The **users** table has two rows, for `user1` and `user2`, each row counting two connections per user name.

When a client connects, the Performance Schema determines which row in each connection table applies, using the tracking value appropriate to each table. If there is no such row, one is added. Then the Performance Schema increments by one the `CURRENT_CONNECTIONS` and `TOTAL_CONNECTIONS` columns in that row.

When a client disconnects, the Performance Schema decrements by one the `CURRENT_CONNECTIONS` column in the row and leaves the `TOTAL_CONNECTIONS` column unchanged.

**TRUNCATE TABLE** is permitted for connection tables. It has these effects:

- Rows are removed for accounts, hosts, or users that have no current connections (rows with `CURRENT_CONNECTIONS = 0`).
- Nonremoved rows are reset to count only current connections: For rows with `CURRENT_CONNECTIONS > 0`, `TOTAL_CONNECTIONS` is reset to `CURRENT_CONNECTIONS`.
- Summary tables that depend on the connection table are implicitly truncated, as described later in this section.

The Performance Schema maintains summary tables that aggregate connection statistics for various event types by account, host, or user. These tables have `_summary_by_account`, `_summary_by_host`, or `_summary_by_user` in the name. To identify them, use this query:

```sql
mysql> SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
WHERE TABLE_SCHEMA = 'performance_schema'
AND TABLE_NAME REGEXP '_summary_by_(account|host|user)'
ORDER BY TABLE_NAME;
```

<table>
<thead>
<tr>
<th>TABLE_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>events_stages_summary_by_account_by_event_name</td>
</tr>
<tr>
<td>events_stages_summary_by_host_by_event_name</td>
</tr>
<tr>
<td>events_stages_summary_by_user_by_event_name</td>
</tr>
<tr>
<td>events_statements_summary_by_account_by_event_name</td>
</tr>
<tr>
<td>events_statements_summary_by_host_by_event_name</td>
</tr>
<tr>
<td>events_statements_summary_by_user_by_event_name</td>
</tr>
<tr>
<td>events_waits_summary_by_account_by_event_name</td>
</tr>
<tr>
<td>events_waits_summary_by_host_by_event_name</td>
</tr>
<tr>
<td>events_waits_summary_by_user_by_event_name</td>
</tr>
</tbody>
</table>

For details about individual connection summary tables, consult the section that describes tables for the summarized event type:

- Wait event summaries: Section 22.12.9.1, “Wait Event Summary Tables”
- Stage event summaries: Section 22.12.9.2, “Stage Summary Tables”
- Statement event summaries: Section 22.12.9.3, “Statement Summary Tables”

**TRUNCATE TABLE** is permitted for connection summary tables. It removes rows for accounts, hosts, or users with no connections, and resets the summary columns to zero for the remaining rows. In
addition, each summary table that is aggregated by account, host, user, or thread is implicitly truncated by truncation of the connection table on which it depends. The following table describes the relationship between connection table truncation and implicitly truncated tables.

Table 22.2 Implicit Effects of Connection Table Truncation

<table>
<thead>
<tr>
<th>Truncated Connection Table</th>
<th>Implicitly Truncated Summary Tables</th>
</tr>
</thead>
<tbody>
<tr>
<td>accounts</td>
<td>Tables with names containing _summary_by_account, _summary_by_thread</td>
</tr>
<tr>
<td>hosts</td>
<td>Tables with names containing _summary_by_account, _summary_by_host, _summary_by_thread</td>
</tr>
<tr>
<td>users</td>
<td>Tables with names containing _summary_by_account, _summary_by_user, _summary_by_thread</td>
</tr>
</tbody>
</table>

Truncating a _summary_global summary table also implicitly truncates its corresponding connection and thread summary tables. For example, truncating `events_waits_summary_global_by_event_name` implicitly truncates the wait event summary tables that are aggregated by account, host, user, or thread.

22.12.7.1 The accounts Table

The accounts table contains a row for each account that has connected to the MySQL server. For each account, the table counts the current and total number of connections. The table size is autosized at server startup. To set the table size explicitly, set the `performance_schema_accounts_size` system variable at server startup. To disable account statistics, set this variable to 0.

The accounts table has the following columns. For a description of how the Performance Schema maintains rows in this table, including the effect of `TRUNCATE TABLE`, see Section 22.12.7, “Performance Schema Connection Tables”.

• USER

The client user name for the connection. This is NULL for an internal thread, or for a user session that failed to authenticate.

• HOST

The host from which the client connected. This is NULL for an internal thread, or for a user session that failed to authenticate.

• CURRENT_CONNECTIONS

The current number of connections for the account.

• TOTAL_CONNECTIONS

The total number of connections for the account.

22.12.7.2 The hosts Table

The hosts table contains a row for each host from which clients have connected to the MySQL server. For each host name, the table counts the current and total number of connections. The table size is autosized at server startup. To set the table size explicitly, set the `performance_schema_hosts_size` system variable at server startup. To disable host statistics, set this variable to 0.
The `hosts` table has the following columns. For a description of how the Performance Schema maintains rows in this table, including the effect of `TRUNCATE TABLE`, see Section 22.12.7, “Performance Schema Connection Tables”.

- **HOST**
  The host from which the client connected. This is `NULL` for an internal thread, or for a user session that failed to authenticate.

- **CURRENT_CONNECTIONS**
  The current number of connections for the host.

- **TOTAL_CONNECTIONS**
  The total number of connections for the host.

### 22.12.7.3 The `users` Table

The `users` table contains a row for each user who has connected to the MySQL server. For each user name, the table counts the current and total number of connections. The table size is autosized at server startup. To set the table size explicitly, set the `performance_schema_users_size` system variable at server startup. To disable user statistics, set this variable to 0.

The `users` table has the following columns. For a description of how the Performance Schema maintains rows in this table, including the effect of `TRUNCATE TABLE`, see Section 22.12.7, “Performance Schema Connection Tables”.

- **USER**
  The client user name for the connection. This is `NULL` for an internal thread, or for a user session that failed to authenticate.

- **CURRENT_CONNECTIONS**
  The current number of connections for the user.

- **TOTAL_CONNECTIONS**
  The total number of connections for the user.

### 22.12.8 Performance Schema Connection Attribute Tables

Connection attributes are key-value pairs that application programs can pass to the server at connect time. For applications based on the C API implemented by the `libmysqlclient` client library, the `mysql_options()` and `mysql_options4()` functions define the connection attribute set. Other MySQL Connectors may provide their own attribute-definition methods.

These Performance Schema tables expose attribute information:

- **session_account_connect_attrs**: Connection attributes for the current session, and other sessions associated with the session account

- **session_connect_attrs**: Connection attributes for all sessions

Attribute names that begin with an underscore (__) are reserved for internal use and should not be created by application programs. This convention permits new attributes to be introduced by MySQL without colliding with application attributes, and enables application programs to define their own attributes that do not collide with internal attributes.
Available Connection Attributes

The set of connection attributes visible within a given connection varies depending on factors such as your platform, MySQL Connector used to establish the connection, or client program.

The \texttt{libmysqlclient} client library sets these attributes:

- \texttt{__client_name}: The client name (\texttt{libmysql} for the client library).
- \texttt{__client_version}: The client library version.
- \texttt{__os}: The operating system (for example, \texttt{Linux}, \texttt{Win64}).
- \texttt{__pid}: The client process ID.
- \texttt{__platform}: The machine platform (for example, \texttt{x86_64}).
- \texttt{__thread}: The client thread ID (Windows only).

Other MySQL Connectors may define their own connection attributes.

MySQL Connector/J defines these attributes:

- \texttt{__client_license}: The connector license type.
- \texttt{__runtime_vendor}: The Java runtime environment (JRE) vendor.
- \texttt{__runtime_version}: The Java runtime environment (JRE) version.

MySQL Connector/NET defines these attributes:

- \texttt{__client_version}: The client library version.
- \texttt{__os}: The operating system (for example, \texttt{Linux}, \texttt{Win64}).
- \texttt{__pid}: The client process ID.
- \texttt{__platform}: The machine platform (for example, \texttt{x86_64}).
- \texttt{__program_name}: The client name.
- \texttt{__thread}: The client thread ID (Windows only).

PHP defines attributes that depend on how it was compiled:

- Compiled using \texttt{libmysqlclient}: The standard \texttt{libmysqlclient} attributes, described previously.
- Compiled using \texttt{mysqlnd}: Only the \texttt{__client_name} attribute, with a value of \texttt{mysqlnd}.

Many MySQL client programs set a \texttt{program_name} attribute with a value equal to the client name. For example, \texttt{mysqladmin} and \texttt{mysqldump} set \texttt{program_name} to \texttt{mysqladmin} and \texttt{mysqldump}, respectively.

Some MySQL client programs define additional attributes:

- \texttt{mysqlbinlog}:
  - \texttt{__client_role:binary_log_listener}
Performance Schema Connection Attribute Tables

- Replica connections:
  - `program_name`: mysql
  - `_client_role`: binary_log_listener
- FEDERATED storage engine connections:
  - `program_name`: mysql
  - `_client_role`: federated_storage

**Connection Attribute Limits**

There are limits on the amount of connection attribute data transmitted from client to server:

- A fixed limit imposed by the client prior to connect time.
- A fixed limit imposed by the server at connect time.
- A configurable limit imposed by the Performance Schema at connect time.

For connections initiated using the C API, the `libmysqlclient` library imposes a limit of 64KB on the aggregate size of connection attribute data on the client side: Calls to `mysql_options()` that cause this limit to be exceeded produce a `CR_INVALID_PARAMETER_NO` error. Other MySQL Connectors may impose their own client-side limits on how much connection attribute data can be transmitted to the server.

On the server side, these size checks on connection attribute data occur:

- The server imposes a limit of 64KB on the aggregate size of connection attribute data it can accept. If a client attempts to send more than 64KB of attribute data, the server rejects the connection.

- For accepted connections, the Performance Schema checks aggregate attribute size against the value of the `performance_schema_session_connect_attrs_size` system variable. If attribute size exceeds this value, these actions take place:
  - The Performance Schema truncates the attribute data and increments the `performance_schema_session_connect_attrs_lost` status variable, which indicates the number of connections for which attribute truncation occurred.
  - The Performance Schema writes a message to the error log if the `log_warnings` system variable is greater than zero:

```
[Warning] Connection attributes of length N were truncated
```

**22.12.8.1 The session_account_connect_attrs Table**

Application programs can provide key-value connection attributes to be passed to the server at connect time. For descriptions of common attributes, see Section 22.12.8, “Performance Schema Connection Attribute Tables”.

The `session_account_connect_attrs` table contains connection attributes only for the current session, and other sessions associated with the session account. To see connection attributes for all sessions, use the `session_connect_attrs` table.

The `session_account_connect_attrs` table has these columns:

- `PROCESSLIST_ID`
The connection identifier for the session.

- **ATTR_NAME**
  The attribute name.

- **ATTR_VALUE**
  The attribute value.

- **ORDINAL_POSITION**
  The order in which the attribute was added to the set of connection attributes.

**TRUNCATE TABLE** is not permitted for the `session_account_connect_attrs` table.

### 22.12.8.2 The `session_connect_attrs` Table

Application programs can provide key-value connection attributes to be passed to the server at connect time. For descriptions of common attributes, see Section 22.12.8, “Performance Schema Connection Attribute Tables”.

The `session_connect_attrs` table contains connection attributes for all sessions. To see connection attributes only for the current session, and other sessions associated with the session account, use the `session_account_connect_attrs` table.

The `session_connect_attrs` table has these columns:

- **PROCESSLIST_ID**
  The connection identifier for the session.

- **ATTR_NAME**
  The attribute name.

- **ATTR_VALUE**
  The attribute value.

- **ORDINAL_POSITION**
  The order in which the attribute was added to the set of connection attributes.

**TRUNCATE TABLE** is not permitted for the `session_connect_attrs` table.

### 22.12.9 Performance Schema Summary Tables

Summary tables provide aggregated information for terminated events over time. The tables in this group summarize event data in different ways.

Each summary table has grouping columns that determine how to group the data to be aggregated, and summary columns that contain the aggregated values. Tables that summarize events in similar ways often have similar sets of summary columns and differ only in the grouping columns used to determine how events are aggregated.

Summary tables can be truncated with **TRUNCATE TABLE**. Generally, the effect is to reset the summary columns to 0 or **NULL**, not to remove rows. This enables you to clear collected values and restart
aggregation. That might be useful, for example, after you have made a runtime configuration change. Exceptions to this truncation behavior are noted in individual summary table sections.

### Wait Event Summaries

<table>
<thead>
<tr>
<th>Table Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>events_waits_summary_by_account_by_event_name</td>
<td>Wait events per account and event name</td>

<td>Socket waits and I/O per instance</td>
</tr>
</tbody>
</table>

#### 22.12.9.1 Wait Event Summary Tables

The Performance Schema maintains tables for collecting current and recent wait events, and aggregates that information in summary tables. Section 22.12.4, “Performance Schema Wait Event Tables” describes the events on which wait summaries are based. See that discussion for information about the content of wait events, the current and recent wait event tables, and how to control wait event collection, which is disabled by default.

Example wait event summary information:

```
mysql> SELECT * FROM performance_schema.events_waits_summary_global_by_event_name
... 6. row 9. row

EVENT_NAME: wait/synch/mutex/sql/BINARY_LOG::LOCK_index
COUNT_STAR: 8
SUM_TIMER_WAIT: 2119302
MIN_TIMER_WAIT: 196092
AVG_TIMER_WAIT: 264912
MAX_TIMER_WAIT: 569421
...

EVENT_NAME: wait/synch/mutex/sql/hash_filo::lock
COUNT_STAR: 69
SUM_TIMER_WAIT: 16848828
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 244185
MAX_TIMER_WAIT: 735345
...
```

Each wait event summary table has one or more grouping columns to indicate how the table aggregates events. Event names refer to names of event instruments in the `setup_instruments` table:

- `events_waits_summary_by_account_by_event_name` has `EVENT_NAME`, `USER`, and `HOST` columns. Each row summarizes events for a given account (user and host combination) and event name.
Performance Schema Summary Tables

- `events_waits_summary_by_host_by_event_name` has EVENT_NAME and HOST columns. Each row summarizes events for a given host and event name.

- `events_waits_summary_by_instance` has EVENT_NAME and OBJECT_INSTANCE_BEGIN columns. Each row summarizes events for a given event name and object. If an instrument is used to create multiple instances, each instance has a unique OBJECT_INSTANCE_BEGIN value and is summarized separately in this table.

- `events_waits_summary_by_thread_by_event_name` has THREAD_ID and EVENT_NAME columns. Each row summarizes events for a given thread and event name.

- `events_waits_summary_by_user_by_event_name` has EVENT_NAME and USER columns. Each row summarizes events for a given user and event name.

- `events_waits_summary_global_by_event_name` has an EVENT_NAME column. Each row summarizes events for a given event name. An instrument might be used to create multiple instances of the instrumented object. For example, if there is an instrument for a mutex that is created for each connection, there are as many instances as there are connections. The summary row for the instrument summarizes over all these instances.

Each wait event summary table has these summary columns containing aggregated values:

- **COUNT_STAR**
  The number of summarized events. This value includes all events, whether timed or nontimed.

- **SUM_TIMER_WAIT**
  The total wait time of the summarized timed events. This value is calculated only for timed events because nontimed events have a wait time of NULL. The same is true for the other "xxx_TIMER_WAIT" values.

- **MIN_TIMER_WAIT**
  The minimum wait time of the summarized timed events.

- **AVG_TIMER_WAIT**
  The average wait time of the summarized timed events.

- **MAX_TIMER_WAIT**
  The maximum wait time of the summarized timed events.

`TRUNCATE TABLE` is permitted for wait summary tables. It has these effects:

- For summary tables not aggregated by account, host, or user, truncation resets the summary columns to zero rather than removing rows.

- For summary tables aggregated by account, host, or user, truncation removes rows for accounts, hosts, or users with no connections, and resets the summary columns to zero for the remaining rows.

In addition, each wait summary table that is aggregated by account, host, user, or thread is implicitly truncated by truncation of the connection table on which it depends, or truncation of `events_waits_summary_global_by_event_name`. For details, see Section 22.12.7, “Performance Schema Connection Tables”.

22.12.9.2 Stage Summary Tables
The Performance Schema maintains tables for collecting current and recent stage events, and aggregates that information in summary tables. Section 22.12.5, "Performance Schema Stage Event Tables" describes the events on which stage summaries are based. See that discussion for information about the content of stage events, the current and historical stage event tables, and how to control stage event collection, which is disabled by default.

Example stage event summary information:

```
mysql> SELECT *
    -> FROM performance_schema.events_stages_summary_global_by_event_name\G
... 5 rows...
*************************** 5. row ***************************
EVENT_NAME: stage/sql/checking permissions
COUNT_STAR: 57
SUM_TIMER_WAIT: 26501888880
MIN_TIMER_WAIT: 7317456
AVG_TIMER_WAIT: 464945295
MAX_TIMER_WAIT: 12858936792
...
*************************** 9. row ***************************
EVENT_NAME: stage/sql/closing tables
COUNT_STAR: 37
SUM_TIMER_WAIT: 662606568
MIN_TIMER_WAIT: 1593864
AVG_TIMER_WAIT: 17907891
MAX_TIMER_WAIT: 437977248
...
```

Each stage summary table has one or more grouping columns to indicate how the table aggregates events. Event names refer to names of event instruments in the `setup_instruments` table:

- `events_stages_summary_by_account_by_event_name` has EVENT_NAME, USER, and HOST columns. Each row summarizes events for a given account (user and host combination) and event name.

- `events_stages_summary_by_host_by_event_name` has EVENT_NAME and HOST columns. Each row summarizes events for a given host and event name.

- `events_stages_summary_by_thread_by_event_name` has THREAD_ID and EVENT_NAME columns. Each row summarizes events for a given thread and event name.

- `events_stages_summary_by_user_by_event_name` has EVENT_NAME and USER columns. Each row summarizes events for a given user and event name.

- `events_stages_summary_global_by_event_name` has an EVENT_NAME column. Each row summarizes events for a given event name.

Each stage summary table has these summary columns containing aggregated values: COUNT_STAR, SUM_TIMER_WAIT, MIN_TIMER_WAIT, AVG_TIMER_WAIT, and MAX_TIMER_WAIT. These columns are analogous to the columns of the same names in the wait event summary tables (see Section 22.12.9.1, "Wait Event Summary Tables"), except that the stage summary tables aggregate events from `events_stages_current` rather than `events_waits_current`.

TRUNCATE TABLE is permitted for stage summary tables. It has these effects:

- For summary tables not aggregated by account, host, or user, truncation resets the summary columns to zero rather than removing rows.

- For summary tables aggregated by account, host, or user, truncation removes rows for accounts, hosts, or users with no connections, and resets the summary columns to zero for the remaining rows.
In addition, each stage summary table that is aggregated by account, host, user, or thread is implicitly truncated by truncation of the connection table on which it depends, or truncation of `events_stages_summary_global_by_event_name`. For details, see Section 22.12.7, “Performance Schema Connection Tables”.

### 22.12.9.3 Statement Summary Tables

The Performance Schema maintains tables for collecting current and recent statement events, and aggregates that information in summary tables. Section 22.12.6, “Performance Schema Statement Event Tables” describes the events on which statement summaries are based. See that discussion for information about the content of statement events, the current and historical statement event tables, and how to control statement event collection, which is partially disabled by default.

Example statement event summary information:

```sql
mysql> SELECT * FROM performance_schema.events_statements_summary_global_by_event_name;
```

```
*************************** 1. row ***************************
EVENT_NAME: statement/sql/select
COUNT_STAR: 25
SUM_TIMER_WAIT: 1535983999000
MIN_TIMER_WAIT: 209823000
AVG_TIMER_WAIT: 61439359000
MAX_TIMER_WAIT: 1363397650000
SUM_LOCK_TIME: 20186000000
SUM_ERRORS: 0
SUM_WARNINGS: 0
SUM_ROWS_AFFECTED: 0
SUM_ROWS_SENT: 388
SUM_ROWS_EXAMINED: 370
SUM_CREATED_TMP_DISK_TABLES: 0
SUM_CREATED_TMP_TABLES: 0
SUM_SELECT_FULL_JOIN: 0
SUM_SELECT_FULL_RANGE_JOIN: 0
SUM_SELECT_RANGE: 6
SUM_SELECT_RANGE_CHECK: 0
SUM_SELECT_SCAN: 0
SUM_SORT_MERGE_PASSES: 0
SUM_SORT_RANGE: 0
SUM_SORT_ROWS: 0
SUM_SORT_SCAN: 0
SUM_NO_INDEX_USED: 6
SUM_NO_GOOD_INDEX_USED: 0
...
```

Each statement summary table has one or more grouping columns to indicate how the table aggregates events. Event names refer to names of event instruments in the `setup_instruments` table:

- `events_statements_summary_by_account_by_event_name` has `EVENT_NAME`, `USER`, and `HOST` columns. Each row summarizes events for a given account (user and host combination) and event name.

- `events_statements_summary_by_digest` has `SCHEMA_NAME` and `DIGEST` columns. Each row summarizes events per schema and digest value. (The `DIGEST_TEXT` column contains the corresponding normalized statement digest text, but is neither a grouping nor a summary column.)

The maximum number of rows in the table is autosized at server startup. To set this maximum explicitly, set the `performance_schema_digests_size` system variable at server startup.

- `events_statements_summary_by_host_by_event_name` has `EVENT_NAME` and `HOST` columns. Each row summarizes events for a given host and event name.
Performance Schema Summary Tables

- `events_statements_summary_by_thread_by_event_name` has `THREAD_ID` and `EVENT_NAME` columns. Each row summarizes events for a given thread and event name.

- `events_statements_summary_by_user_by_event_name` has `EVENT_NAME` and `USER` columns. Each row summarizes events for a given user and event name.

- `events_statements_summary_global_by_event_name` has an `EVENT_NAME` column. Each row summarizes events for a given event name.

Each statement summary table has these summary columns containing aggregated values:

- `COUNT_STAR`, `SUM_TIMER_WAIT`, `MIN_TIMER_WAIT`, `AVG_TIMER_WAIT`, `MAX_TIMER_WAIT`

  These columns are analogous to the columns of the same names in the wait event summary tables (see Section 22.12.9.1, “Wait Event Summary Tables”), except that the statement summary tables aggregate events from `events_statements_current` rather than `events_waits_current`.

- `SUM_xxx`

  The aggregate of the corresponding `xxx` column in the `events_statements_current` table. For example, the `SUM_LOCK_TIME` and `SUM_ERRORS` columns in statement summary tables are the aggregates of the `LOCK_TIME` and `ERRORS` columns in `events_statements_current` table.

The `events_statements_summary_by_digest` table has these additional summary columns:

- `FIRST_SEEN`, `LAST_SEEN`

  Timestamps indicating when statements with the given digest value were first seen and most recently seen.

`TRUNCATE TABLE` is permitted for statement summary tables. It has these effects:

- For `events_statements_summary_by_digest`, it removes the rows.

- For other summary tables not aggregated by account, host, or user, truncation resets the summary columns to zero rather than removing rows.

- For other summary tables aggregated by account, host, or user, truncation removes rows for accounts, hosts, or users with no connections, and resets the summary columns to zero for the remaining rows.

In addition, each statement summary table that is aggregated by account, host, user, or thread is implicitly truncated by truncation of the connection table on which it depends, or truncation of `events_statements_summary_global_by_event_name`. For details, see Section 22.12.7, “Performance Schema Connection Tables”.

**Statement Digest Aggregation Rules**

If the `statements_digest` consumer is enabled, aggregation into `events_statements_summary_by_digest` occurs as follows when a statement completes. Aggregation is based on the `DIGEST` value computed for the statement.

- If a `events_statements_summary_by_digest` row already exists with the digest value for the statement that just completed, statistics for the statement are aggregated to that row. The `LAST_SEEN` column is updated to the current time.

- If no row has the digest value for the statement that just completed, and the table is not full, a new row is created for the statement. The `FIRST_SEEN` and `LAST_SEEN` columns are initialized with the current time.
• If no row has the statement digest value for the statement that just completed, and the table is full, the
  statistics for the statement that just completed are added to a special “catch-all” row with DIGEST =
  NULL, which is created if necessary. If the row is created, the FIRST_SEEN and LAST_SEEN columns
  are initialized with the current time. Otherwise, the LAST_SEEN column is updated with the current time.

The row with DIGEST = NULL is maintained because Performance Schema tables have a maximum size
due to memory constraints. The DIGEST = NULL row permits digests that do not match other rows to be
counted even if the summary table is full, using a common “other” bucket. This row helps you estimate
whether the digest summary is representative:

• A DIGEST = NULL row that has a COUNT_STAR value that represents 5% of all digests shows that the
digest summary table is very representative; the other rows cover 95% of the statements seen.

• A DIGEST = NULL row that has a COUNT_STAR value that represents 50% of all digests shows that
the digest summary table is not very representative; the other rows cover only half the statements
seen. Most likely the DBA should increase the maximum table size so that more of the rows counted
in the DIGEST = NULL row would be counted using more specific rows instead. By default, the table is
autosized, but if this size is too small, set the performance_schema_digests_size system variable
to a larger value at server startup.

22.12.9.4 Object Wait Summary Table

The Performance Schema maintains the objects_summary_global_by_type table for aggregating
object wait events.

Example object wait event summary information:

```
mysql> SELECT * FROM performance_schema.objects_summary_global_by_type;
...  
*************************** 3. row ***************************
  OBJECT_TYPE: TABLE
  OBJECT_SCHEMA: test
  OBJECT_NAME: t
  COUNT_STAR: 3
  SUM_TIMER_WAIT: 263126976
  MIN_TIMER_WAIT: 1522272
  AVG_TIMER_WAIT: 87708678
  MAX_TIMER_WAIT: 258428280
  ...  
*************************** 10. row ***************************
  OBJECT_TYPE: TABLE
  OBJECT_SCHEMA: mysql
  OBJECT_NAME: user
  COUNT_STAR: 14
  SUM_TIMER_WAIT: 365567592
  MIN_TIMER_WAIT: 1141704
  AVG_TIMER_WAIT: 26111769
  MAX_TIMER_WAIT: 334783032
  ...  
```

The objects_summary_global_by_type table has these grouping columns to indicate how the table
aggregates events: OBJECT_TYPE, OBJECT_SCHEMA, and OBJECT_NAME. Each row summarizes events
for the given object.

objects_summary_global_by_type has the same summary columns as the
events_waits_summary_by_xxx tables. See Section 22.12.9.1, “Wait Event Summary Tables”.

TRUNCATE TABLE is permitted for the object summary table. It resets the summary columns to zero rather
than removing rows.
22.12.9.5 File I/O Summary Tables

The Performance Schema maintains file I/O summary tables that aggregate information about I/O operations.

Example file I/O event summary information:

```
mysql> SELECT * FROM performance_schema.file_summary_by_event_name;
...
+-----------------------------+-----------------------------+--------+-----------------------------+-----------------------------+--------+-----------------------------+--------+-----------------------------+--------+-----------------------------+--------+-----------------------------+--------+
| EVENT_NAME                  | COUNT_STAR                  | SUM_TIMER_WAIT | MIN_TIMER_WAIT              | AVG_TIMER_WAIT              | MAX_TIMER_WAIT              |
+-----------------------------+-----------------------------+--------+-----------------------------+-----------------------------+--------+-----------------------------+--------+-----------------------------+--------+-----------------------------+--------+-----------------------------+--------|
| wait/io/file/sql/binlog     | 31                          | 8243784888   | 0                           | 265928484                  | 6490658832                 |
...                          |                             |           |                             |                             |                    |
mysql> SELECT * FROM performance_schema.file_summary_by_instance;
...
+-----------------------------+-----------------------------+-----------------------------+-----------------------------+-----------------------------+-----------------------------+-----------------------------+-----------------------------+-----------------------------+--------+
| FILE_NAME                   | EVENT_NAME                  | OBJECT_INSTANCE_BEGIN      | COUNT_STAR                  | SUM_TIMER_WAIT | MIN_TIMER_WAIT | AVG_TIMER_WAIT | MAX_TIMER_WAIT | SUM_NUMBER_OF_BYTES_READ |
+-----------------------------+-----------------------------+-----------------------------+-----------------------------+-----------------------------+-----------------------------+-----------------------------+-----------------------------+--------+
| /var/mysql/share/english/errmsg.sys | wait/io/file/sql/ERRMSG     | 4686193384                  | 5                          | 13990154448    | 26349624       | 2798030607    | 8150662536     |                  |
| wait/io/file/sql/ERRMSG     | wait/io/file/sql/ERRMSG     |                             |                             |                             |                             |                             |                             |                  |
| OBJECT_INSTANCE_BEGIN      |                             |                             |                             |                             |                             |                             |                             |                  |
+-----------------------------+-----------------------------+-----------------------------+-----------------------------+-----------------------------+-----------------------------+-----------------------------+-----------------------------+--------+
```

Each file I/O summary table has one or more grouping columns to indicate how the table aggregates events. Event names refer to names of event instruments in the `setup_instruments` table:

- `file_summary_by_event_name` has an `EVENT_NAME` column. Each row summarizes events for a given event name.
- `file_summary_by_instance` has `FILE_NAME`, `EVENT_NAME`, and `OBJECT_INSTANCE_BEGIN` columns. Each row summarizes events for a given file and event name.

Each file I/O summary table has the following summary columns containing aggregated values. Some columns are more general and have values that are the same as the sum of the values of more fine-grained columns. In this way, aggregations at higher levels are available directly without the need for user-defined views that sum lower-level columns.

- `COUNT_STAR`, `SUM_TIMER_WAIT`, `MIN_TIMER_WAIT`, `AVG_TIMER_WAIT`, `MAX_TIMER_WAIT`
  These columns aggregate all I/O operations.
- `COUNT_READ`, `SUM_TIMER_READ`, `MIN_TIMER_READ`, `AVG_TIMER_READ`, `MAX_TIMER_READ`, `SUM_NUMBER_OF_BYTES_READ`
  These columns aggregate all read operations, including `FGETS`, `FGETC`, `FREAD`, and `READ`.
- `COUNT_WRITE`, `SUM_TIMER_WRITE`, `MIN_TIMER_WRITE`, `AVG_TIMER_WRITE`, `MAX_TIMER_WRITE`, `SUM_NUMBER_OF_BYTES_WRITE`
  These columns aggregate all write operations, including `FPUTS`, `FPUTC`, `FPRINTF`, `VFPRINTF`, `FWRITE`, and `PWRITE`.
- `COUNT_MISC`, `SUM_TIMER_MISC`, `MIN_TIMER_MISC`, `AVG_TIMER_MISC`, `MAX_TIMER_MISC`
These columns aggregate all other I/O operations, including CREATE, DELETE, OPEN, CLOSE, STREAM_OPEN, STREAM_CLOSE, SEEK, TELL, FLUSH, STAT, FSTAT, CHSIZE, RENAME, and SYNC. There are no byte counts for these operations.

TRUNCATE TABLE is permitted for file I/O summary tables. It resets the summary columns to zero rather than removing rows.

The MySQL server uses several techniques to avoid I/O operations by caching information read from files, so it is possible that statements you might expect to result in I/O events do not. You may be able to ensure that I/O does occur by flushing caches or restarting the server to reset its state.

22.12.9.6 Table I/O and Lock Wait Summary Tables

The following sections describe the table I/O and lock wait summary tables:

- table_io_waits_summary_by_index_usage: Table I/O waits per index
- table_io_waits_summary_by_table: Table I/O waits per table
- table_lock_waits_summary_by_table: Table lock waits per table

The table_io_waits_summary_by_table Table

The table_io_waits_summary_by_table table aggregates all table I/O wait events, as generated by the wait/io/table/sql/handler instrument. The grouping is by table.

The table_io_waits_summary_by_table table has these grouping columns to indicate how the table aggregates events: OBJECT_TYPE, OBJECT_SCHEMA, and OBJECT_NAME. These columns have the same meaning as in the events_waits_current table. They identify the table to which the row applies.

table_io_waits_summary_by_table has the following summary columns containing aggregated values. As indicated in the column descriptions, some columns are more general and have values that are the same as the sum of the values of more fine-grained columns. For example, columns that aggregate all writes hold the sum of the corresponding columns that aggregate inserts, updates, and deletes. In this way, aggregations at higher levels are available directly without the need for user-defined views that sum lower-level columns.

- COUNT_STAR, SUM_TIMER_WAIT, MIN_TIMER_WAIT, AVG_TIMER_WAIT, MAX_TIMER_WAIT
  These columns aggregate all I/O operations. They are the same as the sum of the corresponding xxx_READ and xxx_WRITE columns.

- COUNT_READ, SUM_TIMER_READ, MIN_TIMER_READ, AVG_TIMER_READ, MAX_TIMER_READ
  These columns aggregate all read operations. They are the same as the sum of the corresponding xxx_FETCH columns.

- COUNT_WRITE, SUM_TIMER_WRITE, MIN_TIMER_WRITE, AVG_TIMER_WRITE, MAX_TIMER_WRITE
  These columns aggregate all write operations. They are the same as the sum of the corresponding xxx_INSERT, xxx_UPDATE, and xxx_DELETE columns.

- COUNT_FETCH, SUM_TIMER_FETCH, MIN_TIMER_FETCH, AVG_TIMER_FETCH, MAX_TIMER_FETCH
  These columns aggregate all fetch operations.

- COUNT_INSERT, SUM_TIMER_INSERT, MIN_TIMER_INSERT, AVG_TIMER_INSERT, MAX_TIMER_INSERT
Performance Schema Summary Tables

These columns aggregate all insert operations.

- `COUNT_UPDATE`, `SUM_TIMER_UPDATE`, `MIN_TIMER_UPDATE`, `AVG_TIMER_UPDATE`, `MAX_TIMER_UPDATE`

These columns aggregate all update operations.

- `COUNT_DELETE`, `SUM_TIMER_DELETE`, `MIN_TIMER_DELETE`, `AVG_TIMER_DELETE`, `MAX_TIMER_DELETE`

These columns aggregate all delete operations.

`TRUNCATE TABLE` is permitted for table I/O summary tables. It resets the summary columns to zero rather than removing rows. Truncating this table also truncates the `table_io_waits_summary_by_index_usage` table.

The `table_io_waits_summary_by_index_usage` Table

The `table_io_waits_summary_by_index_usage` table aggregates all table index I/O wait events, as generated by the `wait/io/table/sql/handler` instrument. The grouping is by table index.

The columns of `table_io_waits_summary_by_index_usage` are nearly identical to `table_io_waits_summary_by_table`. The only difference is the additional group column, `INDEX_NAME`, which corresponds to the name of the index that was used when the table I/O wait event was recorded:

- A value of `PRIMARY` indicates that table I/O used the primary index.
- A value of `NULL` means that table I/O used no index.
- Inserts are counted against `INDEX_NAME = NULL`.

`TRUNCATE TABLE` is permitted for table I/O summary tables. It resets the summary columns to zero rather than removing rows. This table is also truncated by truncation of the `table_io_waits_summary_by_table` table. A DDL operation that changes the index structure of a table may cause the per-index statistics to be reset.

The `table_lock_waits_summary_by_table` Table

The `table_lock_waits_summary_by_table` table aggregates all table lock wait events, as generated by the `wait/lock/table/sql/handler` instrument. The grouping is by table.

This table contains information about internal and external locks:

- An internal lock corresponds to a lock in the SQL layer. This is currently implemented by a call to `thr_lock()`. In event rows, these locks are distinguished by the `OPERATION` column, which has one of these values:

  - `read normal`
  - `read with shared locks`
  - `read high priority`
  - `read no insert`
  - `write allow write`
  - `write concurrent insert`
  - `write delayed`
  - `write low priority`
  - `write normal`
An external lock corresponds to a lock in the storage engine layer. This is currently implemented by a call to `handler::external_lock()`. In event rows, these locks are distinguished by the `OPERATION` column, which has one of these values:

| read external | write external |

The `table_lock_waits_summary_by_table` table has these grouping columns to indicate how the table aggregates events: `OBJECT_TYPE`, `OBJECT_SCHEMA`, and `OBJECT_NAME`. These columns have the same meaning as in the `events_waits_current` table. They identify the table to which the row applies.

`table_lock_waits_summary_by_table` has the following summary columns containing aggregated values. As indicated in the column descriptions, some columns are more general and have values that are the same as the sum of the values of more fine-grained columns. For example, columns that aggregate all locks hold the sum of the corresponding columns that aggregate read and write locks. In this way, aggregations at higher levels are available directly without the need for user-defined views that sum lower-level columns.

- **COUNT_STAR, SUM_TIMER_WAIT, MIN_TIMER_WAIT, AVG_TIMER_WAIT, MAX_TIMER_WAIT**
  These columns aggregate all lock operations. They are the same as the sum of the corresponding `xxx_READ` and `xxx_WRITE` columns.

- **COUNT_READ, SUM_TIMER_READ, MIN_TIMER_READ, AVG_TIMER_READ, MAX_TIMER_READ**
  These columns aggregate all read-lock operations. They are the same as the sum of the corresponding `xxx_READ_NORMAL`, `xxx_READ_WITH_SHARED_LOCKS`, `xxx_READ_HIGH_PRIORITY`, and `xxx_READ_NO_INSERT` columns.

- **COUNT_WRITE, SUM_TIMER_WRITE, MIN_TIMER_WRITE, AVG_TIMER_WRITE, MAX_TIMER_WRITE**
  These columns aggregate all write-lock operations. They are the same as the sum of the corresponding `xxx_WRITE_ALLOW_WRITE`, `xxx_WRITE_CONCURRENT_INSERT`, `xxx_WRITE_DELAYED`, `xxx_WRITE_LOW_PRIORITY`, and `xxx_WRITE_NORMAL` columns.

- **COUNT_READ_NORMAL, SUM_TIMER_READ_NORMAL, MIN_TIMER_READ_NORMAL, AVG_TIMER_READ_NORMAL, MAX_TIMER_READ_NORMAL**
  These columns aggregate internal read locks.

- **COUNT_READ_WITH_SHARED_LOCKS, SUM_TIMER_READ_WITH_SHARED_LOCKS, MIN_TIMER_READ_WITH_SHARED_LOCKS, AVG_TIMER_READ_WITH_SHARED_LOCKS, MAX_TIMER_READ_WITH_SHARED_LOCKS**
  These columns aggregate internal read locks.

- **COUNT_READ_HIGH_PRIORITY, SUM_TIMER_READ_HIGH_PRIORITY, MIN_TIMER_READ_HIGH_PRIORITY, AVG_TIMER_READ_HIGH_PRIORITY, MAX_TIMER_READ_HIGH_PRIORITY**
  These columns aggregate internal read locks.

- **COUNT_READ_NO_INSERT, SUM_TIMER_READ_NO_INSERT, MIN_TIMER_READ_NO_INSERT, AVG_TIMER_READ_NO_INSERT, MAX_TIMER_READ_NO_INSERT**
  These columns aggregate internal read locks.

- **COUNT_READ_EXTERNAL, SUM_TIMER_READ_EXTERNAL, MIN_TIMER_READ_EXTERNAL, AVG_TIMER_READ_EXTERNAL, MAX_TIMER_READ_EXTERNAL**
  These columns aggregate internal read locks.
These columns aggregate external read locks.

- \texttt{COUNT\_WRITE\_ALLOW\_WRITE}, \texttt{SUM\_TIMER\_WRITE\_ALLOW\_WRITE}, \\
  \texttt{MIN\_TIMER\_WRITE\_ALLOW\_WRITE}, \texttt{AVG\_TIMER\_WRITE\_ALLOW\_WRITE}, \\
  \texttt{MAX\_TIMER\_WRITE\_ALLOW\_WRITE}

These columns aggregate internal write locks.

- \texttt{COUNT\_WRITE\_CONCURRENT\_INSERT}, \texttt{SUM\_TIMER\_WRITE\_CONCURRENT\_INSERT}, \\
  \texttt{MIN\_TIMER\_WRITE\_CONCURRENT\_INSERT}, \texttt{AVG\_TIMER\_WRITE\_CONCURRENT\_INSERT}, \\
  \texttt{MAX\_TIMER\_WRITE\_CONCURRENT\_INSERT}

These columns aggregate internal write locks.

- \texttt{COUNT\_WRITE\_DELAYED}, \texttt{SUM\_TIMER\_WRITE\_DELAYED}, \texttt{MIN\_TIMER\_WRITE\_DELAYED}, \\
  \texttt{AVG\_TIMER\_WRITE\_DELAYED}, \texttt{MAX\_TIMER\_WRITE\_DELAYED}

\texttt{DELAYED} inserts are deprecated; expect these columns to be removed in a future release.

- \texttt{COUNT\_WRITE\_LOW\_PRIORITY}, \texttt{SUM\_TIMER\_WRITE\_LOW\_PRIORITY}, \\
  \texttt{MIN\_TIMER\_WRITE\_LOW\_PRIORITY}, \texttt{AVG\_TIMER\_WRITE\_LOW\_PRIORITY}, \\
  \texttt{MAX\_TIMER\_WRITE\_LOW\_PRIORITY}

These columns aggregate internal write locks.

- \texttt{COUNT\_WRITE\_NORMAL}, \texttt{SUM\_TIMER\_WRITE\_NORMAL}, \texttt{MIN\_TIMER\_WRITE\_NORMAL}, \\
  \texttt{AVG\_TIMER\_WRITE\_NORMAL}, \texttt{MAX\_TIMER\_WRITE\_NORMAL}

These columns aggregate internal write locks.

- \texttt{COUNT\_WRITE\_EXTERNAL}, \texttt{SUM\_TIMER\_WRITE\_EXTERNAL}, \texttt{MIN\_TIMER\_WRITE\_EXTERNAL}, \\
  \texttt{AVG\_TIMER\_WRITE\_EXTERNAL}, \texttt{MAX\_TIMER\_WRITE\_EXTERNAL}

\texttt{TRUNCATE\ TABLE} is permitted for table lock summary tables. It resets the summary columns to zero rather than removing rows.

### 22.12.9.7 Socket Summary Tables

The Performance Schema maintains socket summary tables, which aggregate timer and byte count information for socket operations:

- \texttt{socket\_summary\_by\_event\_name}: Aggregate timer and byte count statistics generated by the \texttt{wait/io/socket/*/} instruments for all socket I/O operations, per socket instrument.

- \texttt{socket\_summary\_by\_instance}: Aggregate timer and byte count statistics generated by the \texttt{wait/io/socket/*/} instruments for all socket I/O operations, per socket instance. When a connection terminates, the row in \texttt{socket\_summary\_by\_instance} corresponding to it is deleted.

The socket summary tables do not aggregate waits generated by \texttt{idle} events while sockets are waiting for the next request from the client. For \texttt{idle} event aggregations, use the wait-event summary tables; see \texttt{Section 22.12.9.1, "Wait Event Summary Tables"}.

Each socket summary table has one or more grouping columns to indicate how the table aggregates events. Event names refer to names of event instruments in the \texttt{setup\_instruments} table:
socket_summary_by_event_name has an EVENT_NAME column. Each row summarizes events for a given event name.

socket_summary_by_instance has an OBJECT_INSTANCE_BEGIN column. Each row summarizes events for a given object.

Each socket summary table has these summary columns containing aggregated values:

- **COUNT_STAR**, **SUM_TIMER_WAIT**, **MIN_TIMER_WAIT**, **AVG_TIMER_WAIT**, **MAX_TIMER_WAIT**

  These columns aggregate all operations.

- **COUNT_READ**, **SUM_TIMER_READ**, **MIN_TIMER_READ**, **AVG_TIMER_READ**, **MAX_TIMER_READ**, **SUM_NUMBER_OF_BYTES_READ**

  These columns aggregate all receive operations (RECV, RECVFROM, and RECVMSG).

- **COUNT_WRITE**, **SUM_TIMER_WRITE**, **MIN_TIMER_WRITE**, **AVG_TIMER_WRITE**, **MAX_TIMER_WRITE**, **SUM_NUMBER_OF_BYTES_WRITE**

  These columns aggregate all send operations (SEND, SENDTO, and SENDMSG).

- **COUNT_MISC**, **SUM_TIMER_MISC**, **MIN_TIMER_MISC**, **AVG_TIMER_MISC**, **MAX_TIMER_MISC**

  These columns aggregate all other socket operations, such as CONNECT, LISTEN, ACCEPT, CLOSE, and SHUTDOWN. There are no byte counts for these operations.

The socket_summary_by_instance table also has an EVENT_NAME column that indicates the class of the socket: client_connection, server_tcpip_socket, server_unix_socket. This column can be grouped on to isolate, for example, client activity from that of the server listening sockets.

**TRUNCATE TABLE** is permitted for socket summary tables. Except for events_statements_summary_by_digest, it resets the summary columns to zero rather than removing rows.

### 22.12.10 Performance Schema Miscellaneous Tables

The following sections describe tables that do not fall into the table categories discussed in the preceding sections:

- **host_cache**: Information from the internal host cache.

- **performance_timers**: Which event timers are available.

- **threads**: Information about server threads.

### 22.12.10.1 The host_cache Table

The MySQL server maintains an in-memory host cache that contains client host name and IP address information and is used to avoid Domain Name System (DNS) lookups. The host_cache table exposes the contents of this cache. The **host_cache_size** system variable controls the size of the host cache, as well as the size of the host_cache table. For operational and configuration information about the host cache, see Section 5.1.11.2, “DNS Lookups and the Host Cache”.

Because the host_cache table exposes the contents of the host cache, it can be examined using **SELECT** statements. This may help you diagnose the causes of connection problems. The Performance Schema must be enabled or this table is empty.
The `host_cache` table has these columns:

- **IP**
  The IP address of the client that connected to the server, expressed as a string.

- **HOST**
  The resolved DNS host name for that client IP, or **NULL** if the name is unknown.

- **HOST_VALIDATED**
  Whether the IP-to-host name-to-IP DNS resolution was performed successfully for the client IP. If `HOST_VALIDATED` is **YES**, the `HOST` column is used as the host name corresponding to the IP so that additional calls to DNS can be avoided. While `HOST_VALIDATED` is **NO**, DNS resolution is attempted for each connection attempt, until it eventually completes with either a valid result or a permanent error. This information enables the server to avoid caching bad or missing host names during temporary DNS failures, which would negatively affect clients forever.

- **SUM_CONNECT_ERRORS**
  The number of connection errors that are deemed “blocking” (assessed against the `max_connect_errors` system variable). Only protocol handshake errors are counted, and only for hosts that passed validation (`HOST_VALIDATED = YES`).

  Once `SUM_CONNECT_ERRORS` for a given host reaches the value of `max_connect_errors`, new connections from that host are blocked. The `SUM_CONNECT_ERRORS` value can exceed the `max_connect_errors` value because multiple connection attempts from a host can occur simultaneously while the host is not blocked. Any or all of them can fail, independently incrementing `SUM_CONNECT_ERRORS`, possibly beyond the value of `max_connect_errors`.

  Suppose that `max_connect_errors` is 200 and `SUM_CONNECT_ERRORS` for a given host is 199. If 10 clients attempt to connect from that host simultaneously, none of them are blocked because `SUM_CONNECT_ERRORS` has not reached 200. If blocking errors occur for five of the clients, `SUM_CONNECT_ERRORS` is increased by one for each client, for a resulting `SUM_CONNECT_ERRORS` value of 204. The other five clients succeed and are not blocked because the value of `SUM_CONNECT_ERRORS` when their connection attempts began had not reached 200. New connections from the host that begin after `SUM_CONNECT_ERRORS` reaches 200 are blocked.

- **COUNT_HOST_BLOCKED_ERRORS**
  The number of connections that were blocked because `SUM_CONNECT_ERRORS` exceeded the value of the `max_connect_errors` system variable.

- **COUNT_NAMEINFO_TRANSIENT_ERRORS**
  The number of transient errors during IP-to-host name DNS resolution.

- **COUNT_NAMEINFO_PERMANENT_ERRORS**
  The number of permanent errors during IP-to-host name DNS resolution.

- **COUNT_FORMAT_ERRORS**
  The number of host name format errors. MySQL does not perform matching of `Host` column values in the `mysql.user` system table against host names for which one or more of the initial components of the name are entirely numeric, such as `1.2.example.com`. The client IP address is used instead. For the rationale why this type of matching does not occur, see Section 6.2.4, “Specifying Account Names”. 
• **COUNT_ADDRINFO_TRANSIENT_ERRORS**
  The number of transient errors during host name-to-IP reverse DNS resolution.

• **COUNT_ADDRINFO_PERMANENT_ERRORS**
  The number of permanent errors during host name-to-IP reverse DNS resolution.

• **COUNT_FCRDNS_ERRORS**
  The number of forward-confirmed reverse DNS errors. These errors occur when IP-to-host name-to-IP DNS resolution produces an IP address that does not match the client originating IP address.

• **COUNT_HOST_ACL_ERRORS**
  The number of errors that occur because no users are permitted to connect from the client host. In such cases, the server returns `ER_HOST_NOT_PRIVILEGED` and does not even ask for a user name or password.

• **COUNT_NO_AUTH_PLUGIN_ERRORS**
  The number of errors due to requests for an unavailable authentication plugin. A plugin can be unavailable if, for example, it was never loaded or a load attempt failed.

• **COUNT_AUTH_PLUGIN_ERRORS**
  The number of errors reported by authentication plugins.

  An authentication plugin can report different error codes to indicate the root cause of a failure. Depending on the type of error, one of these columns is incremented: `COUNT_AUTHENTICATION_ERRORS`, `COUNT_AUTH_PLUGIN_ERRORS`, `COUNT_HANDSHAKE_ERRORS`. New return codes are an optional extension to the existing plugin API. Unknown or unexpected plugin errors are counted in the `COUNT_AUTH_PLUGIN_ERRORS` column.

• **COUNT_HANDSHAKE_ERRORS**
  The number of errors detected at the wire protocol level.

• **COUNT_PROXY_USER_ERRORS**
  The number of errors detected when proxy user A is proxied to another user B who does not exist.

• **COUNT_PROXY_USER_ACL_ERRORS**
  The number of errors detected when proxy user A is proxied to another user B who does exist but for whom A does not have the `PROXY` privilege.

• **COUNT_AUTHENTICATION_ERRORS**
  The number of errors caused by failed authentication.

• **COUNT_SSL_ERRORS**
  The number of errors due to SSL problems.

• **COUNT_MAX_USER_CONNECTIONS_ERRORS**
  The number of errors caused by exceeding per-user connection quotas. See Section 6.2.13, “Setting Account Resource Limits”.
• **COUNT_MAX_USER_CONNECTIONS_PER_HOUR_ERRORS**

The number of errors caused by exceeding per-user connections-per-hour quotas. See Section 6.2.13, “Setting Account Resource Limits”.

• **COUNT_DEFAULT_DATABASE_ERRORS**

The number of errors related to the default database. For example, the database does not exist or the user has no privileges to access it.

• **COUNT_INIT_CONNECT_ERRORS**

The number of errors caused by execution failures of statements in the `init_connect` system variable value.

• **COUNT_LOCAL_ERRORS**

The number of errors local to the server implementation and not related to the network, authentication, or authorization. For example, out-of-memory conditions fall into this category.

• **COUNT_UNKNOWN_ERRORS**

The number of other, unknown errors not accounted for by other columns in this table. This column is reserved for future use, in case new error conditions must be reported, and if preserving the backward compatibility and structure of the `host_cache` table is required.

• **FIRST_SEEN**

The timestamp of the first connection attempt seen from the client in the `IP` column.

• **LAST_SEEN**

The timestamp of the most recent connection attempt seen from the client in the `IP` column.

• **FIRST_ERROR_SEEN**

The timestamp of the first error seen from the client in the `IP` column.

• **LAST_ERROR_SEEN**

The timestamp of the most recent error seen from the client in the `IP` column.

**TRUNCATE TABLE** is permitted for the `host_cache` table. It requires the `DROP` privilege for the table. Truncating the table flushes the host cache, which has the effects described in Flushing the Host Cache.

### 22.12.10.2 The performance_timers Table

The **performance_timers** table shows which event timers are available:

```sql
mysql> SELECT * FROM performance_schema.performance_timers;
+-------------+-----------------+------------------+----------------+
| TIMER_NAME  | TIMER_FREQUENCY | TIMER_RESOLUTION | TIMER_OVERHEAD |
+-------------+-----------------+------------------+----------------+
| CYCLE       | 2389029850      | 1                | 72             |
| NANOSECOND  | 1000000000       | 1                | 112            |
| MICROSECOND | 1000000          | 1                | 136            |
| MILLISECOND | 1036             | 1                | 168            |
| TICK        | 105              | 1                | 2416           |
+-------------+-----------------+------------------+----------------+
```

![Table](image-url)
If the values associated with a given timer name are NULL, that timer is not supported on your platform. The rows that do not contain NULL indicate which timers you can use in setup_timers. For an explanation of how event timing occurs, see Section 22.4.1, “Performance Schema Event Timing”.

The performance_timers table has these columns:

- **TIMER_NAME**
  The name by which to refer to the timer when configuring the setup_timers table.

- **TIMER_FREQUENCY**
  The number of timer units per second. For a cycle timer, the frequency is generally related to the CPU speed. For example, on a system with a 2.4GHz processor, the CYCLE may be close to 2400000000.

- **TIMER_RESOLUTION**
  Indicates the number of timer units by which timer values increase. If a timer has a resolution of 10, its value increases by 10 each time.

- **TIMER_OVERHEAD**
  The minimal number of cycles of overhead to obtain one timing with the given timer. The Performance Schema determines this value by invoking the timer 20 times during initialization and picking the smallest value. The total overhead really is twice this amount because the instrumentation invokes the timer at the start and end of each event. The timer code is called only for timed events, so this overhead does not apply for nontimed events.

TRUNCATE TABLE is not permitted for the performance_timers table.

### 22.12.10.3 The threads Table

The threads table contains a row for each server thread. Each row contains information about a thread and indicates whether monitoring is enabled for it:

```sql
mysql> SELECT * FROM performance_schema.threads\G
```

```
*************************** 1. row ***************************
THREAD_ID: 1
NAME: thread/sql/main
TYPE: BACKGROUND
PROCESSLIST_ID: NULL
PROCESSLIST_USER: NULL
PROCESSLIST_HOST: NULL
PROCESSLIST_DB: NULL
PROCESSLIST_COMMAND: NULL
PROCESSLIST_TIME: 80284
PROCESSLIST_STATE: NULL
PROCESSLIST_INFO: NULL
PARENT_THREAD_ID: NULL
ROLE: NULL
INSTRUMENTED: YES
...
*************************** 4. row ***************************
THREAD_ID: 51
NAME: thread/sql/one_connection
TYPE: FOREGROUND
PROCESSLIST_ID: 34
PROCESSLIST_USER: isabella
PROCESSLIST_HOST: localhost
PROCESSLIST_DB: performance_schema
PROCESSLIST_COMMAND: Query
PROCESSLIST_TIME: 0
```

3440
When the Performance Schema initializes, it populates the `threads` table based on the threads in existence then. Thereafter, a new row is added each time the server creates a thread.

The `INSTRUMENTED` column value for new threads is determined by the contents of the `setup_actors` table. For information about how to use the `setup_actors` table to control this column, see Section 22.4.6, “Pre-Filtering by Thread”.

Removal of rows from the `threads` table occurs when threads end. For a thread associated with a client session, removal occurs when the session ends. If a client has auto-reconnect enabled and the session reconnects after a disconnect, the session becomes associated with a new row in the `threads` table that has a different `PROCESSLIST_ID` value. The initial `INSTRUMENTED` value for the new thread may be different from that of the original thread: The `setup_actors` table may have changed in the meantime, and if the `INSTRUMENTED` value for the original thread was changed after it was initialized, that change does not carry over to the new thread.

You can enable or disable thread monitoring (that is, whether events executed by the thread are instrumented). To control the initial `INSTRUMENTED` value for new foreground threads, use the `setup_actors` table. To control monitoring of existing threads, set the `INSTRUMENTED` column of `threads` table rows. (For more information about the conditions under which thread monitoring occurs, see the description of the `INSTRUMENTED` column.)

For a comparison of the `threads` table columns with names having a prefix of `PROCESSLIST_` to other process information sources, see Sources of Process Information.

For thread information sources other than the `threads` table, information about threads for other users is shown only if the current user has the `PROCESS` privilege. That is not true of the `threads` table; all rows are shown to any user who has the `SELECT` privilege for the table. Users who should not be able to see threads for other users by accessing the `threads` table should not be given the `SELECT` privilege for it.

The `threads` table has these columns:

- **THREAD_ID**
  
  A unique thread identifier.

- **NAME**
  
  The name associated with the thread instrumentation code in the server. For example, `thread/sql/one_connection` corresponds to the thread function in the code responsible for handling a user connection, and `thread/sql/main` stands for the `main()` function of the server.

- **TYPE**
  
  The thread type, either `FOREGROUND` or `BACKGROUND`. User connection threads are foreground threads. Threads associated with internal server activity are background threads. Examples are internal InnoDB threads, “binlog dump” threads sending information to replicas, and replica I/O and SQL threads.

- **PROCESSLIST_ID**

---

### Important

For thread information sources other than the `threads` table, information about threads for other users is shown only if the current user has the `PROCESS` privilege. That is not true of the `threads` table; all rows are shown to any user who has the `SELECT` privilege for the table. Users who should not be able to see threads for other users by accessing the `threads` table should not be given the `SELECT` privilege for it.
Performance Schema Miscellaneous Tables

For a foreground thread (associated with a user connection), this is the connection identifier. This is the same value displayed in the ID column of the INFORMATION_SCHEMAPROCESSLIST table, displayed in the Id column of SHOW PROCESSLIST output, and returned by the CONNECTION_ID() function within the thread.

For a background thread (not associated with a user connection), PROCESSLIST_ID is NULL, so the values are not unique.

- **PROCESSLIST_USER**

  The user associated with a foreground thread, NULL for a background thread.

- **PROCESSLIST_HOST**

  The host name of the client associated with a foreground thread, NULL for a background thread.

  Unlike the HOST column of the INFORMATION_SCHEMAPROCESSLIST table or the Host column of SHOW PROCESSLIST output, the PROCESSLIST_HOST column does not include the port number for TCP/IP connections. To obtain this information from the Performance Schema, enable the socket instrumentation (which is not enabled by default) and examine the socket_instances table:

  ```
  mysql> SELECT * FROM performance_schema.setup_instruments
  WHERE NAME LIKE 'wait/io/socket%';
  +----------------------------------------+---------+-------+
  | NAME                                   | ENABLED | TIMED |
  +----------------------------------------+---------+-------+
  | wait/io/socket/sql/server_tcpip_socket | NO      | NO    |
  | wait/io/socket/sql/server_unix_socket  | NO      | NO    |
  | wait/io/socket/sql/client_connection   | NO      | NO    |
  +----------------------------------------+---------+-------+
  3 rows in set (0.01 sec)
  mysql> UPDATE performance_schema.setup_instruments
  SET ENABLED='YES'
  WHERE NAME LIKE 'wait/io/socket%';
  Query OK, 3 rows affected (0.00 sec)
  Rows matched: 3  Changed: 3  Warnings: 0
  mysql> SELECT * FROM performance_schema.socket_instances\G
  *************************** 1. row ***************************
  EVENT_NAME: wait/io/socket/sql/client_connection
  OBJECT_INSTANCE_BEGIN: 140612577298432
  THREAD_ID: 31
  SOCKET_ID: 53
  IP: ::ffff:127.0.0.1
  PORT: 55642
  STATE: ACTIVE
  ...
  ```

- **PROCESSLIST_DB**

  The default database for the thread, or NULL if none has been selected.

- **PROCESSLIST_COMMAND**

  For foreground threads, the type of command the thread is executing on behalf of the client, or Sleep if the session is idle. For descriptions of thread commands, see Section 8.14, “Examining Server Thread (Process) Information”. The value of this column corresponds to the COM_xxx commands of the client/server protocol and Com_xxx status variables. See Section 5.1.9, “Server Status Variables”

  Background threads do not execute commands on behalf of clients, so this column may be NULL.

3442
• **PROCESSLIST_TIME**

The time in seconds that the thread has been in its current state. For a replica SQL thread, the value is the number of seconds between the timestamp of the last replicated event and the real time of the replica host. See Section 17.2.1, “Replication Threads”.

• **PROCESSLIST_STATE**

An action, event, or state that indicates what the thread is doing. For descriptions of PROCESSLIST_STATE values, see Section 8.14, “Examining Server Thread (Process) Information”. If the value is NULL, the thread may correspond to an idle client session or the work it is doing is not instrumented with stages.

Most states correspond to very quick operations. If a thread stays in a given state for many seconds, there might be a problem that bears investigation.

• **PROCESSLIST_INFO**

The statement the thread is executing, or NULL if it is executing no statement. The statement might be the one sent to the server, or an innermost statement if the statement executes other statements. For example, if a CALL statement executes a stored procedure that is executing a SELECT statement, the PROCESSLIST_INFO value shows the SELECT statement.

• **PARENT_THREAD_ID**

If this thread is a subthread (spawned by another thread), this is the THREAD_ID value of the spawning thread. Thread spawning occurs, for example, to handle insertion of rows from INSERT DELAYED statements.

• **ROLE**

Unused.

• **INSTRUMENTED**

Whether events executed by the thread are instrumented. The value is YES or NO.

- For foreground threads, the initial INSTRUMENTED value is determined by whether the user account associated with the thread matches any row in the setup_actors table. Matching is based on the values of the PROCESSLIST_USER and PROCESSLIST_HOST columns.

  If the thread spawns a subthread, matching occurs again for the threads table row created for the subthread.

- For background threads, INSTRUMENTED is YES by default. setup_actors is not consulted because there is no associated user for background threads.

- For any thread, its INSTRUMENTED value can be changed during the lifetime of the thread. This is the only threads table column that can be modified.

For monitoring of events executed by the thread to occur, these things must be true:

- The thread_instrumentation consumer in the setup_consumers table must be YES.

- The threads.INSTRUMENTED column must be YES.

- Monitoring occurs only for those thread events produced from instruments that have the ENABLED column set to YES in the setup_instruments table.
TRUNCATE TABLE is not permitted for the threads table.

Performance Schema Command Options

22.14 Performance Schema Command Options

Performance Schema parameters can be specified at server startup on the command line or in option files to configure Performance Schema instruments and consumers. Runtime configuration is also possible in many cases (see Section 22.4, “Performance Schema Runtime Configuration”), but startup configuration must be used when runtime configuration is too late to affect instruments that have already been initialized during the startup process.

Performance Schema consumers and instruments can be configured at startup using the following syntax. For additional details, see Section 22.3, “Performance Schema Startup Configuration”.

