When you create a new table, you can specify which storage engine to use by adding an `ENGINE` table option to the `CREATE TABLE` statement:

```
-- ENGINE=INNODB not needed unless you have set a different
-- default storage engine.
CREATE TABLE t1 (i INT) ENGINE = INNODB;
-- Simple table definitions can be switched from one to another.
CREATE TABLE t2 (i INT) ENGINE = CSV;
CREATE TABLE t3 (i INT) ENGINE = MEMORY;
```

When you omit the `ENGINE` option, the default storage engine is used. The default engine is InnoDB in MySQL 5.6. You can specify the default engine by using the `--default-storage-engine` server startup option, or by setting the `default-storage-engine` option in the `my.cnf` configuration file.

You can set the default storage engine for the current session by setting the `default_storage_engine` variable:

```
SET default_storage_engine=NDBCLUSTER;
```

As of MySQL 5.6.3, the storage engine for TEMPORARY tables created with `CREATE TEMPORARY TABLE` can be set separately from the engine for permanent tables by setting the `default_tmp_storage_engine`, either at startup or at runtime. Before MySQL 5.6.3, `default_storage_engine` sets the engine for both permanent and TEMPORARY tables.

To convert a table from one storage engine to another, use an `ALTER TABLE` statement that indicates the new engine:

```
ALTER TABLE t ENGINE = InnoDB;
```

See Section 13.1.17, “CREATE TABLE Syntax”, and Section 13.1.7, “ALTER TABLE Syntax”.

If you try to use a storage engine that is not compiled in or that is compiled in but deactivated, MySQL instead creates a table using the default storage engine. For example, in a replication setup, perhaps your master server uses InnoDB tables for maximum safety, but the slave servers use alternative storage engines for speed at the expense of durability or concurrency.
By default, a warning is generated whenever `CREATE TABLE` or `ALTER TABLE` cannot use the default storage engine. To prevent confusing, unintended behavior if the desired engine is unavailable, enable the `NO_ENGINE_SUBSTITUTION` SQL mode. If the desired engine is unavailable, this setting produces an error instead of a warning, and the table is not created or altered. See Section 5.1.10, “Server SQL Modes”.

For new tables, MySQL always creates an `.frm` file to hold the table and column definitions. The table's index and data may be stored in one or more other files, depending on the storage engine. The server creates the `.frm` file above the storage engine level. Individual storage engines create any additional files required for the tables that they manage. If a table name contains special characters, the names for the table files contain encoded versions of those characters as described in Section 9.2.3, “Mapping of Identifiers to File Names”.

### 15.2 The MyISAM Storage Engine

MyISAM is based on the older (and no longer available) ISAM storage engine but has many useful extensions.

### The MyISAM Storage Engine

<table>
<thead>
<tr>
<th>Feature</th>
<th>Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>Update statistics for data dictionary</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Each MyISAM table is stored on disk in three files. The files have names that begin with the table name and have an extension to indicate the file type. An .frm file stores the table format. The data file has an .MYD (MYData) extension. The index file has an .MYI (MYIndex) extension.

To specify explicitly that you want a MyISAM table, indicate that with an ENGINE table option:

```sql
CREATE TABLE t (i INT) ENGINE = MYISAM;
```

In MySQL 5.6, it is normally necessary to use ENGINE to specify the MyISAM storage engine because InnoDB is the default engine.

You can check or repair MyISAM tables with the mysqlcheck client or myisamchk utility. You can also compress MyISAM tables with myisampack to take up much less space. See Section 4.5.3, "mysqlcheck — A Table Maintenance Program", Section 4.6.3, "myisamchk — MyISAM Table-Maintenance Utility", and Section 4.6.5, "myisampack — Generate Compressed, Read-Only MyISAM Tables".

MyISAM tables have the following characteristics:

- All data values are stored with the low byte first. This makes the data machine and operating system independent. The only requirements for binary portability are that the machine uses two's-complement signed integers and IEEE floating-point format. These requirements are widely used among mainstream machines. Binary compatibility might not be applicable to embedded systems, which sometimes have peculiar processors.

  There is no significant speed penalty for storing data low byte first; the bytes in a table row normally are unaligned and it takes little more processing to read an unaligned byte in order than in reverse order. Also, the code in the server that fetches column values is not time critical compared to other code.

- All numeric key values are stored with the high byte first to permit better index compression.

- Large files (up to 63-bit file length) are supported on file systems and operating systems that support large files.

- There is a limit of \((2^{32})^2 (1.844E+19)\) rows in a MyISAM table.

- The maximum number of indexes per MyISAM table is 64.

  The maximum number of columns per index is 16.

- The maximum key length is 1000 bytes. This can also be changed by changing the source and recompiling. For the case of a key longer than 250 bytes, a larger key block size than the default of 1024 bytes is used.

- When rows are inserted in sorted order (as when you are using an AUTO_INCREMENT column), the index tree is split so that the high node only contains one key. This improves space utilization in the index tree.

- Internal handling of one AUTO_INCREMENT column per table is supported. MyISAM automatically updates this column for INSERT and UPDATE operations. This makes AUTO_INCREMENT columns faster (at least 10%). Values at the top of the sequence are not reused after being deleted. (When an AUTO_INCREMENT column is defined as the last column of a multiple-column index, reuse of values deleted from the top of a sequence does occur.) The AUTO_INCREMENT value can be reset with ALTER TABLE or myisamchk.
• Dynamic-sized rows are much less fragmented when mixing deletes with updates and inserts. This is done by automatically combining adjacent deleted blocks and by extending blocks if the next block is deleted.

• **MyISAM** supports concurrent inserts: If a table has no free blocks in the middle of the data file, you can **INSERT** new rows into it at the same time that other threads are reading from the table. A free block can occur as a result of deleting rows or an update of a dynamic length row with more data than its current contents. When all free blocks are used up (filled in), future inserts become concurrent again. See Section 8.11.3, “Concurrent Inserts”.

• You can put the data file and index file in different directories on different physical devices to get more speed with the **DATA DIRECTORY** and **INDEX DIRECTORY** table options to **CREATE TABLE**. See Section 13.1.17, “CREATE TABLE Syntax”.

• **BLOB** and **TEXT** columns can be indexed.

• **NULL** values are permitted in indexed columns. This takes 0 to 1 bytes per key.

• Each character column can have a different character set. See Chapter 10, **Character Sets, Collations, Unicode**.

• There is a flag in the **MyISAM** index file that indicates whether the table was closed correctly. If **mysql** is started with the **--myisam-recover-options** option, **MyISAM** tables are automatically checked when opened, and are repaired if the table wasn't closed properly.

• **myisamchk** marks tables as checked if you run it with the **--update-state** option. **myisamchk --fast** checks only those tables that don't have this mark.

• **myisamchk --analyze** stores statistics for portions of keys, as well as for entire keys.

• **myisampack** can pack **BLOB** and **VARCHAR** columns.

**MyISAM** also supports the following features:

• Support for a true **VARCHAR** type; a **VARCHAR** column starts with a length stored in one or two bytes.

• Tables with **VARCHAR** columns may have fixed or dynamic row length.

• The sum of the lengths of the **VARCHAR** and **CHAR** columns in a table may be up to 64KB.

• Arbitrary length **UNIQUE** constraints.

- **--myisam-recover-options=mode**

  Set the mode for automatic recovery of crashed MyISAM tables.

- **--delay-key-write=ALL**

  Don't flush key buffers between writes for any MyISAM table.

![Note](https://example.com/note.png)

If you do this, you should not access MyISAM tables from another program (such as another MySQL server or with myisamchk) when the tables are in use. Doing so risks index corruption. Using **--external-locking** does not eliminate this risk.

The following system variables affect the behavior of MyISAM tables. For additional information, see Section 5.1.7, “Server System Variables”.

- **bulk_insert_buffer_size**

  The size of the tree cache used in bulk insert optimization.

![Note](https://example.com/note.png)

  This is a limit per thread!

- **myisam_max_sort_file_size**
Space Needed for Keys

The maximum size of the temporary file that MySQL is permitted to use while re-creating a MyISAM index (during REPAIR TABLE, ALTER TABLE, or LOAD DATA). If the file size would be larger than this value, the index is created using the key cache instead, which is slower. The value is given in bytes.

- **myisam_sort_buffer_size**

  Set the size of the buffer used when recovering tables.

Automatic recovery is activated if you start `mysqld` with the `--myisam-recover-options` option. In this case, when the server opens a MyISAM table, it checks whether the table is marked as crashed or whether the open count variable for the table is not 0 and you are running the server with external locking disabled. If either of these conditions is true, the following happens:

- The server checks the table for errors.
- If the server finds an error, it tries to do a fast table repair (with sorting and without re-creating the data file).
- If the repair fails because of an error in the data file (for example, a duplicate-key error), the server tries again, this time re-creating the data file.
- If the repair still fails, the server tries once more with the old repair option method (write row by row without sorting). This method should be able to repair any type of error and has low disk space requirements.

If the recovery wouldn't be able to recover all rows from previously completed statements and you didn't specify `FORCE` in the value of the `--myisam-recover-options` option, automatic repair aborts with an error message in the error log:

```
Error: Couldn't repair table: test.g00pages
```

If you specify `FORCE`, a warning like this is written instead:

```
Warning: Found 344 of 354 rows when repairing ./test/g00pages
```

If the automatic recovery value includes `BACKUP`, the recovery process creates files with names of the form `tbl_name-datetime.BAK`. You should have a `cron` script that automatically moves these files from the database directories to backup media.

### 15.2.2 Space Needed for Keys

MyISAM tables use B-tree indexes. You can roughly calculate the size for the index file as `(key_length +4)/0.67`, summed over all keys. This is for the worst case when all keys are inserted in sorted order and the table doesn't have any compressed keys.

String indexes are space compressed. If the first index part is a string, it is also prefix compressed. Space compression makes the index file smaller than the worst-case figure if a string column has a lot of trailing space or is a `VARCHAR` column that is not always used to the full length. Prefix compression is used on keys that start with a string. Prefix compression helps if there are many strings with an identical prefix.

In MyISAM tables, you can also prefix compress numbers by specifying the `PACK_KEYS=1` table option when you create the table. Numbers are stored with the high byte first, so this helps when you have many integer keys that have an identical prefix.
15.2.3 MyISAM Table Storage Formats

MyISAM supports three different storage formats. Two of them, fixed and dynamic format, are chosen automatically depending on the type of columns you are using. The third, compressed format, can be created only with the myisampack utility (see Section 4.6.5, "myisampack — Generate Compressed, Read-Only MyISAM Tables").

When you use CREATE TABLE or ALTER TABLE for a table that has no BLOB or TEXT columns, you can force the table format to FIXED or DYNAMIC with the ROW_FORMAT table option.

See Section 13.1.17, "CREATE TABLE Syntax", for information about ROW_FORMAT.

You can decompress (unpack) compressed MyISAM tables using myisamchk --unpack; see Section 4.6.3, "myisamchk — MyISAM Table-Maintenance Utility", for more information.

15.2.3.1 Static (Fixed-Length) Table Characteristics

Static format is the default for MyISAM tables. It is used when the table contains no variable-length columns (VARCHAR, VARBINARY, BLOB, or TEXT). Each row is stored using a fixed number of bytes.

Of the three MyISAM storage formats, static format is the simplest and most secure (least subject to corruption). It is also one of the fastest of the on-disk formats due to the ease with which rows in the data file can be found on disk: To look up a row based on a row number in the index, multiply the row number by the row length to calculate the row position. Also, when scanning a table, it is very easy to read a constant number of rows with each disk read operation.

The security is evidenced if your computer crashes while the MySQL server is writing to a fixed-format MyISAM file. In this case, myisamchk can easily determine where each row starts and ends, so it can usually reclaim all rows except the partially written one. MyISAM table indexes can always be reconstructed based on the data rows.

**Note**

Fixed-length row format is only available for tables without BLOB or TEXT columns. Creating a table with these columns with an explicit ROW_FORMAT clause will not raise an error or warning; the format specification will be ignored.

Static-format tables have these characteristics:

- **CHAR** and VARCHAR columns are space-padded to the specified column width, although the column type is not altered. BINARY and VARBINARY columns are padded with 0x00 bytes to the column width.

- NULL columns require additional space in the row to record whether their values are NULL. Each NULL column takes one bit extra, rounded up to the nearest byte.

- Very quick.

- Easy to cache.

- Easy to reconstruct after a crash, because rows are located in fixed positions.

- Reorganization is unnecessary unless you delete a huge number of rows and want to return free disk space to the operating system. To do this, use OPTIMIZE TABLE or myisamchk -r.

- Usually require more disk space than dynamic-format tables.

- The expected row length in bytes for static-sized rows is calculated using the following expression:
MyISAM Table Storage Formats

row length = 1
+ (sum of column lengths)
+ (number of NULL columns + delete_flag + 7)/8
+ (number of variable-length columns)

*delete_flag* is 1 for tables with static row format. Static tables use a bit in the row record for a flag that indicates whether the row has been deleted. *delete_flag* is 0 for dynamic tables because the flag is stored in the dynamic row header.

### 15.2.3.2 Dynamic Table Characteristics

Dynamic storage format is used if a MyISAM table contains any variable-length columns (*VARCHAR*, *VARBINARY*, *BLOB*, or *TEXT*), or if the table was created with the `ROW_FORMAT=DYNAMIC` table option.

Dynamic format is a little more complex than static format because each row has a header that indicates how long it is. A row can become fragmented (stored in noncontiguous pieces) when it is made longer as a result of an update.

You can use `OPTIMIZE TABLE` or `myisamchk -r` to defragment a table. If you have fixed-length columns that you access or change frequently in a table that also contains some variable-length columns, it might be a good idea to move the variable-length columns to other tables just to avoid fragmentation.

Dynamic-format tables have these characteristics:

- All string columns are dynamic except those with a length less than four.
- Each row is preceded by a bitmap that indicates which columns contain the empty string (for string columns) or zero (for numeric columns). This does not include columns that contain *NULL* values. If a string column has a length of zero after trailing space removal, or a numeric column has a value of zero, it is marked in the bitmap and not saved to disk. Nonempty strings are saved as a length byte plus the string contents.
- *NULL* columns require additional space in the row to record whether their values are *NULL*. Each *NULL* column takes one bit extra, rounded up to the nearest byte.
- Much less disk space usually is required than for fixed-length tables.
- Each row uses only as much space as is required. However, if a row becomes larger, it is split into as many pieces as are required, resulting in row fragmentation. For example, if you update a row with information that extends the row length, the row becomes fragmented. In this case, you may have to run `OPTIMIZE TABLE` or `myisamchk -r` from time to time to improve performance. Use `myisamchk -ei` to obtain table statistics.
- More difficult than static-format tables to reconstruct after a crash, because rows may be fragmented into many pieces and links (fragments) may be missing.
- The expected row length for dynamic-sized rows is calculated using the following expression:

```
3 + (number of columns + 7) / 8
+ (number of char columns)
+ (packed size of numeric columns)
+ (length of strings)
+ (number of NULL columns + 7) / 8
```

There is a penalty of 6 bytes for each link. A dynamic row is linked whenever an update causes an enlargement of the row. Each new link is at least 20 bytes, so the next enlargement probably goes in the same link. If not, another link is created. You can find the number of links using `myisamchk -ed`. All links may be removed with `OPTIMIZE TABLE` or `myisamchk -r`. 
15.2.3.3 Compressed Table Characteristics

Compressed storage format is a read-only format that is generated with the `myisampack` tool. Compressed tables can be uncompressed with `myisamchk`.

Compressed tables have the following characteristics:

- Compressed tables take very little disk space. This minimizes disk usage, which is helpful when using slow disks (such as CD-ROMs).
- Each row is compressed separately, so there is very little access overhead. The header for a row takes up one to three bytes depending on the biggest row in the table. Each column is compressed differently. There is usually a different Huffman tree for each column. Some of the compression types are:
  - Suffix space compression.
  - Prefix space compression.
  - Numbers with a value of zero are stored using one bit.
  - If values in an integer column have a small range, the column is stored using the smallest possible type. For example, a `BIGINT` column (eight bytes) can be stored as a `TINYINT` column (one byte) if all its values are in the range from \(-128\) to \(127\).
  - If a column has only a small set of possible values, the data type is converted to `ENUM`.
  - A column may use any combination of the preceding compression types.
- Can be used for fixed-length or dynamic-length rows.

**Note**

While a compressed table is read only, and you cannot therefore update or add rows in the table, DDL (Data Definition Language) operations are still valid. For example, you may still use `DROP` to drop the table, and `TRUNCATE TABLE` to empty the table.

15.2.4 MyISAM Table Problems

The file format that MySQL uses to store data has been extensively tested, but there are always circumstances that may cause database tables to become corrupted. The following discussion describes how this can happen and how to handle it.

15.2.4.1 Corrupted MyISAM Tables

Even though the MyISAM table format is very reliable (all changes to a table made by an SQL statement are written before the statement returns), you can still get corrupted tables if any of the following events occur:

- The `mysqld` process is killed in the middle of a write.
- An unexpected computer shutdown occurs (for example, the computer is turned off).
- Hardware failures.
- You are using an external program (such as `myisamchk`) to modify a table that is being modified by the server at the same time.
• A software bug in the MySQL or MyISAM code.

Typical symptoms of a corrupt table are:

• You get the following error while selecting data from the table:

Incorrect key file for table: '...'. Try to repair it

• Queries don't find rows in the table or return incomplete results.

You can check the health of a MyISAM table using the CHECK TABLE statement, and repair a corrupted MyISAM table with REPAIR TABLE. When mysqld is not running, you can also check or repair a table with the myisamchk command. See Section 13.7.2.2, “CHECK TABLE Syntax”, Section 13.7.2.5, “REPAIR TABLE Syntax”, and Section 4.6.3, “myisamchk — MyISAM Table-Maintenance Utility”.

If your tables become corrupted frequently, you should try to determine why this is happening. The most important thing to know is whether the table became corrupted as a result of a server crash. You can verify this easily by looking for a recent restarted mysqld message in the error log. If there is such a message, it is likely that table corruption is a result of the server dying. Otherwise, corruption may have occurred during normal operation. This is a bug. You should try to create a reproducible test case that demonstrates the problem. See Section B.4.3.3, “What to Do If MySQL Keeps Crashing”, and Section 24.5, “Debugging and Porting MySQL”.

15.2.4.2 Problems from Tables Not Being Closed Properly

Each MyISAM index file (.MYI file) has a counter in the header that can be used to check whether a table has been closed properly. If you get the following warning from CHECK TABLE or myisamchk, it means that this counter has gone out of sync:

clients are using or haven't closed the table properly

This warning doesn't necessarily mean that the table is corrupted, but you should at least check the table.

The counter works as follows:

• The first time a table is updated in MySQL, a counter in the header of the index files is incremented.

• The counter is not changed during further updates.

• When the last instance of a table is closed (because a FLUSH TABLES operation was performed or because there is no room in the table cache), the counter is decremented if the table has been updated at any point.

• When you repair the table or check the table and it is found to be okay, the counter is reset to zero.

• To avoid problems with interaction with other processes that might check the table, the counter is not decremented on close if it was zero.

In other words, the counter can become incorrect only under these conditions:

• A MyISAM table is copied without first issuing LOCK TABLES and FLUSH TABLES.

• MySQL has crashed between an update and the final close. (The table may still be okay because MySQL always issues writes for everything between each statement.)

• A table was modified by myisamchk --recover or myisamchk --update-state at the same time that it was in use by mysqld.
Multiple `mysqld` servers are using the table and one server performed a `REPAIR TABLE` or `CHECK TABLE` on the table while it was in use by another server. In this setup, it is safe to use `CHECK TABLE`, although you might get the warning from other servers. However, `REPAIR TABLE` should be avoided because when one server replaces the data file with a new one, this is not known to the other servers.

In general, it is a bad idea to share a data directory among multiple servers. See Section 5.7, “Running Multiple MySQL Instances on One Machine”, for additional discussion.

### 15.3 The MEMORY Storage Engine

The `MEMORY` storage engine (formerly known as `HEAP`) creates special-purpose tables with contents that are stored in memory. Because the data is vulnerable to crashes, hardware issues, or power outages, only use these tables as temporary work areas or read-only caches for data pulled from other tables.

#### Table 15.4 MEMORY Storage Engine Features

- **Characteristics of MEMORY Tables**
- **DDL Operations for MEMORY Tables**
When to Use MEMORY or NDB Cluster

Developers looking to deploy applications that use the MEMORY storage engine for important, highly available, or frequently updated data should consider whether NDB Cluster is a better choice. A typical use case for the MEMORY engine involves these characteristics:

- Operations involving transient, non-critical data such as session management or caching. When the MySQL server halts or restarts, the data in MEMORY tables is lost.
- In-memory storage for fast access and low latency. Data volume can fit entirely in memory without causing the operating system to swap out virtual memory pages.
- A read-only or read-mostly data access pattern (limited updates).

NDB Cluster offers the same features as the MEMORY engine with higher performance levels, and provides additional features not available with MEMORY:

- Row-level locking and multiple-thread operation for low contention between clients.
- Scalability even with statement mixes that include writes.
- Optional disk-backed operation for data durability.
- Shared-nothing architecture and multiple-host operation with no single point of failure, enabling 99.999% availability.
- Automatic data distribution across nodes; application developers need not craft custom sharding or partitioning solutions.
- Support for variable-length data types (including BLOB and TEXT) not supported by MEMORY.

Performance Characteristics

MEMORY performance is constrained by contention resulting from single-thread execution and table lock overhead when processing updates. This limits scalability when load increases, particularly for statement mixes that include writes.

Despite the in-memory processing for MEMORY tables, they are not necessarily faster than InnoDB tables on a busy server, for general-purpose queries, or under a read/write workload. In particular, the table locking involved with performing updates can slow down concurrent usage of MEMORY tables from multiple sessions.

Depending on the kinds of queries performed on a MEMORY table, you might create indexes as either the default hash data structure (for looking up single values based on a unique key), or a general-purpose B-tree data structure (for all kinds of queries involving equality, inequality, or range operators such as less than or greater than). The following sections illustrate the syntax for creating both kinds of indexes.
common performance issue is using the default hash indexes in workloads where B-tree indexes are more efficient.

Characteristics of MEMORY Tables

The MEMORY storage engine associates each table with one disk file, which stores the table definition (not the data). The file name begins with the table name and has an extension of .frm.

MEMORY tables have the following characteristics:

• Space for MEMORY tables is allocated in small blocks. Tables use 100% dynamic hashing for inserts. No overflow area or extra key space is needed. No extra space is needed for free lists. Deleted rows are put in a linked list and are reused when you insert new data into the table. MEMORY tables also have none of the problems commonly associated with deletes plus inserts in hashed tables.

• MEMORY tables use a fixed-length row-storage format. Variable-length types such as VARCHAR are stored using a fixed length.

• MEMORY tables cannot contain BLOB or TEXT columns.

• MEMORY includes support for AUTO_INCREMENT columns.

• Non-TEMPORARY MEMORY tables are shared among all clients, just like any other non-TEMPORARY table.

DDL Operations for MEMORY Tables

To create a MEMORY table, specify the clause ENGINE=MEMORY on the CREATE TABLE statement.

```
CREATE TABLE t (i INT) ENGINE = MEMORY;
```

As indicated by the engine name, MEMORY tables are stored in memory. They use hash indexes by default, which makes them very fast for single-value lookups, and very useful for creating temporary tables. However, when the server shuts down, all rows stored in MEMORY tables are lost. The tables themselves continue to exist because their definitions are stored in .frm files on disk, but they are empty when the server restarts.

This example shows how you might create, use, and remove a MEMORY table:

```
mysql> CREATE TABLE test ENGINE=MEMORY
    -> SELECT ip,SUM(downloads) AS down
    -> FROM log_table GROUP BY ip;
mysql> SELECT COUNT(ip),AVG(down) FROM test;
mysql> DROP TABLE test;
```

The maximum size of MEMORY tables is limited by the max_heap_table_size system variable, which has a default value of 16MB. To enforce different size limits for MEMORY tables, change the value of this variable. The value in effect for CREATE TABLE, or a subsequent ALTER TABLE or TRUNCATE TABLE, is the value used for the life of the table. A server restart also sets the maximum size of existing MEMORY tables to the global max_heap_table_size value. You can set the size for individual tables as described later in this section.

Indexes

The MEMORY storage engine supports both HASH and BTREE indexes. You can specify one or the other for a given index by adding a USING clause as shown here:
User-Created and Temporary Tables

For general characteristics of B-tree and hash indexes, see Section 8.3.1, “How MySQL Uses Indexes".

MEMORY tables can have up to 64 indexes per table, 16 columns per index and a maximum key length of 3072 bytes.

If a MEMORY table hash index has a high degree of key duplication (many index entries containing the same value), updates to the table that affect key values and all deletes are significantly slower. The degree of this slowdown is proportional to the degree of duplication (or, inversely proportional to the index cardinality). You can use a BTREE index to avoid this problem.

MEMORY tables can have nonunique keys. (This is an uncommon feature for implementations of hash indexes.)

Columns that are indexed can contain NULL values.

User-Created and Temporary Tables

MEMORY table contents are stored in memory, which is a property that MEMORY tables share with internal temporary tables that the server creates on the fly while processing queries. However, the two types of tables differ in that MEMORY tables are not subject to storage conversion, whereas internal temporary tables are:

- If an internal temporary table becomes too large, the server automatically converts it to on-disk storage, as described in Section 8.4.4, “Internal Temporary Table Use in MySQL".

- User-created MEMORY tables are never converted to disk tables.

Loading Data

To populate a MEMORY table when the MySQL server starts, you can use the --init-file option. For example, you can put statements such as INSERT INTO ... SELECT or LOAD DATA into this file to load the table from a persistent data source. See Section 5.1.6, “Server Command Options", and Section 13.2.6, “LOAD DATA Syntax".

For loading data into MEMORY tables accessed by other sessions concurrently, MEMORY supports INSERT DELAYED. See Section 13.2.5.3, "INSERT DELAYED Syntax".

MEMORY Tables and Replication

A server’s MEMORY tables become empty when it is shut down and restarted. If the server is a replication master, its slaves are not aware that these tables have become empty, so you see out-of-date content if you select data from the tables on the slaves. To synchronize master and slave MEMORY tables, when a MEMORY table is used on a master for the first time since it was started, a DELETE statement is written to the master’s binary log, to empty the table on the slaves also. The slave still has outdated data in the table during the interval between the master’s restart and its first use of the table. To avoid this interval when a direct query to the slave could return stale data, use the --init-file option to populate the MEMORY table on the master at startup.

Managing Memory Use

The server needs sufficient memory to maintain all MEMORY tables that are in use at the same time.
Memory is not reclaimed if you delete individual rows from a MEMORY table. Memory is reclaimed only when the entire table is deleted. Memory that was previously used for deleted rows is re-used for new rows within the same table. To free all the memory used by a MEMORY table when you no longer require its contents, execute DELETE or TRUNCATE TABLE to remove all rows, or remove the table altogether using DROP TABLE. To free up the memory used by deleted rows, use ALTER TABLE ENGINE=MEMORY to force a table rebuild.

The memory needed for one row in a MEMORY table is calculated using the following expression:

\[
\text{Memory per row} = \text{SUM_OVER_ALL_BTREE_KEYS}(\text{max_length_of_key} + \text{sizeof(char*)} \times 4) \\
+ \text{SUM_OVER_ALL_HASH.Keys}(\text{sizeof(char*)} \times 2) \\
+ \text{ALIGN}(\text{length_of_row}+1, \text{sizeof(char*)})
\]

ALIGN() represents a round-up factor to cause the row length to be an exact multiple of the char pointer size. sizeof(char*) is 4 on 32-bit machines and 8 on 64-bit machines.

As mentioned earlier, the max_heap_table_size system variable sets the limit on the maximum size of MEMORY tables. To control the maximum size for individual tables, set the session value of this variable before creating each table. (Do not change the global max_heap_table_size value unless you intend the value to be used for MEMORY tables created by all clients.) The following example creates two MEMORY tables, with a maximum size of 1MB and 2MB, respectively:

```sql
mysql> SET max_heap_table_size = 1024*1024;
Query OK, 0 rows affected (0.00 sec)
mysql> CREATE TABLE t1 (id INT, UNIQUE(id)) ENGINE = MEMORY;
Query OK, 0 rows affected (0.01 sec)
mysql> SET max_heap_table_size = 1024*1024*2;
Query OK, 0 rows affected (0.00 sec)
mysql> CREATE TABLE t2 (id INT, UNIQUE(id)) ENGINE = MEMORY;
Query OK, 0 rows affected (0.00 sec)
```

Both tables revert to the server's global max_heap_table_size value if the server restarts.

You can also specify a MAX_ROWS table option in CREATE TABLE statements for MEMORY tables to provide a hint about the number of rows you plan to store in them. This does not enable the table to grow beyond the max_heap_table_size value, which still acts as a constraint on maximum table size. For maximum flexibility in being able to use MAX_ROWS, set max_heap_table_size at least as high as the value to which you want each MEMORY table to be able to grow.

Additional Resources

A forum dedicated to the MEMORY storage engine is available at https://forums.mysql.com/list.php?92.

15.4 The CSV Storage Engine

The CSV storage engine stores data in text files using comma-separated values format.

The CSV storage engine is always compiled into the MySQL server.

To examine the source for the CSV engine, look in the storage/csv directory of a MySQL source distribution.

When you create a CSV table, the server creates a table format file in the database directory. The file begins with the table name and has an .frm extension. The storage engine also creates plain text data file
Repairing and Checking CSV Tables

having a name that begins with the table name and has a .CSV extension. When you store data into the table, the storage engine saves it into the data file in comma-separated values format.

```
CREATE TABLE test (i INT NOT NULL, c CHAR(10) NOT NULL) ENGINE = CSV;
Query OK, 0 rows affected (0.06 sec)
```

```
INSERT INTO test VALUES(1,'record one'),(2,'record two');
Query OK, 2 rows affected (0.05 sec)
```

```
SELECT * FROM test;
```

```
+---+------------+
<table>
<thead>
<tr>
<th>i</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>record one</td>
</tr>
<tr>
<td>2</td>
<td>record two</td>
</tr>
</tbody>
</table>
+---+------------+
```

Creating a CSV table also creates a corresponding metafile that stores the state of the table and the number of rows that exist in the table. The name of this file is the same as the name of the table with the extension CSM.

If you examine the test.CSV file in the database directory created by executing the preceding statements, its contents should look like this:

```
"1","record one"
"2","record two"
```

This format can be read, and even written, by spreadsheet applications such as Microsoft Excel or StarOffice Calc.

### 15.4.1 Repairing and Checking CSV Tables

The CSV storage engine supports the CHECK TABLE and REPAIR TABLE statements to verify and, if possible, repair a damaged CSV table.

When running the CHECK TABLE statement, the CSV file will be checked for validity by looking for the correct field separators, escaped fields (matching or missing quotation marks), the correct number of fields compared to the table definition and the existence of a corresponding CSV metafile. The first invalid row discovered will report an error. Checking a valid table produces output like that shown below:

```
CHECK TABLE csvtest;
```

```
+--------------+-------+----------+----------+
<table>
<thead>
<tr>
<th>Table</th>
<th>Op</th>
<th>Msg_type</th>
<th>Msg_text</th>
</tr>
</thead>
<tbody>
<tr>
<td>test.csvtest</td>
<td>check</td>
<td>status</td>
<td>OK</td>
</tr>
</tbody>
</table>
+--------------+-------+----------+----------+
```

A check on a corrupted table returns a fault:

```
CHECK TABLE csvtest;
```

```
+--------------+-------+----------+----------+
<table>
<thead>
<tr>
<th>Table</th>
<th>Op</th>
<th>Msg_Type</th>
<th>Msg_text</th>
</tr>
</thead>
<tbody>
<tr>
<td>test.csvtest</td>
<td>check</td>
<td>error</td>
<td>Corrupt</td>
</tr>
</tbody>
</table>
+--------------+-------+----------+----------+
```
If the check fails, the table is marked as crashed (corrupt). Once a table has been marked as corrupt, it is automatically repaired when you next run `CHECK TABLE` or execute a `SELECT` statement. The corresponding corrupt status and new status will be displayed when running `CHECK TABLE`:

```
mysql> CHECK TABLE csvtest;
```

```
+--------------+-------+----------+----------------------------+
<table>
<thead>
<tr>
<th>Table</th>
<th>Op</th>
<th>Msg_type</th>
<th>Msg_text</th>
</tr>
</thead>
<tbody>
<tr>
<td>test.csvtest</td>
<td>check</td>
<td>warning</td>
<td>Table is marked as crashed</td>
</tr>
<tr>
<td>test.csvtest</td>
<td>check</td>
<td>status</td>
<td>OK</td>
</tr>
</tbody>
</table>
```

To repair a table, use `REPAIR TABLE`, which copies as many valid rows from the existing `CSV` data as possible, and then replaces the existing `CSV` file with the recovered rows. Any rows beyond the corrupted data are lost.

```
mysql> REPAIR TABLE csvtest;
```

```
+--------------+--------+----------+----------+
<table>
<thead>
<tr>
<th>Table</th>
<th>Op</th>
<th>Msg_type</th>
<th>Msg_text</th>
</tr>
</thead>
<tbody>
<tr>
<td>test.csvtest</td>
<td>repair</td>
<td>status</td>
<td>OK</td>
</tr>
</tbody>
</table>
```

**Warning**

During repair, only the rows from the `CSV` file up to the first damaged row are copied to the new table. All other rows from the first damaged row to the end of the table are removed, even valid rows.

### 15.4.2 CSV Limitations

The `CSV` storage engine does not support indexing.

Partitioning is not supported for tables using the `CSV` storage engine.

All tables that you create using the `CSV` storage engine must have the `NOT NULL` attribute on all columns.

### 15.5 The ARCHIVE Storage Engine

The `ARCHIVE` storage engine produces special-purpose tables that store large amounts of unindexed data in a very small footprint.

**Table 15.5 ARCHIVE Storage Engine Features**

<table>
<thead>
<tr>
<th>Feature</th>
<th>Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>B-tree indexes</td>
<td>No</td>
</tr>
<tr>
<td>Backup/point-in-time recovery (Implemented in the server, rather than in the storage engine.)</td>
<td>Yes</td>
</tr>
<tr>
<td>Cluster database support</td>
<td>No</td>
</tr>
<tr>
<td>Clustered indexes</td>
<td>No</td>
</tr>
<tr>

<td>Yes</td>
</tr>
<tr>
<td>Data caches</td>
<td>No</td>
</tr>
<tr>
<td>Encrypted data</td>
<td>Yes (Implemented in the server via encryption functions.)</td>
</tr>
<tr>
<td>Foreign key support</td>
<td>No</td>
</tr>
</tbody>
</table>
The ARCHIVE storage engine is included in MySQL binary distributions. To enable this storage engine if you build MySQL from source, invoke CMake with the `-DWITH_ARCHIVE_STORAGE_ENGINE` option.

To examine the source for the ARCHIVE engine, look in the `storage/archive` directory of a MySQL source distribution.

You can check whether the ARCHIVE storage engine is available with the SHOW ENGINES statement.

When you create an ARCHIVE table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. The storage engine creates other files, all having names beginning with the table name. The data file has an extension of `.ARZ`. An `.ARN` file may appear during optimization operations.

The ARCHIVE engine supports INSERT, REPLACE, and SELECT, but not DELETE or UPDATE. It does support ORDER BY operations, BLOB columns, and basically all data types including spatial data types (see Section 11.5.1, “Spatial Data Types”). Geographic spatial reference systems are not supported. The ARCHIVE engine uses row-level locking.

The ARCHIVE engine supports the AUTO_INCREMENT column attribute. The AUTO_INCREMENT column can have either a unique or nonunique index. Attempting to create an index on any other column results in an error. The ARCHIVE engine also supports the AUTO_INCREMENT table option in CREATE TABLE statements to specify the initial sequence value for a new table or reset the sequence value for an existing table, respectively.

ARCHIVE does not support inserting a value into an AUTO_INCREMENT column less than the current maximum column value. Attempts to do so result in an ER_DUP_KEY error.

The ARCHIVE engine ignores BLOB columns if they are not requested and scans past them while reading.

Storage: Rows are compressed as they are inserted. The ARCHIVE engine uses zlib lossless data compression (see http://www.zlib.net/). You can use OPTIMIZE TABLE to analyze the table and pack it into a smaller format (for a reason to use OPTIMIZE TABLE, see later in this section). The engine also supports CHECK TABLE. There are several types of insertions that are used:

- An INSERT statement just pushes rows into a compression buffer, and that buffer flushes as necessary. The insertion into the buffer is protected by a lock. A SELECT forces a flush to occur, unless the only

</table>
insertions that have come in were \texttt{INSERT DELAYED} (those flush as necessary). See Section 13.2.5.3, “\texttt{INSERT DELAYED Syntax}”.

• A bulk insert is visible only after it completes, unless other inserts occur at the same time, in which case it can be seen partially. A \texttt{SELECT} never causes a flush of a bulk insert unless a normal insert occurs while it is loading.

\textbf{Retrieval}: On retrieval, rows are uncompressed on demand; there is no row cache. A \texttt{SELECT} operation performs a complete table scan: When a \texttt{SELECT} occurs, it finds out how many rows are currently available and reads that number of rows. \texttt{SELECT} is performed as a consistent read. Note that lots of \texttt{SELECT} statements during insertion can deteriorate the compression, unless only bulk or delayed inserts are used. To achieve better compression, you can use \texttt{OPTIMIZE TABLE} or \texttt{REPAIR TABLE}. The number of rows in \texttt{ARCHIVE} tables reported by \texttt{SHOW TABLE STATUS} is always accurate. See Section 13.7.2.4, “\texttt{OPTIMIZE TABLE Syntax}”, Section 13.7.2.5, “\texttt{REPAIR TABLE Syntax}”, and Section 13.7.5.37, “\texttt{SHOW TABLE STATUS Syntax}”.

\textbf{Additional Resources}

• A forum dedicated to the \texttt{ARCHIVE} storage engine is available at https://forums.mysql.com/list.php?112.

15.6 The BLACKHOLE Storage Engine

The \texttt{BLACKHOLE} storage engine acts as a “black hole” that accepts data but throws it away and does not store it. Retrievals always return an empty result:

\begin{verbatim}
mysql> CREATE TABLE test(i INT, c CHAR(10)) ENGINE = BLACKHOLE;
Query OK, 0 rows affected (0.03 sec)

mysql> INSERT INTO test VALUES(1,'record one'),(2,'record two');
Query OK, 2 rows affected (0.00 sec)
Records: 2  Duplicates: 0  Warnings: 0

mysql> SELECT * FROM test;
Empty set (0.00 sec)
\end{verbatim}

To enable the \texttt{BLACKHOLE} storage engine if you build MySQL from source, invoke \texttt{CMake} with the \texttt{-DWITH_BLACKHOLE_STORAGE_ENGINE} option.

To examine the source for the \texttt{BLACKHOLE} engine, look in the \texttt{sql} directory of a MySQL source distribution.

When you create a \texttt{BLACKHOLE} table, the server creates a table format file in the database directory. The file begins with the table name and has an \texttt{.frm} extension. There are no other files associated with the table.

The \texttt{BLACKHOLE} storage engine supports all kinds of indexes. That is, you can include index declarations in the table definition.

You can check whether the \texttt{BLACKHOLE} storage engine is available with the \texttt{SHOW ENGINES} statement.

Inserts into a \texttt{BLACKHOLE} table do not store any data, but if statement based binary logging is enabled, the SQL statements are logged and replicated to slave servers. This can be useful as a repeater or filter mechanism.

Suppose that your application requires slave-side filtering rules, but transferring all binary log data to the slave first results in too much traffic. In such a case, it is possible to set up on the master host a “dummy” slave process whose default storage engine is \texttt{BLACKHOLE}, depicted as follows:
The master writes to its binary log. The “dummy” `mysqld` process acts as a slave, applying the desired combination of `replicate-do-`* and `replicate-ignore-`* rules, and writes a new, filtered binary log of its own. (See Section 17.1.4, “Replication and Binary Logging Options and Variables”.) This filtered log is provided to the slave.

The dummy process does not actually store any data, so there is little processing overhead incurred by running the additional `mysqld` process on the replication master host. This type of setup can be repeated with additional replication slaves.

`INSERT` triggers for `BLACKHOLE` tables work as expected. However, because the `BLACKHOLE` table does not actually store any data, `UPDATE` and `DELETE` triggers are not activated: The `FOR EACH ROW` clause in the trigger definition does not apply because there are no rows.

Other possible uses for the `BLACKHOLE` storage engine include:

- Verification of dump file syntax.
- Measurement of the overhead from binary logging, by comparing performance using `BLACKHOLE` with and without binary logging enabled.
- `BLACKHOLE` is essentially a “no-op” storage engine, so it could be used for finding performance bottlenecks not related to the storage engine itself.

The `BLACKHOLE` engine is transaction-aware, in the sense that committed transactions are written to the binary log and rolled-back transactions are not.

**Blackhole Engine and Auto Increment Columns**

The Blackhole engine is a no-op engine. Any operations performed on a table using Blackhole will have no effect. This should be born in mind when considering the behavior of primary key columns that auto increment. The engine will not automatically increment field values, and does not retain auto increment field state. This has important implications in replication.

Consider the following replication scenario where all three of the following conditions apply:
1. On a master server there is a blackhole table with an auto increment field that is a primary key.

2. On a slave the same table exists but using the MyISAM engine.

3. Inserts are performed into the master's table without explicitly setting the auto increment value in the `INSERT` statement itself or through using a `SET INSERT_ID` statement.

In this scenario replication will fail with a duplicate entry error on the primary key column.

In statement based replication, the value of `INSERT_ID` in the context event will always be the same. Replication will therefore fail due to trying insert a row with a duplicate value for a primary key column.

In row based replication, the value that the engine returns for the row always be the same for each insert. This will result in the slave attempting to replay two insert log entries using the same value for the primary key column, and so replication will fail.

**Column Filtering**

When using row-based replication, (`binlog_format=ROW`), a slave where the last columns are missing from a table is supported, as described in the section Section 17.4.1.9, “Replication with Differing Table Definitions on Master and Slave”.

This filtering works on the slave side, that is, the columns are copied to the slave before they are filtered out. There are at least two cases where it is not desirable to copy the columns to the slave:

1. If the data is confidential, so the slave server should not have access to it.
2. If the master has many slaves, filtering before sending to the slaves may reduce network traffic.

Master column filtering can be achieved using the `BLACKHOLE` engine. This is carried out in a way similar to how master table filtering is achieved - by using the `BLACKHOLE` engine and the `--replicate-do-table` or `--replicate-ignore-table` option.

The setup for the master is:

```sql
CREATE TABLE t1 (public_col_1, ..., public_col_N, secret_col_1, ..., secret_col_M) ENGINE=MyISAM;
```

The setup for the trusted slave is:

```sql
CREATE TABLE t1 (public_col_1, ..., public_col_N) ENGINE=BLACKHOLE;
```

The setup for the untrusted slave is:

```sql
CREATE TABLE t1 (public_col_1, ..., public_col_N) ENGINE=MyISAM;
```

### 15.7 The MERGE Storage Engine

The MERGE storage engine, also known as the `MRG_MyISAM` engine, is a collection of identical MyISAM tables that can be used as one. “Identical” means that all tables have identical column data types and index information. You cannot merge MyISAM tables in which the columns are listed in a different order, do not have exactly the same data types in corresponding columns, or have the indexes in different order. However, any or all of the MyISAM tables can be compressed with `myisampack`. See Section 4.6.5, "myisampack — Generate Compressed, Read-Only MyISAM Tables". Differences between tables such as these do not matter:

- Names of corresponding columns and indexes can differ.
• Comments for tables, columns, and indexes can differ.

• Table options such as AVG_ROW_LENGTH, MAX_ROWS, or PACK_KEYS can differ.

An alternative to a MERGE table is a partitioned table, which stores partitions of a single table in separate files. Partitioning enables some operations to be performed more efficiently and is not limited to the MyISAM storage engine. For more information, see Chapter 19, Partitioning.

When you create a MERGE table, MySQL creates two files on disk. The files have names that begin with the table name and have an extension to indicate the file type. An .frm file stores the table format, and an .MRG file contains the names of the underlying MyISAM tables that should be used as one. The tables do not have to be in the same database as the MERGE table.

You can use SELECT, DELETE, UPDATE, and INSERT on MERGE tables. You must have SELECT, DELETE, and UPDATE privileges on the MyISAM tables that you map to a MERGE table.

Note
The use of MERGE tables entails the following security issue: If a user has access to MyISAM table t, that user can create a MERGE table m that accesses t. However, if the user's privileges on t are subsequently revoked, the user can continue to access t by doing so through m.

Use of DROP TABLE with a MERGE table drops only the MERGE specification. The underlying tables are not affected.

To create a MERGE table, you must specify a UNION=(list-of-tables) option that indicates which MyISAM tables to use. You can optionally specify an INSERT_METHOD option to control how inserts into the MERGE table take place. Use a value of FIRST or LAST to cause inserts to be made in the first or last underlying table, respectively. If you specify no INSERT_METHOD option or if you specify it with a value of NO, inserts into the MERGE table are not permitted and attempts to do so result in an error.

The following example shows how to create a MERGE table:

```sql
mysql> CREATE TABLE t1 (    
    ->   a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,    
    ->   message CHAR(20)) ENGINE=MyISAM;
mysql> CREATE TABLE t2 (    
    ->   a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,    
    ->   message CHAR(20)) ENGINE=MyISAM;
mysql> INSERT INTO t1 (message) VALUES ('Testing'),('table'),('t1');
mysql> INSERT INTO t2 (message) VALUES ('Testing'),('table'),('t2');
mysql> CREATE TABLE total (    
    ->   a INT NOT NULL AUTO_INCREMENT,    
    ->   message CHAR(20), INDEX(a))    
    ->   ENGINE=MERGE UNION=(t1,t2) INSERT_METHOD=LAST;
```

Column a is indexed as a PRIMARY KEY in the underlying MyISAM tables, but not in the MERGE table. There it is indexed but not as a PRIMARY KEY because a MERGE table cannot enforce uniqueness over the set of underlying tables. (Similarly, a column with a UNIQUE index in the underlying tables should be indexed in the MERGE table but not as a UNIQUE index.)

After creating the MERGE table, you can use it to issue queries that operate on the group of tables as a whole:

```sql
mysql> SELECT * FROM total;
+-----+---------+
| a   | message |
+-----+---------+
```
To remap a **MERGE** table to a different collection of **MyISAM** tables, you can use one of the following methods:

- **DROP** the **MERGE** table and re-create it.

- Use **ALTER TABLE** `tbl_name UNION=(...)` to change the list of underlying tables.

  It is also possible to use **ALTER TABLE ... UNION=()** (that is, with an empty **UNION** clause) to remove all of the underlying tables. However, in this case, the table is effectively empty and inserts fail because there is no underlying table to take new rows. Such a table might be useful as a template for creating new **MERGE** tables with **CREATE TABLE ... LIKE**.

The underlying table definitions and indexes must conform closely to the definition of the **MERGE** table. Conformance is checked when a table that is part of a **MERGE** table is opened, not when the **MERGE** table is created. If any table fails the conformance checks, the operation that triggered the opening of the table fails. This means that changes to the definitions of tables within a **MERGE** may cause a failure when the **MERGE** table is accessed. The conformance checks applied to each table are:

- The underlying table and the **MERGE** table must have the same number of columns.

- The column order in the underlying table and the **MERGE** table must match.

- Additionally, the specification for each corresponding column in the parent **MERGE** table and the underlying tables are compared and must satisfy these checks:

  - The column type in the underlying table and the **MERGE** table must be equal.

  - The column length in the underlying table and the **MERGE** table must be equal.

  - The column of the underlying table and the **MERGE** table can be **NULL**.

- The underlying table must have at least as many indexes as the **MERGE** table. The underlying table may have more indexes than the **MERGE** table, but cannot have fewer.

  **Note**

  A known issue exists where indexes on the same columns must be in identical order, in both the **MERGE** table and the underlying **MyISAM** table. See Bug #33653.

  Each index must satisfy these checks:

  - The index type of the underlying table and the **MERGE** table must be the same.

  - The number of index parts (that is, multiple columns within a compound index) in the index definition for the underlying table and the **MERGE** table must be the same.

  - For each index part:

    - Index part lengths must be equal.
Additional Resources

- Index part types must be equal.
- Index part languages must be equal.
- Check whether index parts can be NULL.

If a **MERGE** table cannot be opened or used because of a problem with an underlying table, **CHECK TABLE** displays information about which table caused the problem.

**Additional Resources**

- A forum dedicated to the **MERGE** storage engine is available at https://forums.mysql.com/list.php?93.

### 15.7.1 MERGE Table Advantages and Disadvantages

**MERGE** tables can help you solve the following problems:

- Easily manage a set of log tables. For example, you can put data from different months into separate tables, compress some of them with **myisampack**, and then create a **MERGE** table to use them as one.

- Obtain more speed. You can split a large read-only table based on some criteria, and then put individual tables on different disks. A **MERGE** table structured this way could be much faster than using a single large table.

- Perform more efficient searches. If you know exactly what you are looking for, you can search in just one of the underlying tables for some queries and use a **MERGE** table for others. You can even have many different **MERGE** tables that use overlapping sets of tables.

- Perform more efficient repairs. It is easier to repair individual smaller tables that are mapped to a **MERGE** table than to repair a single large table.

- Instantly map many tables as one. A **MERGE** table need not maintain an index of its own because it uses the indexes of the individual tables. As a result, **MERGE** table collections are very fast to create or remap. (You must still specify the index definitions when you create a **MERGE** table, even though no indexes are created.)

- If you have a set of tables from which you create a large table on demand, you can instead create a **MERGE** table from them on demand. This is much faster and saves a lot of disk space.

- Exceed the file size limit for the operating system. Each **MyISAM** table is bound by this limit, but a collection of **MyISAM** tables is not.

- You can create an alias or synonym for a **MyISAM** table by defining a **MERGE** table that maps to that single table. There should be no really notable performance impact from doing this (only a couple of indirect calls and **memcpy()** calls for each read).

The disadvantages of **MERGE** tables are:

- You can use only identical **MyISAM** tables for a **MERGE** table.