- `--performance-schema-consumer-consumer_name=value`
  Configure a Performance Schema consumer. Consumer names in the `setup_consumers` table use underscores, but for consumers set at startup, dashes and underscores within the name are equivalent. Options for configuring individual consumers are detailed later in this section.

- `--performance-schema-instrument=instrument_name=value`
  Configure a Performance Schema instrument. The name may be given as a pattern to configure instruments that match the pattern.

The following items configure individual consumers:

- `--performance-schema-consumer-events-stages-current=value`
  Configure the `events-stages-current` consumer.

- `--performance-schema-consumer-events-stages-history=value`
  Configure the `events-stages-history` consumer.

- `--performance-schema-consumer-events-stages-history-long=value`
  Configure the `events-stages-history-long` consumer.

- `--performance-schema-consumer-events-statements-current=value`
  Configure the `events-statements-current` consumer.

- `--performance-schema-consumer-events-statements-history=value`
  Configure the `events-statements-history` consumer.

- `--performance-schema-consumer-events-statements-history-long=value`
  Configure the `events-statements-history-long` consumer.

- `--performance-schema-consumer-events-waits-current=value`
  Configure the `events-waits-current` consumer.

- `--performance-schema-consumer-events-waits-history=value`
  Configure the `events-waits-history` consumer.

- `--performance-schema-consumer-events-waits-history-long=value`
  Configure the `events-waits-history-long` consumer.
Performance Schema System Variables

- `--performance-schema-consumer-global-instrumentation=value`
  Configure the `global-instrumentation` consumer.

- `--performance-schema-consumer-statements-digest=value`
  Configure the `statements-digest` consumer.

- `--performance-schema-consumer-thread-instrumentation=value`
  Configure the `thread-instrumentation` consumer.

### 22.15 Performance Schema System Variables

The Performance Schema implements several system variables that provide configuration information:

```sql
mysql> SHOW VARIABLES LIKE 'perf%';
+--------------------------------------------------------+---------+
| Variable_name                                          | Value   |
+--------------------------------------------------------+---------+
| performance_schema                                     | ON      |
| performance_schema_accounts_size                       | 100     |
| performance_schema_digests_size                        | 200     |
| performance_schema_events_stages_history_long_size     | 10000   |
| performance_schema_events_stages_history_size          | 10      |
| performance_schema_events_statements_history_long_size | 10000   |
| performance_schema_events_statements_history_size      | 10      |
| performance_schema_events_waits_history_long_size      | 10000   |
| performance_schema_events_waits_history_size           | 10      |
| performance_schema_hosts_size                          | 100     |
| performance_schema_max_cond_classes                    | 80      |
| performance_schema_max_cond_instances                  | 1000    |
| performance_schema_max_file_classes                    | 50      |
| performance_schema_max_file_handles                    | 32768   |
| performance_schema_max_file_instances                  | 200     |
| performance_schema_max_mutex_classes                   | 1000000 |
| performance_schema_max_mutex_instances                 | 30      |
| performance_schema_max_rwlock_classes                  | 10      |
| performance_schema_max_rwlock_instances                | 10000   |
| performance_schema_max_socket_classes                  | 100     |
| performance_schema_max_socket_instances                | 1000    |
| performance_schema_max_stage_classes                   | 100     |
| performance_schema_max_statement_classes               | 1000    |
| performance_schema_max_thread_classes                  | 10000   |
| performance_schema_max_thread_instances                | 1000000 |
| performance_schema_max_mem_units_size                  | 512     |
| performance_schema_setup_actors_size                   | 100     |
| performance_schema_setup_objects_size                  | 100     |
| performance_schema_setup_nodes_size                    | 100     |
+--------------------------------------------------------+---------+
```

Performance Schema system variables can be set at server startup on the command line or in option files, and many can be set at runtime. See Section 22.13, "Performance Schema Option and Variable Reference".

The Performance Schema automatically sizes the values of several of its parameters at server startup if they are not set explicitly. For more information, see Section 22.3, "Performance Schema Startup Configuration".

Performance Schema system variables have the following meanings:

- `performance_schema`
### Performance Schema System Variables

| Command-Line Format     | --performance-schema[={OFF|ON}] |
|-------------------------|---------------------------------|
| System Variable         | performance_schema              |
| Scope                   | Global                          |
| Dynamic                 | No                              |
| Type                    | Boolean                         |
| Default Value           | ON                              |

The value of this variable is **ON** or **OFF** to indicate whether the Performance Schema is enabled. By default, the value is **ON**. At server startup, you can specify this variable with no value or a value of **ON** or 1 to enable it, or with a value of **OFF** or 0 to disable it.

- **performance_schema_accounts_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--performance-schema-accounts-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>performance_schema_accounts_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>-1 (signifies autosizing; do not assign this literal value)</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>-1 (signifies autosizing; do not assign this literal value)</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1048576</td>
</tr>
</tbody>
</table>

The number of rows in the **accounts** table. If this variable is 0, the Performance Schema does not maintain connection statistics in the **accounts** table.

- **performance_schema_digests_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--performance-schema-digests-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>performance_schema_digests_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>-1 (signifies autosizing; do not assign this literal value)</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>-1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1048576</td>
</tr>
</tbody>
</table>

The maximum number of rows in the **events_statements_summary_by_digest** table. If this maximum is exceeded such that a digest cannot be instrumented, the Performance Schema increments the **Performance_schema_digest_lost** status variable.

For more information about statement digesting, see Section 22.10, “Performance Schema Statement Digests”.  

3449
Performance Schema System Variables

- **performance_schema_events_stages_history_long_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--performance-schema-events-stages-history-long-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>performance_schema_events_stages_history_long_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>-1 (signifies autosizing; do not assign this literal value)</td>
</tr>
</tbody>
</table>

  The number of rows in the events_stages_history_long table.

- **performance_schema_events_stages_history_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--performance-schema-events-stages-history-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>performance_schema_events_stages_history_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>-1 (signifies autosizing; do not assign this literal value)</td>
</tr>
</tbody>
</table>

  The number of rows per thread in the events_stages_history table.

- **performance_schema_events_statements_history_long_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--performance-schema-events-statements-history-long-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>performance_schema_events_statements_history_long_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>-1 (signifies autosizing; do not assign this literal value)</td>
</tr>
</tbody>
</table>

  The number of rows in the events_statements_history_long table.

- **performance_schema_events_statements_history_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--performance-schema-events-statements-history-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>performance_schema_events_statements_history_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
</tbody>
</table>
### Performance Schema System Variables

<table>
<thead>
<tr>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1 (signifies autosizing; do not assign this literal value)</td>
<td></td>
</tr>
</tbody>
</table>

The number of rows per thread in the `events_statements_history` table.

- **performance_schema_events_waits_history_long_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--performance-schema-events-waits-history-long-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>performance_schema_events_waits_history_long_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>-1 (signifies autosizing; do not assign this literal value)</td>
</tr>
</tbody>
</table>

The number of rows in the `events_waits_history_long` table.

- **performance_schema_events_waits_history_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--performance-schema-events-waits-history-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>performance_schema_events_waits_history_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>-1 (signifies autosizing; do not assign this literal value)</td>
</tr>
</tbody>
</table>

The number of rows per thread in the `events_waits_history` table.

- **performance_schema_hosts_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--performance-schema-hosts-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>performance_schema_hosts_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>-1 (signifies autosizing; do not assign this literal value)</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>-1 (signifies autosizing; do not assign this literal value)</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1048576</td>
</tr>
</tbody>
</table>

The number of rows in the `hosts` table. If this variable is 0, the Performance Schema does not maintain connection statistics in the `hosts` table.

- **performance_schema_max_cond_classes**
### Performance Schema System Variables

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--performance-schema-max-cond-classes=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>performance_schema_max_cond_classes</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>80</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>256</td>
</tr>
</tbody>
</table>

The maximum number of condition instruments. For information about how to set and use this variable, see Section 22.7, “Performance Schema Status Monitoring”.

- **performance_schema_max_cond_instances**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--performance-schema-max-cond-instances=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>performance_schema_max_cond_instances</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>-1 (signifies autosizing; do not assign this literal value)</td>
</tr>
</tbody>
</table>

The maximum number of instrumented condition objects. For information about how to set and use this variable, see Section 22.7, “Performance Schema Status Monitoring”.

- **performance_schema_max_digest_length**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--performance-schema-max-digest-length=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>5.6.26</td>
</tr>
<tr>
<td>System Variable</td>
<td>performance_schema_max_digest_length</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1024</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1048576</td>
</tr>
</tbody>
</table>

The maximum number of bytes of memory reserved per statement for computation of normalized statement digest values in the Performance Schema. This variable is related to max_digest_length; see the description of that variable in Section 5.1.7, “Server System Variables”.

For more information about statement digesting, including considerations regarding memory use, see Section 22.10, “Performance Schema Statement Digests”.

3452
• **performance_schema_max_file_classes**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--performance-schema-max-file-classes=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>performance_schema_max_file_classes</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>50</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>256</td>
</tr>
</tbody>
</table>

The maximum number of file instruments. For information about how to set and use this variable, see Section 22.7, “Performance Schema Status Monitoring”.

• **performance_schema_max_file_handles**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--performance-schema-max-file-handles=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>performance_schema_max_file_handles</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>32768</td>
</tr>
</tbody>
</table>

The maximum number of opened file objects. For information about how to set and use this variable, see Section 22.7, “Performance Schema Status Monitoring”.

The value of `performance_schema_max_file_handles` should be greater than the value of `open_files_limit`. `open_files_limit` affects the maximum number of open file handles the server can support and `performance_schema_max_file_handles` affects how many of these file handles can be instrumented.

• **performance_schema_max_file_instances**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--performance-schema-max-file-instances=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>performance_schema_max_file_instances</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>-1 (signifies autosizing; do not assign this literal value)</td>
</tr>
</tbody>
</table>

The maximum number of instrumented file objects. For information about how to set and use this variable, see Section 22.7, “Performance Schema Status Monitoring”.
• **performance_schema_max_mutex_classes**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--performance-schema-max-mutex-classes=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>performance_schema_max_mutex_classes</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>200</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>256</td>
</tr>
</tbody>
</table>

The maximum number of mutex instruments. For information about how to set and use this variable, see Section 22.7, “Performance Schema Status Monitoring”.

• **performance_schema_max_mutex_instances**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--performance-schema-max-mutex-instances=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>performance_schema_max_mutex_instances</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>-1 (signifies autosizing; do not assign this literal value)</td>
</tr>
</tbody>
</table>

The maximum number of instrumented mutex objects. For information about how to set and use this variable, see Section 22.7, “Performance Schema Status Monitoring”.

• **performance_schema_max_rwlock_classes**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--performance-schema-max-rwlock-classes=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>performance_schema_max_rwlock_classes</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value (≥ 5.6.15)</td>
<td>40</td>
</tr>
<tr>
<td>Default Value (≤ 5.6.14)</td>
<td>30</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>256</td>
</tr>
</tbody>
</table>

The maximum number of rwlock instruments. For information about how to set and use this variable, see Section 22.7, “Performance Schema Status Monitoring”.
• **performance_schema_max_rwlock_instances**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--performance-schema-max-rwlock-instances=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>performance_schema_max_rwlock_instances</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>-1 (signifies autosizing; do not assign this literal value)</td>
</tr>
</tbody>
</table>

The maximum number of instrumented rwlock objects. For information about how to set and use this variable, see Section 22.7, “Performance Schema Status Monitoring”.

• **performance_schema_max_socket_classes**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--performance-schema-max-socket-classes=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>performance_schema_max_socket_classes</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>10</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>256</td>
</tr>
</tbody>
</table>

The maximum number of socket instruments. For information about how to set and use this variable, see Section 22.7, “Performance Schema Status Monitoring”.

• **performance_schema_max_socket_instances**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--performance-schema-max-socket-instances=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>performance_schema_max_socket_instances</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>-1 (signifies autosizing; do not assign this literal value)</td>
</tr>
</tbody>
</table>

The maximum number of instrumented socket objects. For information about how to set and use this variable, see Section 22.7, “Performance Schema Status Monitoring”.

• **performance_schema_max_stage_classes**

### Performance Schema System Variables

<table>
<thead>
<tr>
<th>System Variable</th>
<th>performance_schema_max_stage_classes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>150</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>256</td>
</tr>
</tbody>
</table>

The maximum number of stage instruments. For information about how to set and use this variable, see [Section 22.7, “Performance Schema Status Monitoring”](#).

- **performance_schema_max_statement_classes**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--performance-schema-max-statement-classes=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>performance_schema_max_statement_classes</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>-1 (signifies autosizing; do not assign this literal value)</td>
</tr>
</tbody>
</table>

The maximum number of statement instruments. For information about how to set and use this variable, see [Section 22.7, “Performance Schema Status Monitoring”](#).

The default value is calculated at server build time based on the number of commands in the client/server protocol and the number of SQL statement types supported by the server.

This variable should not be changed, unless to set it to 0 to disable all statement instrumentation and save all memory associated with it. Setting the variable to nonzero values other than the default has no benefit; in particular, values larger than the default cause more memory to be allocated then is needed.

- **performance_schema_max_table_handles**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--performance-schema-max-table-handles=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>performance_schema_max_table_handles</td>
</tr>
<tr>

<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>-1 (signifies autosizing; do not assign this literal value)</td>
</tr>
</tbody>
</table>

The maximum number of opened table objects. For information about how to set and use this variable, see [Section 22.7, “Performance Schema Status Monitoring”](#).
• **performance_schema_max_table_instances**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--performance-schema-max-table-instances=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>performance_schema_max_table_instances</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>-1 (signifies autosizing; do not assign this literal value)</td>
</tr>
</tbody>
</table>

The maximum number of instrumented table objects. For information about how to set and use this variable, see Section 22.7, “Performance Schema Status Monitoring”.

• **performance_schema_max_thread_classes**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--performance-schema-max-thread-classes=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>performance_schema_max_thread_classes</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>50</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>256</td>
</tr>
</tbody>
</table>

The maximum number of thread instruments. For information about how to set and use this variable, see Section 22.7, “Performance Schema Status Monitoring”.

• **performance_schema_max_thread_instances**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--performance-schema-max-thread-instances=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>performance_schema_max_thread_instances</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>-1 (signifies autosizing; do not assign this literal value)</td>
</tr>
</tbody>
</table>

The maximum number of instrumented thread objects. The value controls the size of the threads table. If this maximum is exceeded such that a thread cannot be instrumented, the Performance Schema increments the Performance_schema_thread_instances_lost status variable. For information about how to set and use this variable, see Section 22.7, “Performance Schema Status Monitoring”.

The `max_connections` system variable affects how many threads are run in the server. `performance_schema_max_thread_instances` affects how many of these running threads can...
be instrumented. The default value of `performance_schema_max_thread_instances` is autosized based on the value of `max_connections`.

- **performance_schema_session_connect_attrs_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--performance-schema-session-connect-attrs-size=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>performance_schema_session_connect_attrs_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>-1 (signifies autosizing; do not assign this literal value)</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>-1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1048576</td>
</tr>
</tbody>
</table>

The amount of preallocated memory per thread reserved to hold connection attribute key-value pairs. If the aggregate size of connection attribute data sent by a client is larger than this amount, the Performance Schema truncates the attribute data, increments the `Performance_schema_session_connect_attrs_lost` status variable, and writes a message to the error log indicating that truncation occurred if the `log_warnings` system variable value is greater than zero.

The default value of `performance_schema_session_connect_attrs_size` is autosized at server startup. This value may be small, so if truncation occurs (`Performance_schema_session_connect_attrs_lost` becomes nonzero), you may wish to set `performance_schema_session_connect_attrs_size` explicitly to a larger value.

Although the maximum permitted `performance_schema_session_connect_attrs_size` value is 1MB, the effective maximum is 64KB because the server imposes a limit of 64KB on the aggregate size of connection attribute data it can accept. If a client attempts to send more than 64KB of attribute data, the server rejects the connection. For more information, see Section 22.12.8, “Performance Schema Connection Attribute Tables”.

- **performance_schema_setup_actors_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--performance-schema-setup-actors-size=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>performance_schema_setup_actors_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>100</td>
</tr>
</tbody>
</table>

The number of rows in the `setup_actors` table.

- **performance_schema_setup_objects_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--performance-schema-setup-objects-size=#</code></th>
</tr>
</thead>
</table>
### Performance Schema Status Variables

</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>100</td>
</tr>
</tbody>
</table>

The number of rows in the `setup_objects` table.

- **performance_schema_users_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--performance-schema-users-size=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>performance_schema_users_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>-1</code> (signifies autosizing; do not assign this literal value)</td>
</tr>
<tr>
<td>Minimum Value</td>
<td><code>-1</code> (signifies autosizing; do not assign this literal value)</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1048576</td>
</tr>
</tbody>
</table>

The number of rows in the `users` table. If this variable is 0, the Performance Schema does not maintain connection statistics in the `users` table.

## 22.16 Performance Schema Status Variables

The Performance Schema implements several status variables that provide information about instrumentation that could not be loaded or created due to memory constraints:

```sql
mysql> SHOW STATUS LIKE 'perf%';
+-------------------------------------------+-------+
| Variable_name                             | Value |
+-------------------------------------------+-------+
| Performance_schema_accounts_lost          | 0     |
| Performance_schema_cond_classes_lost      | 0     |
| Performance_schema_cond_instances_lost    | 0     |
| Performance_schema_file_classes_lost      | 0     |
| Performance_schema_file_handles_lost      | 0     |
| Performance_schema_file_instances_lost    | 0     |
| Performance_schema_hosts_lost             | 0     |
| Performance_schema_locker_lost            | 0     |
| Performance_schema_mutex_classes_lost     | 0     |
| Performance_schema_mutex_instances_lost   | 0     |
| Performance_schema_rwlock_classes_lost    | 0     |
| Performance_schema_rwlock_instances_lost  | 0     |
| Performance_schema_socket_classes_lost    | 0     |
| Performance_schema_socket_instances_lost  | 0     |
| Performance_schema_stage_classes_lost     | 0     |
| Performance_schema_statement_classes_lost | 0     |
| Performance_schema_table_handles_lost     | 0     |
| Performance_schema_table_instances_lost   | 0     |
| Performance_schema_thread_classes_lost    | 0     |
| Performance_schema_thread_instances_lost  | 0     |
| Performance_schema_users_lost             | 0     |
+-------------------------------------------+-------+```
For information on using these variables to check Performance Schema status, see Section 22.7, “Performance Schema Status Monitoring”.

Performance Schema status variables have the following meanings:

- **Performance_schema_accounts_lost**
  The number of times a row could not be added to the `accounts` table because it was full.

- **Performance_schema_cond_classes_lost**
  How many condition instruments could not be loaded.

- **Performance_schema_cond_instances_lost**
  How many condition instrument instances could not be created.

- **Performance_schema_digest_lost**
  The number of digest instances that could not be instrumented in the `events_statements_summary_by_digest` table. This can be nonzero if the value of `performance_schema_digests_size` is too small.

- **Performance_schema_file_classes_lost**
  How many file instruments could not be loaded.

- **Performance_schema_file_handles_lost**
  How many file instrument instances could not be opened.

- **Performance_schema_file_instances_lost**
  How many file instrument instances could not be created.

- **Performance_schema_hosts_lost**
  The number of times a row could not be added to the `hosts` table because it was full.

- **Performance_schema_locker_lost**
  How many events are “lost” or not recorded, due to the following conditions:
  - Events are recursive (for example, waiting for A caused a wait on B, which caused a wait on C).
  - The depth of the nested events stack is greater than the limit imposed by the implementation.
  Events recorded by the Performance Schema are not recursive, so this variable should always be 0.

- **Performance_schema_mutex_classes_lost**
  How many mutex instruments could not be loaded.

- **Performance_schema_mutex_instances_lost**
  How many mutex instrument instances could not be created.

- **Performance_schema_rwlock_classes_lost**
  How many rwlock instruments could not be loaded.
• **Performance_schema_rwlock_instances_lost**

How many rwlock instrument instances could not be created.

• **Performance_schema_session_connect_attrs_lost**

The number of connections for which connection attribute truncation has occurred. For a given connection, if the client sends connection attribute key-value pairs for which the aggregate size is larger than the reserved storage permitted by the value of the `performance_schema_session_connect_attrs_size` system variable, the Performance Schema truncates the attribute data and increments `Performance_schema_session_connect_attrs_lost`. If this value is nonzero, you may wish to set `performance_schema_session_connect_attrs_size` to a larger value.

For more information about connection attributes, see Section 22.12.8, “Performance Schema Connection Attribute Tables”.

• **Performance_schema_socket_classes_lost**

How many socket instruments could not be loaded.

• **Performance_schema_socket_instances_lost**

How many socket instrument instances could not be created.

• **Performance_schema_stage_classes_lost**

How many stage instruments could not be loaded.

• **Performance_schema_statement_classes_lost**

How many statement instruments could not be loaded.

• **Performance_schema_table_handles_lost**

How many table instrument instances could not be opened.

• **Performance_schema_table_instances_lost**

How many table instrument instances could not be created.

• **Performance_schema_thread_classes_lost**

How many thread instruments could not be loaded.

• **Performance_schema_thread_instances_lost**

The number of thread instances that could not be instrumented in the `threads` table. This can be nonzero if the value of `performance_schema_max_thread_instances` is too small.

• **Performance_schema_users_lost**

The number of times a row could not be added to the `users` table because it was full.

### 22.17 Performance Schema and Plugins

Removing a plugin with `UNINSTALL PLUGIN` does not affect information already collected for code in that plugin. Time spent executing the code while the plugin was loaded was still spent even if the plugin
is unloaded later. The associated event information, including aggregate information, remains readable in performance_schema database tables. For additional information about the effect of plugin installation and removal, see Section 22.7, “Performance Schema Status Monitoring”.

A plugin implementor who instruments plugin code should document its instrumentation characteristics to enable those who load the plugin to account for its requirements. For example, a third-party storage engine should include in its documentation how much memory the engine needs for mutex and other instruments.

22.18 Using the Performance Schema to Diagnose Problems

The Performance Schema is a tool to help a DBA do performance tuning by taking real measurements instead of “wild guesses.” This section demonstrates some ways to use the Performance Schema for this purpose. The discussion here relies on the use of event filtering, which is described in Section 22.4.2, “Performance Schema Event Filtering”.

The following example provides one methodology that you can use to analyze a repeatable problem, such as investigating a performance bottleneck. To begin, you should have a repeatable use case where performance is deemed “too slow” and needs optimization, and you should enable all instrumentation (no pre-filtering at all).

1. Run the use case.

2. Using the Performance Schema tables, analyze the root cause of the performance problem. This analysis relies heavily on post-filtering.

3. For problem areas that are ruled out, disable the corresponding instruments. For example, if analysis shows that the issue is not related to file I/O in a particular storage engine, disable the file I/O instruments for that engine. Then truncate the history and summary tables to remove previously collected events.

4. Repeat the process at step 1.

At each iteration, the Performance Schema output, particularly the events_waits_history_long table, contains less and less “noise” caused by nonsignificant instruments, and given that this table has a fixed size, contains more and more data relevant to the analysis of the problem at hand.

At each iteration, investigation should lead closer and closer to the root cause of the problem, as the signal-to-noise ratio improves, making analysis easier.

5. Once a root cause of performance bottleneck is identified, take the appropriate corrective action, such as:
   • Tune the server parameters (cache sizes, memory, and so forth).
   • Tune a query by writing it differently,
   • Tune the database schema (tables, indexes, and so forth).
   • Tune the code (this applies to storage engine or server developers only).

6. Start again at step 1, to see the effects of the changes on performance.

The mutex_instances.LOCKED_BY_THREAD_ID and rwlock_instances.WRITE_LOCKED_BY_THREAD_ID columns are extremely important for investigating performance bottlenecks or deadlocks. This is made possible by Performance Schema instrumentation as follows:
1. Suppose that thread 1 is stuck waiting for a mutex.

2. You can determine what the thread is waiting for:

   ```sql
   SELECT * FROM performance_schema.events_waits_current
   WHERE THREAD_ID = thread_1;
   ```

   Say the query result identifies that the thread is waiting for mutex A, found in
   `events_waits_current.OBJECT_INSTANCE_BEGIN`.

3. You can determine which thread is holding mutex A:

   ```sql
   SELECT * FROM performance_schema.mutex_instances
   WHERE OBJECT_INSTANCE_BEGIN = mutex_A;
   ```

   Say the query result identifies that it is thread 2 holding mutex A, as found in
   `mutex_instances.LOCKED_BY_THREAD_ID`.

4. You can see what thread 2 is doing:

   ```sql
   SELECT * FROM performance_schema.events_waits_current
   WHERE THREAD_ID = thread_2;
   ```

22.18.1 Query Profiling Using Performance Schema

The following example demonstrates how to use Performance Schema statement events and stage events to retrieve data comparable to profiling information provided by `SHOW PROFILES` and `SHOW PROFILE` statements.

In this example, statement and stage event data is collected in the `events_statements_history_long` and `events_stages_history_long` tables. On a busy server with many active foreground threads, data could age out of the history tables before you are able to retrieve the information you want to analyze. If you encounter this problem, options include:

- Running the query on a test instance where there is less foreground thread activity.

- Disabling instrumentation for other existing foreground threads by setting the `INSTRUMENTED` field of the `threads` table to NO for other thread records. For example, the following statement disables instrumentation for all foreground threads except the `test_user` thread:

  ```sql
  mysql> UPDATE performance_schema.threads
       SET INSTRUMENTED = 'NO'
       WHERE TYPE='FOREGROUND' AND PROCESSLIST_USER NOT LIKE 'test_user';
  ```

However, be aware that new threads are always instrumented by default.

- Increasing the number of rows in the `events_statements_history_long` and `events_stages_history_long` tables. The `performance_schema_events_statements_history_size` and `performance_schema_events_stages_history_size` configuration options are autosized by default but can also be set explicitly at startup. You can view current settings by running `SHOW VARIABLES`. For information about autosized Performance Schema parameters, see Section 22.3, “Performance Schema Startup Configuration”.

Performance Schema displays event timer information in picoseconds (trillionths of a second) to normalize timing data to a standard unit. In the following example, `TIMER_WAIT` values are divided by 1000000000000 to show data in units of seconds. Values are also truncated to 6 decimal places to display data in the same format as `SHOW PROFILES` and `SHOW PROFILE` statements.
1. Ensure that statement and stage instrumentation is enabled by updating the `setup_instruments` table. Some instruments may already be enabled by default.

```sql
mysql> UPDATE performance_schema.setup_instruments
SET ENABLED = 'YES', TIMED = 'YES'
WHERE NAME LIKE '%statement/%';
mysql> UPDATE performance_schema.setup_instruments
SET ENABLED = 'YES', TIMED = 'YES'
WHERE NAME LIKE '%stage/%';
```

2. Ensure that `events_statements_*` and `events_stages_*` consumers are enabled. Some consumers may already be enabled by default.

```sql
mysql> UPDATE performance_schema.setup_consumers
SET ENABLED = 'YES'
WHERE NAME LIKE '%events_statements_%';
mysql> UPDATE performance_schema.setup_consumers
SET ENABLED = 'YES'
WHERE NAME LIKE '%events_stages_%';
```

3. Run the statement that you want to profile. For example:

```sql
mysql> SELECT * FROM employees.employees WHERE emp_no = 10001;
+--------+------------+------------+-----------+--------+------------+
<table>
<thead>
<tr>
<th>emp_no</th>
<th>birth_date</th>
<th>first_name</th>
<th>last_name</th>
<th>gender</th>
<th>hire_date</th>
</tr>
</thead>
<tbody>
<tr>
<td>10001</td>
<td>1953-09-02</td>
<td>Georgi</td>
<td>Facello</td>
<td>M</td>
<td>1986-06-26</td>
</tr>
</tbody>
</table>
+--------+------------+------------+-----------+--------+------------+
```

4. Identify the `EVENT_ID` of the statement by querying the `events_statements_history_long` table. This step is similar to running `SHOW PROFILES` to identify the `Query_ID`. The following query produces output similar to `SHOW PROFILES`:

```sql
mysql> SELECT EVENT_ID, TRUNCATE(TIMER_WAIT/1000000000000,6) as Duration, SQL_TEXT
FROM performance_schema.events_statements_history_long WHERE SQL_TEXT like '%10001%';
+----------+----------+--------------------------------------------------------+
<table>
<thead>
<tr>
<th>event_id</th>
<th>duration</th>
<th>sql_text</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>0.028310</td>
<td>SELECT * FROM employees.employees WHERE emp_no = 10001</td>
</tr>
</tbody>
</table>
+----------+----------+--------------------------------------------------------+
```

5. Query the `events_stages_history_long` table to retrieve the statement’s stage events. Stages are linked to statements using event nesting. Each stage event record has a `NESTING_EVENT_ID` column that contains the `EVENT_ID` of the parent statement.

```sql
mysql> SELECT event_name AS Stage, TRUNCATE(TIMER_WAIT/1000000000000,6) AS Duration
FROM performance_schema.events_stages_history_long WHERE NESTING_EVENT_ID=31;
+--------+----------+
<table>
<thead>
<tr>
<th>Stage</th>
<th>Duration</th>
</tr>
</thead>
<tbody>
<tr>
<td>stage/sql/starting</td>
<td>0.000080</td>
</tr>
<tr>
<td>stage/sql/checking permissions</td>
<td>0.000005</td>
</tr>
<tr>
<td>stage/sql/Opening tables</td>
<td>0.027759</td>
</tr>
<tr>
<td>stage/sql/init</td>
<td>0.000052</td>
</tr>
<tr>
<td>stage/sql/System lock</td>
<td>0.000009</td>
</tr>
<tr>
<td>stage/sql/optimizing</td>
<td>0.000006</td>
</tr>
<tr>
<td>stage/sql/statistics</td>
<td>0.000082</td>
</tr>
<tr>
<td>stage/sql/preparing</td>
<td>0.000008</td>
</tr>
<tr>
<td>stage/sql/executing</td>
<td>0.000000</td>
</tr>
<tr>
<td>stage/sql/Sending data</td>
<td>0.000017</td>
</tr>
<tr>
<td>stage/sql/end</td>
<td>0.000001</td>
</tr>
<tr>
<td>stage/sql/query end</td>
<td>0.000004</td>
</tr>
<tr>
<td>stage/sql/closing tables</td>
<td>0.000006</td>
</tr>
</tbody>
</table>
3464
22.19 Restrictions on Performance Schema

The Performance Schema avoids using mutexes to collect or produce data, so there are no guarantees of consistency and results can sometimes be incorrect. Event values in `performance_schema` tables are nondeterministic and nonrepeatable.

If you save event information in another table, you should not assume that the original events remain available later. For example, if you select events from a `performance_schema` table into a temporary table, intending to join that table with the original table later, there might be no matches.

`mysqldump` and `backup database` ignore tables in the `performance_schema` database.

Tables in the `performance_schema` database cannot be locked with `LOCK TABLES`, except the `setup_xxx` tables.

Tables in the `performance_schema` database cannot be indexed.

Results for queries that refer to tables in the `performance_schema` database are not saved in the query cache.

Tables in the `performance_schema` database are not replicated.

The Performance Schema is not available in `libmysqld`, the embedded server.

The types of timers might vary per platform. The `performance_timers` table shows which event timers are available. If the values in this table for a given timer name are `NULL`, that timer is not supported on your platform.

Instruments that apply to storage engines might not be implemented for all storage engines. Instrumentation of each third-party engine is the responsibility of the engine maintainer.

MySQL Connectors provide connectivity to the MySQL server for client programs. APIs provide low-level access to the MySQL protocol and MySQL resources. Both Connectors and the APIs enable you to connect and execute MySQL statements from another language or environment, including ODBC, Java (JDBC), Perl, Python, PHP, Ruby, and native C and embedded MySQL instances.

MySQL Connectors

Oracle develops a number of connectors:

• Connector/C++ enables C++ applications to connect to MySQL.

• Connector/J provides driver support for connecting to MySQL from Java applications using the standard Java Database Connectivity (JDBC) API.

• Connector/NET enables developers to create .NET applications that connect to MySQL. Connector/NET implements a fully functional ADO.NET interface and provides support for use with ADO.NET aware tools. Applications that use Connector/NET can be written in any supported .NET language.

• Connector/ODBC provides driver support for connecting to MySQL using the Open Database Connectivity (ODBC) API. Support is available for ODBC connectivity from Windows, Unix, and macOS platforms.
• Connector/Python provides driver support for connecting to MySQL from Python applications using an API that is compliant with the Python DB API version 2.0. No additional Python modules or MySQL client libraries are required.

The MySQL C API

For direct access to using MySQL natively within a C application, there are two methods:

• The C API provides low-level access to the MySQL client/server protocol through the libmysqlclient client library. This is the primary method used to connect to an instance of the MySQL server, and is used both by MySQL command-line clients and many of the MySQL Connectors and third-party APIs detailed here.

  libmysqlclient is included in MySQL distributions.

• libmysqld is an embedded MySQL server library that enables you to embed an instance of the MySQL server into your C applications.

  libmysqld is included in MySQL distributions.

See also MySQL C API Implementations.

To access MySQL from a C application, or to build an interface to MySQL for a language not supported by the Connectors or APIs in this chapter, the C API is where to start. A number of programmer’s utilities are available to help with the process; see Section 4.7, “Program Development Utilities”.

Third-Party MySQL APIs

The remaining APIs described in this chapter provide an interface to MySQL from specific application languages. These third-party solutions are not developed or supported by Oracle. Basic information on their usage and abilities is provided here for reference purposes only.

All the third-party language APIs are developed using one of two methods, using libmysqlclient or by implementing a native driver. The two solutions offer different benefits:

• Using libmysqlclient offers complete compatibility with MySQL because it uses the same libraries as the MySQL client applications. However, the feature set is limited to the implementation and interfaces exposed through libmysqlclient and the performance may be lower as data is copied between the native language, and the MySQL API components.

• Native drivers are an implementation of the MySQL network protocol entirely within the host language or environment. Native drivers are fast, as there is less copying of data between components, and they can offer advanced functionality not available through the standard MySQL API. Native drivers are also easier for end users to build and deploy because no copy of the MySQL client libraries is needed to build the native driver components.

Table 23.1, “MySQL APIs and Interfaces” lists many of the libraries and interfaces available for MySQL.

Table 23.1 MySQL APIs and Interfaces

23.6 libmysqld, the Embedded MySQL Server Library

The embedded MySQL server library makes it possible to run a full-featured MySQL server inside a client application. The main benefits are increased speed and more simple management for embedded applications.

The embedded server library is based on the client/server version of MySQL, which is written in C/C++. Consequently, the embedded server also is written in C/C++. There is no embedded server available in other languages.

The API is identical for the embedded MySQL version and the client/server version. To change a threaded application to use the embedded library, you normally only have to add calls to the following functions.

<table>
<thead>
<tr>
<th>Function</th>
<th>When to Call</th>
</tr>
</thead>
<tbody>
<tr>
<td>mysql_library_init()</td>
<td>Call it before any other MySQL function is called, preferably early in the main() function.</td>
</tr>
<tr>
<td>mysql_library_end()</td>
<td>Call it before your program exits.</td>
</tr>
<tr>
<td>mysql_thread_init()</td>
<td>Call it in each thread you create that accesses MySQL.</td>
</tr>
<tr>
<td>mysql_thread_end()</td>
<td>Call it before calling pthread_exit().</td>
</tr>
</tbody>
</table>

Then, link your code with libmysqld.a instead of libmysqlclient.a. To ensure binary compatibility between your application and the server library, always compile your application against headers for the same series of MySQL that was used to compile the server library. For example, if libmysqld was compiled against MySQL 5.5 headers, do not compile your application against MySQL 5.6 headers, or vice versa.

Because the mysql_library_xxx() functions are also included in libmysqlclient.a, you can change between the embedded and the client/server version by just linking your application with the right library. See mysql_library_init().

One difference between the embedded server and the standalone server is that for the embedded server, authentication for connections is disabled by default.

23.6.1 Compiling Programs with libmysqld

In precompiled binary MySQL distributions that include libmysqld, the embedded server library, MySQL builds the library using the appropriate vendor compiler if there is one.

To get a libmysqld library if you build MySQL from source yourself, you should configure MySQL with the -DWITH_EMBEDDED_SERVER=1 option. See Section 2.9.7, “MySQL Source-Configuration Options”.

When you link your program with libmysqld, you must also include the system-specific pthread libraries and some libraries that the MySQL server uses. You can get the full list of libraries by executing mysql_config --libmysqld-libs.

The correct flags for compiling and linking a threaded program must be used, even if you do not directly call any thread functions in your code.
To compile a C program to include the necessary files to embed the MySQL server library into an executable version of a program, the compiler needs to know where to find various files and needs instructions on how to compile the program. The following example shows how a program could be compiled from the command line, assuming that you are using `gcc`, use the GNU C compiler:

```bash
gcc mysql_test.c -o mysql_test \
`/usr/local/mysql/bin/mysql_config --include --libmysqld-libs`
```

Immediately following the `gcc` command is the name of the C program source file. After it, the `-o` option is given to indicate that the file name that follows is the name that the compiler is to give to the output file, the compiled program. The next line of code tells the compiler to obtain the location of the include files and libraries and other settings for the system on which it is compiled. The `mysql_config` command is contained in backticks, not single quotation marks.

On some non-`gcc` platforms, the embedded library depends on C++ runtime libraries and linking against the embedded library might result in missing-symbol errors. To solve this, link using a C++ compiler or explicitly list the required libraries on the link command line.

### 23.6.2 Restrictions When Using the Embedded MySQL Server

The embedded server has the following limitations:

- No loadable functions.
- No stack trace on core dump.
- You cannot set this up as a source or a replica (no replication).
- Very large result sets may be unusable on low memory systems.
- You cannot connect to an embedded server from an outside process with sockets or TCP/IP. However, you can connect to an intermediate application, which in turn can connect to an embedded server on the behalf of a remote client or outside process.
- `libmysqld` does not support encrypted connections. An implication is that if an application linked against `libmysqld` establishes a connection to a remote server, the connection cannot be encrypted.
- `InnoDB` is not reentrant in the embedded server and cannot be used for multiple connections, either successively or simultaneously.
- The Event Scheduler is not available. Because of this, the `event_scheduler` system variable is disabled.
- The Performance Schema is not available.

Some of these limitations can be changed by editing the `mysql_embed.h` include file and recompiling MySQL.

### 23.6.3 Options with the Embedded Server

Any options that may be given with the `mysqld` server daemon, may be used with an embedded server library. Server options may be given in an array as an argument to the `mysql_library_init()`, which initializes the server. They also may be given in an option file like `my.cnf`. To specify an option file for a C program, use the `--defaults-file` option as one of the elements of the second argument of the `mysql_library_init()` function. See `mysql_library_init()`, for more information on the `mysql_library_init()` function.
Using option files can make it easier to switch between a client/server application and one where MySQL is embedded. Put common options under the [server] group. These are read by both MySQL versions. Client/server-specific options should go under the [mysqld] section. Put options specific to the embedded MySQL server library in the [embedded] section. Options specific to applications go under section labeled [ApplicationName_SERVER]. See Section 4.2.2.2, “Using Option Files”.

23.6.4 Embedded Server Examples

These two example programs should work without any changes on a Linux or FreeBSD system. For other operating systems, minor changes are needed, mostly with file paths. These examples are designed to give enough details for you to understand the problem, without the clutter that is a necessary part of a real application. The first example is very straightforward. The second example is a little more advanced with some error checking. The first is followed by a command-line entry for compiling the program. The second is followed by a GNUmake file that may be used for compiling instead.

Example 1

test1_libmysqld.c

```c
#include <stdio.h>
#include <stdlib.h>
#include <stdarg.h>
#include "mysql.h"

MYSQL *mysql;
MYSQL_RES *results;
MYSQL_ROW record;
static char *server_options[] = 
    { "mysql_test", "--defaults-file=my.cnf", NULL };
int num_elements = (sizeof(server_options) / sizeof(char *)) - 1;
static char *server_groups[] = { "libmysqld_server",
                                      "libmysqld_client", NULL };

int main(void)
{
    mysql_library_init(num_elements, server_options, server_groups);
    mysql = mysql_init(NULL);
    mysql_options(mysql, MYSQL_READ_DEFAULT_GROUP, "libmysqld_client");
    mysql_options(mysql, MYSQL_OPT_USE_EMBEDDED_CONNECTION, NULL);
    mysql_real_connect(mysql, NULL, NULL, NULL, "database1", 0, NULL, 0);
    mysql_query(mysql, "SELECT column1, column2 FROM table1");
    results = mysql_store_result(mysql);
    while((record = mysql_fetch_row(results))) {
        printf("%s - %s\n", record[0], record[1]);
    }
    mysql_free_result(results);
    mysql_close(mysql);
    mysql_library_end();
    return 0;
}
```

Here is the command line for compiling the above program:

gcc test1_libmysqld.c -o test1_libmysqld \
`/usr/local/mysql/bin/mysql_config --include --libmysqld-libs`
Example 2

To try the example, create an `test2_libmysqld` directory at the same level as the MySQL source directory. Save the `test2_libmysqld.c` source and the GNU `makefile` in the directory, and run GNU `make` from inside the `test2_libmysqld` directory.

test2_libmysqld.c

```c
/*
 * A simple example client, using the embedded MySQL server library
 */
#include <mysql.h>
#include <stdarg.h>
#include <stdio.h>
#include <stdlib.h>

MYSQL *db_connect(const char *dbname);
void db_disconnect(MYSQL *db);
void db_do_query(MYSQL *db, const char *query);

const char *server_groups[] = {
  "test2_libmysqld_SERVER", "embedded", "server", NULL
};

int
main(int argc, char **argv)
{
  MYSQL *one, *two;

  /* mysql_library_init() must be called before any other mysql
   * functions.
   *
   * You can use mysql_library_init(0, NULL, NULL), and it
   * initializes the server using groups = {
   *   "server", "embedded", NULL
   * },
   *
   * In your $HOME/.my.cnf file, you probably want to put:
   *
   * [test2_libmysqld_SERVER]
   * language = /path/to/source/of/mysql/sql/share/english
   *
   * You could, of course, modify argc and argv before passing
   * them to this function. Or you could create new ones in any
   * way you like. But all of the arguments in argv (except for
   * argv[0], which is the program name) should be valid options
   * for the MySQL server.
   *
   * If you link this client against the normal mysqlclient
   * library, this function is just a stub that does nothing.
   */
  mysql_library_init(argc, argv, (char **)server_groups);

  one = db_connect("test");
  two = db_connect(NULL);

  db_do_query(one, "SHOW TABLE STATUS");
  db_do_query(two, "SHOW DATABASES");

  mysql_close(two);
  mysql_close(one);

  /* This must be called after all other mysql functions */
  mysql_library_end();
}
```
Embedded Server Examples

exit(EXIT_SUCCESS);
}

static void
die(MYSQL *db, char *fmt, ...)
{
    va_list ap;
    va_start(ap, fmt);
    vfprintf(stderr, fmt, ap);
    va_end(ap);
    (void)putc(\n', stderr);
    if (db)
        db_disconnect(db);
    exit(EXIT_FAILURE);
}

MYSQL *
db_connect(const char *dbname)
{
    MYSQL *db = mysql_init(NULL);
    if (!db)
        die(db, "mysql_init failed: no memory");
    /*
    * Notice that the client and server use separate group names.
    * This is critical, because the server does not accept the
    * client's options, and vice versa.
    */
    mysql_options(db, MYSQL_READ_DEFAULT_GROUP, "test2_libmysqld_CLIENT");
    if (!mysql_real_connect(db, NULL, NULL, NULL, dbname, 0, NULL, 0))
        die(db, "mysql_real_connect failed: %s", mysql_error(db));
    return db;
}

void
db_disconnect(MYSQL *db)
{
    mysql_close(db);
}

void
db_do_query(MYSQL *db, const char *query)
{
    if (mysql_query(db, query) != 0)
        goto err;
    if (mysql_field_count(db) > 0)
    {
        MYSQL_RES   *res;
        MYSQL_ROW    row, end_row;
        int num_fields;

        if ((res = mysql_store_result(db)))
            goto err;
        num_fields = mysql_num_fields(res);
        while ((row = mysql_fetch_row(res)))
            {
                (void)fputs(">> ", stdout);
                for (end_row = row + num_fields; row < end_row; ++row)
                    (void)printf("%s\t", row ? (char*)*row : "NULL");
                (void)putc(\n', stdout);
            }
        mysql_free_result(res);
    }
    else
        (void)printf("Affected rows: %lld\n", mysql_affected_rows(db));
```c
return;
err:
  die(db, "db_do_query failed: %s [%s]", mysql_error(db), query);
}
```

### GNUmakefile

```makefile
# This assumes the MySQL software is installed in /usr/local/mysql
inc      := /usr/local/mysql/include/mysql
lib      := /usr/local/mysql/lib

# If you have not installed the MySQL software yet, try this instead
#inc      := $(HOME)/mysql-5.6/include
#lib      := $(HOME)/mysql-5.6/libmysqld

CC       := gcc
CPPFLAGS := -I$(inc) -D_THREAD_SAFE -D_REENTRANT
CFLAGS   := -g -W -Wall
LDFLAGS  := -static
# You can change -lmysqld to -lmysqlclient to use the
# client/server library
LDLIBS   := -L$(lib) -lmysqld -lm -ldl -lcrypt

ifneq (,$(shell grep FreeBSD /COPYRIGHT 2>/dev/null))
  # FreeBSD
  LDFLAGS += -pthread
else
  # Assume Linux
  LDLIBS += -lpthread
endif

# This works for simple one-file test programs
sources := $(wildcard *.c)
objects := $(patsubst %c,%o,$(sources))
targets := $(basename $(sources))

all: $(targets)
clean:
  rm -f $(targets) $(objects) *.core
```

### 23.7 MySQL C API

The MySQL C API Developer Guide is published in standalone form, not as part of the MySQL Reference Manual. See MySQL 5.6 C API Developer Guide.

### 23.8 MySQL PHP API

The MySQL PHP API manual is now published in standalone form, not as part of the MySQL Reference Manual. See MySQL and PHP.

### 23.9 MySQL Perl API

The Perl DBI module provides a generic interface for database access. You can write a DBI script that works with many different database engines without change. To use DBI with MySQL, install the following:

1. The DBI module.
2. The DBD::mysql module. This is the DataBase Driver (DBD) module for Perl.
3. Optionally, the DBD module for any other type of database server you want to access.

Perl DBI is the recommended Perl interface. It replaces an older interface called mysqlperl, which should be considered obsolete.

These sections contain information about using Perl with MySQL and writing MySQL applications in Perl:

- For installation instructions for Perl DBI support, see Section 2.13, “Perl Installation Notes”.
- For an example of reading options from option files, see Section 5.7.4, “Using Client Programs in a Multiple-Server Environment”.
- For secure coding tips, see Section 6.1.1, “Security Guidelines”.
- For debugging tips, see Section 5.8.1.4, “Debugging mysqld under gdb”.
- For some Perl-specific environment variables, see Section 4.9, “Environment Variables”.
- For considerations for running on macOS, see Section 2.4, “Installing MySQL on macOS”.
- For ways to quote string literals, see Section 9.1.1, “String Literals”.

DBI information is available at the command line, online, or in printed form:

- Once you have the DBI and DBD::mysql modules installed, you can get information about them at the command line with the perldoc command:
  
  ```
  $> perldoc DBI
  $> perldoc FAQ
  $> perldoc DBD::mysql
  ```

  You can also use pod2man, pod2html, and so on to translate this information into other formats.

- For online information about Perl DBI, visit the DBI website, http://dbi.perl.org/. That site hosts a general DBI mailing list.

### 23.10 MySQL Python API

MySQLdb is a third-party driver that provides MySQL support for Python, compliant with the Python DB API version 2.0. It can be found at http://sourceforge.net/projects/mysql-python/.

The new MySQL Connector/Python component provides an interface to the same Python API, and is built into the MySQL Server and supported by Oracle. See MySQL Connector/Python Developer Guide for details on the Connector, as well as coding guidelines for Python applications and sample Python code.

### 23.11 MySQL Ruby APIs

The mysql2 Ruby gem provides an API for connecting to MySQL, performing queries, and iterating through results; it is intended to support MySQL 5.6, 5.7, and 8.0. For more information, see the mysql2 page at RubyGems.org or the project's GitHub page.

For background and syntax information about the Ruby language, see Ruby Programming Language.
23.11.1 The MySQL/Ruby API

The MySQL/Ruby module provides access to MySQL databases using Ruby through `libmysqlclient`. For information on installing the module, and the functions exposed, see MySQL/Ruby.

23.11.2 The Ruby/MySQL API

The Ruby/MySQL module provides access to MySQL databases using Ruby through a native driver interface using the MySQL network protocol. For information on installing the module, and the functions exposed, see Ruby/MySQL.

23.12 MySQL Tcl API

MySQLtcl is a simple API for accessing a MySQL database server from the Tcl programming language. It can be found at http://www.xdobry.de/mysqltcl/.

23.13 MySQL Eiffel Wrapper

Eiffel MySQL is an interface to the MySQL database server using the Eiffel programming language, written by Michael Ravits. It can be found at http://efsa.sourceforge.net/archive/ravits/mysql.htm.
MySQL Enterprise Edition is a commercial product. Like MySQL Community Edition, MySQL Enterprise Edition includes MySQL Server, a fully integrated transaction-safe, ACID-compliant database with full commit, rollback, crash-recovery, and row-level locking capabilities. In addition, MySQL Enterprise Edition includes the following components designed to provide monitoring and online backup, as well as improved security and scalability:

- MySQL Enterprise Monitor
- MySQL Enterprise Backup
- MySQL Enterprise Security
- MySQL Enterprise Encryption
- MySQL Enterprise Audit
- MySQL Enterprise Firewall
- MySQL Enterprise Thread Pool
- MySQL Enterprise Data Masking and De-Identification

The following sections briefly discuss each of these components and indicate where to find more detailed information. To learn more about commercial products, see https://www.mysql.com/products/.

### 24.1 MySQL Enterprise Monitor Overview

MySQL Enterprise Monitor is an enterprise monitoring system for MySQL that keeps an eye on your MySQL servers, notifies you of potential issues and problems, and advises you how to fix the issues. MySQL Enterprise Monitor can monitor all kinds of configurations, from a single MySQL server that is important to your business, all the way up to a huge farm of MySQL servers powering a busy website.

The following discussion briefly summarizes the basic components that make up the MySQL Enterprise Monitor product. For more information, see the MySQL Enterprise Monitor manual, available at https://dev.mysql.com/doc/mysql-monitor/en/.

MySQL Enterprise Monitor components can be installed in various configurations depending on your database and network topology, to give you the best combination of reliable and responsive monitoring data, with minimal overhead on the database server machines. A typical MySQL Enterprise Monitor installation consists of:
MySQL Enterprise Monitor is designed to monitor one or more MySQL servers. The monitoring information is collected by using an agent, MySQL Enterprise Monitor Agent. The agent communicates with the hosts and MySQL servers that it monitors, collecting variables, status and health information, and sending this information to the MySQL Enterprise Service Manager.

The information collected by the agent about each MySQL server and host you are monitoring is sent to the MySQL Enterprise Service Manager. This server collates all of the information from the agents. As it collates the information sent by the agents, the MySQL Enterprise Service Manager continually tests the collected data, comparing the status of the server to reasonable values. When thresholds are reached, the server can trigger an event (including an alarm and notification) to highlight a potential issue, such as low memory, high CPU usage, or more complex conditions such insufficient buffer sizes and status information. We call each test, with its associated threshold value, a rule.

These rules, and the alarms and notifications, are each known as a MySQL Enterprise Advisors. Advisors form a critical part of the MySQL Enterprise Service Manager, as they provide warning information and troubleshooting advice about potential problems.

The MySQL Enterprise Service Manager includes a web server, and you interact with it through any web browser. This interface, the MySQL Enterprise Monitor User Interface, displays all of the information collected by the agents, and lets you view all of your servers and their current status as a group or individually. You control and configure all aspects of the service using the MySQL Enterprise Monitor User Interface.

The information supplied by the MySQL Enterprise Monitor Agent processes also includes statistical and query information, which you can view in the form of graphs. For example, you can view aspects such as server load, query numbers, or index usage information as a graph over time. The graph lets you pinpoint problems or potential issues on your server, and can help diagnose the impact from database or external problems (such as external system or network failure) by examining the data from a specific time interval.

The MySQL Enterprise Monitor Agent can also be configured to collect detailed information about the queries executed on your server, including the row counts and performance times for executing each query. You can correlate the detailed query data with the graphical information to identify which queries were executing when you experienced a particularly high load, index or other issue. The query data is supported by a system called Query Analyzer, and the data can be presented in different ways depending on your needs.

24.2 MySQL Enterprise Backup Overview

MySQL Enterprise Backup performs hot backup operations for MySQL databases. The product is architected for efficient and reliable backups of tables created by the InnoDB storage engine. For completeness, it can also back up tables from MyISAM and other storage engines.

The following discussion briefly summarizes MySQL Enterprise Backup. For more information, see the MySQL Enterprise Backup manual, available at https://dev.mysql.com/doc/mysql-enterprise-backup/en/.

Hot backups are performed while the database is running and applications are reading and writing to it. This type of backup does not block normal database operations, and it captures even changes that occur while the backup is happening. For these reasons, hot backups are desirable when your database...
“grows up” -- when the data is large enough that the backup takes significant time, and when your data is important enough to your business that you must capture every last change, without taking your application, website, or web service offline.

MySQL Enterprise Backup does a hot backup of all tables that use the InnoDB storage engine. For tables using MyISAM or other non-InnoDB storage engines, it does a “warm” backup, where the database continues to run, but those tables cannot be modified while being backed up. For efficient backup operations, you can designate InnoDB as the default storage engine for new tables, or convert existing tables to use the InnoDB storage engine.

### 24.3 MySQL Enterprise Security Overview

MySQL Enterprise Edition provides plugins that implement security features using external services:

- MySQL Enterprise Edition includes an authentication plugin that enables MySQL Server to use LDAP (Lightweight Directory Access Protocol) to authenticate MySQL users. LDAP Authentications supports user name and password, SASL, and GSSAPI/Kerberos authentication methods to LDAP services. For more information, see LDAP Pluggable Authentication.

- MySQL Enterprise Edition includes an authentication plugin that enables MySQL Server to use Native Kerberos to authenticate MySQL users using their Kerberos Principals. For more information, see Kerberos Pluggable Authentication.

- MySQL Enterprise Edition includes an authentication plugin that enables MySQL Server to use PAM (Pluggable Authentication Modules) to authenticate MySQL users. PAM enables a system to use a standard interface to access various kinds of authentication methods, such as Unix passwords or an LDAP directory. For more information, see Section 6.4.1.6, “PAM Pluggable Authentication”.

- MySQL Enterprise Edition includes a suite of masking and de-identification functions that perform subsetting, random generation, and dictionary replacement to de-identify strings, numerics, phone numbers, emails and more. These functions enable masking existing data using several methods such as obfuscation (removing identifying characteristics), generation of formatted random data, and data replacement or substitution. For more information, see Using MySQL Enterprise Data Masking and De-Identification.

- MySQL Enterprise Edition includes a set of encryption functions based on the OpenSSL library that expose OpenSSL capabilities at the SQL level. For more information, see Section 24.4, “MySQL Enterprise Encryption Overview”.

- MySQL Enterprise Edition 5.7 and higher includes a keyring plugin that uses Oracle Key Vault as a backend for keyring storage. For more information, see The MySQL Keyring.

- MySQL Transparent Data Encryption (TDE) provides at-rest encryption for MySQL Server for all files that might contain sensitive data. For more information, see InnoDB Data-at-Rest Encryption, Encrypting Binary Log Files and Relay Log Files, and Encrypting Audit Log Files.

For other related Enterprise security features, see Section 24.4, “MySQL Enterprise Encryption Overview”.

### 24.4 MySQL Enterprise Encryption Overview
MySQL Enterprise Edition includes a set of encryption functions based on the OpenSSL library that expose OpenSSL capabilities at the SQL level. These functions enable Enterprise applications to perform the following operations:

- Implement added data protection using public-key asymmetric cryptography
- Create public and private keys and digital signatures
- Perform asymmetric encryption and decryption
- Use cryptographic hashing for digital signing and data verification and validation

For more information, see Section 6.5, “MySQL Enterprise Encryption”.

For other related Enterprise security features, see Section 24.3, “MySQL Enterprise Security Overview”.

24.5 MySQL Enterprise Audit Overview

MySQL Enterprise Edition includes MySQL Enterprise Audit, implemented using a server plugin. MySQL Enterprise Audit uses the open MySQL Audit API to enable standard, policy-based monitoring and logging of connection and query activity executed on specific MySQL servers. Designed to meet the Oracle audit specification, MySQL Enterprise Audit provides an out of box, easy to use auditing and compliance solution for applications that are governed by both internal and external regulatory guidelines.

When installed, the audit plugin enables MySQL Server to produce a log file containing an audit record of server activity. The log contents include when clients connect and disconnect, and what actions they perform while connected, such as which databases and tables they access.

For more information, see Section 6.4.4, “MySQL Enterprise Audit”.

24.6 MySQL Enterprise Firewall Overview

MySQL Enterprise Edition includes MySQL Enterprise Firewall, an application-level firewall that enables database administrators to permit or deny SQL statement execution based on matching against allowlists of accepted statement patterns. This helps harden MySQL Server against attacks such as SQL injection or attempts to exploit applications by using them outside of their legitimate query workload characteristics.

Each MySQL account registered with the firewall has its own statement allowlist, enabling protection to be tailored per account. For a given account, the firewall can operate in recording or protecting mode, for training in the accepted statement patterns or protection against unacceptable statements.

For more information, see Section 6.4.5, “MySQL Enterprise Firewall”.

24.7 MySQL Enterprise Thread Pool Overview

MySQL Enterprise Edition includes MySQL Enterprise Thread Pool, implemented using a server plugin. The default thread-handling model in MySQL Server executes statements using one thread per client connection. As more clients connect to the server and execute statements, overall performance degrades. In MySQL Enterprise Edition, a thread pool plugin provides an alternative thread-handling model designed to reduce overhead and improve performance. The plugin implements a thread pool that increases server performance by efficiently managing statement execution threads for large numbers of client connections.

For more information, see Section 5.5.3, “MySQL Enterprise Thread Pool”.

24.8 MySQL Enterprise Data Masking and De-Identification Overview
MySQL Enterprise Edition 5.7 and higher includes MySQL Enterprise Data Masking and De-Identification, implemented as a plugin library containing a plugin and several loadable functions. Data masking hides sensitive information by replacing real values with substitutes. MySQL Enterprise Data Masking and De-Identification functions enable masking existing data using several methods such as obfuscation (removing identifying characteristics), generation of formatted random data, and data replacement or substitution.

For more information, see MySQL Enterprise Data Masking and De-Identification.
Chapter 25 MySQL Workbench

MySQL Workbench provides a graphical tool for working with MySQL servers and databases. MySQL Workbench fully supports MySQL versions 5.5 and higher.

The following discussion briefly describes MySQL Workbench capabilities. For more information, see the MySQL Workbench manual, available at https://docs.oracle.com/cd/E17952_01/workbench-en/.

MySQL Workbench provides five main areas of functionality:

• **SQL Development**: Enables you to create and manage connections to database servers. As well as enabling you to configure connection parameters, MySQL Workbench provides the capability to execute SQL queries on the database connections using the built-in SQL Editor. This functionality replaces that previously provided by the Query Browser standalone application.

• **Data Modeling**: Enables you to create models of your database schema graphically, reverse and forward engineer between a schema and a live database, and edit all aspects of your database using the comprehensive Table Editor. The Table Editor provides easy-to-use facilities for editing Tables, Columns, Indexes, Triggers, Partitioning, Options, Inserts and Privileges, Routines and Views.

• **Server Administration**: Enables you to create and administer server instances.

• **Data Migration**: Allows you to migrate from Microsoft SQL Server, Sybase ASE, SQLite, SQL Anywhere, PostreSQL, and other RDBMS tables, objects and data to MySQL. Migration also supports migrating from earlier versions of MySQL to the latest releases.

• **MySQL Enterprise Support**: Support for Enterprise products such as MySQL Enterprise Backup and MySQL Audit.

MySQL Workbench is available in two editions, the Community Edition and the Commercial Edition. The Community Edition is available free of charge. The Commercial Edition provides additional Enterprise features, such as database documentation generation, at low cost.

A.17 MySQL 5.6 FAQ: Virtualization Support ....................................... 3534

A.1 MySQL 5.6 FAQ: General

A.1.1 Which version of MySQL is production-ready (GA)? ...................... 3487
A.1.2 Can MySQL 5.6 do subqueries? ................................................ 3488
A.1.3 Can MySQL 5.6 perform multiple-table inserts, updates, and deletes? ................................................. 3488
A.1.4 Does MySQL 5.6 have a Query Cache? Does it work on Server, Instance or Database? 3488
A.1.5 Does MySQL 5.6 have Sequences? ............................................. 3488
A.1.6 Does MySQL 5.6 have a NOW() function with fractions of seconds? 3488
A.1.7 Does MySQL 5.6 work with multi-core processors? ....................... 3488
A.1.8 Why do I see multiple processes for mysqld? .............................. 3488
A.1.9 Can MySQL 5.6 perform ACID transactions? ............................... 3489

A.1.1. Which version of MySQL is production-ready (GA)?

MySQL 8.0, 5.7, and MySQL 5.6 are supported for production use.

MySQL 8.0 achieved General Availability (GA) status with MySQL 8.0.11, which was released for production use on 19 April 2018.

MySQL 5.7 achieved General Availability (GA) status with MySQL 5.7.9, which was released for production use on 21 October 2015.

MySQL 5.6 achieved General Availability (GA) status with MySQL 5.6.10, which was released for production use on 5 February 2013.

MySQL 5.5 achieved General Availability (GA) status with MySQL 5.5.8, which was released for production use on 3 December 2010. Active development for MySQL 5.5 has ended.

MySQL 5.1 achieved General Availability (GA) status with MySQL 5.1.30, which was released for production use on 14 November 2008. Active development for MySQL 5.1 has ended.
MySQL 5.0 achieved General Availability (GA) status with MySQL 5.0.15, which was released for production use on 19 October 2005. Active development for MySQL 5.0 has ended.

A.1.2. Can MySQL 5.6 do subqueries?

Yes. See Section 13.2.10, “Subqueries”.

A.1.3. Can MySQL 5.6 perform multiple-table inserts, updates, and deletes?

Yes. For the syntax required to perform multiple-table updates, see Section 13.2.11, “UPDATE Statement”; for that required to perform multiple-table deletes, see Section 13.2.2, “DELETE Statement”.

A multiple-table insert can be accomplished using a trigger whose FOR EACH ROW clause contains multiple INSERT statements within a BEGIN ... END block. See Section 20.3, “Using Triggers”.