- Some **MyISAM** features are unavailable in **MERGE** tables. For example, you cannot create **FULLTEXT** indexes on **MERGE** tables. (You can create **FULLTEXT** indexes on the underlying **MyISAM** tables, but you cannot search the **MERGE** table with a full-text search.)

- If the **MERGE** table is nontemporary, all underlying **MyISAM** tables must be nontemporary. If the **MERGE** table is temporary, the **MyISAM** tables can be any mix of temporary and nontemporary.
MERGE Table Problems

• **MERGE** tables use more file descriptors than **MyISAM** tables. If 10 clients are using a **MERGE** table that maps to 10 tables, the server uses \((10 \times 10) + 10\) file descriptors. \((10\text{ data file descriptors for each of the 10 clients, and 10 index file descriptors shared among the clients.})\)

• Index reads are slower. When you read an index, the **MERGE** storage engine needs to issue a read on all underlying tables to check which one most closely matches a given index value. To read the next index value, the **MERGE** storage engine needs to search the read buffers to find the next value. Only when one index buffer is used up does the storage engine need to read the next index block. This makes **MERGE** indexes much slower on **eq_ref** searches, but not much slower on **ref** searches. For more information about **eq_ref** and **ref**, see **Section 13.8.2, “EXPLAIN Syntax”**.

### 15.7.2 MERGE Table Problems

The following are known problems with **MERGE** tables:

• In versions of MySQL Server prior to 5.1.23, it was possible to create temporary merge tables with non-temporary child **MyISAM** tables.

  From versions 5.1.23, **MERGE** children were locked through the parent table. If the parent was temporary, it was not locked and so the children were not locked either. Parallel use of the **MyISAM** tables corrupted them.

• If you use **ALTER TABLE** to change a **MERGE** table to another storage engine, the mapping to the underlying tables is lost. Instead, the rows from the underlying **MyISAM** tables are copied into the altered table, which then uses the specified storage engine.

• The **INSERT_METHOD** table option for a **MERGE** table indicates which underlying **MyISAM** table to use for inserts into the **MERGE** table. However, use of the **AUTO_INCREMENT** table option for that **MyISAM** table has no effect for inserts into the **MERGE** table until at least one row has been inserted directly into the **MyISAM** table.

• A **MERGE** table cannot maintain uniqueness constraints over the entire table. When you perform an **INSERT**, the data goes into the first or last **MyISAM** table (as determined by the **INSERT_METHOD** option). MySQL ensures that unique key values remain unique within that **MyISAM** table, but not over all the underlying tables in the collection.

• Because the **MERGE** engine cannot enforce uniqueness over the set of underlying tables, **REPLACE** does not work as expected. The two key facts are:

  • **REPLACE** can detect unique key violations only in the underlying table to which it is going to write (which is determined by the **INSERT_METHOD** option). This differs from violations in the **MERGE** table itself.

  • If **REPLACE** detects a unique key violation, it will change only the corresponding row in the underlying table it is writing to; that is, the first or last table, as determined by the **INSERT_METHOD** option.

  Similar considerations apply for **INSERT ... ON DUPLICATE KEY UPDATE**.

• **MERGE** tables do not support partitioning. That is, you cannot partition a **MERGE** table, nor can any of a **MERGE** table’s underlying **MyISAM** tables be partitioned.

• You should not use **ANALYZE TABLE, REPAIR TABLE, OPTIMIZE TABLE, ALTER TABLE, DROP TABLE, DELETE** without a **WHERE** clause, or **TRUNCATE TABLE** on any of the tables that are mapped into an open **MERGE** table. If you do so, the **MERGE** table may still refer to the original table and yield unexpected results. To work around this problem, ensure that no **MERGE** tables remain open by issuing a **FLUSH TABLES** statement prior to performing any of the named operations.
The unexpected results include the possibility that the operation on the **MERGE** table will report table corruption. If this occurs after one of the named operations on the underlying **MyISAM** tables, the corruption message is spurious. To deal with this, issue a **FLUSH TABLES** statement after modifying the **MyISAM** tables.

- **DROP TABLE** on a table that is in use by a **MERGE** table does not work on Windows because the **MERGE** storage engine's table mapping is hidden from the upper layer of MySQL. Windows does not permit open files to be deleted, so you first must flush all **MERGE** tables (with **FLUSH TABLES**) or drop the **MERGE** table before dropping the table.

- The definition of the **MyISAM** tables and the **MERGE** table are checked when the tables are accessed (for example, as part of a **SELECT** or **INSERT** statement). The checks ensure that the definitions of the tables and the parent **MERGE** table definition match by comparing column order, types, sizes and associated indexes. If there is a difference between the tables, an error is returned and the statement fails. Because these checks take place when the tables are opened, any changes to the definition of a single table, including column changes, column ordering, and engine alterations will cause the statement to fail.

- The order of indexes in the **MERGE** table and its underlying tables should be the same. If you use **ALTER TABLE** to add a **UNIQUE** index to a table used in a **MERGE** table, and then use **ALTER TABLE** to add a nonunique index on the **MERGE** table, the index ordering is different for the tables if there was already a nonunique index in the underlying table. (This happens because **ALTER TABLE** puts **UNIQUE** indexes before nonunique indexes to facilitate rapid detection of duplicate keys.) Consequently, queries on tables with such indexes may return unexpected results.

- If you encounter an error message similar to **ERROR 1017 (HY000): Can't find file: 'tbl_name.MRG'** (errno: 2), it generally indicates that some of the underlying tables do not use the **MyISAM** storage engine. Confirm that all of these tables are **MyISAM**.

- The maximum number of rows in a **MERGE** table is \(2^{64}\) (~1.844E+19; the same as for a **MyISAM** table). It is not possible to merge multiple **MyISAM** tables into a single **MERGE** table that would have more than this number of rows.

- The **MERGE** storage engine does not support **INSERT DELAYED** statements.

- Use of underlying **MyISAM** tables of differing row formats with a parent **MERGE** table is currently known to fail. See Bug #32364.

- You cannot change the union list of a nontemporary **MERGE** table when **LOCK TABLES** is in effect. The following does **not** work:

```
CREATE TABLE m1 ... ENGINE=MRG_MYISAM ...;
LOCK TABLES t1 WRITE, t2 WRITE, m1 WRITE;
ALTER TABLE m1 ... UNION=(t1,t2) ...;
```

However, you can do this with a temporary **MERGE** table.

- You cannot create a **MERGE** table with **CREATE ... SELECT**, neither as a temporary **MERGE** table, nor as a nontemporary **MERGE** table. For example:

```
CREATE TABLE m1 ... ENGINE=MRG_MYISAM ... SELECT ...
```

Attempts to do this result in an error: **tbi_name** is not **BASE TABLE**.

- In some cases, differing **PACK_KEYS** table option values among the **MERGE** and underlying tables cause unexpected results if the underlying tables contain **CHAR** or **BINARY** columns. As a workaround, use **ALTER TABLE** to ensure that all involved tables have the same **PACK_KEYS** value. (Bug #50646)
15.8 The FEDERATED Storage Engine

The FEDERATED storage engine lets you access data from a remote MySQL database without using replication or cluster technology. Querying a local FEDERATED table automatically pulls the data from the remote (federated) tables. No data is stored on the local tables.

To include the FEDERATED storage engine if you build MySQL from source, invoke CMake with the `-DWITH_FEDERATED_STORAGE_ENGINE` option.

The FEDERATED storage engine is not enabled by default in the running server; to enable FEDERATED, you must start the MySQL server binary using the `--federated` option.

To examine the source for the FEDERATED engine, look in the `storage/federated` directory of a MySQL source distribution.

15.8.1 FEDERATED Storage Engine Overview

When you create a table using one of the standard storage engines (such as MyISAM, CSV or InnoDB), the table consists of the table definition and the associated data. When you create a FEDERATED table, the table definition is the same, but the physical storage of the data is handled on a remote server.

A FEDERATED table consists of two elements:

- A remote server with a database table, which in turn consists of the table definition (stored in the `.frm` file) and the associated table. The table type of the remote table may be any type supported by the remote `mysqld` server, including MyISAM or InnoDB.

- A local server with a database table, where the table definition matches that of the corresponding table on the remote server. The table definition is stored within the `.frm` file. However, there is no data file on the local server. Instead, the table definition includes a connection string that points to the remote table.

When executing queries and statements on a FEDERATED table on the local server, the operations that would normally insert, update or delete information from a local data file are instead sent to the remote server for execution, where they update the data file on the remote server or return matching rows from the remote server.

The basic structure of a FEDERATED table setup is shown in Figure 15.2, “FEDERATED Table Structure”.

Figure 15.2 FEDERATED Table Structure
How to Create FEDERATED Tables

When a client issues an SQL statement that refers to a FEDERATED table, the flow of information between the local server (where the SQL statement is executed) and the remote server (where the data is physically stored) is as follows:

1. The storage engine looks through each column that the FEDERATED table has and constructs an appropriate SQL statement that refers to the remote table.

2. The statement is sent to the remote server using the MySQL client API.

3. The remote server processes the statement and the local server retrieves any result that the statement produces (an affected-rows count or a result set).

4. If the statement produces a result set, each column is converted to internal storage engine format that the FEDERATED engine expects and can use to display the result to the client that issued the original statement.

The local server communicates with the remote server using MySQL client C API functions. It invokes mysql_real_query() to send the statement. To read a result set, it uses mysql_store_result() and fetches rows one at a time using mysql_fetch_row().

15.8.2 How to Create FEDERATED Tables

To create a FEDERATED table you should follow these steps:

1. Create the table on the remote server. Alternatively, make a note of the table definition of an existing table, perhaps using the SHOW CREATE TABLE statement.

2. Create the table on the local server with an identical table definition, but adding the connection information that links the local table to the remote table.

For example, you could create the following table on the remote server:

```
CREATE TABLE test_table (  
id INT(20) NOT NULL AUTO_INCREMENT,  
name VARCHAR(32) NOT NULL DEFAULT '',  
other INT(20) NOT NULL DEFAULT '0',  
PRIMARY KEY (id),  
INDEX name (name),  
INDEX other_key (other)
) ENGINE=MyISAM DEFAULT CHARSET=latin1;
```

To create the local table that will be federated to the remote table, there are two options available. You can either create the local table and specify the connection string (containing the server name, login, password) to be used to connect to the remote table using the CONNECTION, or you can use an existing connection that you have previously created using the CREATE SERVER statement.

**Important**

When you create the local table it must have an identical field definition to the remote table.

**Note**

You can improve the performance of a FEDERATED table by adding indexes to the table on the host. The optimization will occur because the query sent to the remote server will include the contents of the WHERE clause and will be sent to the remote.
server and subsequently executed locally. This reduces the network traffic that would otherwise request the entire table from the server for local processing.

15.8.2.1 Creating a FEDERATED Table Using CONNECTION

To use the first method, you must specify the CONNECTION string after the engine type in a CREATE TABLE statement. For example:

```
CREATE TABLE federated_table (  
id     INT(20) NOT NULL AUTO_INCREMENT,  
name   VARCHAR(32) NOT NULL DEFAULT '',  
other  INT(20) NOT NULL DEFAULT '0',  
PRIMARY KEY  (id),  
INDEX name (name),  
INDEX other_key (other)  
)  
ENGINE=FEDERATED  
DEFAULT CHARSET=latin1  
CONNECTION='mysql://fed_user@remote_host:9306/federated/test_table';
```

**Note**

CONNECTION replaces the COMMENT used in some previous versions of MySQL.

The CONNECTION string contains the information required to connect to the remote server containing the table that will be used to physically store the data. The connection string specifies the server name, login credentials, port number and database/table information. In the example, the remote table is on the server remote_host, using port 9306. The name and port number should match the host name (or IP address) and port number of the remote MySQL server instance you want to use as your remote table.

The format of the connection string is as follows:

```
scheme://user_name[:password]@host_name[:port_num]/db_name.tbl_name
```

Where:

- **scheme**: A recognized connection protocol. Only mysql is supported as the scheme value at this point.
- **user_name**: The user name for the connection. This user must have been created on the remote server, and must have suitable privileges to perform the required actions (SELECT, INSERT, UPDATE, and so forth) on the remote table.
- **password**: (Optional) The corresponding password for user_name.
- **host_name**: The host name or IP address of the remote server.
- **port_num**: (Optional) The port number for the remote server. The default is 3306.
- **db_name**: The name of the database holding the remote table.
- **tbl_name**: The name of the remote table. The name of the local and the remote table do not have to match.

Sample connection strings:

```
CONNECTION='mysql://username:password@hostname:port/database/tablename'
CONNECTION='mysql://username@hostname/database/tablename'
CONNECTION='mysql://username:password@hostname/database/tablename'
```
15.8.2.2 Creating a FEDERATED Table Using CREATE SERVER

If you are creating a number of FEDERATED tables on the same server, or if you want to simplify the process of creating FEDERATED tables, you can use the CREATE SERVER statement to define the server connection parameters, just as you would with the CONNECTION string.

The format of the CREATE SERVER statement is:

```
CREATE SERVER server_name
FOREIGN DATA WRAPPER wrapper_name
OPTIONS (option [, option] ...)
```

The server_name is used in the connection string when creating a new FEDERATED table.

For example, to create a server connection identical to the CONNECTION string:

```
CONNECTION='mysql://fed_user@remote_host:9306/federated/test_table';
```

You would use the following statement:

```
CREATE SERVER fedlink
FOREIGN DATA WRAPPER mysql
OPTIONS (USER 'fed_user', HOST 'remote_host', PORT 9306, DATABASE 'federated');
```

To create a FEDERATED table that uses this connection, you still use the CONNECTION keyword, but specify the name you used in the CREATE SERVER statement.

```
CREATE TABLE test_table (  
    id     INT(20) NOT NULL AUTO_INCREMENT,  
    name   VARCHAR(32) NOT NULL DEFAULT '',  
    other  INT(20) NOT NULL DEFAULT '0',  
    PRIMARY KEY  (id),  
    INDEX name (name),  
    INDEX other_key (other)  
)  
ENGINE=FEDERATED  
DEFAULT CHARSET=latin1  
CONNECTION='fedlink/test_table';
```

The connection name in this example contains the name of the connection (fedlink) and the name of the table (test_table) to link to, separated by a slash. If you specify only the connection name without a table name, the table name of the local table is used instead.

For more information on CREATE SERVER, see Section 13.1.16, “CREATE SERVER Syntax”.

The CREATE SERVER statement accepts the same arguments as the CONNECTION string. The CREATE SERVER statement updates the rows in the mysql.servers table. See the following table for information on the correspondence between parameters in a connection string, options in the CREATE SERVER statement, and the columns in the mysql.servers table. For reference, the format of the CONNECTION string is as follows:

```
scheme://user_name[:password]@host_name[:port_num]/db_name/tbl_name
```

<table>
<thead>
<tr>
<th>Description</th>
<th>CONNECTION string</th>
<th>CREATE SERVER option</th>
<th>mysql.servers column</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connection scheme</td>
<td>scheme</td>
<td>wrapper_name</td>
<td>Wrapper</td>
</tr>
<tr>
<td>Remote user</td>
<td>user_name</td>
<td>USER</td>
<td>Username</td>
</tr>
</tbody>
</table>
15.8.3 FEDERATED Storage Engine Notes and Tips

You should be aware of the following points when using the FEDERATED storage engine:

- **FEDERATED** tables may be replicated to other slaves, but you must ensure that the slave servers are able to use the user/password combination that is defined in the CONNECTION string (or the row in the mysql.servers table) to connect to the remote server.

The following items indicate features that the FEDERATED storage engine does and does not support:

- The remote server must be a MySQL server.

- The remote table that a FEDERATED table points to must exist before you try to access the table through the FEDERATED table.

- It is possible for one FEDERATED table to point to another, but you must be careful not to create a loop.

- A FEDERATED table does not support indexes in the usual sense; because access to the table data is handled remotely, it is actually the remote table that makes use of indexes. This means that, for a query that cannot use any indexes and so requires a full table scan, the server fetches all rows from the remote table and filters them locally. This occurs regardless of any WHERE or LIMIT used with this SELECT statement; these clauses are applied locally to the returned rows.

Queries that fail to use indexes can thus cause poor performance and network overload. In addition, since returned rows must be stored in memory, such a query can also lead to the local server swapping, or even hanging.

- Care should be taken when creating a FEDERATED table since the index definition from an equivalent MyISAM or other table may not be supported. For example, creating a FEDERATED table with an index prefix on VARCHAR, TEXT or BLOB columns will fail. The following definition in MyISAM is valid:

  ```
  CREATE TABLE `T1`(`A` VARCHAR(100),UNIQUE KEY(`A`(30))) ENGINE=MYISAM;
  ```

  The key prefix in this example is incompatible with the FEDERATED engine, and the equivalent statement will fail:

  ```
  CREATE TABLE `T1`(`A` VARCHAR(100),UNIQUE KEY(`A`(30))) ENGINE=FEDERATED
  CONNECTION='MYSQL://127.0.0.1:3306/TEST/T1';
  ```

  If possible, you should try to separate the column and index definition when creating tables on both the remote server and the local server to avoid these index issues.

- Internally, the implementation uses SELECT, INSERT, UPDATE, and DELETE, but not HANDLER.

- The FEDERATED storage engine supports SELECT, INSERT, UPDATE, DELETE, TRUNCATE TABLE, and indexes. It does not support ALTER TABLE, or any Data Definition Language statements that directly affect the structure of the table, other than DROP TABLE. The current implementation does not use prepared statements.
• **FEDERATED** accepts `INSERT ... ON DUPLICATE KEY UPDATE` statements, but if a duplicate-key violation occurs, the statement fails with an error.

• Transactions are not supported.

• **FEDERATED** performs bulk-insert handling such that multiple rows are sent to the remote table in a batch, which improves performance. Also, if the remote table is transactional, it enables the remote storage engine to perform statement rollback properly should an error occur. This capability has the following limitations:

  • The size of the insert cannot exceed the maximum packet size between servers. If the insert exceeds this size, it is broken into multiple packets and the rollback problem can occur.

  • Bulk-insert handling does not occur for `INSERT ... ON DUPLICATE KEY UPDATE`.

  • There is no way for the **FEDERATED** engine to know if the remote table has changed. The reason for this is that this table must work like a data file that would never be written to by anything other than the database system. The integrity of the data in the local table could be breached if there was any change to the remote database.

  • When using a `CONNECTION` string, you cannot use an '@' character in the password. You can get round this limitation by using the `CREATE SERVER` statement to create a server connection.

  • The `insert_id` and `timestamp` options are not propagated to the data provider.

  • Any `DROP TABLE` statement issued against a **FEDERATED** table drops only the local table, not the remote table.

  • **FEDERATED** tables do not work with the query cache.

  • User-defined partitioning is not supported for **FEDERATED** tables.

### 15.8.4 FEDERATED Storage Engine Resources

The following additional resources are available for the **FEDERATED** storage engine:

### 15.9 The EXAMPLE Storage Engine

The **EXAMPLE** storage engine is a stub engine that does nothing. Its purpose is to serve as an example in the MySQL source code that illustrates how to begin writing new storage engines. As such, it is primarily of interest to developers.

To enable the **EXAMPLE** storage engine if you build MySQL from source, invoke `CMake` with the `-DWITH_EXAMPLE_STORAGE_ENGINE` option.

To examine the source for the **EXAMPLE** engine, look in the `storage/example` directory of a MySQL source distribution.

When you create an **EXAMPLE** table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. No other files are created. No data can be stored into the table. Retrievals return an empty result.
15.10 Other Storage Engines

Other storage engines may be available from third parties and community members that have used the Custom Storage Engine interface.

Third party engines are not supported by MySQL. For further information, documentation, installation guides, bug reporting or for any help or assistance with these engines, please contact the developer of the engine directly.

For more information on developing a customer storage engine that can be used with the Pluggable Storage Engine Architecture, see MySQL Internals: Writing a Custom Storage Engine.

15.11 Overview of MySQL Storage Engine Architecture

The MySQL pluggable storage engine architecture enables a database professional to select a specialized storage engine for a particular application need while being completely shielded from the need to manage any specific application coding requirements. The MySQL server architecture isolates the application programmer and DBA from all of the low-level implementation details at the storage level, providing a consistent and easy application model and API. Thus, although there are different capabilities across different storage engines, the application is shielded from these differences.

The pluggable storage engine architecture provides a standard set of management and support services that are common among all underlying storage engines. The storage engines themselves are the components of the database server that actually perform actions on the underlying data that is maintained at the physical server level.

This efficient and modular architecture provides huge benefits for those wishing to specifically target a particular application need—such as data warehousing, transaction processing, or high availability situations—while enjoying the advantage of utilizing a set of interfaces and services that are independent of any one storage engine.

The application programmer and DBA interact with the MySQL database through Connector APIs and service layers that are above the storage engines. If application changes bring about requirements that demand the underlying storage engine change, or that one or more storage engines be added to support new needs, no significant coding or process changes are required to make things work. The MySQL server architecture shields the application from the underlying complexity of the storage engine by presenting a consistent and easy-to-use API that applies across storage engines.

15.11.1 Pluggable Storage Engine Architecture

MySQL Server uses a pluggable storage engine architecture that enables storage engines to be loaded into and unloaded from a running MySQL server.

Plugging in a Storage Engine
Before a storage engine can be used, the storage engine plugin shared library must be loaded into MySQL using the `INSTALL PLUGIN` statement. For example, if the `EXAMPLE` engine plugin is named `example` and the shared library is named `ha_example.so`, you load it with the following statement:

```
INSTALL PLUGIN example SONAME 'ha_example.so';
```

To install a pluggable storage engine, the plugin file must be located in the MySQL plugin directory, and the user issuing the `INSTALL PLUGIN` statement must have `INSERT` privilege for the `mysql.plugin` table.

The shared library must be located in the MySQL server plugin directory, the location of which is given by the `plugin_dir` system variable.

**Unplugging a Storage Engine**

To unplug a storage engine, use the `UNINSTALL PLUGIN` statement:

```
UNINSTALL PLUGIN example;
```

If you unplug a storage engine that is needed by existing tables, those tables become inaccessible, but will still be present on disk (where applicable). Ensure that there are no tables using a storage engine before you unplug the storage engine.

### 15.11.2 The Common Database Server Layer

A MySQL pluggable storage engine is the component in the MySQL database server that is responsible for performing the actual data I/O operations for a database as well as enabling and enforcing certain feature sets that target a specific application need. A major benefit of using specific storage engines is that you are only delivered the features needed for a particular application, and therefore you have less system overhead in the database, with the end result being more efficient and higher database performance. This is one of the reasons that MySQL has always been known to have such high performance, matching or beating proprietary monolithic databases in industry standard benchmarks.

From a technical perspective, what are some of the unique supporting infrastructure components that are in a storage engine? Some of the key feature differentiations include:

- **Concurrency**: Some applications have more granular lock requirements (such as row-level locks) than others. Choosing the right locking strategy can reduce overhead and therefore improve overall performance. This area also includes support for capabilities such as multi-version concurrency control or “snapshot” read.

- **Transaction Support**: Not every application needs transactions, but for those that do, there are very well defined requirements such as ACID compliance and more.

- **Referential Integrity**: The need to have the server enforce relational database referential integrity through DDL defined foreign keys.

- **Physical Storage**: This involves everything from the overall page size for tables and indexes as well as the format used for storing data to physical disk.

- **Index Support**: Different application scenarios tend to benefit from different index strategies. Each storage engine generally has its own indexing methods, although some (such as B-tree indexes) are common to nearly all engines.

- **Memory Caches**: Different applications respond better to some memory caching strategies than others, so although some memory caches are common to all storage engines (such as those used for user
connections or MySQL’s high-speed Query Cache), others are uniquely defined only when a particular storage engine is put in play.

- **Performance Aids**: This includes multiple I/O threads for parallel operations, thread concurrency, database checkpointing, bulk insert handling, and more.

- **Miscellaneous Target Features**: This may include support for geospatial operations, security restrictions for certain data manipulation operations, and other similar features.

Each set of the pluggable storage engine infrastructure components are designed to offer a selective set of benefits for a particular application. Conversely, avoiding a set of component features helps reduce unnecessary overhead. It stands to reason that understanding a particular application’s set of requirements and selecting the proper MySQL storage engine can have a dramatic impact on overall system efficiency and performance.

Data is the currency of today’s web, mobile, social, enterprise and cloud applications. Ensuring data is always available is a top priority for any organization. Minutes of downtime can result in significant loss of revenue and reputation.

There is no “one size fits all” approach to delivering High Availability (HA). Unique application attributes, business requirements, operational capabilities and legacy infrastructure can all influence HA technology selection. And technology is only one element in delivering HA: people and processes are just as critical as the technology itself.

MySQL is deployed into many applications demanding availability and scalability. Availability refers to the ability to cope with, and if necessary recover from, failures on the host, including failures of MySQL, the operating system, or the hardware and maintenance activity that may otherwise cause downtime. Scalability refers to the ability to spread both the database and the load of your application queries across multiple MySQL servers.

Because each application has different operational and availability requirements, MySQL offers a range of certified and supported solutions, delivering the appropriate levels of High Availability (HA) and scalability to meet service level requirements. Such solutions extend from replication, through virtualization and geographically redundant, multi-data center solutions delivering 99.999% uptime.

Selecting the right high availability solution for an application largely depends on:

• The level of availability required.
• The type of application being deployed.
• Accepted best practices within your own environment.

The primary solutions supported by MySQL include:

• MySQL Replication. Learn more: Chapter 17, Replication.
• MySQL Cluster. Learn more: Chapter 18, MySQL NDB Cluster 7.3 and NDB Cluster 7.4.
• Oracle MySQL Cloud Service. Learn more about MySQL Cloud Service.
• Oracle Clusterware Agent for MySQL. Learn more about Oracle Clusterware.
• MySQL with Solaris Cluster. Learn more about Solaris Cluster.
Further options are available using third-party solutions.

Each architecture used to achieve highly available database services is differentiated by the levels of uptime it offers. These architectures can be grouped into three main categories:

- Data Replication.
- Clustered & Virtualized Systems.
- Shared-Nothing, Geographically-Replicated Clusters.

As illustrated in the following figure, each of these architectures offers progressively higher levels of uptime, which must be balanced against potentially greater levels of cost and complexity that each can incur. Simply deploying a high availability architecture is not a guarantee of actually delivering HA. In fact, a poorly implemented and maintained shared-nothing cluster could easily deliver lower levels of availability than a simple data replication solution.

Figure 16.1 Tradeoffs: Cost and Complexity versus Availability

The following table compares the HA and Scalability capabilities of the various MySQL solutions:

Table 16.1 Feature Comparison of MySQL HA Solutions

Using ZFS Replication

To support high availability environments, providing an instant copy of the information on both the currently active machine and the hot backup is a critical part of the HA solution. There are many solutions to this problem, such as Chapter 17, Replication.

The ZFS file system provides functionality to create a snapshot of the file system contents, transfer the snapshot to another machine, and extract the snapshot to recreate the file system. You can create a snapshot at any time, and you can create as many snapshots as you like. By continually creating, transferring, and restoring snapshots, you can provide synchronization between one or more machines in a fashion similar to DRBD.

The following example shows a simple Solaris system running with a single ZFS pool, mounted at `/scratchpool`:

```
Filesystem size used avail capacity Mounted on
/dev/dsk/c0d0s0 4.6G 3.7G 886M 82% /
/devices 0K 0K 0K 0% /devices
tf 0K 0K 0K 0% /system/contract
proc 0K 0K 0K 0% /proc
mnttab 0K 0K 0K 0% /etc/mnttab
swap 1.4G 892K 1.4G 1% /etc/svc/volatile
objfs 0K 0K 0K 0% /system/object
/usr/lib/libc/libc_hwcapi.so.1 4.6G 3.7G 886M 82% /lib/libc.so.1
fd 0K 0K 0K 0% /dev/fd
swap 1.4G 40K 1.4G 1% /tmp
swap 1.4G 28K 1.4G 1% /var/run
/dev/dsk/c0d0s7 26G 913M 25G 4% /export/home
scratchpool 16G 24K 16G 1% /scratchpool
```

The MySQL data is stored in a directory on `/scratchpool`. To help demonstrate some of the basic replication functionality, there are also other items stored in `/scratchpool` as well:
To create a snapshot of the file system, you use `zfs snapshot`, specifying the pool and the snapshot name:

```
root-shell> zfs snapshot scratchpool@snap1
```

To list the snapshots already taken:

```
root-shell> zfs list -t snapshot
```

```
NAME                USED  AVAIL  REFER  MOUNTPOINT
scratchpool@snap1      0      -  24.5K  -
scratchpool@snap2      0      -  24.5K  -
```

The snapshots themselves are stored within the file system metadata, and the space required to keep them varies as time goes on because of the way the snapshots are created. The initial creation of a snapshot is very quick, because instead of taking an entire copy of the data and metadata required to hold the entire snapshot, ZFS records only the point in time and metadata of when the snapshot was created.

As more changes to the original file system are made, the size of the snapshot increases because more space is required to keep the record of the old blocks. If you create lots of snapshots, say one per day, and then delete the snapshots from earlier in the week, the size of the newer snapshots might also increase, as the changes that make up the newer state have to be included in the more recent snapshots, rather than being spread over the seven snapshots that make up the week.

You cannot directly back up the snapshots because they exist within the file system metadata rather than as regular files. To get the snapshot into a format that you can copy to another file system, tape, and so on, you use the `zfs send` command to create a stream version of the snapshot.

For example, to write the snapshot out to a file:

```
root-shell> zfs send scratchpool@snap1 >/backup/scratchpool-snap1
```

Or tape:

```
root-shell> zfs send scratchpool@snap1 >/dev/rmt/0
```

You can also write out the incremental changes between two snapshots using `zfs send`:

```
root-shell> zfs send scratchpool@snap1 scratchpool@snap2 >/backup/scratchpool-changes
```

To recover a snapshot, you use `zfs recv`, which applies the snapshot information either to a new file system, or to an existing one.

### 16.1.1 Using ZFS for File System Replication

Because `zfs send` and `zfs recv` use streams to exchange data, you can use them to replicate information from one system to another by combining `zfs send`, `ssh`, and `zfs recv`.

For example, to copy a snapshot of the `scratchpool` file system to a new file system called `slavepool` on a new server, you would use the following command. This sequence combines the snapshot of
Configuring MySQL for ZFS Replication

scratchpool, the transmission to the slave machine (using ssh with login credentials), and the recovery of the snapshot on the slave using zfs recv:

```
root-shell> zfs send scratchpool@snap1 |ssh id@host pfexec zfs recv -F slavepool
```

The first part of the pipeline, zfs send scratchpool@snap1, streams the snapshot. The ssh command, and the command that it executes on the other server, pfexec zfs recv -F slavepool, receives the streamed snapshot data and writes it to slavepool. In this instance, I've specified the -F option which forces the snapshot data to be applied, and is therefore destructive. This is fine, as I'm creating the first version of my replicated file system.

On the slave machine, the replicated file system contains the exact same content:

```
root-shell> ls -al /slavepool/
```

Once a snapshot has been created, to synchronize the file system again, you create a new snapshot and then use the incremental snapshot feature of zfs send to send the changes between the two snapshots to the slave machine again:

```
root-shell> zfs send -i scratchpool@snapshot1 scratchpool@snapshot2 |ssh id@host pfexec zfs recv slavepool
```

This operation only succeeds if the file system on the slave machine has not been modified at all. You cannot apply the incremental changes to a destination file system that has changed. In the example above, the ls command would cause problems by changing the metadata, such as the last access time for files or directories.

To prevent changes on the slave file system, set the file system on the slave to be read-only:

```
root-shell> zfs set readonly=on slavepool
```

Setting readonly means that you cannot change the file system on the slave by normal means, including the file system metadata. Operations that would normally update metadata (like our ls) silently perform their function without attempting to update the file system state.

In essence, the slave file system is nothing but a static copy of the original file system. However, even when configured to be read-only, a file system can have snapshots applied to it. With the file system set to read only, re-run the initial copy:

```
root-shell> zfs send scratchpool@snap1 |ssh id@host pfexec zfs recv -F slavepool
```

Now you can make changes to the original file system and replicate them to the slave.

### 16.1.2 Configuring MySQL for ZFS Replication

Configuring MySQL on the source file system is a case of creating the data on the file system that you intend to replicate. The configuration file in the example below has been updated to use /scratchpool/mysql-data as the data directory, and now you can initialize the tables:
Handling MySQL Recovery with ZFS

To synchronize the initial information, perform a new snapshot and then send an incremental snapshot to the slave using `zfs send`:

```
root-shell> zfs snapshot scratchpool@snap2
root-shell> zfs send -i scratchpool@snap1 scratchpool@snap2|ssh id@host pfexec zfs recv slavepool
```

Doublecheck that the slave has the data by looking at the MySQL data directory on the `slavepool`:

```
root-shell> ls -al /slavepool/mysql-data/
```

Now you can start up MySQL, create some data, and then replicate the changes using `zfs send`/`zfs recv` to the slave to synchronize the changes.

The rate at which you perform the synchronization depends on your application and environment. The limitation is the speed required to perform the snapshot and then to send the changes over the network.

To automate the process, create a script that performs the snapshot, send, and receive operation, and use `cron` to synchronize the changes at set times or intervals.

### 16.1.3 Handling MySQL Recovery with ZFS

When using ZFS replication to provide a constant copy of your data, ensure that you can recover your tables, either manually or automatically, in the event of a failure of the original system.

In the event of a failure, follow this sequence:

1. Stop the script on the master, if it is still up and running.
2. Set the slave file system to be read/write:

```
root-shell> zfs set readonly=off slavepool
```
3. Start up `mysqld` on the slave. If you are using InnoDB, you get auto-recovery, if it is needed, to make sure the table data is correct, as shown here when I started up from our mid-INSERT snapshot:

```
InnoDB: The log sequence number in ibdata files does not match
InnoDB: the log sequence number in the ib_logfiles!
081109 15:59:59 InnoDB: Database was not shut down normally!
InnoDB: Starting crash recovery.
InnoDB: Reading tablespace information from the .ibd files...
InnoDB: Restoring possible half-written data pages from the doublewrite
InnoDB: buffer...
081109 16:00:03 InnoDB: Started; log sequence number 0 1142807951
081109 16:00:03 [Note] /slavepool/mysql-5.0.67-solaris10-i386/bin/mysqld: ready for connections.
Version: '5.0.67' socket: '/tmp/mysql.sock' port: 3306 MySQL Community Server (GPL)
```

Use InnoDB tables and a regular synchronization schedule to reduce the risk for significant data loss. On MyISAM tables, you might need to run `REPAIR TABLE`, and you might even have lost some information.

### 16.2 Using MySQL with memcached

`memcached` is a simple, highly scalable key-based cache that stores data and objects wherever dedicated or spare RAM is available for quick access by applications, without going through layers of parsing or disk
Using MySQL with `memcached`  

I/O. To use, you run the `memcached` command on one or more hosts and then use the shared cache to store objects. For more usage instructions, see Section 16.2.2, “Using `memcached`”  

Benefits of using `memcached` include:  

• Because all information is stored in RAM, the access speed is faster than loading the information each time from disk.  

• Because the “value” portion of the key-value pair does not have any data type restrictions, you can cache data such as complex structures, documents, images, or a mixture of such things.  

• If you use the in-memory cache to hold transient information, or as a read-only cache for information also stored in a database, the failure of any `memcached` server is not critical. For persistent data, you can fall back to an alternative lookup method using database queries, and reload the data into RAM on a different server.  

The typical usage environment is to modify your application so that information is read from the cache provided by `memcached`. If the information is not in `memcached`, then the data is loaded from the MySQL database and written into the cache so that future requests for the same object benefit from the cached data.  

For a typical deployment layout, see Figure 16.2, “`memcached` Architecture Overview”.  

**Figure 16.2** `memcached` Architecture Overview  

In the example structure, any of the clients can contact one of the `memcached` servers to request a given key. Each client is configured to talk to all of the servers shown in the illustration. Within the client, when the request is made to store the information, the key used to reference the data is hashed and this hash is then used to select one of the `memcached` servers. The selection of the `memcached` server takes place on the client before the server is contacted, keeping the process lightweight.  

The same algorithm is used again when a client requests the same key. The same key generates the same hash, and the same `memcached` server is selected as the source for the data. Using this method, the cached data is spread among all of the `memcached` servers, and the cached information is accessible from any client. The result is a distributed, memory-based, cache that can return information, particularly complex data and structures, much faster than natively reading the information from the database.  

The data held within a traditional `memcached` server is never stored on disk (only in RAM, which means there is no persistence of data), and the RAM cache is always populated from the backing store (a MySQL database). If a `memcached` server fails, the data can always be recovered from the MySQL database.
16.2.1 Installing memcached

You can build and install memcached from the source code directly, or you can use an existing operating system package or installation.

Installing memcached from a Binary Distribution

To install memcached on a Red Hat, or Fedora host, use yum:

```shell
root-shell> yum install memcached
```

Note
On CentOS, you may be able to obtain a suitable RPM from another source, or use the source tarball.

To install memcached on a Debian or Ubuntu host, use apt-get:

```shell
root-shell> apt-get install memcached
```

To install memcached on a Gentoo host, use emerge:

```shell
root-shell> emerge install memcached
```

Building memcached from Source

On other Unix-based platforms, including Solaris, AIX, HP-UX and OS X, and Linux distributions not mentioned already, you must install from source. For Linux, make sure you have a 2.6-based kernel, which includes the improved epoll interface. For all platforms, ensure that you have libevent 1.1 or higher installed. You can obtain libevent from libevent web page.

You can obtain the source for memcached from memcached website.

To build memcached, follow these steps:

1. Extract the memcached source package:

   ```shell
   shell> gunzip -c memcached-1.2.5.tar.gz | tar xf -
   ```

2. Change to the memcached-1.2.5 directory:

   ```shell
   shell> cd memcached-1.2.5
   ```

3. Run configure

   ```shell
   shell> ./configure
   ```

   Some additional options you might specify to the configure:

   • --prefix

   To specify a different installation directory, use the --prefix option:
Using **memcached**

### Step 2: Configure and Build

- **shell> ./configure --prefix=/opt**
  
The default is to use the `/usr/local` directory.
  
- **--with-libevent**
  
  If you have installed `libevent` and `configure` cannot find the library, use the `--with-libevent` option to specify the location of the installed library.
  
- **--enable-64bit**
  
  To build a 64-bit version of **memcached** (which enables you to use a single instance with a large RAM allocation), use `--enable-64bit`.
  
- **--enable-threads**
  
  To enable multithreading support in **memcached**, which improves the response times on servers with a heavy load, use `--enable-threads`. You must have support for the POSIX threads within your operating system to enable thread support. For more information on the threading support, see Section 16.2.2.8, "**memcached** Thread Support".

- **--enable-dtrace**
  
  **memcached** includes a range of DTrace threads that can be used to monitor and benchmark a **memcached** instance. For more information, see Section 16.2.2.6, "Using **memcached** and DTrace".

### Step 3: Build

- **4. Run `make` to build **memcached**:**

  ```shell
  shell> make
  ```

### Step 4: Install

- **5. Run `make install` to install **memcached**:**

  ```shell
  shell> make install
  ```

### 16.2.2 Using **memcached**

To start using **memcached**, start the **memcached** service on one or more servers. Running **memcached** sets up the server, allocates the memory and starts listening for connections from clients.

#### Note

You do not need to be a privileged user (**root**) to run **memcached** except to listen on one of the privileged TCP/IP ports (below 1024). You must, however, use a user that has not had their memory limits restricted using `setrlimit` or similar.

To start the server, run **memcached** as a nonprivileged (that is, **non-root**) user:

```shell
shell> memcached
```

By default, **memcached** uses the following settings:

- Memory allocation of 64MB
- Listens for connections on all network interfaces, using port 11211
• Supports a maximum of 1024 simultaneous connections

Typically, you would specify the full combination of options that you want when starting `memcached`, and normally provide a startup script to handle the initialization of `memcached`. For example, the following line starts `memcached` with a maximum of 1024MB RAM for the cache, listening on port 11211 on the IP address 198.51.100.110, running as a background daemon:

```
shell> memcached -d -m 1024 -p 11211 -l 198.51.100.110
```

To ensure that `memcached` is started up on boot, check the init script and configuration parameters.

### 16.2.2.1 `memcached` Command-Line Options

`memcached` supports the following options:

- **-u user**
  
  If you start `memcached` as root, use the `-u` option to specify the user for executing `memcached`:

  ```
  shell> memcached -u memcache
  ```

- **-m memory**

  Set the amount of memory allocated to `memcached` for object storage. Default is 64MB.

  To increase the amount of memory allocated for the cache, use the `-m` option to specify the amount of RAM to be allocated (in megabytes). The more RAM you allocate, the more data you can store and therefore the more effective your cache is.

**Warning**

Do not specify a memory allocation larger than your available RAM. If you specify too large a value, then some RAM allocated for `memcached` uses swap space, and not physical RAM. This may lead to delays when storing and retrieving values, because data is swapped to disk, instead of storing the data directly in RAM.

You can use the output of the `vmstat` command to get the free memory, as shown in `free` column:

```
shell> vmstat
```

For example, to allocate 3GB of RAM:

```
shell> memcached -m 3072
```

On 32-bit x86 systems where you are using PAE to access memory above the 4GB limit, you cannot allocate RAM beyond the maximum process size. You can get around this by running multiple instances of `memcached`, each listening on a different port:

```
shell> memcached -m 1024 -p11211
shell> memcached -m 1024 -p11212
shell> memcached -m 1024 -p11213
```
Using `memcached`

### Note

On all systems, particularly 32-bit, ensure that you leave enough room for both `memcached` application in addition to the memory setting. For example, if you have a dedicated `memcached` host with 4GB of RAM, do not set the memory size above 3500MB. Failure to do this may cause either a crash or severe performance issues.

- **-l interface**

  Specify a network interface/address to listen for connections. The default is to listen on all available address (`INADDR_ANY`).

  ```shell
  shell> memcached -l 198.51.100.110
  ```

  Support for IPv6 address support was added in `memcached 1.2.5`.

- **-p port**

  Specify the TCP port to use for connections. Default is 18080.

  ```shell
  shell> memcached -p 18080
  ```

- **-U port**

  Specify the UDP port to use for connections. Default is 11211, 0 switches UDP off.

  ```shell
  shell> memcached -U 18080
  ```

- **-s socket**

  Specify a Unix socket to listen on.

  If you are running `memcached` on the same server as the clients, you can disable the network interface and use a local Unix socket using the `-s` option:

  ```shell
  shell> memcached -s /tmp/memcached
  ```

  Using a Unix socket automatically disables network support, and saves network ports (allowing more ports to be used by your web server or other process).

- **-a mask**

  Specify the access mask to be used for the Unix socket, in octal. Default is 0700.

- **-c connections**

  Specify the maximum number of simultaneous connections to the `memcached` service. The default is 1024.

  ```shell
  shell> memcached -c 2048
  ```

  Use this option, either to reduce the number of connections (to prevent overloading `memcached` service) or to increase the number to make more effective use of the server running `memcached` server.
Using memcached

- **-t threads**
  Specify the number of threads to use when processing incoming requests.

  By default, memcached is configured to use 4 concurrent threads. The threading improves the performance of storing and retrieving data in the cache, using a locking system to prevent different threads overwriting or updating the same values. To increase or decrease the number of threads, use the `-t` option:

  ```shell
  shell> memcached -t 8
  ```

- **-d**
  Run memcached as a daemon (background) process:

  ```shell
  shell> memcached -d
  ```

- **-r**
  Maximize the size of the core file limit. In the event of a failure, this attempts to dump the entire memory space to disk as a core file, up to any limits imposed by `setrlimit`.

- **-M**
  Return an error to the client when the memory has been exhausted. This replaces the normal behavior of removing older items from the cache to make way for new items.

- **-k**
  Lock down all paged memory. This reserves the memory before use, instead of allocating new slabs of memory as new items are stored in the cache.

  **Note**

  There is a user-level limit on how much memory you can lock. Trying to allocate more than the available memory fails. You can set the limit for the user you started the daemon with (not for the `-u user` user) within the shell by using `ulimit -S -l NUM_KB`

- **-v**
  Verbose mode. Prints errors and warnings while executing the main event loop.

- **-vv**
  Very verbose mode. In addition to information printed by `-v`, also prints each client command and the response.

- **-vvv**
  Extremely verbose mode. In addition to information printed by `-vv`, also show the internal state transitions.

- **-h**
  Print the help message and exit.
Print the `memcached` and `libevent` license.

- **-I mem**
  Specify the maximum size permitted for storing an object within the `memcached` instance. The size supports a unit postfix (k for kilobytes, m for megabytes). For example, to increase the maximum supported object size to 32MB:

  ```shell
  memcached -I 32m
  ```

  The maximum object size you can specify is 128MB, the default remains at 1MB.

  This option was added in 1.4.2.

- **-b**
  Set the backlog queue limit. The backlog queue configures how many network connections can be waiting to be processed by `memcached`. Increasing this limit may reduce errors received by the client that it is not able to connect to the `memcached` instance, but does not improve the performance of the server. The default is 1024.

- **-P pidfile**
  Save the process ID of the `memcached` instance into `file`.

- **-f**
  Set the chunk size growth factor. When allocating new memory chunks, the allocated size of new chunks is determined by multiplying the default slab size by this factor.

  To see the effects of this option without extensive testing, use the `-vv` command-line option to show the calculated slab sizes. For more information, see Section 16.2.2.9, "memcached Logs".

- **-n bytes**
  The minimum space allocated for the key+value+flags information. The default is 48 bytes.

- **-L**
  On systems that support large memory pages, enables large memory page use. Using large memory pages enables `memcached` to allocate the item cache in one large chunk, which can improve the performance by reducing the number misses when accessing memory.

- **-C**
  Disable the use of compare and swap (CAS) operations.

  This option was added in `memcached` 1.3.x.

- **-D char**
  Set the default character to be used as a delimiter between the key prefixes and IDs. This is used for the per-prefix statistics reporting (see Section 16.2.4, "Getting `memcached` Statistics"). The default is the colon (:) If this option is used, statistics collection is turned on automatically. If not used, you can enable stats collection by sending the `stats detail on` command to the server.

  This option was added in `memcached` 1.3.x.
Using memcached

- **-R num**
  
  Sets the maximum number of requests per event process. The default is 20.

- **-B protocol**
  
  Set the binding protocol, that is, the default memcached protocol support for client connections. Options are ascii, binary or auto. Automatic (auto) is the default.

  This option was added in memcached 1.4.0.

### 16.2.2.2 memcached Deployment

When using memcached you can use a number of different potential deployment strategies and topologies. The exact strategy to use depends on your application and environment. When developing a system for deploying memcached within your system, keep in mind the following points:

- memcached is only a caching mechanism. It shouldn't be used to store information that you cannot otherwise afford to lose and then load from a different location.

- There is no security built into the memcached protocol. At a minimum, make sure that the servers running memcached are only accessible from inside your network, and that the network ports being used are blocked (using a firewall or similar). If the information on the memcached servers that is being stored is any sensitive, then encrypt the information before storing it in memcached.

- memcached does not provide any sort of failover. Because there is no communication between different memcached instances. If an instance fails, your application must capable of removing it from the list, reloading the data and then writing data to another memcached instance.

- Latency between the clients and the memcached can be a problem if you are using different physical machines for these tasks. If you find that the latency is a problem, move the memcached instances to be on the clients.

- Key length is determined by the memcached server. The default maximum key size is 250 bytes.

- Try to use at least two memcached instances, especially for multiple clients, to avoid having a single point of failure. Ideally, create as many memcached nodes as possible. When adding and removing memcached instances from a pool, the hashing and distribution of key-value pairs may be affected. For information on how to avoid problems, see Section 16.2.2.5, “memcached Hashing/Distribution Types”.

### 16.2.2.3 Using Namespaces

The memcached cache is a very simple massive key-value storage system, and as such there is no way of compartmentalizing data automatically into different sections. For example, if you are storing information by the unique ID returned from a MySQL database, then storing the data from two different tables could run into issues because the same ID might be valid in both tables.

Some interfaces provide an automated mechanism for creating namespaces when storing information into the cache. In practice, these namespaces are merely a prefix before a given ID that is applied every time a value is stored or retrieve from the cache.

You can implement the same basic principle by using keys that describe the object and the unique identifier within the key that you supply when the object is stored. For example, when storing user data, prefix the ID of the user with user: or user-.
16.2.2.4 Data Expiry

There are two types of data expiry within a *memcached* instance. The first type is applied at the point when you store a new key-value pair into the *memcached* instance. If there is not enough space within a suitable slab to store the value, then an existing least recently used (LRU) object is removed (evicted) from the cache to make room for the new item.

The LRU algorithm ensures that the object that is removed is one that is either no longer in active use or that was used so long ago that its data is potentially out of date or of little value. However, in a system where the memory allocated to *memcached* is smaller than the number of regularly used objects required in the cache, a lot of expired items could be removed from the cache even though they are in active use. You use the statistics mechanism to get a better idea of the level of evictions (expired objects). For more information, see Section 16.2.4, “Getting *memcached* Statistics”.

You can change this eviction behavior by setting the `-M` command-line option when starting *memcached*. This option forces an error to be returned when the memory has been exhausted, instead of automatically evicting older data.

The second type of expiry system is an explicit mechanism that you can set when a key-value pair is inserted into the cache, or when deleting an item from the cache. Using an expiration time can be a useful way of ensuring that the data in the cache is up to date and in line with your application needs and requirements.

A typical scenario for explicitly setting the expiry time might include caching session data for a user when accessing a website. *memcached* uses a lazy expiry mechanism where the explicit expiry time that has been set is compared with the current time when the object is requested. Only objects that have not expired are returned.

You can also set the expiry time when explicitly deleting an object from the cache. In this case, the expiry time is really a timeout and indicates the period when any attempts to set the value for a given key are rejected.

16.2.2.5 *memcached* Hashing/Distribution Types

The *memcached* client interface supports a number of different distribution algorithms that are used in multi-server configurations to determine which host should be used when setting or getting data from a given *memcached* instance. When you get or set a value, a hash is constructed from the supplied key and then used to select a host from the list of configured servers. Because the hashing mechanism uses the supplied key as the basis for the hash, the same server is selected during both set and get operations.