A.1.4. Does MySQL 5.6 have a Query Cache? Does it work on Server, Instance or Database?

Yes. The query cache operates on the server level, caching complete result sets matched with the original query string. If an exactly identical query is made (which often happens, particularly in web applications), no parsing or execution is necessary; the result is sent directly from the cache. Various tuning options are available. See Section 8.10.3, “The MySQL Query Cache”.

A.1.5. Does MySQL 5.6 have Sequences?

No. However, MySQL has an AUTO_INCREMENT system, which in MySQL 5.6 can also handle inserts in a multi-source replication setup. With the auto_increment_increment and auto_increment_offset system variables, you can set each server to generate auto-increment values that don’t conflict with other servers. The auto_increment_increment value should be greater than the number of servers, and each server should have a unique offset.

A.1.6. Does MySQL 5.6 have a NOW() function with fractions of seconds?

Yes, see Section 11.2.7, “Fractional Seconds in Time Values”.

A.1.7. Does MySQL 5.6 work with multi-core processors?

Yes. MySQL is fully multithreaded, and makes use of all CPUs made available to it. Not all CPUs may be available; modern operating systems should be able to utilize all underlying CPUs, but also make it possible to restrict a process to a specific CPU or sets of CPUs.

On Windows, there is currently a limit to the number of (logical) processors that mysqld can use: a single processor group, which is limited to a maximum of 64 logical processors.

Use of multiple cores may be seen in these ways:

- A single core is usually used to service the commands issued from one session.
- A few background threads make limited use of extra cores; for example, to keep background I/O tasks moving.
- If the database is I/O-bound (indicated by CPU consumption less than capacity), adding more CPUs is futile. If the database is partitioned into an I/O-bound part and a CPU-bound part, adding CPUs may still be useful.

A.1.8. Why do I see multiple processes for mysqld?
mysqld is a single-process program, not a multi-process program, and does not fork or launch other processes. However, mysqld is multithreaded and some process-reporting system utilities display separate entries for each thread of multithreaded processes, which may lead to the appearance of multiple mysqld processes when in fact there is only one.

A.1.9. Can MySQL 5.6 perform ACID transactions?

Yes. All current MySQL versions support transactions. The InnoDB storage engine offers full ACID transactions with row-level locking, multi-versioning, nonlocking repeatable reads, and all four SQL standard isolation levels.

The NDB storage engine supports the READ COMMITTED transaction isolation level only.

A.2 MySQL 5.6 FAQ: Storage Engines

A.2.1. Where can I obtain complete documentation for MySQL storage engines?

See Chapter 15, Alternative Storage Engines. That chapter contains information about all MySQL storage engines except for the InnoDB storage engine and the NDB storage engine (used for MySQL Cluster). InnoDB is covered in Chapter 14, The InnoDB Storage Engine. NDB is covered in Chapter 18, MySQL NDB Cluster 7.3 and NDB Cluster 7.4.

A.2.2. Are there any new storage engines in MySQL 5.6?

The features from the optional InnoDB Plugin from MySQL 5.1 are folded into the built-in InnoDB storage engine, so you can take advantage of features such as the Barracuda file format, InnoDB table compression, and the new configuration options for performance. See Chapter 14, The InnoDB Storage Engine for details. InnoDB also becomes the default storage engine for new tables. See Section 14.1, “Introduction to InnoDB” for details.

A.2.3. Have any storage engines been removed in MySQL 5.6?

No.

A.2.4. What are the unique benefits of the ARCHIVE storage engine?

The ARCHIVE storage engine stores large amounts of data without indexes; it has a small footprint, and performs selects using table scans. See Section 15.5, “The ARCHIVE Storage Engine”, for details.

A.3 MySQL 5.6 FAQ: Server SQL Mode

A.3.1. What are server SQL modes?

A.3.2. How many server SQL modes are there?

A.3.3. How do you determine the server SQL mode?

A.3.4. Is the mode dependent on the database or connection?

A.3.5. Can the rules for strict mode be extended?

A.3.6. Does strict mode impact performance?

A.3.7. What is the default server SQL mode when MySQL 5.6 is installed?
Server SQL modes define what SQL syntax MySQL should support and what kind of data validation checks it should perform. This makes it easier to use MySQL in different environments and to use MySQL together with other database servers. The MySQL Server apply these modes individually to different clients. For more information, see Section 5.1.10, “Server SQL Modes”.

A.3.2. How many server SQL modes are there?

Each mode can be independently switched on and off. See Section 5.1.10, “Server SQL Modes”, for a complete list of available modes.

A.3.3. How do you determine the server SQL mode?

You can set the default SQL mode (for \texttt{mysqld} startup) with the \texttt{--sql-mode} option. Using the statement \texttt{SET [GLOBAL|SESSION] sql_mode='modes'}, you can change the settings from within a connection, either locally to the connection, or to take effect globally. You can retrieve the current mode by issuing a \texttt{SELECT @@sql_mode} statement.

A.3.4. Is the mode dependent on the database or connection?

A mode is not linked to a particular database. Modes can be set locally to the session (connection), or globally for the server. you can change these settings using \texttt{SET [GLOBAL|SESSION] sql_mode='modes'}.

A.3.5. Can the rules for strict mode be extended?

When we refer to \texttt{strict mode}, we mean a mode where at least one of the modes \texttt{TRADITIONAL}, \texttt{STRICT_TRANS_TABLES}, or \texttt{STRICT_ALL_TABLES} is enabled. Options can be combined, so you can add restrictions to a mode. See Section 5.1.10, “Server SQL Modes”, for more information.

A.3.6. Does strict mode impact performance?

The intensive validation of input data that some settings requires more time than if the validation is not done. While the performance impact is not that great, if you do not require such validation (perhaps your application already handles all of this), then MySQL gives you the option of leaving strict mode disabled. However, if you do require it, strict mode can provide such validation.

A.3.7. What is the default server SQL mode when MySQL 5.6 is installed?

The default SQL mode is \texttt{NO_ENGINE_SUBSTITUTION}. For information about all available modes and default MySQL behavior, see Section 5.1.10, “Server SQL Modes”.

A.4 MySQL 5.6 FAQ: Stored Procedures and Functions

A.4.1 Does MySQL 5.6 support stored procedures and functions? ........................................ 3491
A.4.2 Where can I find documentation for MySQL stored procedures and stored functions? .......... 3491
A.4.3 Is there a discussion forum for MySQL stored procedures? ........................................... 3491
A.4.4 Where can I find the ANSI SQL 2003 specification for stored procedures? .......................... 3491
A.4.5 How do you manage stored routines? ................................................................................. 3491
A.4.6 Is there a way to view all stored procedures and stored functions in a given database? ........... 3491
A.4.7 Where are stored procedures stored? .................................................................................. 3492
A.4.8 Is it possible to group stored procedures or stored functions into packages? ....................... 3492
A.4.9 Can a stored procedure call another stored procedure? ..................................................... 3492
A.4.10 Can a stored procedure call a trigger? ............................................................................... 3492
A.4.11 Can a stored procedure access tables? .............................................................................. 3492
A.4.12 Do stored procedures have a statement for raising application errors? ............................... 3492
A.4.13 Do stored procedures provide exception handling? ......................................................... 3492
A.4.14 Can MySQL 5.6 stored routines return result sets? ......................................................... 3492
A.4.15 Is \texttt{WITH RECOMPILE} supported for stored procedures? ........................................ 3492
A.4.16 Is there a MySQL equivalent to using mod_plsql as a gateway on Apache to talk directly to a stored procedure in the database? ................................. 3492
A.4.17 Can I pass an array as input to a stored procedure? ................................................. 3492
A.4.18 Can I pass a cursor as an IN parameter to a stored procedure? ................................. 3492
A.4.19 Can I return a cursor as an OUT parameter from a stored procedure? ......................... 3493
A.4.20 Can I print out a variable’s value within a stored routine for debugging purposes? ........ 3493
A.4.21 Can I commit or roll back transactions inside a stored procedure? .............................. 3493
A.4.22 Do MySQL 5.6 stored procedures and functions work with replication? ....................... 3493
A.4.23 Are stored procedures and functions created on a replication source server replicated to a replica? ........................................................................ 3493
A.4.24 How are actions that take place inside stored procedures and functions replicated? ....... 3493
A.4.25 Are there special security requirements for using stored procedures and functions together with replication? ................................................................. 3493
A.4.26 What limitations exist for replicating stored procedure and function actions? ............... 3493
A.4.27 Do the preceding limitations affect the ability of MySQL to do point-in-time recovery? .... 3494
A.4.28 What is being done to correct the aforementioned limitations? .................................. 3494

A.4.1. Does MySQL 5.6 support stored procedures and functions?

Yes. MySQL 5.6 supports two types of stored routines, stored procedures and stored functions.

A.4.2. Where can I find documentation for MySQL stored procedures and stored functions?

See Section 20.2, “Using Stored Routines”.

A.4.3. Is there a discussion forum for MySQL stored procedures?

A.4.4. Where can I find the ANSI SQL 2003 specification for stored procedures?

Unfortunately, the official specifications are not freely available (ANSI makes them available for purchase). However, there are books, such as SQL-99 Complete, Really by Peter Gulutzan and Trudy Pelzer, that provide a comprehensive overview of the standard, including coverage of stored procedures.

A.4.5. How do you manage stored routines?

It is always good practice to use a clear naming scheme for your stored routines. You can manage stored procedures with CREATE [FUNCTION|PROCEDURE], ALTER [FUNCTION|PROCEDURE], DROP [FUNCTION|PROCEDURE], and SHOW CREATE [FUNCTION|PROCEDURE]. You can obtain information about existing stored procedures using the ROUTINES table in the INFORMATION_SCHEMA database (see Section 21.3.19, “The INFORMATION_SCHEMA ROUTINES Table”).

A.4.6. Is there a way to view all stored procedures and stored functions in a given database?

Yes. For a database named dbname, use this query on the INFORMATION_SCHEMA.ROUTINES table:

```
SELECT ROUTINE_TYPE, ROUTINE_NAME
FROM INFORMATION_SCHEMA.ROUTINES
WHERE ROUTINE_SCHEMA='dbname';
```

For more information, see Section 21.3.19, “The INFORMATION_SCHEMA ROUTINES Table”.

The body of a stored routine can be viewed using SHOW CREATE FUNCTION (for a stored function) or SHOW CREATE PROCEDURE (for a stored procedure). See Section 13.7.5.11, “SHOW CREATE PROCEDURE Statement”, for more information.
A.4.7. Where are stored procedures stored?

In the `proc` table of the `mysql` system database. However, you should not access the tables in the system database directly. Instead, query the `INFORMATION_SCHEMA ROUTINES` and `PARAMETERS` tables. See Section 21.3.19, “The INFORMATION_SCHEMA ROUTINES Table”, and Section 21.3.13, “The INFORMATION_SCHEMA PARAMETERS Table”.

You can also use `SHOW CREATE FUNCTION` to obtain information about stored functions, and `SHOW CREATE PROCEDURE` to obtain information about stored procedures. See Section 13.7.5.11, “SHOW CREATE PROCEDURE Statement”.

A.4.8. Is it possible to group stored procedures or stored functions into packages?

No. This is not supported in MySQL 5.6.

A.4.9. Can a stored procedure call another stored procedure?

Yes.

A.4.10. Can a stored procedure call a trigger?

A stored procedure can execute an SQL statement, such as an `UPDATE`, that causes a trigger to activate.

A.4.11. Can a stored procedure access tables?

Yes. A stored procedure can access one or more tables as required.

A.4.12. Do stored procedures have a statement for raising application errors?

Yes. MySQL 5.6 implements the SQL standard `SIGNAL` and `RESIGNAL` statements. See Section 13.6.7, “Condition Handling”.

A.4.13. Do stored procedures provide exception handling?

MySQL implements `HANDLER` definitions according to the SQL standard. See Section 13.6.7.2, “DECLARE ... HANDLER Statement”, for details.

A.4.14. Can MySQL 5.6 stored routines return result sets?

`Stored procedures` can, but stored functions cannot. If you perform an ordinary `SELECT` inside a stored procedure, the result set is returned directly to the client. You need to use the MySQL 4.1 (or higher) client/server protocol for this to work. This means that, for example, in PHP, you need to use the `mysqli` extension rather than the old `mysql` extension.

A.4.15. Is `WITH RECOMPILE` supported for stored procedures?

Not in MySQL 5.6.

A.4.16. Is there a MySQL equivalent to using `mod_plsql` as a gateway on Apache to talk directly to a stored procedure in the database?

There is no equivalent in MySQL 5.6.

A.4.17. Can I pass an array as input to a stored procedure?

Not in MySQL 5.6.

A.4.18. Can I pass a cursor as an `IN` parameter to a stored procedure?

In MySQL 5.6, cursors are available inside stored procedures only.
MySQL 5.6 FAQ: Stored Procedures and Functions

A.4.19 Can I return a cursor as an **OUT** parameter from a stored procedure?

In MySQL 5.6, cursors are available inside stored procedures only. However, if you do not open a cursor on a **SELECT**, the result is sent directly to the client. You can also **SELECT INTO** variables. See Section 13.2.9, “**SELECT Statement**”.

A.4.20 Can I print out a variable's value within a stored routine for debugging purposes?

Yes, you can do this in a **stored procedure**, but not in a stored function. If you perform an ordinary **SELECT** inside a stored procedure, the result set is returned directly to the client. You must use the MySQL 4.1 (or above) client/server protocol for this to work. This means that, for example, in PHP, you need to use the **mysqli** extension rather than the old **mysql** extension.

A.4.21 Can I commit or roll back transactions inside a stored procedure?

Yes. However, you cannot perform transactional operations within a stored function.

A.4.22 Do MySQL 5.6 stored procedures and functions work with replication?

Yes, standard actions carried out in stored procedures and functions are replicated from a replication source server to a replica. There are a few limitations that are described in detail in Section 20.7, “**Stored Program Binary Logging**”.

A.4.23 Are stored procedures and functions created on a replication source server replicated to a replica?

Yes, creation of stored procedures and functions carried out through normal DDL statements on a replication source server are replicated to a replica, so that the objects exist on both servers. **ALTER** and **DROP** statements for stored procedures and functions are also replicated.

A.4.24 How are actions that take place inside stored procedures and functions replicated?

MySQL records each DML event that occurs in a stored procedure and replicates those individual actions to a replica. The actual calls made to execute stored procedures are not replicated.

Stored functions that change data are logged as function invocations, not as the DML events that occur inside each function.

A.4.25 Are there special security requirements for using stored procedures and functions together with replication?

Yes. Because a replica has authority to execute any statement read from a source's binary log, special security constraints exist for using stored functions with replication. If replication or binary logging in general (for the purpose of point-in-time recovery) is active, then MySQL DBAs have two security options open to them:

1. Any user wishing to create stored functions must be granted the **SUPER** privilege.

2. Alternatively, a DBA can set the **log_bin_trust_function_creators** system variable to 1, which enables anyone with the standard **CREATE ROUTINE** privilege to create stored functions.

A.4.26 What limitations exist for replicating stored procedure and function actions?

Nondeterministic (random) or time-based actions embedded in stored procedures may not replicate properly. By their very nature, randomly produced results are not predictable and cannot be exactly reproduced; therefore, random actions replicated to a replica do not mirror those performed on a source. Declaring stored functions to be **DETERMINISTIC** or setting the **log_bin_trust_function_creators** system variable to 0 keeps random operations producing random values from being invoked.
In addition, time-based actions cannot be reproduced on a replica because the timing of such actions in a stored procedure is not reproducible through the binary log used for replication. It records only DML events and does not factor in timing constraints.

Finally, nontransactional tables for which errors occur during large DML actions (such as bulk inserts) may experience replication issues in that a source may be partially updated from DML activity, but no updates are done to the replica because of the errors that occurred. A workaround is for a function’s DML actions to be carried out with the `IGNORE` keyword so that updates on the source that cause errors are ignored and updates that do not cause errors are replicated to the replica.

A.4.27 Do the preceding limitations affect the ability of MySQL to do point-in-time recovery?

The same limitations that affect replication do affect point-in-time recovery.

A.4.28 What is being done to correct the aforementioned limitations?

You can choose either statement-based replication or row-based replication. The original replication implementation is based on statement-based binary logging. Row-based binary logging resolves the limitations mentioned earlier.

Mixed replication is also available (by starting the server with `--binlog-format=mixed`). This hybrid form of replication “knows” whether statement-level replication can safely be used, or row-level replication is required.

For additional information, see Section 17.1.2, “Replication Formats”.

A.5 MySQL 5.6 FAQ: Triggers

A.5.1 Where can I find the documentation for MySQL 5.6 triggers? .......................................................... 3494
A.5.2 Is there a discussion forum for MySQL Triggers? .......................................................... 3494
A.5.3 Does MySQL 5.6 have statement-level or row-level triggers? .......................................................... 3494
A.5.4 Are there any default triggers? .................................................................................. 3494
A.5.5 How are triggers managed in MySQL? .......................................................... 3495
A.5.6 Is there a way to view all triggers in a given database? .................................................. 3495
A.5.7 Where are triggers stored? ................................................................................ 3495
A.5.8 Can a trigger call a stored procedure? .......................................................................... 3495
A.5.9 Can triggers access tables? .................................................................................. 3495
A.5.10 Can a table have multiple triggers with the same trigger event and action time? .... 3495
A.5.11 Is it possible for a trigger to update tables on a remote server? ................................. 3495
A.5.12 Do triggers work with replication? ........................................................................ 3495
A.5.13 How are actions carried out through triggers on a source replicated to a replica? ........ 3496

A.5.1. Where can I find the documentation for MySQL 5.6 triggers?

See Section 20.3, “Using Triggers”.

A.5.2. Is there a discussion forum for MySQL Triggers?

A.5.3. Does MySQL 5.6 have statement-level or row-level triggers?

In MySQL 5.6, all triggers are `FOR EACH ROW`; that is, the trigger is activated for each row that is inserted, updated, or deleted. MySQL 5.6 does not support triggers using `FOR EACH STATEMENT`.

A.5.4. Are there any default triggers?
Not explicitly. MySQL does have specific special behavior for some `TIMESTAMP` columns, as well as for columns which are defined using `AUTO_INCREMENT`.

**A.5.5.** How are triggers managed in MySQL?

In MySQL 5.6, triggers can be created using the `CREATE TRIGGER` statement, and dropped using `DROP TRIGGER`. See Section 13.1.19, “CREATE TRIGGER Statement”, and Section 13.1.30, “DROP TRIGGER Statement”, for more about these statements.

Information about triggers can be obtained by querying the `INFORMATION_SCHEMA.TRIGGERS` table. See Section 21.3.27, “The INFORMATION_SCHEMA TRIGGERS Table”.

**A.5.6.** Is there a way to view all triggers in a given database?

Yes. You can obtain a listing of all triggers defined on database `dbname` using a query on the `INFORMATION_SCHEMA.TRIGGERS` table such as the one shown here:

```sql
SELECT TRIGGER_NAME, EVENT_MANIPULATION, EVENT_OBJECT_TABLE, ACTION_STATEMENT
FROM INFORMATION_SCHEMA.TRIGGERS
WHERE TRIGGER_SCHEMA='dbname';
```

For more information about this table, see Section 21.3.27, “The INFORMATION_SCHEMA TRIGGERS Table”.

You can also use the `SHOW TRIGGERS` statement, which is specific to MySQL. See Section 13.7.5.39, “SHOW TRIGGERS Statement”.

**A.5.7.** Where are triggers stored?

Triggers are stored in `.TRG` files, with one such file one per table.

**A.5.8.** Can a trigger call a stored procedure?

Yes.

**A.5.9.** Can triggers access tables?

A trigger can access both old and new data in its own table. A trigger can also affect other tables, but it is not permitted to modify a table that is already being used (for reading or writing) by the statement that invoked the function or trigger.

**A.5.10.** Can a table have multiple triggers with the same trigger event and action time?

In MySQL 5.6, there cannot be multiple triggers for a given table that have the same trigger event and action time. For example, you cannot have two `BEFORE UPDATE` triggers for a table. This limitation is lifted in MySQL 5.7.

**A.5.11.** Is it possible for a trigger to update tables on a remote server?

Yes. A table on a remote server could be updated using the `FEDERATED` storage engine. (See Section 15.8, “The FEDERATED Storage Engine”)

**A.5.12.** Do triggers work with replication?

Yes. However, the way in which they work depends whether you are using MySQL’s “classic” statement-based or row-based replication format.

When using statement-based replication, triggers on the replica are executed by statements that are executed on the source (and replicated to the replica).
When using row-based replication, triggers are not executed on the replica due to statements that were run on the source and then replicated to the replica. Instead, when using row-based replication, the changes caused by executing the trigger on the source are applied on the replica.

For more information, see Section 17.4.1.33, “Replication and Triggers”.

A.5.13 How are actions carried out through triggers on a source replicated to a replica?

Again, this depends on whether you are using statement-based or row-based replication.

Statement-based replication. First, the triggers that exist on a source must be re-created on the replica server. Once this is done, the replication flow works as any other standard DML statement that participates in replication. For example, consider a table EMP that has an AFTER insert trigger, which exists on a replication source server. The same EMP table and AFTER insert trigger exist on the replica server as well. The replication flow would be:

1. An INSERT statement is made to EMP.
2. The AFTER trigger on EMP activates.
3. The INSERT statement is written to the binary log.
4. The replica picks up the INSERT statement to EMP and executes it.
5. The AFTER trigger on EMP that exists on the replica activates.

Row-based replication. When you use row-based replication, the changes caused by executing the trigger on the source are applied on the replica. However, the triggers themselves are not actually executed on the replica under row-based replication. This is because, if both the source and the replica applied the changes from the source and, in addition, the trigger causing these changes were applied on the replica, the changes would in effect be applied twice on the replica, leading to different data on the source and the replica.

In most cases, the outcome is the same for both row-based and statement-based replication. However, if you use different triggers on the source and replica, you cannot use row-based replication. (This is because the row-based format replicates the changes made by triggers executing on the source to the replicas, rather than the statements that caused the triggers to execute, and the corresponding triggers on the replica are not executed.) Instead, any statements causing such triggers to be executed must be replicated using statement-based replication.

For more information, see Section 17.4.1.33, “Replication and Triggers”.

A.6 MySQL 5.6 FAQ: Views

A.6.1 Where can I find documentation covering MySQL Views? .......................................................... 3496
A.6.2 Is there a discussion forum for MySQL Views? .......................................................... 3496
A.6.3 What happens to a view if an underlying table is dropped or renamed? ................................. 3497
A.6.4 Does MySQL 5.6 have table snapshots? .......................................................... 3497
A.6.5 Does MySQL 5.6 have materialized views? .......................................................... 3497
A.6.6 Can you insert into views that are based on joins? .......................................................... 3497

A.6.1. Where can I find documentation covering MySQL Views?

See Section 20.5, “Using Views”.

A.6.2. Is there a discussion forum for MySQL Views?
A.6.3. What happens to a view if an underlying table is dropped or renamed?

After a view has been created, it is possible to drop or alter a table or view to which the definition refers. To check a view definition for problems of this kind, use the \texttt{CHECK TABLE} statement. (See Section 13.7.2.2, “CHECK TABLE Statement”.)

A.6.4. Does MySQL 5.6 have table snapshots?

No.

A.6.5. Does MySQL 5.6 have materialized views?

No.

A.6.6. Can you insert into views that are based on joins?

It is possible, provided that your \texttt{INSERT} statement has a column list that makes it clear there is only one table involved.

You \textit{cannot} insert into multiple tables with a single insert on a view.

A.7 MySQL 5.6 FAQ: INFORMATION_SCHEMA

A.7.1. Where can I find documentation for the MySQL \texttt{INFORMATION_SCHEMA} database? .......... 3497

A.7.2. Is there a discussion forum for \texttt{INFORMATION_SCHEMA}?. ................................. 3497

A.7.3. Where can I find the ANSI SQL 2003 specification for \texttt{INFORMATION_SCHEMA}?. ........... 3497

A.7.4. What is the difference between the Oracle Data Dictionary and MySQL \texttt{INFORMATION_SCHEMA}?. .......................................................... 3497

A.7.5. Can I add to or otherwise modify the tables found in the \texttt{INFORMATION_SCHEMA} database? .... 3497

A.7.1. Where can I find documentation for the MySQL \texttt{INFORMATION_SCHEMA} database?

See Chapter 21, \textit{INFORMATION_SCHEMA Tables}

A.7.2. Is there a discussion forum for \texttt{INFORMATION_SCHEMA}?

A.7.3. Where can I find the ANSI SQL 2003 specification for \texttt{INFORMATION_SCHEMA}?

Unfortunately, the official specifications are not freely available. (ANSI makes them available for purchase.) However, there are books available, such as \textit{SQL-99 Complete, Really} by Peter Gulutzan and Trudy Pelzer, that provide a comprehensive overview of the standard, including \texttt{INFORMATION_SCHEMA}.

A.7.4. What is the difference between the Oracle Data Dictionary and MySQL \texttt{INFORMATION_SCHEMA}?

Both Oracle and MySQL provide metadata in tables. However, Oracle and MySQL use different table names and column names. The MySQL implementation is more similar to those found in DB2 and SQL Server, which also support \texttt{INFORMATION_SCHEMA} as defined in the SQL standard.

A.7.5. Can I add to or otherwise modify the tables found in the \texttt{INFORMATION_SCHEMA} database?

No. Since applications may rely on a certain standard structure, this should not be modified. For this reason, we \textit{cannot support bugs or other issues which result from modifying} \texttt{INFORMATION_SCHEMA} \texttt{tables or data}. 

3497
A.8 MySQL 5.6 FAQ: Migration

A.8.1 Where can I find information on how to migrate from MySQL 5.5 to MySQL 5.6?

For detailed upgrade information, see Section 2.11, “Upgrading MySQL”. Do not skip a major version when upgrading, but rather complete the process in steps, upgrading from one major version to the next in each step. This may seem more complicated, but ultimately saves time and trouble. If you encounter problems during the upgrade, their origin is easier to identify, either by you or, if you have a MySQL Enterprise subscription, by MySQL support.

A.8.2 How has storage engine (table type) support changed in MySQL 5.6 from previous versions?

Storage engine support has changed as follows:

- Support for ISAM tables was removed in MySQL 5.0 and you should now use the MyISAM storage engine in place of ISAM. To convert a table tblname from ISAM to MyISAM, simply issue a statement such as this one:

  ```sql
  ALTER TABLE tblname ENGINE=MYISAM;
  ```

- Internal RAID for MyISAM tables was also removed in MySQL 5.0. This was formerly used to allow large tables in file systems that did not support file sizes greater than 2GB. All modern file systems allow for larger tables; in addition, there are now other solutions such as MERGE tables and views.

- The VARCHAR column type now retains trailing spaces in all storage engines.

- MEMORY tables (formerly known as HEAP tables) can also contain VARCHAR columns.

A.9 MySQL 5.6 FAQ: Security

A.9.1 Where can I find documentation that addresses security issues for MySQL?

The best place to start is Chapter 6, Security.

Other portions of the MySQL Documentation which you may find useful with regard to specific security concerns include the following:

- Section 6.1.1, “Security Guidelines”.
- Section 6.1.3, “Making MySQL Secure Against Attackers”.
- Section B.3.3.2, “How to Reset the Root Password”.
- Section 6.1.5, “How to Run MySQL as a Normal User”.
- Section 6.1.4, “Security-Related mysqld Options and Variables”.

A.9.2 What is the default authentication plugin in MySQL 5.6?

A.9.3 Does MySQL 5.6 have native support for SSL?

A.9.4 Is SSL support built into MySQL binaries, or must I recompile the binary myself to enable it?

A.9.5 Does MySQL 5.6 have built-in authentication against LDAP directories?

A.9.6 Does MySQL 5.6 include support for Roles Based Access Control (RBAC)?
• Section 6.1.6, “Security Considerations for LOAD DATA LOCAL”.
• Section 2.10, “Postinstallation Setup and Testing”.
• Section 6.3, “Using Encrypted Connections”.
• Loadable Function Security Precautions.

There is also the Secure Deployment Guide, which provides procedures for deploying a generic binary distribution of MySQL Enterprise Edition Server with features for managing the security of your MySQL installation.

A.9.2. What is the default authentication plugin in MySQL 5.6?

The default authentication plugin in MySQL 5.6 is mysql_native_password. For information about this plugin, see Section 6.4.1.1, “Native Pluggable Authentication”. For general information about pluggable authentication and other available authentication plugins, see Section 6.2.11, “Pluggable Authentication”, and Section 6.4.1, “Authentication Plugins”.

A.9.3. Does MySQL 5.6 have native support for SSL?

Most 5.6 binaries have support for SSL connections between the client and server. See Section 6.3, “Using Encrypted Connections”.

You can also tunnel a connection using SSH, if (for example) the client application does not support SSL connections. For an example, see Section 6.3.5, “Connecting to MySQL Remotely from Windows with SSH”.

A.9.4. Is SSL support built into MySQL binaries, or must I recompile the binary myself to enable it?

Most 5.6 binaries have SSL enabled for client/server connections that are secured, authenticated, or both. See Section 6.3, “Using Encrypted Connections”.

A.9.5. Does MySQL 5.6 have built-in authentication against LDAP directories?

The Enterprise edition includes a PAM Authentication Plugin that supports authentication against an LDAP directory.

A.9.6. Does MySQL 5.6 include support for Roles Based Access Control (RBAC)?

Not at this time.

A.10 MySQL 5.6 FAQ: NDB Cluster

In the following section, we answer questions that are frequently asked about NDB Cluster and the NDB storage engine.

A.10.1 Which versions of the MySQL software support NDB Cluster? Do I have to compile from source? ................................................................. 3500
A.10.2 What do “NDB” and “NDBCLUSTER” mean? ................................................................. 3501
A.10.3 What is the difference between using NDB Cluster versus using MySQL Replication? .......... 3501
A.10.4 Do I need any special networking to run NDB Cluster? How do computers in a cluster communicate? .................................................................................... 3502
A.10.5 How many computers do I need to run an NDB Cluster, and why? ................................. 3502
A.10.6 What do the different computers do in an NDB Cluster? .............................................. 3502
A.10.1 Which versions of the MySQL software support NDB Cluster? Do I have to compile from source?

NDB Cluster is not supported in standard MySQL Server 5.6 releases. Instead, MySQL NDB Cluster is provided as a separate product. Available NDB Cluster release series include the following:

- **NDB Cluster 7.2.** This series is no longer supported for new deployments or maintained. Users of NDB Cluster 7.2 should upgrade to a newer release series as soon as possible. We recommend that new deployments use the latest NDB Cluster 8.0 release.

- **NDB Cluster 7.3.** This series is a previous General Availability (GA) version of NDB Cluster, still available for production use, although we recommend that new deployments use the latest NDB Cluster 8.0 release. The most recent NDB Cluster 7.3 release can be obtained from https://dev.mysql.com/downloads/cluster/.
MySQL 5.6 FAQ: NDB Cluster

- **NDB Cluster 7.4.** This series is a previous General Availability (GA) version of NDB Cluster, still available for production use, although we recommend that new deployments use the latest NDB Cluster 8.0 release. The most recent NDB Cluster 7.4 release can be obtained from https://dev.mysql.com/downloads/cluster/.

- **NDB Cluster 7.5.** This series is a previous General Availability (GA) version of NDB Cluster, still available for production use, although we recommend that new deployments use the latest NDB Cluster 7.6 release. The latest NDB Cluster 7.5 releases can be obtained from https://dev.mysql.com/downloads/cluster/.

- **NDB Cluster 7.6.** This series is a previous General Availability (GA) version of NDB Cluster, still available for production use, although we recommend that new deployments use the latest NDB Cluster 8.0 release. The latest NDB Cluster 7.6 releases can be obtained from https://dev.mysql.com/downloads/cluster/.

- **NDB Cluster 8.0.** This series is the most recent General Availability (GA) version of NDB Cluster, based on version 8.0 of the NDB storage engine and MySQL Server 8.0. NDB Cluster 8.0 is available for production use; new deployments intended for production should use the latest GA release in this series, which is currently NDB Cluster 8.0.28. You can obtain the most recent NDB Cluster 8.0 release from https://dev.mysql.com/downloads/cluster/. For information about new features and other important changes in this series, see What is New in NDB Cluster.

You can obtain and compile NDB Cluster from source (see Section 18.3.1.4, “Building NDB Cluster from Source on Linux”, and Section 18.3.2.2, “Compiling and Installing NDB Cluster from Source on Windows”), but for all but the most specialized cases, we recommend using one of the following installers provided by Oracle that is appropriate to your operating platform and circumstances:

- The web-based **NDB Cluster Auto-Installer** (works on all platforms supported by NDB)
- Linux *binary release* (`.tar.gz` file)
- Linux *RPM package*
- Linux `.deb` file
- Windows *binary "no-install" release*
- Windows *MSI Installer*

Installation packages may also be available from your platform's package management system.

You can determine whether your MySQL Server has NDB support using one of the statements `SHOW VARIABLES LIKE 'have_%'`, `SHOW ENGINES`, or `SHOW PLUGINS`.

**A.10.2** What do “NDB” and “NDBCLUSTER” mean?

“NDB” stands for “Network Database”. NDB and NDBCLUSTER are both names for the storage engine that enables clustering support with MySQL. NDB is preferred, but either name is correct.

**A.10.3** What is the difference between using NDB Cluster versus using MySQL Replication?

In traditional MySQL replication, a source MySQL server updates one or more replicas. Transactions are committed sequentially, and a slow transaction can cause the replica to lag behind the source. This means that if the source fails, it is possible that the replica might not have recorded the last few transactions. If a transaction-safe engine such as InnoDB is being used, a transaction is either completed on the replica or not applied at all, but replication does not guarantee that all
data on the source and the replica remains consistent at all times. In NDB Cluster, all data nodes are kept in synchrony, and a transaction committed by any one data node is committed for all data nodes. In the event of a data node failure, all remaining data nodes remain in a consistent state.

In short, whereas standard MySQL replication is *asynchronous*, NDB Cluster is *synchronous*.

Asynchronous replication is also available in NDB Cluster. *NDB Cluster Replication* (also sometimes known as “geo-replication”) includes the capability to replicate both between two NDB Clusters, and from an NDB Cluster to a non-Cluster MySQL server. See Section 18.7, “NDB Cluster Replication”.

A.10.4 How do I need any special networking to run NDB Cluster? How do computers in a cluster communicate?

NDB Cluster is intended to be used in a high-bandwidth environment, with computers connecting using TCP/IP. Its performance depends directly upon the connection speed between the cluster's computers. The minimum connectivity requirements for NDB Cluster include a typical 100-megabit Ethernet network or the equivalent. We recommend you use gigabit Ethernet whenever available.

A.10.5 How many computers do I need to run an NDB Cluster, and why?

A minimum of three computers is required to run a viable cluster. However, the minimum *recommended* number of computers in an NDB Cluster is four: one each to run the management and SQL nodes, and two computers to serve as data nodes. The purpose of the two data nodes is to provide redundancy; the management node must run on a separate machine to guarantee continued arbitration services in the event that one of the data nodes fails.

To provide increased throughput and high availability, you should use multiple SQL nodes (MySQL Servers connected to the cluster). It is also possible (although not strictly necessary) to run multiple management servers.

A.10.6 What do the different computers do in an NDB Cluster?

An NDB Cluster has both a physical and logical organization, with computers being the physical elements. The logical or functional elements of a cluster are referred to as *nodes*, and a computer housing a cluster node is sometimes referred to as a *cluster host*. There are three types of nodes, each corresponding to a specific role within the cluster. These are:

- **Management node.** This node provides management services for the cluster as a whole, including startup, shutdown, backups, and configuration data for the other nodes. The management node server is implemented as the application `ndb_mgmd`; the management client used to control NDB Cluster is `ndb_mgm`. See Section 18.5.4, “`ndb_mgmd` — The NDB Cluster Management Server Daemon”, and Section 18.5.5, “`ndb_mgm` — The NDB Cluster Management Client”, for information about these programs.

- **Data node.** This type of node stores and replicates data. Data node functionality is handled by instances of the NDB data node process `ndbd`. For more information, see Section 18.5.1, “`ndbd` — The NDB Cluster Data Node Daemon”.

- **SQL node.** This is simply an instance of MySQL Server (`mysqld`) that is built with support for the NDBCLUSTER storage engine and started with the `--ndb-cluster` option to enable the engine and the `--ndb-connectstring` option to enable it to connect to an NDB Cluster management server. For more about these options, see MySQL Server Options for NDB Cluster.

Note

An *API node* is any application that makes direct use of Cluster data nodes for data storage and retrieval. An SQL node can thus be considered a
type of API node that uses a MySQL Server to provide an SQL interface to the Cluster. You can write such applications (that do not depend on a MySQL Server) using the NDB API, which supplies a direct, object-oriented transaction and scanning interface to NDB Cluster data; see NDB Cluster API Overview: The NDB API, for more information.

A.10.7 When I run the `SHOW` command in the NDB Cluster management client, I see a line of output that looks like this:

```
id=2   @10.100.10.32  (Version: 8.0.28-ndb-8.0.28 Nodegroup: 0, *)
```

What does the * mean? How is this node different from the others?

The simplest answer is, “It’s not something you can control, and it’s nothing that you need to worry about in any case, unless you’re a software engineer writing or analyzing the NDB Cluster source code”.

If you don’t find that answer satisfactory, here’s a longer and more technical version:

A number of mechanisms in NDB Cluster require distributed coordination among the data nodes. These distributed algorithms and protocols include global checkpointing, DDL (schema) changes, and node restart handling. To make this coordination simpler, the data nodes “elect” one of their number to act as leader. There is no user-facing mechanism for influencing this selection, which is completely automatic; the fact that it is automatic is a key part of NDB Cluster’s internal architecture.

When a node acts as the “leader” for any of these mechanisms, it is usually the point of coordination for the activity, and the other nodes act as “followers”, carrying out their parts of the activity as directed by the leader. If the node acting as leader fails, then the remaining nodes elect a new leader. Tasks in progress that were being coordinated by the old leader may either fail or be continued by the new leader, depending on the actual mechanism involved.

It is possible for some of these different mechanisms and protocols to have different leader nodes, but in general the same leader is chosen for all of them. The node indicated as the leader in the output of `SHOW` in the management client is known internally as the DICT manager, responsible for coordinating DDL and metadata activity.

NDB Cluster is designed in such a way that the choice of leader has no discernible effect outside the cluster itself. For example, the current leader does not have significantly higher CPU or resource usage than the other data nodes, and failure of the leader should not have a significantly different impact on the cluster than the failure of any other data node.

A.10.8 With which operating systems can I use NDB Cluster?

NDB Cluster is supported on most Unix-like operating systems. NDB Cluster is also supported in production settings on Microsoft Windows operating systems.

For more detailed information concerning the level of support which is offered for NDB Cluster on various operating system versions, operating system distributions, and hardware platforms, please refer to [https://www.mysql.com/support/supportedplatforms/cluster.html](https://www.mysql.com/support/supportedplatforms/cluster.html).

A.10.9 What are the hardware requirements for running NDB Cluster?

NDB Cluster should run on any platform for which NDB-enabled binaries are available. For data nodes and API nodes, faster CPUs and more memory are likely to improve performance, and 64-bit CPUs are likely to be more effective than 32-bit processors. There must be sufficient memory on machines used for data nodes to hold each node's share of the database (see *How much RAM do I Need?* for more information). For a computer which is used only for running the NDB Cluster
management server, the requirements are minimal; a common desktop PC (or the equivalent) is generally sufficient for this task. Nodes can communicate through the standard TCP/IP network and hardware. They can also use the high-speed SCI protocol; however, special networking hardware and software are required to use SCI (see Section 18.4.4, “Using High-Speed Interconnects with NDB Cluster”).

A.10.10. How much RAM do I need to use NDB Cluster? Is it possible to use disk memory at all?

NDB Cluster was originally implemented as in-memory only, but all versions currently available also provide the ability to store NDB Cluster on disk. See Section 18.6.10, “NDB Cluster Disk Data Tables”, for more information.

For in-memory NDB tables, you can use the following formula for obtaining a rough estimate of how much RAM is needed for each data node in the cluster:

\[
\frac{(\text{Size of Database} \times \text{Number of Replicas} \times 1.1)}{\text{Number of Data Nodes}}
\]

To calculate the memory requirements more exactly requires determining, for each table in the cluster database, the storage space required per row (see Section 11.6, “Data Type Storage Requirements”, for details), and multiplying this by the number of rows. You must also remember to account for any column indexes as follows:

- Each primary key or hash index created for an NDBCLUSTER table requires 21–25 bytes per record. These indexes use IndexMemory.

- Each ordered index requires 10 bytes storage per record, using DataMemory.

- Creating a primary key or unique index also creates an ordered index, unless this index is created with USING HASH. In other words:
  - A primary key or unique index on a Cluster table normally takes up 31 to 35 bytes per record.
  - However, if the primary key or unique index is created with USING HASH, then it requires only 21 to 25 bytes per record.

Creating NDB Cluster tables with USING HASH for all primary keys and unique indexes generally causes table updates to run more quickly—in some cases by as much as 20 to 30 percent faster than updates on tables where USING HASH was not used in creating primary and unique keys. This is due to the fact that less memory is required (because no ordered indexes are created), and that less CPU must be utilized (because fewer indexes must be read and possibly updated). However, it also means that queries that could otherwise use range scans must be satisfied by other means, which can result in slower selects.

When calculating Cluster memory requirements, you may find useful the ndb_size.pl utility which is available in recent MySQL 5.6 releases. This Perl script connects to a current (non-Cluster) MySQL database and creates a report on how much space that database would require if it used the NDBCLUSTER storage engine. For more information, see Section 18.5.27, “ndb_size.pl — NDBCLUSTER Size Requirement Estimator”.

It is especially important to keep in mind that every NDB Cluster table must have a primary key. The NDB storage engine creates a primary key automatically if none is defined; this primary key is created without USING HASH.

You can determine how much memory is being used for storage of NDB Cluster data and indexes at any given time using the REPORT MEMORYUSAGE command in the ndb_mgm client; see Section 18.6.1, “Commands in the NDB Cluster Management Client”, for more information. In
addition, warnings are written to the cluster log when 80% of available DataMemory or (prior to NDB 7.6) IndexMemory is in use, and again when usage reaches 90%, 99%, and 100%.

A.10.1 What file systems can I use with NDB Cluster? What about network file systems or network shares?

Generally, any file system that is native to the host operating system should work well with NDB Cluster. If you find that a given file system works particularly well (or not so especially well) with NDB Cluster, we invite you to discuss your findings in the NDB Cluster Forums.

For Windows, we recommend that you use NTFS file systems for NDB Cluster, just as we do for standard MySQL. We do not test NDB Cluster with FAT or VFAT file systems. Because of this, we do not recommend their use with MySQL or NDB Cluster.

NDB Cluster is implemented as a shared-nothing solution; the idea behind this is that the failure of a single piece of hardware should not cause the failure of multiple cluster nodes, or possibly even the failure of the cluster as a whole. For this reason, the use of network shares or network file systems is not supported for NDB Cluster. This also applies to shared storage devices such as SANs.

A.10.12 Can I run NDB Cluster nodes inside virtual machines (such as those created by VMWare, VirtualBox, Parallels, or Xen)?

NDB Cluster is supported for use in virtual machines. We currently support and test using Oracle VM.

Some NDB Cluster users have successfully deployed NDB Cluster using other virtualization products; in such cases, Oracle can provide NDB Cluster support, but issues specific to the virtual environment must be referred to that product's vendor.

A.10.13 I am trying to populate an NDB Cluster database. The loading process terminates prematurely and I get an error message like this one:

```
ERROR 1114: The table 'my_cluster_table' is full
```

Why is this happening?

The cause is very likely to be that your setup does not provide sufficient RAM for all table data and all indexes, including the primary key required by the NDB storage engine and automatically created in the event that the table definition does not include the definition of a primary key.

It is also worth noting that all data nodes should have the same amount of RAM, since no data node in a cluster can use more memory than the least amount available to any individual data node. For example, if there are four computers hosting Cluster data nodes, and three of these have 3GB of RAM available to store Cluster data while the remaining data node has only 1GB RAM, then each data node can devote at most 1GB to NDB Cluster data and indexes.

In some cases it is possible to get Table is full errors in MySQL client applications even when ndb_mgm -e "ALL REPORT MEMORYUSAGE" shows significant free DataMemory. You can force NDB to create extra partitions for NDB Cluster tables and thus have more memory available for hash indexes by using the MAX_ROWS option for CREATE TABLE. In general, setting MAX_ROWS to twice the number of rows that you expect to store in the table should be sufficient.

For similar reasons, you can also sometimes encounter problems with data node restarts on nodes that are heavily loaded with data. The MinFreePct parameter can help with this issue by reserving a portion (5% by default) of DataMemory and (prior to NDB 7.6) IndexMemory for use in restarts. This reserved memory is not available for storing NDB tables or data.
A.10.14. NDB Cluster uses TCP/IP. Does this mean that I can run it over the Internet, with one or more nodes in remote locations?

It is very unlikely that a cluster would perform reliably under such conditions, as NDB Cluster was designed and implemented with the assumption that it would be run under conditions guaranteeing dedicated high-speed connectivity such as that found in a LAN setting using 100 Mbps or gigabit Ethernet—preferably the latter. We neither test nor warrant its performance using anything slower than this.

Also, it is extremely important to keep in mind that communications between the nodes in an NDB Cluster are not secure; they are neither encrypted nor safeguarded by any other protective mechanism. The most secure configuration for a cluster is in a private network behind a firewall, with no direct access to any Cluster data or management nodes from outside. (For SQL nodes, you should take the same precautions as you would with any other instance of the MySQL server.) For more information, see Section 18.6.16, “NDB Cluster Security Issues”.

A.10.15. Do I have to learn a new programming or query language to use NDB Cluster?

No. Although some specialized commands are used to manage and configure the cluster itself, only standard (My)SQL statements are required for the following operations:

- Creating, altering, and dropping tables
- Inserting, updating, and deleting table data
- Creating, changing, and dropping primary and unique indexes

Some specialized configuration parameters and files are required to set up an NDB Cluster—see Section 18.4.3, “NDB Cluster Configuration Files”, for information about these.

A few simple commands are used in the NDB Cluster management client (ndb_mgm) for tasks such as starting and stopping cluster nodes. See Section 18.6.1, “Commands in the NDB Cluster Management Client”.

A.10.16. What programming languages and APIs are supported by NDB Cluster?

NDB Cluster supports the same programming APIs and languages as the standard MySQL Server, including ODBC, .Net, the MySQL C API, and numerous drivers for popular scripting languages such as PHP, Perl, and Python. NDB Cluster applications written using these APIs behave similarly to other MySQL applications; they transmit SQL statements to a MySQL Server (in the case of NDB Cluster, an SQL node), and receive responses containing rows of data. For more information about these APIs, see Chapter 23, Connectors and APIs.

NDB Cluster also supports application programming using the NDB API, which provides a low-level C++ interface to NDB Cluster data without needing to go through a MySQL Server. See The NDB API. In addition, many NDDB CLUSTER management functions are exposed by the C-language MGM API; see The MGM API, for more information.

NDB Cluster also supports Java application programming using ClusterJ, which supports a domain object model of data using sessions and transactions. See Java and NDB Cluster, for more information.

In addition, NDB Cluster provides support for memcached, allowing developers to access data stored in NDB Cluster using the memcached interface; for more information, see ndbmemcache—Memcache API for NDB Cluster (NO LONGER SUPPORTED).
NDB Cluster also includes adapters supporting NoSQL applications written against Node.js, with NDB Cluster as the data store. See MySQL NoSQL Connector for JavaScript, for more information.

A.10.17. Does NDB Cluster include any management tools?

NDB Cluster includes a command line client for performing basic management functions. See Section 18.5.5, “ndb_mgm — The NDB Cluster Management Client”, and Section 18.6.1, “Commands in the NDB Cluster Management Client”.

NDB Cluster 7.6 and earlier are also supported by MySQL Cluster Manager, a separate product providing an advanced command line interface that can automate many NDB Cluster management tasks such as rolling restarts and configuration changes. Beginning with version 1.4.8, MySQL Cluster Manager also provides experimental support for NDB Cluster 8.0. For more information about MySQL Cluster Manager, see MySQL Cluster Manager 1.4.8 User Manual.

NDB Cluster also provides a graphical, browser-based Auto-Installer for setting up and deploying NDB Cluster, as part of the NDB Cluster software distribution. For more information, see Section 18.3.8, “The NDB Cluster Auto-Installer (No longer supported)”.

A.10.18. How do I find out what an error or warning message means when using NDB Cluster?

There are two ways in which this can be done:

• From within the mysql client, use SHOW ERRORS or SHOW WARNINGS immediately upon being notified of the error or warning condition.

• From a system shell prompt, use perror --ndb error_code.

A.10.19. Is NDB Cluster transaction-safe? What isolation levels are supported?

Yes. For tables created with the NDB storage engine, transactions are supported. Currently, NDB Cluster supports only the READ COMMITTED transaction isolation level.

A.10.20. What storage engines are supported by NDB Cluster?

NDB Cluster requires the NDB storage engine. That is, in order for a table to be shared between nodes in an NDB Cluster, the table must be created using ENGINE=NDB (or the equivalent option ENGINE=NDBCLUSTER).

It is possible to create tables using other storage engines (such as InnoDB or MyISAM) on a MySQL server being used with NDB Cluster, but since these tables do not use NDB, they do not participate in clustering; each such table is strictly local to the individual MySQL server instance on which it is created.

An NDB Cluster cannot be created using the InnoDB storage engine. For information about the differences between the NDB and InnoDB storage engines, see Section 18.2.6, “MySQL Server Using InnoDB Compared with NDB Cluster”.

A.10.21. In the event of a catastrophic failure— for example, the whole city loses power and my UPS fails— would I lose all my data?

All committed transactions are logged. Therefore, although it is possible that some data could be lost in the event of a catastrophe, this should be quite limited. Data loss can be further reduced by minimizing the number of operations per transaction. (It is not a good idea to perform large numbers of operations per transaction in any case.)

A.10.22. Is it possible to use FULLTEXT indexes with NDB Cluster?
FULLTEXT indexing is currently supported only by the InnoDB and MyISAM storage engines. See Section 12.10, “Full-Text Search Functions”, for more information.

A.10.23. Can I run multiple nodes on a single computer?

It is possible but not always advisable. One of the chief reasons to run a cluster is to provide redundancy. To obtain the full benefits of this redundancy, each node should reside on a separate machine. If you place multiple nodes on a single machine and that machine fails, you lose all of those nodes. For this reason, if you do run multiple data nodes on a single machine, it is extremely important that they be set up in such a way that the failure of this machine does not cause the loss of all the data nodes in a given node group.

Given that NDB Cluster can be run on commodity hardware loaded with a low-cost (or even no-cost) operating system, the expense of an extra machine or two is well worth it to safeguard mission-critical data. It also worth noting that the requirements for a cluster host running a management node are minimal. This task can be accomplished with a 300 MHz Pentium or equivalent CPU and sufficient RAM for the operating system, plus a small amount of overhead for the ndb_mgmd and ndb_mgm processes.

It is acceptable to run multiple cluster data nodes on a single host that has multiple CPUs, cores, or both. The NDB Cluster distribution also provides a multithreaded version of the data node binary intended for use on such systems. For more information, see Section 18.5.3, “ndbmt — The NDB Cluster Data Node Daemon (Multi-Threaded)”.

It is also possible in some cases to run data nodes and SQL nodes concurrently on the same machine; how well such an arrangement performs is dependent on a number of factors such as number of cores and CPUs as well as the amount of disk and memory available to the data node and SQL node processes, and you must take these factors into account when planning such a configuration.

A.10.24. Can I add data nodes to an NDB Cluster without restarting it?

It is possible to add new data nodes to a running NDB Cluster without taking the cluster offline. For more information, see Section 18.6.7, “Adding NDB Cluster Data Nodes Online”.

For other types of NDB Cluster nodes, a rolling restart is all that is required (see Section 18.6.5, “Performing a Rolling Restart of an NDB Cluster”).

A.10.25. Are there any limitations that I should be aware of when using NDB Cluster?

Limitations on NDB tables in MySQL NDB Cluster include the following:

- Temporary tables are not supported; a CREATE TEMPORARY TABLE statement using ENGINE=NDB or ENGINE=NDBCLUSTER fails with an error.

- The only types of user-defined partitioning supported for NDBCLUSTER tables are KEY and LINEAR KEY. Trying to create an NDB table using any other partitioning type fails with an error.

- FULLTEXT indexes are not supported.

- Index prefixes are not supported. Only complete columns may be indexed.

- Spatial indexes are not supported (although spatial columns can be used). See Section 11.4, “Spatial Data Types”.

- Support for partial transactions and partial rollbacks is comparable to that of other transactional storage engines such as InnoDB that can roll back individual statements.
• The maximum number of attributes allowed per table is 512. Attribute names cannot be any longer than 31 characters. For each table, the maximum combined length of the table and database names is 122 characters.

• Prior to NDB 8.0, the maximum size for a table row is 14 kilobytes, not counting BLOB values. In NDB 8.0, this maximum is increased to 30000 bytes. See Section 18.2.7.5, “Limits Associated with Database Objects in NDB Cluster”, for more information.

There is no set limit for the number of rows per NDB table. Limits on table size depend on a number of factors, in particular on the amount of RAM available to each data node.

For a complete listing of limitations in NDB Cluster, see Section 18.2.7, “Known Limitations of NDB Cluster”. See also Section 18.2.7.11, “Previous NDB Cluster Issues Resolved in NDB Cluster 7.3”.

A.10.26. Does NDB Cluster support foreign keys?

NDB Cluster provides support for foreign key constraints which is comparable to that found in the InnoDB storage engine; see Section 1.7.3.2, “FOREIGN KEY Constraints”, for more detailed information, as well as Section 13.1.17.5, “FOREIGN KEY Constraints”. Applications requiring foreign key support should use NDB Cluster 7.3, 7.4, 7.5, or later.

A.10.27. How do I import an existing MySQL database into an NDB Cluster?

You can import databases into NDB Cluster much as you would with any other version of MySQL. Other than the limitations mentioned elsewhere in this FAQ, the only other special requirement is that any tables to be included in the cluster must use the NDB storage engine. This means that the tables must be created with ENGINE=NDB or ENGINE=NDBCLUSTER.

It is also possible to convert existing tables that use other storage engines to NDBCLUSTER using one or more ALTER TABLE statement. However, the definition of the table must be compatible with the NDBCLUSTER storage engine prior to making the conversion. In MySQL 5.6, an additional workaround is also required; see Section 18.2.7, “Known Limitations of NDB Cluster”, for details.

A.10.28. How do NDB Cluster nodes communicate with one another?

Cluster nodes can communicate through any of three different transport mechanisms: TCP/IP, SHM (shared memory), and SCI (Scalable Coherent Interface). Where available, SHM is used by default between nodes residing on the same cluster host; however, this is considered experimental. SCI is a high-speed (1 gigabit per second and higher), high-availability protocol used in building scalable multi-processor systems; it requires special hardware and drivers. See Section 18.4.4, “Using High-Speed Interconnects with NDB Cluster”, for more about using SCI as a transport mechanism for NDB Cluster.

A.10.29. What is an arbitrator?

If one or more data nodes in a cluster fail, it is possible that not all cluster data nodes are able to “see” one another. In fact, it is possible that two sets of data nodes might become isolated from one another in a network partitioning, also known as a “split-brain” scenario. This type of situation is undesirable because each set of data nodes tries to behave as though it is the entire cluster. An arbitrator is required to decide between the competing sets of data nodes.

When all data nodes in at least one node group are alive, network partitioning is not an issue, because no single subset of the cluster can form a functional cluster on its own. The real problem arises when no single node group has all its nodes alive, in which case network partitioning (the “split-brain” scenario) becomes possible. Then an arbitrator is required. All cluster nodes recognize the same node as the arbitrator, which is normally the management server; however, it is possible
to configure any of the MySQL Servers in the cluster to act as the arbitrator instead. The arbitrator accepts the first set of cluster nodes to contact it, and tells the remaining set to shut down. Arbitrator selection is controlled by the `ArbitrationRank` configuration parameter for MySQL Server and management server nodes. You can also use the `ArbitrationRank` configuration parameter to control the arbitrator selection process. For more information about these parameters, see Section 18.4.3.5, “Defining an NDB Cluster Management Server”.

The role of arbitrator does not in and of itself impose any heavy demands upon the host so designated, and thus the arbitrator host does not need to be particularly fast or to have extra memory especially for this purpose.

**A.10.30 What data types are supported by NDB Cluster?**

NDB Cluster supports all of the usual MySQL data types, including those associated with MySQL’s spatial extensions; however, the NDB storage engine does not support spatial indexes. (Spatial indexes are supported only by MyISAM; see Section 11.4, “Spatial Data Types”, for more information.) In addition, there are some differences with regard to indexes when used with NDB tables.

**Note**

NDB Cluster Disk Data tables (that is, tables created with `TABLESPACE ... STORAGE DISK ENGINE=NDB` or `TABLESPACE ... STORAGE DISK ENGINE=NDBCLUSTER`) have only fixed-width rows. This means that (for example) each Disk Data table record containing a `VARCHAR(255)` column requires space for 255 characters (as required for the character set and collation being used for the table), regardless of the actual number of characters stored therein.

See Section 18.2.7, “Known Limitations of NDB Cluster”, for more information about these issues.

**A.10.31 How do I start and stop NDB Cluster?**

It is necessary to start each node in the cluster separately, in the following order:

1. Start the management node, using the `ndb_mgmd` command.
   
   You must include the `-f` or `--config-file` option to tell the management node where its configuration file can be found.

2. Start each data node with the `ndbd` command.
   
   Each data node must be started with the `-c` or `--ndb-connectstring` option so that the data node knows how to connect to the management server.

3. Start each MySQL Server (SQL node) using your preferred startup script, such as `mysqld_safe`.
   
   Each MySQL Server must be started with the `--ndbcluster` and `--ndb-connectstring` options. These options cause `mysqld` to enable `NDBCLUSTER` storage engine support and how to connect to the management server.

Each of these commands must be run from a system shell on the machine housing the affected node. (You do not have to be physically present at the machine—a remote login shell can be used for this purpose.) You can verify that the cluster is running by starting the NDB management client `ndb_mgm` on the machine housing the management node and issuing the `SHOW` or `ALL STATUS` command.
To shut down a running cluster, issue the command `SHUTDOWN` in the management client. Alternatively, you may enter the following command in a system shell:

```
$> ndb_mgm -e "SHUTDOWN"
```

(The quotation marks in this example are optional, since there are no spaces in the command string following the `-e` option; in addition, the `SHUTDOWN` command, like other management client commands, is not case-sensitive.)

Either of these commands causes the `ndb_mgm`, `ndb_mgm`, and any `ndbd` processes to terminate gracefully. MySQL servers running as SQL nodes can be stopped using `mysqladmin shutdown`.

For more information, see Section 18.6.1, “Commands in the NDB Cluster Management Client”, and Section 18.3.6, “Safe Shutdown and Restart of NDB Cluster”.

MySQL Cluster Manager and the NDB Cluster Auto-Installer provide additional ways to handle starting and stopping of NDB Cluster nodes. See MySQL Cluster Manager 1.4.8 User Manual, and The NDB Cluster Auto-Installer (NDB 7.6) (No longer supported), for more information about these tools.

**A.10.32** What happens to NDB Cluster data when the NDB Cluster is shut down?

The data that was held in memory by the cluster's data nodes is written to disk, and is reloaded into memory the next time that the cluster is started.

**A.10.33** Is it a good idea to have more than one management node for an NDB Cluster?

It can be helpful as a fail-safe. Only one management node controls the cluster at any given time, but it is possible to configure one management node as primary, and one or more additional management nodes to take over in the event that the primary management node fails.

See Section 18.4.3, “NDB Cluster Configuration Files”, for information on how to configure NDB Cluster management nodes.

**A.10.34** Can I mix different kinds of hardware and operating systems in one NDB Cluster?

Yes, as long as all machines and operating systems have the same “endianness” (all big-endian or all little-endian).

It is also possible to use software from different NDB Cluster releases on different nodes. However, we support such use only as part of a rolling upgrade procedure (see Section 18.6.5, “Performing a Rolling Restart of an NDB Cluster”).

**A.10.35** Can I run two data nodes on a single host? Two SQL nodes?

Yes, it is possible to do this. In the case of multiple data nodes, it is advisable (but not required) for each node to use a different data directory. If you want to run multiple SQL nodes on one machine, each instance of `mysqld` must use a different TCP/IP port.

Running data nodes and SQL nodes together on the same host is possible, but you should be aware that the `ndbd` or `ndbmtd` processes may compete for memory with `mysqld`.

**A.10.36** Can I use host names with NDB Cluster?

Yes, it is possible to use DNS and DHCP for cluster hosts. However, if your application requires “five nines” availability, you should use fixed (numeric) IP addresses, since making communication between Cluster hosts dependent on services such as DNS and DHCP introduces additional potential points of failure.
A.10.37. Does NDB Cluster support IPv6?

IPv6 is supported for connections between SQL nodes (MySQL servers), but connections between all other types of NDB Cluster nodes must use IPv4.

In practical terms, this means that you can use IPv6 for replication between NDB Clusters, but connections between nodes in the same NDB Cluster must use IPv4. For more information, see Section 18.7.3, “Known Issues in NDB Cluster Replication”.

A.10.38. How do I handle MySQL users in an NDB Cluster having multiple MySQL servers?

MySQL user accounts and privileges are normally not automatically propagated between different MySQL servers accessing the same NDB Cluster. MySQL NDB Cluster provides support for distributed privileges, which you can enable by following a procedure provided in the documentation; see Section 18.6.12, “Distributed Privileges Using Shared Grant Tables”, for more information.

Important

The mechanism for handling users distributed or shared between NDB Cluster SQL nodes has changed significantly in NDB 8.0; this implementation is not compatible with that in NDB 7.6 and earlier. See Distributed MySQL Privileges with NDB_STORED_USER, for details.

A.10.39. How do I continue to send queries in the event that one of the SQL nodes fails?

MySQL NDB Cluster does not provide any sort of automatic failover between SQL nodes. Your application must be prepared to handle the loss of SQL nodes and to fail over between them.

A.10.40. How do I back up and restore an NDB Cluster?

You can use the NDB Cluster native backup and restore functionality in the NDB management client and the ndb_restore program. See Section 18.6.8, “Online Backup of NDB Cluster”, and Section 18.5.22, “ndb_restore — Restore an NDB Cluster Backup”.

You can also use the traditional functionality provided for this purpose in mysqldump and the MySQL server. See Section 4.5.4, “mysqldump — A Database Backup Program”, for more information.