You can think of this process as follows. Given an array of servers (a, b, and c), the client uses a hashing algorithm that returns an integer based on the key being stored or retrieved. The resulting value is then used to select a server from the list of servers configured in the client. Most standard client hashing within *memcache* clients uses a simple modulus calculation on the value against the number of configured *memcached* servers. You can summarize the process in pseudocode as:

```
@memcservers = ['a.memc','b.memc','c.memc'];
$value = hash($key);
$chosen = $value % length(@memcservers);
```
Replacing the above with values:

```perl
@memcservers = ['a.memc','b.memc','c.memc'];
$value = hash('myid');
$chosen = 7009 % 3;
```

In the above example, the client hashing algorithm chooses the server at index 1 \((7009 \mod 3 = 1)\), and stores or retrieves the key and value with that server.

**Note**

This selection and hashing process is handled automatically by the `memcached` client you are using; you need only provide the list of `memcached` servers to use.

You can see a graphical representation of this below in Figure 16.3, “`memcached` Hash Selection”.

**Figure 16.3 `memcached` Hash Selection**

The same hashing and selection process takes place during any operation on the specified key within the `memcached` client.

Using this method provides a number of advantages:

- The hashing and selection of the server to contact is handled entirely within the client. This eliminates the need to perform network communication to determine the right machine to contact.

- Because the determination of the `memcached` server occurs entirely within the client, the server can be selected automatically regardless of the operation being executed (set, get, increment, etc.).

- Because the determination is handled within the client, the hashing algorithm returns the same value for a given key; values are not affected or reset by differences in the server environment.

- Selection is very fast. The hashing algorithm on the key value is quick and the resulting selection of the server is from a simple array of available machines.

- Using client-side hashing simplifies the distribution of data over each `memcached` server. Natural distribution of the values returned by the hashing algorithm means that keys are automatically spread over the available servers.

Providing that the list of servers configured within the client remains the same, the same stored key returns the same value, and therefore selects the same server.

However, if you do not use the same hashing mechanism then the same data may be recorded on different servers by different interfaces, both wasting space on your `memcached` and leading to potential differences in the information.
One way to use a multi-interface compatible hashing mechanism is to use the \texttt{libmemcached} library and the associated interfaces. Because the interfaces for the different languages (including C, Ruby, Perl and Python) use the same client library interface, they always generate the same hash code from the ID.

The problem with client-side selection of the server is that the list of the servers (including their sequential order) \textit{must} remain consistent on each client using the \texttt{memcached} servers, and the servers must be available. If you try to perform an operation on a key when:

- A new \texttt{memcached} instance has been added to the list of available instances
- A \texttt{memcached} instance has been removed from the list of available instances
- The order of the \texttt{memcached} instances has changed

When the hashing algorithm is used on the given key, but with a different list of servers, the hash calculation may choose a different server from the list.

If a new \texttt{memcached} instance is added into the list of servers, as \texttt{new.memc} is in the example below, then a GET operation using the same key, \texttt{myid}, can result in a cache-miss. This is because the same value is computed from the key, which selects the same index from the array of servers, but index 2 now points to the new server, not the server \texttt{c.memc} where the data was originally stored. This would result in a cache miss, even though the key exists within the cache on another \texttt{memcached} instance.

\textbf{Figure 16.4} \texttt{memcached} Hash Selection with New \texttt{memcached} instance

This means that servers \texttt{c.memc} and \texttt{new.memc} both contain the information for key \texttt{myid}, but the information stored against the key in each server may be different in each instance. A more significant problem is a much higher number of cache-misses when retrieving data, as the addition of a new server changes the distribution of keys, and this in turn requires rebuilding the cached data on the \texttt{memcached} instances, causing an increase in database reads.

The same effect can occur if you actively manage the list of servers configured in your clients, adding and removing the configured \texttt{memcached} instances as each instance is identified as being available. For example, removing a \texttt{memcached} instance when the client notices that the instance can no longer be contacted can cause the server selection to fail as described here.

To prevent this causing significant problems and invalidating your cache, you can select the hashing algorithm used to select the server. There are two common types of hashing algorithm, \textit{consistent} and \textit{modula}.

With \textit{consistent} hashing algorithms, the same key when applied to a list of servers always uses the same server to store or retrieve the keys, even if the list of configured servers changes. This means that you can
Using **memcached**

add and remove servers from the configure list and always use the same server for a given key. There are two types of consistent hashing algorithms available, Ketama and Wheel. Both types are supported by `libmemcached`, and implementations are available for PHP and Java.

Any consistent hashing algorithm has some limitations. When you add servers to an existing list of configured servers, keys are distributed to the new servers as part of the normal distribution. When you remove servers from the list, the keys are re-allocated to another server within the list, meaning that the cache needs to be re-populated with the information. Also, a consistent hashing algorithm does not resolve the issue where you want consistent selection of a server across multiple clients, but where each client contains a different list of servers. The consistency is enforced only within a single client.

With a *modula* hashing algorithm, the client selects a server by first computing the hash and then choosing a server from the list of configured servers. As the list of servers changes, so the server selected when using a modula hashing algorithm also changes. The result is the behavior described above; changes to the list of servers mean that different servers are selected when retrieving data, leading to cache misses and increase in database load as the cache is re-seeded with information.

If you use only a single memcached instance for each client, or your list of memcached servers configured for a client never changes, then the selection of a hashing algorithm is irrelevant, as it has no noticeable effect.

If you change your servers regularly, or you use a common set of servers that are shared among a large number of clients, then using a consistent hashing algorithm should help to ensure that your cache data is not duplicated and the data is evenly distributed.

### 16.2.2.6 Using **memcached** and DTrace

**memcached** includes a number of different DTrace probes that can be used to monitor the operation of the server. The probes included can monitor individual connections, slab allocations, and modifications to the hash table when a key-value pair is added, updated, or removed.

For more information on DTrace and writing DTrace scripts, read the DTrace User Guide.

Support for DTrace probes was added to **memcached** 1.2.6 includes a number of DTrace probes that can be used to help monitor your application. DTrace is supported on Solaris 10, OpenSolaris, OS X 10.5 and FreeBSD. To enable the DTrace probes in **memcached**, build from source and use the `--enable-dtrace` option. For more information, see Section 16.2.1, “Installing **memcached**”.

The probes supported by **memcached** are:

- **conn-allocate(connid)**
  
  Fired when a connection object is allocated from the connection pool.

  - **connid**: The connection ID.

- **conn-release(connid)**
  
  Fired when a connection object is released back to the connection pool.

  Arguments:

  - **connid**: The connection ID.

- **conn-create(ptr)**
  
  Fired when a new connection object is being created (that is, there are no free connection objects in the connection pool).
Arguments:

- **ptr**: A pointer to the connection object.

- **conn-destroy(ptr)**
  Fired when a connection object is being destroyed.
  Arguments:
  - **ptr**: A pointer to the connection object.

- **conn-dispatch(connid, threadid)**
  Fired when a connection is dispatched from the main or connection-management thread to a worker thread.
  Arguments:
  - **connid**: The connection ID.
  - **threadid**: The thread ID.

- **slabs-allocate(size, slabclass, slabsize, ptr)**
  Allocate memory from the slab allocator.
  Arguments:
  - **size**: The requested size.
  - **slabclass**: The allocation is fulfilled in this class.
  - **slabsize**: The size of each item in this class.
  - **ptr**: A pointer to allocated memory.

- **slabs-allocate-failed(size, slabclass)**
  Failed to allocate memory (out of memory).
  Arguments:
  - **size**: The requested size.
  - **slabclass**: The class that failed to fulfill the request.

- **slabs-slabclass-allocate(slabclass)**
  Fired when a slab class needs more space.
  Arguments:
  - **slabclass**: The class that needs more memory.

- **slabs-slabclass-allocate-failed(slabclass)**
  Failed to allocate memory (out of memory).
Using memcached

Arguments:

- **slabclass**: The class that failed to grab more memory.
- **slabs-free(size, slabclass, ptr)**

  Release memory.

  Arguments:
  
  - **size**: The amount of memory to release, in bytes.
  - **slabclass**: The class the memory belongs to.
  - **ptr**: A pointer to the memory to release.

- **assoc-find(key, depth)**

  Fired when we have searched the hash table for a named key. These two elements provide an insight into how well the hash function operates. Traversals are a sign of a less optimal function, wasting CPU capacity.

  Arguments:
  
  - **key**: The key searched for.
  - **depth**: The depth in the list of hash table.

- **assoc-insert(key, nokeys)**

  Fired when a new item has been inserted.

  Arguments:
  
  - **key**: The key just inserted.
  - **nokeys**: The total number of keys currently being stored, including the key for which insert was called.

- **assoc-delete(key, nokeys)**

  Fired when a new item has been removed.

  Arguments:
  
  - **key**: The key just deleted.
  - **nokeys**: The total number of keys currently being stored, excluding the key for which delete was called.

- **item-link(key, size)**

  Fired when an item is being linked in the cache.

  Arguments:
  
  - **key**: The items key.
  - **size**: The size of the data.
• **item-unlink(key, size)**
  Fired when an item is being deleted.
  Arguments:
  • **key**: The item's key.
  • **size**: The size of the data.

• **item-remove(key, size)**
  Fired when the refcount for an item is reduced.
  Arguments:
  • **key**: The item's key.
  • **size**: The size of the data.

• **item-update(key, size)**
  Fired when the "last referenced" time is updated.
  Arguments:
  • **key**: The item's key.
  • **size**: The size of the data.

• **item-replace(oldkey, oldsize, newkey, newsize)**
  Fired when an item is being replaced with another item.
  Arguments:
  • **oldkey**: The key of the item to replace.
  • **oldsize**: The size of the old item.
  • **newkey**: The key of the new item.
  • **newsize**: The size of the new item.

• **process-command-start(connid, request, size)**
  Fired when the processing of a command starts.
  Arguments:
  • **connid**: The connection ID.
  • **request**: The incoming request.
  • **size**: The size of the request.

• **process-command-end(connid, response, size)**
  Fired when the processing of a command is done.
Arguments:

• **connid:** The connection ID.
• **response:** The response to send back to the client.
• **size:** The size of the response.
• **command-get(connid, key, size)**

   Fired for a **get** command.

Arguments:

• **connid:** The connection ID.
• **key:** The requested key.
• **size:** The size of the key's data (or -1 if not found).
• **command-gets(connid, key, size, casid)**

   Fired for a **gets** command.

Arguments:

• **connid:** The connection ID.
• **key:** The requested key.
• **size:** The size of the key's data (or -1 if not found).
• **casid:** The casid for the item.
• **command-add(connid, key, size)**

   Fired for a **add** command.

Arguments:

• **connid:** The connection ID.
• **key:** The requested key.
• **size:** The new size of the key's data (or -1 if not found).
• **command-set(connid, key, size)**

   Fired for a **set** command.

Arguments:

• **connid:** The connection ID.
• **key:** The requested key.
• **size:** The new size of the key's data (or -1 if not found).
Using memcached

- **command-replace(connid, key, size)**
  Fired for a `replace` command.
  Arguments:
  - `connid`: The connection ID.
  - `key`: The requested key.
  - `size`: The new size of the key's data (or -1 if not found).

- **command-prepend(connid, key, size)**
  Fired for a `prepend` command.
  Arguments:
  - `connid`: The connection ID.
  - `key`: The requested key.
  - `size`: The new size of the key's data (or -1 if not found).

- **command-append(connid, key, size)**
  Fired for a `append` command.
  Arguments:
  - `connid`: The connection ID.
  - `key`: The requested key.
  - `size`: The new size of the key's data (or -1 if not found).

- **command-cas(connid, key, size, casid)**
  Fired for a `cas` command.
  Arguments:
  - `connid`: The connection ID.
  - `key`: The requested key.
  - `size`: The size of the key's data (or -1 if not found).
  - `casid`: The cas ID requested.

- **command-incr(connid, key, val)**
  Fired for `incr` command.
  Arguments:
  - `connid`: The connection ID.
  - `key`: The requested key.
Using memcached

- **val**: The new value.
- **command-decr** (connid, key, val)

  Fired for **decr** command.
  Arguments:
  - **connid**: The connection ID.
  - **key**: The requested key.
  - **val**: The new value.

- **command-delete** (connid, key, exptime)

  Fired for a **delete** command.
  Arguments:
  - **connid**: The connection ID.
  - **key**: The requested key.
  - **exptime**: The expiry time.

### 16.2.2.7 Memory Allocation within memcached

When you first start **memcached**, the memory that you have configured is not automatically allocated. Instead, **memcached** only starts allocating and reserving physical memory once you start saving information into the cache.

When you start to store data into the cache, **memcached** does not allocate the memory for the data on an item by item basis. Instead, a slab allocation is used to optimize memory usage and prevent memory fragmentation when information expires from the cache.

With slab allocation, memory is reserved in blocks of 1MB. The slab is divided up into a number of blocks of equal size. When you try to store a value into the cache, **memcached** checks the size of the value that you are adding to the cache and determines which slab contains the right size allocation for the item. If a slab with the item size already exists, the item is written to the block within the slab.

If the new item is bigger than the size of any existing blocks, then a new slab is created, divided up into blocks of a suitable size. If an existing slab with the right block size already exists, but there are no free blocks, a new slab is created. If you update an existing item with data that is larger than the existing block allocation for that key, then the key is re-allocated into a suitable slab.

For example, the default size for the smallest block is 88 bytes (40 bytes of value, and the default 48 bytes for the key and flag data). If the size of the first item you store into the cache is less than 40 bytes, then a slab with a block size of 88 bytes is created and the value stored.

If the size of the data that you intend to store is larger than this value, then the block size is increased by the chunk size factor until a block size large enough to hold the value is determined. The block size is always a function of the scale factor, rounded up to a block size which is exactly divisible into the chunk size.

For a sample of the structure, see Figure 16.5, “Memory Allocation in **memcached**”.
The result is that you have multiple pages allocated within the range of memory allocated to memcached. Each page is 1MB in size (by default), and is split into a different number of chunks, according to the chunk size required to store the key-value pairs. Each instance has multiple pages allocated, and a page is always created when a new item needs to be created requiring a chunk of a particular size. A slab may consist of multiple pages, and each page within a slab contains an equal number of chunks.

The chunk size of a new slab is determined by the base chunk size combined with the chunk size growth factor. For example, if the initial chunks are 104 bytes in size, and the default chunk size growth factor is used (1.25), then the next chunk size allocated would be the best power of 2 fit for 104*1.25, or 136 bytes.

Allocating the pages in this way ensures that memory does not get fragmented. However, depending on the distribution of the objects that you store, it may lead to an inefficient distribution of the slabs and chunks if you have significantly different sized items. For example, having a relatively small number of items within each chunk size may waste a lot of memory with just few chunks in each allocated page.

You can tune the growth factor to reduce this effect by using the \(-f\) command line option, which adapts the growth factor applied to make more effective use of the chunks and slabs allocated. For information on how to determine the current slab allocation statistics, see Section 16.2.4.2, “memcached Slabs Statistics”.

If your operating system supports it, you can also start memcached with the \(-L\) command line option. This option preallocates all the memory during startup using large memory pages. This can improve performance by reducing the number of misses in the CPU memory cache.

### 16.2.2.8 memcached Thread Support

If you enable the thread implementation within when building memcached from source, then memcached uses multiple threads in addition to the libevent system to handle requests.

When enabled, the threading implementation operates as follows:

- Threading is handled by wrapping functions within the code to provide basic protection from updating the same global structures at the same time.

- Each thread uses its own instance of the libevent to help improve performance.

- TCP/IP connections are handled with a single thread listening on the TCP/IP socket. Each connection is then distributed to one of the active threads on a simple round-robin basis. Each connection then operates solely within this thread while the connection remains open.

- For UDP connections, all the threads listen to a single UDP socket for incoming requests. Threads that are not currently dealing with another request ignore the incoming packet. One of the remaining, nonbusy, threads reads the request and sends the response. This implementation can lead to increased CPU load as threads wake from sleep to potentially process the request.
Using threads can increase the performance on servers that have multiple CPU cores available, as the requests to update the hash table can be spread between the individual threads. To minimize overhead from the locking mechanism employed, experiment with different thread values to achieve the best performance based on the number and type of requests within your given workload.

16.2.2.9 memcached Logs

If you enable verbose mode, using the \(-v, -vv, \text{ or } -vvv\) options, then the information output by \texttt{memcached} includes details of the operations being performed.

Without the verbose options, \texttt{memcached} normally produces no output during normal operating.

- **Output when using \(-v\)**

  The lowest verbosity level shows you:

  - Errors and warnings
  - Transient errors
  - Protocol and socket errors, including exhausting available connections
  - Each registered client connection, including the socket descriptor number and the protocol used.

  For example:

  32: Client using the ascii protocol
  33: Client using the ascii protocol

  The socket descriptor is only valid while the client remains connected. Non-persistent connections may not be effectively represented.

  Examples of the error messages output at this level include:

  \(<%d \text{ send buffer was } %d, \text{ now } %d\>
  
  \(\text{Can't listen for events on fd } %d\>
  
  \(\text{Can't read from libevent pipe}\>
  
  \(\text{Catastrophic: event fd doesn't match conn fd!}\>
  
  \(\text{Couldn't build response}\>
  
  \(\text{Couldn't realloc input buffer}\>
  
  \(\text{Couldn't update event}\>
  
  \(\text{Failed to build UDP headers}\>
  
  \(\text{Failed to read, and not due to blocking}\>
  
  \(\text{Too many open connections}\>
  
  \(\text{Unexpected state } %d\>

- **Output when using \(-vv\)**

  When using the second level of verbosity, you get more detailed information about protocol operations, keys updated, chunk and network operatings and details.

  During the initial start-up of \texttt{memcached} with this level of verbosity, you are shown the sizes of the individual slab classes, the chunk sizes, and the number of entries per slab. These do not show the allocation of the slabs, just the slabs that would be created when data is added. You are also given information about the listen queues and buffers used to send information. A sample of the output generated for a TCP/IP based system with the default memory and growth factors is given below:

  \(\text{shell> memcached } -vv\rangle
Using memcached

Using this verbosity level can be a useful way to check the effects of the growth factor used on slabs with different memory allocations, which in turn can be used to better tune the growth factor to suit the data you are storing in the cache. For example, if you set the growth factor to 4 (quadrupling the size of each slab):

```shell
$ memcached -f 4 -m 1g -vv
```

```
slab class 1: chunk size  80 perslab 13107
slab class 2: chunk size 320 perslab 1276
slab class 3: chunk size 1280 perslab 819
slab class 4: chunk size 5120 perslab 204
slab class 5: chunk size 20480 perslab 51
slab class 6: chunk size 81920 perslab 12
slab class 7: chunk size 327680 perslab 2
```

2339
Using `memcached`

During use of the cache, this verbosity level also prints out detailed information on the storage and recovery of keys and other information. An example of the output during a typical set/get and increment/decrement operation is shown below.

```
32: Client using the ascii protocol
<32 set my_key 0 0 10
>32 STORED
<32 set object_key 1 0 36
>32 STORED
<32 get my_key
>32 sending key my_key
>32 END
<32 get object_key
>32 sending key object_key
>32 END
<32 set key 0 0 6
>32 STORED
<32 incr key 1
>32 789544
<32 decr key 1
>32 789543
<32 incr key 2
>32 789545
<32 set my_key 0 0 10
>32 STORED
<32 set object_key 1 0 36
>32 STORED
<32 get my_key
>32 sending key my_key
>32 END
<32 get object_key
>32 sending key object_key 1 36
>32 END
<32 set key 0 0 6
>32 STORED
<32 incr key 1
>32 789544
<32 decr key 1
>32 789543
<32 incr key 2
>32 789545
```

During client communication, for each line, the initial character shows the direction of flow of the information. The `<` for communication from the client to the `memcached` server and `>` for communication back to the client. The number is the numeric socket descriptor for the connection.

- **Output when using `-vvv`**

This level of verbosity includes the transitions of connections between different states in the event library while reading and writing content to/from the clients. It should be used to diagnose and identify issues in client communication. For example, you can use this information to determine if `memcached` is taking a long time to return information to the client, during the read of the client operation or before returning and completing the operation. An example of the typical sequence for a set operation is provided below:

```
<32 new auto-negotiating client connection
32: going from conn_new_cmd to conn_waiting
32: going from conn_waiting to conn_read
32: going from conn_read to conn_parse_cmd
32: Client using the ascii protocol
```
Developing a `memcached` Application

All of the verbosity levels in `memcached` are designed to be used during debugging or examination of issues. The quantity of information generated, particularly when using `-vvv`, is significant, particularly on a busy server. Also be aware that writing the error information out, especially to disk, may negate some of the performance gains you achieve by using `memcached`. Therefore, use in production or deployment environments is not recommended.

### 16.2.3 Developing a `memcached` Application

A number of language interfaces let applications store and retrieve information with `memcached` servers. You can write `memcached` applications in popular languages such as Perl, PHP, Python, Ruby, C, and Java.

Data stored into a `memcached` server is referred to by a single string (the key), with storage into the cache and retrieval from the cache using the key as the reference. The cache therefore operates like a large associative array or hash table. It is not possible to structure or otherwise organize the information stored in the cache. To emulate database notions such as multiple tables or composite key values, you must encode the extra information into the strings used as keys. For example, to store or look up the address corresponding to a specific latitude and longitude, you might turn those two numeric values into a single comma-separated string to use as a key.

#### 16.2.3.1 Basic `memcached` Operations

The interface to `memcached` supports the following methods for storing and retrieving information in the cache, and these are consistent across all the different APIs, although the language specific mechanics might be different:

- **get**(key): Retrieves information from the cache. Returns the value associated with the key if the specified key exists. Returns `NULL`, `nil`, `undefined`, or the closest equivalent in the corresponding language, if the specified key does not exist.

- **set**(key, value [, expiry]): Sets the item associated with a key in the cache to the specified value. This either updates an existing item if the key already exists, or adds a new key-value pair if the key doesn't exist. If the expiry time is specified, then the item expires (and is deleted) when the expiry time is reached. The time is specified in seconds, and is taken as a relative time if the value is less than 30 days (30*24*60*60), or an absolute time (epoch) if larger than this value.

- **add**(key, value [, expiry]): Adds the key and associated value to the cache, if the specified key does not already exist.

- **replace**(key, value [, expiry]): Replaces the item associated with the specified key, only if the key already exists. The new value is given by the value parameter.

- **delete**(key [, time]): Deletes the key and its associated item from the cache. If you supply a time, then adding another item with the specified key is blocked for the specified period.

- **incr**(key, value): Increments the item associated with the key by the specified value.
Developing a **memcached** Application

- **decr(key, value):** Decrements the item associated with the key by the specified value.
- **flush_all:** Invalidates (or expires) all the current items in the cache. Technically they still exist (they are not deleted), but they are silently destroyed the next time you try to access them.

In all implementations, most or all of these functions are duplicated through the corresponding native language interface.

When practical, use **memcached** to store full items, rather than caching a single column value from the database. For example, when displaying a record about an object (invoice, user history, or blog post), load all the data for the associated entry from the database, and compile it into the internal structure that would normally be required by the application. Save the complete object in the cache.

Complex data structures cannot be stored directly. Most interfaces serialize the data for you, that is, put it in a textual form that can reconstruct the original pointers and nesting. Perl uses **Storable**, PHP uses **serialize**, Python uses **cPickle** (or **Pickle**) and Java uses the **Serializable** interface. In most cases, the serialization interface used is customizable. To share data stored in **memcached** instances between different language interfaces, consider using a common serialization solution such as JSON (Javascript Object Notation).

### 16.2.3.2 Using **memcached** as a MySQL Caching Layer

When using **memcached** to cache MySQL data, your application must retrieve data from the database and load the appropriate key-value pairs into the cache. Then, subsequent lookups can be done directly from the cache.

Because MySQL has its own in-memory caching mechanisms for queried data, such as the **InnoDB buffer pool** and the MySQL query cache, look for opportunities beyond loading individual column values or rows into the cache. Prefer to cache composite values, such as those retrieved from multiple tables through a join query, or result sets assembled from multiple rows.

**Caution**

Limit the information in the cache to non-sensitive data, because there is no security required to access or update the information within a **memcached** instance. Anybody with access to the machine has the ability to read, view and potentially update the information. To keep the data secure, encrypt the information before caching it. To restrict the users capable of connecting to the server, either disable network access, or use **iptables** or similar techniques to restrict access to the **memcached** ports to a select set of hosts.

You can introduce **memcached** to an existing application, even if caching was not part of the original design. In many languages and environments the changes to the application will be just a few lines, first to attempt to read from the cache when loading data, fall back to the old method if the information is not cached, and to update the cache with information once the data has been read.

The general sequence for using **memcached** in any language as a caching solution for MySQL is as follows:

1. Request the item from the cache.
2. If the item exists, use the item data.
3. If the item does not exist, load the data from MySQL, and store the value into the cache. This means the value is available to the next client that requests it from the cache.

For a flow diagram of this sequence, see **Figure 16.6, “Typical memcached Application Flowchart”**.
Adapting Database Best Practices to \texttt{memcached} Applications

The most direct way to cache MySQL data is to use a 2-column table, where the first column is a primary key. Because of the uniqueness requirements for \texttt{memcached} keys, make sure your database schema makes appropriate use of primary keys and unique constraints.

If you combine multiple column values into a single \texttt{memcached} item value, choose data types to make it easy to parse the value back into its components, for example by using a separator character between numeric values.

The queries that map most easily to \texttt{memcached} lookups are those with a single \texttt{WHERE} clause, using an = or \texttt{IN} operator. For complicated \texttt{WHERE} clauses, or those using operators such as <, >, \texttt{BETWEEN}, or \texttt{LIKE}, \texttt{memcached} does not provide a simple or efficient way to scan through or filter the keys or associated values, so typically you perform those operations as SQL queries on the underlying database.

16.2.3.3 Using \texttt{libmemcached} with C and C++

The \texttt{libmemcached} library provides both C and C++ interfaces to \texttt{memcached} and is also the basis for a number of different additional API implementations, including Perl, Python and Ruby. Understanding the core \texttt{libmemcached} functions can help when using these other interfaces.

The C library is the most comprehensive interface library for \texttt{memcached} and provides functions and operational systems not always exposed in interfaces not based on the \texttt{libmemcached} library.

The different functions can be divided up according to their basic operation. In addition to functions that interface to the core API, a number of utility functions provide extended functionality, such as appending and prepending data.

To build and install \texttt{libmemcached}, download the \texttt{libmemcached} package, run \texttt{configure}, and then build and install:
Developing a *memcached* Application

On many Linux operating systems, you can install the corresponding *libmemcached* package through the usual *yum*, *apt-get*, or similar commands.

To build an application that uses the library, first set the list of servers. Either directly manipulate the servers configured within the main *memcached_st* structure, or separately populate a list of servers, and then add this list to the *memcached_st* structure. The latter method is used in the following example. Once the server list has been set, you can call the functions to store or retrieve data. A simple application for setting a preset value to *localhost* is provided here:

```c
#include <stdio.h>
#include <string.h>
#include <unistd.h>
#include <libmemcached/memcached.h>

int main(int argc, char *argv[]) {
    memcached_server_st *servers = NULL;
    memcached_st *memc;
    memcached_return rc;
    char *key = "keystring";
    char *value = "keyvalue";

    memcached_server_st *memcached_servers_parse (char *server_strings);
    memc= memcached_create(NULL);
    servers= memcached_server_list_append(servers, "localhost", 11211, &rc);
    rc= memcached_server_push(memc, servers);
    if (rc == MEMCACHED_SUCCESS)
        fprintf(stderr,"Added server successfully\n");
    else
        fprintf(stderr,"Couldn't add server: %s\n",memcached_strerror(memc, rc));

    rc= memcached_set(memc, key, strlen(key), value, strlen(value), (time_t)0, (uint32_t)0);
    if (rc == MEMCACHED_SUCCESS)
        fprintf(stderr,"Key stored successfully\n");
    else
        fprintf(stderr,"Couldn't store key: %s\n",memcached_strerror(memc, rc));

    return 0;
}
```

To test the success of an operation, use the return value, or populated result code, for a given function. The value is always set to *MEMCACHED_SUCCESS* if the operation succeeded. In the event of a failure, use the *memcached_strerror()* function to translate the result code into a printable string.

To build the application, specify the *memcached* library:

```shell
shell> gcc -o memc_basic memc_basic.c -lmemcached
```

Running the above sample application, after starting a *memcached* server, should return a success message:

```shell
shell> memc_basic
```
Developing a `memcached` Application

**Added server successfully**
**Key stored successfully**

**libmemcached Base Functions**

The base `libmemcached` functions let you create, destroy and clone the main `memcached_st` structure that is used to interface with the `memcached` servers. The main functions are defined below:

```c
memcached_st *memcached_create (memcached_st *ptr);
```

Creates a new `memcached_st` structure for use with the other `libmemcached` API functions. You can supply an existing, static, `memcached_st` structure, or `NULL` to have a new structured allocated. Returns a pointer to the created structure, or `NULL` on failure.

```c
void memcached_free (memcached_st *ptr);
```

Frees the structure and memory allocated to a previously created `memcached_st` structure.

```c
memcached_st *memcached_clone(memcached_st *clone, memcached_st *source);
```

Clones an existing `memcached` structure from the specified `source`, copying the defaults and list of servers defined in the structure.

**libmemcached Server Functions**

The `libmemcached` API uses a list of servers, stored within the `memcached_server_st` structure, to act as the list of servers used by the rest of the functions. To use `memcached`, you first create the server list, and then apply the list of servers to a valid `libmemcached` object.

Because the list of servers, and the list of servers within an active `libmemcached` object can be manipulated separately, you can update and manage server lists while an active `libmemcached` interface is running.

The functions for manipulating the list of servers within a `memcached_st` structure are:

```c
memcached_return
    memcached_server_add (memcached_st *ptr,
                         char *hostname,
                         unsigned int port);
```

Adds a server, using the given `hostname` and `port` into the `memcached_st` structure given in `ptr`.

```c
memcached_return
    memcached_server_add_unix_socket (memcached_st *ptr,
                                       char *socket);
```

Adds a Unix socket to the list of servers configured in the `memcached_st` structure.

```c
unsigned int memcached_server_count (memcached_st *ptr);
```

Returns a count of the number of configured servers within the `memcached_st` structure.

```c
memcached_server_st *
    memcached_server_list (memcached_st *ptr);
```

Returns an array of all the defined hosts within a `memcached_st` structure.
Developing a memcached Application

```
memcached_return
    memcached_server_push (memcached_st *ptr,
                          memcached_server_st *list);
```

Pushes an existing list of servers onto list of servers configured for a current memcached_st structure. This adds servers to the end of the existing list, and duplicates are not checked.

The `memcached_server_st` structure can be used to create a list of memcached servers which can then be applied individually to `memcached_st` structures.

```
memcached_server_st *
    memcached_server_list_append (memcached_server_st *ptr,
                                   char *hostname,
                                   unsigned int port,
                                   memcached_return *error);
```

Adds a server, with hostname and port, to the server list in `ptr`. The result code is handled by the `error` argument, which should point to an existing `memcached_return` variable. The function returns a pointer to the returned list.

```
unsigned int memcached_server_list_count (memcached_server_st *ptr);
```

Returns the number of the servers in the server list.

```
void memcached_server_list_free (memcached_server_st *ptr);
```

Frees the memory associated with a server list.

```
memcached_server_st *
    memcached_servers_parse (char *server_strings);
```

 Parses a string containing a list of servers, where individual servers are separated by a comma, space, or both, and where individual servers are of the form `server[:port]`. The return value is a server list structure.

**libmemcached Set Functions**

The set-related functions within libmemcached provide the same functionality as the core functions supported by the memcached protocol. The full definition for the different functions is the same for all the base functions (`add`, `replace`, `prepend`, `append`). For example, the function definition for `memcached_set() is`:

```
memcached_return
    memcached_set (memcached_st *ptr,
                   const char *key,
                   size_t key_length,
                   const char *value,
                   size_t value_length,
                   time_t expiration,
                   uint32_t flags);
```

The `ptr` is the `memcached_st` structure. The `key` and `key_length` define the key name and length, and `value` and `value_length` the corresponding value and length. You can also set the expiration and optional flags. For more information, see Controlling libmemcached Behaviors.

The following table outlines the remainder of the set-related libmemcached functions and the equivalent core functions supported by the memcached protocol.
### Developing a `memcached` Application

<table>
<thead>
<tr>
<th><code>libmemcached</code> Function</th>
<th>Equivalent Core Function</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>memcached_set(memc, key, key_length, value, value_length, expiration, flags)</code></td>
<td>Generic <code>set()</code> operation.</td>
</tr>
<tr>
<td><code>memcached_add(memc, key, key_length, value, value_length, expiration, flags)</code></td>
<td>Generic <code>add()</code> function.</td>
</tr>
<tr>
<td><code>memcached_replace(memc, key, key_length, value, value_length, expiration, flags)</code></td>
<td>Generic <code>replace()</code></td>
</tr>
<tr>
<td><code>memcached_prepend(memc, key, key_length, value, value_length, expiration, flags)</code></td>
<td>Prepends the specified <code>value</code> before the current value of the specified <code>key</code>.</td>
</tr>
<tr>
<td><code>memcached_append(memc, key, key_length, value, value_length, expiration, flags)</code></td>
<td>Appends the specified <code>value</code> after the current value of the specified <code>key</code>.</td>
</tr>
<tr>
<td><code>memcached_cas(memc, key, key_length, value, value_length, expiration, flags, cas)</code></td>
<td>Overwrites the data for a given key as long as the corresponding <code>cas</code> value is still the same within the server.</td>
</tr>
<tr>
<td><code>memcached_set_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code></td>
<td>Similar to the generic <code>set()</code>, but has the option of an additional master key that can be used to identify an individual server.</td>
</tr>
<tr>
<td><code>memcached_add_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code></td>
<td>Similar to the generic <code>add()</code>, but has the option of an additional master key that can be used to identify an individual server.</td>
</tr>
<tr>
<td><code>memcached_replace_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code></td>
<td>Similar to the generic <code>replace()</code>, but has the option of an additional master key that can be used to identify an individual server.</td>
</tr>
<tr>
<td><code>memcached_prepend_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code></td>
<td>Similar to the <code>memcached_prepend()</code>, but has the option of an additional master key that can be used to identify an individual server.</td>
</tr>
<tr>
<td><code>memcached_append_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code></td>
<td>Similar to the <code>memcached_append()</code>, but has the option of an additional master key that can be used to identify an individual server.</td>
</tr>
<tr>
<td><code>memcached_cas_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code></td>
<td>Similar to the <code>memcached_cas()</code>, but has the option of an additional master key that can be used to identify an individual server.</td>
</tr>
</tbody>
</table>

The `by_key` methods add two further arguments that define the master key, to be used and applied during the hashing stage for selecting the servers. You can see this in the following definition:

```c
memcached_return
    memcached_set_by_key(memcached_st *ptr,
```
Developing a **memcached** Application

All the functions return a value of type **memcached_return**, which you can compare against the **MEMCACHED_SUCCESS** constant.

### libmemcached Get Functions

The *libmemcached* functions provide both direct access to a single item, and a multiple-key request mechanism that provides much faster responses when fetching a large number of keys simultaneously.

The main get-style function, which is equivalent to the generic `get()` is **memcached_get()**. This function returns a string pointer, pointing to the value associated with the specified key.

```c
char *memcached_get (memcached_st *ptr,
                     const char *key, size_t key_length,
                     size_t *value_length,
                     uint32_t *flags,
                     memcached_return *error);
```

A multi-key get, **memcached_mget()**, is also available. Using a multiple key get operation is much quicker to do in one block than retrieving the key values with individual calls to **memcached_get()**. To start the multi-key get, call **memcached_mget()**:

```c
memcached_return
memcached_mget (memcached_st *ptr,
                char **keys, size_t *key_length,
                unsigned int number_of_keys);
```

The return value is the success of the operation. The **keys** parameter should be an array of strings containing the keys, and **key_length** an array containing the length of each corresponding key. **number_of_keys** is the number of keys supplied in the array.

To fetch the individual values, use **memcached_fetch()** to get each corresponding value.

```c
char *memcached_fetch (memcached_st *ptr,
                        const char *key, size_t *key_length,
                        size_t *value_length,
                        uint32_t *flags,
                        memcached_return *error);
```

The function returns the key value, with the **key**, **key_length** and **value_length** parameters being populated with the corresponding key and length information. The function returns **NULL** when there are no more values to be returned. A full example, including the populating of the key data and the return of the information is provided here.

```c
#include <stdio.h>
#include <string.h>
#include <unistd.h>
#include <libmemcached/memcached.h>

int main(int argc, char *argv[])
```
Developing a **memcached** Application

```c
{  
    memcached_server_st *servers = NULL;
    memcached_st *memc;
    memcached_return rc;
    char *keys[] = {"huey", "dewey", "louie");
    size_t key_length[3];
    char *values[] = {"red", "blue", "green");
    size_t value_length[3];
    unsigned int x;
    uint32_t flags;

    char return_key[MEMCACHED_MAX_KEY];
    size_t return_key_length;
    char *return_value;
    size_t return_value_length;

    memc = memcached_create(NULL);

    servers = memcached_server_list_append(servers, "localhost", 11211, &rc);
    rc = memcached_server_push(memc, servers);

    if (rc == MEMCACHED_SUCCESS)
        fprintf(stderr,"Added server successfully\n");
    else
        fprintf(stderr,"Couldn't add server: %s\n", memcached_strerror(memc, rc));

    for(x = 0; x < 3; x++)
    {
        key_length[x] = strlen(keys[x]);
        value_length[x] = strlen(values[x]);

        rc = memcached_set(memc, keys[x], key_length[x], values[x],
                                value_length[x], (time_t)0, (uint32_t)0);
        if (rc == MEMCACHED_SUCCESS)
            fprintf(stderr,"Key %s stored successfully\n", keys[x]);
        else
            fprintf(stderr,"Couldn't store key: %s\n", memcached_strerror(memc, rc));
    }

    rc = memcached_mget(memc, keys, key_length, 3);

    if (rc == MEMCACHED_SUCCESS)
    {
        while ((return_value = memcached_fetch(memc, return_key, &return_key_length,
                                      &return_value_length, &flags, &rc)) != NULL)
        {  
            if (rc == MEMCACHED_SUCCESS)
                {  
                    fprintf(stderr,"Key %s returned %s\n", return_key, return_value);
                }
        }
    }

    return 0;
}
```

Running the above application produces the following output:

```
shell> memc_multi_fetch
Added server successfully
Key huey stored successfully
Key dewey stored successfully
Key louie stored successfully
Key huey returned red
Key dewey returned blue
Key louie returned green
```
Developing a *memcached* Application

**Controlling *libmemcached* Behaviors**

The behavior of *libmemcached* can be modified by setting one or more behavior flags. These can either be set globally, or they can be applied during the call to individual functions. Some behaviors also accept an additional setting, such as the hashing mechanism used when selecting servers.

To set global behaviors:

```c
memcached_return
memcached_behavior_set (memcached_st *ptr,
                        memcached_behavior flag,
                        uint64_t data);
```

To get the current behavior setting:

```c
uint64_t
memcached_behavior_get (memcached_st *ptr,
                        memcached_behavior flag);
```

The following table describes *libmemcached* behavior flags.

<table>
<thead>
<tr>
<th>Behavior</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MEMCACHED_BEHAVIOR_NO_BLOCK</td>
<td>Caused <em>libmemcached</em> to use asynchronous I/O.</td>
</tr>
<tr>
<td>MEMCACHED_BEHAVIOR_TCP_NODELAY</td>
<td>Turns on no-delay for network sockets.</td>
</tr>
<tr>
<td>MEMCACHED_BEHAVIOR_HASH</td>
<td>Without a value, sets the default hashing algorithm for keys to use MD5.</td>
</tr>
<tr>
<td></td>
<td>Other valid values include MEMCACHED_HASH_DEFAULT, MEMCACHED_HASH_MD5,</td>
</tr>
<tr>
<td></td>
<td>MEMCACHED_HASH_CRC, MEMCACHED_HASH_FNV1_64, MEMCACHED_HASH_FNV1A_64,</td>
</tr>
<tr>
<td></td>
<td>MEMCACHED_HASH_FNV1_32, and MEMCACHED_HASH_FNV1A_32.</td>
</tr>
<tr>
<td>MEMCACHED_BEHAVIOR_DISTRIBUTION</td>
<td>Changes the method of selecting the server used to store a given value.</td>
</tr>
<tr>
<td></td>
<td>The default method is MEMCACHED_DISTRIBUTION_MODULA.</td>
</tr>
<tr>
<td></td>
<td>You can enable consistent hashing by setting MEMCACHED_DISTRIBUTION_CONSISTENT.</td>
</tr>
<tr>
<td></td>
<td>MEMCACHED_DISTRIBUTION_CONSISTENT is an alias for the value MEMCACHED_DISTRIBUTION_CONSISTENT_KETAMA.</td>
</tr>
<tr>
<td>MEMCACHED_BEHAVIOR_CACHE_LOOKUP</td>
<td>Cache the lookups made to the DNS service. This can improve the performance</td>
</tr>
<tr>
<td></td>
<td>if you are using names instead of IP addresses for individual hosts.</td>
</tr>
<tr>
<td>MEMCACHED_BEHAVIOR_SUPPORT_CAS</td>
<td>Support CAS operations. By default, this is disabled because it imposes</td>
</tr>
<tr>
<td></td>
<td>a performance penalty.</td>
</tr>
<tr>
<td>MEMCACHED_BEHAVIOR_KETAMA</td>
<td>Sets the default distribution to MEMCACHED_DISTRIBUTION_CONSISTENT_KETAMA and the hash to MEMCACHED_HASH_MD5.</td>
</tr>
<tr>
<td>MEMCACHED_BEHAVIOR_POLL_TIMEOUT</td>
<td>Modify the timeout value used by poll(). Supply a signed int pointer for the timeout value.</td>
</tr>
<tr>
<td>MEMCACHED_BEHAVIOR_BUFFER_REQUEST</td>
<td>Buffers IO requests instead of them being sent. A get operation, or closing the connection causes the data to be flushed.</td>
</tr>
<tr>
<td>MEMCACHED_BEHAVIOR_VERIFY_KEY</td>
<td>Forces <em>libmemcached</em> to verify that a specified key is valid.</td>
</tr>
</tbody>
</table>

<tr>
<th>Behavior</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>MEMCACHED_BEHAVIOR_SORT_HOSTS</code></td>
<td>If set, hosts added to the list of configured hosts for a <code>memcached_server</code> structure are placed into the host list in sorted order. This breaks consistent hashing if that behavior has been enabled.</td>
</tr>
<tr>
<td><code>MEMCACHED_BEHAVIOR_CONNECT_TIMEOUT</code></td>
<td>In nonblocking mode this changes the value of the timeout during socket connection.</td>
</tr>
</tbody>
</table>

**libmemcached** Command-Line Utilities

In addition to the main C library interface, libmemcached also includes a number of command-line utilities that can be useful when working with and debugging `memcached` applications.

All of the command-line tools accept a number of arguments, the most critical of which is `servers`, which specifies the list of servers to connect to when returning information.

The main tools are:

- **memcat**: Display the value for each ID given on the command line:
  ```shell
  shell> memcat --servers=localhost hwkey
  Hello world
  ```

- **memcp**: Copy the contents of a file into the cache, using the file name as the key:
  ```shell
  shell> echo "Hello World" > hwkey
  shell> memcp --servers=localhost hwkey
  shell> memcat --servers=localhost hwkey
  Hello world
  ```

- **memrm**: Remove an item from the cache:
  ```shell
  shell> memcat --servers=localhost hwkey
  Hello world
  shell> memrm --servers=localhost hwkey
  shell> memcat --servers=localhost hwkey
  ```

- **memslap**: Test the load on one or more `memcached` servers, simulating get/set and multiple client operations. For example, you can simulate the load of 100 clients performing get operations:
  ```shell
  shell> memslap --servers=localhost --concurrency=100 --flush --test=get
  memslap --servers=localhost --concurrency=100 --flush --test=get Threads connecting to servers 100
  Took 13.571 seconds to read data
  ```

- **memflush**: Flush (empty) the contents of the `memcached` cache.
  ```shell
  shell> memflush --servers=localhost
  ```

### 16.2.3.4 Using MySQL and `memcached` with Perl

The `Cache::Memcached` module provides a native interface to the Memcache protocol, and provides support for the core functions offered by `memcached`. Install the module using your operating system's package management system, or using CPAN:
To use `memcached` from Perl through the `Cache::Memcached` module, first create a new `Cache::Memcached` object that defines the list of servers and other parameters for the connection. The only argument is a hash containing the options for the cache interface. For example, to create a new instance that uses three `memcached` servers:

```perl
use Cache::Memcached;
my $cache = new Cache::Memcached {
    'servers' => ['198.51.100.100:11211', '198.51.100.101:11211', '198.51.100.102:11211'],
};
```

**Note**

When using the `Cache::Memcached` interface with multiple servers, the API automatically performs certain operations across all the servers in the group. For example, getting statistical information through `Cache::Memcached` returns a hash that contains data on a host-by-host basis, as well as generalized statistics for all the servers in the group.

You can set additional properties on the cache object instance when it is created by specifying the option as part of the option hash. Alternatively, you can use a corresponding method on the instance:

- **servers** or method `set_servers()`: Specifies the list of the servers to be used. The servers list should be a reference to an array of servers, with each element as the address and port number combination (separated by a colon). You can also specify a local connection through a Unix socket (for example, `/tmp/sock/memcached`). To specify the server with a weight (indicating how much more frequently the server should be used during hashing), specify an array reference with the `memcached` server instance and a weight number. Higher numbers give higher priority.

- **compress_threshold** or method `set_compress_threshold()`: Specifies the threshold when values are compressed. Values larger than the specified number are automatically compressed (using `zlib`) during storage and retrieval.

- **no_rehash** or method `set_norehash()`: Disables finding a new server if the original choice is unavailable.

- **readonly** or method `set_readonly()`: Disables writes to the `memcached` servers.

Once the `Cache::Memcached` object instance has been configured, you can use the `set()` and `get()` methods to store and retrieve information from the `memcached` servers. Objects stored in the cache are automatically serialized and deserialized using the `Storable` module.

The `Cache::Memcached` interface supports the following methods for storing/retrieving data, and relate to the generic methods as shown in the table.

<table>
<thead>
<tr>
<th><code>Cache::Memcached</code> Function</th>
<th>Equivalent Generic Method</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>get()</code></td>
<td>Generic <code>get()</code>.</td>
</tr>
<tr>
<td><code>get_multi(keys)</code></td>
<td>Gets multiple keys from memcache using just one query. Returns a hash reference of key-value pairs.</td>
</tr>
<tr>
<td><code>set()</code></td>
<td>Generic <code>set()</code></td>
</tr>
</tbody>
</table>
Developing a memcached Application

<table>
<thead>
<tr>
<th><strong>Cache::Memcached Function</strong></th>
<th>Equivalent Generic Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>add()</td>
<td>Generic add().</td>
</tr>
<tr>
<td>replace()</td>
<td>Generic replace().</td>
</tr>
<tr>
<td>delete()</td>
<td>Generic delete().</td>
</tr>
<tr>
<td>incr()</td>
<td>Generic incr().</td>
</tr>
<tr>
<td>decr()</td>
<td>Generic decr().</td>
</tr>
</tbody>
</table>

Below is a complete example for using memcached with Perl and the Cache::Memcached module:

```perl
#!/usr/bin/perl
use Cache::Memcached;
use DBI;
use Data::Dumper;

# Configure the memcached server
my $cache = new Cache::Memcached {
    'servers' => [
        'localhost:11211',
    ],
};

# Get the film name from the command line
# memcached keys must not contain spaces, so create
# a key name by replacing spaces with underscores
my $filmname = shift or die "Must specify the film name\n";
my $filmkey = $filmname;
$filmkey =~ s/ /_/;

# Load the data from the cache
my $filmdata = $cache->get($filmkey);

# If the data wasn't in the cache, then we load it from the database
if (!defined($filmdata))
{
    $filmdata = load_filmdata($filmname);
    if (defined($filmdata))
    {
        print STDERR "Film data loaded from database and cached\n";
    }
    else
    {
        print STDERR "Couldn't store to cache\n";
    }
}
else
{

```
Developing a memcached Application

```perl
print STDERR "Film data loaded from Memcached\n";
}

sub load_filmdata
{
    my ($filmname) = @_;
    my $dsn = "DBI:mysql:database=sakila;host=localhost;port=3306";
    $dbh = DBI->connect($dsn, 'sakila', 'password');
    my ($filmbase) = $dbh->selectrow_hashref(sprintf('select * from film where title = %s', $dbh->quote($filmname)));
    if (!defined($filmname))
    {
        return (undef);
    }
    $filmbase->{stars} = $dbh->selectall_arrayref(sprintf('select concat(first_name," ",last_name) from film_actor left join (actor) on (film_actor.actor_id = actor.actor_id) ' .
                                               'where film_id=%s', $dbh->quote($filmbase->{film_id})));
    return($filmbase);
}
```

The example uses the Sakila database, obtaining film data from the database and writing a composite record of the film and actors to memcached. When calling it for a film does not exist, you get this result:

```
shell> memcached-sakila.pl "ROCK INSTINCT"
Film data loaded from database and cached
```

When accessing a film that has already been added to the cache:

```
shell> memcached-sakila.pl "ROCK INSTINCT"
Film data loaded from Memcached
```

16.2.3.5 Using MySQL and memcached with Python

The Python memcache module interfaces to memcached servers, and is written in pure Python (that is, without using one of the C APIs). You can download and install a copy from Python Memcached.

To install, download the package and then run the Python installer:

```
python setup.py install
running install
running bdist_egg
running egg_info
creating python_memcached.egg-info
...removing 'build/bdist.linux-x86_64/egg' (and everything under it)
Processing python_memcached-1.43-py2.4.egg
Creating /usr/lib64/python2.4/site-packages/python_memcached-1.43-py2.4.egg
Extracting python_memcached-1.43-py2.4.egg to /usr/lib64/python2.4/site-packages
Adding python-memcached 1.43 to easy-install.pth file

Installed /usr/lib64/python2.4/site-packages/python_memcached-1.43-py2.4.egg
Processing dependencies for python-memcached==1.43
Finished processing dependencies for python-memcached==1.43
```
Once installed, the **memcache** module provides a class-based interface to your **memcached** servers. When you store Python data structures as **memcached** items, they are automatically serialized (turned into string values) using the Python **cPickle** or **pickle** modules.

To create a new **memcache** interface, import the **memcache** module and create a new instance of the **memcache.Client** class. For example, if the **memcached** daemon is running on localhost using the default port:

```python
import memcache
memc = memcache.Client( ['127.0.0.1:11211'] )
```

The first argument is an array of strings containing the server and port number for each **memcached** instance to use. To enable debugging, set the optional **debug** parameter to 1.

By default, the hashing mechanism used to divide the items among multiple servers is **crc32**. To change the function used, set the value of **memcache.serverHashFunction** to the alternate function to use. For example:

```python
from zlib import adler32
memcache.serverHashFunction = adler32
```

Once you have defined the servers to use within the **memcache** instance, the core functions provide the same functionality as in the generic interface specification. The following table provides a summary of the supported functions.

<table>
<thead>
<tr>
<th>Python <strong>memcache</strong> Function</th>
<th>Equivalent Generic Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>get()</td>
<td>Generic <strong>get()</strong>.</td>
</tr>
<tr>
<td>get_multi(keys)</td>
<td>Gets multiple values from the supplied array of keys. Returns a hash reference of key-value pairs.</td>
</tr>
<tr>
<td>set()</td>
<td>Generic <strong>set()</strong>.</td>
</tr>
<tr>
<td>set_multi(dict [, expiry [, key_prefix]])</td>
<td>Sets multiple key-value pairs from the supplied dict.</td>
</tr>
<tr>
<td>add()</td>
<td>Generic <strong>add()</strong>.</td>
</tr>
<tr>
<td>replace()</td>
<td>Generic <strong>replace()</strong>.</td>
</tr>
<tr>
<td>prepend(key, value [, expiry])</td>
<td>Prepends the supplied value to the value of the existing key.</td>
</tr>
<tr>
<td>append(key, value [, expiry])</td>
<td>Appends the supplied value to the value of the existing key.</td>
</tr>
<tr>
<td>delete()</td>
<td>Generic <strong>delete()</strong>.</td>
</tr>
<tr>
<td>delete_multi(keys [, expiry [, key_prefix]])</td>
<td>Deletes all the keys from the hash matching each string in the array keys.</td>
</tr>
<tr>
<td>incr()</td>
<td>Generic <strong>incr()</strong>.</td>
</tr>
<tr>
<td>decr()</td>
<td>Generic <strong>decr()</strong>.</td>
</tr>
</tbody>
</table>

**Note**

Within the Python **memcache** module, all the ***_multi()*** functions support an optional **key_prefix** parameter. If supplied, then the string is used as a prefix to all key lookups. For example, if you call:
Developing a **memcached** Application

Here is an example showing the storage and retrieval of information to a **memcache** instance, loading the raw data from MySQL:

```python
import sys
import MySQLdb
import memcache

memc = memcache.Client(['127.0.0.1:11211'], debug=1);

try:
    conn = MySQLdb.connect (host = "localhost",
        user = "sakila",
        passwd = "password",
        db = "sakila")
except MySQLdb.Error, e:
    print "Error %d: %s" % (e.args[0], e.args[1])
    sys.exit (1)

popularfilms = memc.get('top5films')

if not popularfilms:
    cursor = conn.cursor()
    cursor.execute('select film_id,title from film order by rental_rate desc limit 5')
    rows = cursor.fetchall()
    memc.set('top5films',rows,60)
    print "Updated memcached with MySQL data"
else:
    print "Loaded data from memcached"
    for row in popularfilms:
        print "%s, %s" % (row[0], row[1])
```

When executed for the first time, the data is loaded from the MySQL database and stored to the **memcached** server.

shell> python memc_python.py
Updated memcached with MySQL data

Because the data is automatically serialized using cPickle/pickle, when you load the data back from memcached, you can use the object directly. In the example above, the information stored to memcached is in the form of rows from a Python DB cursor. When accessing the information (within the 60 second expiry time), the data is loaded from memcached and dumped:

shell> python memc_python.py
Loaded data from memcached
2, ACE GOLDFINGER
7, AIRPLANE SIERRA
8, AIRPORT POLLOCK
10, ALADDIN CALENDAR
13, ALI FOREVER

The serialization and deserialization happens automatically. Because serialization of Python data may be incompatible with other interfaces and languages, you can change the serialization module used during initialization. For example, you might use JSON format when you store complex data structures using a script written in one language, and access them in a script written in a different language.
16.2.3.6 Using MySQL and memcached with PHP

PHP provides support for the Memcache functions through a PECL extension. To enable the PHP memcache extensions, build PHP using the `--enable-memcache` option to configure when building from source.

If you are installing on a Red Hat-based server, you can install the `php-pecl-memcache` RPM:

```
root-shell> yum --install php-pecl-memcache
```

On Debian-based distributions, use the `php-memcache` package.

To set global runtime configuration options, specify the configuration option values within your `php.ini` file. The following table provides the name, default value, and a description for each global runtime configuration option.

<table>
<thead>
<tr>
<th>Configuration option</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>memcache.allow_failover</td>
<td>1</td>
<td>Specifies whether another server in the list should be queried if the first server selected fails.</td>
</tr>
<tr>
<td>memcache.max_failover_attempts</td>
<td>20</td>
<td>Specifies the number of servers to try before returning a failure.</td>
</tr>
<tr>
<td>memcache.chunk_size</td>
<td>8192</td>
<td>Defines the size of network chunks used to exchange data with the memcached server.</td>
</tr>
<tr>
<td>memcache.default_port</td>
<td>11211</td>
<td>Defines the default port to use when communicating with the memcached servers.</td>
</tr>
<tr>
<td>memcache.hash_strategy</td>
<td>standard</td>
<td>Specifies which hash strategy to use. Set to consistent to enable servers to be added or removed from the pool without causing the keys to be remapped to other servers. When set to standard, an older (modula) strategy is used that potentially uses different servers for storage.</td>
</tr>
<tr>
<td>memcache.hash_function</td>
<td>crc32</td>
<td>Specifies which function to use when mapping keys to servers. crc32 uses the standard CRC32 hash. fnv uses the FNV-1a hashing algorithm.</td>
</tr>
</tbody>
</table>

To create a connection to a memcached server, create a new Memcache object and then specify the connection options. For example:

```php
<?php
$cache = new Memcache;
$cache->connect('localhost',11211);
?>
```

This opens an immediate connection to the specified server.

To use multiple memcached servers, you need to add servers to the memcache object using `addServer()`:

```php
bool Memcache::addServer ( string $host [, int $port [, bool $persistent [, int $weight [, int $timeout [, int $retry_interval]]]]]
```
Developing a **memcached** Application

The server management mechanism within the **php-memcache** module is a critical part of the interface as it controls the main interface to the **memcached** instances and how the different instances are selected through the hashing mechanism.

To create a simple connection to two **memcached** instances:

```php
<?php
    $cache = new Memcache;
    $cache->addServer('198.51.100.100',11211);
    $cache->addServer('198.51.100.101',11211);
?>
```

In this scenario, the instance connection is not explicitly opened, but only opened when you try to store or retrieve a value. To enable persistent connections to **memcached** instances, set the `$persistent` argument to true. This is the default setting, and causes the connections to remain open.

To help control the distribution of keys to different instances, use the global **memcache.hash_strategy** setting. This sets the hashing mechanism used to select. You can also add another weight to each server, which effectively increases the number of times the instance entry appears in the instance list, therefore increasing the likelihood of the instance being chosen over other instances. To set the weight, set the value of the `$weight` argument to more than one.

The functions for setting and retrieving information are identical to the generic functional interface offered by **memcached**, as shown in the following table.

<table>
<thead>
<tr>
<th><strong>PECL memcache Function</strong></th>
<th><strong>Generic Function</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>get()</td>
<td>Generic get().</td>
</tr>
<tr>
<td>set()</td>
<td>Generic set().</td>
</tr>
<tr>
<td>add()</td>
<td>Generic add().</td>
</tr>
<tr>
<td>replace()</td>
<td>Generic replace().</td>
</tr>
<tr>
<td>delete()</td>
<td>Generic delete().</td>
</tr>
<tr>
<td>increment()</td>
<td>Generic incr().</td>
</tr>
<tr>
<td>decrement()</td>
<td>Generic decr().</td>
</tr>
</tbody>
</table>

A full example of the PECL **memcache** interface is provided below. The code loads film data from the Sakila database when the user provides a film name. The data stored into the **memcached** instance is recorded as a **mysqli** result row, and the API automatically serializes the information for you.

```php
<?php
    $memc = new Memcache;
    $memc->addServer('localhost','11211');

    if(!empty($_POST['film'])) {
        ?>
        <html xmlns="http://www.w3.org/1999/xhtml" xml:lang="en" lang="en">
        <head>
            <meta http-equiv="Content-Type" content="text/html; charset=utf-8" />
            <title>Simple Memcache Lookup</title>
        </head>
        <body>
```

2358
Developing a **memcached** Application

With PHP, the connections to the **memcached** instances are kept open as long as the PHP and associated Apache instance remain running. When adding or removing servers from the list in a running instance (for example, when starting another script that mentions additional servers), the connections are shared, but the script only selects among the instances explicitly configured within the script.

To ensure that changes to the server list within a script do not cause problems, make sure to use the consistent hashing mechanism.

### 16.2.3.7 Using MySQL and **memcached** with Ruby

There are a number of different modules for interfacing to **memcached** within Ruby. The **Ruby-MemCache** client library provides a native interface to **memcached** that does not require any external libraries, such as **libmemcached**. You can obtain the installer package from [http://www.deveiate.org/projects/RMemCache](http://www.deveiate.org/projects/RMemCache).
Developing a **memcached** Application

To install, extract the package and then run `install.rb`:

```
shell> install.rb
```

If you have RubyGems, you can install the **Ruby-MemCache** gem:

```
shell> gem install Ruby-MemCache
Bulk updating Gem source index for: http://gems.rubyforge.org
Install required dependency io-reactor? [Yn]  y
Successfully installed Ruby-MemCache-0.0.1
Successfully installed io-reactor-0.05
Installing ri documentation for io-reactor-0.05...
Installing RDoc documentation for io-reactor-0.05...
```

To use a **memcached** instance from within Ruby, create a new instance of the **MemCache** object.

```
require 'memcache'
mec = MemCache::new '198.51.100.100:11211'
```

You can add a weight to each server to increase the likelihood of the server being selected during hashing by appending the weight count to the server host name/port string:

```
require 'memcache'
mec = MemCache::new '198.51.100.100:11211:3'
```

To add servers to an existing list, you can append them directly to the **MemCache** object:

```
mec += ['198.51.100.101:11211']
```

To set data into the cache, you can just assign a value to a key within the new cache object, which works just like a standard Ruby hash object:

```
mec['key'] = "value"
```

Or to retrieve the value:

```
print mec['key']
```

For more explicit actions, you can use the method interface, which mimics the main **memcached** API functions, as summarized in the following table.

<table>
<thead>
<tr>
<th>Ruby <strong>MemCache</strong> Method</th>
<th>Equivalent <strong>memcached</strong> API Functions</th>
</tr>
</thead>
<tbody>
<tr>
<td>get()</td>
<td>Generic <code>get().</code></td>
</tr>
<tr>
<td>get_hash(keys)</td>
<td>Get the values of multiple <code>keys</code>, returning the information as a hash of the keys and their values.</td>
</tr>
<tr>
<td>set()</td>
<td>Generic <code>set().</code></td>
</tr>
<tr>
<td>set_many(pairs)</td>
<td>Set the values of the keys and values in the hash <code>pairs</code>.</td>
</tr>
<tr>
<td>add()</td>
<td>Generic <code>add().</code></td>
</tr>
<tr>
<td>replace()</td>
<td>Generic <code>replace().</code></td>
</tr>
</tbody>
</table>
Developing a memcached Application

<table>

</tbody>
</table>

### 16.2.3.8 Using MySQL and memcached with Java

The `com.danga.MemCached` class within Java provides a native interface to memcached instances. You can obtain the client from [https://github.com/gwhalin/Memcached-Java-Client/downloads](https://github.com/gwhalin/Memcached-Java-Client/downloads). The Java class uses hashes that are compatible with libmemcached, so you can mix and match Java and libmemcached applications accessing the same memcached instances. The serialization between Java and other interfaces are not compatible. If this is a problem, use JSON or a similar nonbinary serialization format.

On most systems, you can download the package and use the jar directly.

To use the `com.danga.MemCached` interface, you create a `MemCachedClient` instance and then configure the list of servers by configuring the `SockIOPool`. Through the pool specification you set up the server list, weighting, and the connection parameters to optimized the connections between your client and the memcached instances that you configure.

Generally, you can configure the memcached interface once within a single class, then use this interface throughout the rest of your application.

For example, to create a basic interface, first configure the `MemCachedClient` and base `SockIOPool` settings:

```java
default public class MyClass {
    protected static MemCachedClient mcc = new MemCachedClient();
    static {
        String[] servers = {
            "localhost:11211",
        }
        Integer[] weights = { 1 };
        SockIOPool pool = SockIOPool.getInstance();
        pool.setServers(servers);
        pool.setWeights(weights);
    }
}
```

In the above sample, the list of servers is configured by creating an array of the memcached instances to use. You can then configure individual weights for each server.

The remainder of the properties for the connection are optional, but you can set the connection numbers (initial connections, minimum connections, maximum connections, and the idle timeout) by setting the pool parameters:

```java
default   pool.setInitConn( 5 );
pool.setMinConn( 5 );
pool.setMaxConn( 250 );
```
Once the parameters have been configured, initialize the connection pool:

```java
pool.initialize();
```

The pool, and the connection to your memcached instances should now be ready to use.

To set the hashing algorithm used to select the server used when storing a given key, use `pool.setHashingAlg()`:

```java
pool.setHashingAlg( SockIOPool.NEW_COMPAT_HASH );
```

Valid values are `NEW_COMPAT_HASH`, `OLD_COMPAT_HASH` and `NATIVE_HASH` are also basic modula hashing algorithms. For a consistent hashing algorithm, use `CONSISTENT_HASH`. These constants are equivalent to the corresponding hash settings within libmemcached.

The following table outlines the Java `com.danga.MemCached` methods and the equivalent generic methods in the `memcached` interface specification.

<table>
<thead>
<tr>
<th>Java <code>com.danga.MemCached</code> Method</th>
<th>Equivalent Generic Method</th>

</tr>
<tr>
<td><code>decr()</code></td>
<td>Generic <code>decr()</code></td>
</tr>
</tbody>
</table>

### 16.2.3.9 Using the memcached TCP Text Protocol

Communicating with a memcached server can be achieved through either the TCP or UDP protocols. When using the TCP protocol, you can use a simple text based interface for the exchange of information.

When communicating with memcached, you can connect to the server using the port configured for the server. You can open a connection with the server without requiring authorization or login. As soon as you have connected, you can start to send commands to the server. When you have finished, you can terminate the connection without sending any specific disconnection command. Clients are encouraged to keep their connections open to decrease latency and improve performance.

Data is sent to the memcached server in two forms:

- Text lines, which are used to send commands to the server, and receive responses from the server.
- Unstructured data, which is used to receive or send the value information for a given key. Data is returned to the client in exactly the format it was provided.
Both text lines (commands and responses) and unstructured data are always terminated with the string `\r
`. Because the data being stored may contain this sequence, the length of the data (returned by the client before the unstructured data is transmitted should be used to determine the end of the data.

Commands to the server are structured according to their operation:

- **Storage commands**: `set`, `add`, `replace`, `append`, `prepend`, `cas`

  Storage commands to the server take the form:

  ```
  command key [flags] [exptime] length [noreply]
  ```

  Or when using compare and swap (cas):

  ```
  cas key [flags] [exptime] length [casunique] [noreply]
  ```

  Where:

  - **command**: The command name.
    - **set**: Store value against key
    - **add**: Store this value against key if the key does not already exist
    - **replace**: Store this value against key if the key already exists
    - **append**: Append the supplied value to the end of the value for the specified key. The flags and exptime arguments should not be used.
    - **prepend**: Append value currently in the cache to the end of the supplied value for the specified key. The flags and exptime arguments should not be used.
    - **cas**: Set the specified key to the supplied value, only if the supplied casunique matches. This is effectively the equivalent of change the information if nobody has updated it since I last fetched it.
    - **key**: The key. All data is stored using a the specific key. The key cannot contain control characters or whitespace, and can be up to 250 characters in size.
    - **flags**: The flags for the operation (as an integer). Flags in memcached are transparent. The memcached server ignores the contents of the flags. They can be used by the client to indicate any type of information. In memcached 1.2.0 and lower the value is a 16-bit integer value. In memcached 1.2.1 and higher the value is a 32-bit integer.
    - **exptime**: The expiry time, or zero for no expiry.
    - **length**: The length of the supplied value block in bytes, excluding the terminating `\r\n` characters.
    - **casunique**: A unique 64-bit value of an existing entry. This is used to compare against the existing value. Use the value returned by the `gets` command when issuing `cas` updates.
    - **noreply**: Tells the server not to reply to the command.

  For example, to store the value `abcdef` into the key `xyzkey`, you would use:

  ```
  set xyzkey 0 0 6\r\nabcdef\r\n```
The return value from the server is one line, specifying the status or error information. For more information, see Table 16.3, “memcached Protocol Responses”.

- **Retrieval commands**: `get`, `gets`

Retrieval commands take the form:

```plaintext
get key1 [key2 .... keyn]
gets key1 [key2 ... keyn]
```

You can supply multiple keys to the commands, with each requested key separated by whitespace.

The server responds with an information line of the form:

```plaintext
VALUE key flags bytes [casunique]
```

Where:
- **key**: The key name.
- **flags**: The value of the flag integer supplied to the memcached server when the value was stored.
- **bytes**: The size (excluding the terminating \r\n character sequence) of the stored value.
- **casunique**: The unique 64-bit integer that identifies the item.

The information line is immediately followed by the value data block. For example:

```plaintext
get xyzkey\r\nVALUE xyzkey 0 6\r\nabcdef\r\n```

If you have requested multiple keys, an information line and data block is returned for each key found. If a requested key does not exist in the cache, no information is returned.

- **Delete commands**: `delete`

Deletion commands take the form:

```plaintext
delete key [time] [noreply]
```

Where:
- **key**: The key name.
- **time**: The time in seconds (or a specific Unix time) for which the client wishes the server to refuse `add` or `replace` commands on this key. All `add`, `replace`, `get`, and `gets` commands fail during this period. `set` operations succeed. After this period, the key is deleted permanently and all commands are accepted.

If not supplied, the value is assumed to be zero (delete immediately).
- **noreply**: Tells the server not to reply to the command.
Responses to the command are either **DELETED** to indicate that the key was successfully removed, or **NOT_FOUND** to indicate that the specified key could not be found.

- **Increment/Decrement:** `incr, decr`

  The increment and decrement commands change the value of a key within the server without performing a separate get/set sequence. The operations assume that the currently stored value is a 64-bit integer. If the stored value is not a 64-bit integer, then the value is assumed to be zero before the increment or decrement operation is applied.

  Increment and decrement commands take the form:

  ```
  incr key value [noreply]
  decr key value [noreply]
  ```

  Where:

  - **key:** The key name.
  - **value:** An integer to be used as the increment or decrement value.
  - **noreply:** Tells the server not to reply to the command.

  The response is:

  - **NOT_FOUND:** The specified key could not be located.
  - **value:** The new value associated with the specified key.

  Values are assumed to be unsigned. For `decr` operations, the value is never decremented below 0. For `incr` operations, the value wraps around the 64-bit maximum.

- **Statistics commands:** `stats`

  The `stats` command provides detailed statistical information about the current status of the memcached instance and the data it is storing.

  Statistics commands take the form:

  ```
  STAT [name] [value]
  ```

  Where:

  - **name:** The optional name of the statistics to return. If not specified, the general statistics are returned.
  - **value:** A specific value to be used when performing certain statistics operations.

  The return value is a list of statistics data, formatted as follows:

  ```
  STAT name value
  ```

  The statistics are terminated with a single line, **END**.

  For more information, see Section 16.2.4, **“Getting memcached Statistics”**.

  For reference, a list of the different commands supported and their formats is provided below.
## Table 16.2 memcached Command Reference

<table>
<thead>
<tr>
<th>Command</th>
<th>Command Formats</th>
</tr>
</thead>
<tbody>
<tr>
<td>set</td>
<td><code>set key flags exptime length, set key flags exptime length noreply</code></td>

### 16.2.4 Getting memcached Statistics

The memcached system has a built-in statistics system that collects information about the data being stored into the cache, cache hit ratios, and detailed information on the memory usage and distribution of information through the slab allocation used to store individual items. Statistics are provided at both a basic level that provide the core statistics, and more specific statistics for specific areas of the memcached server.

This information can be useful to ensure that you are getting the correct level of cache and memory usage, and that your slab allocation and configuration properties are set at an optimal level.

The stats interface is available through the standard memcached protocol, so the reports can be accessed by using `telnet` to connect to the memcached. The supplied memcached-tool includes support for obtaining the Section 16.2.4.2, "memcached Slabs Statistics" and Section 16.2.4.1, "memcached General Statistics" information. For more information, see Section 16.2.4.6, "Using memcached-tool".

Alternatively, most of the language API interfaces provide a function for obtaining the statistics from the server.

For example, to get the basic stats using `telnet`:

```
shell> telnet localhost 11211
Trying ::1...
Connected to localhost.
Escape character is '^]'.
stats
STAT pid 23599
STAT uptime 675
STAT time 1211439587
STAT version 1.2.5
STAT pointer_size 32
STAT rusage_user 1.404992
STAT rusage_system 4.694685
STAT curr_items 32
STAT total_items 56361
STAT bytes 2642
STAT curr_connections 53
STAT total_connections 438
STAT connection_structures 55
STAT cmd_get 113482
STAT cmd_set 80519
STAT get_hits 78926
STAT get_misses 34556
STAT evictions 0
STAT bytes_read 6379783
STAT bytes_written 4860179
STAT limit_maxbytes 67108864
STAT threads 1
END
```

When using Perl and the `Cache::Memcached` module, the `stats()` function returns information about all the servers currently configured in the connection object, and total statistics for all the memcached servers as a whole.

For example, the following Perl script obtains the stats and dumps the hash reference that is returned:
use Cache::Memcached;
use Data::Dumper;

my $memc = new Cache::Memcached;
$memc->set_servers(ARGV);
print Dumper($memc->stats());

When executed on the same `memcached` as used in the `Telnet` example above we get a hash reference with the host by host and total statistics:

```perl
$VAR1 = {
    'hosts' => {
        'localhost:11211' => {
            'misc' => {
                'bytes' => '2421',
                'curr_connections' => '3',
                'connection_structures' => '56',
                'pointer_size' => '32',
                'time' => '1211440166',
                'total_items' => '410956',
                'cmd_set' => '588167',
                'bytes_written' => '35715151',
                'evictions' => '0',
                'curr_items' => '31',
                'pid' => '23599',
                'limit_maxbytes' => '67108864',
                'uptime' => '1254',
                'rusage_user' => '9.857805',
                'cmd_get' => '838451',
                'rusage_system' => '34.096988',
                'version' => '1.2.5',
                'get_hits' => '581511',
                'bytes_read' => '46665716',
                'threads' => '1',
                'total_connections' => '3104',
                'get_misses' => '256940'
            },
            'sizes' => {
                '128' => '16',
                '64' => '15'
            }
        }
    },
    'self' => {},
    'total' => {
        'cmd_get' => '838451',
        'bytes' => '2421',
        'get_hits' => '581511',
        'connection_structures' => '56',
        'bytes_read' => '46665716',
        'total_items' => '410956',
        'total_connections' => '3104',
        'cmd_set' => '588167',
        'bytes_written' => '35715151',
        'curr_items' => '31',
        'get_misses' => '256940'
    }
};
```

The statistics are divided up into a number of distinct sections, and then can be requested by adding the type to the `stats` command. Each statistics output is covered in more detail in the following sections.

- General statistics, see Section 16.2.4.1, “memcached General Statistics”.
• Slab statistics ([slabs](https://www.memcached.org/)), see Section 16.2.4.2, "memcached Slabs Statistics".
• Item statistics ([items](https://www.memcached.org/)), see Section 16.2.4.3, "memcached Item Statistics".
• Size statistics ([sizes](https://www.memcached.org/)), see Section 16.2.4.4, "memcached Size Statistics".
• Detailed status ([detail](https://www.memcached.org/)), see Section 16.2.4.5, "memcached Detail Statistics".

### 16.2.4.1 memcached General Statistics

The output of the general statistics provides an overview of the performance and use of the memcached instance. The statistics returned by the command and their meaning is shown in the following table.

The following terms are used to define the value type for each statistics value:

- **32u**: 32-bit unsigned integer
- **64u**: 64-bit unsigned integer
- **32u:32u**: Two 32-bit unsigned integers separated by a colon
- **String**: Character string

<table>
<thead>

<td>Number of yields for connections (related to the <code>-R</code> option).</td>
<td>1.4.0</td>
</tr>
</tbody>
</table>

The most useful statistics from those given here are the number of cache hits, misses, and evictions.

A large number of `get_misses` may just be an indication that the cache is still being populated with information. The number should, over time, decrease in comparison to the number of cache `get_hits`. If, however, you have a large number of cache misses compared to cache hits after an extended period of execution, it may be an indication that the size of the cache is too small and you either need to increase the total memory size, or increase the number of the `memcached` instances to improve the hit ratio.

A large number of `evictions` from the cache, particularly in comparison to the number of items stored is a sign that your cache is too small to hold the amount of information that you regularly want to keep cached. Instead of items being retained in the cache, items are being evicted to make way for new items keeping the turnover of items in the cache high, reducing the efficiency of the cache.

### 16.2.4.2 `memcached` Slabs Statistics

To get the `slabs` statistics, use the `stats slabs` command, or the API equivalent.

The slab statistics provide you with information about the slabs that have created and allocated for storing information within the cache. You get information both on each individual slab-class and total statistics for the whole slab.
Individual stats for each slab class are prefixed with the slab ID. A unique ID is given to each allocated slab from the smallest size up to the largest. The prefix number indicates the slab class number in relation to the calculated chunk from the specified growth factor. Hence in the example, 1 is the first chunk size and 9 is the 9th chunk allocated size.

The parameters returned for each chunk size and a description of each parameter are provided in the following table.

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
<th>Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>chunk_size</td>
<td>Space allocated to each chunk within this slab class.</td>
<td></td>
</tr>
<tr>
<td>chunks_per_page</td>
<td>Number of chunks within a single page for this slab class.</td>
<td></td>
</tr>
<tr>
<td>total_pages</td>
<td>Number of pages allocated to this slab class.</td>
<td></td>
</tr>
<tr>
<td>total_chunks</td>
<td>Number of chunks allocated to the slab class.</td>
<td></td>
</tr>
<tr>
<td>used_chunks</td>
<td>Number of chunks allocated to an item.</td>
<td></td>
</tr>
<tr>
<td>free_chunks</td>
<td>Number of chunks not yet allocated to items.</td>
<td></td>
</tr>
<tr>
<td>free_chunks_end</td>
<td>Number of free chunks at the end of the last allocated page.</td>
<td></td>
</tr>
<tr>
<td>get_hits</td>
<td>Number of get hits to this chunk</td>
<td>1.3.x</td>
</tr>
<tr>
<td>cmd_set</td>
<td>Number of set commands on this chunk</td>
<td>1.3.x</td>
</tr>
<tr>
<td>delete_hits</td>
<td>Number of delete hits to this chunk</td>
<td>1.3.x</td>
</tr>
<tr>
<td>incr_hits</td>
<td>Number of increment hits to this chunk</td>
<td>1.3.x</td>
</tr>
<tr>
<td>decr_hits</td>
<td>Number of decrement hits to this chunk</td>
<td>1.3.x</td>
</tr>
<tr>
<td>cas_hits</td>
<td>Number of CAS hits to this chunk</td>
<td>1.3.x</td>
</tr>
<tr>
<td>cas_badval</td>
<td>Number of CAS hits on this chunk where the existing value did not match</td>
<td>1.3.x</td>
</tr>
<tr>
<td>mem_requested</td>
<td>The true amount of memory of memory requested within this chunk</td>
<td>1.4.1</td>
</tr>
</tbody>
</table>

The following additional statistics cover the information for the entire server, rather than on a chunk by chunk basis:

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
<th>Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>active_slabs</td>
<td>Total number of slab classes allocated.</td>
<td></td>
</tr>
</tbody>
</table>
Getting memcached Statistics

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
<th>Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>total_malloced</td>
<td>Total amount of memory allocated to slab pages.</td>
<td></td>
</tr>
</tbody>
</table>

The key values in the slab statistics are the chunk_size, and the corresponding total_chunks and used_chunks parameters. These given an indication of the size usage of the chunks within the system. Remember that one key-value pair is placed into a chunk of a suitable size.

From these stats, you can get an idea of your size and chunk allocation and distribution. If you store many items with a number of largely different sizes, consider adjusting the chunk size growth factor to increase in larger steps to prevent chunk and memory wastage. A good indication of a bad growth factor is a high number of different slab classes, but with relatively few chunks actually in use within each slab. Increasing the growth factor creates fewer slab classes and therefore makes better use of the allocated pages.

16.2.4.3 memcached Item Statistics

To get the items statistics, use the stats items command, or the API equivalent.

The items statistics give information about the individual items allocated within a given slab class.

```
STAT items:2:number 1
STAT items:2:age 452
STAT items:2:evicted 0
STAT items:2:evicted_nonzero 0
STAT items:2:evicted_time 2
STAT items:2:outofmemory 0
STAT items:2:tailrepairs 0
...
STAT items:27:number 1
STAT items:27:age 452
STAT items:27:evicted 0
STAT items:27:evicted_nonzero 0
STAT items:27:evicted_time 2
STAT items:27:outofmemory 0
STAT items:27:tailrepairs 0
```

The prefix number against each statistics relates to the corresponding chunk size, as returned by the stats slabs statistics. The result is a display of the number of items stored within each chunk within each slab size, and specific statistics about their age, eviction counts, and out of memory counts. A summary of the statistics is given in the following table.

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>number</td>
<td>The number of items currently stored in this slab class.</td>
<td></td>
</tr>
<tr>
<td>age</td>
<td>The age of the oldest item within the slab class, in seconds.</td>
<td></td>
</tr>
<tr>
<td>evicted</td>
<td>The number of items evicted to make way for new entries.</td>
<td></td>
</tr>
<tr>
<td>evicted_time</td>
<td>The time of the last evicted entry</td>
<td></td>
</tr>
<tr>
<td>evicted_nonzero</td>
<td>The time of the last evicted non-zero entry</td>
<td>1.4.0</td>
</tr>
<tr>
<td>outofmemory</td>
<td>The number of items for this slab class that have triggered an out of memory error (only value when the -M command line option is in effect).</td>
<td></td>
</tr>
<tr>
<td>tailrepairs</td>
<td>Number of times the entries for a particular ID need repairing</td>
<td></td>
</tr>
</tbody>
</table>

Item level statistics can be used to determine how many items are stored within a given slab and their freshness and recycle rate. You can use this to help identify whether there are certain slab classes that are triggering a much larger number of evictions that others.
16.2.4.4 **memcached** Size Statistics

To get size statistics, use the `stats sizes` command, or the API equivalent.

The size statistics provide information about the sizes and number of items of each size within the cache. The information is returned as two columns, the first column is the size of the item (rounded up to the nearest 32 byte boundary), and the second column is the count of the number of items of that size within the cache:

```
96 35
128 38
160 807
192 804
224 410
256 222
288 83
320 39
352 53
384 33
416 64
448 51
480 40
512 54
544 39
576 10065
```

**Caution**

Running this statistic locks up your cache as each item is read from the cache and its size calculated. On a large cache, this may take some time and prevent any set or get operations until the process completes.

The item size statistics are useful only to determine the sizes of the objects you are storing. Since the actual memory allocation is relevant only in terms of the chunk size and page size, the information is only useful during a careful debugging or diagnostic session.

16.2.4.5 **memcached** Detail Statistics

For **memcached** 1.3.x and higher, you can enable and obtain detailed statistics about the get, set, and del operations on the individual keys stored in the cache, and determine whether the attempts hit (found) a particular key. These operations are only recorded while the detailed stats analysis is turned on.

To enable detailed statistics, you must send the `stats detail on` command to the **memcached** server:

```
$ telnet localhost 11211
Trying 127.0.0.1...
Connected to tiger.
Escape character is '^]'.
stats detail on
OK
```

Individual statistics are recorded for every `get`, `set` and `del` operation on a key, including keys that are not currently stored in the server. For example, if an attempt is made to obtain the value of key `abckey` and it does not exist, the `get` operating on the specified key are recorded while detailed statistics are in effect, even if the key is not currently stored. The `hits`, that is, the number of `get` or `del` operations for a key that exists in the server are also counted.

To turn detailed statistics off, send the `stats detail off` command to the **memcached** server:
Getting memcached Statistics

$ telnet localhost 11211
Trying 127.0.0.1...
Connected to tiger.
Escape character is '^]'.
stats detail off
OK

To obtain the detailed statistics recorded during the process, send the `stats detail dump` command to the memcached server:

```
stats detail dump
PREFIX hykey get 0 hit 0 set 1 del 0
PREFIX xyzkey get 0 hit 0 set 1 del 0
PREFIX yukkey get 1 hit 0 set 0 del 0
PREFIX abckey get 3 hit 3 set 1 del 0
END
```

You can use the detailed statistics information to determine whether your memcached clients are using a large number of keys that do not exist in the server by comparing the hit and get or del counts. Because the information is recorded by key, you can also determine whether the failures or operations are clustered around specific keys.

16.2.4.6 Using memcached-tool

The memcached-tool, located within the scripts directory within the memcached source directory. The tool provides convenient access to some reports and statistics from any memcached instance.

The basic format of the command is:

```
shell> ./memcached-tool hostname:port [command]
```

The default output produces a list of the slab allocations and usage. For example:

```
shell> memcached-tool localhost:11211 display

<table>
<thead>
<tr>
<th>#</th>
<th>Item Size</th>
<th>Max age</th>
<th>Pages</th>
<th>Count</th>
<th>Full?</th>
<th>Evicted</th>
<th>Evict Time</th>

Getting memcached Statistics

This output is the same if you specify the command as display:

```
shell> memcached-tool localhost:11211 display
#  Item_Size  Max_age   Pages   Count   Full?  Evicted Evict_Time OOM
1      80B        93s       1      20      no        0        0    0
2     104B        93s       1      16      no        0        0    0
...
```

The output shows a summarized version of the output from the slabs statistics. The columns provided in the output are shown below:

- #: The slab number
- Item_Size: The size of the slab
- Max_age: The age of the oldest item in the slab
- Pages: The number of pages allocated to the slab
- Count: The number of items in this slab
- Full?: Whether the slab is fully populated
- Evicted: The number of objects evicted from this slab
- Evict_Time: The time (in seconds) since the last eviction
- OOM: The number of items that have triggered an out of memory error

You can also obtain a dump of the general statistics for the server using the stats command:

```
shell> memcached-tool localhost:11211 stats
#localhost:11211   Field       Value
accepting_conns           1
bytes         162
bytes_read         485
bytes_written        6820
cas_badval           0
cas_hits           0
cas_misses           0
cmd_flush           0
cmd_get           4
cmd_set           2
conn_yields           0
connection_structures          11
curr_connections          10
curr_items           2
decr_hits           0
decr_misses           1
delete_hits           0
delete_misses           0
```

16.2.5 Can memcached be run on a Windows environment?

No. Currently memcached is available only on the Unix/Linux platform. There is an unofficial port available, see http://www.codeplex.com/memcachedproviders.

16.2.5.2 What is the maximum size of an object you can store in memcached? Is that configurable?

The default maximum object size is 1MB. In memcached 1.4.2 and later, you can change the maximum size of an object using the -I command line option.

For versions before this, to increase this size, you have to re-compile memcached. You can modify the value of the POWER_BLOCK within the slabs.c file within the source.

In memcached 1.4.2 and higher, you can configure the maximum supported object size by using the -I command-line option. For example, to increase the maximum object size to 5MB:

If an object is larger than the maximum object size, you must manually split it. `memcached` is very simple: you give it a key and some data, it tries to cache it in RAM. If you try to store more than the default maximum size, the value is just truncated for speed reasons.

**16.2.5.3.** Is it true `memcached` will be much more effective with db-read-intensive applications than with db-write-intensive applications?

Yes. `memcached` plays no role in database writes, it is a method of caching data already read from the database in RAM.

**16.2.5.4.** Is there any overhead in not using persistent connections? If persistent is always recommended, what are the downsides (for example, locking up)?

If you don't use persistent connections when communicating with `memcached`, there will be a small increase in the latency of opening the connection each time. The effect is comparable to use nonpersistent connections with MySQL.

In general, the chance of locking or other issues with persistent connections is minimal, because there is very little locking within `memcached`. If there is a problem, eventually your request will time out and return no result, so your application will need to load from MySQL again.

**16.2.5.5.** How is an event such as a crash of one of the `memcached` servers handled by the `memcached` client?

There is no automatic handling of this. If your client fails to get a response from a server, code a fallback mechanism to load the data from the MySQL database.

The client APIs all provide the ability to add and remove `memcached` instances on the fly. If within your application you notice that `memcached` server is no longer responding, you can remove the server from the list of servers, and keys will automatically be redistributed to another `memcached` server in the list. If retaining the cache content on all your servers is important, make sure you use an API that supports a consistent hashing algorithm. For more information, see Section 16.2.2.5, “memcached Hashing/Distribution Types”.

**16.2.5.6.** What is a recommended hardware configuration for a `memcached` server?

`memcached` has a very low processing overhead. All that is required is spare physical RAM capacity. A `memcached` server does not require a dedicated machine. If you have web, application, or database servers that have spare RAM capacity, then use them with `memcached`.

To build and deploy a dedicated `memcached` server, use a relatively low-power CPU, lots of RAM, and one or more Gigabit Ethernet interfaces.

**16.2.5.7.** Is `memcached` more effective for video and audio as opposed to textual read/writes?

`memcached` works equally well for all kinds of data. To `memcached`, any value you store is just a stream of data. Remember, though, that the maximum size of an object you can store in `memcached` is 1MB, but can be configured to be larger by using the `-I` option in `memcached` 1.4.2 and later, or by modifying the source in versions before 1.4.2. If you plan on using `memcached` with audio and video content, you will probably want to increase the maximum object size. Also remember that `memcached` is a solution for caching information for reading. It shouldn't be used for writes, except when updating the information in the cache.

**16.2.5.8.** Can `memcached` work with ASPX?
There are ports and interfaces for many languages and environments. ASPX relies on an underlying language such as C# or VisualBasic, and if you are using ASP.NET then there is a C# memcached library. For more information, see https://sourceforge.net/projects/memcacheddotnet/.

16.2.5.9. How expensive is it to establish a memcache connection? Should those connections be pooled?

Opening the connection is relatively inexpensive, because there is no security, authentication or other handshake taking place before you can start sending requests and getting results. Most APIs support a persistent connection to a memcached instance to reduce the latency. Connection pooling would depend on the API you are using, but if you are communicating directly over TCP/IP, then connection pooling would provide some small performance benefit.

16.2.5.10. How is the data handled when the memcached server is down?

The behavior is entirely application dependent. Most applications fall back to loading the data from the database (just as if they were updating the memcached information). If you are using multiple memcached servers, you might also remove a downed server from the list to prevent it from affecting performance. Otherwise, the client will still attempt to communicate with the memcached server that corresponds to the key you are trying to load.

16.2.5.11. How are auto-increment columns in the MySQL database coordinated across multiple instances of memcached?

They aren’t. There is no relationship between MySQL and memcached unless your application (or, if you are using the MySQL UDFs for memcached, your database definition) creates one.

If you are storing information based on an auto-increment key into multiple instances of memcached, the information is only stored on one of the memcached instances anyway. The client uses the key value to determine which memcached instance to store the information. It doesn’t store the same information across all the instances, as that would be a waste of cache memory.

16.2.5.12. Is compression available?

Yes. Most of the client APIs support some sort of compression, and some even allow you to specify the threshold at which a value is deemed appropriate for compression during storage.

16.2.5.13. Can we implement different types of memcached as different nodes in the same server, so can there be deterministic and non-deterministic in the same server?

Yes. You can run multiple instances of memcached on a single server, and in your client configuration you choose the list of servers you want to use.

16.2.5.14. What are best practices for testing an implementation, to ensure that it improves performance, and to measure the impact of memcached configuration changes? And would you recommend keeping the configuration very simple to start?

The best way to test the performance is to start up a memcached instance. First, modify your application so that it stores the data just before the data is about to be used or displayed into memcached. Since the APIs handle the serialization of the data, it should just be a one-line modification to your code. Then, modify the start of the process that would normally load that information from MySQL with the code that requests the data from memcached. If the data cannot be loaded from memcached, default to the MySQL process.

All of the changes required will probably amount to just a few lines of code. To get the best benefit, make sure you cache entire objects (for example, all the components of a web page, blog post, discussion thread, and so on), rather than using memcached as a simple cache of individual rows of MySQL tables.
Keeping the configuration simple at the start, or even over the long term, is easy with memcached. Once you have the basic structure up and running, often the only ongoing change is to add more servers into the list of servers used by your applications. You don't need to manage the memcached servers, and there is no complex configuration; just add more servers to the list and let the client API and the memcached servers make the decisions.

Replication enables data from one MySQL database server (the master) to be replicated to one or more MySQL database servers (the slaves). Replication is asynchronous by default, therefore slaves do not need to be connected permanently to receive updates from the master. This means that updates can occur over long-distance connections and even over temporary or intermittent connections such as a dial-up service. Depending on the configuration, you can replicate all databases, selected databases, or even selected tables within a database.

For answers to some questions often asked by those who are new to MySQL Replication, see Section A.13, “MySQL 5.6 FAQ: Replication”.

Advantages of replication in MySQL include:

• Scale-out solutions - spreading the load among multiple slaves to improve performance. In this environment, all writes and updates must take place on the master server. Reads, however, may take place on one or more slaves. This model can improve the performance of writes (since the master is dedicated to updates), while dramatically increasing read speed across an increasing number of slaves.

• Data security - because data is replicated to the slave, and the slave can pause the replication process, it is possible to run backup services on the slave without corrupting the corresponding master data.
• Analytics - live data can be created on the master, while the analysis of the information can take place on the slave without affecting the performance of the master.

• Long-distance data distribution - if a branch office would like to work with a copy of your main data, you can use replication to create a local copy of the data for their use without requiring permanent access to the master.

Replication in MySQL features support for one-way, asynchronous replication, in which one server acts as the master, while one or more other servers act as slaves. This is in contrast to the synchronous replication which is a characteristic of NDB Cluster (see Chapter 18, MySQL NDB Cluster 7.3 and NDB Cluster 7.4). In MySQL 5.6, an interface to semisynchronous replication is supported in addition to the built-in asynchronous replication. With semisynchronous replication, a commit performed on the master blocks before returning to the session that performed the transaction until at least one slave acknowledges that it has received and logged the events for the transaction. See Section 17.3.9, “Semisynchronous Replication” MySQL 5.6 also supports delayed replication such that a slave server deliberately lags behind the master by at least a specified amount of time. See Section 17.3.10, “Delayed Replication”. For scenarios where synchronous replication is required, use NDB Cluster (see Chapter 18, MySQL NDB Cluster 7.3 and NDB Cluster 7.4).

There are a number of solutions available for setting up replication between two servers, but the best method to use depends on the presence of data and the engine types you are using. For more information on the available options, see Section 17.1.1, “How to Set Up Replication”.

There are two core types of replication format, Statement Based Replication (SBR), which replicates entire SQL statements, and Row Based Replication (RBR), which replicates only the changed rows. You may also use a third variety, Mixed Based Replication (MBR). For more information on the different replication formats, see Section 17.1.2, “Replication Formats”. In MySQL 5.6, statement-based format is the default.

MySQL 5.6.5 and later supports transactional replication based on global transaction identifiers (GTIDs). When using this type of replication, it is not necessary to work directly with log files or positions within these files, which greatly simplifies many common replication tasks. Because replication using GTIDs is entirely transactional, consistency between master and slave is guaranteed as long as all transactions committed on the master have also been applied on the slave. For more information about GTIDs and GTID-based replication, see Section 17.1.3, “Replication with Global Transaction Identifiers”.

Replication is controlled through a number of different options and variables. These control the core operation of the replication, timeouts, and the databases and filters that can be applied on databases and tables. For more information on the available options, see Section 17.1.4, “Replication and Binary Logging Options and Variables”.

You can use replication to solve a number of different problems, including problems with performance, supporting the backup of different databases, and as part of a larger solution to alleviate system failures. For information on how to address these issues, see Section 17.3, “Replication Solutions”.

For notes and tips on how different data types and statements are treated during replication, including details of replication features, version compatibility, upgrades, and problems and their resolution, including an FAQ, see Section 17.4, “Replication Notes and Tips”.

For detailed information on the implementation of replication, how replication works, the process and contents of the binary log, background threads and the rules used to decide how statements are recorded and replication, see Section 17.2, “Replication Implementation”.

17.1 Replication Configuration

Replication between servers in MySQL is based on the binary logging mechanism. The MySQL instance operating as the master (the source of the database changes) writes updates and changes as “events”
to the binary log. The information in the binary log is stored in different logging formats according to the
database changes being recorded. Slaves are configured to read the binary log from the master and to
execute the events in the binary log on the slave’s local database.

Important

You cannot configure the master to log only certain events.

The master is “dumb” in this scenario. Once binary logging has been enabled, all statements are recorded
in the binary log. Each slave receives a copy of the entire contents of the binary log. It is the responsibility
of the slave to decide which statements in the binary log should be executed; you cannot configure the
master to log only certain events. If you do not specify otherwise, all events in the master binary log
are executed on the slave. If required, you can configure the slave to process only events that apply to
particular databases or tables.

Each slave keeps a record of the binary log coordinates: The file name and position within the file that it
has read and processed from the master. This means that multiple slaves can be connected to the master
and executing different parts of the same binary log. Because the slaves control this process, individual
slaves can be connected and disconnected from the server without affecting the master's operation.
Also, because each slave records the current position within the binary log, it is possible for slaves to be
disconnected, reconnect and then resume processing.

The master and each slave must be configured with a unique ID (using the server-id option). In
addition, each slave must be configured with information about the master host name, log file name, and
position within that file. These details can be controlled from within a MySQL session using the CHANGE
MASTER TO statement on the slave. The details are stored within the slave’s master info repository, which
can be either a file or a table (see Section 17.2.2, “Replication Relay and Status Logs”).

This section describes the setup and configuration required for a replication environment, including step-
by-step instructions for creating a new replication environment. The major components of this section are:

• For a guide to setting up two or more servers for replication, Section 17.1.1, “How to Set Up Replication”,
deals with the configuration of the systems and provides methods for copying data between the master
and slaves.

• Events in the binary log are recorded using a number of formats. These are referred to as statement-
based replication (SBR) or row-based replication (RBR). A third type, mixed-format replication (MIXED),
uses SBR or RBR replication automatically to take advantage of the benefits of both SBR and RBR
formats when appropriate. The different formats are discussed in Section 17.1.2, “Replication Formats”.

• Detailed information on the different configuration options and variables that apply to replication is
provided in Section 17.1.4, “Replication and Binary Logging Options and Variables”.

• Once started, the replication process should require little administration or monitoring. However, for
advice on common tasks that you may want to execute, see Section 17.1.5, “Common Replication
Administration Tasks”.

17.1.1 How to Set Up Replication

This section describes how to set up complete replication of a MySQL server. There are a number of
different methods for setting up replication, and the exact method to use depends on how you are setting
up replication, and whether you already have data within your master database.

There are some generic tasks that are common to all replication setups:
How to Set Up Replication

• On the master, you must enable binary logging and configure a unique server ID. This might require a server restart. See Section 17.1.1.1, “Setting the Replication Master Configuration”.

• On each slave that you want to connect to the master, you must configure a unique server ID. This might require a server restart. See Section 17.1.1.2, “Setting the Replication Slave Configuration”.

• Optionally, create a separate user for your slaves to use during authentication with the master when reading the binary log for replication. See Section 17.1.1.3, “Creating a User for Replication”.

• Before creating a data snapshot or starting the replication process, you should record the position of the binary log on the master. You will need this information when configuring the slave so that the slave knows where within the binary log to start executing events. See Section 17.1.1.4, “Obtaining the Replication Master Binary Log Coordinates”.

• If you already have data on your master and want to use it to synchronize your slave, you need to create a data snapshot. There are different methods to create the database snapshot, depending on the size of the database and the location of the files. Create a snapshot using `mysqldump` (see Section 17.1.1.5, “Creating a Data Snapshot Using mysqldump”) or by copying the data files directly (see Section 17.1.1.6, “Creating a Data Snapshot Using Raw Data Files”).

• Configure the slave with settings for connecting to the master, such as the host name, login credentials, and binary log file name and position. See Section 17.1.1.10, “Setting the Master Configuration on the Slave”.

After configuring the basic options, select your scenario:

• To set up replication for a fresh installation of a master and slaves that contain no data, see Section 17.1.1.7, “Setting Up Replication with New Master and Slaves”.

• To set up replication of a new master using the data from an existing MySQL server, see Section 17.1.1.8, “Setting Up Replication with Existing Data”.

• To add replication slaves to an existing replication environment, see Section 17.1.1.9, “Introducing Additional Slaves to an Existing Replication Environment”.

Before administering MySQL replication servers, read this entire chapter and try all statements mentioned in Section 13.4.1, “SQL Statements for Controlling Master Servers”, and Section 13.4.2, “SQL Statements for Controlling Slave Servers”. Also familiarize yourself with the replication startup options described in Section 17.1.4, “Replication and Binary Logging Options and Variables”.

Note

Certain steps within the setup process require the `SUPER` privilege. If you do not have this privilege, it might not be possible to enable replication.

17.1.1.1 Setting the Replication Master Configuration

On a replication master, you must enable binary logging and establish a unique server ID. If this has not already been done, a server restart is required.

Binary logging must be enabled on the master because the binary log is the basis for replicating changes from the master to its slaves. If binary logging is not enabled using the `log-bin` option, replication is not possible.

Each server within a replication group must be configured with a unique server ID. This ID is used to identify individual servers within the group, and must be a positive integer between 1 and \(2^{32}-1\). How you organize and select the numbers is your choice.
To configure the binary log and server ID options, shut down the MySQL server and edit the `my.cnf` or `my.ini` file. Within the `[mysqld]` section of the configuration file, add the `log-bin` and `server-id` options. If these options already exist, but are commented out, uncomment the options and alter them according to your needs. For example, to enable binary logging using a log file name prefix of `mysql-bin`, and configure a server ID of 1, use these lines:

```
[mysqld]
log-bin=mysql-bin
server-id=1
```

After making the changes, restart the server.

**Note**

If you omit `server-id` (or set it explicitly to its default value of 0), the master refuses any connections from slaves.

**Note**

For the greatest possible durability and consistency in a replication setup using InnoDB with transactions, you should use `innodb_flush_log_at_trx_commit=1` and `sync_binlog=1` in the master `my.cnf` file.

**Note**

Ensure that the `skip-networking` option is not enabled on your replication master. If networking has been disabled, the slave can not communicate with the master and replication fails.

### 17.1.1.2 Setting the Replication Slave Configuration

On a replication slave, you must establish a unique server ID. If this has not already been done, this part of slave setup requires a server restart.

If the slave server ID is not already set, or the current value conflicts with the value that you have chosen for the master server, shut down the slave server and edit the `[mysqld]` section of the configuration file to specify a unique server ID. For example:

```
[mysqld]
server-id=2
```

After making the changes, restart the server.

If you are setting up multiple slaves, each one must have a unique `server-id` value that differs from that of the master and from any of the other slaves.

**Note**

If you omit `server-id` (or set it explicitly to its default value of 0), the slave refuses to connect to a master.

You do not have to enable binary logging on the slave for replication to be set up. However, if you enable binary logging on the slave, you can use the slave’s binary log for data backups and crash recovery, and also use the slave as part of a more complex replication topology. For example, where this slave then acts as a master to other slaves.
17.1.1.3 Creating a User for Replication

Each slave connects to the master using a MySQL user name and password, so there must be a user account on the master that the slave can use to connect. Any account can be used for this operation, providing it has been granted the `REPLICATION SLAVE` privilege. You can choose to create a different account for each slave, or connect to the master using the same account for each slave.

Although you do not have to create an account specifically for replication, you should be aware that the replication user name and password are stored in plain text in the master info repository file or table (see Section 17.2.2.2, “Slave Status Logs”). Therefore, you may want to create a separate account that has privileges only for the replication process, to minimize the possibility of compromise to other accounts.

To create a new account, use `CREATE USER`. To grant this account the privileges required for replication, use the `GRANT` statement. If you create an account solely for the purposes of replication, that account needs only the `REPLICATION SLAVE` privilege. For example, to set up a new user, `repl`, that can connect for replication from any host within the `example.com` domain, issue these statements on the master:

```
mysql> CREATE USER 'repl'@'%.example.com' IDENTIFIED BY 'password';
mymysql> GRANT REPLICATION SLAVE ON *.* TO 'repl'@'%.example.com';
```

See Section 13.7.1, “Account Management Statements”, for more information on statements for manipulation of user accounts.

17.1.1.4 Obtaining the Replication Master Binary Log Coordinates

To configure the slave to start the replication process at the correct point, you need to note the master's current coordinates within its binary log.

**Warning**

This procedure uses `FLUSH TABLES WITH READ LOCK`, which blocks `COMMIT` operations for InnoDB tables.

If you have existing data on your master that you want to synchronize on your slaves before starting the replication process, you must stop processing statements on the master, and then obtain its current binary log coordinates and dump its data, before permitting the master to continue executing statements. If you do not stop the execution of statements, the data dump and the master status information that you use will not match and you will end up with inconsistent or corrupted databases on the slaves.

If you are planning to shut down the master to create a data snapshot, you can optionally skip this procedure and instead store a copy of the binary log index file along with the data snapshot. In that situation, the master creates a new binary log file on restart. The master binary log coordinates where the slave must start the replication process are therefore the start of that new file, which is the next binary log file on the master following after the files that are listed in the copied binary log index file.

To obtain the master binary log coordinates, follow these steps:

1. Start a session on the master by connecting to it with the command-line client, and flush all tables and block write statements by executing the `FLUSH TABLES WITH READ LOCK` statement:

   ```
   mysql> FLUSH TABLES WITH READ LOCK;
   ```

   **Warning**

   Leave the client from which you issued the `FLUSH TABLES` statement running so that the read lock remains in effect. If you exit the client, the lock is released.
How to Set Up Replication

2. In a different session on the master, use the `SHOW MASTER STATUS` statement to determine the current binary log file name and position:

```
mysql > SHOW MASTER STATUS;
+------------------+----------+--------------+------------------+
| File             | Position | Binlog_Do_DB | Binlog_Ignore_DB |
|------------------|----------|--------------+------------------+
| mysql-bin.000003 | 73       | test         | manual,mysql     |
+------------------+----------+--------------+------------------+
```

The `File` column shows the name of the log file and `Position` shows the position within the file. In this example, the binary log file is `mysql-bin.000003` and the position is 73. Record these values. You need them later when you are setting up the slave. They represent the replication coordinates at which the slave should begin processing new updates from the master.

If the master has been running previously without binary logging enabled, the log file name and position values displayed by `SHOW MASTER STATUS` or `mysqldump --master-data` will be empty. In that case, the values that you need to use later when specifying the slave's log file and position are the empty string (`''`) and 4.

You now have the information you need to enable the slave to start reading from the binary log in the correct place to start replication.

If you have existing data that needs to be synchronized with the slave before you start replication, leave the client running so that the lock remains in place and then proceed to Section 17.1.1.5, “Creating a Data Snapshot Using mysqldump”, or Section 17.1.1.6, “Creating a Data Snapshot Using Raw Data Files”. The idea here is to prevent any further changes so that the data copied to the slaves is in synchrony with the master.

If you are setting up a brand new master and slave replication group, you can exit the first session to release the read lock.

### 17.1.1.5 Creating a Data Snapshot Using mysqldump

One way to create a snapshot of the data in an existing master database is to use the `mysqldump` tool to create a dump of all the databases you want to replicate. Once the data dump has been completed, you then import this data into the slave before starting the replication process.

The example shown here dumps all databases to a file named `dbdump.db`, and includes the `--master-data` option which automatically appends the `CHANGE MASTER TO` statement required on the slave to start the replication process:

```
shell> mysqldump --all-databases --master-data > dbdump.db
```

If you do not use `--master-data`, then it is necessary to lock all tables in a separate session manually (using `FLUSH TABLES WITH READ LOCK`) prior to running `mysqldump`, then exiting or running `UNLOCK TABLES` from the second session to release the locks. You must also obtain binary log position information matching the snapshot, using `SHOW MASTER STATUS`, and use this to issue the appropriate `CHANGE MASTER TO` statement when starting the slave.

When choosing databases to include in the dump, remember that you need to filter out databases on each slave that you do not want to include in the replication process.

To import the data, either copy the dump file to the slave, or access the file from the master when connecting remotely to the slave.
17.1.1.6 Creating a Data Snapshot Using Raw Data Files

If your database is large, copying the raw data files can be more efficient than using `mysqldump` and importing the file on each slave. This technique skips the overhead of updating indexes as the `INSERT` statements are replayed.

Using this method with tables in storage engines with complex caching or logging algorithms requires extra steps to produce a perfect “point in time” snapshot: the initial copy command might leave out cache information and logging updates, even if you have acquired a global read lock. How the storage engine responds to this depends on its crash recovery abilities.

This method also does not work reliably if the master and slave have different values for `ft_stopword_file`, `ft_min_word_len`, or `ft_max_word_len` and you are copying tables having full-text indexes.

If you use InnoDB tables, you can use the `mysqlbackup` command from the MySQL Enterprise Backup component to produce a consistent snapshot. This command records the log name and offset corresponding to the snapshot to be later used on the slave. MySQL Enterprise Backup is a commercial product that is included as part of a MySQL Enterprise subscription. See Section 25.2, “MySQL Enterprise Backup Overview” for detailed information.

Otherwise, use the cold backup technique to obtain a reliable binary snapshot of InnoDB tables: copy all data files after doing a slow shutdown of the MySQL Server.

To create a raw data snapshot of MyISAM tables, you can use standard copy tools such as `cp` or `copy`, a remote copy tool such as `scp` or `rsync`, an archiving tool such as `zip` or `tar`, or a file system snapshot tool such as `dump`, providing that your MySQL data files exist on a single file system. If you are replicating only certain databases, copy only those files that relate to those tables. (For InnoDB, all tables in all databases are stored in the system tablespace files, unless you have the `innodb_file_per_table` option enabled.)

You might want to specifically exclude the following files from your archive:

- Files relating to the `mysql` database.
- The master info repository file, if used (see Section 17.2.2, “Replication Relay and Status Logs”).
- The master’s binary log files, with the exception of the binary log index file if you are going to use this to locate the master binary log coordinates for the slave.
- Any relay log files.

To get the most consistent results with a raw data snapshot, shut down the master server during the process, as follows:

1. Acquire a read lock and get the master’s status. See Section 17.1.1.4, “Obtaining the Replication Master Binary Log Coordinates”.

2. In a separate session, shut down the master server:

   ```shell
   mysqladmin shutdown
   ```

3. Make a copy of the MySQL data files. The following examples show common ways to do this. You need to choose only one of them:
4. Restart the master server.

If you are not using InnoDB tables, you can get a snapshot of the system from a master without shutting down the server as described in the following steps:

1. Acquire a read lock and get the master's status. See Section 17.1.1.4, “Obtaining the Replication Master Binary Log Coordinates”.

2. Make a copy of the MySQL data files. The following examples show common ways to do this. You need to choose only one of them:

```
shell> tar cf /tmp/db.tar ./data
shell> zip -r /tmp/db.zip ./data
shell> rsync --recursive ./data /tmp/dbdata
```

3. In the client where you acquired the read lock, release the lock:

```
mysql> UNLOCK TABLES;
```

Once you have created the archive or copy of the database, copy the files to each slave before starting the slave replication process.

### 17.1.1.7 Setting Up Replication with New Master and Slaves

The easiest and most straightforward method for setting up replication is to use new master and slave servers.

You can also use this method if you are setting up new servers but have an existing dump of the databases from a different server that you want to load into your replication configuration. By loading the data into a new master, the data will be automatically replicated to the slaves.

To set up replication between a new master and slave:

1. Configure the MySQL master with the necessary configuration properties. See Section 17.1.1.1, “Setting the Replication Master Configuration”.

2. Start up the MySQL master.

3. Set up a user. See Section 17.1.1.3, “Creating a User for Replication”.

4. Obtain the master status information, or a copy of the master's binary log index file made during a shutdown for the data snapshot. See Section 17.1.1.4, “Obtaining the Replication Master Binary Log Coordinates”.

5. On the master, release the read lock:

```
mysql> UNLOCK TABLES;
```

6. On the slave, edit the MySQL configuration. See Section 17.1.1.2, “Setting the Replication Slave Configuration”.

7. Start up the MySQL slave.
8. Execute a `CHANGE MASTER TO` statement to set the master replication server configuration. See Section 17.1.1.10, "Setting the Master Configuration on the Slave".

Perform the slave setup steps on each slave.

Because there is no data to load or exchange on a new server configuration you do not need to copy or import any information.

If you are setting up a new replication environment using the data from a different existing database server, you will now need to run the dump file generated from that server on the new master. The database updates will automatically be propagated to the slaves:

```
shell> mysql -h master < fulldb.dump
```

### 17.1.1.8 Setting Up Replication with Existing Data

When setting up replication with existing data, you will need to decide how best to get the data from the master to the slave before starting the replication service.

The basic process for setting up replication with existing data is as follows:

1. With the MySQL master running, create a user to be used by the slave when connecting to the master during replication. See Section 17.1.1.3, "Creating a User for Replication".

2. If you have not already configured the `server-id` and enabled binary logging on the master server, you will need to shut it down to configure these options. See Section 17.1.1.1, "Setting the Replication Master Configuration".

   If you have to shut down your master server, this is a good opportunity to take a snapshot of its databases. You should obtain the master status (see Section 17.1.1.4, "Obtaining the Replication Master Binary Log Coordinates") before taking down the master, updating the configuration and taking a snapshot. For information on how to create a snapshot using raw data files, see Section 17.1.1.6, "Creating a Data Snapshot Using Raw Data Files".

3. If your master server is already correctly configured, obtain its status (see Section 17.1.1.4, "Obtaining the Replication Master Binary Log Coordinates") and then use `mysqldump` to take a snapshot (see Section 17.1.1.5, "Creating a Data Snapshot Using mysqldump") or take a raw snapshot of the live server using the guide in Section 17.1.1.6, "Creating a Data Snapshot Using Raw Data Files".

4. Update the configuration of the slave. See Section 17.1.1.2, "Setting the Replication Slave Configuration".

5. The next step depends on how you created the snapshot of data on the master.

   If you used `mysqldump`:

   a. Start the slave, using the `--skip-slave-start` option so that replication does not start.

   b. Import the dump file:

```
shell> mysql < fulldb.dump
```

   If you created a snapshot using the raw data files:

   a. Extract the data files into your slave data directory. For example:
How to Set Up Replication

```
shell> tar xvf dbdump.tar
```

You may need to set permissions and ownership on the files so that the slave server can access and modify them.

b. Start the slave, using the `--skip-slave-start` option so that replication does not start.

6. Configure the slave with the replication coordinates from the master. This tells the slave the binary log file and position within the file where replication needs to start. Also, configure the slave with the login credentials and host name of the master. For more information on the `CHANGE MASTER TO` statement required, see Section 17.1.1.10, “Setting the Master Configuration on the Slave”.

7. Start the slave threads:

```
mysql> START SLAVE;
```

After you have performed this procedure, the slave should connect to the master and catch up on any updates that have occurred since the snapshot was taken.

If you have forgotten to set the `server-id` option for the master, slaves cannot connect to it.

If you have forgotten to set the `server-id` option for the slave, you get the following error in the slave’s error log:

```
Warning: You should set server-id to a non-0 value if master_host is set; we will force server id to 2, but this MySQL server will not act as a slave.
```

You also find error messages in the slave’s error log if it is not able to replicate for any other reason.

The slave uses information stored in its master info repository to keep track of how much of the master’s binary log it has processed. The repository can be in the form of files or a table, as determined by the value set for `--master-info-repository`. When a slave runs with `--master-info-repository=FILE`, you can find in its data directory two files, named `master.info` and `relay-log.info`. If `--master-info-repository=TABLE` instead, this information is saved in the table `master_slave_info` in the `mysql` database. In either case, do not remove or edit the files or table unless you know exactly what you are doing and fully understand the implications. Even in that case, it is preferred that you use the `CHANGE MASTER TO` statement to change replication parameters. The slave can use the values specified in the statement to update the status files automatically. See Section 17.2.2, “Replication Relay and Status Logs”, for more information.

**Note**

The contents of the master info repository override some of the server options specified on the command line or in `my.cnf`. See Section 17.1.4, “Replication and Binary Logging Options and Variables”, for more details.

A single snapshot of the master suffices for multiple slaves. To set up additional slaves, use the same master snapshot and follow the slave portion of the procedure just described.

### 17.1.1.9 Introducing Additional Slaves to an Existing Replication Environment

You can add another slave to an existing replication configuration without stopping the master. To do this, you can set up the new slave by copying the data directory of an existing slave, and giving the new slave a different server ID (which is user-specified) and server UUID (which is generated at startup).
To duplicate an existing slave:

1. Stop the existing slave and record the slave status information, particularly the master binary log file and relay log file positions. You can view the slave status by issuing `SHOW SLAVE STATUS` as follows:

   ```
   mysql> STOP SLAVE;
   mysql> SHOW SLAVE STATUS\G
   ```

2. Shut down the existing slave:

   ```
   shell> mysqladmin shutdown
   ```

3. Copy the data directory from the existing slave to the new slave, including the log files and relay log files. You can do this by creating an archive using `tar` or `WinZip`, or by performing a direct copy using a tool such as `cp` or `rsync`.

   **Important**
   - Before copying, verify that all the files relating to the existing slave actually are stored in the data directory. For example, the InnoDB system tablespace, undo tablespace, and redo log might be stored in an alternative location. InnoDB tablespace files and file-per-table table spaces might have been created in other directories. The binary logs and relay logs for the slave might be in their own directories outside the data directory. Check through the system variables that are set for the existing slave and look for any alternative paths that have been specified. If you find any, copy these directories over as well.

   - During copying, if files have been used for the master info and relay log info repositories (see Section 17.2.2, “Replication Relay and Status Logs”), which is the default in MySQL 5.6, ensure that you also copy these files from the existing slave to the new slave. If tables have been used for the repositories, the tables are in the data directory.

   - After copying, delete the `auto.cnf` file from the copy of the data directory on the new slave, so that the new slave is started with a different generated server UUID. The server UUID must be unique.

   A common problem that is encountered when adding new replication slaves is that the new slave fails with a series of warning and error messages like these:

   ```
   071118 16:44:10 [Warning] Neither --relay-log nor --relay-log-index were used; so replication may break when this MySQL server acts as a slave and has his hostname changed!! Please use '--relay-log=new_slave_hostname-relay-bin' to avoid this problem.
   071118 16:44:10 [ERROR] Failed to open the relay log './old_slave_hostname-relay-bin.003525' (relay_log_pos 22940879)
   071118 16:44:10 [ERROR] Could not find target log during relay log initialization
   071118 16:44:10 [ERROR] Failed to initialize the master info structure
   ```

   This situation can occur if the `--relay-log` option is not specified, as the relay log files contain the host name as part of their file names. This is also true of the relay log index file if the `--relay-log-index` option is not used. See Section 17.1.4, “Replication and Binary Logging Options and Variables”, for more information about these options.

   To avoid this problem, use the same value for `--relay-log` on the new slave that was used on the existing slave. If this option was not set explicitly on the existing slave, use
existing_slave_hostname-relay-bin. If this is not possible, copy the existing slave’s relay log index file to the new slave and set the --relay-log-index option on the new slave to match what was used on the existing slave. If this option was not set explicitly on the existing slave, use existing_slave_hostname-relay-bin.index. Alternatively, if you have already tried to start the new slave after following the remaining steps in this section and have encountered errors like those described previously, then perform the following steps:

a. If you have not already done so, issue STOP SLAVE on the new slave.

If you have already started the existing slave again, issue STOP SLAVE on the existing slave as well.

b. Copy the contents of the existing slave’s relay log index file into the new slave’s relay log index file, making sure to overwrite any content already in the file.

c. Proceed with the remaining steps in this section.

4. When copying is complete, restart the existing slave.

5. On the new slave, edit the configuration and give the new slave a unique server ID (using the server-id option) that is not used by the master or any of the existing slaves.

6. Start the new slave server, specifying the --skip-slave-start option so that replication does not start yet. Issue SHOW SLAVE STATUS to confirm that the new slave has the correct settings when compared with the existing slave. Also display the server ID and server UUID and verify that these are correct and unique for the new slave.

7. Start the slave threads by issuing a START SLAVE statement:

```
mysql> START SLAVE;
```

The new slave now uses the information in its master info repository to start the replication process.

### 17.1.1.10 Setting the Master Configuration on the Slave

To set up the slave to communicate with the master for replication, you must tell the slave the necessary connection information. To do this, execute the following statement on the slave, replacing the option values with the actual values relevant to your system:

```
mysql> CHANGE MASTER TO
    -> MASTER_HOST='master_host_name',
    -> MASTER_USER='replication_user_name',
    -> MASTER_PASSWORD='replication_password',
    -> MASTER_LOG_FILE='recorded_log_file_name',
    -> MASTER_LOG_POS=recorded_log_position;
```

**Note**

Replication cannot use Unix socket files. You must be able to connect to the master MySQL server using TCP/IP.

The CHANGE MASTER TO statement has other options as well. For example, it is possible to set up secure replication using SSL. For a full list of options, and information about the maximum permissible length for the string-valued options, see Section 13.4.2.1, “CHANGE MASTER TO Syntax”.
17.1.2 Replication Formats

Replication works because events written to the binary log are read from the master and then processed on the slave. The events are recorded within the binary log in different formats according to the type of event. The different replication formats used correspond to the binary logging format used when the events were recorded in the master’s binary log. The correlation between binary logging formats and the terms used during replication are:

- When using statement-based binary logging, the master writes SQL statements to the binary log. Replication of the master to the slave works by executing the SQL statements on the slave. This is called statement-based replication (often abbreviated as SBR), which corresponds to the standard MySQL statement-based binary logging format. Replication capabilities in MySQL version 5.1.4 and earlier used this format exclusively.

- When using row-based logging, the master writes events to the binary log that indicate how individual table rows are changed. Replication of the master to the slave works by copying the events representing the changes to the table rows to the slave. This is called row-based replication (often abbreviated as RBR). In row-based replication, the master writes events to the binary log that indicate how individual table rows are changed.

- You can also configure MySQL to use a mix of both statement-based and row-based logging, depending on which is most appropriate for the change to be logged. This is called mixed-format logging. When using mixed-format logging, a statement-based log is used by default. Depending on certain statements, and also the storage engine being used, the log is automatically switched to row-based in particular cases. Replication using the mixed format is often referred to as mixed-based replication or mixed-format replication. For more information, see Section 5.4.4.3, “Mixed Binary Logging Format”.

In MySQL 5.6, statement-based format is the default.

**NDB Cluster.** The default binary logging format in all MySQL NDB Cluster 7.3 and MySQL NDB Cluster 7.4 releases is MIXED. You should note that NDB Cluster Replication always uses row-based replication, and that the NDB storage engine is incompatible with statement-based replication. See Section 18.6.2, “General Requirements for NDB Cluster Replication”, for more information.

When using MIXED format, the binary logging format is determined in part by the storage engine being used and the statement being executed. For more information on mixed-format logging and the rules governing the support of different logging formats, see Section 5.4.4.3, “Mixed Binary Logging Format”.

The logging format in a running MySQL server is controlled by setting the binlog_format server system variable. This variable can be set with session or global scope. The rules governing when and how the new setting takes effect are the same as for other MySQL server system variables. Setting the variable for the current session lasts only until the end of that session, and the change is not visible to other sessions. Setting the variable globally takes effect for clients that connect after the change, but not for any current client sessions, including the session where the variable setting was changed. To make the global system variable setting permanent so that it applies across server restarts, you must set it in an option file. For more information, see Section 13.7.4.1, “SET Syntax for Variable Assignment”.

There are conditions under which you cannot change the binary logging format at runtime or doing so causes replication to fail. See Section 5.4.4.2, “Setting The Binary Log Format”.

Changing the global binlog_format value requires privileges sufficient to set global system variables. Changing the session binlog_format value requires privileges sufficient to set restricted session system variables. See Section 5.1.8.1, “System Variable Privileges”.

The statement-based and row-based replication formats have different issues and limitations. For a comparison of their relative advantages and disadvantages, see Section 17.1.2.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”.
With statement-based replication, you may encounter issues with replicating stored routines or
triggers. You can avoid these issues by using row-based replication instead. For more information, see
Section 20.7, "Stored Program Binary Logging".

17.1.2.1 Advantages and Disadvantages of Statement-Based and Row-Based Replication

Each binary logging format has advantages and disadvantages. For most users, the mixed replication
format should provide the best combination of data integrity and performance. If, however, you want to
take advantage of the features specific to the statement-based or row-based replication format when
performing certain tasks, you can use the information in this section, which provides a summary of their
relative advantages and disadvantages, to determine which is best for your needs.

- Advantages of statement-based replication
- Disadvantages of statement-based replication
- Advantages of row-based replication
- Disadvantages of row-based replication

Advantages of statement-based replication

- Proven technology.
- Less data written to log files. When updates or deletes affect many rows, this results in much less
  storage space required for log files. This also means that taking and restoring from backups can be
  accomplished more quickly.
- Log files contain all statements that made any changes, so they can be used to audit the database.

Disadvantages of statement-based replication

- **Statements that are unsafe for SBR.**
  Not all statements which modify data (such as INSERT DELETE UPDATE, and REPLACE statements)
  can be replicated using statement-based replication. Any nondeterministic behavior is difficult to
  replicate when using statement-based replication. Examples of such DML (Data Modification Language)
  statements include the following:

  - A statement that depends on a UDF or stored program that is nondeterministic, since the value
    returned by such a UDF or stored program or depends on factors other than the parameters supplied
    to it. (Row-based replication, however, simply replicates the value returned by the UDF or stored
    program, so its effect on table rows and data is the same on both the master and slave.) See
    Section 17.4.1.16, “Replication of Invoked Features”, for more information.

  - DELETE and UPDATE statements that use a LIMIT clause without an ORDER BY are nondeterministic.
    See Section 17.4.1.17, “Replication and LIMIT”.

  - Statements using any of the following functions cannot be replicated properly using statement-based
    replication:

    - LOAD_FILE()
    - UUID(), UUID_SHORT()
    - USER()
    - FOUND_ROWS()
• **SYSDATE()** (unless both the master and the slave are started with the `--sysdate-is-now` option)
• **GET_LOCK()**
• **IS_FREE_LOCK()**
• **IS_USED_LOCK()**
• **MASTER_POS_WAIT()**
• **RAND()**
• **RELEASE_LOCK()**
• **SLEEP()**
• **VERSION()**

However, all other functions are replicated correctly using statement-based replication, including **NOW()** and so forth.

For more information, see Section 17.4.1.15, “Replication and System Functions”.

Statements that cannot be replicated correctly using statement-based replication are logged with a warning like the one shown here:

```
[Warning] Statement is not safe to log in statement format.
```

A similar warning is also issued to the client in such cases. The client can display it using **SHOW WARNINGS**.

• **INSERT ... SELECT** requires a greater number of row-level locks than with row-based replication.
• **UPDATE** statements that require a table scan (because no index is used in the **WHERE** clause) must lock a greater number of rows than with row-based replication.
• For **InnoDB**: An **INSERT** statement that uses **AUTO_INCREMENT** blocks other nonconflicting **INSERT** statements.
• For complex statements, the statement must be evaluated and executed on the slave before the rows are updated or inserted. With row-based replication, the slave only has to modify the affected rows, not execute the full statement.
• If there is an error in evaluation on the slave, particularly when executing complex statements, statement-based replication may slowly increase the margin of error across the affected rows over time. See Section 17.4.1.27, “Slave Errors During Replication”.
• Stored functions execute with the same **NOW()** value as the calling statement. However, this is not true of stored procedures.
• Deterministic UDFs must be applied on the slaves.
• Table definitions must be (nearly) identical on master and slave. See Section 17.4.1.9, “Replication with Differing Table Definitions on Master and Slave”, for more information.

**Advantages of row-based replication**
Replication Formats

• All changes can be replicated. This is the safest form of replication.

Note

Statements that update the information in the `mysql` database—such as `GRANT`, `REVOKE` and the manipulation of triggers, stored routines (including stored procedures), and views—are all replicated to slaves using statement-based replication.

For statements such as `CREATE TABLE ... SELECT`, a `CREATE` statement is generated from the table definition and replicated using statement-based format, while the row insertions are replicated using row-based format.

• The technology is the same as in most other database management systems; knowledge about other systems transfers to MySQL.

• Fewer row locks are required on the master, which thus achieves higher concurrency, for the following types of statements:
  
  • `INSERT ... SELECT`
  
  • `INSERT` statements with `AUTO_INCREMENT`
  
  • `UPDATE` or `DELETE` statements with `WHERE` clauses that do not use keys or do not change most of the examined rows.

  • Fewer row locks are required on the slave for any `INSERT, UPDATE, or DELETE` statement.

Disadvantages of row-based replication

• RBR can generate more data that must be logged. To replicate a DML statement (such as an `UPDATE` or `DELETE` statement), statement-based replication writes only the statement to the binary log. By contrast, row-based replication writes each changed row to the binary log. If the statement changes many rows, row-based replication may write significantly more data to the binary log; this is true even for statements that are rolled back. This also means that taking and restoring from backup can require more time. In addition, the binary log is locked for a longer time to write the data, which may cause concurrency problems. Use `binlog_row_image=minimal` to reduce the disadvantage considerably.

• Deterministic UDFs that generate large `BLOB` values take longer to replicate with row-based replication than with statement-based replication. This is because the `BLOB` column value is logged, rather than the statement generating the data.

• You cannot see on the slave what statements were received from the master and executed. However, you can see what data was changed using `mysqlbinlog` with the options `--base64-output=DECODE-ROWS` and `--verbose`.

Alternatively, use the `binlog_rows_query_log_events` variable added in MySQL 5.6.2, which if enabled adds a `Rows_query` event with the statement to `mysqlbinlog` output when the `-vv` option is used.

• For tables using the `MyISAM` storage engine, a stronger lock is required on the slave for `INSERT` statements when applying them as row-based events to the binary log than when applying them as statements. This means that concurrent inserts on `MyISAM` tables are not supported when using row-based replication.
17.1.2.2 Usage of Row-Based Logging and Replication

MySQL uses statement-based logging (SBL), row-based logging (RBL) or mixed-format logging. The type of binary log used impacts the size and efficiency of logging. Therefore the choice between row-based replication (RBR) or statement-based replication (SBR) depends on your application and environment. This section describes known issues when using a row-based format log, and discusses some best practices using it in replication.

For additional information, see Section 17.1.2, “Replication Formats”, and Section 17.1.2.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”.

For information about issues specific to NDB Cluster Replication (which depends on row-based replication), see Section 18.6.3, “Known Issues in NDB Cluster Replication”.

- Row-based logging of temporary tables. As noted in Section 17.4.1.29, “Replication and Temporary Tables”, temporary tables are not replicated when using row-based format. When using mixed format logging, “safe” statements involving temporary tables are logged using statement-based format. For more information, see Section 17.1.2.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”.

Temporary tables are not replicated when using row-based format because there is no need. In addition, because temporary tables can be read only from the thread which created them, there is seldom if ever any benefit obtained from replicating them, even when using statement-based format.

In MySQL 5.6, you can switch from statement-based to row-based binary logging mode even when temporary tables have been created. However, while using the row-based format, the MySQL server cannot determine the logging mode that was in effect when a given temporary table was created. For this reason, the server in such cases logs a `DROP TEMPORARY TABLE IF EXISTS` statement for each temporary table that still exists for a given client session when that session ends. While this means that it is possible that an unnecessary `DROP TEMPORARY TABLE` statement might be logged in some cases, the statement is harmless, and does not cause an error even if the table does not exist, due to the presence of the `IF EXISTS` option.

Note

From MySQL 8.0, this behavior is changed because the MySQL server tracks the logging mode that was in effect when each temporary table was created. The `DROP TEMPORARY TABLE IF EXISTS` statement is therefore not necessarily logged for each temporary table. From that release, when a given client session ends, the server logs a `DROP TEMPORARY TABLE IF EXISTS` statement for each temporary table that still exists and was created when statement-based binary logging was in use. If row-based or mixed format binary logging was in use when the table was created, the `DROP TEMPORARY TABLE IF EXISTS` statement is not logged.

In MySQL 5.6.6 and earlier, the `--disable-gtid-unsafe-statements` option caused any nontransactional DML statement involving temporary tables to fail with an error when using row-based logging, in spite of the fact that they are not written to the binary log. In MySQL 5.6.7 and later, such statements are allowed when using `binlog_format=ROW`, as long as any nontransactional tables affected by the statements are temporary tables (Bug #14272672).

- RBL and synchronization of nontransactional tables. When many rows are affected, the set of changes is split into several events; when the statement commits, all of these events are written to the binary log. When executing on the slave, a table lock is taken on all tables involved, and then the rows are applied in batch mode. (This may or may not be effective, depending on the engine used for the slave’s copy of the table.)
• **Latency and binary log size.** RBL writes changes for each row to the binary log and so its size can increase quite rapidly. This can significantly increase the time required to make changes on the slave that match those on the master. You should be aware of the potential for this delay in your applications.

• **Reading the binary log.** `mysqlbinlog` displays row-based events in the binary log using the `BINLOG` statement (see Section 13.7.6.1, “BINLOG Syntax”). This statement displays an event as a base 64-encoded string, the meaning of which is not evident. When invoked with the `--base64` output=DECODE-ROWS and `--verbose` options, `mysqlbinlog` formats the contents of the binary log to be human readable. When binary log events were written in row-based format and you want to read or recover from a replication or database failure you can use this command to read contents of the binary log. For more information, see Section 4.6.8.2, “mysqlbinlog Row Event Display”.

• **Binary log execution errors and `slave_exec_mode`**. If `slave_exec_mode` is `IDEMPOTENT`, a failure to apply changes from RBL because the original row cannot be found does not trigger an error or cause replication to fail. This means that it is possible that updates are not applied on the slave, so that the master and slave are no longer synchronized. Latency issues and use of nontransactional tables with RBR when `slave_exec_mode` is `IDEMPOTENT` can cause the master and slave to diverge even further. For more information about `slave_exec_mode`, see Section 5.1.7, “Server System Variables”.

**Note**

`slave_exec_mode=IDEMPOTENT` is generally useful only for circular replication or multi-master replication with NDB Cluster, for which `IDEMPOTENT` is the default value. For other scenarios, setting `slave_exec_mode` to `STRICT` is normally sufficient; this is the default value.

**Note**

Formerly, the default value when using NDB Cluster was `slave_exec_mode=IDEMPOTENT`, but this is no longer the case in MySQL NDB Cluster 7.3 and later.

• **Filtering based on server ID not supported.** In MySQL 5.6, you can filter based on server ID by using the `IGNORE_SERVER_IDS` option for the `CHANGE MASTER TO` statement. This option works with statement-based and row-based logging formats. Another method to filter out changes on some slaves is to use a `WHERE` clause that includes the relation `@server_id <> id_value` clause with `UPDATE` and `DELETE` statements. For example, `WHERE @server_id <> 1`. However, this does not work correctly with row-based logging. To use the `server_id` system variable for statement filtering, use statement-based logging.

• **Database-level replication options.** The effects of the `--replicate-do-db`, `--replicate-ignore-db`, and `--replicate-rewrite-db` options differ considerably depending on whether row-based or statement-based logging is used. Therefore, it is recommended to avoid database-level options and instead use table-level options such as `--replicate-do-table` and `--replicate-ignore-table`. For more information about these options and the impact replication format has on how they operate, see Section 17.1.4, “Replication and Binary Logging Options and Variables”.

• **RBL, nontransactional tables, and stopped slaves.** When using row-based logging, if the slave server is stopped while a slave thread is updating a nontransactional table, the slave database can reach an inconsistent state. For this reason, it is recommended that you use a transactional storage engine such as InnoDB for all tables replicated using the row-based format. Use of `STOP_SLAVE` or `STOP_SLAVE SQL_THREAD` prior to shutting down the slave MySQL server helps prevent issues from occurring, and is always recommended regardless of the logging format or storage engine you use.
17.1.2.3 Determination of Safe and Unsafe Statements in Binary Logging

The “safeness” of a statement in MySQL Replication, refers to whether the statement and its effects can be replicated correctly using statement-based format. If this is true of the statement, we refer to the statement as safe; otherwise, we refer to it as unsafe.

In general, a statement is safe if it deterministic, and unsafe if it is not. However, certain nondeterministic functions are not considered unsafe (see Nondeterministic functions not considered unsafe, later in this section). In addition, statements using results from floating-point math functions—which are hardware-dependent—are always considered unsafe (see Section 17.4.1.12, “Replication and Floating-Point Values”).

Handling of safe and unsafe statements. A statement is treated differently depending on whether the statement is considered safe, and with respect to the binary logging format (that is, the current value of binlog_format).

• When using row-based logging, no distinction is made in the treatment of safe and unsafe statements.

• When using mixed-format logging, statements flagged as unsafe are logged using the row-based format; statements regarded as safe are logged using the statement-based format.

• When using statement-based logging, statements flagged as being unsafe generate a warning to this effect. Safe statements are logged normally.

Each statement flagged as unsafe generates a warning. Formerly, if a large number of such statements were executed on the master, this could lead to excessively large error log files. To prevent this, MySQL provides a warning suppression mechanism (introduced in MySQL 5.6.7), which behaves as follows: Whenever the 50 most recent ER_BINLOG_UNSAFE_STATEMENT warnings have been generated more than 50 times in any 50-second period, warning suppression is enabled. When activated, this causes such warnings not to be written to the error log; instead, for each 50 warnings of this type, a note The last warning was repeated N times in last S seconds is written to the error log. This continues as long as the 50 most recent such warnings were issued in 50 seconds or less; once the rate has decreased below this threshold, the warnings are once again logged normally. Warning suppression has no effect on how the safety of statements for statement-based logging is determined, nor on how warnings are sent to the client. MySQL clients still receive one warning for each such statement.

For more information, see Section 17.1.2, “Replication Formats”.

Statements considered unsafe.
Statements with the following characteristics are considered unsafe:

• Statements containing system functions that may return a different value on slave. These functions include FOUND_ROWS(), GET_LOCK(), IS_FREE_LOCK(), IS_USED_LOCK(), LOAD_FILE(), MASTER_POS_WAIT(), PASSWORD(), RAND(), RELEASE_LOCK(), ROW_COUNT(), SESSION_USER(), SLEEP(), SYSDATE(), SYSTEM_USER(), USER(), UUID(), and UUID_SHORT().

Nondeterministic functions not considered unsafe. Although these functions are not deterministic, they are treated as safe for purposes of logging and replication: CONNECTION_ID(), CURDATE(), CURRENT_DATE(), CURRENT_TIME(), CURRENT_TIMESTAMP(), CURTIME(), LAST_INSERT_ID(), LOCALTIME(), LOCALTIMESTAMP(), NOW(), UNIX_TIMESTAMP(), UTC_DATE(), UTC_TIME(), and UTC_TIMESTAMP().

For more information, see Section 17.4.1.15, “Replication and System Functions”.

• References to system variables. Most system variables are not replicated correctly using the statement-based format. See Section 17.4.1.35, “Replication and Variables”. For exceptions, see Section 5.4.4.3, “Mixed Binary Logging Format”.

2400
Replication with Global Transaction Identifiers

- **UDFs.** Since we have no control over what a UDF does, we must assume that it is executing unsafe statements.

- **Trigger or stored program updates a table having an AUTO_INCREMENT column.** This is unsafe because the order in which the rows are updated may differ on the master and the slave.

  In addition, an INSERT into a table that has a composite primary key containing an AUTO_INCREMENT column that is not the first column of this composite key is unsafe.

  For more information, see Section 17.4.1.1, “Replication and AUTO_INCREMENT”.

- **INSERT DELAYED statement.** This statement is considered unsafe because the insertion of the rows may interleave with concurrently executing statements.

- **INSERT ... ON DUPLICATE KEY UPDATE statements on tables with multiple primary or unique keys.** When executed against a table that contains more than one primary or unique key, this statement is considered unsafe, being sensitive to the order in which the storage engine checks the keys, which is not deterministic, and on which the choice of rows updated by the MySQL Server depends.

  An INSERT ... ON DUPLICATE KEY UPDATE statement against a table having more than one unique or primary key is marked as unsafe for statement-based replication beginning with MySQL 5.6.6. (Bug #11765650, Bug #58637)

- **Updates using LIMIT.** The order in which rows are retrieved is not specified, and is therefore considered unsafe. See Section 17.4.1.17, “Replication and LIMIT”.

- **Accesses or references log tables.** The contents of the system log table may differ between master and slave.

- **Nontransactional operations after transactional operations.** Within a transaction, allowing any nontransactional reads or writes to execute after any transactional reads or writes is considered unsafe.

  For more information, see Section 17.4.1.32, “Replication and Transactions”.

- **Accesses or references self-logging tables.** All reads and writes to self-logging tables are considered unsafe. Within a transaction, any statement following a read or write to self-logging tables is also considered unsafe.

- **LOAD DATA statements.** LOAD DATA is treated as unsafe and when binlog_format=mixed the statement is logged in row-based format. When binlog_format=statement LOAD DATA does not generate a warning, unlike other unsafe statements.

  For additional information, see Section 17.4.1, “Replication Features and Issues”.

### 17.1.3 Replication with Global Transaction Identifiers

This section explains transaction-based replication using **global transaction identifiers** (GTIDs), introduced in MySQL 5.6.5. When using GTIDs, each transaction can be identified and tracked as it is committed on the originating server and applied by any slaves; this means that it is not necessary when using GTIDs to refer to log files or positions within those files when starting a new slave or failing over to a new master, which greatly simplifies these tasks. Because GTID-based replication is completely transaction-based, it is simple to determine whether masters and slaves are consistent; as long as all transactions committed on a master are also committed on a slave, consistency between the two is guaranteed. You can use either statement-based or row-based replication with GTIDs (see Section 17.1.2, “Replication Formats”); however, for best results, we recommend that you use the row-based format.
This section discusses the following topics:

- How GTIDs are defined and created, and how they are represented in the MySQL Server (see Section 17.1.3.1, “GTID Concepts”).
- A general procedure for setting up and starting GTID-based replication (see Section 17.1.3.2, “Setting Up Replication Using GTIDs”).
- Suggested methods for provisioning new replication servers when using GTIDs (see Section 17.1.3.3, “Using GTIDs for Failover and Scaleout”).
- Restrictions and limitations that you should be aware of when using GTID-based replication (see Section 17.1.3.4, “Restrictions on Replication with GTIDs”).
- A procedure for disabling GTIDs, which you must do if you have enabled GTIDs and are downgrading to a MySQL release that does not support GTIDs (see Section 17.1.3.5, “Disabling GTID Transactions”).

For information about MySQL Server options and variables relating to GTID-based replication, see Section 17.1.4.5, “Global Transaction ID Options and Variables”. See also Section 12.17, “Functions Used with Global Transaction IDs”, which describes SQL functions supported by MySQL 5.6 for use with GTIDs.

Note

GTIDs are not compatible or supported with the NDB storage engine used by NDB Cluster. Enabling GTIDs in NDB Cluster is very likely to cause problems with NDB, and to cause NDB Cluster Replication to fail as well.

17.1.3.1 GTID Concepts

A global transaction identifier (GTID) is a unique identifier created and associated with each transaction committed on the server of origin (master). This identifier is unique not only to the server on which it originated, but is unique across all servers in a given replication setup. There is a 1-to-1 mapping between all transactions and all GTIDs.

A GTID is represented as a pair of coordinates, separated by a colon character (:), as shown here:

\[
\text{GTID} = \text{source_id:transaction_id}
\]

The source_id identifies the originating server. Normally, the server’s server_uuid is used for this purpose. The transaction_id is a sequence number determined by the order in which the transaction was committed on this server; for example, the first transaction to be committed has 1 as its transaction_id, and the tenth transaction to be committed on the same originating server is assigned a transaction_id of 10. It is not possible for a transaction to have 0 as a sequence number in a GTID. For example, the twenty-third transaction to be committed originally on the server with the UUID 3E11FA47-71CA-11E1-9E33-C80AA9429562 has this GTID:

3E11FA47-71CA-11E1-9E33-C80AA9429562:23

This format is used to represent GTIDs in the output of statements such as SHOW SLAVE STATUS as well as in the binary log. They can also be seen when viewing the log file with mysqlbinlog --base64-output=DECODE-ROWS or in the output from SHOW BINLOG EVENTS.

As written in the output of statements such as SHOW MASTER STATUS or SHOW SLAVE STATUS, a sequence of GTIDs originating from the same server may be collapsed into a single expression, as shown here.
Replication with Global Transaction Identifiers

The example just shown represents the first through fifth transactions originating on the MySQL Server whose `server_uuid` is `3E11FA47-71CA-11E1-9E33-C80AA9429562`.

In MySQL 5.6.6 and later, this format is also used to supply the argument required by the `START SLAVE` options `SQL_BEFORE_GTIDS` and `SQL_AFTER_GTIDS`.

GTID Sets

A GTID set is a set of global transaction identifiers which is represented as shown here:

```
gtid_set:
  | uuid_set [, uuid_set] ... | ..
  | ..
uuid_set:
  | uuid:interval[:interval]... |
uuid:
  | hhhhhhh:hhhh:hhhh:hhhh:hhhh:hhhhhhhhhh |
  | h: [0-9|A-F] |
interval:
  | n[-n] |
(n >= 1)
```

GTID sets are used in the MySQL Server in several ways. For example, the values stored by the `gtid_executed` and `gtid_purged` system variables are represented as GTID sets. In addition, the functions `GTID_SUBSET()` and `GTID_SUBTRACT()` require GTID sets as input.

GTIDs are always preserved between master and slave. This means that you can always determine the source for any transaction applied on any slave by examining its binary log. In addition, once a transaction with a given GTID is committed on a given server, any subsequent transaction having the same GTID is ignored by that server. Thus, a transaction committed on the master can be applied no more than once on the slave, which helps to guarantee consistency.

When GTIDs are in use, the slave has no need for any nonlocal data, such as the name of a file on the master and a position within that file. All necessary information for synchronizing with the master is obtained directly from the replication data stream. From the perspective of the database administrator or developer, GTIDs entirely take the place of the file-offset pairs previously required to determine points for starting, stopping, or resuming the flow of data between master and slave. This means that, when you are using GTIDs for replication, you do not need (or want) to include `MASTER_LOG_FILE` or `MASTER_LOG_POS` options in the `CHANGE MASTER TO` statement used to direct a slave to replicate from a given master; in place of these options, it is necessary only to enable the `MASTER_AUTO_POSITION` option introduced in MySQL 5.6.5. For the exact steps needed to configure and start masters and slaves using GTID-based replication, see Section 17.1.3.2, “Setting Up Replication Using GTIDs”.

The generation and lifecycle of a GTID consists of the following steps:

1. A transaction is executed and committed on the master.

   This transaction is assigned a GTID using the master’s UUID and the smallest nonzero transaction sequence number not yet used on this server; the GTID is written to the master’s binary log (immediately preceding the transaction itself in the log).
2. After the binary log data is transmitted to the slave and stored in the slave's relay log (using established mechanisms for this process—see Section 17.2, “Replication Implementation”, for details), the slave reads the GTID and sets the value of its `gtid_next` system variable as this GTID. This tells the slave that the next transaction must be logged using this GTID.

The slave sets `gtid_next` in a session context.

3. The slave checks to make sure that this GTID has not already been used to log a transaction in its own binary log. If and only if this GTID has not been used, the slave then writes the GTID and applies the transaction (and writes the transaction to its binary log). By reading and checking the transaction's GTID first, before processing the transaction itself, the slave guarantees not only that no previous transaction having this GTID has been applied on the slave, but also that no other session has already read this GTID but has not yet committed the associated transaction. In other words, multiple clients are not permitted to apply the same transaction concurrently.

4. Because `gtid_next` is not empty, the slave does not attempt to generate a GTID for this transaction but instead writes the GTID stored in this variable—that is, the GTID obtained from the master—immediately preceding the transaction in its binary log.

### 17.1.3.2 Setting Up Replication Using GTIDs

This section describes a process for configuring and starting GTID-based replication in MySQL 5.6. This is a “cold start” procedure that assumes either that you are starting the replication master for the first time, or that it is possible to stop it; for information about provisioning replication slaves using GTIDs from a running master, see Section 17.1.3.3, “Using GTIDs for Failover and Scaleout”.

The key steps in this startup process for the simplest possible GTID replication topology—consisting of one master and one slave—are as follows:

1. If replication is already running, synchronize both servers by making them read-only.

2. Stop both servers.

3. Restart both servers with GTIDs, binary logging, and slave update logging enabled, and with statements that are unsafe for GTID-based replication disabled. In addition, the servers should be started in read-only mode, and the slave SQL and I/O threads should be prevented from starting on the slave.

   The `mysqld` options necessary to start the servers as described are discussed in the example that follows later in this section.

4. Instruct the slave to use the master as the replication data source and to use auto-positioning. The SQL statements needed to accomplish this step are described in the example that follows later in this section.

5. Take a new backup. Binary logs containing transactions without GTIDs cannot be used on servers where GTIDs are enabled, so backups taken before this point cannot be used with your new configuration.

6. Start the slave, then disable read-only mode again on both servers, so that they can accept updates.

In the following example, two servers are already running as master and slave, using MySQL's “classic” file-based replication protocol.

Most of the steps that follow require the use of the MySQL root account or another MySQL user account that has the `SUPER` privilege. `mysqladmin shutdown` requires either the `SUPER` privilege or the `SHUTDOWN` privilege.
Replication with Global Transaction Identifiers

Step 1: Synchronize the servers. Make the servers read-only. To do this, enable the `read_only` system variable by executing the following statement on both servers:

```
mysql> SET @@GLOBAL.read_only = ON;
```

Wait for all ongoing transactions to commit or roll back. Then, allow the slave to catch up with the master. *It is extremely important that you make sure the slave has processed all updates before continuing.*

If you use binary logs for anything other than replication, for example to do point in time backup and restore, wait until you do not need the old binary logs containing transactions without GTIDs. Ideally, wait for the server to purge all binary logs, and wait for any existing backup to expire.

⚠️ Important

It is important to understand that logs containing transactions without GTIDs cannot be used on servers where GTIDs are enabled. Before proceeding, you must be sure that transactions without GTIDs do not exist anywhere in the topology.

Step 2: Stop both servers. Stop each server using `mysqladmin` as shown here, where `username` is the user name for a MySQL user having sufficient privileges to shut down the server:

```
shell> mysqladmin -u username -p shutdown
```

Then supply this user's password at the prompt.

Step 3: Restart both servers with GTIDs enabled. To enable binary logging with global transaction identifiers, each server must be started with GTID mode, binary logging, slave update logging enabled, and with statements that are unsafe for GTID-based replication disabled. In addition, you should prevent unwanted or accidental updates from being performed on either server by starting both in read-only mode. This means that both servers must be started with (at least) the options shown in the following invocation of `mysqld_safe`:

```
shell> mysqld_safe --gtid_mode=ON --log-bin --log-slave-updates --enforce-gtid-consistency &
```

Note

Prior to MySQL 5.6.9, `--enforce-gtid-consistency` was named `--disable-gtid-unsafe-statements`.

In addition, you should start the slave with the `--skip-slave-start` option along with the other server options specified in the example just shown.

Note

`--gtid-mode` is not a boolean, but an enumeration. Use one of the values `ON` or `OFF` only, when setting this option. Using a numeric value such as 0 or 1 can lead to unexpected results.

For more information about the `--gtid-mode` and `--enforce-gtid-consistency` server options, see Section 17.1.4.5, “Global Transaction ID Options and Variables”.

Depending on your configuration, supply additional options to `mysqld_safe` or other `mysqld` startup script.

Step 4: Direct the slave to use the master. Tell the slave to use the master as the replication data source, and to use GTID-based auto-positioning rather than file-based positioning. Execute a `CHANGE`
Replication with Global Transaction Identifiers

 Einsatz des MASTER TO Statement auf der Sklave, mithilfe der MASTER_AUTO_POSITION Option zu sagen, dass die Transaktionen durch GTIDs identifiziert werden. 

 Sie müssen auch die passenden Werte für die Hostname und Portnummer des Masters sowie das Benutzernamen und Passwort für einen Benutzeraccount liefern, der verwendet werden soll, um die Sklave an den Master zu verbinden; falls Sie diese bereits vor dem ersten Schritt gesetzt und keine weiteren Änderungen benötigen, können diese Optionen sicherlich aus der Anweisung entfernt werden.

 mysql> CHANGE MASTER TO
 > MASTER_HOST = host,
 > MASTER_PORT = port,
 > MASTER_USER = user,
 > MASTER_PASSWORD = password,
 > MASTER_AUTO_POSITION = 1;

 Keine von den MASTER_LOG_FILE Option oder MASTER_LOG_POS Optionen können mit MASTER_AUTO_POSITION 1 verwendet werden. Versuchen Sie dies, führt zur Fehlernachricht des CHANGE MASTER TO Statement. 

 **Schritt 5: Eine neue Sicherung erstellen.** Bestehende Sicherungen, die Sie vor der Aktivierung von GTIDs erstellt haben, können auf diesen Servern nicht mehr verwendet werden, nachdem Sie GTIDs aktiviert haben. Erstellen Sie eine neue Sicherung, um sicherzustellen, dass Sie eine nutzbarer Sicherung haben.

 Zum Beispiel können Sie FLUSH LOGS auf dem Server ausführen, auf dem Sie Sicherungen erstellen. Dann entweder explizit Sicherung erstellen oder warten Sie auf die nächste Iteration einer geplanten Sicherung.

 **Schritt 6: Der Sklave starten und den lesensamen Modus deaktivieren.** Starten Sie den Sklave wie folgt:

 mysql> START SLAVE;

 Lassen Sie den Master wieder annehmen, wenn Sie die folgende Anweisung ausführen:

 mysql> SET @@GLOBAL.read_only = OFF;

 GTID-basierte Replication sollte nun laufen, und Sie können den Master wie vorherigen aufnehmen. Abschnitt 17.1.3.3, ”Gehen Sie mit GTIDs für Failover und Scaleout“, diskutiert die Erstellung von neuen Sklavenservern, die für Scaleout verwendet werden können. 

 **17.1.3.3 Verwenden Sie GTIDs für Failover und Scaleout**

 Es gibt eine Vielzahl von Techniken, wenn Sie MySQL Replication mit Global Transaction Identifiers (GTIDs) in MySQL 5.6.9 und später für die Erstellung eines neuen Sklavenserverns, der dann für Scaleout verwendet werden kann, und dann zum Master für Failover erhöht werden kann. In diesem Abschnitt, diskutieren wir die vier Techniken, die hier aufgeführt sind:

 - Einfache Replication
 - Kopieren von Daten und Transaktionen zum Sklave
 - Einfügen von leeren Transaktionen
 - Ausblenden von Transaktionen mit gtid_purged

 2406
The mapping between identifiers and sets of events comprising a given transaction is captured in the binary log. This poses some challenges when provisioning a new server with data from another existing server. To reproduce the identifier set on the new server, it is necessary to copy the identifiers from the old server to the new one, and to preserve the relationship between the identifiers and the actual events. This is necessary for restoring a slave that is immediately available as a candidate to become a new master on failover or switchover.

**Simple replication.** This is the easiest way to reproduce all identifiers and transactions on a new server; you simply make the new server into the slave of a master that has the entire execution history, and enable global transaction identifiers on both servers. See Section 17.1.3.2, “Setting Up Replication Using GTIDs”, for more information.

Once replication is started, the new server copies the entire binary log from the master and thus obtains all information about all GTIDs.

This method is simple and effective, but requires the slave to read the binary log from the master; it can sometimes take a comparatively long time for the new slave to catch up with the master, so this method is not suitable for fast failover or restoring from backup. This section explains how to avoid fetching all of the execution history from the master by copying binary log files to the new server.

**Copying data and transactions to the slave.** Playing back the entire transaction history can be time-consuming, and represents a major bottleneck when setting up a new replication slave. To eliminate this requirement, a snapshot of the data set, the binary logs and the global transaction information the master contains is imported to the slave. The binary log is played back, after which replication can be started, allowing the slave to become current with any remaining transactions.

There are several variants of this method, the difference being in the manner in which data dumps and transactions from binary logs are transferred to the slave, as outlined here:

<table>
<thead>
<tr>
<th>Data Set</th>
<th>Transaction History</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Use the <code>mysql</code> client to import a dump file created with <code>mysqldump</code>. Use the <code>--master-data</code> option to include binary logging information and <code>--set-gtid-purged</code> (available in MySQL 5.6.9 and later) to <code>AUTO</code> (the default) or <code>ON</code>, to include information about executed transactions. You should have <code>--gtid-mode=ON</code> while importing the dump on the slave. (Bug #14832472)</td>
<td>If <code>gtid_mode</code> is not <code>ON</code>, restart the server with GTID mode enabled.</td>
</tr>
<tr>
<td>• Stop the slave, copy the contents of the master’s data directory to the slave’s data directory, then restart the slave.</td>
<td>• Import the binary log using <code>mysqlbinlog</code>, with the <code>--read-from-remote-server</code> and <code>--read-from-remote-master</code> options.</td>
</tr>
<tr>
<td>• Stop the slave, copy the contents of the master’s data directory to the slave’s data directory, then restart the slave.</td>
<td>• Copy the master’s binary log files to the slave. You can make copies from the slave using <code>mysqlbinlog --read-from-remote-server --raw</code>. These can be read in to the slave in either of the following ways:</td>
</tr>
<tr>
<td></td>
<td>• Update the slave’s <code>binlog.index</code> file to point to the copied log files. Then execute a <code>CHANGE MASTER TO</code> statement in the <code>mysql</code> client to point to the first log file, and <code>START SLAVE</code> to read them.</td>
</tr>
<tr>
<td></td>
<td>• Use <code>mysqlbinlog &gt; file</code> (without the <code>--raw</code> option) to export the binary log files to SQL files that can be processed by the <code>mysql</code> client.</td>
</tr>
</tbody>
</table>

See also Section 4.6.8.3, “Using mysqlbinlog to Back Up Binary Log Files”.

2407
This method has the advantage that a new server is available almost immediately; only those transactions that were committed while the snapshot or dump file was being replayed still need to be obtained from the existing master. This means that the slave's availability is not instantaneous—but only a relatively short amount of time should be required for the slave to catch up with these few remaining transactions.

Copying over binary logs to the target server in advance is usually faster than reading the entire transaction execution history from the master in real time. However, it may not always be feasible to move these files to the target when required, due to size or other considerations. The two remaining methods for provisioning a new slave discussed in this section use other means to transfer information about transactions to the new slave.

**Injecting empty transactions.** The master's global `gtid_executed` variable contains the set of all transactions executed on the master. Rather than copy the binary logs when taking a snapshot to provision a new server, you can instead note the content of `gtid_executed` on the server from which the snapshot was taken. Before adding the new server to the replication chain, simply commit an empty transaction on the new server for each transaction identifier contained in the master's `gtid_executed`, like this:

```
SET GTID_NEXT='aaa-bbb-ccc-ddd:N';
BEGIN;
COMMIT;
SET GTID_NEXT='AUTOMATIC';
```

Once all transaction identifiers have been reinstated in this way using empty transactions, you must flush and purge the slave's binary logs, as shown here, where \(N\) is the nonzero suffix of the current binary log file name:

```
FLUSH LOGS;
PURGE BINARY LOGS TO 'master-bin.00000\(N\)';
```

You should do this to prevent this server from flooding the replication stream with false transactions in the event that it is later promoted to master. (The `FLUSH LOGS` statement forces the creation of a new binary log file; `PURGE BINARY LOGS` purges the empty transactions, but retains their identifiers.)

This method creates a server that is essentially a snapshot, but in time is able to become a master as its binary log history converges with that of the replication stream (that is, as it catches up with the master or masters). This outcome is similar in effect to that obtained using the remaining provisioning method, which we discuss in the next few paragraphs.

**Excluding transactions with gtid_purged.** The master's global `gtid_purged` variable contains the set of all transactions that have been purged from the master's binary log. As with the method discussed previously (see **Injecting empty transactions**), you can record the value of `gtid_executed` on the server from which the snapshot was taken (in place of copying the binary logs to the new server). Unlike the previous method, there is no need to commit empty transactions (or to issue `PURGE BINARY LOGS`); instead, you can set `gtid_purged` on the slave directly, based on the value of `gtid_executed` on the server from which the backup or snapshot was taken.

```
Note
Prior to MySQL 5.6.9, `gtid_purged` was not settable. (Bug #14797808)
```

As with the method using empty transactions, this method creates a server that is functionally a snapshot, but in time is able to become a master as its binary log history converges with that of the replication master or group.
17.1.3.4 Restrictions on Replication with GTIDs

Because GTID-based replication is dependent on transactions, some features otherwise available in MySQL are not supported when using it. This section provides information about restrictions on and limitations of replication with GTIDs.

Updates involving nontransactional storage engines. When using GTIDs, updates to tables using nontransactional storage engines such as MyISAM cannot be made in the same statement or transaction as updates to tables using transactional storage engines such as InnoDB.

This restriction is due to the fact that updates to tables that use a nontransactional storage engine mixed with updates to tables that use a transactional storage engine within the same transaction can result in multiple GTIDs being assigned to the same transaction.

Such problems can also occur when the master and the slave use different storage engines for their respective versions of the same table, where one storage engine is transactional and the other is not.

In any of the cases just mentioned, the one-to-one correspondence between transactions and GTIDs is broken, with the result that GTID-based replication cannot function correctly.

CREATE TABLE ... SELECT statements. CREATE TABLE ... SELECT is not safe for statement-based replication. When using row-based replication, this statement is actually logged as two separate events—one for the creation of the table, and another for the insertion of rows from the source table into the new table just created. When this statement is executed within a transaction, it is possible in some cases for these two events to receive the same transaction identifier, which means that the transaction containing the inserts is skipped by the slave. Therefore, CREATE TABLE ... SELECT is not supported when using GTID-based replication.

Temporary tables. CREATE TEMPORARY TABLE and DROP TEMPORARY TABLE statements are not supported inside transactions when using GTIDs (that is, when the server was started with the --enforce-gtid-consistency option). It is possible to use these statements with GTIDs enabled, but only outside of any transaction, and only with autocommit=1.

Preventing execution of unsupported statements. In order to prevent execution of statements that would cause GTID-based replication to fail, all servers must be started with the --enforce-gtid-consistency option when enabling GTIDs. This causes statements of any of the types discussed previously in this section to fail with an error.

For information about other required startup options when enabling GTIDs, see Section 17.1.3.2, "Setting Up Replication Using GTIDs”.

sql_slave_skip_counter is not supported when using GTIDs. If you need to skip transactions, use the value of the master's gtid_executed variable instead; see Injecting empty transactions, for more information.

GTID mode and mysqldump. In MySQL 5.6.9 and later, it is possible to import a dump made using mysqldump into a MySQL Server running with GTID mode enabled, provided that there are no GTIDs in the target server's binary log.

Prior to MySQL 5.6.9, mysqldump did not record global transaction IDs, and it was necessary to use the binary log and mysqlbinlog to restore GTIDs. (Bug #14797808, Bug #14832472)

GTID mode and mysql_upgrade. Prior to MySQL 5.6.7, mysql_upgrade could not connect to a MySQL Server that was running with global transaction identifiers (GTIDs) enabled (--gtid-mode=ON) unless mysql_upgrade was run with --write-binlog=OFF. Otherwise, mysqld had to be restarted with --gtid-mode=OFF before running mysql_upgrade, then restarted with --gtid_mode=ON.
Replication with Global Transaction Identifiers

afterwards. In MySQL 5.6.7 and later, where `mysql_upgrade` runs with `--write-binlog=OFF` by default. (Bug #13833710). Do not enable this option when the server is running with `(gtid_mode=ON)`.

### 17.1.3.5 Disabling GTID Transactions

If you have enabled GTIDs in MySQL 5.6 and want to downgrade to a MySQL release that does not support GTIDs, you must carry out this procedure to disable GTIDs before downgrading. In MySQL 5.6, you must take the servers offline in order to disable GTIDs.

1. On each slave, disable auto-positioning by running the following statements:

   ```
   STOP SLAVE;
   CHANGE MASTER TO MASTER_AUTO_POSITION = 0, MASTER_LOG_FILE = file, \ 
   MASTER_LOG_POS = position;
   START SLAVE;
   ```

2. On each server, stop updates by running the following statement:

   ```
   SET @@GLOBAL.READ_ONLY = ON;
   ```

3. Wait for all ongoing transactions to commit or roll back. Then, wait for a safe period of time, depending on your deployment, for all transactions that currently exist in any binary log to replicate to all slaves. It is extremely important that you make sure all slaves have processed all updates before continuing.

   If you use binary logs for anything other than replication, for example to do point in time backup and restore, wait until you do not need the old binary logs containing GTID transactions. Ideally, wait for the server to purge all binary logs, and wait for any existing backup to expire.

   ! IMPORTANT

   It is important to understand that logs containing GTID transactions cannot be used on servers where GTIDs are disabled. Before proceeding, you must be sure that GTID transactions do not exist anywhere in the topology.

4. Stop each server using `mysqladmin` as shown here, where `username` is the user name for a MySQL user having sufficient privileges to shut down the server:

   ```
   shell> mysqladmin -u username -p shutdown
   ```

   Then supply this user's password at the prompt.

5. On each server, set `gtid-mode=OFF` and `enforce_gtid_consistency=OFF` in `my.cnf`.

6. Restart each server in read-only mode, using `mysqld_safe` or another `mysqld` startup script, and specifying the option `--read_only=ON` on the command line. Starting the servers in read-only mode prevents unwanted or accidental updates from being performed on any server.

7. Take a new backup at this point, so that you are not left without a usable backup. Existing backups that were made before you disabled GTIDs can no longer be used on these servers now that you have disabled GTIDs. For instance, you can execute `FLUSH LOGS` on the server where you are taking backups. Then either explicitly take a backup or wait for the next iteration of any periodic backup routine you may have set up.

8. On each server, re-enable updates by running the following statement:
If you want to downgrade to an earlier version of MySQL, you can do so now, using the normal downgrade procedure.

17.1.4 Replication and Binary Logging Options and Variables

The following sections contain information about `mysqld` options and server variables that are used in replication and for controlling the binary log. Options and variables for use on replication masters and replication slaves are covered separately, as are options and variables relating to binary logging. A set of quick-reference tables providing basic information about these options and variables is also included.

Of particular importance is the `--server-id` option.

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--server-id=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>server_id</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

This option specifies the server ID that is set in the `server_id` system variable.

On a replication master and each replication slave, you must specify the `--server-id` option to establish a unique replication ID in the range from 1 to $2^{32} - 1$. “Unique”, means that each ID must be different from every other ID in use by any other replication master or slave. For example, `server-id=3`. For additional information, see Section 17.1.4.2, “Replication Master Options and Variables”, and Section 17.1.4.3, “Replication Slave Options and Variables”.

If you omit `--server-id`, the default server ID is 0. If the server ID is set to 0, binary logging takes place, but a master with a server ID of 0 refuses any connections from slaves, and a slave with a server ID of 0 refuses to connect to a master. Note that although you can change the server ID dynamically to a nonzero value, doing so does not enable replication to start immediately. You must change the server ID and then restart the server to initialize the replication slave.

In MySQL 5.6, whether the server ID is set to 0 explicitly or the default is allowed to be used, the server sets the `server_id` system variable to 1; this is a known issue that is fixed in MySQL 5.7.

For more information, see Section 17.1.1.2, “Setting the Replication Slave Configuration”.

`server_uuid`

Beginning with MySQL 5.6, the server generates a true UUID in addition to the `--server-id` supplied by the user. This is available as the global, read-only variable `server_uuid`.

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>server_uuid</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
</tbody>
</table>
When starting, the MySQL server automatically obtains a UUID as follows:

1. Attempt to read and use the UUID written in the file `data_dir/auto.cnf` (where `data_dir` is the server's data directory).

2. If `data_dir/auto.cnf` is not found, generate a new UUID and save it to this file, creating the file if necessary.

The `auto.cnf` file has a format similar to that used for `my.cnf` or `my.ini` files. In MySQL 5.6, `auto.cnf` has only a single `[auto]` section containing a single `server_uuid` setting and value; the file's contents appear similar to what is shown here:

```
[auto]
server_uuid=8a94f357-aab4-11df-86ab-c80aa9429562
```

**Important**
The `auto.cnf` file is automatically generated; do not attempt to write or modify this file.

Also beginning with MySQL 5.6, when using MySQL replication, masters and slaves know one another's UUIDs. The value of a slave's UUID can be seen in the output of `SHOW SLAVE HOSTS`. Once `START SLAVE` has been executed (but not before), the value of the master's UUID is available on the slave in the output of `SHOW SLAVE STATUS`.

**Note**
Issuing a `STOP SLAVE` or `RESET SLAVE` statement does not reset the master's UUID as used on the slave.

In MySQL 5.6.5 and later, a server's `server_uuid` is also used in GTIDs for transactions originating on that server. For more information, see Section 17.1.3, "Replication with Global Transaction Identifiers".

When starting, the slave I/O thread generates an error and aborts if its master's UUID is equal to its own unless the `--replicate-same-server-id` option has been set. In addition, the slave I/O thread generates a warning if either of the following is true:

- No master having the expected `server_uuid` exists.
- The master's `server_uuid` has changed, although no `CHANGE MASTER TO` statement has ever been executed.

**Note**
The addition of the `server_uuid` system variable in MySQL 5.6 does not change the requirement for setting a unique `--server-id` for each MySQL server as part of preparing and running MySQL replication, as described earlier in this section.

### 17.1.4.1 Replication and Binary Logging Option and Variable Reference

The following two lists provide basic information about the MySQL command-line options and system variables applicable to replication and the binary log.
The command-line options and system variables in the following list relate to replication masters and replication slaves. Section 17.1.4.2, “Replication Master Options and Variables”, provides more detailed information about options and variables relating to replication master servers. For more information about options and variables relating to replication slaves, see Section 17.1.4.3, “Replication Slave Options and Variables”.

- **abort_slave_event_count**: Option used by mysql-test for debugging and testing of replication
- **auto_increment_increment**: AUTO_INCREMENT columns are incremented by this value
- **auto_increment_offset**: Offset added to AUTO_INCREMENT columns
- **binlog_gtid_simple_recovery**: Controls how binary logs are iterated during GTID recovery
- **Com_change_master**: Count of CHANGE MASTER TO statements
- **Com_show_master_status**: Count of SHOW MASTER STATUS statements
- **Com_show_new_master**: Count of SHOW NEW MASTER statements
- **Com_show_slave_hosts**: Count of SHOW SLAVE HOSTS statements
- **Com_show_slave_status**: Count of SHOW SLAVE STATUS statements
- **Com_slave_start**: Count of START SLAVE statements
- **Com_slave_stop**: Count of STOP SLAVE statements
- **disable_gtid_unsafe_statements**: Obsolete: Replaced by --enforce-gtid-consistency in MySQL 5.6.9
- **disable_gtid_unsafe_statements**: Obsolete: Replaced by enforce_gtid_consistency in MySQL 5.6.9
- **disconnect_slave_event_count**: Option used by mysql-test for debugging and testing of replication
- **enforce-gtid-consistency**: Prevents execution of statements that cannot be logged in a transactionally safe manner
- **enforce_gtid_consistency**: Prevents execution of statements that cannot be logged in a transactionally safe manner
- **expire_logs_days**: Purge binary logs after this many days
- **gtid-mode**: Controls whether GTID based logging is enabled and what type of transactions the logs can contain
- **gtid_done**: Obsolete: Replaced by gtid_executed in MySQL 5.6.9
- **gtid_executed**: Global: All GTIDs in the binary log (global) or current transaction (session). Read-only.
- **gtid_lost**: Obsolete: Replaced by gtid_purged in MySQL 5.6.9
- **gtid_mode**: Controls whether GTID based logging is enabled and what type of transactions the logs can contain
- **gtid_next**: Specifies the GTID for the next statement to execute; see documentation for details
Replication and Binary Logging Options and Variables

- **gtid_owned**: The set of GTIDs owned by this client (session), or by all clients, together with the thread ID of the owner (global). Read-only.
- **gtid_purged**: The set of all GTIDs that have been purged from the binary log
- **init_slave**: Statements that are executed when a slave connects to a master
- **log-bin-trust-function-creators**: If equal to 0 (the default), then when `--log-bin` is used, creation of a stored function is allowed only to users having the SUPER privilege and only if the function created does not break binary logging
- **master-info-file**: The location and name of the file that remembers the master and where the I/O replication thread is in the master's binary logs
- **master-info-repository**: Whether to write master status information and replication I/O thread location in the master's binary logs to a file or table
- **master-retry-count**: Number of tries the slave makes to connect to the master before giving up
- **master_info_repository**: Whether to write master status information and replication I/O thread location in the master's binary logs to a file or table
- **max_relay_log_size**: If nonzero, relay log is rotated automatically when its size exceeds this value. If zero, size at which rotation occurs is determined by the value of `max_binlog_size`.
- **relay-log**: The location and base name to use for relay logs
- **relay-log-index**: The location and name to use for the file that keeps a list of the last relay logs
- **relay-log-info-file**: The location and name of the file that remembers where the SQL replication thread is in the relay logs
- **relay-log-info-repository**: Whether to write the replication SQL thread's location in the relay logs to a file or a table
- **relay-log-recovery**: Enables automatic recovery of relay log files from master at startup
- **relay_log_basename**: Complete path to relay log, including filename
- **relay_log_index**: The name of the relay log index file
- **relay_log_info_file**: The name of the file in which the slave records information about the relay logs
- **relay_log_info_repository**: Whether to write the replication SQL thread's location in the relay logs to a file or a table
- **relay_log_purge**: Determines whether relay logs are purged
- **relay_log_recovery**: Whether automatic recovery of relay log files from master at startup is enabled; must be enabled for a crash-safe slave
- **relay_log_space_limit**: Maximum space to use for all relay logs
- **replicate-do-db**: Tells the slave SQL thread to restrict replication to the specified database
- **replicate-do-table**: Tells the slave SQL thread to restrict replication to the specified table
- **replicate-ignore-db**: Tells the slave SQL thread not to replicate to the specified database
- `replicate-ignore-table`: Tells the slave SQL thread not to replicate to the specified table.
- `replicate-rewrite-db`: Updates to a database with a different name than the original.
- `replicate-same-server-id`: In replication, if enabled, do not skip events having our server id.
- `replicate-wild-do-table`: Tells the slave thread to restrict replication to the tables that match the specified wildcard pattern.
- `replicate-wild-ignore-table`: Tells the slave thread not to replicate to the tables that match the given wildcard pattern.
- `report-host`: Host name or IP of the slave to be reported to the master during slave registration.
- `report-password`: An arbitrary password that the slave server should report to the master. Not the same as the password for the MySQL replication user account.
- `report-port`: Port for connecting to slave reported to the master during slave registration.
- `report-user`: An arbitrary user name that a slave server should report to the master. Not the same as the name used with the MySQL replication user account.
- `Rpl_semi_sync_master_clients`: Number of semisynchronous slaves.
- `rpl_semi_sync_master_enabled`: Whether semisynchronous replication is enabled on the master.
- `Rpl_semi_sync_master_net_avg_wait_time`: The average time the master waited for a slave reply.
- `Rpl_semi_sync_master_net_wait_time`: The total time the master waited for slave replies.
- `Rpl_semi_sync_master_net_waits`: The total number of times the master waited for slave replies.
- `Rpl_semi_sync_master_no_times`: Number of times the master turned off semisynchronous replication.
- `Rpl_semi_sync_master_no_tx`: Number of commits not acknowledged successfully.
- `Rpl_semi_sync_master_status`: Whether semisynchronous replication is operational on the master.
- `Rpl_semi_sync_master_timefunc_failures`: Number of times the master failed when calling time functions.
- `rpl_semi_sync_master_timeout`: Number of milliseconds to wait for slave acknowledgment.
- `rpl_semi_sync_master_trace_level`: The semisynchronous replication debug trace level on the master.
- `Rpl_semi_sync_master_tx_avg_wait_time`: The average time the master waited for each transaction.
- `Rpl_semi_sync_master_tx_wait_time`: The total time the master waited for transactions.
- `Rpl_semi_sync_master_tx_waits`: The total number of times the master waited for transactions.
- `rpl_semi_sync_master_wait_no_slave`: Whether master waits for timeout even with no slaves.
- `Rpl_semi_sync_master_wait_pos_backtraverse`: The total number of times the master waited for an event with binary coordinates lower than events waited for previously.
• **Rpl_semi_sync_master_wait_sessions**: Number of sessions currently waiting for slave replies
• **Rpl_semi_sync_master_yes_tx**: Number of commits acknowledged successfully
• **rpl_semi_sync_slave_enabled**: Whether semisynchronous replication is enabled on slave
• **Rpl_semi_sync_slave_status**: Whether semisynchronous replication is operational on slave
• **rpl_semi_sync_slave_trace_level**: The semisynchronous replication debug trace level on the slave
• **rpl_stop_slave_timeout**: Set the number of seconds that STOP SLAVE waits before timing out
• **server_uuid**: The server’s globally unique ID, automatically (re)generated at server start
• **show-slave-auth-info**: Show user name and password in SHOW SLAVE HOSTS on this master
• **simplified_binlog_gtid_recovery**: Renamed to binlog_gtid_simple_recovery
• **skip-slave-start**: If set, slave is not autostarted
• **slave-checkpoint-group**: Maximum number of transactions processed by a multithreaded slave before a checkpoint operation is called to update progress status. Not supported by NDB Cluster.
• **slave-checkpoint-period**: Update progress status of multithreaded slave and flush relay log info to disk after this number of milliseconds. Not supported by NDB Cluster.
• **slave-load-tmpdir**: The location where the slave should put its temporary files when replicating a LOAD DATA statement
• **slave-max-allowed-packet**: Maximum size, in bytes, of a packet that can be sent from a replication master to a slave; overrides max_allowed_packet
• **slave-net-timeout**: Number of seconds to wait for more data from a master/slave connection before aborting the read
• **slave-parallel-workers**: Number of applier threads for executing replication transactions in parallel. The default is 4 applier threads. Set to 0 to disable slave multithreading. Not supported by MySQL Cluster.
• **slave-pending-jobs-size-max**: Maximum size of slave worker queues holding events not yet applied
• **slave-rows-search-algorithms**: Determines search algorithms used for slave update batching. Any 2 or 3 from the list INDEX_SEARCH, TABLE_SCAN, HASH_SCAN
• **slave-skip-errors**: Tells the slave thread to continue replication when a query returns an error from the provided list
• **slave_checkpoint_group**: Maximum number of transactions processed by a multithreaded slave before a checkpoint operation is called to update progress status. Not supported by NDB Cluster.
• **slave_checkpoint_period**: Update progress status of multithreaded slave and flush relay log info to disk after this number of milliseconds. Not supported by NDB Cluster.
• **slave_compressed_protocol**: Use compression of master/slave protocol
• **slave_exec_mode**: Allows for switching the slave thread between IDEMPOTENT mode (key and some other errors suppressed) and STRICT mode; STRICT mode is the default, except for NDB Cluster, where IDEMPOTENT is always used
Replication and Binary Logging Options and Variables

- **Slave_heartbeat_period**: The slave’s replication heartbeat interval, in seconds
- **Slave_last_heartbeat**: Shows when the latest heartbeat signal was received, in TIMESTAMP format
- **slave_max_allowed_packet**: Maximum size, in bytes, of a packet that can be sent from a replication master to a slave; overrides max_allowed_packet
- **Slave_open_temp_tables**: Number of temporary tables that the slave SQL thread currently has open
- **slave_parallel_workers**: Number of applier threads for executing replication transactions in parallel. A value of 0 disables slave multithreading. Not supported by MySQL Cluster.
- **slave_pending_jobs_size_max**: Maximum size of slave worker queues holding events not yet applied
- **Slave_received_heartbeats**: Number of heartbeats received by a replication slave since previous reset
- **Slave_retried_transactions**: The total number of times since startup that the replication slave SQL thread has retried transactions
- **slave_rows_search_algorithms**: Determines search algorithms used for slave update batching. Any 2 or 3 from the list INDEX_SEARCH, TABLE_SCAN, HASH_SCAN.
- **Slave_rows_last_search_algorithm_used**: Search algorithm most recently used by this slave to locate rows for row-based replication (index, table, or hash scan)
- **Slave_running**: The state of this server as a replication slave (slave I/O thread status)
- **slave_transaction_retries**: Number of times the slave SQL thread will retry a transaction in case it failed with a deadlock or elapsed lock wait timeout, before giving up and stopping
- **slave_type_conversions**: Controls type conversion mode on replication slave. Value is a list of zero or more elements from the list: ALL_LOSSY, ALL_NON_LOSSY. Set to an empty string to disallow type conversions between master and slave.
- **sql_log_bin**: Controls binary logging for the current session
- **sql_slave_skip_counter**: Number of events from the master that a slave server should skip. Not compatible with GTID replication.
- **sync_master_info**: Synchronize master.info to disk after every #th event
- **sync_relay_log**: Synchronize relay log to disk after every #th event
- **sync_relay_log_info**: Synchronize relay.info file to disk after every #th event

The command-line options and system variables in the following list relate to the binary log. Section 17.1.4.4, “Binary Log Options and Variables”, provides more detailed information about options and variables relating to binary logging. For additional general information about the binary log, see Section 5.4.4, “The Binary Log”.

- **binlog-checksum**: Enable/disable binary log checksums
- **binlog-do-db**: Limits binary logging to specific databases
- **binlog_format**: Specifies the format of the binary log
Replication and Binary Logging Options and Variables

- **binlog-ignore-db**: Tells the master that updates to the given database should not be logged to the binary log

- **binlog-row-event-max-size**: Binary log event size

- **Binlog_cache_disk_use**: Number of transactions that used a temporary file instead of the binary log cache

- **binlog_cache_size**: Size of the cache to hold the SQL statements for the binary log during a transaction

- **Binlog_cache_use**: Number of transactions that used the temporary binary log cache

- **binlog_checksum**: Enable/disable binary log checksums

- **binlog_direct_non_transactional_updates**: Causes updates using statement format to nontransactional engines to be written directly to binary log. See documentation before using.

- **binlog_error_action**: Controls what happens when the server cannot write to the binary log

- **binlog_max_flush_queue_time**: How long to read transactions before flushing to binary log

- **binlog_order_commits**: Whether to commit in same order as writes to binary log

- **binlog_row_image**: Use full or minimal images when logging row changes

- **binlog_rows_query_log_events**: When enabled, enables logging of rows query log events when using row-based logging. Disabled by default. Do not enable when producing logs for pre-5.6 slaves/readers.

- **Binlog_stmt_cache_disk_use**: Number of nontransactional statements that used a temporary file instead of the binary log statement cache

- **binlog_stmt_cache_size**: Size of the cache to hold nontransactional statements for the binary log during a transaction

- **Binlog_stmt_cache_use**: Number of statements that used the temporary binary log statement cache

- **binlogging_impossible_mode**: Deprecated and will be removed in a future version. Use the renamed binlog_error_action instead.

- **Com_show_binlog_events**: Count of SHOW BINLOG EVENTS statements

- **Com_show_binlogs**: Count of SHOW BINLOGS statements

- **log-bin**: Specifies the base name for binary log files

- **log-bin-index**: Specifies the name for the binary log index file

- **log-bin-use-v1-row-events**: Use version 1 binary log row events

- **log-slave-updates**: Tells the slave to log the updates performed by its SQL thread to its own binary log

- **log_bin**: Whether the binary log is enabled

- **log_bin_basename**: Path and base name for binary log files

- **log_bin_use_v1_row_events**: Shows whether server is using version 1 binary log row events
Replication and Binary Logging Options and Variables

- **log_slave_updates**: Whether the slave should log the updates performed by its SQL thread to its own binary log. Read-only; set using the --log-slave-updates server option.

- **master-verify-checksum**: Cause master to examine checksums when reading from the binary log

- **master_verify_checksum**: Cause master to read checksums from binary log

- **max-binlog-dump-events**: Option used by mysql-test for debugging and testing of replication

- **max_binlog_cache_size**: Can be used to restrict the total size used to cache a multi-statement transaction

- **max_binlog_size**: Binary log will be rotated automatically when size exceeds this value

- **max_binlog_stmt_cache_size**: Can be used to restrict the total size used to cache all nontransactional statements during a transaction

- **slave-sql-verify-checksum**: Cause slave to examine checksums when reading from the relay log

- **slave_sql_verify_checksum**: Cause slave to examine checksums when reading from relay log

- **sporadic-binlog-dump-fail**: Option used by mysql-test for debugging and testing of replication

- **sync_binlog**: Synchronously flush binary log to disk after every #th event

For a listing of all command-line options, system and status variables used with mysql, see Section 5.1.3, “Server Option, System Variable, and Status Variable Reference”.

17.1.4.2 Replication Master Options and Variables

This section describes the server options and system variables that you can use on replication master servers. You can specify the options either on the command line or in an option file. You can specify system variable values using SET.

On the master and each slave, you must use the server-id option to establish a unique replication ID. For each server, you should pick a unique positive integer in the range from 1 to $2^{32} - 1$, and each ID must be different from every other ID in use by any other replication master or slave. Example: server-id=3.

For options used on the master for controlling binary logging, see Section 17.1.4.4, “Binary Log Options and Variables”.

Startup Options for Replication Masters

The following list describes startup options for controlling replication master servers. Replication-related system variables are discussed later in this section.

- **--show-slave-auth-info**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--show-slave-auth-info[{=OFF</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Display slave user names and passwords in the output of `SHOW SLAVE HOSTS` on the master server for slaves started with the `--report-user` and `--report-password` options.
System Variables Used on Replication Masters

The following system variables are used to control replication masters:

- `auto_increment_increment`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--auto-increment-increment=#</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>auto_increment_increment</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>65535</td>
</tr>
</tbody>
</table>

`auto_increment_increment` and `auto_increment_offset` are intended for use with master-to-master replication, and can be used to control the operation of `AUTO_INCREMENT` columns. Both variables have global and session values, and each can assume an integer value between 1 and 65,535 inclusive. Setting the value of either of these two variables to 0 causes its value to be set to 1 instead. Attempting to set the value of either of these two variables to an integer greater than 65,535 or less than 0 causes its value to be set to 65,535 instead. Attempting to set the value of `auto_increment_increment` or `auto_increment_offset` to a noninteger value produces an error, and the actual value of the variable remains unchanged.

**Note**

`auto_increment_increment` is also supported for use with `NDB` tables.

These two variables affect `AUTO_INCREMENT` column behavior as follows:

- `auto_increment_increment` controls the interval between successive column values. For example:

```sql
mysql> SHOW VARIABLES LIKE 'auto_inc%';
+--------------------------+-------+
| Variable_name            | Value |
+--------------------------+-------+
| auto_increment_increment | 1     |
| auto_increment_offset    | 1     |
+--------------------------+-------+
2 rows in set (0.00 sec)

mysql> CREATE TABLE autoinc1
    -> (col INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
Query OK, 0 rows affected (0.04 sec)

mysql> SET @@auto_increment_increment=10;
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW VARIABLES LIKE 'auto_inc%';
+--------------------------+-------+
| Variable_name            | Value |
|--------------------------+-------+
| auto_increment_increment | 10    |
```
• *auto_increment_offset* determines the starting point for the `AUTO_INCREMENT` column value. Consider the following, assuming that these statements are executed during the same session as the example given in the description for `auto_increment_increment`:

MySQL> SET @@auto_increment_offset=5;
Query OK, 0 rows affected (0.00 sec)

MySQL> SHOW VARIABLES LIKE 'auto_inc%';
+--------------------------+-------+
| Variable_name            | Value |
|--------------------------+-------|
| auto_increment_increment | 10    |
| auto_increment_offset    | 5     |
+--------------------------+-------+
2 rows in set (0.00 sec)

MySQL> CREATE TABLE autoinc2
       -> (col INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
Query OK, 0 rows affected (0.06 sec)

MySQL> INSERT INTO autoinc2 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4 Duplicates: 0 Warnings: 0

MySQL> SELECT col FROM autoinc2;

+-----+
| col  |
+-----+
|  5   |
| 15   |
| 25   |
| 35   |
+-----+
4 rows in set (0.02 sec)

When the value of `auto_increment_offset` is greater than that of `auto_increment_increment`, the value of `auto_increment_offset` is ignored.

If either of these variables is changed, and then new rows inserted into a table containing an `AUTO_INCREMENT` column, the results may seem counterintuitive because the series of `AUTO_INCREMENT` values is calculated without regard to any values already present in the column, and the next value inserted is the least value in the series that is greater than the maximum existing value in the `AUTO_INCREMENT` column. The series is calculated like this:
auto_increment_offset + \( N \times \text{auto_increment_increment} \)

where \( N \) is a positive integer value in the series \([1, 2, 3, \ldots]\). For example:

```sql
mysql> SHOW VARIABLES LIKE 'auto_inc%';
+--------------------------+-------+
| Variable_name            | Value |
+--------------------------+-------+
| auto_increment_increment | 10    |
| auto_increment_offset    | 5     |
+--------------------------+-------+
2 rows in set (0.00 sec)

mysql> SELECT col FROM autoinc1;
+-----+
<table>
<thead>
<tr>
<th>col</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
<tr>
<td>11</td>
</tr>
<tr>
<td>21</td>
</tr>
<tr>
<td>31</td>
</tr>
</tbody>
</table>
+-----+
4 rows in set (0.00 sec)

mysql> INSERT INTO autoinc1 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4  Duplicates: 0  Warnings: 0

mysql> SELECT col FROM autoinc1;
+-----+
<table>
<thead>
<tr>
<th>col</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
<tr>
<td>11</td>
</tr>
<tr>
<td>21</td>
</tr>
<tr>
<td>31</td>
</tr>
<tr>
<td>35</td>
</tr>
<tr>
<td>45</td>
</tr>
<tr>
<td>55</td>
</tr>
<tr>
<td>65</td>
</tr>
</tbody>
</table>
+-----+
8 rows in set (0.00 sec)
```

The values shown for `auto_increment_increment` and `auto_increment_offset` generate the series \( 5 + N \times 10 \), that is, \([5, 15, 25, 35, 45, \ldots]\). The highest value present in the `col` column prior to the `INSERT` is 31, and the next available value in the `AUTO_INCREMENT` series is 35, so the inserted values for `col` begin at that point and the results are as shown for the `SELECT` query.

It is not possible to restrict the effects of these two variables to a single table; these variables control the behavior of all `AUTO_INCREMENT` columns in all tables on the MySQL server. If the global value of either variable is set, its effects persist until the global value is changed or overridden by setting the session value, or until `mysqld` is restarted. If the local value is set, the new value affects `AUTO_INCREMENT` columns for all tables into which new rows are inserted by the current user for the duration of the session, unless the values are changed during that session.

The default value of `auto_increment_increment` is 1. See Section 17.4.1.1, “Replication and `AUTO_INCREMENT`”.

- `auto_increment_offset`
### auto_increment_offset

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--auto-increment-offset=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>auto_increment_offset</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>65535</td>
</tr>
</tbody>
</table>

This variable has a default value of 1. For more information, see the description for `auto_increment_increment`.

**Note**  
`auto_increment_offset` is also supported for use with NDB tables.

- **rpl_semi_sync_master_enabled**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--rpl-semi-sync-master-enabled[={OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>rpl_semi_sync_master_enabled</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Controls whether semisynchronous replication is enabled on the master. To enable or disable the plugin, set this variable to **ON** or **OFF** (or 1 or 0), respectively. The default is **OFF**.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- **rpl_semi_sync_master_timeout**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--rpl-semi-sync-master-timeout=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>rpl_semi_sync_master_timeout</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>10000</td>
</tr>
</tbody>
</table>

A value in milliseconds that controls how long the master waits on a commit for acknowledgment from a slave before timing out and reverting to asynchronous replication. The default value is 10000 (10 seconds).
This variable is available only if the master-side semisynchronous replication plugin is installed.

- rpl_semi_sync_master_trace_level

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--rpl-semi-sync-master-trace-level=#</td>
</tr>
<tr>
<td>System Variable</td>
<td>rpl_semi_sync_master_trace_level</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>32</td>
</tr>
</tbody>
</table>

The semisynchronous replication debug trace level on the master. Four levels are defined:

- 1 = general level (for example, time function failures)
- 16 = detail level (more verbose information)
- 32 = net wait level (more information about network waits)
- 64 = function level (information about function entry and exit)

This variable is available only if the master-side semisynchronous replication plugin is installed.

- rpl_semi_sync_master_wait_no_slave

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--rpl-semi-sync-master-wait-no-slave[={OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td>rpl_semi_sync_master_wait_no_slave</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

With semisynchronous replication, for each transaction, the master waits until timeout for acknowledgment of receipt from some semisynchronous slave. If no response occurs during this period, the master reverts to normal replication. This variable controls whether the master waits for the timeout to expire before reverting to normal replication even if the slave count drops to zero during the timeout period.

If the value is ON (the default), it is permissible for the slave count to drop to zero during the timeout period (for example, if slaves disconnect). The master still waits for the timeout, so as long as some slave reconnects and acknowledges the transaction within the timeout interval, semisynchronous replication continues.

If the value is OFF, the master reverts to normal replication if the slave count drops to zero during the timeout period.

This variable is available only if the master-side semisynchronous replication plugin is installed.
### 17.1.4.3 Replication Slave Options and Variables

- **Startup Options for Replication Slaves**
- **Options for Logging Slave Status to Tables**
- **Obsolete Replication Slave Options**
- **System Variables Used on Replication Slaves**

Specify the options either on the command line or in an option file. Many of the options can be set while the server is running by using the `CHANGE MASTER TO` statement. Specify system variable values using `SET`.

**Server ID.** On the master and each slave, you must use the `server-id` option to establish a unique replication ID in the range from 1 to $2^{32} - 1$. "Unique" means that each ID must be different from every other ID in use by any other replication master or slave. Example `my.cnf` file:

```
[mysqld]
server-id=3
```

#### Startup Options for Replication Slaves

This section explains startup options for controlling replication slave servers. Many of these options can be set while the server is running by using the `CHANGE MASTER TO` statement. Others, such as the `--replicate-*` options, can be set only when the slave server starts. Replication-related system variables are discussed later in this section.

- **--abort-slave-event-count**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--abort-slave-event-count=#</code></td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
</tbody>
</table>

When this option is set to some positive integer `value` other than 0 (the default) it affects replication behavior as follows: After the slave SQL thread has started, `value` log events are permitted to be executed; after that, the slave SQL thread does not receive any more events, just as if the network connection from the master were cut. The slave thread continues to run, and the output from `SHOW SLAVE STATUS` displays `Yes` in both the `Slave_IO_Running` and the `Slave_SQL_Running` columns, but no further events are read from the relay log.

This option is used internally by the MySQL test suite for replication testing and debugging. It is not intended for use in a production setting.

- **--disconnect-slave-event-count**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--disconnect-slave-event-count=#</code></td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
</tbody>
</table>

This option is used internally by the MySQL test suite for replication testing and debugging.
• **--log-slave-updates**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--log-slave-updates[={OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td>log_slave_updates</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Normally, a slave does not write to its own binary log any updates that are received from a master server. This option causes the slave to write the updates performed by its SQL thread to its own binary log. For this option to have any effect, the slave must also be started with the **--log-bin** option to enable binary logging. A warning is issued if you use the **--log-slave-updates** option without also starting the server with the **--log-bin** option.

**--log-slave-updates** is used when you want to chain replication servers. For example, you might want to set up replication servers using this arrangement:

```
A -> B -> C
```

Here, A serves as the master for the slave B, and B serves as the master for the slave C. For this to work, B must be both a master and a slave. You must start both A and B with **--log-bin** to enable binary logging, and B with the **--log-slave-updates** option so that updates received from A are logged by B to its binary log.

• **--log-slow-slave-statements**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--log-slow-slave-statements[={OFF</td>
</tr>
<tr>
<td>Removed</td>
<td>5.6.11</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

When the slow query log is enabled, this option enables logging for queries that have taken more than `long_query_time` seconds to execute on the slave.

Note that all statements logged in row format in the master will not be logged in the slave's slow log, even if this option is enabled.

This command-line option was removed in MySQL 5.6.11 and replaced by the `log_slow_slave_statements` system variable. The system variable can be set on the command line or in option files the same way as the option, so there is no need for any changes at server startup, but the system variable also makes it possible to examine or set the value at runtime.

• **--log-warnings[=level]**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--log-warnings[=#]</td>
</tr>
<tr>
<td>System Variable</td>
<td>log_warnings</td>
</tr>
</tbody>
</table>
Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope (&gt;= 5.6.4)</td>
<td>Global</td>
</tr>
<tr>
<td>Scope (&lt;= 5.6.3)</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Causes the server to record more messages to the error log about what it is doing. With respect to replication, the server generates warnings that it succeeded in reconnecting after a network or connection failure, and provides information about how each slave thread started. This option is enabled (1) by default; to disable it, use `--log-warnings=0`. If the value is greater than 1, aborted connections are written to the error log, and access-denied errors for new connection attempts are written. See Section B.4.2.11, “Communication Errors and Aborted Connections”.

**Note**
The effects of this option are not limited to replication. It affects diagnostic messages across a spectrum of server activities.

- `--master-info-file=file_name`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--master-info-file=file_name</code></td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>master.info</td>
</tr>
</tbody>
</table>

The name to use for the file in which the slave records information about the master. The default name is `master.info` in the data directory. For information about the format of this file, see Section 17.2.2.2, “Slave Status Logs”.

- `--master-retry-count=count`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--master-retry-count=#</code></td>
</tr>
<tr>
<td>Deprecated</td>
<td>5.6.1</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>86400</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>
Replication and Binary Logging Options and Variables

The number of times that the slave tries to connect to the master before giving up. Reconnects are attempted at intervals set by the `MASTER_CONNECT_RETRY` option of the `CHANGE MASTER TO` statement (default 60). Reconnects are triggered when data reads by the slave time out according to the `--slave-net-timeout` option. The default value is 86400. A value of 0 means “infinite”; the slave attempts to connect forever.

This option is deprecated as of MySQL 5.6.1 and will be removed in a future MySQL release. Applications should be updated to use the `MASTER_RETRY_COUNT` option of the `CHANGE MASTER TO` statement instead.

- `--max-relay-log-size=size`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--max-relay-log-size=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>max_relay_log_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1073741824</td>
</tr>
</tbody>
</table>

The size at which the server rotates relay log files automatically. If this value is nonzero, the relay log is rotated automatically when its size exceeds this value. If this value is zero (the default), the size at which relay log rotation occurs is determined by the value of `max_binlog_size`. For more information, see Section 17.2.2.1, “The Slave Relay Log”.

- `--relay-log=file_name`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--relay-log=file_name</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>relay_log</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
</tbody>
</table>

The base name for the relay log. The default base name is `host_name-relay-bin`. The server writes the file in the data directory unless the base name is given with a leading absolute path name to specify a different directory. The server creates relay log files in sequence by adding a numeric suffix to the base name.

Due to the manner in which MySQL parses server options, if you specify this option, you must supply a value; the default base name is used only if the option is not actually specified. If you use the `--relay-log` option without specifying a value, unexpected behavior is likely to result; this behavior depends on the other options used, the order in which they are specified, and whether they are specified on the command line or in an option file. For more information about how MySQL handles server options, see Section 4.2.2, “Specifying Program Options”.
If you specify this option, the value specified is also used as the base name for the relay log index file. You can override this behavior by specifying a different relay log index file base name using the `--relay-log-index` option.

Starting with MySQL 5.6.5, when the server reads an entry from the index file, it checks whether the entry contains a relative path. If it does, the relative part of the path is replaced with the absolute path set using the `--relay-log` option. An absolute path remains unchanged; in such a case, the index must be edited manually to enable the new path or paths to be used. Prior to MySQL 5.6.5, manual intervention was required whenever relocating the binary log or relay log files. (Bug #11745230, Bug #12133)

You may find the `--relay-log` option useful in performing the following tasks:

- Creating relay logs whose names are independent of host names.
- If you need to put the relay logs in some area other than the data directory because your relay logs tend to be very large and you do not want to decrease `max_relay_log_size`.
- To increase speed by using load-balancing between disks.

Beginning with MySQL 5.6.2, you can obtain the relay log filename (and path) from the `relay_log_basename` system variable.

```
• --relay-log-index=file_name
```

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--relay-log-index=file_name</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>relay_log_index</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
</tbody>
</table>

The name for the relay log index file. The default name is `host_name-relay-bin.index` in the data directory, where `host_name` is the name of the slave server.

Due to the manner in which MySQL parses server options, if you specify this option, you must supply a value; the default base name is used only if the option is not actually specified. If you use the `--relay-log-index` option without specifying a value, unexpected behavior is likely to result; this behavior depends on the other options used, the order in which they are specified, and whether they are specified on the command line or in an option file. For more information about how MySQL handles server options, see Section 4.2.2, “Specifying Program Options”.