A.10.41. What is an “angel process”?

This process monitors and, if necessary, attempts to restart the data node process. If you check the list of active processes on your system after starting ndbd, you can see that there are actually 2 processes running by that name, as shown here (we omit the output from ndb_mgmd and ndbd for brevity):

```bash
$> ./ndb_mgmd
$> ps aux | grep ndb
me  23002  0.0  0.0  122948  3104 ?        Ssl  14:14   0:00 ./ndb_mgmd
me  23025  0.0  0.0   5284   820 pts/2    S+  14:14   0:00 grep ndb
$> ./ndbd --c 127.0.0.1 --initial
$> ps aux | grep ndb
me  23002  0.0  0.0  123080  3316  ?        Ssl  14:14   0:00 ./ndb_mgmd
me  23096  0.0  0.0  35876  2036 pts/2    S+  14:14   0:00 ./ndb_mtd -c 127.0.0.1 --initial
me  23097  1.0  2.4  524116 91096 ?        Sl   14:14   0:00 ./ndb_mtd -c 127.0.0.1 --initial
me  23168  0.0  0.0   5284   812 pts/2    R+  14:15   0:00 grep ndb
```
A.11 MySQL 5.6 FAQ: MySQL Chinese, Japanese, and Korean Character Sets

This set of Frequently Asked Questions derives from the experience of MySQL's Support and Development groups in handling many inquiries about CJK (Chinese-Japanese-Korean) issues.

A.11.1 What CJK character sets are available in MySQL?

A.11.2 I have inserted CJK characters into my table. Why does SELECT display them as “?” characters?

A.11.3 What problems should I be aware of when working with the Big5 Chinese character set?

A.11.4 Why do Japanese character set conversions fail?

A.11.5 What should I do if I want to convert SJIS 81CA to cp932?

A.11.6 How does MySQL represent the Yen (¥) sign?

A.11.7 Of what issues should I be aware when working with Korean character sets in MySQL?

A.11.8 Why do I get incorrect string value error messages?

A.11.9 Why does my GUI front end or browser display CJK characters incorrectly in my application using Access, PHP, or another API?

A.11.10 I've upgraded to MySQL 5.6. How can I revert to behavior like that in MySQL 4.0 with regard to character sets?

A.11.11 Why do some LIKE and FULLTEXT searches with CJK characters fail?

A.11.12 How do I know whether character x is available in all character sets?

A.11.13 Why do CJK strings sort incorrectly in Unicode? (I)

A.11.14 Why do CJK strings sort incorrectly in Unicode? (II)

A.11.15 Why are my supplementary characters rejected by MySQL?

A.11.16 Should “CJK” be “CJKV”?

A.11.17 Does MySQL permit CJK characters to be used in database and table names?

A.11.18 Where can I find translations of the MySQL Manual into Chinese, Japanese, and Korean?

A.11.19 Where can I get help with CJK and related issues in MySQL?

A.11.1 What CJK character sets are available in MySQL?

The list of CJK character sets may vary depending on your MySQL version. For example, the gb18030 character set is not supported prior to MySQL 5.7.4. However, since the name of the applicable language appears in the DESCRIPTION column for every entry in the INFORMATION_SCHEMA.CHARACTER_SETS table, you can obtain a current list of all the non-Unicode CJK character sets using this query:

```
mysql> SELECT CHARACTER_SET_NAME, DESCRIPTION
    -> FROM INFORMATION_SCHEMA.CHARACTER_SETS
    -> WHERE DESCRIPTION LIKE '%Chin%'
    -> OR DESCRIPTION LIKE '%Japanese%'
    -> OR DESCRIPTION LIKE '%Korean%'
    -> ORDER BY CHARACTER_SET_NAME;
```

<table>
<thead>
<tr>
<th>CHARACTER_SET_NAME</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>big5</td>
<td>Big5 Traditional Chinese</td>
</tr>
<tr>
<td>cp932</td>
<td>SJIS for Windows Japanese</td>
</tr>
<tr>
<td>eucjpms</td>
<td>UJIS for Windows Japanese</td>
</tr>
<tr>
<td>euckr</td>
<td>EUC-KR Korean</td>
</tr>
</tbody>
</table>

The ndbd process showing 0.0 for both memory and CPU usage is the angel process (although it actually does use a very small amount of each). This process merely checks to see if the main ndbd or ndbmt process (the primary data node process which actually handles the data) is running. If permitted to do so (for example, if the StopOnError configuration parameter is set to false), the angel process tries to restart the primary data node process.
MySQL supports three variants of the GB (Guojia Biaozhun, or National Standard, or Simplified Chinese) character sets which are official in the People's Republic of China: `gb2312`, `gbk`, and (as of MySQL 5.7.4) `gb18030`.

Sometimes people try to insert `gbk` characters into `gb2312`, and it works most of the time because `gbk` is a superset of `gb2312`. But eventually they try to insert a rarer Chinese character and it does not work. (For an example, see Bug #16072).

Here, we try to clarify exactly what characters are legitimate in `gb2312` or `gbk`, with reference to the official documents. Please check these references before reporting `gb2312` or `gbk` bugs:

- The MySQL `gbk` character set is in reality "Microsoft code page 936". This differs from the official `gbk` for characters A1A4 (middle dot), A1AA (em dash), A6E0–A6F5, and A8BB–A8C0.

- For a listing of `gbk`/Unicode mappings, see http://www.unicode.org/Public/MAPPINGS/VENDORS/MICROSOFT/WINDOWS/CP936.TXT.

It is also possible to store CJK characters in Unicode character sets, although the available collations may not sort characters quite as you expect:

- The `utf8` and `ucs2` character sets support the characters from Unicode Basic Multilingual Plane (BMP). These characters have code point values between U+0000 and U+FFFF.

- The `utf8mb4`, `utf16`, `utf16le`, and `utf32` character sets support BMP characters, as well as supplementary characters that lie outside the BMP. Supplementary characters have code point values between U+10000 and U+10FFFF.

The collation used for a Unicode character set determines the ability to sort (that is, distinguish) characters in the set:

- Collations based on Unicode Collation Algorithm (UCA) 4.0.0 distinguish only BMP characters.

- Collations based on UCA 5.2.0 or 9.0.0 distinguish BMP and supplementary characters.

- Non-UCA collations may not distinguish all Unicode characters. For example, the `utf8mb4` default collation is `utf8mb4_general_ci`, which distinguishes only BMP characters.

Moreover, distinguishing characters is not the same as ordering them per the conventions of a given CJK language. Currently, MySQL has only one CJK-specific UCA collation, `gb18030_unicode_520_ci` (which requires use of the non-Unicode `gb18030` character set).

For information about Unicode collations and their differentiating properties, including collation properties for supplementary characters, see Section 10.10.1, "Unicode Character Sets".

A.11.2J have inserted CJK characters into my table. Why does `SELECT` display them as “?” characters?
This problem is usually due to a setting in MySQL that does not match the settings for the application program or the operating system. Here are some common steps for correcting these types of issues:

- **Be certain of what MySQL version you are using.**
  
  Use the statement `SELECT VERSION();` to determine this.

- **Make sure that the database is actually using the desired character set.**
  
  People often think that the client character set is always the same as either the server character set or the character set used for display purposes. However, both of these are false assumptions. You can make sure by checking the result of `SHOW CREATE TABLE tablename` or, better yet, by using this statement:

  ```sql
  SELECT character_set_name, collation_name
  FROM information_schema.columns
  WHERE table_schema = your_database_name
  AND table_name = your_table_name
  AND column_name = your_column_name;
  ```

- **Determine the hexadecimal value of the character or characters that are not being displayed correctly.**
  
  You can obtain this information for a column `column_name` in the table `table_name` using the following query:

  ```sql
  SELECT HEX(column_name)
  FROM table_name;
  ```

  3F is the encoding for the ? character; this means that ? is the character actually stored in the column. This most often happens because of a problem converting a particular character from your client character set to the target character set.

- **Make sure that a round trip is possible. When you select literal (or _introducer hexadecimal-value), do you obtain literal as a result?**
  
  For example, the Japanese Katakana character Pe (ペ) exists in all CJK character sets, and has the code point value (hexadecimal coding) 0x30da. To test a round trip for this character, use this query:

  ```sql
  SELECT 'ペ' AS `ペ`;         /* or SELECT _ucs2 0x30da; */
  ```

  If the result is not also ペ, the round trip failed.

  For bug reports regarding such failures, we might ask you to follow up with `SELECT HEX('ペ');`. Then we can determine whether the client encoding is correct.

- **Make sure that the problem is not with the browser or other application, rather than with MySQL.**
  
  Use the `mysql` client program to accomplish this task. If `mysql` displays characters correctly but your application does not, your problem is probably due to system settings.

  To determine your settings, use the `SHOW VARIABLES` statement, whose output should resemble what is shown here:

  ```sql
  mysql> SHOW VARIABLES LIKE 'chart';
  +------------------------------------------+-------------------+
  | Variable_name | Value |
  +------------------------------------------+-------------------+
  ```
These are typical character-set settings for an international-oriented client (notice the use of **utf8** Unicode) connected to a server in the West (**latin1** is a West Europe character set).

Although Unicode (usually the **utf8** variant on Unix, and the **ucs2** variant on Windows) is preferable to Latin, it is often not what your operating system utilities support best. Many Windows users find that a Microsoft character set, such as **cp932** for Japanese Windows, is suitable.

If you cannot control the server settings, and you have no idea what setting your underlying computer uses, try changing to a common character set for the country that you're in (**euckr** = Korea; **gb18030**, **gb2312** or **gbk** = People's Republic of China; **big5** = Taiwan; **sjis**, **ujis**, **cp932**, or **eucjpms** = Japan; **ucs2** or **utf8** = anywhere). Usually it is necessary to change only the client and connection and results settings. The **SET NAMES** statement changes all three at once. For example:

```
SET NAMES 'big5';
```

Once the setting is correct, you can make it permanent by editing **my.cnf** or **my.ini**. For example you might add lines looking like these:

```
[mysqld]
character-set-server=big5

[client]
default-character-set=big5
```

It is also possible that there are issues with the API configuration setting being used in your application; see **Why does my GUI front end or browser not display CJK characters correctly...?** for more information.

### A.11.3 What problems should I be aware of when working with the Big5 Chinese character set?

MySQL supports the Big5 character set which is common in Hong Kong and Taiwan (Republic of China). The MySQL **big5** character set is in reality Microsoft code page 950, which is very similar to the original **big5** character set.

A feature request for adding **HKSCS** extensions has been filed. People who need this extension may find the suggested patch for Bug #13577 to be of interest.

### A.11.4 Why do Japanese character set conversions fail?

MySQL supports the **sjis**, **ujis**, **cp932**, and **eucjpms** character sets, as well as Unicode. A common need is to convert between character sets. For example, there might be a Unix server (typically with **sjis** or **ujis**) and a Windows client (typically with **cp932**).

In the following conversion table, the **ucs2** column represents the source, and the **sjis**, **cp932**, **ujis**, and **eucjpms** columns represent the destinations; that is, the last 4 columns provide the hexadecimal result when we use **CONVERT(ucs2)** or we assign a **ucs2** column containing the value to an **sjis**, **cp932**, **ujis**, or **eucjpms** column.

<table>
<thead>
<tr>
<th>ucs2</th>
<th>sjis</th>
<th>cp932</th>
</tr>
</thead>
<tbody>
<tr>
<td>NOT SIGN</td>
<td>00AC</td>
<td>81CA</td>
</tr>
</tbody>
</table>
A.11.5 What should I do if I want to convert SJIS 81CA to cp932?

Our answer is: “?”. There are disadvantages to this, and many people would prefer a “loose” conversion, so that 81CA (NOT SIGN) in sjis becomes 81CA (FULLWIDTH NOT SIGN) in cp932.

A.11.6 How does MySQL represent the Yen (¥) sign?

A problem arises because some versions of Japanese character sets (both sjis and euc) treat 5C as a reverse solidus (\, also known as a backslash), whereas others treat it as a yen sign (¥).

MySQL follows only one version of the JIS (Japanese Industrial Standards) standard description. In MySQL, 5C is always the reverse solidus (\).

A.11.7 Of what issues should I be aware when working with Korean character sets in MySQL?

In theory, while there have been several versions of the euckr (Extended Unix Code Korea) character set, only one problem has been noted. We use the “ASCII” variant of EUC-KR, in which the code point 0x5c is REVERSE SOLIDUS, that is, instead of the “KS-Roman” variant of EUC-KR, in which the code point 0x5c is WON SIGN (₩). This means that you cannot convert Unicode U +20A9 to euckr:

```sql
mysql> SELECT CONVERT('₩' USING euckr) AS euckr,
             HEX(CONVERT('₩' USING euckr)) AS hexeuckr;
```

```
+-------+----------+
| euckr | hexeuckr |
| ?     | 3F       |
+-------+----------+
```

A.11.8 Why do I get Incorrect string value error messages?

To see the problem, create a table with one Unicode (ucs2) column and one Chinese (gb2312) column.

```sql
mysql> CREATE TABLE ch
     (ucs2 CHAR(3) CHARACTER SET ucs2,
      gb2312 CHAR(3) CHARACTER SET gb2312);
```

In nonstrict SQL mode, try to place the rare character 虤 in both columns.

```sql
mysql> SET sql_mode = '';
mysql> INSERT INTO ch VALUES ('A xuyên B','A xuyên B');
Query OK, 1 row affected, 1 warning (0.00 sec)
```

The INSERT produces a warning. Use the following statement to see what it is:

```sql
mysql> SHOW WARNINGS\G
```

```
*************************** 1. row ***************************
Level: Warning
Code: 1366
```
Message: Incorrect string value: '\xE6\xB1\x8CB' for column 'gb2312' at row 1

So it is a warning about the gb2312 column only.

Several things need explanation here:

1. The 呸 character is not in the gb2312 character set, as described earlier.
2. If you are using an old version of MySQL, you may see a different message.
3. A warning occurs rather than an error because MySQL is not set to use strict SQL mode. In nonstrict mode, MySQL tries to do what it can, to get the best fit, rather than give up. With strict SQL mode, the Incorrect string value message occurs as an error rather than a warning, and the INSERT fails.

A.11.9 Why does my GUI front end or browser display CJK characters incorrectly in my application using Access, PHP, or another API?

Obtain a direct connection to the server using the mysql client, and try the same query there. If mysql responds correctly, the trouble may be that your application interface requires initialization. Use mysql to tell you what character set or sets it uses with the statement SHOW VARIABLES LIKE 'char%';. If you are using Access, you are most likely connecting with Connector/ODBC. In this case, you should check Configuring Connector/ODBC. If, for example, you use big5, you would enter SET NAMES 'big5'. (In this case, no ; character is required.) If you are using ASP, you might need to add SET NAMES in the code. Here is an example that has worked in the past:

```html
<%
Session.CodePage=0
Dim strConnection
Dim Conn
strConnection="driver={MySQL ODBC 3.51 Driver};server=server;uid=username;" \
& "pwd=password;database=database;stmt=SET NAMES 'big5';"
Set Conn = Server.CreateObject("ADODB.Connection")
Conn.Open strConnection
%>
```

In much the same way, if you are using any character set other than latin1 with Connector/NET, you must specify the character set in the connection string. See Connector/NET Connections, for more information.

If you are using PHP, try this:

```php
$link = new mysqli($host, $usr, $pwd, $db);
if( mysqli_connect_errno() )
{
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}
$link->query("SET NAMES 'utf8'");
?>
```
In this case, we used `SET NAMES` to change `character_set_client`, `character_set_connection`, and `character_set_results`.

Another issue often encountered in PHP applications has to do with assumptions made by the browser. Sometimes adding or changing a `<meta>` tag suffices to correct the problem: for example, to insure that the user agent interprets page content as UTF-8, include `<meta http-equiv="Content-Type" content="text/html; charset=utf-8">` in the `<head>` section of the HTML page.

If you are using Connector/J, see Using Character Sets and Unicode.

### A.11.10

If you upgraded to MySQL 5.6. How can I revert to behavior like that in MySQL 4.0 with regard to character sets?

In MySQL Version 4.0, there was a single “global” character set for both server and client, and the decision as to which character to use was made by the server administrator. This changed starting with MySQL Version 4.1. What happens now is a “handshake”, as described in Section 10.4, “Connection Character Sets and Collations”:

When a client connects, it sends to the server the name of the character set that it wants to use. The server uses the name to set the `character_set_client`, `character_set_results`, and `character_set_connection` system variables. In effect, the server performs a `SET NAMES` operation using the character set name.

The effect of this is that you cannot control the client character set by starting `mysqld` with `--character-set-server=utf8`. However, some Asian customers prefer the MySQL 4.0 behavior. To make it possible to retain this behavior, we added a `mysqld` switch, `--character-set-client-handshake`, which can be turned off with `--skip-character-set-client-handshake`. If you start `mysqld` with `--skip-character-set-client-handshake`, then, when a client connects, it sends to the server the name of the character set that it wants to use. However, *the server ignores this request from the client.*

By way of example, suppose that your favorite server character set is `latin1`. Suppose further that the client uses `utf8` because this is what the client’s operating system supports. Start the server with `latin1` as its default character set:

```
mysqld --character-set-server=latin1
```

And then start the client with the default character set `utf8`:

```
mysql --default-character-set=utf8
```

The resulting settings can be seen by viewing the output of `SHOW VARIABLES`:

```
mysql> SHOW VARIABLES LIKE 'char%';
+--------------------------+----------------------------------------+
| Variable_name            | Value                                  |
+--------------------------+----------------------------------------+
| character_set_client     | utf8                                   |
| character_set_connection | utf8                                   |
| character_set_database   | latin1                                 |
| character_set_filesystem | binary                                 |
| character_set_results    | utf8                                   |
| character_set_server     | latin1                                 |
| character_set_system     | utf8                                   |
| character_sets_dir       | /usr/local/mysql/share/mysql/charsets/ |
+--------------------------+----------------------------------------+
```
Now stop the client, and stop the server using `mysqladmin`. Then start the server again, but this time tell it to skip the handshake like so:

```
mysqld --character-set-server=utf8 --skip-character-set-client-handshake
```

Start the client with `utf8` once again as the default character set, then display the resulting settings:

```
SHOW VARIABLES LIKE 'char%';
```

<table>
<thead>
<tr>
<th>Variable_name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>character_set_client</td>
<td>latin1</td>
</tr>
<tr>
<td>character_set_connection</td>
<td>latin1</td>
</tr>
<tr>
<td>character_set_database</td>
<td>latin1</td>
</tr>
<tr>
<td>character_set_filesystem</td>
<td>binary</td>
</tr>
<tr>
<td>character_set_results</td>
<td>latin1</td>
</tr>
<tr>
<td>character_set_server</td>
<td>latin1</td>
</tr>
<tr>
<td>character_set_system</td>
<td>utf8</td>
</tr>
<tr>
<td>character_sets_dir</td>
<td>/usr/local/mysql/share/mysql/charsets/</td>
</tr>
</tbody>
</table>

As you can see by comparing the differing results from `SHOW VARIABLES`, the server ignores the client’s initial settings if the `--skip-character-set-client-handshake` option is used.

**A.11.1** Why do some LIKE and FULLTEXT searches with CJK characters fail?

For LIKE searches, there is a very simple problem with binary string column types such as `BINARY` and `BLOB`: we must know where characters end. With multibyte character sets, different characters might have different octet lengths. For example, in `utf8`, `A` requires one byte but `゚` requires three bytes, as shown here:

<table>
<thead>
<tr>
<th>OCTET_LENGTH(_utf8 'A')</th>
<th>OCTET_LENGTH(_utf8 '゚')</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>3</td>
</tr>
</tbody>
</table>

If we do not know where the first character in a string ends, we do not know where the second character begins, in which case even very simple searches such as LIKE '_A%' fail. The solution is to use a nonbinary string column type defined to have the proper CJK character set. For example:

```
mycol TEXT CHARACTER SET sjis
```

Alternatively, convert to a CJK character set before comparing.

This is one reason why MySQL cannot permit encodings of nonexistent characters. If it is not strict about rejecting bad input, it has no way of knowing where characters end.

For FULLTEXT searches, we must know where words begin and end. With Western languages, this is rarely a problem because most (if not all) of these use an easy-to-identify word boundary: the space character. However, this is not usually the case with Asian writing. We could use arbitrary halfway measures, like assuming that all Han characters represent words, or (for Japanese) depending on changes from Katakana to Hiragana due to grammatical endings. However, the only sure solution requires a comprehensive word list, which means that we would have to include a dictionary in the server for each Asian language supported. This is simply not feasible.

**A.11.12** How do I know whether character `X` is available in all character sets?

The majority of simplified Chinese and basic nonhalfwidth Japanese Kana characters appear in all CJK character sets. The following stored procedure accepts a UCS-2 Unicode character, converts it to other character sets, and displays the results in hexadecimal.
DELIMITER //

CREATE PROCEDURE p_convert(ucs2_char CHAR(1) CHARACTER SET ucs2)
BEGIN

CREATE TABLE tj
(ucs2 CHAR(1) character set ucs2,
 utf8 CHAR(1) character set utf8,
 big5 CHAR(1) character set big5,
 cp932 CHAR(1) character set cp932,
 eucjpms CHAR(1) character set eucjpms,
 euckr CHAR(1) character set euckr,
 gb2312 CHAR(1) character set gb2312,
 gbk CHAR(1) character set gbk,
 sjis CHAR(1) character set sjis,
 ujis CHAR(1) character set ujis);

INSERT INTO tj (ucs2) VALUES (ucs2_char);

UPDATE tj SET utf8=ucs2,
 big5=ucs2,
 cp932=ucs2,
 eucjpms=ucs2,
 euckr=ucs2,
 gb2312=ucs2,
 gbk=ucs2,
 sjis=ucs2,
 ujis=ucs2;

/* If there are conversion problems, UPDATE produces warnings. */

SELECT hex(ucs2) AS ucs2,
 hex(utf8) AS utf8,
 hex(big5) AS big5,
 hex(cp932) AS cp932,
 hex(eucjpms) AS eucjpms,
 hex(euckr) AS euckr,
 hex(gb2312) AS gb2312,
 hex(gbk) AS gbk,
 hex(sjis) AS sjis,
 hex(ujis) AS ujis
FROM tj;

DROP TABLE tj;

END//

DELIMITER ;

The input can be any single ucs2 character, or it can be the code value (hexadecimal representation) of that character. For example, from Unicode's list of ucs2 encodings and names (http://www.unicode.org/Public/UNIDATA/UnicodeData.txt), we know that the Katakana character Pe appears in all CJK character sets, and that its code value is `X'30DA'`. If we use this value as the argument to `p_convert()`, the result is as shown here:

```
mysql> CALL p_convert(X'30DA');
+----------+----------+----------+----------+----------+----------+----------+----------+----------+----------+
| ucs2     | utf8     | big5     | cp932    | eucjpms  | euckr    | gb2312   | gbk      | sjis     | ujis     |
|----------+----------+----------+----------+----------+----------+----------+----------+----------+----------|
| 30DA     | E3839A   | C772     | 8379     | A5DA     | ABDA     | A5DA     | A5DA     | 8379     | A5DA     |
+----------+----------+----------+----------+----------+----------+----------+----------+----------+----------+
```

Since none of the column values is `3F` (that is, the question mark character, `?`), we know that every conversion worked.
A.11.13 Why do CJK strings sort incorrectly in Unicode? (I)

Note

The CJK sorting problems described here can occur for MySQL versions prior to MySQL 8.0. As of MySQL 8.0, they can be solved by using the utf8mb4 character set and the utf8mb4_ja_0900_as_cs collation.

Sometimes people observe that the result of a utf8_unicode_ci or ucs2_unicode_ci search, or of an ORDER BY sort is not what they think a native would expect. Although we never rule out the possibility that there is a bug, we have found in the past that many people do not correctly read the standard table of weights for the Unicode Collation Algorithm. MySQL uses the tables found under http://www.unicode.org/Public/UCA/:

- UCA 4.0.0 table: http://www.unicode.org/Public/UCA/4.0.0/allkeys-4.0.0.txt
  
  This includes xxx_unicode_ci collations with no version number in the collation name.

- UCA 5.2.0 table: http://www.unicode.org/Public/UCA/5.2.0/allkeys.txt
  
  This includes collations with _520_ in the collation name.

- UCA 9.0.0 table: http://www.unicode.org/Public/UCA/9.0.0/allkeys.txt
  
  This includes collations with _0900_ in the collation name.

To handle newer UCA versions, we create new collations. We are very wary about changing ordering of existing collations because that affects indexes, which can bring about situations such as that reported in Bug #16526, illustrated as follows:

```
mysql> CREATE TABLE tj (s1 CHAR(1) CHARACTER SET utf8 COLLATE utf8_unicode_ci);
Query OK, 0 rows affected (0.05 sec)

mysql> INSERT INTO tj VALUES ('が'), ('か');
Query OK, 2 rows affected (0.00 sec)
Records: 2  Duplicates: 0  Warnings: 0

mysql> SELECT * FROM tj WHERE s1 = 'か';
+------+
<table>
<thead>
<tr>
<th>s1</th>
</tr>
</thead>
<tbody>
<tr>
<td>が</td>
</tr>
<tr>
<td>か</td>
</tr>
</tbody>
</table>
+------+

The character in the first result row is not the one that we searched for. Why did MySQL retrieve it? First we look for the Unicode code point value, which is possible by reading the hexadecimal number for the ucs2 version of the characters:

```
mysql> SELECT s1, HEX(CONVERT(s1 USING ucs2)) FROM tj;
```

<table>
<thead>
<tr>
<th>s1</th>
<th>HEX(CONVERT(s1 USING ucs2))</th>
</tr>
</thead>
<tbody>
<tr>
<td>が</td>
<td>304C</td>
</tr>
<tr>
<td>か</td>
<td>304B</td>
</tr>
</tbody>
</table>

Now we search for 304B and 304C in the 4.0.0 allkeys table, and find these lines:

```
304B ; [.1E57.0020.000E.304B] # HIRAGANA LETTER KA
```

3523
The official Unicode names (following the "#" mark) tell us the Japanese syllabary (Hiragana), the informal classification (letter, digit, or punctuation mark), and the Western identifier (KA or GA, which happen to be voiced and unvoiced components of the same letter pair). More importantly, the primary weight (the first hexadecimal number inside the square brackets) is 1E57 on both lines. For comparisons in both searching and sorting, MySQL pays attention to the primary weight only, ignoring all the other numbers. This means that we are sorting が and か correctly according to the Unicode specification. If we wanted to distinguish them, we'd have to use a non-UCA (Unicode Collation Algorithm) collation (utf8_bin or utf8_general_ci), or to compare the HEX() values, or use ORDER BY CONVERT(s1 USING sjis). Being correct “according to Unicode” is not enough, of course: the person who submitted the bug was equally correct. To solve this, we need another collation for Japanese according to the JIS X 4061 standard, in which voiced/unvoiced letter pairs like KA/GA are distinguishable for ordering purposes.

A.11.14 Why do CJK strings sort incorrectly in Unicode? (II)

Note

The CJK sorting problems described here can occur for MySQL versions prior to MySQL 8.0. As of MySQL 8.0, they can be solved by using the utf8mb4 character set and the utf8mb4_ja_0900_as_cs collation.

If you are using Unicode (ucs2 or utf8), and you know what the Unicode sort order is (see Section A.11, "MySQL 5.6 FAQ: MySQL Chinese, Japanese, and Korean Character Sets"), but MySQL still seems to sort your table incorrectly, first verify the character set in the table definition:

```
mysql> SHOW CREATE TABLE t
+--------------------------+--------------------------+--------------------------+
| Create Table: CREATE TABLE `t` ( |`s1` char(1) CHARACTER SET ucs2 DEFAULT NULL |} ENGINE=MyISAM DEFAULT CHARSET=latin1
```

Since the character set for the column s1 appears to be correct (ucs2), check what information the INFORMATION_SCHEMA.COLUMNS table can provide about this column:

```
mysql> SELECT COLUMN_NAME, CHARACTER_SET_NAME, COLLATION_NAME
FROM INFORMATION_SCHEMA.COLUMNS
WHERE COLUMN_NAME = 's1'
AND TABLE_NAME = 't';
```

(See Section 21.3.5, “The INFORMATION_SCHEMA COLUMNS Table”, for more information.)

You can see that the collation is ucs2_general_ci instead of ucs2_unicode_ci. The reason why this is so can be found using SHOW CHARACTER SET, as shown here:

```
mysql> SHOW CHARSET LIKE 'ucs2%';
```

<table>
<thead>
<tr>
<th>Charset</th>
<th>Description</th>
<th>Default collation</th>
<th>Maxlen</th>
</tr>
</thead>
<tbody>
<tr>
<td>ucs2</td>
<td>UCS-2 Unicode</td>
<td>ucs2_general_ci</td>
<td>2</td>
</tr>
</tbody>
</table>
For `ucs2` and `utf8`, the default collation is “general”. To specify a Unicode UCA collation, use `COLLATE ucs2_unicode_ci`, as shown in the preceding item.

**A.11.15** Why are my supplementary characters rejected by MySQL?

Supplementary characters lie outside the Unicode *Basic Multilingual Plane / Plane 0*. BMP characters have code point values between `U+0000` and `U+FFFF`. Supplementary characters have code point values between `U+10000` and `U+10FFFF`.

To store supplementary characters, you must use a character set that permits them:

- The `utf8` and `ucs2` character sets support BMP characters only.

  The `utf8` character set permits only UTF-8 characters that take up to three bytes. This has led to reports such as that found in Bug #12600, which we rejected as “not a bug”. With `utf8`, MySQL must truncate an input string when it encounters bytes that it does not understand. Otherwise, it is unknown how long the bad multibyte character is.

  One possible workaround is to use `ucs2` instead of `utf8`, in which case the “bad” characters are changed to question marks. However, no truncation takes place. You can also change the data type to `BLOB` or `BINARY`, which perform no validity checking.

- The `utf8mb4`, `utf16`, `utf16le`, and `utf32` character sets support BMP characters, as well as supplementary characters outside the BMP.

**A.11.16** Should “CJK” be “CJKV”?

No. The term “CJKV” (*Chinese Japanese Korean Vietnamese*) refers to Vietnamese character sets which contain Han (originally Chinese) characters. MySQL supports the modern Vietnamese script with Western characters, but does not support the old Vietnamese script using Han characters.

As of MySQL 5.6, there are Vietnamese collations for Unicode character sets, as described in Section 10.10.1, “Unicode Character Sets”.

**A.11.17** Does MySQL permit CJK characters to be used in database and table names?

Yes.

**A.11.18** Where can I find translations of the MySQL Manual into Chinese, Japanese, and Korean?

The Japanese translation of the MySQL 5.6 manual can be downloaded from https://dev.mysql.com/doc/.

**A.11.19** Where can I get help with CJK and related issues in MySQL?

The following resources are available:

- A listing of MySQL user groups can be found at https://wikis.oracle.com/display/mysql/List+of+MySQL+User+Groups.

- View feature requests relating to character set issues at http://tinyurl.com/y6xcuf.

**A.12 MySQL 5.6 FAQ: Connectors & APIs**
For common questions, issues, and answers relating to the MySQL Connectors and other APIs, see the following areas of the Manual:

- Using C API Features
- Common Problems with MySQL and PHP
- Connector/ODBC Notes and Tips
- Connector/.NET Programming
- MySQL Connector/J 5.1 Developer Guide

A.13 MySQL 5.6 FAQ: C API, libmysql

Frequently asked questions about MySQL C API and libmysql.

A.13.1 What is “MySQL Native C API”? What are typical benefits and use cases? .................................. 3526
A.13.2 Which version of libmysql should I use? ................................................................. 3526
A.13.3 What if I want to use the “NoSQL” X DevAPI? ................................................................. 3526
A.13.4 How do I download libmysql? ................................................................. 3526
A.13.5 Where is the documentation? ................................................................. 3526
A.13.6 How do I report bugs? ................................................................. 3526
A.13.7 Is it possible to compile the library myself? ................................................................. 3526

A.13.1 What is “MySQL Native C API”? What are typical benefits and use cases?

libmysql is a C-based API that you can use in C applications to connect with the MySQL database server. It is also itself used as the foundation for drivers for standard database APIs like ODBC, Perl's DBI, and Python's DB API.

A.13.2 Which version of libmysql should I use?

For MySQL 8.0, 5.7, 5.6, and 5.5, we recommend libmysql 8.0.

A.13.3 What if I want to use the “NoSQL” X DevAPI?

For C-language and X DevApi Document Store for MySQL 8.0, we recommend MySQL Connector/C++. Connector/C++ 8.0 has compatible C headers. (This is not applicable to MySQL 5.7 or before.)

A.13.4 How do I download libmysql?

- Linux: The Client Utilities Package is available from the MySQL Community Server download page.
- Repos: The Client Utilities Package is available from the Yum, APT, SuSE repositories.
- Windows: The Client Utilities Package is available from Windows Installer.

A.13.5 Where is the documentation?

See MySQL 5.6 C API Developer Guide.

A.13.6 How do I report bugs?

Please report any bugs or inconsistencies you observe to our Bugs Database. Select the C API Client as shown.

A.13.7 Is it possible to compile the library myself?
Yes, you can download the libmysqlclient source code and compile it on your own. Here's an example:

```bash
$ git clone --depth 1 https://github.com/mysql/mysql-server
$ cd mysql-server
$ mkdir build
$ cd build
$ cmake .. -GNinja -DDOWNLOAD_BOOST=1
   -DWITH_BOOST=/tmp -DCMAKE_BUILD_TYPE=Release -DWITHOUT_SERVER=ON
   -DWITH_SSL=system
$ ninja libmysqlclient.a
$ ls -la archive_output_directory/libmysqlclient.a
-rw-rw-r-- 1 kg kg 8,5M wrz 5 04:57 archive_output_directory/libmysqlclient.a
```

Note
This example uses https://ninja-build.org/ as a build system instead of make.

A.14 MySQL 5.6 FAQ: Replication

In the following section, we provide answers to questions that are most frequently asked about MySQL Replication.

A.14.1 Must the replica be connected to the source all the time? .......................... 3527
A.14.2 Must I enable networking on my source and replica to enable replication? ........ 3528
A.14.3 How do I know how late a replica is compared to the source? In other words, how do I know the date of the last statement replicated by the replica? ......................................................... 3528
A.14.4 How do I force the source to block updates until the replica catches up? .......... 3528
A.14.5 What issues should I be aware of when setting up two-way replication? .......... 3528
A.14.6 How can I use replication to improve performance of my system? .................. 3529
A.14.7 What should I do to prepare client code in my own applications to use performance-enhancing replication? ............................................................... 3529
A.14.8 When and how much can MySQL replication improve the performance of my system? 3529
A.14.9 How can I use replication to provide redundancy or high availability? ............ 3530
A.14.10 How do I tell whether a replication source server is using statement-based or row-based binary logging format? ......................................................... 3530
A.14.11 How do I tell a replica to use row-based replication? ........................................ 3530
A.14.12 How do I prevent GRANT and REVOKE statements from replicating to replica machines? 3530
A.14.13 Does replication work on mixed operating systems (for example, the source runs on Linux while replicas run on macOS and Windows)? ......................................................... 3530
A.14.14 Does replication work on mixed hardware architectures (for example, the source runs on a 64-bit machine while replicas run on 32-bit machines)? ........................................ 3531

A.14.1 Must the replica be connected to the source all the time?

No, it does not. The replica can go down or stay disconnected for hours or even days, and then reconnect and catch up on updates. For example, you can set up a source/replica relationship over a dial-up link where the link is up only sporadically and for short periods of time. The implication of this is that, at any given time, the replica is not guaranteed to be in synchrony with the source unless you take some special measures.

To ensure that catchup can occur for a replica that has been disconnected, you must not remove binary log files from the source that contain information that has not yet been replicated to the replicas. Asynchronous replication can work only if the replica is able to continue reading the binary log from the point where it last read events.
A.14.2 Must I enable networking on my source and replica to enable replication?

Yes, networking must be enabled on the source and replica. If networking is not enabled, the replica cannot connect to the source and transfer the binary log. Verify that the `skip_networking` system variable has not been enabled in the configuration file for either server.

A.14.3 How do I know how late a replica is compared to the source? In other words, how do I know the date of the last statement replicated by the replica?

Check the `Seconds_Behind_Master` column in the output from `SHOW REPLICA | SLAVE STATUS`. See Section 17.1.5.1, “Checking Replication Status”.

When the replication SQL thread executes an event read from the source, it modifies its own time to the event timestamp. (This is why `TIMESTAMP` is well replicated.) In the `Time` column in the output of `SHOW PROCESSLIST`, the number of seconds between the timestamp of the last replicated event and the real time of the replica machine. You can use this to determine the date of the last replicated event. Note that if your replica has been disconnected from the source for one hour, and then reconnects, you may immediately see large `Time` values such as 3600 for the replication SQL thread in `SHOW PROCESSLIST`. This is because the replica is executing statements that are one hour old. See Section 17.2.1, “Replication Threads”.

A.14.4 How do I force the source to block updates until the replica catches up?

Use the following procedure:

1. On the source, execute these statements:

```sql
mysql> FLUSH TABLES WITH READ LOCK;
mysql> SHOW MASTER STATUS;
```

Record the replication coordinates (the current binary log file name and position) from the output of the `SHOW` statement.

2. On the replica, issue the following statement, where the arguments to the `SOURCE_POS_WAIT()` or `MASTER_POS_WAIT()` function are the replication coordinate values obtained in the previous step:

```sql
mysql> SELECT MASTER_POS_WAIT('log_name', log_pos);
```

Or from MySQL 8.0.26:

```sql
mysql> SELECT SOURCE_POS_WAIT('log_name', log_pos);
```

The `SELECT` statement blocks until the replica reaches the specified log file and position. At that point, the replica is in synchrony with the source and the statement returns.

3. On the source, issue the following statement to enable the source to begin processing updates again:

```sql
mysql> UNLOCK TABLES;
```

A.14.5 What issues should I be aware of when setting up two-way replication?

MySQL replication currently does not support any locking protocol between source and replica to guarantee the atomicity of a distributed (cross-server) update. In other words, it is possible for client A to make an update to co-source 1, and in the meantime, before it propagates to co-source 2, client B could make an update to co-source 2 that makes the update of client A work differently than it did on co-source 1. Thus, when the update of client A makes it to co-source 2, it produces tables that are different from what you have on co-source 1, even after all the updates from co-source 3528
2 have also propagated. This means that you should not chain two servers together in a two-way replication relationship unless you are sure that your updates can safely happen in any order, or unless you take care of mis-ordered updates somehow in the client code.

You should also realize that two-way replication actually does not improve performance very much (if at all) as far as updates are concerned. Each server must do the same number of updates, just as you would have a single server do. The only difference is that there is a little less lock contention because the updates originating on another server are serialized in one replication thread. Even this benefit might be offset by network delays.

A.14.6 How can I use replication to improve performance of my system?

Set up one server as the source and direct all writes to it. Then configure as many replicas as you have the budget and rackspace for, and distribute the reads among the source and the replicas. You can also start the replicas with the --skip-innodb option, enable the low_priority_updates system variable, and set the delay_key_write system variable to ALL to get speed improvements on the replica end. In this case, the replica uses nontransactional MyISAM tables instead of InnoDB tables to get more speed by eliminating transactional overhead.

A.14.7 What should I do to prepare client code in my own applications to use performance-enhancing replication?

See the guide to using replication as a scale-out solution, Section 17.3.4, “Using Replication for Scale-Out”.

A.14.8 When and how much can MySQL replication improve the performance of my system?

MySQL replication is most beneficial for a system that processes frequent reads and infrequent writes. In theory, by using a single-source/multiple-replica setup, you can scale the system by adding more replicas until you either run out of network bandwidth, or your update load grows to the point that the source cannot handle it.

To determine how many replicas you can use before the added benefits begin to level out, and how much you can improve performance of your site, you must know your query patterns, and determine empirically by benchmarking the relationship between the throughput for reads and writes on a typical source and a typical replica. The example here shows a rather simplified calculation of what you can get with replication for a hypothetical system. Let reads and writes denote the number of reads and writes per second, respectively.

Let's say that system load consists of 10% writes and 90% reads, and we have determined by benchmarking that reads is 1200 - 2 * writes. In other words, the system can do 1,200 reads per second with no writes, the average write is twice as slow as the average read, and the relationship is linear. Suppose that the source and each replica have the same capacity, and that we have one source and N replicas. Then we have for each server (source or replica):

\[
\text{reads} = 1200 - 2 \times \text{writes} \\
\text{reads} = 9 \times \text{writes} / (N + 1) \quad \text{(reads are split, but writes replicated to all replicas)} \\
9 \times \text{writes} / (N + 1) + 2 \times \text{writes} = 1200 \\
\text{writes} = 1200 / (2 + 9/(N + 1))
\]

The last equation indicates the maximum number of writes for N replicas, given a maximum possible read rate of 1,200 per second and a ratio of nine reads per write.

This analysis yields the following conclusions:
• If \( N = 0 \) (which means we have no replication), our system can handle about \( 1200/11 = 109 \) writes per second.

• If \( N = 1 \), we get up to 184 writes per second.

• If \( N = 8 \), we get up to 400 writes per second.

• If \( N = 17 \), we get up to 480 writes per second.

• Eventually, as \( N \) approaches infinity (and our budget negative infinity), we can get very close to 600 writes per second, increasing system throughput about 5.5 times. However, with only eight servers, we increase it nearly four times.

These computations assume infinite network bandwidth and neglect several other factors that could be significant on your system. In many cases, you may not be able to perform a computation similar to the one just shown that accurately predicts what happens on your system if you add \( N \) replicas. However, answering the following questions should help you decide whether and by how much replication may improve the performance of your system:

• What is the read/write ratio on your system?

• How much more write load can one server handle if you reduce the reads?

• For how many replicas do you have bandwidth available on your network?

A.14.9 How can I use replication to provide redundancy or high availability?

How you implement redundancy is entirely dependent on your application and circumstances. High-availability solutions (with automatic failover) require active monitoring and either custom scripts or third party tools to provide the failover support from the original MySQL server to the replica.

To handle the process manually, you should be able to switch from a failed source to a pre-configured replica by altering your application to talk to the new server or by adjusting the DNS for the MySQL server from the failed server to the new server.

For more information and some example solutions, see Section 17.3.7, “Switching Sources During Failover”.

A.14.10 How do I tell whether a replication source server is using statement-based or row-based binary logging format?

Check the value of the `binlog_format` system variable:

```
mysql> SHOW VARIABLES LIKE 'binlog_format';
```

The value shown is always one of `STATEMENT`, `ROW`, or `MIXED`. For `MIXED` mode, statement-based logging is used by default but replication switches automatically to row-based logging under certain conditions, such as unsafe statements. For information about when this may occur, see Section 5.4.4.3, “Mixed Binary Logging Format”.

A.14.11 How do I tell a replica to use row-based replication?

Replicas automatically know which format to use.

A.14.12 How do I prevent `GRANT` and `REVOKE` statements from replicating to replica machines?

Start the server with the `--replicate-wild-ignore-table=mysql.%` option to ignore replication for tables in the `mysql` database.
A.14.13. Does replication work on mixed operating systems (for example, the source runs on Linux while replicas run on macOS and Windows)?

Yes.

A.14.14. Does replication work on mixed hardware architectures (for example, the source runs on a 64-bit machine while replicas run on 32-bit machines)?

Yes.

A.15 MySQL 5.6 FAQ: MySQL Enterprise Thread Pool

A.15.1 What is the Thread Pool and what problem does it solve? ......................................................... 3531
A.15.2 How does the Thread Pool limit and manage concurrent sessions and transactions for optimal performance and throughput? .............................................................................................................. 3531
A.15.3 How is the Thread Pool different from the client side Connection Pool? .................................. 3531
A.15.4 When should I use the Thread Pool? .............................................................................................. 3532
A.15.5 Are there recommended Thread Pool configurations? ................................................................. 3532

A.15.1 What is the Thread Pool and what problem does it solve?

The MySQL Thread Pool is a MySQL server plugin that extends the default connection-handling capabilities of the MySQL server to limit the number of concurrently executing statements/queries and transactions to ensure that each has sufficient CPU and memory resources to fulfill its task. For MySQL 5.6, the Thread Pool plugin is included in MySQL Enterprise Edition, a commercial product.

The default thread-handling model in MySQL Server executes statements using one thread per client connection. As more clients connect to the server and execute statements, overall performance degrades. The Thread Pool plugin provides an alternative thread-handling model designed to reduce overhead and improve performance. The Thread Pool plugin increases server performance by efficiently managing statement execution threads for large numbers of client connections, especially on modern multi-CPU/Core systems.

For more information, see Section 5.5.3, “MySQL Enterprise Thread Pool”.

A.15.2 How does the Thread Pool limit and manage concurrent sessions and transactions for optimal performance and throughput?

The Thread Pool uses a “divide and conquer” approach to limiting and balancing concurrency. Unlike the default connection handling of the MySQL Server, the Thread Pool separates connections and threads, so there is no fixed relationship between connections and the threads that execute statements received from those connections. The Thread Pool then manages client connections within configurable thread groups, where they are prioritized and queued based on the nature of the work they were submitted to accomplish.

For more information, see Section 5.5.3.3, “Thread Pool Operation”.

A.15.3 How is the Thread Pool different from the client side Connection Pool?

The MySQL Connection Pool operates on the client side to ensure that a MySQL client does not constantly connect to and disconnect from the MySQL server. It is designed to cache idle connections in the MySQL client for use by other users as they are needed. This minimizes the overhead and expense of establishing and tearing down connections as queries are submitted to the MySQL server. The MySQL Connection Pool has no visibility as to the query handling capabilities or load of the back-end MySQL server. By contrast, the Thread Pool operates on the MySQL server side and is designed to manage the execution of inbound concurrent connections.
and queries as they are received from the client connections accessing the back-end MySQL database. Because of the separation of duties, the MySQL Connection Pool and Thread Pool are orthogonal and can be used independent of each other.

MySQL Connection Pooling via the MySQL Connectors is covered in Chapter 23, Connectors and APIs.

A.15.4 When should I use the Thread Pool?

There are a few rules of thumb to consider for optimal Thread Pool use cases:

The MySQL Threads_running variable keeps track of the number of concurrent statements currently executing in the MySQL Server. If this variable consistently exceeds a region where the server won’t operate optimally (usually going beyond 40 for InnoDB workloads), the Thread Pool should be beneficial, especially in extreme parallel overload situations.

If you are using the innodb_thread_concurrency to limit the number of concurrently executing statements, you should find that the Thread Pool solves the same problem, only better, by assigning connections to thread groups, then queuing executions based on transactional content, user defined designations, and so forth.

Lastly, if your workload comprises mainly short queries, the Thread Pool should be beneficial.

To learn more, see Section 5.5.3.4, “Thread Pool Tuning”.

A.15.5 Are there recommended Thread Pool configurations?

The Thread Pool has a number of user case driven configuration parameters that affect its performance. To learn about these and tips on tuning, see Section 5.5.3.4, “Thread Pool Tuning”.

A.16 MySQL 5.6 FAQ: InnoDB Change Buffer

A.16.1 What types of operations modify secondary indexes and result in change buffering? .............. 3532
A.16.2 What is the benefit of the InnoDB change buffer? .......................................................... 3532
A.16.3 Does the change buffer support other types of indexes? ................................................. 3532
A.16.4 How much space does InnoDB use for the change buffer? ........................................... 3533
A.16.5 How do I determine the current size of the change buffer? ............................................. 3533
A.16.6 When does change buffer merging occur? ..................................................................... 3533
A.16.7 When is the change buffer flushed? .................................................................................. 3533
A.16.8 When should the change buffer be used? ......................................................................... 3534
A.16.9 When should the change buffer not be used? ................................................................. 3534
A.16.10 Where can I find additional information about the change buffer? ............................ 3534

A.16.1 What types of operations modify secondary indexes and result in change buffering?

**INSERT**, **UPDATE**, and **DELETE** operations can modify secondary indexes. If an affected index page is not in the buffer pool, the changes can be buffered in the change buffer.

A.16.2 What is the benefit of the InnoDB change buffer?

Buffering secondary index changes when secondary index pages are not in the buffer pool avoids expensive random access I/O operations that would be required to immediately read in affected index pages from disk. Buffered changes can be applied later, in batches, as pages are read into the buffer pool by other read operations.

A.16.3 Does the change buffer support other types of indexes?
No. The change buffer only supports secondary indexes. Clustered indexes, full-text indexes, and spatial indexes are not supported. Full-text indexes have their own caching mechanism.

**A.16.4** How much space does InnoDB use for the change buffer?

Prior to the introduction of the `innodb_change_buffer_max_size` configuration option in MySQL 5.6, the maximum size of the on-disk change buffer in the system tablespace was 1/3 of the InnoDB buffer pool size.

In MySQL 5.6 and later, the `innodb_change_buffer_max_size` configuration option defines the maximum size of the change buffer as a percentage of the total buffer pool size. By default, `innodb_change_buffer_max_size` is set to 25. The maximum setting is 50.

InnoDB does not buffer an operation if it would cause the on-disk change buffer to exceed the defined limit.

Change buffer pages are not required to persist in the buffer pool and may be evicted by LRU operations.

**A.16.5** How do I determine the current size of the change buffer?

The current size of the change buffer is reported by `SHOW ENGINE INNODB STATUS \G`, under the `INSERT BUFFER AND ADAPTIVE HASH INDEX` heading. For example:

```
-------------------------------------
INSERT BUFFER AND ADAPTIVE HASH INDEX
-------------------------------------
Ibuf: size 1, free list len 0, seg size 2, 0 merges
```

Relevant data points include:

- **size**: The number of pages used within the change buffer. Change buffer size is equal to `seg size - (1 + free list len)`. The `1 +` value represents the change buffer header page.

- **seg size**: The size of the change buffer, in pages.

For information about monitoring change buffer status, see Section 14.5.2, “Change Buffer”.

**A.16.6** When does change buffer merging occur?

- When a page is read into the buffer pool, buffered changes are merged upon completion of the read, before the page is made available.

- Change buffer merging is performed as a background task. The `innodb_io_capacity` parameter sets an upper limit on the I/O activity performed by InnoDB background tasks such as merging data from the change buffer.

- A change buffer merge is performed during crash recovery. Changes are applied from the change buffer (in the system tablespace) to leaf pages of secondary indexes as index pages are read into the buffer pool.

- The change buffer is fully durable and can survive a system crash. Upon restart, change buffer merge operations resume as part of normal operations.

- A full merge of the change buffer can be forced as part of a slow server shutdown using `--innodb-fast-shutdown=0`.

**A.16.7** When is the change buffer flushed?
Updated pages are flushed by the same flushing mechanism that flushes the other pages that occupy the buffer pool.

**A.16.8 When should the change buffer be used?**

The change buffer is a feature designed to reduce random I/O to secondary indexes as indexes grow larger and no longer fit in the InnoDB buffer pool. Generally, the change buffer should be used when the entire data set does not fit into the buffer pool, when there is substantial DML activity that modifies secondary index pages, or when there are lots of secondary indexes that are regularly changed by DML activity.

**A.16.9 When should the change buffer not be used?**

You might consider disabling the change buffer if the entire data set fits within the InnoDB buffer pool, if you have relatively few secondary indexes, or if you are using solid-state storage, where random reads are about as fast as sequential reads. Before making configuration changes, it is recommended that you run tests using a representative workload to determine if disabling the change buffer provides any benefit.

**A.16.10 Where can I find additional information about the change buffer?**

See Section 14.5.2, “Change Buffer”.

**A.17 MySQL 5.6 FAQ: Virtualization Support**

**A.17.1 Is MySQL supported on virtualized environments such as Oracle VM, VMWare, Docker, Microsoft Hyper-V, or others?**

MySQL is supported on virtualized environments, but is certified only for Oracle VM. Contact Oracle Support for more information.

Be aware of potential problems when using virtualization software. The usual ones are related to performance, performance degradations, slowness, or unpredictability of disk, I/O, network, and memory.
Appendix B Error Messages and Common Problems

  B.3.7 Known Issues in MySQL .............................................................................. 3569

This appendix describes the types of error information MySQL provides and how to obtain information about them. The final section is for troubleshooting. It describes common problems and errors that may occur and potential resolutions.

Additional Resources

Other error-related documentation includes:

• Information about configuring where and how the server writes the error log: Section 5.4.2, “The Error Log”
• Information about the character set used for error messages: Section 10.6, “Error Message Character Set”
• Information about the language used for error messages: Section 10.12, “Setting the Error Message Language”
• Information about errors related to InnoDB: Section 14.21.4, “InnoDB Error Handling”
• Information about errors specific to NDB Cluster: NDB Cluster API Errors; see also NDB API Errors and Error Handling, and MGM API Errors
• Descriptions of the error messages that the MySQL server and client programs generate: MySQL 5.6 Error Message Reference

B.1 Error Message Sources and Elements

This section discusses how error messages originate within MySQL and the elements they contain.

• Error Message Sources

B.1.1 Error Message Sources

Error messages can originate on the server side or the client side:

• On the server side, error messages may occur during the startup and shutdown processes, as a result of issues that occur during SQL statement execution, and so forth.
The MySQL server writes some error messages to its error log. These indicate issues of interest to database administrators or that require DBA action.

The server sends other error messages to client programs. These indicate issues pertaining only to a particular client. The MySQL client library takes errors received from the server and makes them available to the host client program.

Client-side error messages are generated from within the MySQL client library, usually involving problems communicating with the server.

Example server-side error messages written to the error log:

- This message produced during the startup process provides a status or progress indicator:

  2018-08-29 08:27:31 16664 [Note] Event Scheduler: scheduler thread started with id 1

- This message indicates an issue that requires DBA action:

  2018-10-02 03:20:39 0 [ERROR] Can't open the mysql.plugin table. Please run mysql_upgrade to create it.

Example server-side error message sent to client programs, as displayed by the mysql client:

  mysql> SELECT * FROM no_such_table;
  ERROR 1146 (42S02): Table 'test.no_such_table' doesn't exist

Example client-side error message originating from within the client library, as displayed by the mysql client:

  $> mysql -h no-such-host
  ERROR 2005 (HY000): Unknown MySQL server host 'no-such-host' (0)

Whether an error originates from within the client library or is received from the server, a MySQL client program may respond in varying ways. As just illustrated, the client may display the error message so the user can take corrective measures. The client may instead internally attempt to resolve or retry a failed operation, or take other action.

Error Message Elements

When an error occurs, error information includes several elements: an error code, SQLSTATE value, and message string. These elements have the following characteristics:

- Error code: This value is numeric. It is MySQL-specific and is not portable to other database systems.

  Each error number has a corresponding symbolic value. Examples:

  - The symbol for server error number 1146 is ER_NO_SUCH_TABLE.
  - The symbol for client error number 2005 is CR_UNKNOWN_HOST.

  Error codes are stable across General Availability (GA) releases of a given MySQL series. Before a series reaches GA status, new codes may still be under development and are subject to change.

- SQLSTATE value: This value is a five-character string (for example, '42S02'). SQLSTATE values are taken from ANSI SQL and ODBC and are more standardized than the numeric error codes. The first two characters of an SQLSTATE value indicate the error class:
Error Information Interfaces

- Class = '00' indicates success.
- Class = '01' indicates a warning.
- Class = '02' indicates “not found.” This is relevant within the context of cursors and is used to control what happens when a cursor reaches the end of a data set. This condition also occurs for `SELECT ... INTO var_list` statements that retrieve no rows.
- Class > '02' indicates an exception.

For server-side errors, not all MySQL error numbers have corresponding SQLSTATE values. In these cases, 'HY000' (general error) is used.

For client-side errors, the SQLSTATE value is always 'HY000' (general error), so it is not meaningful for distinguishing one client error from another.

- Message string: This string provides a textual description of the error.

B.2 Error Information Interfaces

Error messages can originate on the server side or the client side, and each error message includes an error code, SQLSTATE value, and message string, as described in Section B.1, “Error Message Sources and Elements”. For lists of server-side, client-side, and global (shared between server and clients) errors, see MySQL 5.6 Error Message Reference.

For error checking from within programs, use error code numbers or symbols, not error message strings. Message strings do not change often, but it is possible. Also, if the database administrator changes the language setting, that affects the language of message strings; see Section 10.12, “Setting the Error Message Language”.

Error information in MySQL is available in the server error log, at the SQL level, from within client programs, and at the command line.

- Error Log
- SQL Error Message Interface
- Client Error Message Interface
- Command-Line Error Message Interface

Error Log

On the server side, some messages are intended for the error log. For information about configuring where and how the server writes the log, see Section 5.4.2, “The Error Log”.

Other server error messages are intended to be sent to client programs and are available as described in Client Error Message Interface.

SQL Error Message Interface

At the SQL level, there are several sources of error information in MySQL:

- SQL statement warning and error information is available through the `SHOW WARNINGS` and `SHOW ERRORS` statements. The `warning_count` system variable indicates the number of errors, warnings,
and notes (with notes excluded if the `sql_notes` system variable is disabled). The `error_count` system variable indicates the number of errors. Its value excludes warnings and notes.

- The `GET DIAGNOSTICS` statement may be used to inspect the diagnostic information in the diagnostics area. See Section 13.6.7.3, “GET DIAGNOSTICS Statement”.
- `SHOW SLAVE STATUS` statement output includes information about replication errors occurring on replica servers.
- `SHOW ENGINE INNODB STATUS` statement output includes information about the most recent foreign key error if a `CREATE TABLE` statement for an InnoDB table fails.

### Client Error Message Interface

Client programs receive errors from two sources:

- Errors that originate on the client side from within the MySQL client library.
- Errors that originate on the server side and are sent to the client by the server. These are received within the client library, which makes them available to the host client program.

Regardless of whether an error originates from within the client library or is received from the server, a MySQL client program obtains the error code, SQLSTATE value, message string, and other related information by calling C API functions in the client library:

- `mysql_errno()` returns the MySQL error code.
- `mysql_sqlstate()` returns the SQLSTATE value.
- `mysql_error()` returns the message string.
- `mysql_stmt_errno()`, `mysql_stmt_sqlstate()`, and `mysql_stmt_error()` are the corresponding error functions for prepared statements.
- `mysql_warning_count()` returns the number of errors, warnings, and notes for the most recent statement.

For descriptions of the client library error functions, see MySQL 5.6 C API Developer Guide.

A MySQL client program may respond to an error in varying ways. The client may display the error message so the user can take corrective measures, internally attempt to resolve or retry a failed operation, or take other action. For example, (using the `mysql` client), a failure to connect to the server might result in this message:

```
$> mysql -h no-such-host
ERROR 2005 (HY000): Unknown MySQL server host 'no-such-host' (0)
```

### Command-Line Error Message Interface

The `perror` program provides information from the command line about error numbers. See Section 4.8.1, “`perror` — Display MySQL Error Message Information”.

```
$> perror 1231
MySQL error code 1231 (ER_WRONG_VALUE_FOR_VAR): Variable '%-.64s' can't be set to the value of '%-.200s'
```

### B.3 Problems and Common Errors
This section lists some common problems and error messages that you may encounter. It describes how to determine the causes of the problems and what to do to solve them.

**B.3.1 How to Determine What Is Causing a Problem**

When you run into a problem, the first thing you should do is to find out which program or piece of equipment is causing it:

- If you have one of the following symptoms, then it is probably a hardware problems (such as memory, motherboard, CPU, or hard disk) or kernel problem:
  - The keyboard does not work. This can normally be checked by pressing the Caps Lock key. If the Caps Lock light does not change, you have to replace your keyboard. (Before doing this, you should try to restart your computer and check all cables to the keyboard.)
  - The mouse pointer does not move.
  - The machine does not answer to a remote machine's pings.
  - Other programs that are not related to MySQL do not behave correctly.
  - Your system restarted unexpectedly. (A faulty user-level program should never be able to take down your system.)

In this case, you should start by checking all your cables and run some diagnostic tool to check your hardware! You should also check whether there are any patches, updates, or service packs for your operating system that could likely solve your problem. Check also that all your libraries (such as glibc) are up to date.

It is always good to use a machine with ECC memory to discover memory problems early.

- If your keyboard is locked up, you may be able to recover by logging in to your machine from another machine and executing `kbd_mode -a`.

- Please examine your system log file (`/var/log/messages` or similar) for reasons for your problem. If you think the problem is in MySQL, you should also examine MySQL's log files. See Section 5.4, “MySQL Server Logs”.

- If you do not think you have hardware problems, you should try to find out which program is causing problems. Try using `top`, `ps`, Task Manager, or some similar program, to check which program is taking all CPU or is locking the machine.

- Use `top`, `df`, or a similar program to check whether you are out of memory, disk space, file descriptors, or some other critical resource.

- If the problem is some runaway process, you can always try to kill it. If it does not want to die, there is probably a bug in the operating system.

If you have examined all other possibilities and concluded that the MySQL server or a MySQL client is causing the problem, it is time to create a bug report, see Section 1.6, “How to Report Bugs or Problems”. In the bug report, try to give a complete description of how the system is behaving and what you think is happening. Also state why you think that MySQL is causing the problem. Take into consideration all the situations described in this chapter. State any problems exactly how they appear when you examine your system. Use the “copy and paste” method for any output and error messages from programs and log files.

Try to describe in detail which program is not working and all symptoms you see. We have in the past received many bug reports that state only “the system does not work.” This provides us with no information about what could be the problem.
Common Errors When Using MySQL Programs

If a program fails, it is always useful to know the following information:

• Has the program in question made a segmentation fault (did it dump core)?

• Is the program taking up all available CPU time? Check with `top`. Let the program run for a while, it may simply be evaluating something computationally intensive.

• If the `mysqld` server is causing problems, can you get any response from it with `mysqldump -u root ping` or `mysqldump -u root processlist`?

• What does a client program say when you try to connect to the MySQL server? (Try with `mysql`, for example.) Does the client jam? Do you get any output from the program?

When sending a bug report, you should follow the outline described in Section 1.6, “How to Report Bugs or Problems”.

B.3.2 Common Errors When Using MySQL Programs

This section lists some errors that users frequently encounter when running MySQL programs. Although the problems show up when you try to run client programs, the solutions to many of the problems involves changing the configuration of the MySQL server.

B.3.2.1 Access denied

An Access denied error can have many causes. Often the problem is related to the MySQL accounts that the server permits client programs to use when connecting. See Section 6.2, “Access Control and Account Management”, and Section 6.2.14, “Troubleshooting Problems Connecting to MySQL”.

B.3.2.2 Can’t connect to [local] MySQL server

A MySQL client on Unix can connect to the `mysqld` server in two different ways: By using a Unix socket file to connect through a file in the file system (default `/tmp/mysql.sock`), or by using TCP/IP, which connects through a port number. A Unix socket file connection is faster than TCP/IP, but can be used only when connecting to a server on the same computer. A Unix socket file is used if you do not specify a host name or if you specify the special host name `localhost`.

If the MySQL server is running on Windows, you can connect using TCP/IP. If the server is started with the `named_pipe` system variable enabled, you can also connect with named pipes if you run the client on the host where the server is running. The name of the named pipe is `MySQL` by default. If you do not give a host name when connecting to `mysqld`, a MySQL client first tries to connect to the named pipe. If that does not work, it connects to the TCP/IP port. You can force the use of named pipes on Windows by using . as the host name.

The error (2002) Can't connect to ... normally means that there is no MySQL server running on the system or that you are using an incorrect Unix socket file name or TCP/IP port number when trying to connect to the server. You should also check that the TCP/IP port you are using has not been blocked by a firewall or port blocking service.

The error (2003) Can't connect to MySQL server on 'server' (10061) indicates that the network connection has been refused. You should check that there is a MySQL server running, that it has network connections enabled, and that the network port you specified is the one configured on the server.

Start by checking whether there is a process named `mysql` running on your server host. (Use `ps xa` | `grep mysql` on Unix or the Task Manager on Windows.) If there is no such process, you should start the server. See Section 2.10.2, “Starting the Server”.

3540
If a `mysqld` process is running, you can check it by trying the following commands. The port number or Unix socket file name might be different in your setup. `host_ip` represents the IP address of the machine where the server is running.