```
• --relay-log-info-file=file_name
```

<table>
<thead>
<tr>

<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--relay-log-info-file=file_name</code></td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>relay-log.info</code></td>
</tr>
</tbody>
</table>
Replication and Binary Logging Options and Variables

The name to use for the file in which the slave records information about the relay logs. The default name is `relay-log.info` in the data directory. For information about the format of this file, see Section 17.2.2.2, “Slave Status Logs”.

- `--relay-log-purge={0|1}`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--relay-log-purge[={OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>relay_log_purge</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

Disable or enable automatic purging of relay logs as soon as they are no longer needed. The default value is 1 (enabled). This is a global variable that can be changed dynamically with `SET GLOBAL relay_log_purge = N`. Disabling purging of relay logs when using the `--relay-log-recovery` option puts data consistency at risk.

- `--relay-log-recovery={0|1}`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--relay-log-recovery[={OFF</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Enables automatic relay log recovery immediately following server startup. The recovery process creates a new relay log file, initializes the SQL thread position to this new relay log, and initializes the I/O thread to the SQL thread position. Reading of the relay log from the master then continues. This should be used following an unexpected halt of a replication slave to ensure that no possibly corrupted relay logs are processed. The default value is 0 (disabled).

Enabling the `--relay-log-recovery` option when `relay-log-purge` is disabled risks reading the relay log from files that were not purged, leading to data inconsistency.

This option can be used to make replication slaves resilient to unexpected halts. See Section 17.3.2, “Handling an Unexpected Halt of a Replication Slave”, for more information.

Prior to MySQL 5.6.6, if this option is enabled for a multithreaded slave, and the slave fails with errors, you cannot execute `CHANGE MASTER TO` on that slave. In MySQL 5.6.6 or later, you can use `START SLAVE UNTIL SQL_AFTER_MTS_GAPS` to ensure that any gaps in the relay log are processed; after running this statement, you can then use `CHANGE MASTER TO` to fail this slave over to a new master. (Bug #13893363)

- `--relay-log-space-limit=size`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--relay-log-space-limit=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>relay_log_space_limit</code></td>
</tr>
</tbody>
</table>
### Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

This option places an upper limit on the total size in bytes of all relay logs on the slave. A value of 0 means “no limit”. This is useful for a slave server host that has limited disk space. When the limit is reached, the I/O thread stops reading binary log events from the master server until the SQL thread has caught up and deleted some unused relay logs. Note that this limit is not absolute: There are cases where the SQL thread needs more events before it can delete relay logs. In that case, the I/O thread exceeds the limit until it becomes possible for the SQL thread to delete some relay logs because not doing so would cause a deadlock. You should not set `--relay-log-space-limit` to less than twice the value of `--max-relay-log-size` (or `--max-binlog-size` if `--max-relay-log-size` is 0). In that case, there is a chance that the I/O thread waits for free space because `--relay-log-space-limit` is exceeded, but the SQL thread has no relay log to purge and is unable to satisfy the I/O thread. This forces the I/O thread to ignore `--relay-log-space-limit` temporarily.

- `--replicate-do-db=db_name`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--replicate-do-db=name</code></td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

The effects of this option depend on whether statement-based or row-based replication is in use.

**Statement-based replication.** Tell the slave SQL thread to restrict replication to statements where the default database (that is, the one selected by `USE`) is `db_name`. To specify more than one database, use this option multiple times, once for each database; however, doing so does not replicate cross-database statements such as `UPDATE some_db.some_table SET foo='bar'` while a different database (or no database) is selected.

**Warning**

To specify multiple databases you must use multiple instances of this option. Because database names can contain commas, if you supply a comma separated list then the list will be treated as the name of a single database.

An example of what does not work as you might expect when using statement-based replication: If the slave is started with `--replicate-do-db=sales` and you issue the following statements on the master, the `UPDATE` statement is not replicated:

```sql
USE prices;
UPDATE sales.january SET amount=amount+1000;
```
The main reason for this “check just the default database” behavior is that it is difficult from the statement alone to know whether it should be replicated (for example, if you are using multiple-table DELETE statements or multiple-table UPDATE statements that act across multiple databases). It is also faster to check only the default database rather than all databases if there is no need.

**Row-based replication.** Tells the slave SQL thread to restrict replication to database `db_name`. Only tables belonging to `db_name` are changed; the current database has no effect on this. Suppose that the slave is started with `--replicate-do-db=sales` and row-based replication is in effect, and then the following statements are run on the master:

```sql
USE prices;
UPDATE sales.february SET amount=amount+100;
```

The `february` table in the `sales` database on the slave is changed in accordance with the `UPDATE` statement; this occurs whether or not the `USE` statement was issued. However, issuing the following statements on the master has no effect on the slave when using row-based replication and `--replicate-do-db=sales`:

```sql
USE prices;
UPDATE prices.march SET amount=amount-25;
```

Even if the statement `USE prices` were changed to `USE sales`, the `UPDATE` statement’s effects would still not be replicated.

Another important difference in how `--replicate-do-db` is handled in statement-based replication as opposed to row-based replication occurs with regard to statements that refer to multiple databases. Suppose that the slave is started with `--replicate-do-db=db1`, and the following statements are executed on the master:

```sql
USE db1;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

If you are using statement-based replication, then both tables are updated on the slave. However, when using row-based replication, only `table1` is affected on the slave; since `table2` is in a different database, `table2` on the slave is not changed by the `UPDATE`. Now suppose that, instead of the `USE db1` statement, a `USE db4` statement had been used:

```sql
USE db4;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

In this case, the `UPDATE` statement would have no effect on the slave when using statement-based replication. However, if you are using row-based replication, the `UPDATE` would change `table1` on the slave, but not `table2`—in other words, only tables in the database named by `--replicate-do-db` are changed, and the choice of default database has no effect on this behavior.

If you need cross-database updates to work, use `--replicate-wild-do-table=db_name.%` instead. See Section 17.2.3, “How Servers Evaluate Replication Filtering Rules”.

---

**Note**

This option affects replication in the same manner that `--binlog-do-db` affects binary logging, and the effects of the replication format on how `--replicate-do-db` works.
Replication and Binary Logging Options and Variables

do-db affects replication behavior are the same as those of the logging format on the behavior of --binlog-do-db.
This option has no effect on BEGIN, COMMIT, or ROLLBACK statements.

• --replicate-ignore-db=db_name

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--replicate-ignore-db=name</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

As with --replicate-do-db, the effects of this option depend on whether statement-based or row-based replication is in use.

**Statement-based replication.** Tells the slave SQL thread not to replicate any statement where the default database (that is, the one selected by USE) is db_name.

**Row-based replication.** Tells the slave SQL thread not to update any tables in the database db_name. The default database has no effect.

When using statement-based replication, the following example does not work as you might expect. Suppose that the slave is started with --replicate-ignore-db=sales and you issue the following statements on the master:

```sql
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The UPDATE statement is replicated in such a case because --replicate-ignore-db applies only to the default database (determined by the USE statement). Because the sales database was specified explicitly in the statement, the statement has not been filtered. However, when using row-based replication, the UPDATE statement's effects are not propagated to the slave, and the slave's copy of the sales.january table is unchanged; in this instance, --replicate-ignore-db=sales causes all changes made to tables in the master's copy of the sales database to be ignored by the slave.

To specify more than one database to ignore, use this option multiple times, once for each database. Because database names can contain commas, if you supply a comma separated list then the list will be treated as the name of a single database.

You should not use this option if you are using cross-database updates and you do not want these updates to be replicated. See Section 17.2.3, “How Servers Evaluate Replication Filtering Rules”.

If you need cross-database updates to work, use --replicate-wild-ignore-table=db_name.% instead. See Section 17.2.3, “How Servers Evaluate Replication Filtering Rules”.

**Note**
This option affects replication in the same manner that --binlog-ignore-db affects binary logging, and the effects of the replication format on how --replicate-ignore-db affects replication behavior are the same as those of the logging format on the behavior of --binlog-ignore-db.

This option has no effect on BEGIN, COMMIT, or ROLLBACK statements.

• --replicate-do-table=db_name.tbl_name
Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--replicate-do-table=name</code></td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

Creates a replication filter by telling the slave SQL thread to restrict replication to a given table. To specify more than one table, use this option multiple times, once for each table. This works for both cross-database updates and default database updates, in contrast to `--replicate-do-db`. See Section 17.2.3, “How Servers Evaluate Replication Filtering Rules”.

This option affects only statements that apply to tables. It does not affect statements that apply only to other database objects, such as stored routines. To filter statements operating on stored routines, use one or more of the `--replicate-*-db` options.

- `--replicate-ignore-table=db_name.tbl_name`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--replicate-ignore-table=name</code></td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

Creates a replication filter by telling the slave SQL thread not to replicate any statement that updates the specified table, even if any other tables might be updated by the same statement. To specify more than one table to ignore, use this option multiple times, once for each table. This works for cross-database updates, in contrast to `--replicate-ignore-db`. See Section 17.2.3, “How Servers Evaluate Replication Filtering Rules”.

This option affects only statements that apply to tables. It does not affect statements that apply only to other database objects, such as stored routines. To filter statements operating on stored routines, use one or more of the `--replicate-*-db` options.

- `--replicate-rewrite-db=from_name->to_name`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--replicate-rewrite-db=old_name-&gt;new_name</code></td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

Tells the slave to create a replication filter that translates the default database (that is, the one selected by `USE`) to `to_name` if it was `from_name` on the master. Only statements involving tables are affected (not statements such as `CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE`), and only if `from_name` is the default database on the master. To specify multiple rewrites, use this option multiple times. The server uses the first one with a `from_name` value that matches. The database name translation is done before the `--replicate-*` rules are tested.

Statements in which table names are qualified with database names when using this option do not work with table-level replication filtering options such as `--replicate-do-table`. Suppose we have a database named `a` on the master, one named `b` on the slave, each containing a table `t`, and have started the master with `--replicate-rewrite-db='a->b'`. At a later point in time, we execute `DELETE FROM a.t` on the master. In this case, no relevant filtering rule works, for the reasons shown here:

1. `--replicate-do-table=a.t` does not work because the slave has table `t` in database `b`.
2. `--replicate-do-table=b.t` does not match the original statement and so is ignored.
3. `--replicate-do-table=*\.t` is handled identically to `--replicate-do-table=a\.t`, and thus does not work, either.

Similarly, the `--replication-rewrite-db` option does not work with cross-database updates.

If you use this option on the command line and the `>` character is special to your command interpreter, quote the option value. For example:

```
shell> mysqld --replicate-rewrite-db="olddb->newdb"
```

*Note* Prior to MySQL 5.6.7, multithreaded slaves did not honor this option correctly. (Bug #14232958)

- `--replicate-same-server-id`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--replicate-same-server-id=[{OFF</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

To be used on slave servers. Usually you should use the default setting of 0, to prevent infinite loops caused by circular replication. If set to 1, the slave does not skip events having its own server ID. Normally, this is useful only in rare configurations. Cannot be set to 1 if `--log-slave-updates` is used. By default, the slave I/O thread does not write binary log events to the relay log if they have the slave's server ID (this optimization helps save disk usage). If you want to use `--replicate-same-server-id`, be sure to start the slave with this option before you make the slave read its own events that you want the slave SQL thread to execute.

- `--replicate-wild-do-table=\*db_name.tbl_name`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--replicate-wild-do-table=name</code></td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

Creates a replication filter by telling the slave thread to restrict replication to statements where any of the updated tables match the specified database and table name patterns. Patterns can contain the `%` and `_` wildcard characters, which have the same meaning as for the `LIKE` pattern-matching operator. To specify more than one table, use this option multiple times, once for each table. This works for cross-database updates. See Section 17.2.3, “How Servers Evaluate Replication Filtering Rules”.

This option applies to tables, views, and triggers. It does not apply to stored procedures and functions, or events. To filter statements operating on the latter objects, use one or more of the `--replicate-*-db` options.

Example: `--replicate-wild-do-table=foo%\.*.bar%` replicates only updates that use a table where the database name starts with `foo` and the table name starts with `bar`.

If the table name pattern is `%`, it matches any table name and the option also applies to database-level statements (`CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE`). For example, if you use
--replicate-wild-do-table=foo%.% database-level statements are replicated if the database name matches the pattern foo%.

To include literal wildcard characters in the database or table name patterns, escape them with a backslash. For example, to replicate all tables of a database that is named my\own\%db, but not replicate tables from the my1own\AABC\db database, you should escape the _ and % characters like this: --replicate-wild-do-table=my\_own\%db. If you use the option on the command line, you might need to double the backslashes or quote the option value, depending on your command interpreter. For example, with the bash shell, you would need to type --replicate-wild-do-table=my\\\_own\\ %db.

- --replicate-wild-ignore-table=db_name.tbl_name

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--replicate-wild-ignore-table=name</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

Creates a replication filter which keeps the slave thread from replicating a statement in which any table matches the given wildcard pattern. To specify more than one table to ignore, use this option multiple times, once for each table. This works for cross-database updates. See Section 17.2.3, "How Servers Evaluate Replication Filtering Rules".

Example: --replicate-wild-ignore-table=foo%.bar% does not replicate updates that use a table where the database name starts with foo and the table name starts with bar.

For information about how matching works, see the description of the --replicate-wild-do-table option. The rules for including literal wildcard characters in the option value are the same as for --replicate-wild-ignore-table as well.

- --report-host=host_name

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--report-host=host_name</td>
</tr>
<tr>
<td>System Variable</td>
<td>report_host</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

The host name or IP address of the slave to be reported to the master during slave registration. This value appears in the output of SHOW SLAVE HOSTS on the master server. Leave the value unset if you do not want the slave to register itself with the master.

Note

It is not sufficient for the master to simply read the IP address of the slave from the TCP/IP socket after the slave connects. Due to NAT and other routing issues, that IP may not be valid for connecting to the slave from the master or other hosts.

- --report-password=password
Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--report-password=name</td>
</tr>
<tr>
<td>System Variable</td>
<td>report_password</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

The account password of the slave to be reported to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server if the master was started with `--show-slave-auth-info`.

Although the name of this option might imply otherwise, `--report-password` is not connected to the MySQL user privilege system and so is not necessarily (or even likely to be) the same as the password for the MySQL replication user account.

```
• --report-password=slave_port_num
```

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--report-port=port_num</td>
</tr>
<tr>
<td>System Variable</td>
<td>report_port</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value (&gt;= 5.6.5)</td>
<td>[slave_port]</td>
</tr>
<tr>
<td>Default Value (&lt;= 5.6.4)</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>65535</td>
</tr>
</tbody>
</table>

The TCP/IP port number for connecting to the slave, to be reported to the master during slave registration. Set this only if the slave is listening on a nondefault port or if you have a special tunnel from the master or other clients to the slave. If you are not sure, do not use this option.

Prior to MySQL 5.6.5, the default value for this option was 3306. In MySQL 5.6.5 and later, the value shown is the port number actually used by the slave (Bug #13333431). This change also affects the default value displayed by `SHOW SLAVE HOSTS`.

```
• --report-user=user_name
```

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--report-user=name</td>
</tr>
<tr>
<td>System Variable</td>
<td>report_user</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>
The account user name of the slave to be reported to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server if the master was started with `--show-slave-auth-info`.

Although the name of this option might imply otherwise, `--report-user` is not connected to the MySQL user privilege system and so is not necessarily (or even likely to be) the same as the name of the MySQL replication user account.

* `--slave-checkpoint-group= #`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--slave-checkpoint-group= #</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.3</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>512</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>32</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>524280</td>
</tr>
<tr>
<td>Block Size</td>
<td>8</td>
</tr>
</tbody>
</table>

Sets the maximum number of transactions that can be processed by a multithreaded slave before a checkpoint operation is called to update its status as shown by `SHOW SLAVE STATUS`. Setting this option has no effect on slaves for which multithreading is not enabled.

**Note**

Multithreaded slaves are not currently supported by NDB Cluster, which silently ignores the setting for this option. See Section 18.6.3, “Known Issues in NDB Cluster Replication”, for more information.

This option works in combination with the `--slave-checkpoint-period` option in such a way that, when either limit is exceeded, the checkpoint is executed and the counters tracking both the number of transactions and the time elapsed since the last checkpoint are reset.

The minimum allowed value for this option is 32, unless the server was built using `--with-debug`, in which case the minimum value is 1. The effective value is always a multiple of 8; you can set it to a value that is not such a multiple, but the server rounds it down to the next lower multiple of 8 before storing the value. (Exception: No such rounding is performed by the debug server.) Regardless of how the server was built, the default value is 512, and the maximum allowed value is 524280.

`--slave-checkpoint-group` was added in MySQL 5.6.3.

* `--slave-checkpoint-period= #`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--slave-checkpoint-period= #</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.3</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>300</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
</tbody>
</table>
Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum Value</td>
<td>4G</td>
</tr>
</tbody>
</table>

Sets the maximum time (in milliseconds) that is allowed to pass before a checkpoint operation is called to update the status of a multithreaded slave as shown by `SHOW SLAVE STATUS`. Setting this option has no effect on slaves for which multithreading is not enabled.

**Note**

Multithreaded slaves are not currently supported by NDB Cluster, which silently ignores the setting for this option. See Section 18.6.3, “Known Issues in NDB Cluster Replication”, for more information.

This option works in combination with the `--slave-checkpoint-group` option in such a way that, when either limit is exceeded, the checkpoint is executed and the counters tracking both the number of transactions and the time elapsed since the last checkpoint are reset.

The minimum allowed value for this option is 1, unless the server was built using `-DWITH_DEBUG`, in which case the minimum value is 0. Regardless of how the server was built, the default value is 300, and the maximum possible value is 4294967296 (4GB).

--slave-checkpoint-period was added in MySQL 5.6.3.

• --slave-parallel-workers

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--slave-parallel-workers=#</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.3</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1024</td>
</tr>
</tbody>
</table>

Sets the number of slave worker threads for executing replication events (transactions) in parallel. Setting this variable to 0 (the default) disables parallel execution. The maximum is 1024.

**Note**

Multithreaded slaves are not currently supported by NDB Cluster, which silently ignores the setting for this option. See Section 18.6.3, “Known Issues in NDB Cluster Replication”, for more information.

When parallel execution is enabled, the slave SQL thread acts as the coordinator for the slave worker threads, among which transactions are distributed on a per-database basis. This means that a worker thread on the slave can process successive transactions on a given database without waiting for updates to other databases to complete. The current implementation of multithreading on the slave assumes that the data is partitioned per database, and that updates within a given database occur in the same relative order as they do on the master, in order to work correctly. However, transactions do not need to be coordinated between any two databases.

Due to the fact that transactions on different databases can occur in a different order on the slave than on the master, checking for the most recently executed transaction does not guarantee that all previous...
transactions from the master have been executed on the slave. This has implications for logging and recovery when using a multithreaded slave. For information about how to interpret binary logging information when using multithreading on the slave, see Section 13.7.5.35, "SHOW SLAVE STATUS Syntax". In addition, this means that `START SLAVE UNTIL` is not supported with a multithreaded slave.

When multithreading is enabled, `slave_transaction_retries` is treated as equal to 0, and cannot be changed. (Currently, retrying of transactions is not supported with multithreaded slaves.)

You should also note that, in MySQL 5.6.7 and later, enforcing foreign key relationships between tables in different databases causes multithreaded slaves to use sequential rather than parallel mode, which can have a negative impact on performance. (Bug #14092635)

This option was added in MySQL 5.6.3.

- `--slave-pending-jobs-size-max=##`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--slave-pending-jobs-size-max=##</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.3</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>16M</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1024</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>16E1B</td>
</tr>
<tr>
<td>Block Size</td>
<td>1024</td>
</tr>
</tbody>
</table>

For multithreaded slaves, this option sets the maximum amount of memory (in bytes) available to slave worker queues holding events not yet applied. Setting this option has no effect on slaves for which multithreading is not enabled.

The minimum possible value for this option is 1024; the default is 16MB. The maximum possible value is 18446744073709551615 (16 exabytes). Values that are not exact multiples of 1024 are rounded down to the next-highest multiple of 1024 prior to being stored.

The value of this variable is a soft limit and can be set to match the normal workload. If an unusually large event exceeds this size, the transaction is held until all the slave workers have empty queues, and then processed. All subsequent transactions are held until the large transaction has been completed.

This option was added in MySQL 5.6.3.

- `--skip-slave-start`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--skip-slave-start=[{OFF</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Tells the slave server not to start the slave threads when the server starts. To start the threads later, use a `START SLAVE` statement.

- `--slave-load-tmpdir=dir_name`
Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--slave-load-tmpdir=dir_name</code></td>
</tr>
<tr>
<td>System Variable</td>
<td>slave_load_tmpdir</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
<tr>
<td>Default Value</td>
<td>Value of <code>--tmpdir</code></td>
</tr>
</tbody>
</table>

The name of the directory where the slave creates temporary files. This option is by default equal to the value of the `tmpdir` system variable. When the slave SQL thread replicates a `LOAD DATA` statement, it extracts the file to be loaded from the relay log into temporary files, and then loads these into the table. If the file loaded on the master is huge, the temporary files on the slave are huge, too. Therefore, it might be advisable to use this option to tell the slave to put temporary files in a directory located in some file system that has a lot of available space. In that case, the relay logs are huge as well, so you might also want to use the `--relay-log` option to place the relay logs in that file system.

The directory specified by this option should be located in a disk-based file system (not a memory-based file system) because the temporary files used to replicate `LOAD DATA` statements must survive machine restarts. The directory also should not be one that is cleared by the operating system during the system startup process.

- `slave-max-allowed-packet=bytes`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--slave-max-allowed-packet=#</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.6</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1073741824</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1024</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1073741824</td>
</tr>
</tbody>
</table>

In MySQL 5.6.6 and later, this option sets the maximum packet size in bytes for the slave SQL and I/O threads, so that large updates using row-based replication do not cause replication to fail because an update exceeded `max_allowed_packet`. (Bug #12400221, Bug #60926)

The corresponding server variable `slave_max_allowed_packet` always has a value that is a positive integer multiple of 1024; if you set it to some value that is not such a multiple, the value is automatically rounded down to the next highest multiple of 1024. (For example, if you start the server with `--slave-max-allowed-packet=10000`, the value used is 9216; setting 0 as the value causes 1024 to be used.) A truncation warning is issued in such cases.

The maximum (and default) value is 1073741824 (1 GB); the minimum is 1024.

- `--slave-net-timeout=seconds`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--slave-net-timeout=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td>slave_net_timeout</td>
</tr>
</tbody>
</table>
Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>3600</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
</tbody>
</table>

The number of seconds to wait for more data from the master before the slave considers the connection broken, aborts the read, and tries to reconnect. The first retry occurs immediately after the timeout. The interval between retries is controlled by the `MASTER_CONNECT_RETRY` option for the `CHANGE MASTER TO` statement, and the number of reconnection attempts is limited by the `--master-retry-count` option. The default is 3600 seconds (one hour).

- `slave-rows-search-algorithms=list`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--slave-rows-search-algorithms=list</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.6</td>
</tr>
<tr>
<td>Type</td>
<td>Set</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>TABLE_SCAN, INDEX_SCAN</code></td>
</tr>
</tbody>
</table>

When preparing batches of rows for row-based logging and replication, this option controls how the rows are searched for matches—that is, whether or not hashing is used for searches using a primary or unique key, some other key, or no key at all. The option sets the initial value for the `slave_rows_search_algorithms` system variable.

Specify a comma-separated list of any 2 (or all 3) values from the list `INDEX_SCAN, TABLE_SCAN, HASH_SCAN`. The list need not be quoted, but must contain no spaces, whether or not quotes are used. Possible combinations (lists) and their effects are shown in the following table:

<table>
<thead>
<tr>
<th>Index used / option value</th>
<th><code>INDEX_SCAN, HASH_SCAN</code></th>
<th><code>INDEX_SCAN, TABLE_SCAN</code></th>
<th><code>TABLE_SCAN, HASH_SCAN</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Primary key or unique key</td>
<td>Index scan</td>
<td>Index scan</td>
<td>Hash scan over index</td>
</tr>
<tr>
<td>(Other) Key</td>
<td>Hash scan over index</td>
<td>Index scan</td>
<td>Hash scan over index</td>
</tr>
<tr>
<td>No index</td>
<td>Hash scan</td>
<td>Table scan</td>
<td>Hash scan</td>
</tr>
</tbody>
</table>

The order in which the algorithms are specified in the list does not make any difference in the order in which they are displayed by a `SELECT` or `SHOW VARIABLES` statement (which is the same as that used in the table just shown previously).
• The default value is \texttt{TABLE\_SCAN}, \texttt{INDEX\_SCAN}, which means that all searches that can use indexes do use them, and searches without any indexes use table scans.

• To use hashing for any searches that do not use a primary or unique key, set this option to \texttt{INDEX\_SCAN}, \texttt{HASH\_SCAN}. Specifying \texttt{INDEX\_SCAN}, \texttt{TABLE\_SCAN}, \texttt{HASH\_SCAN} has the same effect as specifying \texttt{INDEX\_SCAN}, \texttt{HASH\_SCAN}.

• To force hashing for all searches, set this option to \texttt{TABLE\_SCAN}, \texttt{HASH\_SCAN}.

It is possible to specify single values for this option, but this is not optimal, because setting a single value limits searches to using only that algorithm. In particular, setting \texttt{INDEX\_SCAN} alone is not recommended, as in that case searches are unable to find rows at all if no index is present.

\begin{itemize}
\item\textbf{Note} \vspace{1em}
There is only a performance advantage for \texttt{INDEX\_SCAN} and \texttt{HASH\_SCAN} if the row events are big enough. The size of row events is configured using \texttt{--binlog-row-event-max-size}. For example, suppose a DELETE statement which deletes 25,000 rows generates large \texttt{Delete\_row\_event} events. In this case if \texttt{slave_rows_search_algorithms} is set to \texttt{INDEX\_SCAN} or \texttt{HASH\_SCAN} there is a performance improvement. However, if there are 25,000 DELETE statements and each is represented by a separate event then setting \texttt{slave_rows_search_algorithms} to \texttt{INDEX\_SCAN} or \texttt{HASH\_SCAN} provides no performance improvement while executing these separate events.
\end{itemize}

This option was added in MySQL 5.6.6.

• \texttt{--slave-skip-errors=[err\_code1,err\_code2,...]|all|ddl\_exist\_errors} \\

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>\texttt{--slave-skip-errors=_name}</td>
</tr>
<tr>
<td>System Variable</td>
<td>slave_skip_errors</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
<tr>
<td>Valid Values</td>
<td>OFF</td>
</tr>
<tr>
<td></td>
<td>[list of error codes]</td>
</tr>
<tr>
<td></td>
<td>all</td>
</tr>
<tr>
<td></td>
<td>ddl_exist_errors</td>
</tr>
</tbody>
</table>

Normally, replication stops when an error occurs on the slave. This gives you the opportunity to resolve the inconsistency in the data manually. This option tells the slave SQL thread to continue replication when a statement returns any of the errors listed in the option value.

Do not use this option unless you fully understand why you are getting errors. If there are no bugs in your replication setup and client programs, and no bugs in MySQL itself, an error that stops replication should never occur. Indiscriminate use of this option results in slaves becoming hopelessly out of synchrony with the master, with you having no idea why this has occurred.
For error codes, you should use the numbers provided by the error message in your slave error log and in the output of `SHOW SLAVE STATUS`. Appendix B, *Errors, Error Codes, and Common Problems*, lists server error codes.

You can also (but should not) use the very nonrecommended value of `all` to cause the slave to ignore all error messages and keeps going regardless of what happens. Needless to say, if you use `all`, there are no guarantees regarding the integrity of your data. Please do not complain (or file bug reports) in this case if the slave's data is not anywhere close to what it is on the master. *You have been warned.*

MySQL 5.6 as well as MySQL NDB Cluster 7.3 and later support an additional shorthand value `ddl_exist_errors`, which is equivalent to the error code list `1007,1008,1050,1051,1054,1060,1061,1068,1094,1146`.

Examples:

```
--slave-skip-errors=1062,1053
--slave-skip-errors=all
--slave-skip-errors=ddl_exist_errors
```

```
--slave-sql-verify-checksum={0|1}
```

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--slave-sql-verify-checksum={OFF</td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.2</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

When this option is enabled, the slave examines checksums read from the relay log, in the event of a mismatch, the slave stops with an error.

This option was added in MySQL 5.6.2.

**Options for Logging Slave Status to Tables**

MySQL 5.6 and later supports logging of replication slave status information to tables rather than files. Writing of the master info log and the relay log info log can be configured separately using two server options added in MySQL 5.6.2 and listed here:

```
--master-info-repository={FILE|TABLE}
```

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--master-info-repository={FILE</td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.2</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>FILE</td>
</tr>
<tr>
<td>Valid Values</td>
<td>FILE</td>
</tr>
<tr>
<td></td>
<td>TABLE</td>
</tr>
</tbody>
</table>

This option causes the server to write its master info log to a file or a table. The name of the file defaults to `master.info`; you can change the name of the file using the `--master-info-file` server option.
The default value for this option is `FILE`. If you use `TABLE`, the log is written to the `slave_master_info` table in the `mysql` database.

The `--master-info-repository` option was added in MySQL 5.6.2.

- `--relay-log-info-repository={FILE|TABLE}`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--relay-log-info-repository={FILE</td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.2</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>FILE</code></td>
</tr>
<tr>
<td>Valid Values</td>
<td><code>FILE</code></td>
</tr>
</tbody>
</table>

This option causes the server to log its relay log info to a file or a table. The name of the file defaults to `relay-log.info`; you can change the name of the file using the `--relay-log-info-file` server option.

The default value for this option is `FILE`. If you use `TABLE`, the log is written to the `slave_relay_log_info` table in the `mysql` database.

This option can be used to make replication slaves resilient to unexpected halts. See Section 17.3.2, “Handling an Unexpected Halt of a Replication Slave”, for more information.

The `--relay-log-info-repository` option was added in MySQL 5.6.2.

The info log tables and their contents are considered local to a given MySQL Server. In MySQL 5.6.9 and later, they are not replicated, and changes to them are not written to the binary log. (Bug #14741537)

For more information, see Section 17.2.2, “Replication Relay and Status Logs”.

### Obsolete Replication Slave Options

The following options have been removed and replaced by the functions of the `CHANGE MASTER TO` ... statement (see Section 13.4.2.1, “CHANGE MASTER TO Syntax”). If you attempt to start `mysqld` with any of these options in MySQL 5.6, the server aborts with an `unknown variable` error.

- `--master-host`
- `--master-user`
- `--master-password`
- `--master-port`
- `--master-connect-retry`
- `--master-ssl`
- `--master-ssl-ca`
- `--master-ssl-capath`
- `--master-ssl-cert`
Replication and Binary Logging Options and Variables

- `--master-ssl-cipher`
- `--master-ssl-key`

System Variables Used on Replication Slaves

The following list describes system variables for controlling replication slave servers. They can be set at server startup and some of them can be changed at runtime using `SET`. Server options used with replication slaves are listed earlier in this section.

- `init_slave`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--init-slave=name</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>init_slave</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

This variable is similar to `init_connect`, but is a string to be executed by a slave server each time the SQL thread starts. The format of the string is the same as for the `init_connect` variable.

**Note**

The SQL thread sends an acknowledgment to the client before it executes `init_slave`. Therefore, it is not guaranteed that `init_slave` has been executed when `START_SLAVE` returns. See Section 13.4.2.5, “START SLAVE Syntax”, for more information.

- `log_slow_slave_statements`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--log-slow-slave-statements=[{OFF</td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.11</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>log_slow_slave_statements</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

When the slow query log is enabled, this variable enables logging for queries that have taken more than `long_query_time` seconds to execute on the slave. This variable was added in MySQL 5.6.11.

Note that all statements logged in row format in the master will not be logged in the slave’s slow log, even if `log_slow_slave_statements` is enabled.

- `master_info_repository`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--master-info-repository=(FILE</td>
</tr>
</tbody>
</table>
### Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>5.6.2</td>
</tr>
<tr>
<td>System Variable</td>
<td>master_info_repository</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>FILE</td>
</tr>
<tr>
<td>Valid Values</td>
<td>FILE</td>
</tr>
<tr>
<td></td>
<td>TABLE</td>
</tr>
</tbody>
</table>

The setting of this variable determines whether the slave logs master status and connection information to a **FILE** (`master.info`), or to a **TABLE** (`mysql.slave_master_info`).

The setting of this variable also has a direct bearing on the effect had by the setting of the `sync_master_info` system variable; see that variable's description for further information.

This variable was added in MySQL 5.6.2.

• **max_relay_log_size**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--max-relay-log-size=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>max_relay_log_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1073741824</td>
</tr>
</tbody>
</table>

If a write by a replication slave to its relay log causes the current log file size to exceed the value of this variable, the slave rotates the relay logs (closes the current file and opens the next one). If `max_relay_log_size` is 0, the server uses `max_binlog_size` for both the binary log and the relay log. If `max_relay_log_size` is greater than 0, it constrains the size of the relay log, which enables you to have different sizes for the two logs. You must set `max_relay_log_size` to between 4096 bytes and 1GB (inclusive), or to 0. The default value is 0. See Section 17.2.1, “Replication Implementation Details”.

• **relay_log**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--relay-log=file_name</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>relay_log</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
</tbody>
</table>
The name of the relay log file.

- **relay_log_basename**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>5.6.2</td>
</tr>
<tr>
<td>System Variable</td>
<td>relay_log_basename</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>datadir + '/' + hostname + '-relay-bin'</td>
</tr>
</tbody>
</table>

Holds the name and complete path to the relay log file. This variable is set by the server and is read only.

The `relay_log_basename` system variable was added in MySQL 5.6.2.

- **relay_log_index**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--relay-log-index=file_name</td>
</tr>
<tr>
<td>System Variable</td>
<td>relay_log_index</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td><em>host_name</em>-relay-bin.index</td>
</tr>
</tbody>
</table>

The name of the relay log index file. The default name is `host_name-relay-bin.index` in the data directory, where `host_name` is the name of the slave server.

- **relay_log_info_file**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--relay-log-info-file=file_name</td>
</tr>
<tr>
<td>System Variable</td>
<td>relay_log_info_file</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>relay-log.info</td>
</tr>
</tbody>
</table>

The name of the file in which the slave records information about the relay logs. The default name is `relay-log.info` in the data directory.

- **relay_log_info_repository**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--relay-log-info-repository=value</td>
</tr>
</tbody>
</table>
This variable determines whether the slave’s position in the relay logs is written to a `FILE` (`relay-log.info`) or to a `TABLE` (`mysql.slave_relay_log_info`).

The setting of this variable also has a direct bearing on the effect had by the setting of the `sync_relay_log_info` system variable; see that variable’s description for further information.

This variable was added in MySQL 5.6.2.

- **relay_log_purge**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--relay-log-purge=[{OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>relay_log_purge</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

Disables or enables automatic purging of relay log files as soon as they are not needed any more. The default value is 1 (`ON`).

- **relay_log_recovery**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--relay-log-recovery=[{OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>relay_log_recovery</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic (&gt;= 5.6.6)</td>
<td>No</td>
</tr>
<tr>
<td>Dynamic (&lt;= 5.6.5)</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Enables automatic relay log recovery immediately following server startup. The recovery process creates a new relay log file, initializes the SQL thread position to this new relay log, and initializes the I/O thread to the SQL thread position. Reading of the relay log from the master then continues. In MySQL 5.6.5 and earlier, it was possible to change this global variable dynamically; beginning with MySQL 5.6.6.
it is read-only. (Bug #13840948) Regardless of the MySQL Server version, its value can be changed by starting the slave with the `--relay-log-recovery` option, which should be used following a unexpected halt on the replication slave to ensure that no possibly corrupted relay logs are processed. See Section 17.3.2, “Handling an Unexpected Halt of a Replication Slave” for more information.

When `relay_log_recovery` is enabled and the slave has stopped due to errors encountered while running in multithreaded mode, you cannot execute `CHANGE MASTER TO` if there are any gaps in the log. Beginning with MySQL 5.6.6, you should use `START SLAVE UNTIL SQL_AFTER_MTS_GAPS` to ensure that all gaps are processed before switching back to single-threaded mode or executing a `CHANGE MASTER TO` statement.

- `relay_log_space_limit`

```
<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--relay-log-space-limit=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>relay_log_space_limit</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td></td>
</tr>
<tr>
<td>(64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>(32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>
```

The maximum amount of space to use for all relay logs.

- `report_host`

```
<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--report-host=host_name</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>report_host</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>
```

The value of the `--report-host` option.

- `report_password`

```
<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--report-password=name</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>report_password</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>
```
The value of the `--report-password` option. Not the same as the password used for the MySQL replication user account.

- **report_port**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--report-port=port_num</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>report_port</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value (&gt;= 5.6.5)</td>
<td><code>[slave_port]</code></td>
</tr>
<tr>
<td>Default Value (&lt;= 5.6.4)</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>65535</td>
</tr>
</tbody>
</table>

The value of the `--report-port` option.

- **report_user**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--report-user=name</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>report_user</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

The value of the `--report-user` option. Not the same as the name for the MySQL replication user account.

- **rpl_semi_sync_slave_enabled**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--rpl-semi-sync-slave-enabled=[{OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>rpl_semi_sync_slave_enabled</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Controls whether semisynchronous replication is enabled on the slave. To enable or disable the plugin, set this variable to ON or OFF (or 1 or 0), respectively. The default is OFF.

This variable is available only if the slave-side semisynchronous replication plugin is installed.

- **rpl_semi_sync_slave_trace_level**
Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--rpl-semi-sync-slave-trace-level=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>rpl_semi_sync_slave_trace_level</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>32</td>
</tr>
</tbody>
</table>

The semisynchronous replication debug trace level on the slave. See `rpl_semi_sync_master_trace_level` for the permissible values.

This variable is available only if the slave-side semisynchronous replication plugin is installed.

- `rpl_stop_slave_timeout`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--rpl-stop-slave-timeout=seconds</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.13</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>rpl_stop_slave_timeout</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>31536000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>2</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>31536000</td>
</tr>
</tbody>
</table>

In MySQL 5.6.13 and later, you can control the length of time (in seconds) that `STOP SLAVE` waits before timing out by setting this variable. This can be used to avoid deadlocks between `STOP SLAVE` and other slave SQL statements using different client connections to the slave.

The maximum and default value of `rpl_stop_slave_timeout` is 31536000 seconds (1 year). The minimum is 2 seconds. Changes to this variable take effect for subsequent `STOP SLAVE` statements.

This variable affects only the client that issues a `STOP SLAVE` statement. When the timeout is reached, the issuing client returns an error message stating that the command execution is incomplete. The client then stops waiting for the slave threads to stop, but the slave threads continue to try to stop, and the `STOP SLAVE` instruction remains in effect. Once the slave threads are no longer busy, the `STOP SLAVE` statement is executed and the slave stops.

- `slave_checkpoint_group`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--slave-checkpoint-group=#</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.3</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>slave_checkpoint_group</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
</tbody>
</table>
Sets the maximum number of transactions that can be processed by a multithreaded slave before a checkpoint operation is called to update its status as shown by `SHOW SLAVE STATUS`. Setting this variable has no effect on slaves for which multithreading is not enabled.

```
Note
```

Multithreaded slaves are not currently supported by NDB Cluster, which silently ignores the setting for this variable. See [Section 18.6.3, “Known Issues in NDB Cluster Replication”](#), for more information.

This variable works in combination with the `slave_checkpoint_period` system variable in such a way that, when either limit is exceeded, the checkpoint is executed and the counters tracking both the number of transactions and the time elapsed since the last checkpoint are reset.

The minimum allowed value for this variable is 32, unless the server was built using `-DWITH_DEBUG`, in which case the minimum value is 1. The effective value is always a multiple of 8; you can set it to a value that is not such a multiple, but the server rounds it down to the next lower multiple of 8 before storing the value. *(Exception: No such rounding is performed by the debug server.)* Regardless of how the server was built, the default value is 512, and the maximum allowed value is 524280.

- `slave_checkpoint_group` was added in MySQL 5.6.3.

```
• slave_checkpoint_period
```

Sets the maximum time (in milliseconds) that is allowed to pass before a checkpoint operation is called to update the status of a multithreaded slave as shown by `SHOW SLAVE STATUS`. Setting this variable has no effect on slaves for which multithreading is not enabled.
Multithreaded slaves are not currently supported by NDB Cluster, which silently ignores the setting for this variable. See Section 18.6.3, “Known Issues in NDB Cluster Replication”, for more information.

This variable works in combination with the `slave_checkpoint_group` system variable in such a way that, when either limit is exceeded, the checkpoint is executed and the counters tracking both the number of transactions and the time elapsed since the last checkpoint are reset.

The minimum allowed value for this variable is 1, unless the server was built using `-DWITH_DEBUG`, in which case the minimum value is 0. Regardless of how the server was built, the default value is 300, and the maximum possible value is 4294967296 (4GB).

`slave_checkpoint_period` was added in MySQL 5.6.3.

- **slave_compressed_protocol**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--slave-compressed-protocol[={OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>slave_compressed_protocol</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Whether to use compression of the master/slave protocol if both master and slave support it. If this variable is disabled (the default), connections are uncompressed. See also Section 4.2.5, “Connection Compression Control”.

- **slave_exec_mode**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--slave-exec-mode=mode</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>slave_exec_mode</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>IDEMPOTENT (NDB)</td>
</tr>
<tr>
<td></td>
<td>STRICT (Other)</td>
</tr>
<tr>
<td>Valid Values</td>
<td>IDEMPOTENT</td>
</tr>
<tr>
<td></td>
<td>STRICT</td>
</tr>
</tbody>
</table>

Controls how a slave thread resolves conflicts and errors during replication. **IDEMPOTENT** mode causes suppression of duplicate-key and no-key-found errors; **STRICT** means no such suppression takes place.

**IDEMPOTENT** mode is intended for use in multi-master replication, circular replication, and some other special replication scenarios for NDB Cluster Replication. (See Section 18.6.10, “NDB
Cluster Replication: Multi-Master and Circular Replication", and Section 18.6.11, “NDB Cluster Replication Conflict Resolution”, for more information.) NDB Cluster ignores any value explicitly set for slave_exec_mode, and always treats it as IDEMPOTENT.

In MySQL Server 5.6, STRICT mode is the default value.

For storage engines other than NDB, IDEMPOTENT mode should be used only when you are absolutely sure that duplicate-key errors and key-not-found errors can safely be ignored. It is meant to be used in fail-over scenarios for NDB Cluster where multi-master replication or circular replication is employed, and is not recommended for use in other cases.

• slave_load_tmpdir

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--slave-load-tmpdir=dir_name</td>
</tr>
<tr>
<td>System Variable</td>
<td>slave_load_tmpdir</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
<tr>
<td>Default Value</td>
<td>Value of --tmpdir</td>
</tr>
</tbody>
</table>

The name of the directory where the slave creates temporary files. Setting this variable takes effect for all replication channels immediately, including running channels. This system variable is by default equal to the value of the tmpdir system variable, or the default that applies when that system variable is not specified.

When the slave SQL thread replicates a LOAD DATA statement, it extracts the file to be loaded from the relay log into temporary files, and then loads these into the table. If the file loaded on the master is huge, the temporary files on the slave are huge, too. Therefore, it might be advisable to use this option to tell the slave to put temporary files in a directory located in some file system that has a lot of available space. In that case, the relay logs are huge as well, so you might also want to use the --relay-log option to place the relay logs in that file system.

The directory specified by this option should be located in a disk-based file system (not a memory-based file system) so that the temporary files used to replicate LOAD DATA statements can survive machine restarts. The directory also should not be one that is cleared by the operating system during the system startup process. However, replication can now continue after a restart if the temporary files have been removed.

• slave_max_allowed_packet

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--slave-max-allowed-packet=#</td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.6</td>
</tr>
<tr>
<td>System Variable</td>
<td>slave_max_allowed_packet</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1073741824</td>
</tr>
</tbody>
</table>
Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum Value</td>
<td>1024</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1073741824</td>
</tr>
</tbody>
</table>

In MySQL 5.6.6 and later, this variable sets the maximum packet size for the slave SQL and I/O threads, so that large updates using row-based replication do not cause replication to fail because an update exceeded `max_allowed_packet`.

This global variable always has a value that is a positive integer multiple of 1024; if you set it to some value that is not, the value is rounded down to the next highest multiple of 1024 for it is stored or used; setting `slave_max_allowed_packet` to 0 causes 1024 to be used. (A truncation warning is issued in all such cases.) The default and maximum value is 1073741824 (1 GB); the minimum is 1024.

`slave_max_allowed_packet` can also be set at startup, using the `--slave-max-allowed-packet` option.

- **slave_net_timeout**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--slave-net-timeout=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>slave_net_timeout</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>3600</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
</tbody>
</table>

The number of seconds to wait for more data from a master/slave connection before aborting the read.

- **slave_parallel_workers**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--slave-parallel-workers=#</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.3</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>slave_parallel_workers</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1024</td>
</tr>
</tbody>
</table>

Sets the number of slave worker threads for executing replication events (transactions) in parallel. Setting this variable to 0 (the default) disables parallel execution. The maximum is 1024.
Multithreaded slaves are not currently supported by NDB Cluster, which silently ignores the setting for this variable. See Section 18.6.3, “Known Issues in NDB Cluster Replication”, for more information.

When parallel execution is enabled, the slave SQL thread acts as the coordinator for the slave worker threads, among which transactions are distributed on a per-database basis. This means that a worker thread on the slave can process successive transactions on a given database without waiting for updates to other databases to complete. The current implementation of multithreading on the slave assumes that the data is partitioned per database, and that updates within a given database occur in the same relative order as they do on the master, in order to work correctly. However, transactions do not need to be coordinated between any two databases.

Due to the fact that transactions on different databases can occur in a different order on the slave than on the master, checking for the most recently executed transaction does not guarantee that all previous transactions from the master have been executed on the slave. This has implications for logging and recovery when using a multithreaded slave. For information about how to interpret binary logging information when using multithreading on the slave, see Section 13.7.5.35, “SHOW SLAVE STATUS Syntax”. In addition, this means that `START SLAVE UNTIL` is not supported with a multithreaded slave.

When multithreading is enabled, `slave_transaction_retries` is treated as equal to 0, and cannot be changed. (Currently, retrying of transactions is not supported with multithreaded slaves.)

This variable was added in MySQL 5.6.3.

- `slave_pending_jobs_size_max`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--slave-pending-jobs-size-max=#</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.3</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>slave_pending_jobs_size_max</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>16M</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1024</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>16EiB</td>
</tr>
<tr>
<td>Block Size</td>
<td>1024</td>
</tr>
</tbody>
</table>

For multithreaded slaves, this variable sets the maximum amount of memory (in bytes) available to slave worker queues holding events not yet applied. Setting this variable has no effect on slaves for which multithreading is not enabled.

The minimum possible value for this variable is 1024; the default is 16MB. The maximum possible value is 18446744073709551615 (16 exabytes). Values that are not exact multiples of 1024 are rounded down to the next-highest multiple of 1024 prior to being stored.
The value of this variable is a soft limit and can be set to match the normal workload. If an unusually large event exceeds this size, the transaction is held until all the slave workers have empty queues, and then processed. All subsequent transactions are held until the large transaction has been completed.

`slave_pending_jobs_size_max` was added in MySQL 5.6.3.

• `slave_rows_search_algorithms`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--slave-rows-search-algorithms=value</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.6</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>slave_rows_search_algorithms</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Set</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>TABLE_SCAN, INDEX_SCAN</code></td>
</tr>
<tr>
<td>Valid Values</td>
<td><code>TABLE_SCAN, INDEX_SCAN</code></td>
</tr>
<tr>
<td></td>
<td><code>INDEX_SCAN, HASH_SCAN</code></td>
</tr>
<tr>
<td></td>
<td><code>TABLE_SCAN, HASH_SCAN</code></td>
</tr>
<tr>
<td></td>
<td><code>TABLE_SCAN, INDEX_SCAN, HASH_SCAN</code> (equivalent to <code>INDEX_SCAN,HASH_SCAN</code>)</td>
</tr>
</tbody>
</table>

When preparing batches of rows for row-based logging and replication, this variable controls how the rows are searched for matches—that is, whether or not hashing is used for searches using a primary or unique key, some other key, or using no key at all. Setting this variable takes effect for all replication channels immediately, including running channels. The initial setting for the system variable can be specified using the `--slave-rows-search-algorithms` option.

Specify a comma-separated list of any 2 (or all 3) values from the list `INDEX_SCAN, TABLE_SCAN, HASH_SCAN`. The value is expected as a string, so the value must be quoted. In addition, the value must not contain any spaces. Possible combinations (lists) and their effects are shown in the following table:

<table>
<thead>
<tr>
<th>Index used / option value</th>
<th>INDEX_SCAN, HASH_SCAN or INDEX_SCAN, TABLE_SCAN, HASH_SCAN</th>
<th>INDEX_SCAN, TABLE_SCAN, HASH_SCAN</th>
</tr>
</thead>
<tbody>
<tr>
<td>Primary key or unique key</td>
<td>Index scan</td>
<td>Index scan</td>
</tr>
<tr>
<td></td>
<td>Hash scan over index</td>
<td>Hash scan over index</td>
</tr>
<tr>
<td>(Other) Key</td>
<td>Hash scan over index</td>
<td>Index scan</td>
</tr>
<tr>
<td></td>
<td>Hash scan over index</td>
<td>Hash scan over index</td>
</tr>
<tr>
<td>No index</td>
<td>Hash scan</td>
<td>Table scan</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Hash scan</td>
</tr>
</tbody>
</table>

The order in which the algorithms are specified in the list does not make any difference in the order in which they are displayed by a `SELECT` or `SHOW VARIABLES` statement (which is the same as that used in the table just shown previously).

• The default value is `TABLE_SCAN, INDEX_SCAN`, which means that all searches that can use indexes do use them, and searches without any indexes use table scans.
Replication and Binary Logging Options and Variables

- To use hashing for any searches that do not use a primary or unique key, set this option to `INDEX_SCAN,HASH_SCAN`. Specifying `INDEX_SCAN,TABLE_SCAN,HASH_SCAN` has the same effect as specifying `INDEX_SCAN,HASH_SCAN`.

- To force hashing for all searches, set this option to `TABLE_SCAN,HASH_SCAN`.

It is possible to specify single values for this option, but this is not optimal, because setting a single value limits searches to using only that algorithm. In particular, setting `INDEX_SCAN` alone is not recommended, as in that case searches are unable to find rows at all if no index is present.

**Note**

There is only a performance advantage for `INDEX_SCAN` and `HASH_SCAN` if the row events are big enough. The size of row events is configured using `--binlog-row-event-max-size`. For example, suppose a `DELETE` statement which deletes 25,000 rows generates large `Delete_row_event` events. In this case if `slave_rows_search_algorithms` is set to `INDEX_SCAN` or `HASH_SCAN` there is a performance improvement. However, if there are 25,000 `DELETE` statements and each is represented by a separate event then setting `slave_rows_search_algorithms` to `INDEX_SCAN` or `HASH_SCAN` provides no performance improvement while executing these separate events.