```
$> mysqladmin version
$> mysqladmin variables
$> mysqladmin -h `hostname` version variables
$> mysqladmin -h `hostname` --port=3306 version
$> mysqladmin -h host_ip version
$> mysqladmin --protocol=SOCKET --socket=/tmp/mysql.sock version
```

Regarding the use of backticks rather than forward quotation marks with the `hostname` command; these cause the output of `hostname` (that is, the current host name) to be substituted into the `mysqladmin` command. If you have no `hostname` command or are running on Windows, you can manually type the host name of your machine (without backticks) following the `-h` option. You can also try `-h 127.0.0.1` to connect with TCP/IP to the local host.

Make sure that the server has not been configured to ignore network connections or (if you are attempting to connect remotely) that it has not been configured to listen only locally on its network interfaces. If the server was started with the `skip_networking` system variable enabled, it does accept TCP/IP connections at all. If the server was started with the `bind_address` system variable set to `127.0.0.1`, it listens for TCP/IP connections only locally on the loopback interface and does not accept remote connections.

Check to make sure that there is no firewall blocking access to MySQL. Your firewall may be configured on the basis of the application being executed, or the port number used by MySQL for communication (3306 by default). Under Linux or Unix, check your IP tables (or similar) configuration to ensure that the port has not been blocked. Under Windows, applications such as ZoneAlarm or Windows Firewall may need to be configured not to block the MySQL port.

Here are some reasons the `Can't connect to local MySQL server` error might occur:

- **mysqld** is not running on the local host. Check your operating system's process list to ensure the `mysqld` process is present.

- You're running a MySQL server on Windows with many TCP/IP connections to it. If you're experiencing that quite often your clients get that error, you can find a workaround here: [Connection to MySQL Server Failing on Windows](https://dev.mysql.com/doc/refman/8.0/en/can-t-connect-to-local-mysql-server.html).

- Someone has removed the Unix socket file that `mysqld` uses (`/tmp/mysql.sock` by default). For example, you might have a cron job that removes old files from the `/tmp` directory. You can always run `mysqladmin version` to check whether the Unix socket file that `mysqladmin` is trying to use really exists. The fix in this case is to change the cron job to not remove `mysql.sock` or to place the socket file somewhere else. See Section B.3.3.6, “How to Protect or Change the MySQL Unix Socket File”.

- You have started the `mysqld` server with the `--socket=/path/to/socket` option, but forgotten to tell client programs the new name of the socket file. If you change the socket path name for the server, you must also notify the MySQL clients. You can do this by providing the same `--socket` option when you run client programs. You also need to ensure that clients have permission to access the `mysql.sock` file. To find out where the socket file is, you can do:

  ```
  $> netstat -ln | grep mysql
  ```

  See Section B.3.3.6, “How to Protect or Change the MySQL Unix Socket File”.

- You are using Linux and one server thread has died (dumped core). In this case, you must kill the other `mysqld` threads (for example, with `kill`) before you can restart the MySQL server. See Section B.3.3.3, “What to Do If MySQL Keeps Crashing”.

3541
Common Errors When Using MySQL Programs

• The server or client program might not have the proper access privileges for the directory that holds the Unix socket file or the socket file itself. In this case, you must either change the access privileges for the directory or socket file so that the server and clients can access them, or restart mysqld with a --socket option that specifies a socket file name in a directory where the server can create it and where client programs can access it.

If you get the error message Can't connect to MySQL server on some_host, you can try the following things to find out what the problem is:

• Check whether the server is running on that host by executing telnet some_host 3306 and pressing the Enter key a couple of times. (3306 is the default MySQL port number. Change the value if your server is listening to a different port.) If there is a MySQL server running and listening to the port, you should get a response that includes the server's version number. If you get an error such as telnet: Unable to connect to remote host: Connection refused, then there is no server running on the given port.

• If the server is running on the local host, try using mysqladmin -h localhost variables to connect using the Unix socket file. Verify the TCP/IP port number that the server is configured to listen to (it is the value of the port variable.)

• If you are running under Linux and Security-Enhanced Linux (SELinux) is enabled, see Section 6.6, “SELinux”.

Connection to MySQL Server Failing on Windows

When you're running a MySQL server on Windows with many TCP/IP connections to it, and you're experiencing that quite often your clients get a Can't connect to MySQL server error, the reason might be that Windows does not allow for enough ephemeral (short-lived) ports to serve those connections.

The purpose of TIME_WAIT is to keep a connection accepting packets even after the connection has been closed. This is because Internet routing can cause a packet to take a slow route to its destination and it may arrive after both sides have agreed to close. If the port is in use for a new connection, that packet from the old connection could break the protocol or compromise personal information from the original connection. The TIME_WAIT delay prevents this by ensuring that the port cannot be reused until after some time has been permitted for those delayed packets to arrive.

It is safe to reduce TIME_WAIT greatly on LAN connections because there is little chance of packets arriving at very long delays, as they could through the Internet with its comparatively large distances and latencies.

Windows permits ephemeral (short-lived) TCP ports to the user. After any port is closed it remains in a TIME_WAIT status for 120 seconds. The port is not available again until this time expires. The default range of port numbers depends on the version of Windows, with a more limited number of ports in older versions:

• Windows through Server 2003: Ports in range 1025–5000

• Windows Vista, Server 2008, and newer: Ports in range 49152–65535

With a small stack of available TCP ports (5000) and a high number of TCP ports being open and closed over a short period of time along with the TIME_WAIT status you have a good chance for running out of ports. There are two ways to address this problem:

• Reduce the number of TCP ports consumed quickly by investigating connection pooling or persistent connections where possible

• Tune some settings in the Windows registry (see below)
**Important**

The following procedure involves modifying the Windows registry. Before you modify the registry, make sure to back it up and make sure that you understand how to restore it if a problem occurs. For information about how to back up, restore, and edit the registry, view the following article in the Microsoft Knowledge Base: [http://support.microsoft.com/kb/256986/EN-US/](http://support.microsoft.com/kb/256986/EN-US/).

1. Start Registry Editor (Regedt32.exe).
2. Locate the following key in the registry:
   
   ```
   HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters
   ```
3. On the **Edit** menu, click **Add Value**, and then add the following registry value:
   
   ```
   Value Name: MaxUserPort  
   Data Type: REG_DWORD  
   Value: 65534
   ```

   This sets the number of ephemeral ports available to any user. The valid range is between 5000 and 65534 (decimal). The default value is 0x1388 (5000 decimal).
4. On the **Edit** menu, click **Add Value**, and then add the following registry value:
   
   ```
   Value Name: TcpTimedWaitDelay  
   Data Type: REG_DWORD  
   Value: 30
   ```

   This sets the number of seconds to hold a TCP port connection in **TIME_WAIT** state before closing. The valid range is between 30 and 300 decimal, although you may wish to check with Microsoft for the latest permitted values. The default value is 0x78 (120 decimal).
5. Quit Registry Editor.
6. Reboot the machine.

**Note**

Undoing the above should be as simple as deleting the registry entries you’ve created.

**B.3.2.3 Lost connection to MySQL server**

There are three likely causes for this error message.

Usually it indicates network connectivity trouble and you should check the condition of your network if this error occurs frequently. If the error message includes “during query,” this is probably the case you are experiencing.

Sometimes the “during query” form happens when millions of rows are being sent as part of one or more queries. If you know that this is happening, you should try increasing `net_read_timeout` from its default of 30 seconds to 60 seconds or longer, sufficient for the data transfer to complete.

More rarely, it can happen when the client is attempting the initial connection to the server. In this case, if your `connect_timeout` value is set to only a few seconds, you may be able to resolve the problem by increasing it to ten seconds, perhaps more if you have a very long distance or slow connection. You can determine whether you are experiencing this more uncommon cause by using `SHOW GLOBAL STATUS LIKE 'Aborted_connects'`. It increases by one for each initial connection attempt that the server
aborts. You may see “reading authorization packet” as part of the error message; if so, that also suggests that this is the solution that you need.

If the cause is none of those just described, you may be experiencing a problem with BLOB values that are larger than max_allowed_packet, which can cause this error with some clients. Sometime you may see an ER_NET_PACKET_TOO_LARGE error, and that confirms that you need to increase max_allowed_packet.

B.3.2.4 Client does not support authentication protocol

The current implementation of the authentication protocol uses a password hashing algorithm that is incompatible with that used by older (pre-4.1) clients. Attempts to connect to a 4.1 or higher server with an older client may fail with the following message:

```
$> mysql
Client does not support authentication protocol requested by server; consider upgrading MySQL client
```

To deal with this problem, the preferred solution is to upgrade all client programs to use a 4.1.1 or higher client library. If that is not possible, use one of the following approaches:

- To connect to the server with a pre-4.1 client program, use an account that still has a pre-4.1-style password.

- Reset the password to pre-4.1 style for each user that needs to use a pre-4.1 client program. This can be done using the SET PASSWORD statement and the OLD_PASSWORD() function. As of MySQL 5.6.6, it is also necessary to first ensure that the authentication plugin for the account is mysql_old_password:

  ```
  mysql> UPDATE mysql.user SET plugin = 'mysql_old_password'
  mysql> WHERE User = 'some_user' AND Host = 'some_host';
  mysql> SET PASSWORD FOR '
  --> 'some_user'@'some_host' = OLD_PASSWORD('new_password');
  ```

  Substitute the password you want to use for “new_password” in the preceding example. MySQL cannot tell you what the original password was, so you'll need to pick a new one.

- Tell the server to use the older password hashing algorithm by default:

  1. Start mysqld with the old_passwords system variable set to 1.
  2. Assign an old-format password to each account that has had its password updated to the longer 4.1 format. You can identify these accounts with the following query:

  ```
  mysql> SELECT Host, User, Password FROM mysql.user
  -> WHERE LENGTH(Password) > 16;
  ```

  For each account record displayed by the query, use the Host and User values and assign a password using one of the methods described previously.

The Client does not support authentication protocol error also can occur if multiple versions of MySQL are installed but client programs are dynamically linked and link to an older library. Make sure that clients use the most recent library version with which they are compatible. The procedure to do this depends on your system.

Note

The PHP mysql extension does not support the authentication protocol in MySQL 4.1.1 and higher. This is true regardless of the PHP version being used. If you wish
Common Errors When Using MySQL Programs

To use the `mysql` extension with MySQL 4.1 or higher, you may need to follow one of the options discussed above for configuring MySQL to work with old clients. The `mysqli` extension (stands for "MySQL, Improved"; added in PHP 5) is compatible with the improved password hashing employed in MySQL 4.1 and higher, and no special configuration of MySQL need be done to use this MySQL client library. For more information about the `mysqli` extension, see [http://php.net/mysqli](http://php.net/mysqli).

For additional background on password hashing and authentication, see Section 6.1.2.4, "Password Hashing in MySQL".

**B.3.2.5 Password Fails When Entered Interactively**

MySQL client programs prompt for a password when invoked with a `--password` or `-p` option that has no following password value:

```bash
$> mysql -u user_name -p
Enter password:
```

On some systems, you may find that your password works when specified in an option file or on the command line, but not when you enter it interactively at the `Enter password:` prompt. This occurs when the library provided by the system to read passwords limits password values to a small number of characters (typically eight). That is a problem with the system library, not with MySQL. To work around it, change your MySQL password to a value that is eight or fewer characters long, or put your password in an option file.

**B.3.2.6 Too many connections**

If clients encounter Too many connections errors when attempting to connect to the `mysqld` server, all available connections are in use by other clients.

The permitted number of connections is controlled by the `max_connections` system variable. To support more connections, set `max_connections` to a larger value. `mysqld` actually permits `max_connections` + 1 client connections. The extra connection is reserved for use by accounts that have the `SUPER` privilege. By granting the privilege to administrators and not to normal users (who should not need it), an administrator who also has the `PROCESS` privilege can connect to the server and use `SHOW PROCESSLIST` to diagnose problems even if the maximum number of unprivileged clients are connected. See Section 13.7.5.30, "SHOW PROCESSLIST Statement".

For more information about how the server handles client connections, see Section 5.1.11.1, "Connection Interfaces".

**B.3.2.7 Out of memory**

If you issue a query using the `mysql` client program and receive an error like the following one, it means that `mysql` does not have enough memory to store the entire query result:

```
mysql: Out of memory at line 42, 'malloc.c'
mysql: needed 8136 byte (8k), memory in use: 12481367 bytes (12189k)
ERROR 2008: MySQL client ran out of memory
```

To remedy the problem, first check whether your query is correct. Is it reasonable that it should return so many rows? If not, correct the query and try again. Otherwise, you can invoke `mysql` with the `--quick` option. This causes it to use the `mysql_use_result()` C API function to retrieve the result set, which places less of a load on the client (but more on the server).

**B.3.2.8 MySQL server has gone away**
This section also covers the related **Lost connection to server during query error**.

The most common reason for the **MySQL server has gone away** error is that the server timed out and closed the connection. In this case, you normally get one of the following error codes (which one you get is operating system-dependent).

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CR_SERVER_GONE_ERROR</td>
<td>The client couldn't send a question to the server.</td>
</tr>
<tr>
<td>CR_SERVER_LOST</td>
<td>The client didn't get an error when writing to the server, but it didn't get a full answer (or any answer) to the question.</td>
</tr>
</tbody>
</table>

By default, the server closes the connection after eight hours if nothing has happened. You can change the time limit by setting the `wait_timeout` variable when you start `mysqld`. See Section 5.1.7, "Server System Variables".

If you have a script, you just have to issue the query again for the client to do an automatic reconnection. This assumes that you have automatic reconnection in the client enabled (which is the default for the `mysql` command-line client).

Some other common reasons for the **MySQL server has gone away** error are:

- You (or the db administrator) has killed the running thread with a `KILL` statement or a `mysqladmin kill` command.
- You tried to run a query after closing the connection to the server. This indicates a logic error in the application that should be corrected.
- A client application running on a different host does not have the necessary privileges to connect to the MySQL server from that host.
- You got a timeout from the TCP/IP connection on the client side. This may happen if you have been using the commands: `mysql_options(..., MYSQL_OPT_READ_TIMEOUT,...)` or `mysql_options(..., MYSQL_OPT_WRITE_TIMEOUT,...)`. In this case increasing the timeout may help solve the problem.
- You have encountered a timeout on the server side and the automatic reconnection in the client is disabled (the `reconnect` flag in the `MYSQL` structure is equal to 0).
- You are using a Windows client and the server had dropped the connection (probably because `wait_timeout` expired) before the command was issued.

The problem on Windows is that in some cases MySQL does not get an error from the OS when writing to the TCP/IP connection to the server, but instead gets the error when trying to read the answer from the connection.

The solution to this is to either do a `mysql_ping()` on the connection if there has been a long time since the last query (this is what Connector/ODBC does) or set `wait_timeout` on the `mysqld` server so high that it in practice never times out.

- You can also get these errors if you send a query to the server that is incorrect or too large. If `mysqld` receives a packet that is too large or out of order, it assumes that something has gone wrong with the client and closes the connection. If you need big queries (for example, if you are working with big BLOB columns), you can increase the query limit by setting the server's `max_allowed_packet` variable, which has a default value of 4MB (1MB before MySQL 5.6.6). You may also need to increase
the maximum packet size on the client end. More information on setting the packet size is given in Section B.3.2.9, “Packet Too Large”.

An **INSERT** or **REPLACE** statement that inserts a great many rows can also cause these sorts of errors. Either one of these statements sends a single request to the server irrespective of the number of rows to be inserted; thus, you can often avoid the error by reducing the number of rows sent per **INSERT** or **REPLACE**.

- It is also possible to see this error if host name lookups fail (for example, if the DNS server on which your server or network relies goes down). This is because MySQL is dependent on the host system for name resolution, but has no way of knowing whether it is working—from MySQL’s point of view the problem is indistinguishable from any other network timeout.

You may also see the **MySQL server has gone away** error if MySQL is started with the **skip_networking** system variable enabled.

Another networking issue that can cause this error occurs if the MySQL port (default 3306) is blocked by your firewall, thus preventing any connections at all to the MySQL server.

- You can also encounter this error with applications that fork child processes, all of which try to use the same connection to the MySQL server. This can be avoided by using a separate connection for each child process.

- You have encountered a bug where the server died while executing the query.

You can check whether the MySQL server died and restarted by executing **mysqladmin version** and examining the server’s uptime. If the client connection was broken because **mysqld** crashed and restarted, you should concentrate on finding the reason for the crash. Start by checking whether issuing the query again kills the server again. See Section B.3.3.3, “What to Do If MySQL Keeps Crashing”.

You can obtain more information about lost connections by starting **mysqld** with the **--log-warnings=2** option. This logs some of the disconnected errors in the **hostname.err** file. See Section 5.4.2, “The Error Log”.

If you want to create a bug report regarding this problem, be sure that you include the following information:

- Indicate whether the MySQL server died. You can find information about this in the server error log. See Section B.3.3.3, “What to Do If MySQL Keeps Crashing”.

- If a specific query kills **mysqld** and the tables involved were checked with **CHECK TABLE** before you ran the query, can you provide a reproducible test case? See Section 5.8, “Debugging MySQL”.

- What is the value of the **wait_timeout** system variable in the MySQL server? (**mysqladmin variables** gives you the value of this variable.)

- Have you tried to run **mysqld** with the general query log enabled to determine whether the problem query appears in the log? (See Section 5.4.3, “The General Query Log”.)

See also Section B.3.2.10, “Communication Errors and Aborted Connections”, and Section 1.6, “How to Report Bugs or Problems”.

**B.3.2.9 Packet Too Large**

A communication packet is a single SQL statement sent to the MySQL server, a single row that is sent to the client, or a binary log event sent from a replication source server to a replica.

The largest possible packet that can be transmitted to or from a MySQL 5.6 server or client is 1GB.
When a MySQL client or the `mysqld` server receives a packet bigger than `max_allowed_packet` bytes, it issues an `ER_NET_PACKET_TOO_LARGE` error and closes the connection. With some clients, you may also get a `Lost connection to MySQL server during query` error if the communication packet is too large.

Both the client and the server have their own `max_allowed_packet` variable, so if you want to handle big packets, you must increase this variable both in the client and in the server.

If you are using the `mysql` client program, its default `max_allowed_packet` variable is 16MB. To set a larger value, start `mysql` like this:

```bash
$> mysql --max_allowed_packet=32M
```

That sets the packet size to 32MB.

The server's default `max_allowed_packet` value is 4MB (1MB before MySQL 5.6.6). You can increase this if the server needs to handle big queries (for example, if you are working with big `BLOB` columns). For example, to set the variable to 16MB, start the server like this:

```bash
$> mysqld --max_allowed_packet=16M
```

You can also use an option file to set `max_allowed_packet`. For example, to set the size for the server to 16MB, add the following lines in an option file:

```
[mysqld]
max_allowed_packet=16M
```

It is safe to increase the value of this variable because the extra memory is allocated only when needed. For example, `mysqld` allocates more memory only when you issue a long query or when `mysqld` must return a large result row. The small default value of the variable is a precaution to catch incorrect packets between the client and server and also to ensure that you do not run out of memory by using large packets accidentally.

You can also get strange problems with large packets if you are using large `BLOB` values but have not given `mysqld` access to enough memory to handle the query. If you suspect this is the case, try adding `ulimit -d 256000` to the beginning of the `mysqld_safe` script and restarting `mysqld`.

### B.3.2.10 Communication Errors and Aborted Connections

If connection problems occur such as communication errors or aborted connections, use these sources of information to diagnose problems:

- The error log. See Section 5.4.2, “The Error Log”.
- The general query log. See Section 5.4.3, “The General Query Log”.
- The `Aborted_xxx` and `Connection_errors_xxx` status variables. See Section 5.1.9, “Server Status Variables”.
- The host cache, which is accessible using the Performance Schema `host_cache` table. See Section 5.1.11.2, “DNS Lookups and the Host Cache”, and Section 22.12.10.1, “The host_cache Table”.

If you start the server with the `--log-warnings` option, you might find messages like this in your error log:

```
Aborted connection 854 to db: 'employees' user: 'josh'
```

If a client is unable even to connect, the server increments the `Aborted_connects` status variable. Unsuccessful connection attempts can occur for the following reasons:
Common Errors When Using MySQL Programs

- A client attempts to access a database but has no privileges for it.
- A client uses an incorrect password.
- A connection packet does not contain the right information.
- It takes more than `connect_timeout` seconds to obtain a connect packet. See Section 5.1.7, “Server System Variables”.

If these kinds of things happen, it might indicate that someone is trying to break into your server! If the general query log is enabled, messages for these types of problems are logged to it.

If a client successfully connects but later disconnects improperly or is terminated, the server increments the `Aborted_clients` status variable, and logs an Aborted connection message to the error log. The cause can be any of the following:

- The client program did not call `mysql_close()` before exiting.
- The client had been sleeping more than `wait_timeout` or `interactive_timeout` seconds without issuing any requests to the server. See Section 5.1.7, “Server System Variables”.
- The client program ended abruptly in the middle of a data transfer.

Other reasons for problems with aborted connections or aborted clients:

- The `max_allowed_packet` variable value is too small or queries require more memory than you have allocated for `mysqld`. See Section B.3.2.9, “Packet Too Large”.
- Use of Ethernet protocol with Linux, both half and full duplex. Some Linux Ethernet drivers have this bug. You should test for this bug by transferring a huge file using FTP between the client and server machines. If a transfer goes in burst-pause-burst-pause mode, you are experiencing a Linux duplex syndrome. Switch the duplex mode for both your network card and hub/switch to either full duplex or to half duplex and test the results to determine the best setting.
- A problem with the thread library that causes interrupts on reads.
- Badly configured TCP/IP.
- Faulty Ethernets, hubs, switches, cables, and so forth. This can be diagnosed properly only by replacing hardware.

See also Section B.3.2.8, “MySQL server has gone away”.

**B.3.2.11 The table is full**

If a table-full error occurs, it may be that the disk is full or that the table has reached its maximum size. The effective maximum table size for MySQL databases is usually determined by operating system constraints on file sizes, not by MySQL internal limits. See Section 8.4.6, “Limits on Table Size”.

**B.3.2.12 Can't create/write to file**

If you get an error of the following type for some queries, it means that MySQL cannot create a temporary file for the result set in the temporary directory:

```
Can't create/write to file '\sqla3fe_0.ism'.
```

The preceding error is a typical message for Windows; the Unix message is similar.

One fix is to start `mysqld` with the `--tmpdir` option or to add the option to the `[mysqld]` section of your option file. For example, to specify a directory of `C:\temp`, use these lines:
Common Errors When Using MySQL Programs

[mysqld]
tmpdir=C:/temp

The C:\temp directory must exist and have sufficient space for the MySQL server to write to. See Section 4.2.2.2, “Using Option Files”.

Another cause of this error can be permissions issues. Make sure that the MySQL server can write to the tmpdir directory.

Check also the error code that you get with perror. One reason the server cannot write to a table is that the file system is full:

```bash
$> perror 28
OS error code 28: No space left on device
```

If you get an error of the following type during startup, it indicates that the file system or directory used for storing data files is write protected. Provided that the write error is to a test file, the error is not serious and can be safely ignored.

Can't create test file /usr/local/mysql/data/master.lower-test

B.3.2.13 Commands out of sync

If you get Commands out of sync; you can't run this command now in your client code, you are calling client functions in the wrong order.

This can happen, for example, if you are using mysql_use_result() and try to execute a new query before you have called mysql_free_result(). It can also happen if you try to execute two queries that return data without calling mysql_use_result() or mysql_store_result() in between.

B.3.2.14 Ignoring user

If you get the following error, it means that when mysqld was started or when it reloaded the grant tables, it found an account in the user table that had an invalid password.

```
Found wrong password for user 'some_user '@'some_host'; ignoring user
```

As a result, the account is simply ignored by the permission system.

The following list indicates possible causes of and fixes for this problem:

- You may be running a new version of mysqld with an old user table. Check whether the Password column of that table is shorter than 16 characters. If so, correct this condition by running mysql_upgrade.

- The account has an old password (eight characters long). Update the account in the user table to have a new password.

- You have specified a password in the user table without using the PASSWORD() function. Use mysql to update the account in the user table with a new password, making sure to use the PASSWORD() function:

```sql
mysql> UPDATE user SET Password=PASSWORD('new_password')
    -> WHERE User='some_user' AND Host='some_host';
```

B.3.2.15 Table 'tbl_name' doesn’t exist

If you get either of the following errors, it usually means that no table exists in the default database with the given name:
In some cases, it may be that the table does exist but that you are referring to it incorrectly:

- Because MySQL uses directories and files to store databases and tables, database and table names are case-sensitive if they are located on a file system that has case-sensitive file names.

- Even for file systems that are not case-sensitive, such as on Windows, all references to a given table within a query must use the same lettercase.

You can check which tables are in the default database with `SHOW TABLES`. See Section 13.7.5, “SHOW Statements”.

**B.3.2.16 Can’t initialize character set**

You might see an error like this if you have character set problems:

MySQL Connection Failed: Can't initialize character set `charset_name`

This error can have any of the following causes:

- The character set is a multibyte character set and you have no support for the character set in the client. In this case, you need to recompile the client by running CMake with the `-DDEFAULT_CHARSET=charset_name` or `-DWITH_EXTRA_CHARSETS=charset_name` option. See Section 2.9.7, “MySQL Source-Configuration Options”.

All standard MySQL binaries are compiled with `-DWITH_EXTRA_CHARSETS=complex`, which enables support for all multibyte character sets. See Section 2.9.7, “MySQL Source-Configuration Options”.

- The character set is a simple character set that is not compiled into `mysqld`, and the character set definition files are not in the place where the client expects to find them.

In this case, you need to use one of the following methods to solve the problem:

- Recompile the client with support for the character set. See Section 2.9.7, “MySQL Source-Configuration Options”.

- Specify to the client the directory where the character set definition files are located. For many clients, you can do this with the `--character-sets-dir` option.

- Copy the character definition files to the path where the client expects them to be.

**B.3.2.17 File Not Found and Similar Errors**

If you get `ERROR 'file_name' not found` (errno: 23), `Can't open file: file_name` (errno: 24), or any other error with `errno 23` or `errno 24` from MySQL, it means that you have not allocated enough file descriptors for the MySQL server. You can use the `perror` utility to get a description of what the error number means:

```
$> perror 23
OS error code 23: File table overflow
$> perror 24
OS error code 24: Too many open files
$> perror 11
OS error code 11: Resource temporarily unavailable
```

The problem here is that `mysqld` is trying to keep open too many files simultaneously. You can either tell `mysqld` not to open so many files at once or increase the number of file descriptors available to `mysqld`.
To tell `mysqld` to keep open fewer files at a time, you can make the table cache smaller by reducing the value of the `table_open_cache` system variable (the default value is 64). This may not entirely prevent running out of file descriptors because in some circumstances the server may attempt to extend the cache size temporarily, as described in Section 8.4.3.1, “How MySQL Opens and Closes Tables”. Reducing the value of `max_connections` also reduces the number of open files (the default value is 100).

To change the number of file descriptors available to `mysqld`, you can use the `--open-files-limit` option to `mysqld_safe` or set the `open_files_limit` system variable. See Section 5.1.7, “Server System Variables”. The easiest way to set these values is to add an option to your option file. See Section 4.2.2.2, “Using Option Files”. If you have an old version of `mysqld` that does not support setting the open files limit, you can edit the `mysqld_safe` script. There is a commented-out line `ulimit -n 256` in the script. You can remove the `#` character to uncomment this line, and change the number 256 to set the number of file descriptors to be made available to `mysqld`.

`--open-files-limit` and `ulimit` can increase the number of file descriptors, but only up to the limit imposed by the operating system. There is also a “hard” limit that can be overridden only if you start `mysqld_safe` or `mysqld` as `root` (just remember that you also need to start the server with the `--user` option in this case so that it does not continue to run as `root` after it starts up). If you need to increase the operating system limit on the number of file descriptors available to each process, consult the documentation for your system.

---

**Note**

If you run the `tcsh` shell, `ulimit` does not work! `tcsh` also reports incorrect values when you ask for the current limits. In this case, you should start `mysqld_safe` using `sh`.

---

**B.3.2.18 Table-Corruption Issues**

If you have started `mysqld` with the `myisam_recover_options` system variable set, MySQL automatically checks and tries to repair MyISAM tables if they are marked as 'not closed properly' or 'crashed'. If this happens, MySQL writes an entry in the `hostname.err` file 'Warning: Checking table ...' which is followed by 'Warning: Repairing table' if the table needs to be repaired. If you get a lot of these errors, without `mysqld` having died unexpectedly just before, then something is wrong and needs to be investigated further.

When the server detects MyISAM table corruption, it writes additional information to the error log, such as the name and line number of the source file, and the list of threads accessing the table. Example: `Got an error from thread_id=1, mi_dynrec.c:368`. This is useful information to include in bug reports.

See also Section 5.1.6, “Server Command Options”, and Section 5.8.1.7, “Making a Test Case If You Experience Table Corruption”.

---

**B.3.3 Administration-Related Issues**

**B.3.3.1 Problems with File Permissions**

If you have problems with file permissions, the `UMASK` or `UMASK_DIR` environment variable might be set incorrectly when `mysqld` starts. For example, `mysqld` might issue the following error message when you create a table:

```
ERROR: Can't find file: 'path/with/filename.frm' (Errcode: 13)
```

The default `UMASK` and `UMASK_DIR` values are 0660 and 0700, respectively. `mysqld` assumes that the value for `UMASK` or `UMASK_DIR` is in octal if it starts with a zero. For example, setting `UMASK=0600` is equivalent to `UMASK=384` because 0600 octal is 384 decimal.
Assuming that you start `mysqld` using `mysqld_safe`, change the default `UMASK` value as follows:

```
UMASK=384  # = 600 in octal
export UMASK
mysqld_safe &
```

Note

An exception applies for the error log file if you start `mysqld` using `mysqld_safe`, which does not respect `UMASK`. `mysqld_safe` may create the error log file if it does not exist prior to starting `mysqld`, and `mysqld_safe` uses a umask set to a strict value of 0137. If this is unsuitable, create the error file manually with the desired access mode prior to executing `mysqld_safe`.

By default, `mysqld` creates database directories with an access permission value of 0700. To modify this behavior, set the `UMASK_DIR` variable. If you set its value, new directories are created with the combined `UMASK` and `UMASK_DIR` values. For example, to give group access to all new directories, start `mysqld_safe` as follows:

```
UMASK_DIR=504  # = 770 in octal
export UMASK_DIR
mysqld_safe &
```

For additional details, see Section 4.9, “Environment Variables”.

### B.3.3.2 How to Reset the Root Password

If you have never assigned a root password for MySQL, the server does not require a password at all for connecting as root. However, this is insecure. For instructions on assigning passwords, see Section 2.10.4, “Securing the Initial MySQL Accounts”.

If you know the root password and want to change it, see Section 13.7.1.7, “SET PASSWORD Statement”.

If you assigned a root password previously but have forgotten it, you can assign a new password. The following sections provide instructions for Windows and Unix and Unix-like systems, as well as generic instructions that apply to any system.

#### Resetting the Root Password: Windows Systems

On Windows, use the following procedure to reset the password for the MySQL `root`@`localhost` account. To change the password for a root account with a different host name part, modify the instructions to use that host name.

1. Log on to your system as Administrator.
2. Stop the MySQL server if it is running. For a server that is running as a Windows service, go to the Services manager: From the Start menu, select Control Panel, then Administrative Tools, then Services. Find the MySQL service in the list and stop it.
   
   If your server is not running as a service, you may need to use the Task Manager to force it to stop.
3. Create a text file containing the following statement on a single line. Replace the password with the password that you want to use.

   ```
   SET PASSWORD FOR 'root'@'localhost' = PASSWORD('MyNewPass');
   ```
4. Save the file. This example assumes that you name the file `C:\mysql-init.txt`.

5. Open a console window to get to the command prompt: From the Start menu, select Run, then enter `cmd` as the command to be run.

6. Start the MySQL server with the `init_file` system variable set to name the file (notice that the backslash in the option value is doubled):

   ```
   C:\> cd "C:\Program Files\MySQL\MySQL Server 5.6\bin"
   C:\> mysqld --init-file=C:\mysql-init.txt
   ```

   If you installed MySQL to a different location, adjust the `cd` command accordingly.

   The server executes the contents of the file named by the `init_file` system variable at startup, changing the 'root'@'localhost' account password.

   To have server output to appear in the console window rather than in a log file, add the `--console` option to the `mysqld` command.

   If you installed MySQL using the MySQL Installation Wizard, you may need to specify a `--defaults-file` option. For example:

   ```
   C:\> mysqld
   --defaults-file="C:\ProgramData\MySQL\MySQL Server 5.6\my.ini"
   --init-file=C:\\mysql-init.txt
   ```

   The appropriate `--defaults-file` setting can be found using the Services Manager: From the Start menu, select Control Panel, then Administrative Tools, then Services. Find the MySQL service in the list, right-click it, and choose the Properties option. The Path to executable field contains the `--defaults-file` setting.

7. After the server has started successfully, delete `C:\mysql-init.txt`.

   You should now be able to connect to the MySQL server as root using the new password. Stop the MySQL server and restart it normally. If you run the server as a service, start it from the Windows Services window. If you start the server manually, use whatever command you normally use.

### Resetting the Root Password: Unix and Unix-Like Systems

On Unix, use the following procedure to reset the password for the MySQL 'root'@'localhost' account. To change the password for a root account with a different host name part, modify the instructions to use that host name.

The instructions assume that you start the MySQL server from the Unix login account that you normally use for running it. For example, if you run the server using the `mysql` login account, you should log in as `mysql` before using the instructions. Alternatively, you can log in as `root`, but in this case you must start `mysqld` with the `--user=mysql` option. If you start the server as root without using `--user=mysql`, the server may create root-owned files in the data directory, such as log files, and these may cause permission-related problems for future server startups. If that happens, you must either change the ownership of the files to `mysql` or remove them.

1. Log on to your system as the Unix user that the MySQL server runs as (for example, `mysql`).

2. Stop the MySQL server if it is running. Locate the `.pid` file that contains the server's process ID. The exact location and name of this file depend on your distribution, host name, and configuration. Common locations are `/var/lib/mysql/`, `/var/run/mysqld/`, and `/usr/local/mysql/data/`. Generally, the file name has an extension of `.pid` and begins with either `mysqld` or your system's host name.
Stop the MySQL server by sending a normal `kill` (not `kill -9`) to the `mysqld` process. Use the actual path name of the `.pid` file in the following command:

```
$> kill `cat /mysql-data-directory/host_name.pid`
```

Use backticks (not forward quotation marks) with the `cat` command. These cause the output of `cat` to be substituted into the `kill` command.

3. Create a text file containing the following statement on a single line. Replace the password with the password that you want to use.

```
SET PASSWORD FOR 'root'@'localhost' = PASSWORD('MyNewPass');
```

4. Save the file. This example assumes that you name the file `/home/me/mysql-init`. The file contains the password, so do not save it where it can be read by other users. If you are not logged in as `mysql` (the user the server runs as), make sure that the file has permissions that permit `mysql` to read it.

5. Start the MySQL server with the `init_file` system variable set to name the file:

```
$> mysqld --init-file=/home/me/mysql-init &
```

The server executes the contents of the file named by the `init_file` system variable at startup, changing the `root'@'localhost` account password.

Other options may be necessary as well, depending on how you normally start your server. For example, `--defaults-file` may be needed before the `init_file` argument.

6. After the server has started successfully, delete `/home/me/mysql-init`.

You should now be able to connect to the MySQL server as `root` using the new password. Stop the server and restart it normally.

**Resetting the Root Password: Generic Instructions**

The preceding sections provide password-resetting instructions specifically for Windows and Unix and Unix-like systems. Alternatively, on any platform, you can reset the password using the `mysql` client (but this approach is less secure):

1. Stop the MySQL server if necessary, then restart it with the `--skip-grant-tables` option. This enables anyone to connect without a password and with all privileges, and disables account-management statements such as `SET PASSWORD`. Because this is insecure, you might want to use `--skip-grant-tables` in conjunction with enabling the `skip_networking` system variable to prevent remote clients from connecting.

2. Connect to the MySQL server using the `mysql` client; no password is necessary because the server was started with `--skip-grant-tables`:

```
$> mysql
```

3. In the `mysql` client, tell the server to reload the grant tables so that account-management statements work:

```
mysql> FLUSH PRIVILEGES;
```

Then change the `root'@'localhost` account password. Replace the password with the password that you want to use. To change the password for a `root` account with a different host name part, modify the instructions to use that host name.
mysql> SET PASSWORD FOR 'root'@'localhost' = PASSWORD('MyNewPass');

You should now be able to connect to the MySQL server as root using the new password. Stop the server and restart it normally (without the --skip-grant-tables option and without enabling the skip_networking system variable).

B.3.3.3 What to Do If MySQL Keeps Crashing

Each MySQL version is tested on many platforms before it is released. This does not mean that there are no bugs in MySQL, but if there are bugs, they should be very few and can be hard to find. If you have a problem, it always helps if you try to find out exactly what crashes your system, because you have a much better chance of getting the problem fixed quickly.

First, you should try to find out whether the problem is that the mysqld server dies or whether your problem has to do with your client. You can check how long your mysqld server has been up by executing mysqladmin version. If mysqld has died and restarted, you may find the reason by looking in the server's error log. See Section 5.4.2, “The Error Log”.

On some systems, you can find in the error log a stack trace of where mysqld died that you can resolve with the resolve_stack_dump program. See Section 5.8, “Debugging MySQL”. Note that the variable values written in the error log may not always be 100% correct.

Many unexpected server exits are caused by corrupted data files or index files. MySQL updates the files on disk with the write() system call after every SQL statement and before the client is notified about the result. (This is not true if you are running with the delay_key_write system variable enabled, in which case data files are written but not index files.) This means that data file contents are safe even if mysqld crashes, because the operating system ensures that the unflushed data is written to disk. You can force MySQL to flush everything to disk after every SQL statement by starting mysqld with the --flush option.

The preceding means that normally you should not get corrupted tables unless one of the following happens:

- The MySQL server or the server host was killed in the middle of an update.
- You have found a bug in mysqld that caused it to die in the middle of an update.
- Some external program is manipulating data files or index files at the same time as mysqld without locking the table properly.
- You are running many mysqld servers using the same data directory on a system that does not support good file system locks (normally handled by the lockd lock manager), or you are running multiple servers with external locking disabled.
- You have a crashed data file or index file that contains very corrupt data that confused mysqld.
- You have found a bug in the data storage code. This isn't likely, but it is at least possible. In this case, you can try to change the storage engine to another engine by using ALTER TABLE on a repaired copy of the table.

Because it is very difficult to know why something is crashing, first try to check whether things that work for others result in an unexpected exit for you. Try the following things:

- Stop the mysqld server with mysqladmin shutdown, run myisamchk --silent --force */*.MYI from the data directory to check all MyISAM tables, and restart mysqld. This ensures that you are running from a clean state. See Chapter 5, MySQL Server Administration.
• Start mysql with the general query log enabled (see Section 5.4.3, “The General Query Log”). Then try to determine from the information written to the log whether some specific query kills the server. About 95% of all bugs are related to a particular query. Normally, this is one of the last queries in the log file just before the server restarts. See Section 5.4.3, “The General Query Log”. If you can repeatedly kill MySQL with a specific query, even when you have checked all tables just before issuing it, then you have isolated the bug and should submit a bug report for it. See Section 1.6, “How to Report Bugs or Problems”.

• Try to make a test case that we can use to repeat the problem. See Section 5.8, “Debugging MySQL”.

• Try the fork_big.pl script. (It is located in the tests directory of source distributions.)

• Configuring MySQL for debugging makes it much easier to gather information about possible errors if something goes wrong. Reconfigure MySQL with the -DWITH_DEBUG=1 option to CMake and then recompile. See Section 5.8, “Debugging MySQL”.

• Make sure that you have applied the latest patches for your operating system.

• Use the --skip-external-locking option to mysql. On some systems, the lockd lock manager does not work properly; the --skip-external-locking option tells mysql not to use external locking. (This means that you cannot run two mysql servers on the same data directory and that you must be careful if you use myisamchk. Nevertheless, it may be instructive to try the option as a test.)

• If mysql appears to be running but not responding, try mysqladmin -u root processlist. Sometimes mysql is not hung even though it seems unresponsive. The problem may be that all connections are in use, or there may be some internal lock problem. mysqladmin -u root processlist usually is able to make a connection even in these cases, and can provide useful information about the current number of connections and their status.

• Run the command mysqladmin -i 5 status or mysqladmin -i 5 -r status in a separate window to produce statistics while running other queries.

• Try the following:
  1. Start mysql from gdb (or another debugger). See Section 5.8, “Debugging MySQL”.
  2. Run your test scripts.
  3. Print the backtrace and the local variables at the three lowest levels. In gdb, you can do this with the following commands when mysql has crashed inside gdb:

```
backtrace
info local
up
info local
up
info local
```

With gdb, you can also examine which threads exist with info threads and switch to a specific thread with thread N, where N is the thread ID.

• Try to simulate your application with a Perl script to force MySQL to exit or misbehave.

• Send a normal bug report. See Section 1.6, “How to Report Bugs or Problems”. Be even more detailed than usual. Because MySQL works for many people, the crash might result from something that exists only on your computer (for example, an error that is related to your particular system libraries).

• If you have a problem with tables containing dynamic-length rows and you are using only VARCHAR columns (not BLOB or TEXT columns), you can try to change all VARCHAR to CHAR with ALTER TABLE.
This forces MySQL to use fixed-size rows. Fixed-size rows take a little extra space, but are much more tolerant to corruption.

The current dynamic row code has been in use for several years with very few problems, but dynamic-length rows are by nature more prone to errors, so it may be a good idea to try this strategy to see whether it helps.

- Consider the possibility of hardware faults when diagnosing problems. Defective hardware can be the cause of data corruption. Pay particular attention to your memory and disk subsystems when troubleshooting hardware.

### B.3.3.4 How MySQL Handles a Full Disk

This section describes how MySQL responds to disk-full errors (such as “no space left on device”), and to quota-exceeded errors (such as “write failed” or “user block limit reached”).

This section is relevant for writes to MyISAM tables. It also applies for writes to binary log files and binary log index file, except that references to “row” and “record” should be understood to mean “event.”

When a disk-full condition occurs, MySQL does the following:

- It checks once every minute to see whether there is enough space to write the current row. If there is enough space, it continues as if nothing had happened.
- Every 10 minutes it writes an entry to the log file, warning about the disk-full condition.

To alleviate the problem, take the following actions:

- To continue, you only have to free enough disk space to insert all records.
- Alternatively, to abort the thread, use `mysqladmin kill`. The thread is aborted the next time it checks the disk (in one minute).
- Other threads might be waiting for the table that caused the disk-full condition. If you have several “locked” threads, killing the one thread that is waiting on the disk-full condition enables the other threads to continue.

Exceptions to the preceding behavior are when you use `REPAIR TABLE` or `OPTIMIZE TABLE` or when the indexes are created in a batch after `LOAD DATA` or after an `ALTER TABLE` statement. All of these statements may create large temporary files that, if left to themselves, would cause big problems for the rest of the system. If the disk becomes full while MySQL is doing any of these operations, it removes the big temporary files and mark the table as crashed. The exception is that for `ALTER TABLE`, the old table is left unchanged.

### B.3.3.5 Where MySQL Stores Temporary Files

On Unix, MySQL uses the value of the `TMPDIR` environment variable as the path name of the directory in which to store temporary files. If `TMPDIR` is not set, MySQL uses the system default, which is usually `/tmp`, `/var/tmp`, or `/usr/tmp`.

On Windows, MySQL checks in order the values of the `TMPDIR`, `TEMP`, and `TMP` environment variables. For the first one found to be set, MySQL uses it and does not check those remaining. If none of `TMPDIR`, `TEMP`, or `TMP` are set, MySQL uses the Windows system default, which is usually `C:\windows\temp`.

If the file system containing your temporary file directory is too small, you can use the `mysqld --tmpdir` option to specify a directory in a file system where you have enough space.
The `--tmpdir` option can be set to a list of several paths that are used in round-robin fashion. Paths should be separated by colon characters (:) on Unix and semicolon characters (;) on Windows.

**Note**

To spread the load effectively, these paths should be located on different physical disks, not different partitions of the same disk.

If the MySQL server is acting as a replica, you can set the `slave_load_tmpdir` system variable to specify a separate directory for holding temporary files when replicating `LOAD DATA` statements. This directory should be in a disk-based file system (not a memory-based file system) so that the temporary files used to replicate `LOAD DATA` can survive machine restarts. The directory also should not be one that is cleared by the operating system during the system startup process. However, replication can now continue after a restart if the temporary files have been removed.

MySQL arranges that temporary files are removed if `mysqld` is terminated. On platforms that support it (such as Unix), this is done by unlinking the file after opening it. The disadvantage of this is that the name does not appear in directory listings and you do not see a big temporary file that fills up the file system in which the temporary file directory is located. (In such cases, `ls -l` may be helpful in identifying large files associated with `mysqld`.)

When sorting (`ORDER BY` or `GROUP BY`), MySQL normally uses one or two temporary files. The maximum disk space required is determined by the following expression:

```
(length of what is sorted + sizeof(row pointer))
  * number of matched rows
  * 2
```

The row pointer size is usually four bytes, but may grow in the future for really big tables.

For some statements, MySQL creates temporary SQL tables that are not hidden and have names that begin with `#sql`.

Some `SELECT` queries creates temporary SQL tables to hold intermediate results.

DDL operations that rebuild the table and are not performed online using the `ALGORITHM=INPLACE` technique create a temporary copy of the original table in the same directory as the original table.

Online DDL operations may use temporary log files for recording concurrent DML, temporary sort files when creating an index, and temporary intermediate tables files when rebuilding the table. For more information, see Section 14.13.3, “Online DDL Space Requirements”.

See also Orphan Temporary Tables.

### B.3.3.6 How to Protect or Change the MySQL Unix Socket File

The default location for the Unix socket file that the server uses for communication with local clients is `/tmp/mysql.sock`. (For some distribution formats, the directory might be different, such as `/var/lib/mysql` for RPMs.)

On some versions of Unix, anyone can delete files in the `/tmp` directory or other similar directories used for temporary files. If the socket file is located in such a directory on your system, this might cause problems.

On most versions of Unix, you can protect your `/tmp` directory so that files can be deleted only by their owners or the superuser (`root`). To do this, set the `sticky` bit on the `/tmp` directory by logging in as `root` and using the following command:

```
$> chmod +t /tmp
```
You can check whether the `sticky` bit is set by executing `ls -ld /tmp`. If the last permission character is `t`, the bit is set.

Another approach is to change the place where the server creates the Unix socket file. If you do this, you should also let client programs know the new location of the file. You can specify the file location in several ways:

- Specify the path in a global or local option file. For example, put the following lines in `/etc/my.cnf`:

  ```
  [mysqld]
  socket=/path/to/socket
  
  [client]
  socket=/path/to/socket
  ```

  See Section 4.2.2.2, “Using Option Files”.

- Specify a `--socket` option on the command line to `mysqld_safe` and when you run client programs.

- Set the `MYSQL_UNIX_PORT` environment variable to the path of the Unix socket file.

- Recompile MySQL from source to use a different default Unix socket file location. Define the path to the file with the `MYSQL_UNIX_ADDR` option when you run `CMake`. See Section 2.9.7, “MySQL Source-Configuration Options”.

You can test whether the new socket location works by attempting to connect to the server with this command:

```
$> mysqladmin --socket=/path/to/socket version
```
Query-Related Issues

%", you get all column values that start with A or a. To make this search case-sensitive, make sure that one of the operands has a case-sensitive or binary collation. For example, if you are comparing a column and a string that both have the latin1 character set, you can use the COLLATE operator to cause either operand to have the latin1_general_cs or latin1_bin collation:

```sql
col_name COLLATE latin1_general_cs LIKE 'a%'
col_name LIKE 'a%' COLLATE latin1_general_cs
col_name COLLATE latin1_bin LIKE 'a'
col_name LIKE 'a%' COLLATE latin1_bin
```

If you want a column always to be treated in case-sensitive fashion, declare it with a case-sensitive or binary collation. See Section 13.1.17, “CREATE TABLE Statement”.

To cause a case-sensitive comparison of nonbinary strings to be case-insensitive, use COLLATE to name a case-insensitive collation. The strings in the following example normally are case-sensitive, but COLLATE changes the comparison to be case-insensitive:

```sql
mysql> SET @s1 = 'MySQL' COLLATE latin1_bin,
-> @s2 = 'mysql' COLLATE latin1_bin;

mysql> SELECT @s1 = @s2;
+-----------+
| @s1 = @s2 |
+-----------+
|         0  |
+-----------+

mysql> SELECT @s1 COLLATE latin1_swedish_ci = @s2;
+-------------------------------------+
| @s1 COLLATE latin1_swedish_ci = @s2 |
+-------------------------------------+
|                                   1 |
+-------------------------------------+
```

A binary string is case-sensitive in comparisons. To compare the string as case-insensitive, convert it to a nonbinary string and use COLLATE to name a case-insensitive collation:

```sql
mysql> SET @s = BINARY 'MySQL';
mysql> SELECT @s = 'mysql';
+--------------+
| @s = 'mysql' |
+--------------+
|            0 |
+--------------+

mysql> SELECT CONVERT(@s USING latin1) COLLATE latin1_swedish_ci = 'mysql';
+--------------------------------------------------------------+
| CONVERT(@s USING latin1) COLLATE latin1_swedish_ci = 'mysql' |
+--------------------------------------------------------------+
|                                                            1 |
+--------------------------------------------------------------+
```

To determine whether a value compares as a nonbinary or binary string, use the COLLATION() function. This example shows that VERSION() returns a string that has a case-insensitive collation, so comparisons are case-insensitive:

```sql
mysql> SELECT COLLATION(VERSION());
+----------------------+
| COLLATION(VERSION()) |
| utf8_general_ci      |
+----------------------+
```

For binary strings, the collation value is binary, so comparisons are case-sensitive. One context in which you may see binary is for compression functions, which return binary strings as a general rule: string:

```sql
mysql> SELECT COLLATION(COMPRESS('x'));
```
To check the sort value of a string, the `WEIGHT_STRING()` may be helpful. See Section 12.8, "String Functions and Operators".

### B.3.4.2 Problems Using DATE Columns

The format of a `DATE` value is `YYYY-MM-DD`. According to standard SQL, no other format is permitted. You should use this format in `UPDATE` expressions and in the `WHERE` clause of `SELECT` statements. For example:

```
SELECT * FROM t1 WHERE date >= '2003-05-05';
```

As a convenience, MySQL automatically converts a date to a number if the date is used in numeric context and vice versa. MySQL also permits a “relaxed” string format when updating and in a `WHERE` clause that compares a date to a `DATE`, `DATETIME`, or `TIMESTAMP` column. "Relaxed" format means that any punctuation character may be used as the separator between parts. For example, `'2004-08-15'` and `'2004#08#15'` are equivalent. MySQL can also convert a string containing no separators (such as `'20040815'`), provided it makes sense as a date.

When you compare a `DATE`, `TIME`, `DATETIME`, or `TIMESTAMP` to a constant string with the `<`, `<=`, `=`, `>=`, `>`, or `BETWEEN` operators, MySQL normally converts the string to an internal long integer for faster comparison (and also for a bit more “relaxed” string checking). However, this conversion is subject to the following exceptions:

- When you compare two columns
- When you compare a `DATE`, `TIME`, `DATETIME`, or `TIMESTAMP` column to an expression
- When you use any comparison method other than those just listed, such as `IN` or `STRCMP()`.

For those exceptions, the comparison is done by converting the objects to strings and performing a string comparison.

To be on the safe side, assume that strings are compared as strings and use the appropriate string functions if you want to compare a temporal value to a string.

The special "zero" date `'0000-00-00'` can be stored and retrieved as `'0000-00-00'`. When a `'0000-00-00'` date is used through Connector/ODBC, it is automatically converted to `NULL` because ODBC cannot handle that kind of date.

Because MySQL performs the conversions just described, the following statements work (assume that `idate` is a `DATE` column):

```
INSERT INTO t1 (idate) VALUES (19970505);
INSERT INTO t1 (idate) VALUES ('19970505');
INSERT INTO t1 (idate) VALUES ('97-05-05');
INSERT INTO t1 (idate) VALUES ('1997.05.05');
INSERT INTO t1 (idate) VALUES ('1997 05 05');
INSERT INTO t1 (idate) VALUES ('0000-00-00');

SELECT idate FROM t1 WHERE idate >= '1997-05-05';
SELECT idate FROM t1 WHERE idate >= 19970505;
SELECT MOD(idate,100) FROM t1 WHERE idate >= 19970505;
SELECT idate FROM t1 WHERE idate >= '19970505';
```

However, the following statement does not work:
SELECT idate FROM t1 WHERE STRCMP(idate,'20030505')=0;

`STRCMP()` is a string function, so it converts `idate` to a string in `'YYYY-MM-DD'` format and performs a string comparison. It does not convert `'20030505'` to the date `'2003-05-05'` and perform a date comparison.

If you enable the `ALLOW_INVALID_DATES` SQL mode, MySQL permits you to store dates that are given only limited checking: MySQL requires only that the day is in the range from 1 to 31 and the month is in the range from 1 to 12. This makes MySQL very convenient for Web applications where you obtain year, month, and day in three different fields and you want to store exactly what the user inserted (without date validation).

MySQL permits you to store dates where the day or month and day are zero. This is convenient if you want to store a birthdate in a `DATE` column and you know only part of the date. To disallow zero month or day parts in dates, enable the `NO_ZERO_IN_DATE` SQL mode.

MySQL permits you to store a “zero” value of `'0000-00-00'` as a “dummy date.” This is in some cases more convenient than using `NULL` values. If a date to be stored in a `DATE` column cannot be converted to any reasonable value, MySQL stores `'0000-00-00'`. To disallow `'0000-00-00'`, enable the `NO_ZERO_DATE` SQL mode.

To have MySQL check all dates and accept only legal dates (unless overridden by `IGNORE`), set the `sql_mode` system variable to "NO_ZERO_IN_DATE,NO_ZERO_DATE".

### B.3.4.3 Problems with NULL Values

The concept of the `NULL` value is a common source of confusion for newcomers to SQL, who often think that `NULL` is the same thing as an empty string `''`. This is not the case. For example, the following statements are completely different:

```sql
mysql> INSERT INTO my_table (phone) VALUES (NULL);
mysql> INSERT INTO my_table (phone) VALUES ('');
```

Both statements insert a value into the `phone` column, but the first inserts a `NULL` value and the second inserts an empty string. The meaning of the first can be regarded as “phone number is not known” and the meaning of the second can be regarded as “the person is known to have no phone, and thus no phone number.”

To help with `NULL` handling, you can use the `IS NULL` and `IS NOT NULL` operators and the `IFNULL()` function.

In SQL, the `NULL` value is never true in comparison to any other value, even `NULL`. An expression that contains `NULL` always produces a `NULL` value unless otherwise indicated in the documentation for the operators and functions involved in the expression. All columns in the following example return `NULL`:

```sql
mysql> SELECT NULL, 1+NULL, CONCAT('Invisible',NULL);
```

To search for column values that are `NULL`, you cannot use an `expr = NULL` test. The following statement returns no rows, because `expr = NULL` is never true for any expression:

```sql
mysql> SELECT * FROM my_table WHERE phone = NULL;
```

To look for `NULL` values, you must use the `IS NULL` test. The following statements show how to find the `NULL` phone number and the empty phone number:

```sql
mysql> SELECT * FROM my_table WHERE phone IS NULL;
mysql> SELECT * FROM my_table WHERE phone = '';
```

See Section 3.3.4.6, “Working with NULL Values”, for additional information and examples.
Query-Related Issues

You can add an index on a column that can have NULL values if you are using the MyISAM, InnoDB, or MEMORY storage engine. Otherwise, you must declare an indexed column NOT NULL, and you cannot insert NULL into the column.

When reading data with LOAD DATA, empty or missing columns are updated with '' . To load a NULL value into a column, use \n in the data file. The literal word NULL may also be used under some circumstances. See Section 13.2.6, “LOAD DATA Statement”.

When using DISTINCT, GROUP BY, or ORDER BY, all NULL values are regarded as equal.

When using ORDER BY, NULL values are presented first, or last if you specify DESC to sort in descending order.

Aggregate (group) functions such as COUNT(), MIN(), and SUM() ignore NULL values. The exception to this is COUNT(*), which counts rows and not individual column values. For example, the following statement produces two counts. The first is a count of the number of rows in the table, and the second is a count of the number of non-NULL values in the age column:

```sql
mysql> SELECT COUNT(*), COUNT(age) FROM person;
```

For some data types, MySQL handles NULL values specially. If you insert NULL into a TIMESTAMP column, the current date and time is inserted. If you insert NULL into an integer or floating-point column that has the AUTO_INCREMENT attribute, the next number in the sequence is inserted.

B.3.4.4 Problems with Column Aliases

An alias can be used in a query select list to give a column a different name. You can use the alias in GROUP BY, ORDER BY, or HAVING clauses to refer to the column:

```sql
SELECT SQRT(a*b) AS root FROM tbl_name
GROUP BY root
HAVING root > 0;
SELECT id, COUNT(*) AS cnt FROM tbl_name
GROUP BY id
HAVING cnt > 0;
SELECT id AS 'Customer identity' FROM tbl_name;
```

Standard SQL disallows references to column aliases in a WHERE clause. This restriction is imposed because when the WHERE clause is evaluated, the column value may not yet have been determined. For example, the following query is illegal:

```sql
SELECT id, COUNT(*) AS cnt FROM tbl_name
WHERE cnt > 0 GROUP BY id;
```

The WHERE clause determines which rows should be included in the GROUP BY clause, but it refers to the alias of a column value that is not known until after the rows have been selected, and grouped by the GROUP BY.

In the select list of a query, a quoted column alias can be specified using identifier or string quoting characters:

```sql
SELECT 1 AS `one`, 2 AS 'two';
```

Elsewhere in the statement, quoted references to the alias must use identifier quoting or the reference is treated as a string literal. For example, this statement groups by the values in column id, referenced using the alias `a`:

```sql
SELECT id AS 'a', COUNT(*) AS cnt FROM tbl_name
GROUP BY `a`;
```

But this statement groups by the literal string 'a' and does not work as expected:
B.3.4.5 Rollback Failure for Nontransactional Tables

If you receive the following message when trying to perform a ROLLBACK, it means that one or more of the tables you used in the transaction do not support transactions:

```
Warning: Some non-transactional changed tables couldn't be rolled back
```

These nontransactional tables are not affected by the ROLLBACK statement.

If you were not deliberately mixing transactional and nontransactional tables within the transaction, the most likely cause for this message is that a table you thought was transactional actually is not. This can happen if you try to create a table using a transactional storage engine that is not supported by your mysqld server (or that was disabled with a startup option). If mysqld does not support a storage engine, it instead creates the table as a MyISAM table, which is nontransactional.

You can check the storage engine for a table by using either of these statements:

```
SHOW TABLE STATUS LIKE 'tbl_name';
SHOW CREATE TABLE tbl_name;
```

See Section 13.7.5.37, “SHOW TABLE STATUS Statement”, and Section 13.7.5.12, “SHOW CREATE TABLE Statement”.

To check which storage engines your mysqld server supports, use this statement:

```
SHOW ENGINES;
```

See Section 13.7.5.17, “SHOW ENGINES Statement” for full details.

B.3.4.6 Deleting Rows from Related Tables

If the total length of the DELETE statement for related_table is more than 1MB (the default value of the max_allowed_packet system variable), you should split it into smaller parts and execute multiple DELETE statements. You probably get the fastest DELETE by specifying only 100 to 1,000 related_column values per statement if the related_column is indexed. If the related_column isn't indexed, the speed is independent of the number of arguments in the IN clause.

B.3.4.7 Solving Problems with No Matching Rows

If you have a complicated query that uses many tables but that returns no rows, you should use the following procedure to find out what is wrong:

1. Test the query with EXPLAIN to check whether you can find something that is obviously wrong. See Section 13.8.2, “EXPLAIN Statement”.
2. Select only those columns that are used in the WHERE clause.
3. Remove one table at a time from the query until it returns some rows. If the tables are large, it is a good idea to use LIMIT 10 with the query.
4. Issue a SELECT for the column that should have matched a row against the table that was last removed from the query.
5. If you are comparing FLOAT or DOUBLE columns with numbers that have decimals, you cannot use equality (==) comparisons. This problem is common in most computer languages because not all floating-point values can be stored with exact precision. In some cases, changing the FLOAT to a DOUBLE fixes this. See Section B.3.4.8, “Problems with Floating-Point Values”. 3565
6. If you still cannot figure out what is wrong, create a minimal test that can be run with `mysql test < query.sql` that shows your problems. You can create a test file by dumping the tables with `mysqldump --quick db_name tbl_name_1 ... tbl_name_n > query.sql`. Open the file in an editor, remove some insert lines (if there are more than needed to demonstrate the problem), and add your `SELECT` statement at the end of the file.

Verify that the test file demonstrates the problem by executing these commands:

```bash
$> mysqladmin create test2
$> mysql test2 < query.sql
```

Attach the test file to a bug report, which you can file using the instructions in Section 1.6, “How to Report Bugs or Problems”.

### B.3.4.8 Problems with Floating-Point Values

Floating-point numbers sometimes cause confusion because they are approximate and not stored as exact values. A floating-point value as written in an SQL statement may not be the same as the value represented internally. Attempts to treat floating-point values as exact in comparisons may lead to problems. They are also subject to platform or implementation dependencies. The `FLOAT` and `DOUBLE` data types are subject to these issues. For `DECIMAL` columns, MySQL performs operations with a precision of 65 decimal digits, which should solve most common inaccuracy problems.

The following example uses `DOUBLE` to demonstrate how calculations that are done using floating-point operations are subject to floating-point error.

```sql
mysql> CREATE TABLE t1 (i INT, d1 DOUBLE, d2 DOUBLE);
mysql> INSERT INTO t1 VALUES (1, 101.40, 21.40), (1, -80.00, 0.00),
    -> (2, 0.00, 0.00), (2, -13.20, 0.00), (2, 59.60, 46.40),
    -> (2, 30.40, 30.40), (3, 37.00, 7.40), (3, -29.60, 0.00),
    -> (4, 60.00, 15.40), (4, -10.60, 0.00), (4, -34.00, 0.00),
    -> (5, 33.00, 0.00), (5, -25.80, 0.00), (5, 0.00, 7.20),
    -> (6, 0.00, 0.00), (6, -51.40, 0.00);
mysql> SELECT i, SUM(d1) AS a, SUM(d2) AS b
    -> FROM t1 GROUP BY i HAVING a <> b;
```

<table>
<thead>
<tr>
<th>i</th>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>21.4</td>
<td>21.4</td>
</tr>
<tr>
<td>2</td>
<td>76.8</td>
<td>76.8</td>
</tr>
<tr>
<td>3</td>
<td>7.4</td>
<td>7.4</td>
</tr>
<tr>
<td>4</td>
<td>15.4</td>
<td>15.4</td>
</tr>
<tr>
<td>5</td>
<td>7.2</td>
<td>7.2</td>
</tr>
<tr>
<td>6</td>
<td>-51.4</td>
<td>0</td>
</tr>
</tbody>
</table>

The result is correct. Although the first five records look like they should not satisfy the comparison (the values of `a` and `b` do not appear to be different), they may do so because the difference between the numbers shows up around the tenth decimal or so, depending on factors such as computer architecture or the compiler version or optimization level. For example, different CPUs may evaluate floating-point numbers differently.

If columns `d1` and `d2` had been defined as `DECIMAL` rather than `DOUBLE`, the result of the `SELECT` query would have contained only one row—the last one shown above.

The correct way to do floating-point number comparison is to first decide on an acceptable tolerance for differences between the numbers and then do the comparison against the tolerance value. For example, if we agree that floating-point numbers should be regarded the same if they are same within a precision of
one in ten thousand (0.0001), the comparison should be written to find differences larger than the tolerance value:

```sql
mysql> SELECT i, SUM(d1) AS a, SUM(d2) AS b FROM t1
       -> GROUP BY i HAVING ABS(a - b) > 0.0001;
```

<table>
<thead>
<tr>
<th>i</th>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>6</td>
<td>-51.4</td>
<td>0</td>
</tr>
</tbody>
</table>

1 row in set (0.00 sec)

Conversely, to get rows where the numbers are the same, the test should find differences within the tolerance value:

```sql
mysql> SELECT i, SUM(d1) AS a, SUM(d2) AS b FROM t1
       -> GROUP BY i HAVING ABS(a - b) <= 0.0001;
```

<table>
<thead>
<tr>
<th>i</th>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>21.4</td>
<td>21.4</td>
</tr>
<tr>
<td>2</td>
<td>76.8</td>
<td>76.8</td>
</tr>
<tr>
<td>3</td>
<td>7.4</td>
<td>7.4</td>
</tr>
<tr>
<td>4</td>
<td>15.4</td>
<td>15.4</td>
</tr>
<tr>
<td>5</td>
<td>7.2</td>
<td>7.2</td>
</tr>
</tbody>
</table>

5 rows in set (0.03 sec)

Floating-point values are subject to platform or implementation dependencies. Suppose that you execute the following statements:

```sql
CREATE TABLE t1(c1 FLOAT(53,0), c2 FLOAT(53,0));
INSERT INTO t1 VALUES('1e+52','-1e+52');
SELECT * FROM t1;
```

On some platforms, the `SELECT` statement returns `inf` and `-inf`. On others, it returns `0` and `-0`.

An implication of the preceding issues is that if you attempt to create a replica by dumping table contents with `mysqldump` on the source and reloading the dump file into the replica, tables containing floating-point columns might differ between the two hosts.

### B.3.5 Optimizer-Related Issues

MySQL uses a cost-based optimizer to determine the best way to resolve a query. In many cases, MySQL can calculate the best possible query plan, but sometimes MySQL does not have enough information about the data at hand and has to make “educated” guesses about the data.

For the cases when MySQL does not do the “right” thing, tools that you have available to help MySQL are:

- Use the `EXPLAIN` statement to get information about how MySQL processes a query. To use it, just add the keyword `EXPLAIN` to the front of your `SELECT` statement:
  ```sql
  mysql> EXPLAIN SELECT * FROM t1, t2 WHERE t1.i = t2.i;
  ```
  `EXPLAIN` is discussed in more detail in Section 13.8.2, “EXPLAIN Statement”.

- Use `ANALYZE TABLE tbl_name` to update the key distributions for the scanned table. See Section 13.7.2.1, “ANALYZE TABLE Statement”.

- Use `FORCE INDEX` for the scanned table to tell MySQL that table scans are very expensive compared to using the given index:
Table Definition-Related Issues

B.3.6 Table Definition-Related Issues

B.3.6.1 Problems with ALTER TABLE

If you get a duplicate-key error when using ALTER TABLE to change the character set or collation of a character column, the cause is either that the new column collation maps two keys to the same value or that the table is corrupted. In the latter case, you should run REPAIR TABLE on the table. REPAIR TABLE works for MyISAM, ARCHIVE, and CSV tables.

If ALTER TABLE dies with the following error, the problem may be that MySQL crashed during an earlier ALTER TABLE operation and there is an old table named A–xxx or B–xxx lying around:

Error on rename of './database/name.frm' to './database/B–xxx.frm' (Errcode: 17)

In this case, go to the MySQL data directory and delete all files that have names starting with A– or B–. (You may want to move them elsewhere instead of deleting them.)

ALTER TABLE works in the following way:

• Create a new table named A–xxx with the requested structural changes.
• Copy all rows from the original table to A–xxx.
• Rename the original table to B–xxx.
• Rename A–xxx to your original table name.
• Delete B–xxx.

If something goes wrong with the renaming operation, MySQL tries to undo the changes. If something goes seriously wrong (although this shouldn't happen), MySQL may leave the old table as B–xxx. A simple rename of the table files at the system level should get your data back.

If you use ALTER TABLE on a transactional table or if you are using Windows, ALTER TABLE unlocks the table if you had done a LOCK TABLE on it. This is done because InnoDB and these operating systems cannot drop a table that is in use.

B.3.6.2 TEMPORARY Table Problems

Temporary tables created with CREATE TEMPORARY TABLE have the following limitations:

• TEMPORARY tables are supported only by the InnoDB, MEMORY, MyISAM, and MERGE storage engines.
• Temporary tables are not supported for NDB Cluster.
• The SHOW TABLES statement does not list TEMPORARY tables.
Known Issues in MySQL

• To rename TEMPORARY tables, RENAME TABLE does not work. Use ALTER TABLE instead:

```
ALTER TABLE old_name RENAME new_name;
```

• You cannot refer to a TEMPORARY table more than once in the same query. For example, the following does not work:

```
SELECT * FROM temp_table JOIN temp_table AS t2;
```

The statement produces this error:

```
ERROR 1137: Can't reopen table: 'temp_table'
```

• The Can't reopen table error also occurs if you refer to a temporary table multiple times in a stored function under different aliases, even if the references occur in different statements within the function. It may occur for temporary tables created outside stored functions and referred to across multiple calling and callee functions.

• If a TEMPORARY is created with the same name as an existing non-TEMPORARY table, the non-TEMPORARY table is hidden until the TEMPORARY table is dropped, even if the tables use different storage engines.

• There are known issues in using temporary tables with replication. See Section 17.4.1.29, “Replication and Temporary Tables”, for more information.

B.3.7 Known Issues in MySQL

This section lists known issues in recent versions of MySQL.

For information about platform-specific issues, see the installation and debugging instructions in Section 2.1, “General Installation Guidance”, and Section 5.8, “Debugging MySQL”.

The following problems are known:

• Subquery optimization for IN is not as effective as for =.

• Even if you use lower_case_table_names=2 (which enables MySQL to remember the case used for databases and table names), MySQL does not remember the case used for database names for the function DATABASE() or within the various logs (on case-insensitive systems).

• Dropping a FOREIGN KEY constraint does not work in replication because the constraint may have another name on the replica.

• REPLACE (and LOAD DATA with the REPLACE option) does not trigger ON DELETE CASCADE.

• DISTINCT with ORDER BY does not work inside GROUP_CONCAT() if you do not use all and only those columns that are in the DISTINCT list.

• When inserting a big integer value (between $2^{63}$ and $2^{64}-1$) into a decimal or string column, it is inserted as a negative value because the number is evaluated in signed integer context.

• ANALYZE TABLE, OPTIMIZE TABLE, and REPAIR TABLE may cause problems on nontransactional tables for which you are using INSERT DELAYED.

• With statement-based binary logging, the source server writes the executed queries to the binary log. This is a very fast, compact, and efficient logging method that works perfectly in most cases. However, it is possible for the data on the source and replica to become different if a query is designed in such a
way that the data modification is nondeterministic (generally not a recommended practice, even outside of replication).

For example:

- **CREATE TABLE ... SELECT** or **INSERT ... SELECT** statements that insert zero or **NULL** values into an **AUTO_INCREMENT** column.

- **DELETE** if you are deleting rows from a table that has foreign keys with **ON DELETE CASCADE** properties.

- **REPLACE ... SELECT**, **INSERT IGNORE ... SELECT** if you have duplicate key values in the inserted data.

**If and only if the preceding queries have no ORDER BY clause guaranteeing a deterministic order.**

For example, for **INSERT ... SELECT** with no **ORDER BY**, the **SELECT** may return rows in a different order (which results in a row having different ranks, hence getting a different number in the **AUTO_INCREMENT** column), depending on the choices made by the optimizers on the source and replica.

A query is optimized differently on the source and replica only if:

- The table is stored using a different storage engine on the source than on the replica. (It is possible to use different storage engines on the source and replica. For example, you can use **InnoDB** on the source, but **MyISAM** on the replica if the replica has less available disk space.)

- MySQL buffer sizes (**key_buffer_size**, and so on) are different on the source and replica.

- The source and replica run different MySQL versions, and the optimizer code differs between these versions.

This problem may also affect database restoration using **mysqlbinlog**|**mysql**.

The easiest way to avoid this problem is to add an **ORDER BY** clause to the aforementioned nondeterministic queries to ensure that the rows are always stored or modified in the same order. Using row-based or mixed logging format also avoids the problem.

- Log file names are based on the server host name if you do not specify a file name with the startup option. To retain the same log file names if you change your host name to something else, you must explicitly use options such as **--log-bin=old_host_name-bin**. See **Section 5.1.6, “Server Command Options”**. Alternatively, rename the old files to reflect your host name change. If these are binary logs, you must edit the binary log index file and fix the binary log file names there as well. (The same is true for the relay logs on a replica.)

- **mysqlbinlog** does not delete temporary files left after a **LOAD DATA** statement. See **Section 4.6.8, “mysqlbinlog — Utility for Processing Binary Log Files”**.

- **RENAME** does not work with **TEMPORARY** tables or tables used in a **MERGE** table.

- When using **SET CHARACTER SET**, you cannot use translated characters in database, table, and column names.

- You cannot use _ or % with **ESCAPE** in **LIKE ... ESCAPE**.

- The server uses only the first **max_sort_length** bytes when comparing data values. This means that values cannot reliably be used in **GROUP BY**, **ORDER BY**, or **DISTINCT** if they differ only after the
first `max_sort_length` bytes. To work around this, increase the variable value. The default value of `max_sort_length` is 1024 and can be changed at server startup time or at runtime.

- Numeric calculations are done with `BIGINT` or `DOUBLE` (both are normally 64 bits long). Which precision you get depends on the function. The general rule is that bit functions are performed with `BIGINT` precision, `IF()` and `ELT()` with `BIGINT` or `DOUBLE` precision, and the rest with `DOUBLE` precision. You should try to avoid using unsigned long long values if they resolve to be larger than 63 bits (9223372036854775807) for anything other than bit fields.

- You can have up to 255 `ENUM` and `SET` columns in one table.

- In `MIN()`, `MAX()`, and other aggregate functions, MySQL currently compares `ENUM` and `SET` columns by their string value rather than by the string’s relative position in the set.

- In an `UPDATE` statement, columns are updated from left to right. If you refer to an updated column, you get the updated value instead of the original value. For example, the following statement increments `KEY` by 2, not 1:

  ```sql
  mysql> UPDATE tbl_name SET KEY=KEY+1,KEY=KEY+1;
  ```

- You can refer to multiple temporary tables in the same query, but you cannot refer to any given temporary table more than once. For example, the following does not work:

  ```sql
  mysql> SELECT * FROM temp_table, temp_table AS t2;
  ERROR 1137: Can’t reopen table: 'temp_table'
  ```

- The optimizer may handle `DISTINCT` differently when you are using “hidden” columns in a join than when you are not. In a join, hidden columns are counted as part of the result (even if they are not shown), whereas in normal queries, hidden columns do not participate in the `DISTINCT` comparison.

  An example of this is:

  ```sql
  SELECT DISTINCT mp3id FROM band_downloads
  WHERE userid = 9 ORDER BY id DESC;
  ```

  and

  ```sql
  SELECT DISTINCT band_downloads.mp3id
  FROM band_downloads,band_mp3
  WHERE band_downloads.userid = 9
  AND band_mp3.id = band_downloads.mp3id
  ORDER BY band_downloads.id DESC;
  ```

  In the second case, you may get two identical rows in the result set (because the values in the hidden `id` column may differ).

  This happens only for queries that do not have the `ORDER BY` columns in the result.

- If you execute a `PROCEDURE` on a query that returns an empty set, in some cases the `PROCEDURE` does not transform the columns.

- Creation of a table of type `MERGE` does not check whether the underlying tables are compatible types.

- If you use `ALTER TABLE` to add a `UNIQUE` index to a table used in a `MERGE` table and then add a normal index on the `MERGE` table, the key order is different for the tables if there was an old, non-`UNIQUE` key in the table. This is because `ALTER TABLE` puts `UNIQUE` indexes before normal indexes to be able to detect duplicate keys as early as possible.

MySQL Glossary

These terms are commonly used in information about the MySQL database server. This glossary originated as a reference for terminology about the InnoDB storage engine, and the majority of definitions are InnoDB-related.

A

.ARM file
Metadata for ARCHIVE tables. Contrast with .ARZ file. Files with this extension are always included in backups produced by the mysqlbackup command of the MySQL Enterprise Backup product. See Also .ARZ file, MySQL Enterprise Backup, mysqlbackup command.

.ARZ file
Data for ARCHIVE tables. Contrast with .ARM file. Files with this extension are always included in backups produced by the mysqlbackup command of the MySQL Enterprise Backup product. See Also .ARM file, MySQL Enterprise Backup, mysqlbackup command.

ACID
An acronym standing for atomicity, consistency, isolation, and durability. These properties are all desirable in a database system, and are all closely tied to the notion of a transaction. The transactional features of InnoDB adhere to the ACID principles.

Transactions are atomic units of work that can be committed or rolled back. When a transaction makes multiple changes to the database, either all the changes succeed when the transaction is committed, or all the changes are undone when the transaction is rolled back.

The database remains in a consistent state at all times — after each commit or rollback, and while transactions are in progress. If related data is being updated across multiple tables, queries see either all old values or all new values, not a mix of old and new values.

Transactions are protected (isolated) from each other while they are in progress; they cannot interfere with each other or see each other's uncommitted data. This isolation is achieved through the locking mechanism. Experienced users can adjust the isolation level, trading off less protection in favor of increased performance and concurrency, when they can be sure that the transactions really do not interfere with each other.

The results of transactions are durable: once a commit operation succeeds, the changes made by that transaction are safe from power failures, system crashes, race conditions, or other potential dangers that many non-database applications are vulnerable to. Durability typically involves writing to disk storage, with a certain amount of redundancy to protect against power failures or software crashes during write operations. (In InnoDB, the doublewrite buffer assists with durability.) See Also atomic, commit, concurrency, doublewrite buffer, isolation level, locking, rollback, transaction.

adaptive flushing
An algorithm for InnoDB tables that smooths out the I/O overhead introduced by checkpoints. Instead of flushing all modified pages from the buffer pool to the data files at once, MySQL periodically flushes small sets of modified pages. The adaptive flushing algorithm extends this process by estimating the optimal rate to perform these periodic flushes, based on the rate of flushing and how fast redo information is generated. See Also buffer pool, checkpoint, data files, flush, InnoDB, page, redo log.

adaptive hash index
An optimization for InnoDB tables that can speed up lookups using = and IN operators, by constructing a hash index in memory. MySQL monitors index searches for InnoDB tables, and if queries could benefit from a hash index, it builds one automatically for index pages that are frequently accessed. In a sense, the adaptive hash index configures MySQL at runtime to take advantage of ample main memory, coming closer to the architecture
of main-memory databases. This feature is controlled by the `innodb_adaptive_hash_index` configuration option. Because this feature benefits some workloads and not others, and the memory used for the hash index is reserved in the buffer pool, typically you should benchmark with this feature both enabled and disabled.

The hash index is always built based on an existing B-tree index on the table. MySQL can build a hash index on a prefix of any length of the key defined for the B-tree, depending on the pattern of searches against the index. A hash index can be partial; the whole B-tree index does not need to be cached in the buffer pool.

In MySQL 5.6 and higher, another way to take advantage of fast single-value lookups with InnoDB tables is to use the InnoDB memcached plugin. See Section 14.20, “InnoDB memcached Plugin” for details. See Also B-tree, buffer pool, hash index, memcached, page, secondary index.

ADO.NET
An object-relational mapping (ORM) framework for applications built using .NET technologies such as ASP.NET. Such applications can interface with MySQL through the Connector/NET component. See Also .NET, ASP.net, Connector/NET, Mono, Visual Studio.

AIO
Acronym for asynchronous I/O. You might see this acronym in InnoDB messages or keywords. See Also asynchronous I/O.

ANSI
In ODBC, an alternative method of supporting character sets and other internationalization aspects. Contrast with Unicode. Connector/ODBC 3.51 is an ANSI driver, while Connector/ODBC 5.1 is a Unicode driver. See Also Connector/ODBC, ODBC, Unicode.

Antelope
The code name for the original InnoDB file format. It supports the REDUNDANT and COMPACT row formats, but not the newer DYNAMIC and COMPRESSED row formats available in the Barracuda file format. See Also Barracuda, compact row format, compressed row format, dynamic row format, file format, innodb_file_format, redundant row format.

API
APIs provide low-level access to the MySQL protocol and MySQL resources from client programs. Contrast with the higher-level access provided by a Connector. See Also C API, client, connector, native C API, Perl API, PHP API, Python API, Ruby API.

application programming interface (API)
A set of functions or procedures. An API provides a stable set of names and types for functions, procedures, parameters, and return values.

apply
When a backup produced by the MySQL Enterprise Backup product does not include the most recent changes that occurred while the backup was underway, the process of updating the backup files to include those changes is known as the apply step. It is specified by the apply-log option of the mysqlbackup command.

Before the changes are applied, we refer to the files as a raw backup. After the changes are applied, we refer to the files as a prepared backup. The changes are recorded in the ibbackup_logfile file; once the apply step is finished, this file is no longer necessary. See Also hot backup, ibbackup_logfile, MySQL Enterprise Backup, prepared backup, raw backup.

ASP.net
A framework for developing web-based applications using .NET technologies and languages. Such applications can interface with MySQL through the Connector/NET component.

Another technology for writing server-side web pages with MySQL is PHP.
assembly
A library of compiled code in a .NET system, accessed through Connector/NET. Stored in the GAC to allow versioning without naming conflicts.
See Also .NET, GAC.

asynchronous I/O
A type of I/O operation that allows other processing to proceed before the I/O is completed. Also known as nonblocking I/O and abbreviated as AIO. InnoDB uses this type of I/O for certain operations that can run in parallel without affecting the reliability of the database, such as reading pages into the buffer pool that have not actually been requested, but might be needed soon.

Historically, InnoDB used asynchronous I/O on Windows systems only. Starting with the InnoDB Plugin 1.1 and MySQL 5.5, InnoDB uses asynchronous I/O on Linux systems. This change introduces a dependency on libaio. Asynchronous I/O on Linux systems is configured using the innodb_use_native_aio option, which is enabled by default. On other Unix-like systems, InnoDB uses synchronous I/O only.
See Also buffer pool, nonblocking I/O.

atomic
In the SQL context, transactions are units of work that either succeed entirely (when committed) or have no effect at all (when rolled back). The indivisible (“atomic”) property of transactions is the “A” in the acronym ACID.
See Also ACID, commit, rollback, transaction.

atomic DDL
An atomic DDL statement is one that combines the data dictionary updates, storage engine operations, and binary log writes associated with a DDL operation into a single, atomic transaction. The transaction is either fully committed or rolled back, even if the server halts during the operation. Atomic DDL support was added in MySQL 8.0. For more information, see Atomic Data Definition Statement Support.
See Also binary log, data dictionary, DDL, storage engine.

atomic instruction
Special instructions provided by the CPU, to ensure that critical low-level operations cannot be interrupted.

auto-increment
A property of a table column (specified by the AUTO_INCREMENT keyword) that automatically adds an ascending sequence of values in the column.

It saves work for the developer, not to have to produce new unique values when inserting new rows. It provides useful information for the query optimizer, because the column is known to be not null and with unique values. The values from such a column can be used as lookup keys in various contexts, and because they are auto-generated there is no reason to ever change them; for this reason, primary key columns are often specified as auto-incrementing.

Auto-increment columns can be problematic with statement-based replication, because replaying the statements on a replica might not produce the same set of column values as on the source, due to timing issues. When you have an auto-incrementing primary key, you can use statement-based replication only with the setting innodb_autoinc_lock_mode=1. If you have innodb_autoinc_lock_mode=2, which allows higher concurrency for insert operations, use row-based replication rather than statement-based replication. The setting innodb_autoinc_lock_mode=0 should not be used except for compatibility purposes.

Consecutive lock mode (innodb_autoinc_lock_mode=1) is the default setting prior to MySQL 8.0.3. As of MySQL 8.0.3, interleaved lock mode (innodb_autoinc_lock_mode=2) is the default, which reflects the change from statement-based to row-based replication as the default replication type.
See Also auto-increment locking, innodb_autoinc_lock_mode, primary key, row-based replication, statement-based replication.
auto-increment locking

The convenience of an auto-increment primary key involves some tradeoff with concurrency. In the simplest case, if one transaction is inserting values into the table, any other transactions must wait to do their own inserts into that table, so that rows inserted by the first transaction receive consecutive primary key values. InnoDB includes optimizations and the innodb_autoinc_lock_mode option so that you can configure and optimal balance between predictable sequences of auto-increment values and maximum concurrency for insert operations.

See Also auto-increment, concurrency, innodb_autoinc_lock_mode.

autocommit

A setting that causes a commit operation after each SQL statement. This mode is not recommended for working with InnoDB tables with transactions that span several statements. It can help performance for read-only transactions on InnoDB tables, where it minimizes overhead from locking and generation of undo data, especially in MySQL 5.6.4 and up. It is also appropriate for working with MyISAM tables, where transactions are not applicable.

See Also commit, locking, read-only transaction, SQL, transaction, undo.

availability

The ability to cope with, and if necessary recover from, failures on the host, including failures of MySQL, the operating system, or the hardware and maintenance activity that may otherwise cause downtime. Often paired with scalability as critical aspects of a large-scale deployment.

See Also scalability.

B

B-tree

A tree data structure that is popular for use in database indexes. The structure is kept sorted at all times, enabling fast lookup for exact matches (equals operator) and ranges (for example, greater than, less than, and BETWEEN operators). This type of index is available for most storage engines, such as InnoDB and MyISAM.

Because B-tree nodes can have many children, a B-tree is not the same as a binary tree, which is limited to 2 children per node.

Contrast with hash index, which is only available in the MEMORY storage engine. The MEMORY storage engine can also use B-tree indexes, and you should choose B-tree indexes for MEMORY tables if some queries use range operators.

The use of the term B-tree is intended as a reference to the general class of index design. B-tree structures used by MySQL storage engines may be regarded as variants due to sophistications not present in a classic B-tree design. For related information, refer to the InnoDB Page Structure Fil Header section of the MySQL Internals Manual.

See Also hash index.

backticks

Identifiers within MySQL SQL statements must be quoted using the backtick character (``) if they contain special characters or reserved words. For example, to refer to a table named `FOO#BAR` or a column named `SELECT`, you would specify the identifiers as ``FOO#BAR` and `SELECT`. Since the backticks provide an extra level of safety, they are used extensively in program-generated SQL statements, where the identifier names might not be known in advance.

Many other database systems use double quotation marks (``) around such special names. For portability, you can enable ANSI_QUOTES mode in MySQL and use double quotation marks instead of backticks to qualify identifier names.

See Also SQL.
backup
The process of copying some or all table data and metadata from a MySQL instance, for safekeeping. Can also refer to the set of copied files. This is a crucial task for DBAs. The reverse of this process is the restore operation.

With MySQL, physical backups are performed by the MySQL Enterprise Backup product, and logical backups are performed by the mysqldump command. These techniques have different characteristics in terms of size and representation of the backup data, and speed (especially speed of the restore operation).

Backups are further classified as hot, warm, or cold depending on how much they interfere with normal database operation. (Hot backups have the least interference, cold backups the most.)
See Also cold backup, hot backup, logical backup, MySQL Enterprise Backup, mysqldump, physical backup, warm backup.

Barracuda
The code name for an InnoDB file format that supports the COMPRESSED row format that enables InnoDB table compression, and the DYNAMIC row format that improves the storage layout for long variable-length columns.

The MySQL Enterprise Backup product version 3.5 and above supports backing up tablespaces that use the Barracuda file format.
See Also Antelope, compact row format, compressed row format, dynamic row format, file format, file-per-table, general tablespace, innodb_file_format, MySQL Enterprise Backup, row format, system tablespace.

beta
An early stage in the life of a software product, when it is available only for evaluation, typically without a definite release number or a number less than 1. InnoDB does not use the beta designation, preferring an early adopter phase that can extend over several point releases, leading to a GA release.
See Also early adopter, GA.

binary log
A file containing a record of all statements or row changes that attempt to change table data. The contents of the binary log can be replayed to bring replicas up to date in a replication scenario, or to bring a database up to date after restoring table data from a backup. The binary logging feature can be turned on and off, although Oracle recommends always enabling it if you use replication or perform backups.

You can examine the contents of the binary log, or replay it during replication or recovery, by using the mysqlbinlog command. For full information about the binary log, see Section 5.4.4, “The Binary Log”. For MySQL configuration options related to the binary log, see Section 17.1.4.4, “Binary Log Options and Variables”.

For the MySQL Enterprise Backup product, the file name of the binary log and the current position within the file are important details. To record this information for the source when taking a backup in a replication context, you can specify the --slave-info option.

Prior to MySQL 5.0, a similar capability was available, known as the update log. In MySQL 5.0 and higher, the binary log replaces the update log.
See Also binlog, MySQL Enterprise Backup, replication.

binlog
An informal name for the binary log file. For example, you might see this abbreviation used in e-mail messages or forum discussions.
See Also binary log.

blind query expansion
A special mode of full-text search enabled by the WITH QUERY EXPANSION clause. It performs the search twice, where the search phrase for the second search is the original search phrase concatenated with the few most highly relevant documents from the first search. This technique is mainly applicable for short search
phrases, perhaps only a single word. It can uncover relevant matches where the precise search term does not occur in the document.
See Also full-text search.

BLOB
An SQL data type (TINYBLOB, BLOB, MEDIUMBLOB, and LONGBLOB) for objects containing any kind of binary data, of arbitrary size. Used for storing documents, images, sound files, and other kinds of information that cannot easily be decomposed to rows and columns within a MySQL table. The techniques for handling BLOBs within a MySQL application vary with each Connector and API. MySQL Connector/ODBC defines BLOB values as LONGVARBINARY. For large, free-form collections of character data, the industry term is CLOB, represented by the MySQL TEXT data types.
See Also API, CLOB, connector, Connector/ODBC.

bottleneck
A portion of a system that is constrained in size or capacity, that has the effect of limiting overall throughput. For example, a memory area might be smaller than necessary; access to a single required resource might prevent multiple CPU cores from running simultaneously; or waiting for disk I/O to complete might prevent the CPU from running at full capacity. Removing bottlenecks tends to improve concurrency. For example, the ability to have multiple InnoDB buffer pool instances reduces contention when multiple sessions read from and write to the buffer pool simultaneously.
See Also buffer pool, concurrency.

bounce
A shutdown operation immediately followed by a restart. Ideally with a relatively short warmup period so that performance and throughput quickly return to a high level.
See Also shutdown.

buddy allocator
A mechanism for managing different-sized pages in the InnoDB buffer pool.
See Also buffer pool, page, page size.

buffer
A memory or disk area used for temporary storage. Data is buffered in memory so that it can be written to disk efficiently, with a few large I/O operations rather than many small ones. Data is buffered on disk for greater reliability, so that it can be recovered even when a crash or other failure occurs at the worst possible time. The main types of buffers used by InnoDB are the buffer pool, the doublewrite buffer, and the change buffer.
See Also buffer pool, change buffer, crash, doublewrite buffer.

buffer pool
The memory area that holds cached InnoDB data for both tables and indexes. For efficiency of high-volume read operations, the buffer pool is divided into pages that can potentially hold multiple rows. For efficiency of cache management, the buffer pool is implemented as a linked list of pages; data that is rarely used is aged out of the cache, using a variation of the LRU algorithm. On systems with large memory, you can improve concurrency by dividing the buffer pool into multiple buffer pool instances.

Several InnoDB status variables, INFORMATION_SCHEMA tables, and performance_schema tables help to monitor the internal workings of the buffer pool. Starting in MySQL 5.6, you can avoid a lengthy warmup period after restarting the server, particularly for instances with large buffer pools, by saving the buffer pool state at server shutdown and restoring the buffer pool to the same state at server startup. See Section 14.8.3.5, “Saving and Restoring the Buffer Pool State”.
See Also buffer pool instance, LRU, page, warm up.

buffer pool instance
Any of the multiple regions into which the buffer pool can be divided, controlled by the innodb_buffer_pool_instances configuration option. The total memory size specified by innodb_buffer_pool_size is divided among all buffer pool instances. Typically, having multiple buffer pool
instances is appropriate for systems that allocate multiple gigabytes to the InnoDB buffer pool, with each instance being one gigabyte or larger. On systems loading or looking up large amounts of data in the buffer pool from many concurrent sessions, having multiple buffer pool instances reduces contention for exclusive access to data structures that manage the buffer pool.

See Also buffer pool.

built-in
The built-in InnoDB storage engine within MySQL is the original form of distribution for the storage engine.

Contrast with the InnoDB Plugin. Starting with MySQL 5.5, the InnoDB Plugin is merged back into the MySQL code base as the built-in InnoDB storage engine (known as InnoDB 1.1).

This distinction is important mainly in MySQL 5.1, where a feature or bug fix might apply to the InnoDB Plugin but not the built-in InnoDB, or vice versa.

See Also InnoDB.

business rules
The relationships and sequences of actions that form the basis of business software, used to run a commercial company. Sometimes these rules are dictated by law, other times by company policy. Careful planning ensures that the relationships encoded and enforced by the database, and the actions performed through application logic, accurately reflect the real policies of the company and can handle real-life situations.

For example, an employee leaving a company might trigger a sequence of actions from the human resources department. The human resources database might also need the flexibility to represent data about a person who has been hired, but not yet started work. Closing an account at an online service might result in data being removed from a database, or the data might be moved or flagged so that it could be recovered if the account is re-opened. A company might establish policies regarding salary maximums, minimums, and adjustments, in addition to basic sanity checks such as the salary not being a negative number. A retail database might not allow a purchase with the same serial number to be returned more than once, or might not allow credit card purchases above a certain value, while a database used to detect fraud might allow these kinds of things.

See Also relational.

C
A programming language that combines portability with performance and access to low-level hardware features, making it a popular choice for writing operating systems, drivers, and other kinds of system software. Many complex applications, languages, and reusable modules feature pieces written in C, tied together with high-level components written in other languages. Its core syntax is familiar to C++, Java, and C# developers.

See Also C API, C++, C#, Java.

C API
The C API code is distributed with MySQL. It is included in the libmysqlclient library and enables C programs to access a database.

See Also API, C, libmysqlclient.

C#
A programming language combining strong typing and object-oriented features, running within the Microsoft .NET framework or its open-source counterpart Mono. Often used for creating applications with the ASP.net framework. Its syntax is familiar to C, C++ and Java developers.
C++

A programming language with core syntax familiar to C developers. Provides access to low-level operations for performance, combined with higher-level data types, object-oriented features, and garbage collection. To write C++ applications for MySQL, you use the Connector/C++ component.

See Also C, Connector/C++.

cache

The general term for any memory area that stores copies of data for frequent or high-speed retrieval. In InnoDB, the primary kind of cache structure is the buffer pool.

See Also buffer, buffer pool.

cardinality

The number of different values in a table column. When queries refer to columns that have an associated index, the cardinality of each column influences which access method is most efficient. For example, for a column with a unique constraint, the number of different values is equal to the number of rows in the table. If a table has a million rows but only 10 different values for a particular column, each value occurs (on average) 100,000 times. A query such as SELECT c1 FROM t1 WHERE c1 = 50; thus might return 1 row or a huge number of rows, and the database server might process the query differently depending on the cardinality of c1.

If the values in a column have a very uneven distribution, the cardinality might not be a good way to determine the best query plan. For example, SELECT c1 FROM t1 WHERE c1 = x; might return 1 row when x=50 and a million rows when x=30. In such a case, you might need to use index hints to pass along advice about which lookup method is more efficient for a particular query.

Cardinality can also apply to the number of distinct values present in multiple columns, as in a composite index.

See Also column, composite index, index, index hint, persistent statistics, random dive, selectivity, unique constraint.

change buffer

A special data structure that records changes to pages in secondary indexes. These values could result from SQL INSERT, UPDATE, or DELETE statements (DML). The set of features involving the change buffer is known collectively as change buffering, consisting of insert buffering, delete buffering, and purge buffering.

Changes are only recorded in the change buffer when the relevant page from the secondary index is not in the buffer pool. When the relevant index page is brought into the buffer pool while associated changes are still in the change buffer, the changes for that page are applied in the buffer pool (merged) using the data from the change buffer. Periodically, the purge operation that runs during times when the system is mostly idle, or during a slow shutdown, writes the new index pages to disk. The purge operation can write the disk blocks for a series of index values more efficiently than if each value were written to disk immediately.

Physically, the change buffer is part of the system tablespace, so that the index changes remain buffered across database restarts. The changes are only applied (merged) when the pages are brought into the buffer pool due to some other read operation.

The kinds and amount of data stored in the change buffer are governed by the innodb_change_buffering and innodb_change_buffer_max_size configuration options. To see information about the current data in the change buffer, issue the SHOW ENGINE INNODB STATUS command.

Formerly known as the insert buffer.

See Also buffer pool, change buffering, delete buffering, DML, insert buffer, insert buffering, merge, page, purge, purge buffering, secondary index, system tablespace.

change buffering

The general term for the features involving the change buffer, consisting of insert buffering, delete buffering, and purge buffering. Index changes resulting from SQL statements, which could normally involve random I/
O operations, are held back and performed periodically by a background thread. This sequence of operations can write the disk blocks for a series of index values more efficiently than if each value were written to disk immediately. Controlled by the innodb_change_buffering and innodb_change_buffer_max_size configuration options.

See Also change buffer, delete buffering, insert buffering, purge buffering.

checkpoint
As changes are made to data pages that are cached in the buffer pool, those changes are written to the data files sometime later, a process known as flushing. The checkpoint is a record of the latest changes (represented by an LSN value) that have been successfully written to the data files.

See Also buffer pool, data files, flush, fuzzy checkpointing, LSN.

checksum
In InnoDB, a validation mechanism to detect corruption when a page in a tablespace is read from disk into the InnoDB buffer pool. This feature is controlled by the innodb_checksums configuration option in MySQL 5.5. innodb_checksums is deprecated in MySQL 5.6.3, replaced by innodb_checksum_algorithm.

The innochecksum command helps diagnose corruption problems by testing the checksum values for a specified tablespace file while the MySQL server is shut down.

MySQL also uses checksums for replication purposes. For details, see the configuration options binlog_checksum, source_verify_checksum or master_verify_checksum, and replica_sql_verify_checksum or slave_sql_verify_checksum.

See Also buffer pool, page, tablespace.

child table
In a foreign key relationship, a child table is one whose rows refer (or point) to rows in another table with an identical value for a specific column. This is the table that contains the FOREIGN KEY ... REFERENCES clause and optionally ON UPDATE and ON DELETE clauses. The corresponding row in the parent table must exist before the row can be created in the child table. The values in the child table can prevent delete or update operations on the parent table, or can cause automatic deletion or updates in the child table, based on the ON CASCADE option used when creating the foreign key.

See Also foreign key, parent table.

clean page
A page in the InnoDB buffer pool where all changes made in memory have also been written (flushed) to the data files. The opposite of a dirty page.

See Also buffer pool, data files, dirty page, flush, page.

clean shutdown
A shutdown that completes without errors and applies all changes to InnoDB tables before finishing, as opposed to a crash or a fast shutdown. Synonym for slow shutdown.

See Also crash, fast shutdown, shutdown, slow shutdown.

client
A program that runs outside the database server, communicating with the database by sending requests through a Connector, or an API made available through client libraries. It can run on the same physical machine as the database server, or on a remote machine connected over a network. It can be a special-purpose database application, or a general-purpose program like the mysql command-line processor.

See Also API, client libraries, connector, mysql, server.

client libraries
Files containing collections of functions for working with databases. By compiling your program with these libraries, or installing them on the same system as your application, you can run a database application (known
as a **client** on a machine that does not have the MySQL server installed; the application accesses the database over a network. With MySQL, you can use the **libmysqclient** library from the MySQL server itself. See Also **client**, **libmysqclient**.

**client-side prepared statement**

A type of **prepared statement** where the caching and reuse are managed locally, emulating the functionality of **server-side prepared statements**. Historically, used by some **Connector/J**, **Connector/ODBC**, and **Connector/PHP** developers to work around issues with server-side stored procedures. With modern MySQL server versions, server-side prepared statements are recommended for performance, scalability, and memory efficiency. See Also **Connector/J**, **Connector/ODBC**, **Connector/PHP**, **prepared statement**.

**CLOB**

An SQL data type (**TINYTEXT**, **TEXT**, **MEDIUMTEXT**, or **LONGTEXT**) for objects containing any kind of character data, of arbitrary size. Used for storing text-based documents, with associated character set and collation order. The techniques for handling CLOBs within a MySQL application vary with each **Connector** and **API**. MySQL **Connector/ODBC** defines **TEXT** values as **LONGVARCHAR**. For storing binary data, the equivalent is the **BLOB** type. See Also **API**, **BLOB**, **connector**, **Connector/ODBC**.

**clustered index**

The **InnoDB** term for a **primary key** index. **InnoDB** table storage is organized based on the values of the primary key columns, to speed up queries and sorts involving the primary key columns. For best performance, choose the primary key columns carefully based on the most performance-critical queries. Because modifying the columns of the clustered index is an expensive operation, choose primary columns that are rarely or never updated.

In the Oracle Database product, this type of table is known as an **index-organized table**. See Also **index**, **primary key**, **secondary index**.

**cold backup**

A **backup** taken while the database is shut down. For busy applications and websites, this might not be practical, and you might prefer a **warm backup** or a **hot backup**. See Also **backup**, **hot backup**, **warm backup**.

**column**

A data item within a **row**, whose storage and semantics are defined by a data type. Each **table** and **index** is largely defined by the set of columns it contains.

Each column has a **cardinality** value. A column can be the **primary key** for its table, or part of the primary key. A column can be subject to a **unique constraint**, a **NOT NULL** constraint, or both. Values in different columns, even across different tables, can be linked by a **foreign key** relationship.

In discussions of MySQL internal operations, sometimes **field** is used as a synonym. See Also **cardinality**, **foreign key**, **index**, **NOT NULL constraint**, **primary key**, **row**, **table**, **unique constraint**.

**column index**

An **index** on a single column. See Also **composite index**, **index**.

**column prefix**

When an **index** is created with a length specification, such as **CREATE INDEX idx ON t1 (c1(N))**, only the first N characters of the column value are stored in the index. Keeping the index prefix small makes the index compact, and the memory and disk I/O savings help performance. (Although making the index prefix too small can hinder query optimization by making rows with different values appear to the query optimizer to be duplicates.)
For columns containing binary values or long text strings, where sorting is not a major consideration and storing the entire value in the index would waste space, the index automatically uses the first N (typically 768) characters of the value to do lookups and sorts.

See Also index.

command interceptor

Synonym for statement interceptor. One aspect of the interceptor design pattern available for both Connector.NET and Connector/J. What Connector.NET calls a command, Connector/J refers to as a statement. Contrast with exception interceptor.

See Also Connector/J, Connector/NET, exception interceptor, interceptor, statement interceptor.

commit

A SQL statement that ends a transaction, making permanent any changes made by the transaction. It is the opposite of rollback, which undoes any changes made in the transaction.

InnoDB uses an optimistic mechanism for commits, so that changes can be written to the data files before the commit actually occurs. This technique makes the commit itself faster, with the tradeoff that more work is required in case of a rollback.

By default, MySQL uses the autocommit setting, which automatically issues a commit following each SQL statement.

See Also autocommit, optimistic, rollback, SQL, transaction.

compact row format

The default InnoDB row format for InnoDB tables since MySQL 5.0.3. The COMPACT row format provides a more compact representation for nulls and variable-length columns than the prior default (REDUNDANT row format).

For additional information about InnoDB COMPACT row format, see Section 14.11, "InnoDB Row Formats".

See Also Antelope, dynamic row format, file format, redundant row format, row format.

composite index

An index that includes multiple columns.

See Also index.

compressed backup

The compression feature of the MySQL Enterprise Backup product makes a compressed copy of each tablespace, changing the extension from .ibd to .ibz. Compressing backup data allows you to keep more backups on hand, and reduces the time to transfer backups to a different server. The data is uncompressed during the restore operation. When a compressed backup operation processes a table that is already compressed, it skips the compression step for that table, because compressing again would result in little or no space savings.

A set of files produced by the MySQL Enterprise Backup product, where each tablespace is compressed. The compressed files are renamed with a .ibz file extension.

Applying compression at the start of the backup process helps to avoid storage overhead during the compression process, and to avoid network overhead when transferring the backup files to another server. The process of applying the binary log takes longer, and requires uncompressing the backup files.

See Also apply, binary log, compression, hot backup, MySQL Enterprise Backup, tablespace.

compressed row format

A row format that enables data and index compression for InnoDB tables. It was introduced in the InnoDB Plugin, available as part of the Barracuda file format. Large fields are stored away from the page that holds the rest of the row data, as in dynamic row format. Both index pages and large fields are compressed, yielding memory and disk savings. Depending on the structure of the data, the decrease in memory and disk usage might
or might not outweigh the performance overhead of uncompressing the data as it is used. See Section 14.9, “InnoDB Table Compression” for usage details.

For additional information about InnoDB COMPRESSED row format, see DYNAMIC Row Format. See Also Barracuda, compression, dynamic row format, row format.

compressed table
A table for which the data is stored in compressed form. For InnoDB, it is a table created with ROW_FORMAT=COMPRESSED. See Section 14.9, “InnoDB Table Compression” for more information. See Also compressed row format, compression.

compression
A feature with wide-ranging benefits from using less disk space, performing less I/O, and using less memory for caching. InnoDB table and index data can be kept in a compressed format during database operation.

The data is uncompressed when needed for queries, and re-compressed when changes are made by DML operations. After you enable compression for a table, this processing is transparent to users and application developers. DBAs can consult InnoDB INFORMATION_SCHEMA tables to monitor how efficiently the compression parameters work for the MySQL instance and for particular compressed tables.

When InnoDB table data is compressed, the compression applies to the table itself, any associated index data, and the pages loaded into the buffer pool. Compression does not apply to pages in the undo buffer.

The table compression feature requires using MySQL 5.5 or higher, or the InnoDB Plugin in MySQL 5.1 or earlier, and creating the table using the Barracuda file format and compressed row format, with the innodb_file_per_table setting enabled.

Compression for each table is influenced by the KEY_BLOCK_SIZE clause of the CREATE TABLE and ALTER TABLE statements. In MySQL 5.6 and higher, compression is also affected by the server-wide configuration options innodb_compression_failure_threshold_pct, innodb_compression_level, and innodb_compression_pad_pct_max. See Section 14.9, “InnoDB Table Compression” for usage details.

Another type of compression is the compressed backup feature of the MySQL Enterprise Backup product. See Also Barracuda, buffer pool, compressed backup, compressed row format, DML, transparent page compression.

compression failure
Not actually an error, rather an expensive operation that can occur when using compression in combination with DML operations. It occurs when: updates to a compressed page overflow the area on the page reserved for recording modifications; the page is compressed again, with all changes applied to the table data; the re-compressed data does not fit on the original page, requiring MySQL to split the data into two new pages and compress each one separately. To check the frequency of this condition, query the INFORMATION_SCHEMA.INNODB_CMP table and check how much the value of the COMPRESS_OPS column exceeds the value of the COMPRESS_OPS_OK column. Ideally, compression failures do not occur often; when they do, you can adjust the innodb_compression_level, innodb_compression_failure_threshold_pct, and innodb_compression_pad_pct_max configuration options. See Also compression, DML, page.

concatenated index
See composite index.

concurrency
The ability of multiple operations (in database terminology, transactions) to run simultaneously, without interfering with each other. Concurrency is also involved with performance, because ideally the protection for multiple simultaneous transactions works with a minimum of performance overhead, using efficient mechanisms for locking. See Also ACID, locking, transaction.
configuration file

The file that holds the **option** values used by MySQL at startup. Traditionally, on Linux and Unix this file is named `my.cnf`, and on Windows it is named `my.ini`. You can set a number of options related to InnoDB under the `[mysqld]` section of the file.

See Section 4.2.2.2, “Using Option Files” for information about where MySQL searches for configuration files.

When you use the **MySQL Enterprise Backup** product, you typically use two configuration files: one that specifies where the data comes from and how it is structured (which could be the original configuration file for your server), and a stripped-down one containing only a small set of options that specify where the backup data goes and how it is structured. The configuration files used with the **MySQL Enterprise Backup** product must contain certain options that are typically left out of regular configuration files, so you might need to add options to your existing configuration file for use with **MySQL Enterprise Backup**.

See Also `my.cnf`, **MySQL Enterprise Backup**, `option`, `option file`.

connection

The communication channel between an application and a MySQL server. The performance and scalability of a database applications is influenced by on how quickly a database connection can be established, how many can be made simultaneously, and how long they persist. The parameters such as `host`, `port`, and so on are represented as a **connection string** in **Connector/NET**, and as a **DSN** in **Connector/ODBC**. High-traffic systems make use of an optimization known as the **connection pool**.

See Also `connection pool`, `connection string`, **Connector/NET**, **Connector/ODBC**, `DSN`, `host`, `port`.

connection pool

A cache area that allows database **connections** to be reused within the same application or across different applications, rather than setting up and tearing down a new connection for every database operation. This technique is common with **J2EE** application servers. **Java** applications using **Connector/J** can use the connection pool features of **Tomcat** and other application servers. The reuse is transparent to applications; the application still opens and closes the connection as usual.

See Also `connection`, **Connector/J**, **J2EE**, **Tomcat**.

connection string

A representation of the parameters for a database **connection**, encoded as a string literal so that it can be used in program code. The parts of the string represent connection parameters such as `host` and `port`. A connection string contains several key-value pairs, separated by semicolons. Each key-value pair is joined with an equal sign. Frequently used with **Connector/NET** applications; see Creating a **Connector/NET** Connection String for details.

See Also `connection`, **Connector/NET**, `host`, `port`.

connector

MySQL Connectors provide connectivity to the MySQL server for **client** programs. Several programming languages and frameworks each have their own associated Connector. Contrast with the lower-level access provided by an **API**.

See Also **API**, `client`, **Connector/C++**, **Connector/J**, **Connector/NET**, **Connector/ODBC**.

**Connector/C++**

**Connector/C++ 8.0** can be used to access MySQL servers that implement a **document store**, or in a traditional way using SQL queries. It enables development of **C++** applications using X DevAPI, or plain **C** applications using X DevAPI for **C**. It also enables development of **C++** applications that use the legacy JDBC-based API from **Connector/C++ 1.1**. For more information, see **MySQL Connector/C++ 8.0 Developer Guide**.

See Also `client`, `connector`, **JDBC**.

**Connector/J**

A **JDBC** driver that provides connectivity for **client** applications developed in the **Java** programming language. Different versions are available that are compatible with the **JDBC 3.0** and **JDBC 4.0** specifications. MySQL
Connector/J is a JDBC Type 4 driver: a pure-Java implementation of the MySQL protocol that does not rely on the MySQL client libraries. For full details, see MySQL Connector/J 5.1 Developer Guide. See Also client, client libraries, connector, Java, JDBC.

Connector/NET
A MySQL connector for developers writing applications using languages, technologies, and frameworks such as C#, .NET, Mono, Visual Studio, ASP.net, and ADO.net. See Also ADO.NET, ASP.net, connector, C#, Mono, Visual Studio.

Connector/ODBC
The family of MySQL ODBC drivers that provide access to a MySQL database using the industry standard Open Database Connectivity (ODBC) API. Formerly called MyODBC drivers. For full details, see MySQL Connector/ODBC Developer Guide. See Also connector, ODBC.

Connector/PHP
A version of the mysql and mysqli APIs for PHP optimized for the Windows operating system. See Also connector, PHP, PHP API.

consistent read
A read operation that uses snapshot information to present query results based on a point in time, regardless of changes performed by other transactions running at the same time. If queried data has been changed by another transaction, the original data is reconstructed based on the contents of the undo log. This technique avoids some of the locking issues that can reduce concurrency by forcing transactions to wait for other transactions to finish.

With REPEATABLE READ isolation level, the snapshot is based on the time when the first read operation is performed. With READ COMMITTED isolation level, the snapshot is reset to the time of each consistent read operation.

Consistent read is the default mode in which InnoDB processes SELECT statements in READ COMMITTED and REPEATABLE READ isolation levels. Because a consistent read does not set any locks on the tables it accesses, other sessions are free to modify those tables while a consistent read is being performed on the table.

For technical details about the applicable isolation levels, see Section 14.7.2.3, “Consistent Nonlocking Reads”. See Also concurrency, isolation level, locking, READ COMMITTED, REPEATABLE READ, snapshot, transaction, undo log.

constraint
An automatic test that can block database changes to prevent data from becoming inconsistent. (In computer science terms, a kind of assertion related to an invariant condition.) Constraints are a crucial component of the ACID philosophy, to maintain data consistency. Constraints supported by MySQL include FOREIGN KEY constraints and unique constraints. See Also ACID, foreign key, unique constraint.

counter
A value that is incremented by a particular kind of InnoDB operation. Useful for measuring how busy a server is, troubleshooting the sources of performance issues, and testing whether changes (for example, to configuration settings or indexes used by queries) have the desired low-level effects. Different kinds of counters are available through Performance Schema tables and INFORMATION_SCHEMA tables, particularly INFORMATION_SCHEMA.INNODB_METRICS. See Also INFORMATION_SCHEMA, metrics counter, Performance Schema.

covering index
An index that includes all the columns retrieved by a query. Instead of using the index values as pointers to find the full table rows, the query returns values from the index structure, saving disk I/O. InnoDB can apply this optimization technique to more indexes than MyISAM can, because InnoDB secondary indexes also include the
**primary key** columns. InnoDB cannot apply this technique for queries against tables modified by a transaction, until that transaction ends.

Any **column index** or **composite index** could act as a covering index, given the right query. Design your indexes and queries to take advantage of this optimization technique wherever possible.  
See Also column index, composite index, index, primary key, secondary index.

**CPU-bound**

A type of **workload** where the primary **bottleneck** is CPU operations in memory. Typically involves read-intensive operations where the results can all be cached in the **buffer pool**.
See Also bottleneck, buffer pool, workload.

**crash**

MySQL uses the term “crash” to refer generally to any unexpected **shutdown** operation where the server cannot do its normal cleanup. For example, a crash could happen due to a hardware fault on the database server machine or storage device; a power failure; a potential data mismatch that causes the MySQL server to halt; a **fast shutdown** initiated by the DBA; or many other reasons. The robust, automatic **crash recovery** for InnoDB tables ensures that data is made consistent when the server is restarted, without any extra work for the DBA.  
See Also crash recovery, fast shutdown, InnoDB, shutdown.

**crash recovery**

The cleanup activities that occur when MySQL is started again after a **crash**. For InnoDB tables, changes from incomplete transactions are replayed using data from the **redo log**. Changes that were **committed** before the crash, but not yet written into the **data files**, are reconstructed from the **doublewrite buffer**. When the database is shut down normally, this type of activity is performed during shutdown by the **purge** operation.

During normal operation, committed data can be stored in the **change buffer** for a period of time before being written to the data files. There is always a tradeoff between keeping the data files up-to-date, which introduces performance overhead during normal operation, and buffering the data, which can make shutdown and crash recovery take longer.  
See Also change buffer, commit, crash, data files, doublewrite buffer, InnoDB, purge, redo log.

**CRUD**

Acronym for “create, read, update, delete”, a common sequence of operations in database applications. Often denotes a class of applications with relatively simple database usage (basic **DDL**, **DML** and **query** statements in **SQL**) that can be implemented quickly in any language.  
See Also DDL, DML, query, SQL.

**cursor**

An internal MySQL data structure that represents the result set of an SQL statement. Often used with **prepared statements** and **dynamic SQL**. It works like an iterator in other high-level languages, producing each value from the result set as requested.

Although SQL usually handles the processing of cursors for you, you might delve into the inner workings when dealing with performance-critical code.  
See Also dynamic SQL, prepared statement, query.

**D**

data definition language

See **DDL**.

data dictionary

Metadata that keeps track of InnoDB-related objects such as **tables**, **indexes**, and table **columns**. This metadata is physically located in the **InnoDB system tablespace**. For historical reasons, it overlaps to some degree with information stored in the **.frm files**.
Because the MySQL Enterprise Backup product always backs up the system tablespace, all backups include the contents of the data dictionary.

See Also column, file-per-table, .frm file, index, MySQL Enterprise Backup, system tablespace, table.

data directory
The directory under which each MySQL instance keeps the data files for InnoDB and the directories representing individual databases. Controlled by the datadir configuration option.

See Also data files, instance.

data files
The files that physically contain table and index data.

The InnoDB system tablespace, which holds the InnoDB data dictionary and is capable of holding data for multiple InnoDB tables, is represented by one or more .ibdata data files.

File-per-table tablespaces, which hold data for a single InnoDB table, are represented by a .ibd data file.

General tablespaces (introduced in MySQL 5.7.6), which can hold data for multiple InnoDB tables, are also represented by a .ibd data file.

See Also data dictionary, file-per-table, general tablespace, .ibd file, ibdata file, index, system tablespace, table, tablespace.

data manipulation language
See DML.

data warehouse
A database system or application that primarily runs large queries. The read-only or read-mostly data might be organized in denormalized form for query efficiency. Can benefit from the optimizations for read-only transactions in MySQL 5.6 and higher. Contrast with OLTP.

See Also denormalized, OLTP, query, read-only transaction.

database
Within the MySQL data directory, each database is represented by a separate directory. The InnoDB system tablespace, which can hold table data from multiple databases within a MySQL instance, is kept in data files that reside outside of individual database directories. When file-per-table mode is enabled, the .ibd files representing individual InnoDB tables are stored inside the database directories unless created elsewhere using the DATA DIRECTORY clause. General tablespaces, introduced in MySQL 5.7.6, also hold table data in .ibd files. Unlike file-per-table .ibd files, general tablespace .ibd files can hold table data from multiple databases within a MySQL instance, and can be assigned to directories relative to or independent of the MySQL data directory.

For long-time MySQL users, a database is a familiar notion. Users coming from an Oracle Database background may find that the MySQL meaning of a database is closer to what Oracle Database calls a schema.

See Also data files, file-per-table, .ibd file, ibdata file, index, system tablespace.

DCL
Data control language, a set of SQL statements for managing privileges. In MySQL, consists of the GRANT and REVOKE statements. Contrast with DDL and DML.

See Also DDL, DML, SQL.

DDEX provider
A feature that lets you use the data design tools within Visual Studio to manipulate the schema and objects within a MySQL database. For MySQL applications using Connector.NET, the MySQL Visual Studio Plugin acts as a DDEX provider with MySQL 5.0 and later.

See Also Visual Studio.
DDL
Data definition language, a set of SQL statements for manipulating the database itself rather than individual table rows. Includes all forms of the CREATE, ALTER, and DROP statements. Also includes the TRUNCATE statement, because it works differently than a DELETE FROM table_name statement, even though the ultimate effect is similar.

DDL statements automatically commit the current transaction; they cannot be rolled back.

The InnoDB online DDL feature enhances performance for CREATE INDEX, DROP INDEX, and many types of ALTER TABLE operations. See Section 14.13, “InnoDB and Online DDL” for more information. Also, the InnoDB file-per-table setting can affect the behavior of DROP TABLE and TRUNCATE TABLE operations.

Contrast with DML and DCL.
See Also commit, DCL, DML, file-per-table, rollback, SQL, transaction.

deadlock
A situation where different transactions are unable to proceed, because each holds a lock that the other needs. Because both transactions are waiting for a resource to become available, neither one ever releases the locks it holds.

A deadlock can occur when the transactions lock rows in multiple tables (through statements such as UPDATE or SELECT ... FOR UPDATE), but in the opposite order. A deadlock can also occur when such statements lock ranges of index records and gaps, with each transaction acquiring some locks but not others due to a timing issue.

For background information on how deadlocks are automatically detected and handled, see Section 14.7.5.2, “Deadlock Detection”. For tips on avoiding and recovering from deadlock conditions, see Section 14.7.5.3, “How to Minimize and Handle Deadlocks”.
See Also gap, lock, transaction.

deadlock detection
A mechanism that automatically detects when a deadlock occurs, and automatically rolls back one of the transactions involved (the victim).
See Also deadlock, rollback, transaction, victim.

delete
When InnoDB processes a DELETE statement, the rows are immediately marked for deletion and no longer are returned by queries. The storage is reclaimed sometime later, during the periodic garbage collection known as the purge operation. For removing large quantities of data, related operations with their own performance characteristics are TRUNCATE and DROP.
See Also drop, purge, truncate.

delete buffering
The technique of storing changes to secondary index pages, resulting from DELETE operations, in the change buffer rather than writing the changes immediately, so that the physical writes can be performed to minimize random I/O. (Because delete operations are a two-step process, this operation buffers the write that normally marks an index record for deletion.) It is one of the types of change buffering; the others are insert buffering and purge buffering.
See Also change buffer, change buffering, insert buffer, insert buffering, purge buffering.

denormalized
A data storage strategy that duplicates data across different tables, rather than linking the tables with foreign keys and join queries. Typically used in data warehouse applications, where the data is not updated after loading. In such applications, query performance is more important than making it simple to maintain consistent data during updates. Contrast with normalized.
See Also data warehouse, foreign key, join, normalized.

descending index
A type of index available with some database systems, where index storage is optimized to process ORDER BY column DESC clauses. Currently, although MySQL allows the DESC keyword in the CREATE TABLE statement, it does not use any special storage layout for the resulting index.
See Also index.

dirty page
A page in the InnoDB buffer pool that has been updated in memory, where the changes are not yet written (flushed) to the data files. The opposite of a clean page.
See Also buffer pool, clean page, data files, flush, page.

dirty read
An operation that retrieves unreliable data, data that was updated by another transaction but not yet committed. It is only possible with the isolation level known as read uncommitted.

This kind of operation does not adhere to the ACID principle of database design. It is considered very risky, because the data could be rolled back, or updated further before being committed; then, the transaction doing the dirty read would be using data that was never confirmed as accurate.

Its opposite is consistent read, where InnoDB ensures that a transaction does not read information updated by another transaction, even if the other transaction commits in the meantime.
See Also ACID, commit, consistent read, isolation level, READ UNCOMMITTED, rollback.

disk-based
A kind of database that primarily organizes data on disk storage (hard drives or equivalent). Data is brought back and forth between disk and memory to be operated upon. It is the opposite of an in-memory database. Although InnoDB is disk-based, it also contains features such as the buffer pool, multiple buffer pool instances, and the adaptive hash index that allow certain kinds of workloads to work primarily from memory.
See Also adaptive hash index, buffer pool, in-memory database.

disk-bound
A type of workload where the primary bottleneck is disk I/O. (Also known as I/O-bound.) Typically involves frequent writes to disk, or random reads of more data than can fit into the buffer pool.
See Also bottleneck, buffer pool, workload.

DML
Data manipulation language, a set of SQL statements for performing INSERT, UPDATE, and DELETE operations. The SELECT statement is sometimes considered as a DML statement, because the SELECT ... FOR UPDATE form is subject to the same considerations for locking as INSERT, UPDATE, and DELETE.

DML statements for an InnoDB table operate in the context of a transaction, so their effects can be committed or rolled back as a single unit.

Contrast with DDL and DCL.
See Also commit, DCL, DDL, locking, rollback, SQL, transaction.

document id
In the InnoDB full-text search feature, a special column in the table containing the FULLTEXT index, to uniquely identify the document associated with each ilist value. Its name is PTS_DOC_ID (uppercase required). The column itself must be of BIGINT UNSIGNED NOT NULL type, with a unique index named PTS_DOC_ID_INDEX. Preferably, you define this column when creating the table. If InnoDB must add the column to the table while creating a FULLTEXT index, the indexing operation is considerably more expensive.
See Also full-text search, FULLTEXT index, ilist.
**doublewrite buffer**

*InnoDB* uses a file flush technique called doublewrite. Before writing pages to the data files, *InnoDB* first writes them to a storage area called the doublewrite buffer. Only after the write and the flush to the doublewrite buffer have completed, does *InnoDB* write the pages to their proper positions in the data file. If there is an operating system, storage subsystem, or *mysql* process crash in the middle of a page write, *InnoDB* can later find a good copy of the page from the doublewrite buffer during crash recovery.

Although data is always written twice, the doublewrite buffer does not require twice as much I/O overhead or twice as many I/O operations. Data is written to the buffer itself as a large sequential chunk, with a single `fsync()` call to the operating system.

To turn off the doublewrite buffer, specify the option `innodb_doublewrite=0`.

See Also crash recovery, data files, page, purge.

drop

A kind of **DDL** operation that removes a schema object, through a statement such as *DROP TABLE* or *DROP INDEX*. It maps internally to an *ALTER TABLE* statement. From an *InnoDB* perspective, the performance considerations of such operations involve the time that the data dictionary is locked to ensure that interrelated objects are all updated, and the time to update memory structures such as the buffer pool. For a table, the drop operation has somewhat different characteristics than a *truncate* operation (*TRUNCATE TABLE* statement).

See Also buffer pool, data dictionary, DDL, table, truncate.

**DSN**

Acronym for “Database Source Name”. It is the encoding for connection information within Connector/ODBC. See *Configuring a Connector/ODBC DSN on Windows* for full details. It is the equivalent of the connection string used by Connector/.NET.

See Also connection, connection string, Connector/.NET, Connector/ODBC.

dynamic cursor

A type of **cursor** supported by ODBC that can pick up new and changed results when the rows are read again. Whether and how quickly the changes are visible to the cursor depends on the type of table involved (transactional or non-transactional) and the isolation level for transactional tables. Support for dynamic cursors must be explicitly enabled.

See Also cursor, ODBC.

dynamic row format

A row format introduced in the *InnoDB* Plugin, available as part of the Barracuda file format. Because long variable-length column values are stored outside of the page that holds the row data, it is very efficient for rows that include large objects. Since the large fields are typically not accessed to evaluate query conditions, they are not brought into the buffer pool as often, resulting in fewer I/O operations and better utilization of cache memory.

As of MySQL 5.7.9, the default row format is defined by `innodb_default_row_format`, which has a default value of DYNAMIC.

For additional information about *InnoDB* DYNAMIC row format, see DYNAMIC Row Format.

See Also Barracuda, buffer pool, file format, row format.

dynamic SQL

A feature that lets you create and execute **prepared statements** using more robust, secure, and efficient methods to substitute parameter values than the naive technique of concatenating the parts of the statement into a string variable.

See Also prepared statement.

dynamic statement

A **prepared statement** created and executed through **dynamic SQL**.

See Also dynamic SQL, prepared statement.
early adopter
A stage similar to beta, when a software product is typically evaluated for performance, functionality, and compatibility in a non-mission-critical setting.
See Also beta.

Eiffel
A programming language including many object-oriented features. Some of its concepts are familiar to Java and C# developers. For the open-source Eiffel API for MySQL, see Section 23.13, “MySQL Eiffel Wrapper”.
See Also API, C#, Java.

embedded
The embedded MySQL server library (libmysqld) makes it possible to run a full-featured MySQL server inside a client application. The main benefits are increased speed and more simple management for embedded applications.
See Also client, libmysqld.

error log
A type of log showing information about MySQL startup and critical runtime errors and crash information. For details, see Section 5.4.2, “The Error Log”.
See Also crash, log.
eviction
The process of removing an item from a cache or other temporary storage area, such as the InnoDB buffer pool. Often, but not always, uses the LRU algorithm to determine which item to remove. When a dirty page is evicted, its contents are flushed to disk, and any dirty neighbor pages might be flushed also.
See Also buffer pool, dirty page, flush, LRU, neighbor page.

exception interceptor
A type of interceptor for tracing, debugging, or augmenting SQL errors encountered by a database application. For example, the interceptor code could issue a SHOW WARNINGS statement to retrieve additional information, and add descriptive text or even change the type of the exception returned to the application. Because the interceptor code is only called when SQL statements return errors, it does not impose any performance penalty on the application during normal (error-free) operation.

In Java applications using Connector/J, setting up this type of interceptor involves implementing the com.mysql.jdbc.ExceptionInterceptor interface, and adding a exceptionInterceptors property to the connection string.

In Visual Studio applications using Connector/NET, setting up this type of interceptor involves defining a class that inherits from the BaseExceptionInterceptor class and specifying that class name as part of the connection string.
See Also Connector/J, Connector/NET, interceptor, Java, Visual Studio.
external lock
A kind of lock that prevents any other transaction from locking the same row. Depending on the transaction isolation level, this kind of lock might block other transactions from writing to the same row, or might also block other transactions from reading the same row. The default InnoDB isolation level, REPEATABLE READ, enables higher concurrency by allowing transactions to read rows that have exclusive locks, a technique known as consistent read.
See Also concurrency, consistent read, isolation level, lock, REPEATABLE READ, shared lock, transaction.
extent
A group of pages within a tablespace. For the default page size of 16KB, an extent contains 64 pages. In MySQL 5.6, the page size for an InnoDB instance can be 4KB, 8KB, or 16KB, controlled by the
**InnoDB** page size configuration option. For 4KB, 8KB, and 16KB pages sizes, the extent size is always 1MB (or 1048576 bytes).

Support for 32KB and 64KB InnoDB page sizes was added in MySQL 5.7.6. For a 32KB page size, the extent size is 2MB. For a 64KB page size, the extent size is 4MB.

**InnoDB** features such as segments, read-ahead requests and the doublewrite buffer use I/O operations that read, write, allocate, or free data one extent at a time.

See Also doublewrite buffer, page, page size, read-ahead, segment, tablespace.

### F

**.frm file**

A file containing the metadata, such as the table definition, of a MySQL table.

For backups, you must always keep the full set of .frm files along with the backup data to be able to restore tables that are altered or dropped after the backup.

Although each InnoDB table has a .frm file, InnoDB maintains its own table metadata in the system tablespace.

.frn files are backed up by the MySQL Enterprise Backup product. These files must not be modified by an ALTER TABLE operation while the backup is taking place, which is why backups that include non-InnoDB tables perform a FLUSH TABLES WITH READ LOCK operation to freeze such activity while backing up .frm files. Restoring a backup can result in .frm files being created, changed, or removed to match the state of the database at the time of the backup.

See Also data dictionary, MySQL Enterprise Backup, system tablespace.

**failover**

The ability to automatically switch to a standby server in the event of a failure. In the MySQL context, failover involves a standby database server. Often supported within J2EE environments by the application server or framework.

See Also Connector/J, J2EE.

**Fast Index Creation**

A capability first introduced in the InnoDB Plugin, now part of MySQL in 5.5 and higher, that speeds up creation of InnoDB secondary indexes by avoiding the need to completely rewrite the associated table. The speedup applies to dropping secondary indexes also.

Because index maintenance can add performance overhead to many data transfer operations, consider doing operations such as ALTER TABLE ... ENGINE=INNODB or INSERT INTO ... SELECT * FROM ... without any secondary indexes in place, and creating the indexes afterward.

In MySQL 5.6, this feature becomes more general. You can read and write to tables while an index is being created, and many more kinds of ALTER TABLE operations can be performed without copying the table, without blocking DML operations, or both. Thus in MySQL 5.6 and higher, this set of features is referred to as online DDL rather than Fast Index Creation.

For related information, see Section 14.13, “InnoDB and Online DDL”.

See Also DML, index, online DDL, secondary index.

**fast shutdown**

The default shutdown procedure for InnoDB, based on the configuration setting innodb_fast_shutdown=1. To save time, certain flush operations are skipped. This type of shutdown is safe during normal usage, because
the flush operations are performed during the next startup, using the same mechanism as in crash recovery. In cases where the database is being shut down for an upgrade or downgrade, do a slow shutdown instead to ensure that all relevant changes are applied to the data files during the shutdown. See Also crash recovery, data files, flush, shutdown, slow shutdown.

file format
The file format for InnoDB tables, enabled using the innodb_file_format configuration option. Supported file formats are Antelope and Barracuda. Antelope is the original InnoDB file format and supports the REDUNDANT and COMPACT row formats. Barracuda is the newer InnoDB file format and supports the COMPRESSED and DYNAMIC row formats. See Also Antelope, Barracuda, file-per-table, .ibd file, ibdata file, row format.

file-per-table
A general name for the setting controlled by the innodb_file_per_table option, which is an important configuration option that affects aspects of InnoDB file storage, availability of features, and I/O characteristics. As of MySQL 5.6.7, innodb_file_per_table is enabled by default.

With the innodb_file_per_table option enabled, you can create a table in its own .ibd file rather than in the shared ibdata files of the system tablespace. When table data is stored in an individual .ibd file, you have more flexibility to choose row formats required for features such as data compression. The TRUNCATE TABLE operation is also faster, and reclaimed space can be used by the operating system rather than remaining reserved for InnoDB.

The MySQL Enterprise Backup product is more flexible for tables that are in their own files. For example, tables can be excluded from a backup, but only if they are in separate files. Thus, this setting is suitable for tables that are backed up less frequently or on a different schedule. See Also compressed row format, compression, file format, .ibd file, ibdata file, innodb_file_per_table, MySQL Enterprise Backup, row format, system tablespace.

fill factor
In an InnoDB index, the proportion of a page that is taken up by index data before the page is split. The unused space when index data is first divided between pages allows for rows to be updated with longer string values without requiring expensive index maintenance operations. If the fill factor is too low, the index consumes more space than needed, causing extra I/O overhead when reading the index. If the fill factor is too high, any update that increases the length of column values can cause extra I/O overhead for index maintenance. See Section 14.6.2.2, “The Physical Structure of an InnoDB Index” for more information. See Also index, page.

fixed row format
This row format is used by the MyISAM storage engine, not by InnoDB. If you create an InnoDB table with the option ROW_FORMAT=FIXED in MySQL 5.7.6 or earlier, InnoDB uses the compact row format instead, although the FIXED value might still show up in output such as SHOW TABLE STATUS reports. As of MySQL 5.7.7, InnoDB returns an error if ROW_FORMAT=FIXED is specified. See Also compact row format, row format.

flush
To write changes to the database files, that had been buffered in a memory area or a temporary disk storage area. The InnoDB storage structures that are periodically flushed include the redo log, the undo log, and the buffer pool.

Flushing can happen because a memory area becomes full and the system needs to free some space, because a commit operation means the changes from a transaction can be finalized, or because a slow shutdown operation means that all outstanding work should be finalized. When it is not critical to flush all the buffered data at once, InnoDB can use a technique called fuzzy checkpointing to flush small batches of pages to spread out the I/O overhead.
See Also buffer pool, commit, fuzzy checkpointing, redo log, slow shutdown, undo log.

flush list
An internal InnoDB data structure that tracks dirty pages in the buffer pool: that is, pages that have been changed and need to be written back out to disk. This data structure is updated frequently by InnoDB internal mini-transactions, and so is protected by its own mutex to allow concurrent access to the buffer pool.
See Also buffer pool, dirty page, LRU, mini-transaction, mutex, page, page cleaner.

foreign key
A type of pointer relationship, between rows in separate InnoDB tables. The foreign key relationship is defined on one column in both the parent table and the child table.

In addition to enabling fast lookup of related information, foreign keys help to enforce referential integrity, by preventing any of these pointers from becoming invalid as data is inserted, updated, and deleted. This enforcement mechanism is a type of constraint. A row that points to another table cannot be inserted if the associated foreign key value does not exist in the other table. If a row is deleted or its foreign key value changed, and rows in another table point to that foreign key value, the foreign key can be set up to prevent the deletion, cause the corresponding column values in the other table to become null, or automatically delete the corresponding rows in the other table.

One of the stages in designing a normalized database is to identify data that is duplicated, separate that data into a new table, and set up a foreign key relationship so that the multiple tables can be queried like a single table, using a join operation.
See Also child table, FOREIGN KEY constraint, join, normalized, NULL, parent table, referential integrity, relational.

FOREIGN KEY constraint
The type of constraint that maintains database consistency through a foreign key relationship. Like other kinds of constraints, it can prevent data from being inserted or updated if data would become inconsistent; in this case, the inconsistency being prevented is between data in multiple tables. Alternatively, when a DML operation is performed, FOREIGN KEY constraints can cause data in child rows to be deleted, changed to different values, or set to null, based on the ON CASCADE option specified when creating the foreign key.
See Also child table, constraint, DML, foreign key, NULL.

FTS
In most contexts, an acronym for full-text search. Sometimes in performance discussions, an acronym for full table scan.
See Also full table scan, full-text search.

full backup
A backup that includes all the tables in each MySQL database, and all the databases in a MySQL instance. Contrast with partial backup.
See Also backup, database, instance, partial backup, table.

full table scan
An operation that requires reading the entire contents of a table, rather than just selected portions using an index. Typically performed either with small lookup tables, or in data warehousing situations with large tables where all available data is aggregated and analyzed. How frequently these operations occur, and the sizes of the tables relative to available memory, have implications for the algorithms used in query optimization and managing the buffer pool.

The purpose of indexes is to allow lookups for specific values or ranges of values within a large table, thus avoiding full table scans when practical.
See Also buffer pool, index.
The MySQL feature for finding words, phrases, Boolean combinations of words, and so on within table data, in a faster, more convenient, and more flexible way than using the SQL LIKE operator or writing your own application-level search algorithm. It uses the SQL function MATCH() and FULLTEXT indexes.

See Also FULLTEXT index.

FULLTEXT index
The special kind of index that holds the search index in the MySQL full-text search mechanism. Represents the words from values of a column, omitting any that are specified as stopwords. Originally, only available for MyISAM tables. Starting in MySQL 5.6.4, it is also available for InnoDB tables.
See Also full-text search, index, InnoDB, search index, stopword.

fuzzy checkpointing
A technique that flushes small batches of dirty pages from the buffer pool, rather than flushing all dirty pages at once which would disrupt database processing.
See Also buffer pool, dirty page, flush.

G

GA
“Generally available”, the stage when a software product leaves beta and is available for sale, official support, and production use.
See Also beta.

GAC
Acronym for “Global Assembly Cache”. A central area for storing libraries (assemblies) on a .NET system. Physically consists of nested folders, treated as a single virtual folder by the .NET CLR.
See Also .NET, assembly.

gap
A place in an InnoDB index data structure where new values could be inserted. When you lock a set of rows with a statement such as SELECT ... FOR UPDATE, InnoDB can create locks that apply to the gaps as well as the actual values in the index. For example, if you select all values greater than 10 for update, a gap lock prevents another transaction from inserting a new value that is greater than 10. The supremum record and infimum record represent the gaps containing all values greater than or less than all the current index values.
See Also concurrency, gap lock, index, infimum record, isolation level, supremum record.

gap lock
A lock on a gap between index records, or a lock on the gap before the first or after the last index record. For example, SELECT c1 FROM t WHERE c1 BETWEEN 10 and 20 FOR UPDATE; prevents other transactions from inserting a value of 15 into the column t.c1, whether or not there was already any such value in the column, because the gaps between all existing values in the range are locked. Contrast with record lock and next-key lock.

Gap locks are part of the tradeoff between performance and concurrency, and are used in some transaction isolation levels and not others.
See Also gap, infimum record, lock, next-key lock, record lock, supremum record.

general log
See general query log.

general query log
A type of log used for diagnosis and troubleshooting of SQL statements processed by the MySQL server. Can be stored in a file or in a database table. You must enable this feature through the general_log configuration option to use it. You can disable it for a specific connection through the sql_log_off configuration option.
Records a broader range of queries than the **slow query log**. Unlike the **binary log**, which is used for replication, the general query log contains **SELECT** statements and does not maintain strict ordering. For more information, see Section 5.4.3, “The General Query Log”.

See Also `binary log`, `log`, `slow query log`.

**general tablespace**

A shared **InnoDB tablespace** created using `CREATE TABLESPACE` syntax. General tablespaces can be created outside of the MySQL data directory, are capable of holding multiple **tables**, and support tables of all row formats. General tablespaces were introduced in MySQL 5.7.6.

Tables are added to a general tablespace using `CREATE TABLE tbl_name ... TABLESPACE [=] tablespace_name` or `ALTER TABLE tbl_name TABLESPACE [=] tablespace_name` syntax.

Contrast with **system tablespace** and **file-per-table** tablespace.

For more information, see **General Tablespaces**.

See Also `file-per-table`, `system tablespace`, `table`, `tablespace`.

**Glassfish**

See Also `J2EE`.

**global transaction**

A type of **transaction** involved in **XA** operations. It consists of several actions that are transactional in themselves, but that all must either complete successfully as a group, or all be rolled back as a group. In essence, this extends **ACID** properties “up a level” so that multiple ACID transactions can be executed in concert as components of a global operation that also has ACID properties.

See Also `ACID`, `transaction`, `XA`.

**group commit**

An **InnoDB** optimization that performs some low-level I/O operations (log write) once for a set of **commit** operations, rather than flushing and syncing separately for each commit.

See Also `binary log`, `commit`.

**GUID**

Acronym for “globally unique identifier”, an ID value that can be used to associate data across different databases, languages, operating systems, and so on. (As an alternative to using sequential integers, where the same values could appear in different tables, databases, and so on referring to different data.) Older MySQL versions represented it as `BINARY(16)`. Currently, it is represented as `CHAR(36)`. MySQL has a `UUID()` function that returns GUID values in character format, and a `UUID_SHORT()` function that returns GUID values in integer format. Because successive GUID values are not necessarily in ascending sort order, it is not an efficient value to use as a primary key for large InnoDB tables.

**H**

**hash index**

A type of **index** intended for queries that use equality operators, rather than range operators such as greater-than or `BETWEEN`. It is available for **MEMORY** tables. Although hash indexes are the default for **MEMORY** tables for historic reasons, that storage engine also supports **B-tree** indexes, which are often a better choice for general-purpose queries.

MySQL includes a variant of this index type, the **adaptive hash index**, that is constructed automatically for **InnoDB** tables if needed based on runtime conditions.

See Also `adaptive hash index`, `B-tree`, `index`, `InnoDB`.
HDD
Acronym for “hard disk drive”. Refers to storage media using spinning platters, usually when comparing and contrasting with SSD. Its performance characteristics can influence the throughput of a disk-based workload. See Also disk-based, SSD.

heartbeat
A periodic message that is sent to indicate that a system is functioning properly. In a replication context, if the source stops sending such messages, one of the replicas can take its place. Similar techniques can be used between the servers in a cluster environment, to confirm that all of them are operating properly. See Also replication, source.

high-water mark
A value representing an upper limit, either a hard limit that should not be exceeded at runtime, or a record of the maximum value that was actually reached. Contrast with low-water mark. See Also low-water mark.

history list
A list of transactions with delete-marked records scheduled to be processed by the InnoDB purge operation. Recorded in the undo log. The length of the history list is reported by the command SHOW ENGINE INNODB STATUS. If the history list grows longer than the value of the innodb_max_purge_lag configuration option, each DML operation is delayed slightly to allow the purge operation to finish flushing the deleted records.

Also known as purge lag.
See Also DML, flush, purge, purge lag, rollback segment, transaction, undo log.

hole punching
Releasing empty blocks from a page. The InnoDB transparent page compression feature relies on hole punching support. For more information, see InnoDB Page Compression. See Also sparse file, transparent page compression.

host
The network name of a database server, used to establish a connection. Often specified in conjunction with a port. In some contexts, the IP address 127.0.0.1 works better than the special name localhost for accessing a database on the same server as the application. See Also connection, localhost, port.

hot
A condition where a row, table, or internal data structure is accessed so frequently, requiring some form of locking or mutual exclusion, that it results in a performance or scalability issue.

Although “hot” typically indicates an undesirable condition, a hot backup is the preferred type of backup. See Also hot backup.

hot backup
A backup taken while the database is running and applications are reading and writing to it. The backup involves more than simply copying data files: it must include any data that was inserted or updated while the backup was in process; it must exclude any data that was deleted while the backup was in process; and it must ignore any changes that were not committed.

The Oracle product that performs hot backups, of InnoDB tables especially but also tables from MyISAM and other storage engines, is known as MySQL Enterprise Backup.

The hot backup process consists of two stages. The initial copying of the data files produces a raw backup. The apply step incorporates any changes to the database that happened while the backup was running. Applying the changes produces a prepared backup; these files are ready to be restored whenever necessary. See Also apply, MySQL Enterprise Backup, prepared backup, raw backup.
.ibd file
The data file for file-per-table tablespaces and general tablespaces. File-per-table tablespace .ibd files contain a single table and associated index data. General tablespace .ibd files may contain table and index data for multiple tables. General tablespaces were introduced in MySQL 5.7.6.

The .ibd file extension does not apply to the system tablespace, which consists of one or more ibdata files.

If a file-per-table tablespace or general tablespace is created with the DATA DIRECTORY = clause, the .ibd file is located at the specified path, outside the normal data directory, and is pointed to by a .isl file.

When a .ibd file is included in a compressed backup by the MySQL Enterprise Backup product, the compressed equivalent is a .ibz file.
See Also database, file-per-table, general tablespace, ibdata file, .ibz file, innodb_file_per_table, .isl file, MySQL Enterprise Backup, system tablespace.

.ibz file
When the MySQL Enterprise Backup product performs a compressed backup, it transforms each tablespace file that is created using the file-per-table setting from a .ibd extension to a .ibz extension.

The compression applied during backup is distinct from the compressed row format that keeps table data compressed during normal operation. A compressed backup operation skips the compression step for a tablespace that is already in compressed row format, as compressing a second time would slow down the backup but produce little or no space savings.
See Also compressed backup, compressed row format, file-per-table, .ibd file, MySQL Enterprise Backup, tablespace.

.isl file
A file that specifies the location of an .ibd file for an InnoDB table created with the DATA DIRECTORY = clause in MySQL 5.6 and higher, or with the CREATE TABLESPACE ... ADD DATAFILE clause in MySQL 5.7 and higher. It functions like a symbolic link, without the platform restrictions of the actual symbolic link mechanism. You can store InnoDB tablespace outside the database directory, for example, on an especially large or fast storage device depending on the usage of the table. For details, see Section 14.6.1.2, “Creating Tables Externally”, and General Tablespaces.
See Also database, .ibd file, table, tablespace.

I/O-bound
See disk-bound.

ib-file set
The set of files managed by InnoDB within a MySQL database: the system tablespace, file-per-table tablespace files, and redo log files. Depending on MySQL version and InnoDB configuration, may also include general tablespace, temporary tablespace, and undo tablespace files. This term is sometimes used in detailed discussions of InnoDB file structures and formats to refer to the set of files managed by InnoDB within a MySQL database.
See Also database, file-per-table, general tablespace, redo log, system tablespace, temporary tablespace, undo tablespace.

ibbackup_logfile
A supplemental backup file created by the MySQL Enterprise Backup product during a hot backup operation. It contains information about any data changes that occurred while the backup was running. The initial backup files, including ibbackup_logfile, are known as a raw backup, because the changes that occurred during the backup operation are not yet incorporated. After you perform the apply step to the raw backup files, the resulting files do include those final data changes, and are known as a prepared backup. At this stage, the ibbackup_logfile file is no longer necessary.
See Also **apply**, **hot backup**, **MySQL Enterprise Backup**, **prepared backup**, **raw backup**.

**ibdata file**
A set of files with names such as `ibdata1`, `ibdata2`, and so on, that make up the **InnoDB system tablespace**. For information about the structures and data that reside in the system tablespace `ibdata` files, see Section 14.6.3.1, “The System Tablespace”.

Growth of the `ibdata` files is influenced by the `innodb_autoextend_increment` configuration option.
See Also **change buffer**, **data dictionary**, **doublewrite buffer**, **file-per-table**, `.ibd file`, `innodb_file_per_table`, **system tablespace**, **undo log**.

**ibtmp file**
The **InnoDB temporary tablespace data file** for non-compressed **InnoDB temporary tables** and related objects. The configuration file option, `innodb_temp_data_file_path`, allows users to define a relative path for the temporary tablespace data file. If `innodb_temp_data_file_path` is not specified, the default behavior is to create a single auto-extending 12MB data file named `ibtmp1` in the data directory, alongside `ibdata1`.
See Also **data files**, **temporary table**, **temporary tablespace**.

**ib_logfile**
A set of files, typically named `ib_logfile0` and `ib_logfile1`, that form the **redo log**. Also sometimes referred to as the **log group**. These files record statements that attempt to change data in InnoDB tables. These statements are replayed automatically to correct data written by incomplete transactions, on startup following a crash.

This data cannot be used for manual recovery; for that type of operation, use the **binary log**.
See Also **binary log**, **log group**, **redo log**.

**ilist**
Within an **InnoDB FULLTEXT index**, the data structure consisting of a document ID and positional information for a token (that is, a particular word).
See Also **FULLTEXT index**.

**implicit row lock**
A row lock that InnoDB acquires to ensure consistency, without you specifically requesting it.
See Also **row lock**.

**in-memory database**
A type of database system that maintains data in memory, to avoid overhead due to disk I/O and translation between disk blocks and memory areas. Some in-memory databases sacrifice durability (the “D” in the **ACID** design philosophy) and are vulnerable to hardware, power, and other types of failures, making them more suitable for read-only operations. Other in-memory databases do use durability mechanisms such as logging changes to disk or using non-volatile memory.

MySQL features that address the same kinds of memory-intensive processing include the **InnoDB buffer pool**, **adaptive hash index**, and **read-only transaction** optimization, the **MEMORY** storage engine, the **MyISAM** key cache, and the MySQL query cache.
See Also **ACID**, **adaptive hash index**, **buffer pool**, **disk-based**, **read-only transaction**.

**incremental backup**
A type of **hot backup**, performed by the **MySQL Enterprise Backup** product, that only saves data changed since some point in time. Having a full backup and a succession of incremental backups lets you reconstruct backup data over a long period, without the storage overhead of keeping several full backups on hand. You can restore the full backup and then apply each of the incremental backups in succession, or you can keep the full backup up-to-date by applying each incremental backup to it, then perform a single restore operation.

The granularity of changed data is at the **page** level. A page might actually cover more than one row. Each changed page is included in the backup.
index
A data structure that provides a fast lookup capability for rows of a table, typically by forming a tree structure (B-tree) representing all the values of a particular column or set of columns.

**InnoDB** tables always have a clustered index representing the primary key. They can also have one or more secondary indexes defined on one or more columns. Depending on their structure, secondary indexes can be classified as partial, column, or composite indexes.

Indexes are a crucial aspect of query performance. Database architects design tables, queries, and indexes to allow fast lookups for data needed by applications. The ideal database design uses a covering index where practical; the query results are computed entirely from the index, without reading the actual table data. Each foreign key constraint also requires an index, to efficiently check whether values exist in both the parent and child tables.

Although a B-tree index is the most common, a different kind of data structure is used for hash indexes, as in the MEMORY storage engine and the InnoDB adaptive hash index. R-tree indexes are used for spatial indexing of multi-dimensional information.

See Also adaptive hash index, B-tree, child table, clustered index, column index, composite index, covering index, foreign key, hash index, parent table, partial index, primary key, query, R-tree, row, secondary index, table.

index cache
A memory area that holds the token data for InnoDB full-text search. It buffers the data to minimize disk I/O when data is inserted or updated in columns that are part of a FULLTEXT index. The token data is written to disk when the index cache becomes full. Each InnoDB FULLTEXT index has its own separate index cache, whose size is controlled by the configuration option innodb_ft_cache_size.

See Also full-text search, FULLTEXT index.

index condition pushdown
Index condition pushdown (ICP) is an optimization that pushes part of a WHERE condition down to the storage engine if parts of the condition can be evaluated using fields from the index. ICP can reduce the number of times the storage engine must access the base table and the number of times the MySQL server must access the storage engine. For more information, see Section 8.2.1.5, “Index Condition Pushdown Optimization”.

See Also index, storage engine.

index hint
Extended SQL syntax for overriding the indexes recommended by the optimizer. For example, the FORCE INDEX, USE INDEX, and IGNORE INDEX clauses. Typically used when indexed columns have unevenly distributed values, resulting in inaccurate cardinality estimates.

See Also cardinality, index.

index prefix
In an index that applies to multiple columns (known as a composite index), the initial or leading columns of the index. A query that references the first 1, 2, 3, and so on columns of a composite index can use the index, even if the query does not reference all the columns in the index.

See Also composite index, index.

index statistics
See statistics.

infimum record
A pseudo-record in an index, representing the gap below the smallest value in that index. If a transaction has a statement such as SELECT ... FROM ... WHERE col < 10 FOR UPDATE;, and the smallest value in the column is 5, it is a lock on the infimum record that prevents other transactions from inserting even smaller values such as 0, -10, and so on.
See Also gap, index, pseudo-record, supremum record.

INFORMATION_SCHEMA

The name of the database that provides a query interface to the MySQL data dictionary. (This name is defined by the ANSI SQL standard.) To examine information (metadata) about the database, you can query tables such as INFORMATION_SCHEMA.TABLES and INFORMATION_SCHEMA.COLUMNS, rather than using SHOW commands that produce unstructured output.

The INFORMATION_SCHEMA database also contains tables specific to InnoDB that provide a query interface to the InnoDB data dictionary. You use these tables not to see how the database is structured, but to get real-time information about the workings of InnoDB tables to help with performance monitoring, tuning, and troubleshooting.

See Also data dictionary, database, InnoDB.

InnoDB

A MySQL component that combines high performance with transactional capability for reliability, robustness, and concurrent access. It embodies the ACID design philosophy. Represented as a storage engine; it handles tables created or altered with the ENGINE=INNODB clause. See Chapter 14, The InnoDB Storage Engine for architectural details and administration procedures, and Section 8.5, “Optimizing for InnoDB Tables” for performance advice.

In MySQL 5.5 and higher, InnoDB is the default storage engine for new tables and the ENGINE=INNODB clause is not required.

InnoDB tables are ideally suited for hot backups. See Section 24.2, “MySQL Enterprise Backup Overview” for information about the MySQL Enterprise Backup product for backing up MySQL servers without interrupting normal processing.

See Also ACID, hot backup, MySQL Enterprise Backup, storage engine, transaction.

innodb_autoinc_lock_mode

The innodb_autoinc_lock_mode option controls the algorithm used for auto-increment locking. When you have an auto-incrementing primary key, you can use statement-based replication only with the setting innodb_autoinc_lock_mode=1. This setting is known as consecutive lock mode, because multi-row inserts within a transaction receive consecutive auto-increment values. If you have innodb_autoinc_lock_mode=2, which allows higher concurrency for insert operations, use row-based replication rather than statement-based replication. This setting is known as interleaved lock mode, because multiple multi-row insert statements running at the same time can receive auto-increment values that are interleaved. The setting innodb_autoinc_lock_mode=0 should not be used except for compatibility purposes.

Consecutive lock mode (innodb_autoinc_lock_mode=1) is the default setting prior to MySQL 8.0.3. As of MySQL 8.0.3, interleaved lock mode (innodb_autoinc_lock_mode=2) is the default, which reflects the change from statement-based to row-based replication as the default replication type.

See Also auto-increment, auto-increment locking, mixed-mode insert, primary key.

innodb_file_format

The innodb_file_format option defines the file format to use for new InnoDB file-per-table tablespaces. Currently, you can specify the Antelope and Barracuda file formats.

See Also Antelope, Barracuda, file format, file-per-table, general tablespace, innodb_file_per_table, system tablespace, tablespace.

innodb_file_per_table

An important configuration option that affects many aspects of InnoDB file storage, availability of features, and I/O characteristics. In MySQL 5.6.7 and higher, it is enabled by default. The innodb_file_per_table option turns on file-per-table mode. With this mode enabled, a newly created InnoDB table and associated indexes can be stored in a file-per-table .ibd file, outside the system tablespace.
This option affects the performance and storage considerations for a number of SQL statements, such as DROP TABLE and TRUNCATE TABLE.

Enabling the innodb_file_per_table option allows you to take advantage of features such as table compression and named-table backups in MySQL Enterprise Backup.

For more information, see innodb_file_per_table, and Section 14.6.3.2, “File-Per-Table Tablespaces”. See Also compression, file-per-table, .ibd file, MySQL Enterprise Backup, system tablespace.

innodb_lock_wait_timeout
The innodb_lock_wait_timeout option sets the balance between waiting for shared resources to become available, or giving up and handling the error, retrying, or doing alternative processing in your application. Rolls back any InnoDB transaction that waits more than a specified time to acquire a lock. Especially useful if deadlocks are caused by updates to multiple tables controlled by different storage engines; such deadlocks are not detected automatically.
See Also deadlock, deadlock detection, lock, wait.

innodb_strict_mode
The innodb_strict_mode option controls whether InnoDB operates in strict mode, where conditions that are normally treated as warnings, cause errors instead (and the underlying statements fail).
See Also strict mode.

insert
One of the primary DML operations in SQL. The performance of inserts is a key factor in data warehouse systems that load millions of rows into tables, and OLTP systems where many concurrent connections might insert rows into the same table, in arbitrary order. If insert performance is important to you, you should learn about InnoDB features such as the insert buffer used in change buffering, and auto-increment columns.
See Also auto-increment, change buffering, data warehouse, DML, InnoDB, insert buffer, OLTP, SQL.

insert buffer
The former name of the change buffer. In MySQL 5.5, support was added for buffering changes to secondary index pages for DELETE and UPDATE operations. Previously, only changes resulting from INSERT operations were buffered. The preferred term is now change buffer.
See Also change buffer, change buffering.

insert buffering
The technique of storing changes to secondary index pages, resulting from INSERT operations, in the change buffer rather than writing the changes immediately, so that the physical writes can be performed to minimize random I/O. It is one of the types of change buffering; the others are delete buffering and purge buffering.

Insert buffering is not used if the secondary index is unique, because the uniqueness of new values cannot be verified before the new entries are written out. Other kinds of change buffering do work for unique indexes.
See Also change buffer, change buffering, delete buffering, insert buffer, purge buffering, unique index.

insert intention lock
A type of gap lock that is set by INSERT operations prior to row insertion. This type of lock signals the intent to insert in such a way that multiple transactions inserting into the same index gap need not wait for each other if they are not inserting at the same position within the gap. For more information, see Section 14.7.1, “InnoDB Locking”.
See Also gap lock, lock, next-key lock.

instance
A single mysqld daemon managing a data directory representing one or more databases with a set of tables. It is common in development, testing, and some replication scenarios to have multiple instances on the same server machine, each managing its own data directory and listening on its own port or socket. With one instance running a disk-bound workload, the server might still have extra CPU and memory capacity to run additional instances.
instrumentation
Modifications at the source code level to collect performance data for tuning and debugging. In MySQL, data collected by instrumentation is exposed through an SQL interface using the INFORMATION_SCHEMA and PERFORMANCE_SCHEMA databases.
See Also INFORMATION_SCHEMA, Performance Schema.

intention exclusive lock
See intention lock.

intention lock
A kind of lock that applies to the table, used to indicate the kind of lock the transaction intends to acquire on rows in the table. Different transactions can acquire different kinds of intention locks on the same table, but the first transaction to acquire an intention exclusive (IX) lock on a table prevents other transactions from acquiring any S or X locks on the table. Conversely, the first transaction to acquire an intention shared (IS) lock on a table prevents other transactions from acquiring any X locks on the table. The two-phase process allows the lock requests to be resolved in order, without blocking locks and corresponding operations that are compatible. For more information about this locking mechanism, see Section 14.7.1, “InnoDB Locking”.
See Also lock, lock mode, locking, transaction.

intention shared lock
See intention lock.

interceptor
Code for instrumenting or debugging some aspect of an application, which can be enabled without recompiling or changing the source of the application itself.
See Also command interceptor, Connector/J, Connector/NET, exception interceptor.

inverted index
A data structure optimized for document retrieval systems, used in the implementation of InnoDB full-text search. The InnoDB FULLTEXT index, implemented as an inverted index, records the position of each word within a document, rather than the location of a table row. A single column value (a document stored as a text string) is represented by many entries in the inverted index.
See Also full-text search, FULLTEXT index, ilist.

IOPS
Acronym for I/O operations per second. A common measurement for busy systems, particularly OLTP applications. If this value is near the maximum that the storage devices can handle, the application can become disk-bound, limiting scalability.
See Also disk-bound, OLTP, scalability.

isolation level
One of the foundations of database processing. Isolation is the I in the acronym ACID; the isolation level is the setting that fine-tunes the balance between performance and reliability, consistency, and reproducibility of results when multiple transactions are making changes and performing queries at the same time.

From highest amount of consistency and protection to the least, the isolation levels supported by InnoDB are: Serializable, Repeatable Read, Read Committed, and Read Uncommitted.

With InnoDB tables, many users can keep the default isolation level (Repeatable Read) for all operations. Expert users might choose the Read Committed level as they push the boundaries of scalability with OLTP processing, or during data warehousing operations where minor inconsistencies do not affect the aggregate results of large amounts of data. The levels on the edges (Serializable and Read Uncommitted) change the processing behavior to such an extent that they are rarely used.
See Also ACID, OLTP, READ COMMITTED, READ UNCOMMITTED, REPEATABLE READ, SERIALIZABLE, transaction.

J

J2EE
Java Platform, Enterprise Edition: Oracle's enterprise Java platform. It consists of an API and a runtime environment for enterprise-class Java applications. For full details, see http://www.oracle.com/technetwork/java/javase/overview/index.html. With MySQL applications, you typically use Connector/J for database access, and an application server such as Tomcat or JBoss to handle the middle-tier work, and optionally a framework such as Spring. Database-related features often offered within a J2EE stack include a connection pool and failover support.

See Also connection pool, Connector/J, failover, Java, JBoss, Spring, Tomcat.

Java
A programming language combining high performance, rich built-in features and data types, object-oriented mechanisms, extensive standard library, and wide range of reusable third-party modules. Enterprise development is supported by many frameworks, application servers, and other technologies. Much of its syntax is familiar to C and C++ developers. To write Java applications with MySQL, you use the JDBC driver known as Connector/J.

See Also C, Connector/J, C++, JDBC.

JBoss
See Also J2EE.

JDBC
Abbreviation for “Java Database Connectivity”, an API for database access from Java applications. Java developers writing MySQL applications use the Connector/J component as their JDBC driver.

See Also API, Connector/J, J2EE, Java.

JNDI
See Also Java.

join
A query that retrieves data from more than one table, by referencing columns in the tables that hold identical values. Ideally, these columns are part of an InnoDB foreign key relationship, which ensures referential integrity and that the join columns are indexed. Often used to save space and improve query performance by replacing repeated strings with numeric IDs, in a normalized data design.

See Also foreign key, index, normalized, query, referential integrity.

K

keystore
See Also SSL.

KEY_BLOCK_SIZE
An option to specify the size of data pages within an InnoDB table that uses compressed row format. The default is 8 kilobytes. Lower values risk hitting internal limits that depend on the combination of row size and compression percentage.

For MyISAM tables, KEY_BLOCK_SIZE optionally specifies the size in bytes to use for index key blocks. The value is treated as a hint; a different size could be used if necessary. A KEY_BLOCK_SIZE value specified for an individual index definition overrides a table-level KEY_BLOCK_SIZE value.
See Also compressed row format.

L

latch
A lightweight structure used by InnoDB to implement a lock for its own internal memory structures, typically held for a brief time measured in milliseconds or microseconds. A general term that includes both mutexes (for exclusive access) and rw-locks (for shared access). Certain latches are the focus of InnoDB performance tuning. Statistics about latch use and contention are available through the Performance Schema interface.
See Also lock, locking, mutex, Performance Schema, rw-lock.

libmysql
Informal name for the libmysqlclient library.
See Also libmysqlclient.

libmysqlclient
The library file, named libmysqlclient.a or libmysqlclient.so, that is typically linked into client programs written in C. Sometimes known informally as libmysql or the mysqlclient library.
See Also client, libmysql, mysqlclient.

libmysqld
This embedded MySQL server library makes it possible to run a full-featured MySQL server inside a client application. The main benefits are increased speed and more simple management for embedded applications. You link with the libmysqld library rather than libmysqlclient. The API is identical between all three of these libraries.
See Also client, embedded, libmysql, libmysqlclient.

lifecycle interceptor
A type of interceptor supported by Connector/J. It involves implementing the interface com.mysql.jdbc.ConnectionLifecycleInterceptor.
See Also Connector/J, interceptor.

list
The InnoDB buffer pool is represented as a list of memory pages. The list is reordered as new pages are accessed and enter the buffer pool, as pages within the buffer pool are accessed again and are considered newer, and as pages that are not accessed for a long time are evicted from the buffer pool. The buffer pool is divided into sublists, and the replacement policy is a variation of the familiar LRU technique.
See Also buffer pool, eviction, LRU, page, sublist.

load balancing
A technique for scaling read-only connections by sending query requests to different slave servers in a replication or Cluster configuration. With Connector/J, load balancing is enabled through the com.mysql.jdbc.ReplicationDriver class and controlled by the configuration property loadBalanceStrategy.
See Also Connector/J, J2EE.

localhost
See Also connection.

lock
The high-level notion of an object that controls access to a resource, such as a table, row, or internal data structure, as part of a locking strategy. For intensive performance tuning, you might delve into the actual structures that implement locks, such as mutexes and latches.
See Also latch, lock mode, locking, mutex.

lock escalation
An operation used in some database systems that converts many row locks into a single table lock, saving memory space but reducing concurrent access to the table. InnoDB uses a space-efficient representation for row locks, so that lock escalation is not needed.
See Also locking, row lock, table lock.

lock mode
A shared (S) lock allows a transaction to read a row. Multiple transactions can acquire an S lock on that same row at the same time.

An exclusive (X) lock allows a transaction to update or delete a row. No other transaction can acquire any kind of lock on that same row at the same time.

**Intention locks** apply to the table, and are used to indicate what kind of lock the transaction intends to acquire on rows in the table. Different transactions can acquire different kinds of intention locks on the same table, but the first transaction to acquire an intention exclusive (IX) lock on a table prevents other transactions from acquiring any S or X locks on the table. Conversely, the first transaction to acquire an intention shared (IS) lock on a table prevents other transactions from acquiring any X locks on the table. The two-phase process allows the lock requests to be resolved in order, without blocking locks and corresponding operations that are compatible.
See Also intention lock, lock, locking, transaction.

locking
The system of protecting a transaction from seeing or changing data that is being queried or changed by other transactions. The **locking** strategy must balance reliability and consistency of database operations (the principles of the **ACID** philosophy) against the performance needed for good **concurrency**. Fine-tuning the locking strategy often involves choosing an **isolation level** and ensuring all your database operations are safe and reliable for that isolation level.
See Also ACID, concurrency, isolation level, locking, transaction.

locking read
A **SELECT** statement that also performs a **locking** operation on an InnoDB table. Either **SELECT ... FOR UPDATE** or **SELECT ... LOCK IN SHARE MODE**. It has the potential to produce a deadlock, depending on the isolation level of the transaction. The opposite of a **non-locking read**. Not allowed for global tables in a read-only transaction.

**SELECT ... FOR SHARE** replaces **SELECT ... LOCK IN SHARE MODE** in MySQL 8.0.1, but **LOCK IN SHARE MODE** remains available for backward compatibility.

See Section 14.7.2.4, “Locking Reads”.
See Also deadlock, isolation level, locking, non-locking read, read-only transaction.

log
In the InnoDB context, “log” or “log files” typically refers to the **redo log** represented by the **ib_logfileN** files. Another type of InnoDB log is the **undo log**, which is a storage area that holds copies of data modified by active transactions.

Other kinds of logs that are important in MySQL are the **error log** (for diagnosing startup and runtime problems), **binary log** (for working with replication and performing point-in-time restores), the **general query log** (for diagnosing application problems), and the **slow query log** (for diagnosing performance problems).
See Also binary log, error log, general query log, ib_logfile, redo log, slow query log, undo log.

log buffer
The memory area that holds data to be written to the **log files** that make up the **redo log**. It is controlled by the **innodb_log_buffer_size** configuration option.
See Also log file, redo log.

log file
One of the ib_logfileN files that make up the redo log. Data is written to these files from the log buffer memory area.
See Also ib_logfile, log buffer, redo log.

log group
The set of files that make up the redo log, typically named ib_logfile0 and ib_logfile1. (For that reason, sometimes referred to collectively as ib_logfile.)
See Also ib_logfile, redo log.

logical
A type of operation that involves high-level, abstract aspects such as tables, queries, indexes, and other SQL concepts. Typically, logical aspects are important to make database administration and application development convenient and usable. Contrast with physical.
See Also logical backup, physical.

logical backup
A backup that reproduces table structure and data, without copying the actual data files. For example, the mysqldump command produces a logical backup, because its output contains statements such as CREATE TABLE and INSERT that can re-create the data. Contrast with physical backup. A logical backup offers flexibility (for example, you could edit table definitions or insert statements before restoring), but can take substantially longer to restore than a physical backup.
See Also backup, mysqldump, physical backup, restore.

loose
A prefix added to InnoDB configuration options after server startup, so any new configuration options not recognized by the current level of MySQL do not cause a startup failure. MySQL processes configuration options that start with this prefix, but gives a warning rather than a failure if the part after the prefix is not a recognized option.
See Also startup.

low-water mark
A value representing a lower limit, typically a threshold value at which some corrective action begins or becomes more aggressive. Contrast with high-water mark.
See Also high-water mark.

LRU
An acronym for “least recently used”, a common method for managing storage areas. The items that have not been used recently are evicted when space is needed to cache newer items. InnoDB uses the LRU mechanism by default to manage the pages within the buffer pool, but makes exceptions in cases where a page might be read only a single time, such as during a full table scan. This variation of the LRU algorithm is called the midpoint insertion strategy. For more information, see Section 14.5.1, “Buffer Pool”.
See Also buffer pool, eviction, full table scan, midpoint insertion strategy, page.

LSN
Acronym for “log sequence number”. This arbitrary, ever-increasing value represents a point in time corresponding to operations recorded in the redo log. (This point in time is regardless of transaction boundaries; it can fall in the middle of one or more transactions.) It is used internally by InnoDB during crash recovery and for managing the buffer pool.

Prior to MySQL 5.6.3, the LSN was a 4-byte unsigned integer. The LSN became an 8-byte unsigned integer in MySQL 5.6.3 when the redo log file size limit increased from 4GB to 512GB, as additional bytes were required to store extra size information. Applications built on MySQL 5.6.3 or later that use LSN values should use 64-bit rather than 32-bit variables to store and compare LSN values.
In the MySQL Enterprise Backup product, you can specify an LSN to represent the point in time from which to take an incremental backup. The relevant LSN is displayed by the output of the `mysqlbackup` command. Once you have the LSN corresponding to the time of a full backup, you can specify that value to take a subsequent incremental backup, whose output contains another LSN for the next incremental backup.

See Also buffer pool, crash recovery, incremental backup, MySQL Enterprise Backup, redo log, transaction.

M

.MRG file  
A file containing references to other tables, used by the MERGE storage engine. Files with this extension are always included in backups produced by the `mysqlbackup` command of the MySQL Enterprise Backup product.

See Also MySQL Enterprise Backup, `mysqlbackup` command.

.MYD file  
A file that MySQL uses to store data for a MyISAM table.

See Also .MYI file, MySQL Enterprise Backup, `mysqlbackup` command.

.MYI file  
A file that MySQL uses to store indexes for a MyISAM table.

See Also .MYD file, MySQL Enterprise Backup, `mysqlbackup` command.

master  
See source.

master thread  
An InnoDB thread that performs various tasks in the background. Most of these tasks are I/O related, such as writing changes from the change buffer to the appropriate secondary indexes.

To improve concurrency, sometimes actions are moved from the master thread to separate background threads. For example, in MySQL 5.6 and higher, dirty pages are flushed from the buffer pool by the page cleaner thread rather than the master thread.

See Also buffer pool, change buffer, concurrency, dirty page, flush, page cleaner, thread.

MDL  
Acronym for “metadata lock”.

See Also metadata lock.

medium trust  
Synonym for partial trust. Because the range of trust settings is so broad, “partial trust” is preferred, to avoid the implication that there are only three levels (low, medium, and full).

See Also Connector/NET, partial trust.

memcached  
A popular component of many MySQL and NoSQL software stacks, allowing fast reads and writes for single values and caching the results entirely in memory. Traditionally, applications required extra logic to write the same data to a MySQL database for permanent storage, or to read data from a MySQL database when it was not cached yet in memory. Now, applications can use the simple memcached protocol, supported by client libraries for many languages, to communicate directly with MySQL servers using InnoDB or NDB tables. These NoSQL interfaces to MySQL tables allow applications to achieve higher read and write performance than by issuing SQL statements directly, and can simplify application logic and deployment configurations for systems that already incorporate memcached for in-memory caching.

The memcached interface to InnoDB tables is available in MySQL 5.6 and higher; see Section 14.20, “InnoDB memcached Plugin” for details. The memcached interface to NDB tables is available in NDB Cluster 7.2 and later; see http://dev.mysql.com/doc/ndbapi/en/ndbmemcache.html for details.
merge
To apply changes to data cached in memory, such as when a page is brought into the buffer pool, and any applicable changes recorded in the change buffer are incorporated into the page in the buffer pool. The updated data is eventually written to the tablespace by the flush mechanism.
See Also buffer pool, change buffer, flush, tablespace.

metadata lock
A type of lock that prevents DDL operations on a table that is being used at the same time by another transaction. For details, see Section 8.11.4, “Metadata Locking”.
Enhancements to online operations, particularly in MySQL 5.6 and higher, are focused on reducing the amount of metadata locking. The objective is for DDL operations that do not change the table structure (such as CREATE INDEX and DROP INDEX for InnoDB tables) to proceed while the table is being queried, updated, and so on by other transactions.
See Also DDL, lock, online, transaction.

metrics counter
A feature implemented by the INNODB_METRICS table in the INFORMATION_SCHEMA, in MySQL 5.6 and higher. You can query counts and totals for low-level InnoDB operations, and use the results for performance tuning in combination with data from the Performance Schema.
See Also counter, INFORMATION_SCHEMA, Performance Schema.

midpoint insertion strategy
The technique of initially bringing pages into the InnoDB buffer pool not at the “newest” end of the list, but instead somewhere in the middle. The exact location of this point can vary, based on the setting of the innodb_old_blocks_pct option. The intent is that pages that are only read once, such as during a full table scan, can be aged out of the buffer pool sooner than with a strict LRU algorithm. For more information, see Section 14.5.1, “Buffer Pool”.
See Also buffer pool, full table scan, LRU, page.

mini-transaction
An internal phase of InnoDB processing, when making changes at the physical level to internal data structures during DML operations. A mini-transaction (mtr) has no notion of rollback; multiple mini-transactions can occur within a single transaction. Mini-transactions write information to the redo log that is used during crash recovery. A mini-transaction can also happen outside the context of a regular transaction, for example during purge processing by background threads.
See Also commit, crash recovery, DML, physical, purge, redo log, rollback, transaction.

mixed-mode insert
An INSERT statement where auto-increment values are specified for some but not all of the new rows. For example, a multi-value INSERT could specify a value for the auto-increment column in some cases and NULL in other cases. InnoDB generates auto-increment values for the rows where the column value was specified as NULL. Another example is an INSERT ... ON DUPLICATE KEY UPDATE statement, where auto-increment values might be generated but not used, for any duplicate rows that are processed as UPDATE rather than INSERT statements.
Can cause consistency issues between source and replica servers in a replication configuration. Can require adjusting the value of the innodb_autoinc_lock_mode configuration option.
See Also auto-increment, innodb_autoinc_lock_mode, replica, replication, source.

MM.MySQL
An older JDBC driver for MySQL that evolved into Connector/J when it was integrated with the MySQL product.
See Also Connector/J.
Mono
An Open Source framework developed by Novell, that works with Connector/NET and C# applications on Linux platforms.
See Also Connector/NET, C#.

mtr
See mini-transaction.

multi-core
A type of processor that can take advantage of multithreaded programs, such as the MySQL server.

multiversion concurrency control
See MVCC.

mutex
Informal abbreviation for “mutex variable”. (Mutex itself is short for “mutual exclusion”.) The low-level object that InnoDB uses to represent and enforce exclusive-access locks to internal in-memory data structures. Once the lock is acquired, any other process, thread, and so on is prevented from acquiring the same lock. Contrast with rw-locks, which InnoDB uses to represent and enforce shared-access locks to internal in-memory data structures. Mutexes and rw-locks are known collectively as latches.
See Also latch, lock, Performance Schema, Pthreads, rw-lock.

MVCC
Acronym for “multiversion concurrency control”. This technique lets InnoDB transactions with certain isolation levels perform consistent read operations; that is, to query rows that are being updated by other transactions, and see the values from before those updates occurred. This is a powerful technique to increase concurrency, by allowing queries to proceed without waiting due to locks held by the other transactions.
This technique is not universal in the database world. Some other database products, and some other MySQL storage engines, do not support it.
See Also ACID, concurrency, consistent read, isolation level, lock, transaction.

my.cnf
The name, on Unix or Linux systems, of the MySQL option file.
See Also my.ini, option file.

my.ini
The name, on Windows systems, of the MySQL option file.
See Also my.cnf, option file.

MyODBC drivers
Obsolete name for Connector/ODBC.
See Also Connector/ODBC.

mysql
The mysql program is the command-line interpreter for the MySQL database. It processes SQL statements, and also MySQL-specific commands such as SHOW TABLES, by passing requests to the mysqld daemon.
See Also mysqld, SQL.

MySQL Enterprise Backup
A licensed product that performs hot backups of MySQL databases. It offers the most efficiency and flexibility when backing up InnoDB tables, but can also back up MyISAM and other kinds of tables.
See Also hot backup, InnoDB.

mysqlbackup command
A command-line tool of the MySQL Enterprise Backup product. It performs a hot backup operation for InnoDB tables, and a warm backup for MyISAM and other kinds of tables. See Section 24.2, “MySQL Enterprise Backup Overview” for more information about this command.
See Also hot backup, MySQL Enterprise Backup, warm backup.

**mysqlclient**

The informal name for the library that is implemented by the file `libmysqlclient`, with extension `.a` or `.so`. See Also `libmysqlclient`.

**mysqld**

`mysqld`, also known as MySQL Server, is a single multithreaded program that does most of the work in a MySQL installation. It does not spawn additional processes. MySQL Server manages access to the MySQL data directory that contains databases, tables, and other information such as log files and status files.

`mysqld` runs as a Unix daemon or Windows service, constantly waiting for requests and performing maintenance work in the background.

See Also `instance`, `mysql`.

**MySQLdb**

The name of the open-source Python module that forms the basis of the MySQL Python API.

See Also `Python`, `Python API`.

**mysqldump**

A command that performs a **logical backup** of some combination of databases, tables, and table data. The results are SQL statements that reproduce the original schema objects, data, or both. For substantial amounts of data, a **physical backup** solution such as MySQL Enterprise Backup is faster, particularly for the **restore** operation.

See Also logical backup, MySQL Enterprise Backup, physical backup, restore.

**N**

.NET

See Also ADO.NET, ASP.net, Connector/NET, Mono, Visual Studio.

**native C API**

Synonym for `libmysqlclient`.

See Also `libmysql`.

**natural key**

An indexed column, typically a **primary key**, where the values have some real-world significance. Usually advised against because:

- If the value should ever change, there is potentially a lot of index maintenance to re-sort the **clustered index** and update the copies of the primary key value that are repeated in each **secondary index**.

- Even seemingly stable values can change in unpredictable ways that are difficult to represent correctly in the database. For example, one country can change into two or several, making the original country code obsolete. Or, rules about unique values might have exceptions. For example, even if taxpayer IDs are intended to be unique to a single person, a database might have to handle records that violate that rule, such as in cases of identity theft. Taxpayer IDs and other sensitive ID numbers also make poor primary keys, because they may need to be secured, encrypted, and otherwise treated differently than other columns.

Thus, it is typically better to use arbitrary numeric values to form a **synthetic key**, for example using an **auto-increment** column.

See Also auto-increment, clustered index, primary key, secondary index, synthetic key.

**neighbor page**

Any **page** in the same **extent** as a particular page. When a page is selected to be **flushed**, any neighbor pages that are **dirty** are typically flushed as well, as an I/O optimization for traditional hard disks. In MySQL 5.6 and up,
this behavior can be controlled by the configuration variable `innodb_flush_neighbors`; you might turn that setting off for SSD drives, which do not have the same overhead for writing smaller batches of data at random locations.  
See Also `dirty page`, `extent`, `flush`, `page`.

next-key lock

A combination of a `record lock` on the index record and a `gap lock` on the gap before the index record.  
See Also `gap lock`, `locking`, `record lock`.

non-locking read

A query that does not use the `SELECT ... FOR UPDATE` or `SELECT ... LOCK IN SHARE MODE` clauses. The only kind of query allowed for global tables in a `read-only transaction`. The opposite of a `locking read`. See `Section 14.7.2.3, “Consistent Nonlocking Reads”`.  

`SELECT ... FOR SHARE` replaces `SELECT ... LOCK IN SHARE MODE` in MySQL 8.0.1, but `LOCK IN SHARE MODE` remains available for backward compatibility.  
See Also `locking read`, `query`, `read-only transaction`.

non-repeatable read

The situation when a query retrieves data, and a later query within the same `transaction` retrieves what should be the same data, but the queries return different results (changed by another transaction committing in the meantime).  

This kind of operation goes against the `ACID` principle of database design. Within a transaction, data should be consistent, with predictable and stable relationships.  

Among different `isolation levels`, non-repeatable reads are prevented by the `serializable read` and `repeatable read` levels, and allowed by the `consistent read` and `read uncommitted` levels.  
See Also `ACID`, `consistent read`, `isolation level`, `READ UNCOMMITTED`, `REPEATABLE READ`, `SERIALIZABLE`, `transaction`.

nonblocking I/O

An industry term that means the same as `asynchronous I/O`.  
See Also `asynchronous I/O`.

normalized

A database design strategy where data is split into multiple tables, and duplicate values condensed into single rows represented by an ID, to avoid storing, querying, and updating redundant or lengthy values. It is typically used in OLTP applications.  

For example, an address might be given a unique ID, so that a census database could represent the relationship `lives at this address` by associating that ID with each member of a family, rather than storing multiple copies of a complex value such as `123 Main Street, Anytown, USA`.  

For another example, although a simple address book application might store each phone number in the same table as a person's name and address, a phone company database might give each phone number a special ID, and store the numbers and IDs in a separate table. This normalized representation could simplify large-scale updates when area codes split apart.  

Normalization is not always recommended. Data that is primarily queried, and only updated by deleting entirely and reloading, is often kept in fewer, larger tables with redundant copies of duplicate values. This data representation is referred to as `denormalized`, and is frequently found in data warehousing applications.  
See Also `denormalized`, `foreign key`, `OLTP`, `relational`.

NoSQL

A broad term for a set of data access technologies that do not use the `SQL` language as their primary mechanism for reading and writing data. Some NoSQL technologies act as key-value stores, only accepting
single-value reads and writes; some relax the restrictions of the ACID methodology; still others do not require a pre-planned schema. MySQL users can combine NoSQL-style processing for speed and simplicity with SQL operations for flexibility and convenience, by using the memcached API to directly access some kinds of MySQL tables. The memcached interface to InnoDB tables is available in MySQL 5.6 and higher; see Section 14.20, “InnoDB memcached Plugin” for details. The memcached interface to NDB tables is available in NDB Cluster 7.2 and later; see ndbmemcache—Memcache API for NDB Cluster (NO LONGER SUPPORTED).

See Also ACID, InnoDB, memcached, schema, SQL.

NOT NULL constraint
A type of constraint that specifies that a column cannot contain any NULL values. It helps to preserve referential integrity, as the database server can identify data with erroneous missing values. It also helps in the arithmetic involved in query optimization, allowing the optimizer to predict the number of entries in an index on that column.
See Also column, constraint, NULL, primary key, referential integrity.

NULL
A special value in SQL, indicating the absence of data. Any arithmetic operation or equality test involving a NULL value, in turn produces a NULL result. (Thus it is similar to the IEEE floating-point concept of NaN, “not a number”.) Any aggregate calculation such as AVG() ignores rows with NULL values, when determining how many rows to divide by. The only test that works with NULL values uses the SQL idioms IS NULL or IS NOT NULL.

NULL values play a part in index operations, because for performance a database must minimize the overhead of keeping track of missing data values. Typically, NULL values are not stored in an index, because a query that tests an indexed column using a standard comparison operator could never match a row with a NULL value for that column. For the same reason, unique indexes do not prevent NULL values; those values simply are not represented in the index. Declaring a NOT NULL constraint on a column provides reassurance that there are no rows left out of the index, allowing for better query optimization (accurate counting of rows and estimation of whether to use the index).

Because the primary key must be able to uniquely identify every row in the table, a single-column primary key cannot contain any NULL values, and a multi-column primary key cannot contain any rows with NULL values in all columns.

Although the Oracle database allows a NULL value to be concatenated with a string, InnoDB treats the result of such an operation as NULL.
See Also index, primary key, SQL.

.OPT file
A file containing database configuration information. Files with this extension are included in backups produced by the mysqlbackup command of the MySQL Enterprise Backup product.
See Also MySQL Enterprise Backup, mysqlbackup command.

ODBC
Acronym for Open Database Connectivity, an industry-standard API. Typically used with Windows-based servers, or applications that require ODBC to communicate with MySQL. The MySQL ODBC driver is called Connector/ODBC.
See Also Connector/ODBC.

off-page column
A column containing variable-length data (such as BLOB and VARCHAR) that is too long to fit on a B-tree page. The data is stored in overflow pages. The DYNAMIC row format is more efficient for such storage than the older COMPACT row format.
See Also B-tree, compact row format, dynamic row format, overflow page.
OLTP
Acronym for “Online Transaction Processing”. A database system, or a database application, that runs a workload with many transactions, with frequent writes as well as reads, typically affecting small amounts of data at a time. For example, an airline reservation system or an application that processes bank deposits. The data might be organized in normalized form for a balance between DML (insert/update/delete) efficiency and query efficiency. Contrast with data warehouse.

With its row-level locking and transactional capability, InnoDB is the ideal storage engine for MySQL tables used in OLTP applications.
See Also data warehouse, DML, InnoDB, query, row lock, transaction.

online
A type of operation that involves no downtime, blocking, or restricted operation for the database. Typically applied to DDL. Operations that shorten the periods of restricted operation, such as fast index creation, have evolved into a wider set of online DDL operations in MySQL 5.6.

In the context of backups, a hot backup is an online operation and a warm backup is partially an online operation.
See Also DDL, Fast Index Creation, hot backup, online DDL, warm backup.

online DDL
A feature that improves the performance, concurrency, and availability of InnoDB tables during DDL (primarily ALTER TABLE) operations. See Section 14.13, “InnoDB and Online DDL” for details.

The details vary according to the type of operation. In some cases, the table can be modified concurrently while the ALTER TABLE is in progress. The operation might be able to be performed without a table copy, or using a specially optimized type of table copy. DML log space usage for in-place operations is controlled by the innodb_online_alter_log_max_size configuration option.

This feature is an enhancement of the Fast Index Creation feature in MySQL 5.5.
See Also DDL, Fast Index Creation, online.

optimistic
A methodology that guides low-level implementation decisions for a relational database system. The requirements of performance and concurrency in a relational database mean that operations must be started or dispatched quickly. The requirements of consistency and referential integrity mean that any operation could fail: a transaction might be rolled back, a DML operation could violate a constraint, a request for a lock could cause a deadlock, a network error could cause a timeout. An optimistic strategy is one that assumes most requests or attempts succeed, so that relatively little work is done to prepare for the failure case. When this assumption is true, the database does little unnecessary work; when requests do fail, extra work must be done to clean up and undo changes.

InnoDB uses optimistic strategies for operations such as locking and commits. For example, data changed by a transaction can be written to the data files before the commit occurs, making the commit itself very fast, but requiring more work to undo the changes if the transaction is rolled back.

The opposite of an optimistic strategy is a pessimistic one, where a system is optimized to deal with operations that are unreliable and frequently unsuccessful. This methodology is rare in a database system, because so much care goes into choosing reliable hardware, networks, and algorithms.
See Also commit, concurrency, DML, locking, pessimistic, referential integrity.

optimizer
The MySQL component that determines the best indexes and join order to use for a query, based on characteristics and data distribution of the relevant tables.
See Also index, join, query, table.
option
A configuration parameter for MySQL, either stored in the option file or passed on the command line.

For the options that apply to InnoDB tables, each option name starts with the prefix innodb_.
See Also InnoDB, option, option file.

option file
The file that holds the configuration options for the MySQL instance. Traditionally, on Linux and Unix this file is named my.cnf, and on Windows it is named my.ini.
See Also configuration file, my.cnf, my.ini, option.

overflow page
Separately allocated disk pages that hold variable-length columns (such as BLOB and VARCHAR) that are too long to fit on a B-tree page. The associated columns are known as off-page columns.
See Also B-tree, off-page column, page.

P
.par file
A file containing partition definitions. Files with this extension are included in backups produced by the mysqlbackup command of the MySQL Enterprise Backup product.

With the introduction of native partitioning support for InnoDB tables in MySQL 5.7.6, .par files are no longer created for partitioned InnoDB tables. Partitioned MyISAM tables continue to use .par files in MySQL 5.7. In MySQL 8.0, partitioning support is only provided by the InnoDB storage engine. As such, .par files are no longer used as of MySQL 8.0.
See Also MySQL Enterprise Backup, mysqlbackup command.

page
A unit representing how much data InnoDB transfers at any one time between disk (the data files) and memory (the buffer pool). A page can contain one or more rows, depending on how much data is in each row. If a row does not fit entirely into a single page, InnoDB sets up additional pointer-style data structures so that the information about the row can be stored in one page.

One way to fit more data in each page is to use compressed row format. For tables that use BLOBs or large text fields, compact row format allows those large columns to be stored separately from the rest of the row, reducing I/O overhead and memory usage for queries that do not reference those columns.

When InnoDB reads or writes sets of pages as a batch to increase I/O throughput, it reads or writes an extent at a time.

All the InnoDB disk data structures within a MySQL instance share the same page size.
See Also buffer pool, compact row format, compressed row format, data files, extent, page size, row.

page cleaner
An InnoDB background thread that flushes dirty pages from the buffer pool. Prior to MySQL 5.6, this activity was performed by the master thread. The number of page cleaner threads is controlled by the innodb_page_cleaners configuration option, introduced in MySQL 5.7.4.
See Also buffer pool, dirty page, flush, master thread, thread.

page size
For releases up to and including MySQL 5.5, the size of each InnoDB page is fixed at 16 kilobytes. This value represents a balance: large enough to hold the data for most rows, yet small enough to minimize the performance overhead of transferring unneeded data to memory. Other values are not tested or supported.

Starting in MySQL 5.6, the page size for an InnoDB instance can be either 4KB, 8KB, or 16KB, controlled by the innodb_page_size configuration option. As of MySQL 5.7.6, InnoDB also supports 32KB and 64KB page size.
sizes. For 32KB and 64KB page sizes, ROW_FORMAT=COMPRESSED is not supported and the maximum record size is 16KB.

Page size is set when creating the MySQL instance, and it remains constant afterward. The same page size applies to all InnoDB tablespaces, including the system tablespace, file-per-table tablespaces, and general tablespaces.

Smaller page sizes can help performance with storage devices that use small block sizes, particularly for SSD devices in disk-bound workloads, such as for OLTP applications. As individual rows are updated, less data is copied into memory, written to disk, reorganized, locked, and so on.

See Also disk-bound, file-per-table, general tablespace, instance, OLTP, page, SSD, system tablespace, tablespace.

parent table
The table in a foreign key relationship that holds the initial column values pointed to from the child table. The consequences of deleting, or updating rows in the parent table depend on the ON UPDATE and ON DELETE clauses in the foreign key definition. Rows with corresponding values in the child table could be automatically deleted or updated in turn, or those columns could be set to NULL, or the operation could be prevented.

See Also child table, foreign key.

partial backup
A backup that contains some of the tables in a MySQL database, or some of the databases in a MySQL instance. Contrast with full backup.

See Also backup, full backup, table.

partial index
An index that represents only part of a column value, typically the first N characters (the prefix) of a long VARCHAR value.

See Also index, index prefix.

partial trust
An execution environment typically used by hosting providers, where applications have some permissions but not others. For example, applications might be able to access a database server over a network, but be “sandboxed” with regard to reading and writing local files.

See Also Connector/NET.

Performance Schema
The performance_schema schema, in MySQL 5.5 and up, presents a set of tables that you can query to get detailed information about the performance characteristics of many internal parts of the MySQL server. See Chapter 22, MySQL Performance Schema.

See Also INFORMATION_SCHEMA, latch, mutex, rw-lock.

Perl
A programming language with roots in Unix scripting and report generation. Incorporates high-performance regular expressions and file I/O. Large collection of reusable modules available through repositories such as CPAN.

See Also Perl API.

Perl API
An open-source API for MySQL applications written in the Perl language. Implemented through the DBI and DBD::mysql modules. For details, see Section 23.9, “MySQL Perl API”.

See Also API, Perl.

persistent statistics
A feature that stores index statistics for InnoDB tables on disk, providing better plan stability for queries. For more information, see Section 14.8.11.1, “Configuring Persistent Optimizer Statistics Parameters”.

See Also index, optimizer, plan stability, query, table.
pessimistic

A methodology that sacrifices performance or concurrency in favor of safety. It is appropriate if a high proportion of requests or attempts might fail, or if the consequences of a failed request are severe. InnoDB uses what is known as a pessimistic locking strategy, to minimize the chance of deadlocks. At the application level, you might avoid deadlocks by using a pessimistic strategy of acquiring all locks needed by a transaction at the very beginning.

Many built-in database mechanisms use the opposite optimistic methodology.

See Also deadlock, locking, optimistic.

phantom

A row that appears in the result set of a query, but not in the result set of an earlier query. For example, if a query is run twice within a transaction, and in the meantime, another transaction commits after inserting a new row or updating a row so that it matches the WHERE clause of the query.

This occurrence is known as a phantom read. It is harder to guard against than a non-repeatable read, because locking all the rows from the first query result set does not prevent the changes that cause the phantom to appear.

Among different isolation levels, phantom reads are prevented by the serializable read level, and allowed by the repeatable read, consistent read, and read uncommitted levels.

See Also consistent read, isolation level, non-repeatable read, READ UNCOMMITTED, REPEATABLE READ, SERIALIZABLE, transaction.

PHP

A programming language originating with web applications. The code is typically embedded as blocks within the source of a web page, with the output substituted into the page as it is transmitted by the web server. This is in contrast to applications such as CGI scripts that print output in the form of an entire web page. The PHP style of coding is used for highly interactive and dynamic web pages. Modern PHP programs can also be run as command-line or GUI applications.

MySQL applications are written using one of the PHP APIs. Reusable modules can be written in C and called from PHP.

Another technology for writing server-side web pages with MySQL is ASP.net.

See Also ASP.net, C, PHP API.

PHP API

Several APIs are available for writing MySQL applications in the PHP language: the original MySQL API (Mysql) the MySQL Improved Extension (Mysqli) the MySQL Native Driver (Mysqlnd) the MySQL functions (PDO_MYSQL), and Connector/PHP. For details, see MySQL and PHP.

See Also API, PHP.

physical

A type of operation that involves hardware-related aspects such as disk blocks, memory pages, files, bits, disk reads, and so on. Typically, physical aspects are important during expert-level performance tuning and problem diagnosis. Contrast with logical.

See Also logical, physical backup.

physical backup

A backup that copies the actual data files. For example, the mysqlbackup command of the MySQL Enterprise Backup product produces a physical backup, because its output contains data files that can be used directly by the mysqlld server, resulting in a faster restore operation. Contrast with logical backup.

See Also backup, logical backup, MySQL Enterprise Backup, restore.

PITR

Acronym for point-in-time recovery.
plan stability
A property of a query execution plan, where the optimizer makes the same choices each time for a given query, so that performance is consistent and predictable.
See Also query, query execution plan.

point-in-time recovery
The process of restoring a backup to recreate the state of the database at a specific date and time. Commonly abbreviated “PITR”. Because it is unlikely that the specified time corresponds exactly to the time of a backup, this technique usually requires a combination of a physical backup and a logical backup. For example, with the MySQL Enterprise Backup product, you restore the last backup that you took before the specified point in time, then replay changes from the binary log between the time of the backup and the PITR time.
See Also backup, binary log, logical backup, MySQL Enterprise Backup, physical backup.

port
The number of the TCP/IP socket the database server listens on, used to establish a connection. Often specified in conjunction with a host. Depending on your use of network encryption, there might be one port for unencrypted traffic and another port for SSL connections.
See Also connection, host, SSL.

prefix
See index prefix.

prepared backup
A set of backup files, produced by the MySQL Enterprise Backup product, after all the stages of applying binary logs and incremental backups are finished. The resulting files are ready to be restored. Prior to the apply steps, the files are known as a raw backup.
See Also binary log, hot backup, incremental backup, MySQL Enterprise Backup, raw backup, restore.

prepared statement
An SQL statement that is analyzed in advance to determine an efficient execution plan. It can be executed multiple times, without the overhead for parsing and analysis each time. Different values can be substituted for literals in the WHERE clause each time, through the use of placeholders. This substitution technique improves security, protecting against some kinds of SQL injection attacks. You can also reduce the overhead for converting and copying return values to program variables.

Although you can use prepared statements directly through SQL syntax, the various Connectors have programming interfaces for manipulating prepared statements, and these APIs are more efficient than going through SQL.
See Also client-side prepared statement, connector, server-side prepared statement.

primary key
A set of columns—and by implication, the index based on this set of columns—that can uniquely identify every row in a table. As such, it must be a unique index that does not contain any NULL values.

InnoDB requires that every table has such an index (also called the clustered index or cluster index), and organizes the table storage based on the column values of the primary key.

When choosing primary key values, consider using arbitrary values (a synthetic key) rather than relying on values derived from some other source (a natural key).
See Also clustered index, index, natural key, synthetic key.

process
An instance of an executing program. The operating system switches between multiple running processes, allowing for a certain degree of concurrency. On most operating systems, processes can contain multiple
threads of execution that share resources. Context-switching between threads is faster than the equivalent switching between processes.
See Also concurrency, thread.

pseudo-record
An artificial record in an index, used for locking key values or ranges that do not currently exist.
See Also infimum record, locking, supremum record.

Pthreads
The POSIX threads standard, which defines an API for threading and locking operations on Unix and Linux systems. On Unix and Linux systems, InnoDB uses this implementation for mutexes.
See Also mutex.

purge
A type of garbage collection performed by one or more separate background threads (controlled by innodb_purge_threads) that runs on a periodic schedule. Purge parses and processes undo log pages from the history list for the purpose of removing clustered and secondary index records that were marked for deletion (by previous DELETE statements) and are no longer required for MVCC or rollback. Purge frees undo log pages from the history list after processing them.
See Also history list, MVCC, rollback, undo log.

purge buffering
The technique of storing changes to secondary index pages, resulting from DELETE operations, in the change buffer rather than writing the changes immediately, so that the physical writes can be performed to minimize random I/O. (Because delete operations are a two-step process, this operation buffers the write that normally purges an index record that was previously marked for deletion.) It is one of the types of change buffering; the others are insert buffering and delete buffering.
See Also change buffer, change buffering, delete buffering, insert buffer, insert buffering.

purge lag
Another name for the InnoDB history list. Related to the innodb_max_purge_lag configuration option.
See Also history list, purge.

purge thread
A thread within the InnoDB process that is dedicated to performing the periodic purge operation. In MySQL 5.6 and higher, multiple purge threads are enabled by the innodb_purge_threads configuration option.
See Also purge, thread.

Python
A programming language used in a broad range of fields, from Unix scripting to large-scale applications. Includes runtime typing, built-in high-level data types, object-oriented features, and an extensive standard library. Often used as a “glue” language between components written in other languages. The MySQL Python API is the open-source MySQLdb module.
See Also MySQLdb, Python API.

Python API
See Also API, Python.

query
In SQL, an operation that reads information from one or more tables. Depending on the organization of data and the parameters of the query, the lookup might be optimized by consulting an index. If multiple tables are involved, the query is known as a join.
For historical reasons, sometimes discussions of internal processing for statements use “query” in a broader sense, including other types of MySQL statements such as **DDL** and **DML** statements. See Also **DDL**, **DML**, **index**, **join**, **SQL**, **table**.

**query execution plan**

The set of decisions made by the optimizer about how to perform a **query** most efficiently, including which **index** or indexes to use, and the order in which to **join** tables. **Plan stability** involves the same choices being made consistently for a given query. See Also **index**, **join**, **plan stability**, **query**.

**query log**

See **general query log**.

**quiesce**

To reduce the amount of database activity, often in preparation for an operation such as an **ALTER TABLE**, a **backup**, or a **shutdown**. Might or might not involve doing as much **flushing** as possible, so that **InnoDB** does not continue doing background I/O.

In MySQL 5.6 and higher, the syntax **FLUSH TABLES ... FOR EXPORT** writes some data to disk for **InnoDB** tables that make it simpler to back up those tables by copying the data files. See Also **backup**, **flush**, **InnoDB**, **shutdown**.

**R**

**R-tree**

A tree data structure used for spatial indexing of multi-dimensional data such as geographical coordinates, rectangles or polygons. See Also **B-tree**.

**RAID**

Acronym for “Redundant Array of Inexpensive Drives”. Spreading I/O operations across multiple drives enables greater **concurrency** at the hardware level, and improves the efficiency of low-level write operations that otherwise would be performed in sequence. See Also **concurrency**.

**random dive**

A technique for quickly estimating the number of different values in a column (the column's **cardinality**). **InnoDB** samples pages at random from the index and uses that data to estimate the number of different values. See Also **cardinality**.

**raw backup**

The initial set of backup files produced by the **MySQL Enterprise Backup** product, before the changes reflected in the **binary log** and any **incremental backups** are applied. At this stage, the files are not ready to **restore**. After these changes are applied, the files are known as a **prepared backup**. See Also **binary log**, **hot backup**, **ibbackup_logfile**, **incremental backup**, **MySQL Enterprise Backup**, **prepared backup**, **restore**.

**READ COMMITTED**

An **isolation level** that uses a **locking** strategy that relaxes some of the protection between **transactions**, in the interest of performance. Transactions cannot see uncommitted data from other transactions, but they can see data that is committed by another transaction after the current transaction started. Thus, a transaction never sees any bad data, but the data that it does see may depend to some extent on the timing of other transactions.

When a transaction with this isolation level performs **UPDATE ... WHERE** or **DELETE ... WHERE** operations, other transactions might have to wait. The transaction can perform **SELECT ... FOR UPDATE**, and **LOCK IN SHARE MODE** operations without making other transactions wait.
SELECT ... FOR SHARE replaces SELECT ... LOCK IN SHARE MODE in MySQL 8.0.1, but LOCK IN SHARE MODE remains available for backward compatibility. See Also ACID, isolation level, locking, REPEATABLE READ, SERIALIZABLE, transaction.

read phenomena
Phenomena such as **dirty reads**, **non-repeatable reads**, and **phantom** reads which can occur when a transaction reads data that another transaction has modified. See Also dirty read, non-repeatable read, phantom.

READ UNCOMMITTED
The **isolation level** that provides the least amount of protection between transactions. Queries employ a locking strategy that allows them to proceed in situations where they would normally wait for another transaction. However, this extra performance comes at the cost of less reliable results, including data that has been changed by other transactions and not committed yet (known as **dirty read**). Use this isolation level with great caution, and be aware that the results might not be consistent or reproducible, depending on what other transactions are doing at the same time. Typically, transactions with this isolation level only do queries, not insert, update, or delete operations. See Also ACID, dirty read, isolation level, locking, transaction.

read view
An internal snapshot used by the MVCC mechanism of InnoDB. Certain transactions, depending on their **isolation level**, see the data values as they were at the time the transaction (or in some cases, the statement) started. Isolation levels that use a read view are **REPEATABLE READ**, **READ COMMITTED**, and **READ UNCOMMITTED**. See Also isolation level, MVCC, READ COMMITTED, READ UNCOMMITTED, REPEATABLE READ, transaction.

read-ahead
A type of I/O request that prefetches a group of **pages** (an entire **extent**) into the **buffer pool** asynchronously, in case these pages are needed soon. The linear read-ahead technique prefetches all the pages of one extent based on access patterns for pages in the preceding extent. The random read-ahead technique prefetches all the pages for an extent once a certain number of pages from the same extent are in the buffer pool. Random read-ahead is not part of MySQL 5.5, but is re-introduced in MySQL 5.6 under the control of the `innodb_random_read_ahead` configuration option. See Also buffer pool, extent, page.

read-only transaction
A type of **transaction** that can be optimized for InnoDB tables by eliminating some of the bookkeeping involved with creating a read view for each transaction. Can only perform **non-locking read** queries. It can be started explicitly with the syntax `START TRANSACTION READ ONLY`, or automatically under certain conditions. See Section 8.5.3, “Optimizing InnoDB Read-Only Transactions” for details. See Also non-locking read, read view, transaction.

record lock
A **lock** on an index record. For example, `SELECT c1 FROM t WHERE c1 = 10 FOR UPDATE;` prevents any other transaction from inserting, updating, or deleting rows where the value of `t.c1` is 10. Contrast with **gap lock** and next-key lock. See Also gap lock, lock, next-key lock.

redo
The data, in units of records, recorded in the **redo log** when DML statements make changes to InnoDB tables. It is used during **crash recovery** to correct data written by incomplete transactions. The ever-increasing LSN value represents the cumulative amount of redo data that has passed through the redo log. See Also crash recovery, DML, LSN, redo log, transaction.
redo log

A disk-based data structure used during crash recovery, to correct data written by incomplete transactions. During normal operation, it encodes requests to change InnoDB table data, which result from SQL statements or low-level API calls through NoSQL interfaces. Modifications that did not finish updating the data files before an unexpected shutdown are replayed automatically.

The redo log is physically represented as a set of files, typically named ib_logfile0 and ib_logfile1. The data in the redo log is encoded in terms of records affected; this data is collectively referred to as redo. The passage of data through the redo logs is represented by the ever-increasing LSN value. The original 4GB limit on maximum size for the redo log is raised to 512GB in MySQL 5.6.3.

The disk layout of the redo log is influenced by the configuration options innodb_log_file_size, innodb_log_group_home_dir, and (rarely) innodb_log_files_in_group. The performance of redo log operations is also affected by the log buffer, which is controlled by the innodb_log_buffer_size configuration option.

See Also crash recovery, data files, ib_logfile, log buffer, LSN, redo, shutdown, transaction.

redo log archiving

An InnoDB feature that, when enabled, sequentially writes redo log records to an archive file to avoid potential loss of data than can occur when a backup utility fails to keep pace with redo log generation while a backup operation is in progress. For more information, see Redo Log Archiving.

See Also redo log.

redundant row format

The oldest InnoDB row format. Prior to MySQL 5.0.3, it was the only row format available in InnoDB. From MySQL 5.0.3 to MySQL 5.7.8, the default row format is COMPACT. As of MySQL 5.7.9, the default row format is defined by the innodb_default_row_format configuration option, which has a default setting of DYNAMIC. You can still specify the REDUNDANT row format for compatibility with older InnoDB tables.

For more information, see Section 14.11, “InnoDB Row Formats”.

See Also compact row format, dynamic row format, row format.

referential integrity

The technique of maintaining data always in a consistent format, part of the ACID philosophy. In particular, data in different tables is kept consistent through the use of foreign key constraints, which can prevent changes from happening or automatically propagate those changes to all related tables. Related mechanisms include the unique constraint, which prevents duplicate values from being inserted by mistake, and the NOT NULL constraint, which prevents blank values from being inserted by mistake.

See Also ACID, FOREIGN KEY constraint, NOT NULL constraint, unique constraint.

relational

An important aspect of modern database systems. The database server encodes and enforces relationships such as one-to-one, one-to-many, many-to-one, and uniqueness. For example, a person might have zero, one, or many phone numbers in an address database; a single phone number might be associated with several family members. In a financial database, a person might be required to have exactly one taxpayer ID, and any taxpayer ID could only be associated with one person.

The database server can use these relationships to prevent bad data from being inserted, and to find efficient ways to look up information. For example, if a value is declared to be unique, the server can stop searching as soon as the first match is found, and it can reject attempts to insert a second copy of the same value.

At the database level, these relationships are expressed through SQL features such as columns within a table, unique and NOT NULL constraints, foreign keys, and different kinds of join operations. Complex relationships typically involve data split between more than one table. Often, the data is normalized, so that duplicate values in one-to-many relationships are stored only once.
In a mathematical context, the relations within a database are derived from set theory. For example, the OR and AND operators of a WHERE clause represent the notions of union and intersection.

See Also ACID, column, constraint, foreign key, normalized.

relevance

In the full-text search feature, a number signifying the similarity between the search string and the data in the FULLTEXT index. For example, when you search for a single word, that word is typically more relevant for a row where it occurs several times in the text than a row where it appears only once.

See Also full-text search, FULLTEXT index.

REPEATABLE READ

The default isolation level for InnoDB. It prevents any rows that are queried from being changed by other transactions, thus blocking non-repeatable reads but not phantom reads. It uses a moderately strict locking strategy so that all queries within a transaction see data from the same snapshot, that is, the data as it was at the time the transaction started.

When a transaction with this isolation level performs UPDATE ... WHERE, DELETE ... WHERE, SELECT ... FOR UPDATE, and LOCK IN SHARE MODE operations, other transactions might have to wait.

SELECT ... FOR SHARE replaces SELECT ... LOCK IN SHARE MODE in MySQL 8.0.1, but LOCK IN SHARE MODE remains available for backward compatibility.

See Also ACID, consistent read, isolation level, locking, phantom, transaction.

repertoire

Repertoire is a term applied to character sets. A character set repertoire is the collection of characters in the set.

See Section 10.2.1, “Character Set Repertoire”.

replica

A database server machine in a replication topology that receives changes from another server (the source) and applies those same changes. Thus it maintains the same contents as the source, although it might lag somewhat behind.

In MySQL, replicas are commonly used in disaster recovery, to take the place of a source that fails. They are also commonly used for testing software upgrades and new settings, to ensure that database configuration changes do not cause problems with performance or reliability.

Replicas typically have high workloads, because they process all the DML (write) operations relayed from the source, as well as user queries. To ensure that replicas can apply changes from the source fast enough, they frequently have fast I/O devices and sufficient CPU and memory to run multiple database instances on the same server. For example, the source might use hard drive storage while the replicas use SSDs.

See Also DML, replication, server, source, SSD.

replication

The practice of sending changes from a source, to one or more replicas, so that all databases have the same data. This technique has a wide range of uses, such as load-balancing for better scalability, disaster recovery, and testing software upgrades and configuration changes. The changes can be sent between the databases by methods called row-based replication and statement-based replication.

See Also replica, row-based replication, source, statement-based replication.

restore

The process of putting a set of backup files from the MySQL Enterprise Backup product in place for use by MySQL. This operation can be performed to fix a corrupted database, to return to some earlier point in time, or (in a replication context) to set up a new replica. In the MySQL Enterprise Backup product, this operation is performed by the copy-back option of the mysqlbackup command.

See Also hot backup, MySQL Enterprise Backup, mysqlbackup command, prepared backup, replica, replication.
rollback

A SQL statement that ends a transaction, undoing any changes made by the transaction. It is the opposite of commit, which makes permanent any changes made in the transaction.

By default, MySQL uses the autocommit setting, which automatically issues a commit following each SQL statement. You must change this setting before you can use the rollback technique.

See Also ACID, autocommit, commit, SQL, transaction.

rollback segment

The storage area containing the undo logs. Rollback segments have traditionally resided in the system tablespace. As of MySQL 5.6, rollback segments can reside in undo tablespaces. As of MySQL 5.7, rollback segments are also allocated to the global temporary tablespace.

See Also system tablespace, undo log, undo tablespace.

row

The logical data structure defined by a set of columns. A set of rows makes up a table. Within InnoDB data files, each page can contain one or more rows.

Although InnoDB uses the term row format for consistency with MySQL syntax, the row format is a property of each table and applies to all rows in that table.

See Also column, data files, page, row format, table.

row format

The disk storage format for rows of an InnoDB table. As InnoDB gains new capabilities such as compression, new row formats are introduced to support the resulting improvements in storage efficiency and performance.

The row format of an InnoDB table is specified by the ROW_FORMAT option or by the innodb_default_row_format configuration option (introduced in MySQL 5.7.9). Row formats include REDUNDANT, COMPACT, COMPRESSED, and DYNAMIC. To view the row format of an InnoDB table, issue the SHOW TABLE STATUS statement or query InnoDB table metadata in the INFORMATION_SCHEMA.

See Also compact row format, compressed row format, compression, dynamic row format, redundant row format, row, table.

row lock

A lock that prevents a row from being accessed in an incompatible way by another transaction. Other rows in the same table can be freely written to by other transactions. This is the type of locking done by DML operations on InnoDB tables.

Contrast with table locks used by MyISAM, or during DDL operations on InnoDB tables that cannot be done with online DDL; those locks block concurrent access to the table.

See Also DDL, DML, InnoDB, lock, locking, online DDL, table lock, transaction.

row-based replication

A form of replication where events are propagated from the source specifying how to change individual rows on the replica. It is safe to use for all settings of the innodb_autoinc_lock_mode option.

See Also auto-increment locking, innodb_autoinc_lock_mode, replica, replication, source, statement-based replication.

row-level locking

The locking mechanism used for InnoDB tables, relying on row locks rather than table locks. Multiple transactions can modify the same table concurrently. Only if two transactions try to modify the same row does one of the transactions wait for the other to complete (and release its row locks).

See Also InnoDB, locking, row lock, table lock, transaction.

Ruby

A programming language that emphasizes dynamic typing and object-oriented programming. Some syntax is familiar to Perl developers.
See Also API, Perl, Ruby API.

Ruby API

mysql2, based based on the libmysqlclient API library, is available for Ruby programmers developing MySQL applications. For more information, see Section 23.11, “MySQL Ruby APIs”.

See Also libmysql, Ruby.

rw-lock

The low-level object that InnoDB uses to represent and enforce shared-access locks to internal in-memory data structures following certain rules. Contrast with mutexes, which InnoDB uses to represent and enforce exclusive access to internal in-memory data structures. Mutexes and rw-locks are known collectively as latches.

rw-lock types include s-locks (shared locks), x-locks (exclusive locks), and sx-locks (shared-exclusive locks).

- An s-lock provides read access to a common resource.
- An x-lock provides write access to a common resource while not permitting inconsistent reads by other threads.
- An sx-lock provides write access to a common resource while permitting inconsistent reads by other threads. sx-locks were introduced in MySQL 5.7 to optimize concurrency and improve scalability for read-write workloads.

The following matrix summarizes rw-lock type compatibility.

<table>
<thead>
<tr>
<th></th>
<th>S</th>
<th>SX</th>
<th>X</th>
</tr>
</thead>
<tbody>
<tr>
<td>S</td>
<td>Compatible</td>
<td>SX</td>
<td>Conflict</td>
</tr>
<tr>
<td>SX</td>
<td>Compatible</td>
<td>Conflict</td>
<td>Conflict</td>
</tr>
<tr>
<td>X</td>
<td>Conflict</td>
<td>Conflict</td>
<td>Conflict</td>
</tr>
</tbody>
</table>

See Also latch, lock, mutex, Performance Schema.

S

savepoint

Savepoints help to implement nested transactions. They can be used to provide scope to operations on tables that are part of a larger transaction. For example, scheduling a trip in a reservation system might involve booking several different flights; if a desired flight is unavailable, you might roll back the changes involved in booking that one leg, without rolling back the earlier flights that were successfully booked.

See Also rollback, transaction.

scalability

The ability to add more work and issue more simultaneous requests to a system, without a sudden drop in performance due to exceeding the limits of system capacity. Software architecture, hardware configuration, application coding, and type of workload all play a part in scalability. When the system reaches its maximum capacity, popular techniques for increasing scalability are scale up (increasing the capacity of existing hardware or software) and scale out (adding new servers and more instances of MySQL). Often paired with availability as critical aspects of a large-scale deployment.

See Also availability, scale out, scale up.

scale out

A technique for increasing scalability by adding new servers and more instances of MySQL. For example, setting up replication, NDB Cluster, connection pooling, or other features that spread work across a group of servers. Contrast with scale up.
See Also scalability, scale up.

scale up
A technique for increasing scalability by increasing the capacity of existing hardware or software. For example, increasing the memory on a server and adjusting memory-related parameters such as `innodb_buffer_pool_size` and `innodb_buffer_pool_instances`. Contrast with scale out.
See Also scalability, scale out.

schema
Conceptually, a schema is a set of interrelated database objects, such as tables, table columns, data types of the columns, indexes, foreign keys, and so on. These objects are connected through SQL syntax, because the columns make up the tables, the foreign keys refer to tables and columns, and so on. Ideally, they are also connected logically, working together as part of a unified application or flexible framework. For example, the INFORMATION_SCHEMA and performance_schema databases use “schema” in their names to emphasize the close relationships between the tables and columns they contain.

In MySQL, physically, a schema is synonymous with a database. You can substitute the keyword `SCHEMA` instead of `DATABASE` in MySQL SQL syntax, for example using `CREATE SCHEMA` instead of `CREATE DATABASE`.

Some other database products draw a distinction. For example, in the Oracle Database product, a schema represents only a part of a database: the tables and other objects owned by a single user.
See Also database, INFORMATION_SCHEMA, Performance Schema.

search index
In MySQL, full-text search queries use a special kind of index, the FULLTEXT index. In MySQL 5.6.4 and up, InnoDB and MyISAM tables both support FULLTEXT indexes; formerly, these indexes were only available for MyISAM tables.
See Also full-text search, FULLTEXT index.

secondary index
A type of InnoDB index that represents a subset of table columns. An InnoDB table can have zero, one, or many secondary indexes. (Contrast with the clustered index, which is required for each InnoDB table, and stores the data for all the table columns.)

A secondary index can be used to satisfy queries that only require values from the indexed columns. For more complex queries, it can be used to identify the relevant rows in the table, which are then retrieved through lookups using the clustered index.

Creating and dropping secondary indexes has traditionally involved significant overhead from copying all the data in the InnoDB table. The fast index creation feature makes both `CREATE_INDEX` and `DROP_INDEX` statements much faster for InnoDB secondary indexes.
See Also clustered index, Fast Index Creation, index.

segment
A division within an InnoDB tablespace. If a tablespace is analogous to a directory, the segments are analogous to files within that directory. A segment can grow. New segments can be created.

For example, within a file-per-table tablespace, table data is in one segment and each associated index is in its own segment. The system tablespace contains many different segments, because it can hold many tables and their associated indexes. Prior to MySQL 8.0, the system tablespace also includes one or more rollback segments used for undo logs.

Segments grow and shrink as data is inserted and deleted. When a segment needs more room, it is extended by one extent (1 megabyte) at a time. Similarly, a segment releases one extent's worth of space when all the data in that extent is no longer needed.
See Also extent, file-per-table, rollback segment, system tablespace, tablespace, undo log.
selectivity
A property of data distribution, the number of distinct values in a column (its cardinality) divided by the number of records in the table. High selectivity means that the column values are relatively unique, and can retrieved efficiently through an index. If you (or the query optimizer) can predict that a test in a WHERE clause only matches a small number (or proportion) of rows in a table, the overall query tends to be efficient if it evaluates that test first, using an index.

See Also cardinality, query.

semi-consistent read
A type of read operation used for UPDATE statements, that is a combination of READ COMMITTED and consistent read. When an UPDATE statement examines a row that is already locked, InnoDB returns the latest committed version to MySQL so that MySQL can determine whether the row matches the WHERE condition of the UPDATE. If the row matches (must be updated), MySQL reads the row again, and this time InnoDB either locks it or waits for a lock on it. This type of read operation can only happen when the transaction has the READ COMMITTED isolation level, or when the innodb_locks_unsafe_for_binlog option is enabled. innodb_locks_unsafe_for_binlog was removed in MySQL 8.0.

See Also consistent read, isolation level, READ COMMITTED.

SERIALIZABLE
The isolation level that uses the most conservative locking strategy, to prevent any other transactions from inserting or changing data that was read by this transaction, until it is finished. This way, the same query can be run over and over within a transaction, and be certain to retrieve the same set of results each time. Any attempt to change data that was committed by another transaction since the start of the current transaction, cause the current transaction to wait.

This is the default isolation level specified by the SQL standard. In practice, this degree of strictness is rarely needed, so the default isolation level for InnoDB is the next most strict, REPEATABLE READ.

See Also ACID, consistent read, isolation level, locking, REPEATABLE READ, transaction.

server
A type of program that runs continuously, waiting to receive and act upon requests from another program (the client). Because often an entire computer is dedicated to running one or more server programs (such as a database server, a web server, an application server, or some combination of these), the term server can also refer to the computer that runs the server software.

See Also client, mysqld.

server-side prepared statement
A prepared statement managed by the MySQL server. Historically, issues with server-side prepared statements led Connector/J and Connector/PHP developers to sometimes use client-side prepared statements instead. With modern MySQL server versions, server-side prepared statements are recommended for performance, scalability, and memory efficiency.

See Also client-side prepared statement, Connector/J, Connector/PHP, prepared statement.

servlet
See Also Connector/J.

shared lock
A kind of lock that allows other transactions to read the locked object, and to also acquire other shared locks on it, but not to write to it. The opposite of exclusive lock.

See Also exclusive lock, lock, transaction.

shared tablespace
Another way of referring to the system tablespace or a general tablespace. General tablespaces were introduced in MySQL 5.7. More than one table can reside in a shared tablespace. Only a single table can reside in a file-per-table tablespace.
See Also `general tablespace, system tablespace`.

**sharp checkpoint**

The process of **flushing** to disk all **dirty** buffer pool pages whose redo entries are contained in certain portion of the **redo log**. Occurs before **InnoDB** reuses a portion of a log file; the log files are used in a circular fashion. Typically occurs with write-intensive **workloads**.

See Also `dirty page, flush, redo log, workload`.

**shutdown**

The process of stopping the MySQL server. By default, this process cleans up operations for **InnoDB** tables, so **InnoDB** can be **slow** to shut down, but fast to start up later. If you skip the cleanup operations, it is **fast** to shut down but the cleanup must be performed during the next restart.

The shutdown mode for **InnoDB** is controlled by the `innodb_fast_shutdown` option.

See Also `fast shutdown, InnoDB, slow shutdown, startup`.

**slave**

See `replica`.

**slow query log**

A type of **log** used for performance tuning of SQL statements processed by the MySQL server. The log information is stored in a file. You must enable this feature to use it. You control which categories of “slow” SQL statements are logged. For more information, see Section 5.4.5, “The Slow Query Log”.

See Also `general query log, log`.

**slow shutdown**

A type of **shutdown** that does additional **InnoDB** flushing operations before completing. Also known as a **clean shutdown**. Specified by the configuration parameter `innodb_fast_shutdown=0` or the command `SET GLOBAL innodb_fast_shutdown=0;`. Although the shutdown itself can take longer, that time should be saved on the subsequent startup.

See Also `clean shutdown, fast shutdown, shutdown`.

**snapshot**

A representation of data at a particular time, which remains the same even as changes are **committed** by other **transactions**. Used by certain **isolation levels** to allow **consistent reads**.

See Also `commit, consistent read, isolation level, transaction`.

**sort buffer**

The buffer used for sorting data during creation of an **InnoDB** index. Sort buffer size is configured using the `innodb_sort_buffer_size` configuration option.

**source**

A database server machine in a **replication** scenario that processes the initial insert, update, and delete requests for data. These changes are propagated to, and repeated on, other servers known as **replicas**.

See Also `replica, replication`.

**space ID**

An identifier used to uniquely identify an **InnoDB tablespace** within a MySQL instance. The space ID for the **system tablespace** is always zero; this same ID applies to all tables within the system tablespace or within a general tablespace. Each **file-per-table** tablespace and **general tablespace** has its own space ID.

Prior to MySQL 5.6, this hardcoded value presented difficulties in moving **InnoDB** tablespace files between MySQL instances. Starting in MySQL 5.6, you can copy tablespace files between instances by using the **transportable tablespace** feature involving the statements `FLUSH TABLES ... FOR EXPORT`, `ALTER TABLE ... DISCARD TABLESPACE`, and `ALTER TABLE ... IMPORT TABLESPACE`. The information
needed to adjust the space ID is conveyed in the .cfg file which you copy along with the tablespace. See Section 14.6.1.3, “Importing InnoDB Tables” for details. See Also .cfg file, file-per-table, general tablespace, .ibd file, system tablespace, tablespace, transportable tablespace.

sparse file
A type of file that uses file system space more efficiently by writing metadata representing empty blocks to disk instead of writing the actual empty space. The InnoDB transparent page compression feature relies on sparse file support. For more information, see InnoDB Page Compression. See Also hole punching, transparent page compression.

spin
A type of wait operation that continuously tests whether a resource becomes available. This technique is used for resources that are typically held only for brief periods, where it is more efficient to wait in a “busy loop” than to put the thread to sleep and perform a context switch. If the resource does not become available within a short time, the spin loop ceases and another wait technique is used. See Also latch, lock, mutex, wait.

Spring
A Java-based application framework designed for assisting in application design by providing a way to configure components. See Also J2EE.

SQL
The Structured Query Language that is standard for performing database operations. Often divided into the categories DDL, DML, and queries. MySQL includes some additional statement categories such as replication. See Chapter 9, Language Structure for the building blocks of SQL syntax, Chapter 11, Data Types for the data types to use for MySQL table columns, Chapter 13, SQL Statements for details about SQL statements and their associated categories, and Chapter 12, Functions and Operators for standard and MySQL-specific functions to use in queries. See Also DDL, DML, query, replication.

SQLState
An error code defined by the JDBC standard, for exception handling by applications using Connector/J. See Also Connector/J, JDBC.

SSD
Acronym for “solid-state drive”. A type of storage device with different performance characteristics than a traditional hard disk drive (HDD): smaller storage capacity, faster for random reads, no moving parts, and with a number of considerations affecting write performance. Its performance characteristics can influence the throughput of a disk-bound workload. See Also disk-bound, HDD.

SSL
Acronym for “secure sockets layer”. Provides the encryption layer for network communication between an application and a MySQL database server. See Also keystore, truststore.

startup
The process of starting the MySQL server. Typically done by one of the programs listed in Section 4.3, “Server and Server-Startup Programs”. The opposite of shutdown. See Also shutdown.

statement interceptor
A type of interceptor for tracing, debugging, or augmenting SQL statements issued by a database application. Sometimes also known as a command interceptor.
In Java applications using Connector/J, setting up this type of interceptor involves implementing the com.mysql.jdbc.StatementInterceptorV2 interface, and adding a statementInterceptors property to the connection string.

In Visual Studio applications using Connector/NET, setting up this type of interceptor involves defining a class that inherits from the BaseCommandInterceptor class and specifying that class name as part of the connection string.

See Also command interceptor, connection string, Connector/J, Connector/NET, interceptor, Java, Visual Studio.

statement-based replication
A form of replication where SQL statements are sent from the source and replayed on the replica. It requires some care with the setting for the innodb_autoinc_lock_mode option, to avoid potential timing problems with auto-increment locking.

See Also auto-increment locking, innodb_autoinc_lock_mode, replica, replication, row-based replication, source.

statistics
Estimated values relating to each InnoDB table and index, used to construct an efficient query execution plan. The main values are the cardinality (number of distinct values) and the total number of table rows or index entries. The statistics for the table represent the data in its primary key index. The statistics for a secondary index represent the rows covered by that index.

The values are estimated rather than counted precisely because at any moment, different transactions can be inserting and deleting rows from the same table. To keep the values from being recalculated frequently, you can enable persistent statistics, where the values are stored in InnoDB system tables, and refreshed only when you issue an ANALYZE TABLE statement.

You can control how NULL values are treated when calculating statistics through the innodb_stats_method configuration option.

Other types of statistics are available for database objects and database activity through the INFORMATION_SCHEMA and PERFORMANCE_SCHEMA tables.
See Also cardinality, index, INFORMATION_SCHEMA, NULL, Performance Schema, persistent statistics, primary key, query execution plan, secondary index, table, transaction.

stemming
The ability to search for different variations of a word based on a common root word, such as singular and plural, or past, present, and future verb tense. This feature is currently supported in MyISAM full-text search feature but not in FULLTEXT indexes for InnoDB tables.
See Also full-text search, FULLTEXT index.

stopword
In a FULLTEXT index, a word that is considered common or trivial enough that it is omitted from the search index and ignored in search queries. Different configuration settings control stopword processing for InnoDB and MyISAM tables. See Section 12.10.4, “Full-Text Stopwords” for details.
See Also FULLTEXT index, search index.

storage engine
A component of the MySQL database that performs the low-level work of storing, updating, and querying data. In MySQL 5.5 and higher, InnoDB is the default storage engine for new tables, superceding MyISAM. Different storage engines are designed with different tradeoffs between factors such as memory usage versus disk usage, read speed versus write speed, and speed versus robustness. Each storage engine manages specific tables, so we refer to InnoDB tables, MyISAM tables, and so on.

The MySQL Enterprise Backup product is optimized for backing up InnoDB tables. It can also back up tables handled by MyISAM and other storage engines.
See Also InnoDB, MySQL Enterprise Backup, table type.

stored object
A stored program or view.

stored program
A stored routine (procedure or function), trigger, or Event Scheduler event.

stored routine
A stored procedure or function.

strict mode
The general name for the setting controlled by the innodb_strict_mode option. Turning on this setting causes certain conditions that are normally treated as warnings, to be considered errors. For example, certain invalid combinations of options related to file format and row format, that normally produce a warning and continue with default values, now cause the CREATE TABLE operation to fail. innodb_strict_mode is enabled by default in MySQL 5.7.

MySQL also has something called strict mode. See Section 5.1.10, “Server SQL Modes”.
See Also file format, innodb_strict_mode, row format.

sublist
Within the list structure that represents the buffer pool, pages that are relatively old and relatively new are represented by different portions of the list. A set of parameters control the size of these portions and the dividing point between the new and old pages.
See Also buffer pool, eviction, list, LRU.

supremum record
A pseudo-record in an index, representing the gap above the largest value in that index. If a transaction has a statement such as SELECT ... FROM ... WHERE col > 10 FOR UPDATE;, and the largest value in the column is 20, it is a lock on the supremum record that prevents other transactions from inserting even larger values such as 50, 100, and so on.
See Also gap, infimum record, pseudo-record.

surrogate key
Synonym name for synthetic key.
See Also synthetic key.

synthetic key
An indexed column, typically a primary key, where the values are assigned arbitrarly. Often done using an auto-increment column. By treating the value as completely arbitrary, you can avoid overly restrictive rules and faulty application assumptions. For example, a numeric sequence representing employee numbers might have a gap if an employee was approved for hiring but never actually joined. Or employee number 100 might have a later hiring date than employee number 500, if they left the company and later rejoined. Numeric values also produce shorter values of predictable length. For example, storing numeric codes meaning “Road”, “Boulevard”, “Expressway”, and so on is more space-efficient than repeating those strings over and over.

Also known as a surrogate key. Contrast with natural key.
See Also auto-increment, natural key, primary key, surrogate key.

system tablespace
One or more data files (ibdata files) containing metadata for InnoDB-related objects (the InnoDB data dictionary), and the storage areas for the change buffer, the doublewrite buffer, and possibly undo logs. Depending on the innodb_file_per_table setting, it might also contain table and index data for InnoDB tables. The data and metadata in the system tablespace apply to all databases in a MySQL instance.
Prior to MySQL 5.6.7, the default was to keep all InnoDB tables and indexes inside the system tablespace, often causing this file to become very large. Because the system tablespace never shrinks, storage problems could arise if large amounts of temporary data were loaded and then deleted. In MySQL 5.6.7 and higher, the default is file-per-table mode, where each table and its associated indexes are stored in a separate .ibd file. This default makes it easier to use InnoDB features that rely on the Barracuda file format, such as table compression, efficient storage of off-page columns, and large index key prefixes (innodb_large_prefix).

Keeping all table data in the system tablespace or in separate .ibd files has implications for storage management in general. The MySQL Enterprise Backup product might back up a small set of large files, or many smaller files. On systems with thousands of tables, the file system operations to process thousands of .ibd files can cause bottlenecks.

In MySQL 5.6 and higher, the innodb_undo_tablespaces defines the number of undo tablespaces for undo logs.

See Also Barracuda, change buffer, compression, data dictionary, database, doublewrite buffer, dynamic row format, file-per-table, general tablespace, .ibd file, ibdata file, innodb_file_per_table, instance, MySQL Enterprise Backup, off-page column, tablesapce, undo log.

.TRG file

A file containing trigger parameters. Files with this extension are always included in backups produced by the mysqlbackup command of the MySQL Enterprise Backup product.

See Also MySQL Enterprise Backup, mysqlbackup command, .TRN file.

.TRN file

A file containing trigger namespace information. Files with this extension are always included in backups produced by the mysqlbackup command of the MySQL Enterprise Backup product.

See Also MySQL Enterprise Backup, mysqlbackup command, .TRG file.

table

Each MySQL table is associated with a particular storage engine. InnoDB tables have particular physical and logical characteristics that affect performance, scalability, backup, administration, and application development.

In terms of file storage, an InnoDB table belongs to one of the following tablespace types:

• The shared InnoDB system tablespace, which is comprised of one or more ibdata files.

• A file-per-table tablesapce, comprised of an individual .ibd file.

• A shared general tablespace, comprised of an individual .ibd file. General tablespaces were introduced in MySQL 5.7.6.

.ibd data files contain both table and index data.

InnoDB tables created in file-per-table tablespaces can use the Barracuda file format, and Barracuda tables can use DYNAMIC or COMPRESSED row format. These row formats enable InnoDB features such as compression, efficient storage of off-page columns, and large index key prefixes (see innodb_large_prefix). General tablespaces support all row formats regardless of the innodb_file_format setting.

Up to MySQL 5.7.5, InnoDB tables inside the system tablespace had to use the Antelope file format for backward compatibility with MySQL 5.1 and earlier. The Antelope file format supports COMPACT and REDUNDANT row format. The system tablespace supports tables that use DYNAMIC row format as of MySQL 5.7.6.
The rows of an InnoDB table are organized into an index structure known as the clustered index, with entries sorted based on the primary key columns of the table. Data access is optimized for queries that filter and sort on the primary key columns, and each index contains a copy of the associated primary key columns for each entry. Modifying values for any of the primary key columns is an expensive operation. Thus an important aspect of InnoDB table design is choosing a primary key with columns that are used in the most important queries, and keeping the primary key short, with rarely changing values.

See Also Antelope, backup, Barracuda, clustered index, compact row format, compressed row format, compression, dynamic row format, Fast Index Creation, file-per-table, .ibd file, index, off-page column, primary key, redundant row format, row, system tablespace, tablespace.

table lock
A lock that prevents any other transaction from accessing a table. InnoDB makes considerable effort to make such locks unnecessary, by using techniques such as online DDL, row locks and consistent reads for processing DML statements and queries. You can create such a lock through SQL using the LOCK TABLE statement; one of the steps in migrating from other database systems or MySQL storage engines is to remove such statements wherever practical.

See Also consistent read, DML, lock, locking, online DDL, query, row lock, table, transaction.

table scan
See full table scan.

table statistics
See statistics.

table type
Obsolete synonym for storage engine. We refer to InnoDB tables, MyISAM tables, and so on.

See Also InnoDB, storage engine.

tablespace
A data file that can hold data for one or more InnoDB tables and associated indexes.

The system tablespace contains the InnoDB data dictionary, and prior to MySQL 5.6 holds all other InnoDB tables by default.

The innodb_file_per_table option, enabled by default in MySQL 5.6 and higher, allows tables to be created in their own tablespaces. File-per-table tablespaces support features such as efficient storage of off-page columns, table compression, and transportable tablespaces. See Section 14.6.3.2, “File-Per-Table Tablespaces” for details.

InnoDB introduced general tablespaces in MySQL 5.7.6. General tablespaces are shared tablespaces created using CREATE TABLESPACE syntax. They can be created outside of the MySQL data directory, are capable of holding multiple tables, and support tables of all row formats.

MySQL NDB Cluster also groups its tables into tablespaces. See Section 18.6.10.1, “NDB Cluster Disk Data Objects” for details.

See Also compressed row format, data dictionary, data files, file-per-table, general tablespace, index, innodb_file_per_table, system tablespace, table.

Tcl
A programming language originating in the Unix scripting world. Sometimes extended by code written in C, C++, or Java. For the open-source Tcl API for MySQL, see Section 23.12, “MySQL Tcl API”.

See Also API.

temporary table
A table whose data does not need to be truly permanent. For example, temporary tables might be used as storage areas for intermediate results in complicated calculations or transformations; this intermediate data would...
not need to be recovered after a crash. Database products can take various shortcuts to improve the performance of operations on temporary tables, by being less scrupulous about writing data to disk and other measures to protect the data across restarts.

Sometimes, the data itself is removed automatically at a set time, such as when the transaction ends or when the session ends. With some database products, the table itself is removed automatically too.

See Also table.

temporary tablespace
The tablespace for non-compressed InnoDB temporary tables and related objects, introduced in MySQL 5.7. The innodb_temp_data_file_path configuration file option defines the relative path, name, size, and attributes for temporary tablespace data files. If innodb_temp_data_file_path is not specified, the default behavior is to create a single auto-extending 12MB data file named ibtmp1 in the data directory. The temporary tablespace is recreated on each server start and receives a dynamically generated space ID. The temporary tablespace cannot reside on a raw device. Startup is refused if the temporary tablespace cannot be created.

The temporary tablespace is removed on normal shutdown or on an aborted initialization. The temporary tablespace is not removed when a crash occurs. In this case, the database administrator may remove the temporary tablespace manually or restart the server with the same configuration, which removes and recreates the temporary tablespace.

See Also temporary table.

text collection
The set of columns included in a FULLTEXT index.
See Also FULLTEXT index.

thread
A unit of processing that is typically more lightweight than a process, allowing for greater concurrency.
See Also concurrency, master thread, process, Pthreads.

Tomcat
An open source J2EE application server, implementing the Java Servlet and JavaServer Pages programming technologies. Consists of a web server and Java servlet container. With MySQL, typically used in conjunction with Connector/J.
See Also J2EE.

torn page
An error condition that can occur due to a combination of I/O device configuration and hardware failure. If data is written out in chunks smaller than the InnoDB page size (by default, 16KB), a hardware failure while writing could result in only part of a page being stored to disk. The InnoDB doublewrite buffer guards against this possibility.
See Also doublewrite buffer.

TPS
Acronym for “transactions per second”, a unit of measurement sometimes used in benchmarks. Its value depends on the workload represented by a particular benchmark test, combined with factors that you control such as the hardware capacity and database configuration.
See Also transaction, workload.

transaction
Transactions are atomic units of work that can be committed or rolled back. When a transaction makes multiple changes to the database, either all the changes succeed when the transaction is committed, or all the changes are undone when the transaction is rolled back.

Database transactions, as implemented by InnoDB, have properties that are collectively known by the acronym ACID, for atomicity, consistency, isolation, and durability.
See Also ACID, commit, isolation level, lock, rollback.

transaction ID
An internal field associated with each row. This field is physically changed by INSERT, UPDATE, and DELETE operations to record which transaction has locked the row.
See Also implicit row lock, row, transaction.

transparent page compression
A feature added in MySQL 5.7.8 that permits page-level compression for InnoDB tables that reside in file-per-table tablespaces. Page compression is enabled by specifying the COMPRESSION attribute with CREATE TABLE or ALTER TABLE. For more information, see InnoDB Page Compression.
See Also file-per-table, hole punching, sparse file.

transportable tablespace
A feature that allows a tablespace to be moved from one instance to another. Traditionally, this has not been possible for InnoDB tablespaces because all table data was part of the system tablespace. In MySQL 5.6 and higher, the FLUSH TABLES ... FOR EXPORT syntax prepares an InnoDB table for copying to another server; running ALTER TABLE ... DISCARD TABLESPACE and ALTER TABLE ... IMPORT TABLESPACE on the other server brings the copied data file into the other instance. A separate .cfg file, copied along with the .ibd file, is used to update the table metadata (for example the space ID) as the tablespace is imported. See Section 14.6.1.3, “Importing InnoDB Tables” for usage information.
See Also .cfg file, .ibd file, space ID, system tablespace, tablespace.

troubleshooting
The process of determining the source of a problem. Some of the resources for troubleshooting MySQL problems include:

• Section 2.10.2.1, “Troubleshooting Problems Starting the MySQL Server”
• Section 6.2.14, “Troubleshooting Problems Connecting to MySQL”
• Section B.3.3.2, “How to Reset the Root Password”
• Section B.3.2, “Common Errors When Using MySQL Programs”
• Section 14.21, “InnoDB Troubleshooting”.

truncate
A DDL operation that removes the entire contents of a table, while leaving the table and related indexes intact. Contrast with drop. Although conceptually it has the same result as a DELETE statement with no WHERE clause, it operates differently behind the scenes: InnoDB creates a new empty table, drops the old table, then renames the new table to take the place of the old one. Because this is a DDL operation, it cannot be rolled back.

If the table being truncated contains foreign keys that reference another table, the truncation operation uses a slower method of operation, deleting one row at a time so that corresponding rows in the referenced table can be deleted as needed by any ON DELETE CASCADE clause. (MySQL 5.5 and higher do not allow this slower form of truncate, and return an error instead if foreign keys are involved. In this case, use a DELETE statement instead. See Also DDL, drop, foreign key, rollback.

truststore
See Also SSL.

tuple
A technical term designating an ordered set of elements. It is an abstract notion, used in formal discussions of database theory. In the database field, tuples are usually represented by the columns of a table row. They could
also be represented by the result sets of queries, for example, queries that retrieved only some columns of a
table, or columns from joined tables.
See Also cursor.

two-phase commit
An operation that is part of a distributed transaction, under the XA specification. (Sometimes abbreviated as
2PC.) When multiple databases participate in the transaction, either all databases commit the changes, or all
databases roll back the changes.
See Also commit, rollback, transaction, XA.

U

undo
Data that is maintained throughout the life of a transaction, recording all changes so that they can be undone
in case of a rollback operation. It is stored in undo logs either within the system tablespace (in MySQL 5.7 or
earlier) or in separate undo tablespaces. As of MySQL 8.0, undo logs reside in undo tablespaces by default.
See Also rollback, rollback segment, system tablespace, transaction, undo log, undo tablespace.

undo buffer
See undo log.

undo log
A storage area that holds copies of data modified by active transactions. If another transaction needs to see the
original data (as part of a consistent read operation), the unmodified data is retrieved from this storage area.

In MySQL 5.6 and MySQL 5.7, you can use the innodb_undo_tablespaces variable have undo logs reside in
undo tablespaces, which can be placed on another storage device such as an SSD. In MySQL 8.0, undo logs reside in two default undo tablespaces that are created when MySQL is initialized, and additional undo
tablespaces can be created using CREATE UNDO TABLESPACE syntax.

The undo log is split into separate portions, the insert undo buffer and the update undo buffer.
See Also consistent read, rollback segment, SSD, system tablespace, transaction, undo tablespace.

undo log segment
A collection of undo logs. Undo log segments exists within rollback segments. An undo log segment might
contain undo logs from multiple transactions. An undo log segment can only be used by one transaction at a time
but can be reused after it is released at transaction commit or rollback. May also be referred to as an “undo
segment”.
See Also commit, rollback, rollback segment, undo log.

undo tablespace
An undo tablespace contains undo logs. Undo logs exist within undo log segments, which are contained
within rollback segments. Rollback segments have traditionally resided in the system tablespace. As of MySQL
5.6, rollback segments can reside in undo tablespaces. In MySQL 5.6 and MySQL 5.7, the number of undo
tablespaces is controlled by the innodb_undo_tablespaces configuration option. In MySQL 8.0, two default undo tablespaces are created when the MySQL instance is initialized, and additional undo tablespaces can be
created using CREATE UNDO TABLESPACE syntax.

For more information, see Section 14.6.3.3, “Undo Tablespaces”.
See Also rollback segment, system tablespace, undo log, undo log segment.

Unicode
A system for supporting national characters, character sets, code pages, and other internationalization aspects in
a flexible and standardized way.
Unicode support is an important aspect of the ODBC standard. Connector/ODBC 5.1 is a Unicode driver, as opposed to Connector/ODBC 3.51, which is an ANSI driver.
See Also ANSI, Connector/ODBC, ODBC.

unique constraint
A kind of constraint that asserts that a column cannot contain any duplicate values. In terms of relational algebra, it is used to specify 1-to-1 relationships. For efficiency in checking whether a value can be inserted (that is, the value does not already exist in the column), a unique constraint is supported by an underlying unique index.
See Also constraint, relational, unique index.

unique index
An index on a column or set of columns that have a unique constraint. Because the index is known not to contain any duplicate values, certain kinds of lookups and count operations are more efficient than in the normal kind of index. Most of the lookups against this type of index are simply to determine if a certain value exists or not. The number of values in the index is the same as the number of rows in the table, or at least the number of rows with non-null values for the associated columns.

Change buffering optimization does not apply to unique indexes. As a workaround, you can temporarily set `unique_checks=0` while doing a bulk data load into an InnoDB table.
See Also cardinality, change buffering, unique constraint, unique key.

unique key
The set of columns (one or more) comprising a unique index. When you can define a WHERE condition that matches exactly one row, and the query can use an associated unique index, the lookup and error handling can be performed very efficiently.
See Also cardinality, unique constraint, unique index.

V

variable-length type
A data type of variable length. VARCHAR, VARBINARY, and BLOB and TEXT types are variable-length types.

InnoDB treats fixed-length fields greater than or equal to 768 bytes in length as variable-length fields, which can be stored off-page. For example, a CHAR(255) column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with utf8mb4.
See Also off-page column, overflow page.

victim
The transaction that is automatically chosen to be rolled back when a deadlock is detected. InnoDB rolls back the transaction that has updated the fewest rows.

Deadlock detection can be disabled using the `innodb_deadlock_detect` configuration option.
See Also deadlock, deadlock detection, innodb_lock_wait_timeout, transaction.

view
A stored query that when invoked produces a result set. A view acts as a virtual table.

Visual Studio
For supported versions of Visual Studio, see the following references:

- Connector/.NET: Connector/.NET Versions
- Connector/C++ 8.0: Platform Support and Prerequisites

See Also Connector/C++, Connector/.NET.
When an operation, such as acquiring a lock, mutex, or latch, cannot be completed immediately, InnoDB pauses and tries again. The mechanism for pausing is elaborate enough that this operation has its own name, the wait. Individual threads are paused using a combination of internal InnoDB scheduling, operating system wait() calls, and short-duration spin loops.

On systems with heavy load and many transactions, you might use the output from the SHOW INNODB STATUS command or Performance Schema to determine whether threads are spending too much time waiting, and if so, how you can improve concurrency.

See Also concurrency, latch, lock, mutex, Performance Schema, spin.

A backup taken while the database is running, but that restricts some database operations during the backup process. For example, tables might become read-only. For busy applications and websites, you might prefer a hot backup.

See Also backup, cold backup, hot backup.

To run a system under a typical workload for some time after startup, so that the buffer pool and other memory regions are filled as they would be under normal conditions. This process happens naturally over time when a MySQL server is restarted or subjected to a new workload.

Typically, you run a workload for some time to warm up the buffer pool before running performance tests, to ensure consistent results across multiple runs; otherwise, performance might be artificially low during the first run.

In MySQL 5.6, you can speed up the warmup process by enabling the innodb_buffer_pool_dump_at_shutdown and innodb_buffer_pool_load_at_startup configuration options, to bring the contents of the buffer pool back into memory after a restart. These options are enabled by default in MySQL 5.7. See Section 14.8.3.5, “Saving and Restoring the Buffer Pool State”. See Also buffer pool, workload.

The combination and volume of SQL and other database operations, performed by a database application during typical or peak usage. You can subject the database to a particular workload during performance testing to identify bottlenecks, or during capacity planning.

See Also bottleneck, CPU-bound, disk-bound, SQL.

An optimization technique that reduces write operations when dirty pages are flushed from the InnoDB buffer pool. If a row in a page is updated multiple times, or multiple rows on the same page are updated, all of those changes are stored to the data files in a single write operation rather than one write for each change.

See Also buffer pool, dirty page, flush.

A standard interface for coordinating distributed transactions, allowing multiple databases to participate in a transaction while maintaining ACID compliance. For full details, see Section 13.3.7, “XA Transactions”.

XA Distributed Transaction support is enabled by default. If you are not using this feature, you can disable the innodb_support_xa configuration option, avoiding the performance overhead of an extra fsync for each transaction.
As of MySQL 5.7.10, disabling `innodb_support_xa` is not permitted as it makes replication unsafe and prevents performance gains associated with `binary log` group commit. The `innodb_support_xa` configuration option is removed in MySQL 8.0.

See Also ACID, binary log, commit, transaction, two-phase commit.

**young**

A characteristic of a page in the InnoDB buffer pool meaning that it has been accessed recently, and so is moved within the buffer pool data structure, so that it is not flushed too soon by the LRU algorithm. This term is used in some INFORMATION_SCHEMA column names of tables related to the buffer pool.

See Also buffer pool, flush, INFORMATION_SCHEMA, LRU, page.