This option was added in MySQL 5.6.6.

- `slave_skip_errors`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--slave-skip-errors=name</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>slave_skip_errors</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
<tr>
<td>Valid Values</td>
<td>OFF</td>
</tr>
<tr>
<td></td>
<td>[list of error codes]</td>
</tr>
<tr>
<td></td>
<td>all</td>
</tr>
<tr>
<td></td>
<td><code>ddl_exist_errors</code></td>
</tr>
</tbody>
</table>

Normally, replication stops when an error occurs on the slave. This gives you the opportunity to resolve the inconsistency in the data manually. This variable tells the slave SQL thread to continue replication when a statement returns any of the errors listed in the variable value.

- `slave_sql_verify_checksum`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--slave-sql-verify-checksum=[OFF</td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.2</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>slave_sql_verify_checksum</code></td>
</tr>
</tbody>
</table>
Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>slave_sql_verify_checksum</strong></td>
<td>Cause the slave SQL thread to verify data using the checksums read from the relay log. In the event of a mismatch, the slave stops with an error.</td>
</tr>
<tr>
<td><strong>slave_transaction_retries</strong></td>
<td>If a replication slave SQL thread fails to execute a transaction because of an InnoDB deadlock or because the transaction's execution time exceeded InnoDB's <code>innodb_lock_wait_timeout</code> or NDB's <code>TransactionDeadlockDetectionTimeout</code> or <code>TransactionInactiveTimeout</code>, it automatically retries <code>slave_transaction_retries</code> times before stopping with an error. The default value is 10.</td>
</tr>
<tr>
<td><strong>slave_type_conversions</strong></td>
<td>Transactions cannot be retried when using a multithreaded slave. In other words, whenever <code>slave_parallel_workers</code> is greater than 0, <code>slave_transaction_retries</code> is treated as equal to 0, and cannot be changed.</td>
</tr>
</tbody>
</table>

---

### slave_sql_verify_checksum

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Property</strong></td>
<td><strong>Value</strong></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

Note

The slave I/O thread always reads checksums if possible when accepting events from over the network.

*slave_sql_verify_checksum* was added in MySQL 5.6.2.

### slave_transaction_retries

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td><code>--slave-transaction-retries=#</code></td>
</tr>
<tr>
<td><strong>System Variable</strong></td>

<td>Set</td>
</tr>
</tbody>
</table>
Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>Value</td>
</tr>
<tr>
<td>Valid Values (&gt;= 5.6.13)</td>
<td>ALL_LOSSY, ALL_NON_LOSSY, ALL_SIGNED, ALL_UNSIGNED</td>
</tr>
<tr>
<td>Valid Values (&lt;= 5.6.12)</td>
<td>ALL_LOSSY, ALL_NON_LOSSY</td>
</tr>
</tbody>
</table>

Controls the type conversion mode in effect on the slave when using row-based replication. In MySQL 5.6.13 and later, its value is a comma-delimited set of zero or more elements from the list: ALL_LOSSY, ALL_NON_LOSSY, ALL_SIGNED, ALL_UNSIGNED. Set this variable to an empty string to disallow type conversions between the master and the slave. Changes require a restart of the slave to take effect.

ALL_SIGNED and ALL_UNSIGNED were added in MySQL 5.6.13 (Bug#15831300). For additional information on type conversion modes applicable to attribute promotion and demotion in row-based replication, see Row-based replication: attribute promotion and demotion.

- **sql_slave_skip_counter**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>sql_slave_skip_counter</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
</tbody>
</table>

The number of events from the master that a slave server should skip.

This option is incompatible with GTID-based replication, and must not be set to a nonzero value when --gtid-mode=ON. In MySQL 5.6.10 and later, trying to do so is specifically disallowed. (Bug #15833516) If you need to skip transactions when employing GTIDs, use gtid_executed from the master instead. See Injecting empty transactions, for information about how to do this.

Important

If skipping the number of events specified by setting this variable would cause the slave to begin in the middle of an event group, the slave continues to skip until it finds the beginning of the next event group and begins from that point. For more information, see Section 13.4.2.4, “SET GLOBAL sql_slave_skip_counter Syntax”.

- **sync_master_info**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--sync-master-info=#</td>
</tr>
<tr>
<td>System Variable</td>
<td>sync_master_info</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
</tbody>
</table>
The effects of this variable on a replication slave depend on whether the slave's `master_info_repository` is set to `FILE` or `TABLE`, as explained in the following paragraphs.

**master_info_repository = FILE.** If the value of `sync_master_info` is greater than 0, the slave synchronizes its `master.info` file to disk (using `fdatasync()`) after every `sync_master_info` events. If it is 0, the MySQL server performs no synchronization of the `master.info` file to disk; instead, the server relies on the operating system to flush its contents periodically as with any other file.

**master_info_repository = TABLE.** If the value of `sync_master_info` is greater than 0, the slave updates its master info repository table after every `sync_master_info` events. If it is 0, the table is never updated.

The default value for `sync_master_info` is 10000 as of MySQL 5.6.6, 0 before that.

- `sync_relay_log`
### Property Values

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

If the value of this variable is greater than 0, the MySQL server synchronizes its relay log to disk (using `fdatasync()`) after every `sync_relay_log` events are written to the relay log.

Setting `sync_relay_log` to 0 causes no synchronization to be done to disk; in this case, the server relies on the operating system to flush the relay log's contents from time to time as for any other file.

Prior to MySQL 5.6.6, 0 was the default for this variable. In MySQL 5.6. and later, the default is 10000.

A value of 1 is the safest choice because in the event of a crash you lose at most one event from the relay log. However, it is also the slowest choice (unless the disk has a battery-backed cache, which makes synchronization very fast).

- `sync_relay_log_info`

<table>
<thead>
<tr>

<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

The default value for `sync_relay_log_info` is 10000.

The effects of this variable on the replication slave depend on the server's `relay_log_info_repository` setting (FILE or TABLE). If the setting is TABLE, the effects of the variable also depend on whether the storage engine used by the relay log info table is transactional (such as InnoDB) or not transactional (MyISAM). The effects of these factors on the behavior of the server for `sync_relay_log_info` values of zero and greater than zero are as follows:
Replication and Binary Logging Options and Variables

sync_relay_log_info = 0

- If `relay_log_info_repository` is set to FILE, the MySQL server performs no synchronization of the `relay-log.info` file to disk; instead, the server relies on the operating system to flush its contents periodically as with any other file.

- If `relay_log_info_repository` is set to TABLE, and the storage engine for that table is transactional, the table is updated after each transaction. (The `sync_relay_log_info` setting is effectively ignored in this case.)

- If `relay_log_info_repository` is set to TABLE, and the storage engine for that table is not transactional, the table is never updated.

sync_relay_log_info = N > 0

- If `relay_log_info_repository` is set to FILE, the slave synchronizes its `relay-log.info` file to disk (using `fdatasync()`) after every N transactions.

- If `relay_log_info_repository` is set to TABLE, and the storage engine for that table is transactional, the table is updated after each transaction. (The `sync_relay_log_info` setting is effectively ignored in this case.)

- If `relay_log_info_repository` is set to TABLE, and the storage engine for that table is not transactional, the table is updated after every N events.

17.1.4.4 Binary Log Options and Variables

- **Startup Options Used with Binary Logging**
  - **System Variables Used with Binary Logging**

  You can use the `mysqld` options and system variables that are described in this section to affect the operation of the binary log as well as to control which statements are written to the binary log. For additional information about the binary log, see Section 5.4.4, “The Binary Log”. For additional information about using MySQL server options and system variables, see Section 5.1.6, “Server Command Options”, and Section 5.1.7, “Server System Variables”.

**Startup Options Used with Binary Logging**

The following list describes startup options for enabling and configuring the binary log. System variables used with binary logging are discussed later in this section.

- `--binlog-row-event-max-size=N`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--binlog-row-event-max-size=#</code></td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value (64-bit platforms, &gt;= 5.6.6)</td>
<td>8192</td>
</tr>
<tr>
<td>Default Value (64-bit platforms, &lt;= 5.6.5)</td>
<td>1024</td>
</tr>
</tbody>
</table>
### Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Default Value (32-bit platforms, &gt;= 5.6.6)</strong></td>
<td>8192</td>
</tr>
<tr>
<td><strong>Default Value (32-bit platforms, &lt;= 5.6.5)</strong></td>
<td>1024</td>
</tr>
<tr>
<td><strong>Minimum Value</strong></td>
<td>256</td>
</tr>
<tr>
<td><strong>Maximum Value (64-bit platforms)</strong></td>
<td>18446744073709551615</td>
</tr>
<tr>
<td><strong>Maximum Value (32-bit platforms)</strong></td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Specify the maximum size of a row-based binary log event, in bytes. Rows are grouped into events smaller than this size if possible. The value should be a multiple of 256. The default is 8192 as of MySQL 5.6.6 and 1024 before that. See Section 17.1.2, “Replication Formats”.

- `--log-bin[=base_name]`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td><code>--log-bin=file_name</code></td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>File name</td>
</tr>
</tbody>
</table>

Enables binary logging. With binary logging enabled, the server logs all statements that change data to the binary log, which is used for backup and replication. The binary log is a sequence of files with a base name and numeric extension. For information on the format and management of the binary log, see Section 5.4.4, “The Binary Log”.

The option value, if given, is the base name for the log sequence. The server creates binary log files in sequence by adding a numeric suffix to the base name. It is recommended that you specify a base name (see Section B.4.7, “Known Issues in MySQL”, for the reason). Otherwise, MySQL uses `host_name-bin` as the base name.

If you supply a value for the `--log-bin` option, the value is used as the base name for the log sequence. The server creates binary log files in sequence by adding a numeric suffix to the base name. In MySQL 5.6, the default base name is the name of the process ID file, with the suffix `--bin`. That name can be set with the `--pid-file` option, and it defaults to the name of the host machine. It is recommended that you specify a base name using the `--log-bin` option, so that you can continue to use the same binary log file names regardless of changes to the default name.

The default location for binary log files is the data directory. You can use the `--log-bin` option to specify an alternative location, by adding a leading absolute path name to the base name to specify a different directory. When the server reads an entry from the binary log index file, which tracks the binary log files that have been used, it checks whether the entry contains a relative path. If it does, the relative part of the path is replaced with the absolute path set using the `--log-bin` option. An absolute path recorded in the binary log index file remains unchanged; in such a case, the index file must be edited manually to enable a new path or paths to be used. (Previous to MySQL 5.6.5, this did not apply, and manual intervention was required whenever relocating the binary log or relay log files.) (Bug #11745230, Bug #12133)

Setting this option causes the `log_bin` system variable to be set to `ON` (or `1`), and not to the base name. Beginning with MySQL 5.6.2, the binary log file base name and any specified path are available as the `log_bin_basename` system variable.
Replication and Binary Logging Options and Variables

- **--log-bin-index[=file_name]**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--log-bin-index=file_name</code></td>
</tr>
<tr>
<td>System Variable (&gt;= 5.6.4)</td>
<td><code>log_bin_index</code></td>
</tr>
<tr>
<td>Scope (&gt;= 5.6.4)</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic (&gt;= 5.6.4)</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
</tbody>
</table>

The name for the binary log index file, which contains the names of the binary log files. By default, it has the same location and base name as the value specified for the binary log files using the `--log-bin` option, plus the extension `.index`. If you do not specify `--log-bin`, the default binary log index file name is `binlog.index`. If you omit the file name and do not specify one with `--log-bin`, the default binary log index file name is `host_name-bin.index`, using the name of the host machine.

For information on the format and management of the binary log, see Section 5.4.4, “The Binary Log”.

- **--log-bin-trust-function-creators[=(0|1)]**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--log-bin-trust-function-creators[=(OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>log_bin_trust_function_creators</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

This option sets the corresponding `log_bin_trust_function_creators` system variable. If no argument is given, the option sets the variable to 1. `log_bin_trust_function_creators` affects how MySQL enforces restrictions on stored function and trigger creation. See Section 20.7, “Stored Program Binary Logging”.

- **--log-bin-use-v1-row-events[=(0|1)]**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--log-bin-use-v1-row-events[=(OFF</td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.6</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>log_bin_use_v1_row_events</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Version 2 binary log row events are available beginning with MySQL 5.6.6; however, Version 2 events cannot be read by previous MySQL Server releases. Setting this option to 1 causes `mysqld` to write the binary log using Version 1 logging events, which is the only version of binary log events used in previous
Replication and Binary Logging Options and Variables

Releases, and thus produce binary logs that can be read by older slaves. Setting `--log-bin-use-v1-row-events` to 0 (the default) causes `mysqld` to use Version 2 binary log events.

The value used for this option can be obtained from the read-only `log_bin_use_v1_row_events` system variable.

`--log-bin-use-v1-row-events` is chiefly of interest when setting up replication conflict detection and resolution using `NDB$EPOCH_TRANS()` as the conflict detection function, which requires Version 2 binary log row events. Thus, this option and `--ndb-log-transaction-id` are not compatible.

For more information, see Section 18.6.11, “NDB Cluster Replication Conflict Resolution”.

Statement selection options. The options in the following list affect which statements are written to the binary log, and thus sent by a replication master server to its slaves. There are also options for slave servers that control which statements received from the master should be executed or ignored. For details, see Section 17.1.4.3, “Replication Slave Options and Variables”.

- `--binlog-do-db=db_name`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--binlog-do-db=db_name</code></td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

This option affects binary logging in a manner similar to the way that `--replicate-do-db` affects replication.

The effects of this option depend on whether the statement-based or row-based logging format is in use, in the same way that the effects of `--replicate-do-db` depend on whether statement-based or row-based replication is in use. You should keep in mind that the format used to log a given statement may not necessarily be the same as that indicated by the value of `binlog_format`. For example, DDL statements such as `CREATE TABLE` and `ALTER TABLE` are always logged as statements, without regard to the logging format in effect, so the following statement-based rules for `--binlog-do-db` always apply in determining whether or not the statement is logged.

Statement-based logging. Only those statements are written to the binary log where the default database (that is, the one selected by `USE`) is `db_name`. To specify more than one database, use this option multiple times, once for each database; however, doing so does not cause cross-database statements such as `UPDATE some_db.some_table` `SET foo='bar'` to be logged while a different database (or no database) is selected.

Warning

To specify multiple databases you must use multiple instances of this option. Because database names can contain commas, the list will be treated as the name of a single database if you supply a comma-separated list.

An example of what does not work as you might expect when using statement-based logging: If the server is started with `--binlog-do-db=sales` and you issue the following statements, the `UPDATE` statement is not logged:

```sql
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The main reason for this “just check the default database” behavior is that it is difficult from the statement alone to know whether it should be replicated (for example, if you are using multiple-table DELETE
Replication and Binary Logging Options and Variables

Statements or multiple-table `UPDATE` statements that act across multiple databases. It is also faster to check only the default database rather than all databases if there is no need.

Another case which may not be self-evident occurs when a given database is replicated even though it was not specified when setting the option. If the server is started with `--binlog-do-db=sales`, the following `UPDATE` statement is logged even though `prices` was not included when setting `--binlog-do-db`:

```
USE sales;
UPDATE prices.discounts SET percentage = percentage + 10;
```

Because `sales` is the default database when the `UPDATE` statement is issued, the `UPDATE` is logged.

**Row-based logging.** Logging is restricted to database `db_name`. Only changes to tables belonging to `db_name` are logged; the default database has no effect on this. Suppose that the server is started with `--binlog-do-db=sales` and row-based logging is in effect, and then the following statements are executed:

```
USE prices;
UPDATE sales.february SET amount=amount+100;
```

The changes to the `february` table in the `sales` database are logged in accordance with the `UPDATE` statement; this occurs whether or not the `USE` statement was issued. However, when using the row-based logging format and `--binlog-do-db=sales`, changes made by the following `UPDATE` are not logged:

```
USE prices;
UPDATE prices.march SET amount=amount-25;
```

Even if the `USE prices` statement were changed to `USE sales`, the `UPDATE` statement's effects would still not be written to the binary log.

Another important difference in `--binlog-do-db` handling for statement-based logging as opposed to the row-based logging occurs with regard to statements that refer to multiple databases. Suppose that the server is started with `--binlog-do-db=db1`, and the following statements are executed:

```
USE db1;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

If you are using statement-based logging, the updates to both tables are written to the binary log. However, when using the row-based format, only the changes to `table1` are logged; `table2` is in a different database, so it is not changed by the `UPDATE`. Now suppose that, instead of the `USE db1` statement, a `USE db4` statement had been used:

```
USE db4;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

In this case, the `UPDATE` statement is not written to the binary log when using statement-based logging. However, when using row-based logging, the change to `table1` is logged, but not that to `table2`—in other words, only changes to tables in the database named by `--binlog-do-db` are logged, and the choice of default database has no effect on this behavior.

- `--binlog-ignore-db=db_name`
This option affects binary logging in a manner similar to the way that `--replicate-ignore-db` affects replication.

The effects of this option depend on whether the statement-based or row-based logging format is in use, in the same way that the effects of `--replicate-ignore-db` depend on whether statement-based or row-based replication is in use. You should keep in mind that the format used to log a given statement may not necessarily be the same as that indicated by the value of `binlog_format`. For example, DDL statements such as `CREATE TABLE` and `ALTER TABLE` are always logged as statements, without regard to the logging format in effect, so the following statement-based rules for `--binlog-ignore-db` always apply.

**Statement-based logging.** Tells the server to not log any statement where the default database (that is, the one selected by `USE`) is `db_name`.

Prior to MySQL 5.6.12, this option caused any statements containing fully qualified table names not to be logged if there was no default database specified (that is, when `SELECT DATABASE()` returned `NULL`). In MySQL 5.6.12 and later, when there is no default database, no `--binlog-ignore-db` options are applied, and such statements are always logged. (Bug #11829838, Bug #60188)

**Row-based format.** Tells the server not to log updates to any tables in the database `db_name`. The current database has no effect.

When using statement-based logging, the following example does not work as you might expect. Suppose that the server is started with `--binlog-ignore-db=sales` and you issue the following statements:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The `UPDATE` statement is logged in such a case because `--binlog-ignore-db` applies only to the default database (determined by the `USE` statement). Because the `sales` database was specified explicitly in the statement, the statement has not been filtered. However, when using row-based logging, the `UPDATE` statement's effects are not written to the binary log, which means that no changes to the `sales.january` table are logged; in this instance, `--binlog-ignore-db=sales` causes all changes made to tables in the master's copy of the `sales` database to be ignored for purposes of binary logging.

To specify more than one database to ignore, use this option multiple times, once for each database. Because database names can contain commas, the list will be treated as the name of a single database if you supply a comma-separated list.

You should not use this option if you are using cross-database updates and you do not want these updates to be logged.

**Checksum options.** Beginning with MySQL 5.6.2, MySQL supports reading and writing of binary log checksums. These are enabled using the two options listed here:

- `--binlog-checksum={NONE|CRC32}`
Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--binlog-checksum=type</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.2</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value (&gt;= 5.6.6)</td>
<td>CRC32</td>
</tr>
<tr>
<td>Default Value (&lt;= 5.6.5)</td>
<td>NONE</td>
</tr>
<tr>
<td>Valid Values</td>
<td>NONE, CRC32</td>
</tr>
</tbody>
</table>

Enabling this option causes the master to write checksums for events written to the binary log. Set to `NONE` to disable, or the name of the algorithm to be used for generating checksums; currently, only CRC32 checksums are supported. As of MySQL 5.6.6, CRC32 is the default.

This option was added in MySQL 5.6.2.

- `--master-verify-checksum={0|1}`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--master-verify-checksum=[{OFF</td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.2</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Enabling this option causes the master to verify events from the binary log using checksums, and to stop with an error in the event of a mismatch. Disabled by default.

This option was added in MySQL 5.6.2.

To control reading of checksums by the slave (from the relay) log, use the `--slave-sql-verify-checksum` option.

Testing and debugging options. The following binary log options are used in replication testing and debugging. They are not intended for use in normal operations.

- `--max-binlog-dump-events=N`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--max-binlog-dump-events=#</code></td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
</tbody>
</table>

This option is used internally by the MySQL test suite for replication testing and debugging.

- `--sporadic-binlog-dump-fail`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--sporadic-binlog-dump-fail=[{OFF</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
</tbody>
</table>
Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

This option is used internally by the MySQL test suite for replication testing and debugging.

**System Variables Used with Binary Logging**

The following list describes system variables for controlling binary logging. They can be set at server startup and some of them can be changed at runtime using `SET`. Server options used to control binary logging are listed earlier in this section.

- `binlog_cache_size`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--binlog-cache-size=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>binlog_cache_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>32768</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>4096</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

The size of the cache to hold changes to the binary log during a transaction. A binary log cache is allocated for each client if the server supports any transactional storage engines and if the server has the binary log enabled (`--log-bin` option). If you often use large transactions, you can increase this cache size to get better performance. The `Binlog_cache_use` and `Binlog_cache_disk_use` status variables can be useful for tuning the size of this variable. See Section 5.4.4, “The Binary Log”.

`binlog_cache_size` sets the size for the transaction cache only; the size of the statement cache is governed by the `binlog_stmt_cache_size` system variable.

- `binlog_checksum`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--binlog-checksum=name</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.2</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>binlog_checksum</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value (&gt;= 5.6.6)</td>
<td>CRC32</td>
</tr>
<tr>
<td>Default Value (&lt;= 5.6.5)</td>
<td>NONE</td>
</tr>
<tr>
<td>Valid Values</td>
<td>NONE</td>
</tr>
</tbody>
</table>
Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>CRC32</td>
</tr>
</tbody>
</table>

When enabled, this variable causes the master to write a checksum for each event in the binary log. `binlog_checksum` supports the values `NONE` (disabled) and `CRC32`. The default is `CRC32` as of MySQL 5.6.6, `NONE` before that.

When `binlog_checksum` is disabled (value `NONE`), the server verifies that it is writing only complete events to the binary log by writing and checking the event length (rather than a checksum) for each event.

Changing the value of this variable causes the binary log to be rotated; checksums are always written to an entire binary log file, and never to only part of one.

This variable was added in MySQL 5.6.2.

In MySQL 5.6.6 and later, setting this variable on the master to a value unrecognized by the slave causes the slave to set its own `binlog_checksum` value to `NONE`, and to stop replication with an error. (Bug #13553750, Bug #61096) If backward compatibility with older slaves is a concern, you may want to set the value explicitly to `NONE`.

- `binlog_direct_non_transactional_updates`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--binlog-direct-non-transactional-updates[=(OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>binlog_direct_non_transactional_updates</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Due to concurrency issues, a slave can become inconsistent when a transaction contains updates to both transactional and nontransactional tables. MySQL tries to preserve causality among these statements by writing nontransactional statements to the transaction cache, which is flushed upon commit. However, problems arise when modifications done to nontransactional tables on behalf of a transaction become immediately visible to other connections because these changes may not be written immediately into the binary log.

The `binlog_direct_non_transactional_updates` variable offers one possible workaround to this issue. By default, this variable is disabled. Enabling `binlog_direct_non_transactional_updates` causes updates to nontransactional tables to be written directly to the binary log, rather than to the transaction cache.

`binlog_direct_non_transactional_updates` works only for statements that are replicated using the statement-based binary logging format; that is, it works only when the value of `binlog_format` is `STATEMENT`, or when `binlog_format` is `MIXED` and a given statement is being replicated using the statement-based format. This variable has no effect when the binary log format is `ROW`, or when `binlog_format` is set to `MIXED` and a given statement is replicated using the row-based format.
Important

Before enabling this variable, you must make certain that there are no dependencies between transactional and nontransactional tables; an example of such a dependency would be the statement `INSERT INTO myisam_table SELECT * FROM innodb_table`. Otherwise, such statements are likely to cause the slave to diverge from the master.

In MySQL 5.6, this variable has no effect when the binary log format is `ROW` or `MIXED`. (Bug #51291)

- **binlog_error_action**

<table>
<thead>

</tr>
</tbody>
</table>

Controls what happens when the server encounters an error such as not being able to write to, flush or synchronize the binary log, which can cause the master's binary log to become inconsistent and replication slaves to lose synchronization.

In MySQL 5.6, this variable defaults to `IGNORE_ERROR`. If the server encounters such an error, it continues the ongoing transaction, logs the error then halts logging, and continues performing updates. To resume binary logging `log_bin` must be enabled again, which requires a server restart. This setting provides backward compatibility with older versions of MySQL.

Setting this variable to `ABORT_SERVER` makes the server halt logging and shut down whenever it encounters such an error with the binary log. On restart, recovery proceeds as in the case of an unexpected server halt (see Section 17.3.2, “Handling an Unexpected Halt of a Replication Slave”). This is the recommended setting, particularly in complex replication environments.

In previous releases this variable was named `binlogging_impossible_mode`.

- **binlog_format**

<table>

Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value (&gt;= 5.6.10-ndb-7.3.1)</td>
<td>MIXED</td>
</tr>
<tr>
<td>Default Value</td>
<td>STATEMENT</td>
</tr>
<tr>
<td>Valid Values</td>
<td>ROW</td>
</tr>
<tr>
<td></td>
<td>STATEMENT</td>
</tr>
<tr>
<td></td>
<td>MIXED</td>
</tr>
</tbody>
</table>

This variable sets the binary logging format, and can be any one of STATEMENT, ROW, or MIXED. See Section 17.1.2, “Replication Formats”.

`binlog_format` can be set at startup or at runtime, except that under some conditions, changing this variable at runtime is not possible or causes replication to fail, as described later.

In MySQL 5.6, the default format is STATEMENT. Exception: In MySQL NDB Cluster 7.3 and later, the default is MIXED; statement-based replication is not supported for NDB Cluster.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 5.1.8.1, “System Variable Privileges”.

The rules governing when changes to this variable take effect and how long the effect lasts are the same as for other MySQL server system variables. For more information, see Section 13.7.4.1, “SET Syntax for Variable Assignment”.

When MIXED is specified, statement-based replication is used, except for cases where only row-based replication is guaranteed to lead to proper results. For example, this happens when statements contain user-defined functions (UDF) or the `UUID()` function.

For details of how stored programs (stored procedures and functions, triggers, and events) are handled when each binary logging format is set, see Section 20.7, “Stored Program Binary Logging”.

There are exceptions when you cannot switch the replication format at runtime:

- From within a stored function or a trigger.
- If the session is currently in row-based replication mode and has open temporary tables.
- From within a transaction.

Trying to switch the format in those cases results in an error.

Changing the logging format on a replication master does not cause a replication slave to change its logging format to match. Switching the replication format while replication is ongoing can cause issues if a replication slave has binary logging enabled, and the change results in the slave using STATEMENT format logging while the master is using ROW or MIXED format logging. A replication slave is not able to convert binary log entries received in ROW logging format to STATEMENT format for use in its own binary log, so this situation can cause replication to fail. For more information, see Section 5.4.4.2, “Setting The Binary Log Format”.

The binary log format affects the behavior of the following server options:

- `--replicate-do-db`
• `--replicate-ignore-db`

• `--binlog-do-db`

• `--binlog-ignore-db`

These effects are discussed in detail in the descriptions of the individual options.

• `binlogging_impossible_mode`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--binlogging-impossible-mode [=value]</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.20</td>
</tr>
<tr>
<td>Deprecated</td>
<td>5.6.22</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>binlogging_impossible_mode</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>IGNORE_ERROR</code></td>
</tr>
<tr>
<td>Valid Values</td>
<td><code>IGNORE_ERROR</code>, <code>ABORT_SERVER</code></td>
</tr>
</tbody>
</table>

This option is deprecated and will be removed in a future MySQL release. Use the renamed `binlog_error_action` to control what happens when the server cannot write to the binary log.

• `binlog_max_flush_queue_time`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>

<td>100000</td>
</tr>
</tbody>
</table>

How long in microseconds to keep reading transactions from the flush queue before proceeding with the group commit (and syncing the log to disk, if `sync_binlog` is greater than 0). If the value is 0 (the default), there is no timeout and the server keeps reading new transactions until the queue is empty.

Normally, `binlog_max_flush_queue_time` can remain set to 0. If the server processes a large number of connections (for example, 100 or more) and many short transactions with low-latency requirements, it may be useful to set the value larger than 0 to force more frequent flushes to disk.

This variable was added in MySQL 5.6.6.
Replication and Binary Logging Options and Variables

- **binlog_order_commits**

<table>
<thead>
<tr>
<th>Property</th>

</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

When this variable is enabled on a replication master (which is the default), transaction commit instructions issued to storage engines are serialized on a single thread, so that transactions are always committed in the same order as they are written to the binary log. Disabling this variable permits transaction commit instructions to be issued using multiple threads. Used in combination with binary log group commit, this prevents the commit rate of a single transaction being a bottleneck to throughput, and might therefore produce a performance improvement.

Transactions are written to the binary log at the point when all the storage engines involved have confirmed that the transaction is prepared to commit. The binary log group commit logic then commits a group of transactions after their binary log write has taken place. When `binlog_order_commits` is disabled, because multiple threads are used for this process, transactions in a commit group might be committed in a different order from their order in the binary log. (Transactions from a single client always commit in chronological order.) In many cases this does not matter, as operations carried out in separate transactions should produce consistent results, and if that is not the case, a single transaction ought to be used instead.

- **binlog_row_image**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--binlog-row-image=image_type</code></td>

<td>full</td>
</tr>
<tr>
<td>Valid Values</td>
<td>full (Log all columns)</td>
</tr>
<tr>
<td></td>
<td>minimal (Log only changed columns, and columns needed to identify rows)</td>
</tr>
<tr>
<td></td>
<td>noblob (Log all columns, except for unneeded BLOB and TEXT columns)</td>
</tr>
</tbody>
</table>

For MySQL row-based replication, this variable determines how row images are written to the binary log.

In MySQL row-based replication, each row change event contains two images, a “before” image whose columns are matched against when searching for the row to be updated, and an “after” image containing
the changes. Normally, MySQL logs full rows (that is, all columns) for both the before and after images. However, it is not strictly necessary to include every column in both images, and we can often save disk, memory, and network usage by logging only those columns which are actually required.

Note

When deleting a row, only the before image is logged, since there are no changed values to propagate following the deletion. When inserting a row, only the after image is logged, since there is no existing row to be matched. Only when updating a row are both the before and after images required, and both written to the binary log.

For the before image, it is necessary only that the minimum set of columns required to uniquely identify rows is logged. If the table containing the row has a primary key, then only the primary key column or columns are written to the binary log. Otherwise, if the table has a unique key all of whose columns are NOT NULL, then only the columns in the unique key need be logged. (If the table has neither a primary key nor a unique key without any NULL columns, then all columns must be used in the before image, and logged.) In the after image, it is necessary to log only the columns which have actually changed.

In MySQL 5.6, you can cause the server to log full or minimal rows using the `binlog_row_image` system variable. This variable actually takes one of three possible values, as shown in the following list:

- **full**: Log all columns in both the before image and the after image.
- **minimal**: Log only those columns in the before image that are required to identify the row to be changed; log only those columns in the after image where a value was specified by the SQL statement, or generated by auto-increment.
- **noblob**: Log all columns (same as full), except for BLOB and TEXT columns that are not required to identify rows, or that have not changed.

Note

This variable is not supported by NDB Cluster; setting it has no effect on the logging of NDB tables. (Bug #16316828)

The default value is **full**.

When using **minimal** or **noblob**, deletes and updates are guaranteed to work correctly for a given table if and only if the following conditions are true for both the source and destination tables:

- All columns must be present and in the same order; each column must use the same data type as its counterpart in the other table.
- The tables must have identical primary key definitions.

(In other words, the tables must be identical with the possible exception of indexes that are not part of the tables' primary keys.)

If these conditions are not met, it is possible that the primary key column values in the destination table may prove insufficient to provide a unique match for a delete or update. In this event, no warning or error is issued; the master and slave silently diverge, thus breaking consistency.

Setting this variable has no effect when the binary logging format is **STATEMENT**. When `binlog_format` is **MIXED**, the setting for `binlog_row_image` is applied to changes that are logged using row-based format, but this setting no effect on changes logged as statements.
Setting `binlog_row_image` on either the global or session level does not cause an implicit commit; this means that this variable can be changed while a transaction is in progress without affecting the transaction.

- **`binlog_rows_query_log_events`**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--binlog-rows-query-log-events=[{OFF</td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.2</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>binlog_rows_query_log_events</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

This system variable affects row-based logging only. When enabled, it causes a MySQL 5.6.2 or higher server to write informational log events such as row query log events into its binary log. This information can be used for debugging and related purposes, such as obtaining the original query issued on the master when it cannot be reconstructed from the row updates. Must be disabled (the default) when generating logs for a MySQL 5.6.1 or earlier slave server or version of `mysqlbinlog`.

These informational events are normally ignored by MySQL programs reading the binary log and so cause no issues when replicating or restoring from backup. To view them, increase the verbosity level by using `mysqlbinlog`'s `--verbose` option twice, either as `-vv` or `--verbose --verbose`.

- **`binlog_stmt_cache_size`**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--binlog-stmt-cache-size=#</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.1</td>

<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>32768</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>4096</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

This variable determines the size of the cache for the binary log to hold nontransactional statements issued during a transaction. Separate binary log transaction and statement caches are allocated for each client if the server supports any transactional storage engines and if the server has the binary log enabled (`--log-bin` option). If you often use large nontransactional statements during transactions, you can increase this cache size to get better performance. The `Binlog_stmt_cache_use` and
Binlog_stmt_cache_disk_use status variables can be useful for tuning the size of this variable. See Section 5.4.4, “The Binary Log”.

The binlog_cache_size system variable sets the size for the transaction cache.

- expire_logs_days

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--expire-logs-days=#</td>
</tr>
<tr>
<td>System Variable</td>
<td>expire_logs_days</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>99</td>
</tr>
</tbody>
</table>

The number of days for automatic binary log file removal. The default is 0, which means “no automatic removal.” Possible removals happen at startup and when the binary log is flushed. Log flushing occurs as indicated in Section 5.4, “MySQL Server Logs”.

To remove binary log files manually, use the PURGE BINARY LOGS statement. See Section 13.4.1.1, “PURGE BINARY LOGS Syntax”.

- log_bin

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>log_bin</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
</tbody>
</table>

Whether the binary log is enabled. If the --log-bin option is used, then the value of this variable is ON; otherwise it is OFF. This variable reports only on the status of binary logging (enabled or disabled); it does not actually report the value to which --log-bin is set.

See Section 5.4.4, “The Binary Log”.

- log_bin_basename

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>5.6.2</td>
</tr>
<tr>
<td>System Variable</td>
<td>log_bin_basename</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
</tbody>
</table>

Holds the base name and path for the binary log files, which can be set with the --log-bin server option. In MySQL 5.6, the default base name is the name of the process ID file, with the suffix -bin.
That name can be set with the `--pid-file` option, and it defaults to the name of the host machine. The default location for the binary log files is the data directory.

The `log_bin_basename` system variable was added in MySQL 5.6.2.

- **log_bin_index**

| Property                  | Value                                                                 |
|---------------------------|                                                                     |
| Command-Line Format       | `--log-bin-index=file_name`                                         |
| System Variable (>= 5.6.4) | `log_bin_index`                                                      |
| Scope (>= 5.6.4)          | Global                                                               |
| Dynamic (>= 5.6.4)        | No                                                                   |
| Type                      | File name                                                           |

Holds the base name and path for the binary log index file, which can be set with the `--log-bin-index` server option.

- **log_bin_trust_function_creators**

| Property                  | Value                                                                 |
|---------------------------|                                                                     |
| Command-Line Format       | `--log-bin-trust-function-creators=[{OFF|ON}]`                     |
| System Variable           | `log_bin_trust_function_creators`                                  |
| Scope                     | Global                                                               |
| Dynamic                   | Yes                                                                  |
| Type                      | Boolean                                                             |
| Default Value             | OFF                                                                  |

This variable applies when binary logging is enabled. It controls whether stored function creators can be trusted not to create stored functions that will cause unsafe events to be written to the binary log. If set to 0 (the default), users are not permitted to create or alter stored functions unless they have the `SUPER` privilege in addition to the `CREATE ROUTINE` or `ALTER ROUTINE` privilege. A setting of 0 also enforces the restriction that a function must be declared with the `DETERMINISTIC` characteristic, or with the `READS SQL DATA` or `NO SQL` characteristic. If the variable is set to 1, MySQL does not enforce these restrictions on stored function creation. This variable also applies to trigger creation. See Section 20.7, “Stored Program Binary Logging”.

- **log_bin_use_v1_row_events**

| Property                  | Value                                                                 |
|---------------------------|                                                                     |
| Command-Line Format       | `--log-bin-use-v1-row-events=[{OFF|ON}]`                            |
| Introduced                | 5.6.6                                                                |
| System Variable           | `log_bin_use_v1_row_events`                                         |
| Scope                     | Global                                                               |
| Dynamic                   | No                                                                   |
| Type                      | Boolean                                                             |
| Default Value             | OFF                                                                  |
Replication and Binary Logging Options and Variables

Shows whether Version 2 binary logging, available beginning with MySQL 5.6.6, is in use. A value of 1 shows that the server is writing the binary log using Version 1 logging events (the only version of binary log events used in MySQL 5.6.5 and previous MySQL Server releases), and thus producing a binary log that can be read by older slaves. 0 indicates that Version 2 binary log events are in use.

This variable is read-only. To switch between Version 1 and Version 2 binary event binary logging, it is necessary to restart `mysqld` with the `--log-bin-use-v1-row-events` option.

Other than when performing upgrades of NDB Cluster Replication, `--log-bin-use-v1-events` is chiefly of interest when setting up replication conflict detection and resolution using NDB `$EPOCH_TRANS()`, which requires Version 2 binary row event logging. Thus, this option and `--ndb-log-transaction-id` are not compatible.

Note

MySQL NDB Cluster 7.3 and later use Version 2 binary log row events by default. You should keep this in mind when planning upgrades or downgrades, and for setups using NDB Cluster Replication.

For more information, see Section 18.6.11, “NDB Cluster Replication Conflict Resolution”.

</tbody>
</table>

Whether updates received by a slave server from a master server should be logged to the slave’s own binary log. Binary logging must be enabled on the slave for this variable to have any effect. See Section 17.1.4, “Replication and Binary Logging Options and Variables”.

- `master_verify_checksum`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--master-verify-checksum[={OFF</td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.2</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>master_verify_checksum</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Enabling this variable causes the master to examine checksums when reading from the binary log. `master_verify_checksum` is disabled by default; in this case, the master uses the event length from the binary log to verify events, so that only complete events are read from the binary log.
This variable was added in MySQL 5.6.2.

- **max_binlog_cache_size**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--max-binlog-cache-size=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>max_binlog_cache_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>4096</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>18446744073709551615</td>
</tr>
</tbody>
</table>

If a transaction requires more than this many bytes of memory, the server generates a Multi-statement transaction required more than 'max_binlog_cache_size' bytes of storage error. The minimum value is 4096. The maximum possible value is 16EB (exabytes). The maximum recommended value is 4GB; this is due to the fact that MySQL currently cannot work with binary log positions greater than 4GB.

**Note**

Prior to MySQL 5.6.7, 64-bit Windows platforms truncated the stored value for this variable to 4G, even when it was set to a greater value (Bug #13961678).

*max_binlog_cache_size* sets the size for the transaction cache only; the upper limit for the statement cache is governed by the *max_binlog_stmt_cache_size* system variable.

In MySQL 5.6, the visibility to sessions of *max_binlog_cache_size* matches that of the *binlog_cache_size* system variable; in other words, changing its value effects only new sessions that are started after the value is changed.

- **max_binlog_size**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--max-binlog-size=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>max_binlog_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1073741824</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>4096</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1073741824</td>
</tr>
</tbody>
</table>

If a write to the binary log causes the current log file size to exceed the value of this variable, the server rotates the binary logs (closes the current file and opens the next one). The minimum value is 4096 bytes. The maximum and default value is 1GB.
A transaction is written in one chunk to the binary log, so it is never split between several binary logs. Therefore, if you have big transactions, you might see binary log files larger than `max_binlog_size`.

If `max_relay_log_size` is 0, the value of `max_binlog_size` applies to relay logs as well.

- `max_binlog_stmt_cache_size`

```
<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--max-binlog-stmt-cache-size=#</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.1</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>max_binlog_stmt_cache_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>18446744073709547520</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>4096</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>18446744073709547520</td>
</tr>
</tbody>
</table>
```

If nontransactional statements within a transaction require more than this many bytes of memory, the server generates an error. The minimum value is 4096. The maximum and default values are 4GB on 32-bit platforms and 16EB (exabytes) on 64-bit platforms.

**Note**

Prior to MySQL 5.6.7, 64-bit Windows platforms truncated the stored value for this variable to 4G, even when it was set to a greater value (Bug #13961678).

`max_binlog_stmt_cache_size` sets the size for the statement cache only; the upper limit for the transaction cache is governed exclusively by the `max_binlog_cache_size` system variable.

- `sql_log_bin`

```
<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>sql_log_bin</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>ON</code></td>
</tr>
</tbody>
</table>
```

This variable controls whether logging to the binary log is enabled for the current session (assuming that the binary log itself is enabled). The default value is `ON`. To disable or enable binary logging for the current session, set the session `sql_log_bin` variable to `OFF` or `ON`.

Set this variable to `OFF` for a session to temporarily disable binary logging while making changes to the master you do not want replicated to the slave.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 5.1.8.1, “System Variable Privileges”.

2483
It is not possible to set the session value of `sql_log_bin` within a transaction or subquery.

*Setting this variable to `OFF` prevents GTIDs from being assigned to transactions in the binary log.* If you are using GTIDs for replication, this means that, even when binary logging is later enabled once again, the GTIDs written into the log from this point do not account for any transactions that occurred in the meantime—in effect, those transactions are lost.

As of MySQL 5.6.22, the global `sql_log_bin` variable is read only and cannot be modified. The global scope is deprecated and will be removed in a future MySQL release. Prior to 5.6.22, `sql_log_bin` can be set as a global or session variable. Setting `sql_log_bin` globally is only detected when a new session is started. Any sessions previously running are not impacted when setting `sql_log_bin` globally.

**Warning**

Incorrect use of `sql_log_bin` with a global scope means any changes made in an already running session are still being recorded to the binary log and therefore replicated. Exercise extreme caution using `sql_log_bin` with a global scope as the above situation could cause unexpected results including replication failure.

- `sync_binlog`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--sync-binlog=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>sync_binlog</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Controls how often the MySQL server synchronizes the binary log to disk.

- `sync_binlog=0`: Disables synchronization of the binary log to disk by the MySQL server. Instead, the MySQL server relies on the operating system to flush the binary log to disk from time to time as it does for any other file. This setting provides the best performance, but in the event of a power failure or operating system crash, it is possible that the server has committed transactions that have not been synchronized to the binary log.

- `sync_binlog=1`: Enables synchronization of the binary log to disk before transactions are committed. This is the safest setting but can have a negative impact on performance due to the increased number of disk writes. In the event of a power failure or operating system crash, transactions that are missing from the binary log are only in a prepared state. This permits the automatic recovery routine to roll back the transactions, which guarantees that no transaction is lost from the binary log.

- `sync_binlog=N`, where `N` is a value other than 0 or 1: The binary log is synchronized to disk after `N` binary log commit groups have been collected. In the event of a power failure or operating system crash, it is possible that the server has committed transactions that have not been flushed to the
binary log. This setting can have a negative impact on performance due to the increased number of disk writes. A higher value improves performance, but with an increased risk of data loss.

For the greatest possible durability and consistency in a replication setup that uses InnoDB with transactions, use these settings:

- `sync_binlog=1`.
- `innodb_flush_log_at_trx_commit=1`.

**Caution**

Many operating systems and some disk hardware fool the flush-to-disk operation. They may tell `mysqld` that the flush has taken place, even though it has not. In this case, the durability of transactions is not guaranteed even with the recommended settings, and in the worst case, a power outage can corrupt InnoDB data. Using a battery-backed disk cache in the SCSI disk controller or in the disk itself speeds up file flushes, and makes the operation safer. You can also try to disable the caching of disk writes in hardware caches.

### 17.1.4.5 Global Transaction ID Options and Variables

**Startup Options Used with GTID Replication**

- `--disable-gtid-unsafe-statements`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--disable-gtid-unsafe-statements [= {OFF</td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.5</td>
</tr>
<tr>
<td>Removed</td>
<td>5.6.9</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>disable_gtid_unsafe_statements</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

*Obsolete:* Replaced by `--enforce-gtid-consistency` in MySQL 5.6.9. (Bug #14775984)
Replication and Binary Logging Options and Variables

- **--enforce-gtid-consistency**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--enforce-gtid-consistency[=value]</td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.9</td>
</tr>
<tr>
<td>System Variable</td>
<td>enforce_gtid_consistency</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

When enabled, this option enforces GTID consistency by allowing execution of only those statements that can be logged in a transactionally safe manner. *You must* enable `--enforce-gtid-consistency` before setting `--gtid-mode` to ON; otherwise, enabling GTID mode fails with an error. *You can* (and *should*) use this option *prior* to using `--gtid-mode`, in order to test whether the system is ready to use GTIDs.

Since only transactionally safe statements can be logged when `--enforce-gtid-consistency` is enabled, it follows that the operations listed here cannot be used with this option:

- **CREATE TABLE ... SELECT** statements
- **CREATE TEMPORARY TABLE** statements inside transactions
- Transactions or statements that update both transactional and nontransactional tables.

Prior to MySQL 5.6.9, this option was named `--disable-gtid-unsafe-statements`. (Bug #14775984)

Prior to MySQL 5.6.7, using this option caused nontransactional DML on temporary tables to fail, although changes to temporary tables are not logged when using row-based binary logging. In MySQL 5.6.7 and later, nontransactional DML statements are allowed on temporary tables with `--disable-gtid-unsafe-statements` (`--enforce-gtid-consistency` beginning with MySQL 5.6.9) as long as all affected tables are temporary tables (Bug #14272672).

Prior to MySQL 5.6.7, `mysql_upgrade` could not be used with a MySQL Server running with this option enabled, unless `mysql_upgrade` was running with `--write-binlog` explicitly disabled. (Bug #13833710, Bug #14221043) In MySQL 5.6.7 and later, it is possible but not recommended to run `mysql_upgrade` on a server where `--gtid-mode=ON`, since the MySQL system tables use the MyISAM storage engine, which is nontransactional.

In MySQL 5.6.8 and earlier, you could not use any statements affecting nontransactional tables when `--enforce-gtid-consistency` was used (the option was then called `--disable-gtid-unsafe-statements`). In MySQL 5.6.9 and later, this option allows single statements updating nontransactional tables. This is intended chiefly for use with programs such as `mysql_install_db` and `mysql_upgrade`. (Bug #14722659)

- **--gtid-mode**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--gtid-mode=MODE</td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.5</td>
</tr>
</tbody>
</table>
Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>gtid_mode</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
<tr>
<td>Valid Values</td>
<td>OFF, UPGRADE_STEP_1, UPGRADE_STEP_2, ON</td>
</tr>
</tbody>
</table>

This option specifies whether global transaction identifiers (GTIDs) are used to identify transactions. Starting the server with `--gtid-mode=ON` requires that the server also be started with the `--log-bin`, `--log-slave-updates`, and `--enforce-gtid-consistency` options.

Setting this option to `OFF` when there are GTIDs in the binary log or in the relay log, or to `ON` when there remain anonymous transactions to be executed, causes an error.

![Important](image)

This option does not employ boolean values; its values are in fact enumerated. You should not attempt to use numeric values when setting this option, as these may lead to unexpected results. The values `UPGRADE_STEP_1` and `UPGRADE_STEP_2` are reserved for future use, but currently are not supported in production; if you use one of these two values with `--gtid-mode`, the server refuses to start.

The values of `gtid_purged` and `gtid_executed` are not persistent while `gtid_mode=off`. Therefore, after changing `gtid_mode` to `OFF`, once all binary logs containing GTIDs are purged, the values of these variables are lost.

Prior to MySQL 5.6.7, `mysql_upgrade` could not be used with a MySQL Server running with this option enabled, unless `mysql_upgrade` was running with `--write-binlog` explicitly disabled. (Bug #13833710, Bug #14221043)

Prior to MySQL 5.6.10, setting the global value for the `sql_slave_skip_counter` variable to 1 had no effect when `--gtid-mode` was set to `ON`. (Bug #15833516) A workaround in MySQL 5.6.9 and earlier versions is to reset the slave’s position using `CHANGE MASTER TO ... MASTER_LOG_FILE = ... MASTER_LOG_POS = ...`, including the `MASTER_AUTO_POSITION = 0` option with this statement if needed.

**System Variables Used with GTID Replication**

The following system variables are used with GTID-based replication:

- `binlog_gtid_simple_recovery`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--binlog-gtid-simple-recovery[={OFF</td>
</tr>
</tbody>
</table>
This variable controls how binary log files are iterated during the search for GTIDs when MySQL starts or restarts. In MySQL version 5.6.21, this variable was added as `simplified_binlog_gtid_recovery` and in MySQL version 5.6.23 it was renamed to `binlog_gtid_simple_recovery`.

When `binlog_gtid_simple_recovery=FALSE`, the iteration starts from the newest file to initialize `gtid_executed`, and starts from the oldest file to initialize `gtid_purged`. This process could take a long time if you had a large number of binary log files without GTID events, for example created when `gtid_mode=OFF`.

When `binlog_gtid_simple_recovery=TRUE`, the server does not open more than two binary logs when iterating to populate `gtid_purged` and `gtid_executed`, either during server restart or when binary logs are being purged.

**Note**

If this option is enabled, `gtid_executed` and `gtid_purged` may be initialized incorrectly in the following situations:

- Some binary logs were generated when `gtid_mode` was ON, but `gtid_mode` was OFF for the newest binary log.
- A `SET GTID_PURGED` statement was issued after the oldest existing binary log was generated.

If an incorrect GTID set is computed in either situation, it will remain incorrect even if the server is later restarted, regardless of the value of this option.

**Property** | **Value**
---|---
**Introduced** | 5.6.23
**System Variable** | `binlog_gtid_simple_recovery`
**Scope** | Global

</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

When this variable is true, the server enforces GTID consistency by allowing execution of only those statements that can be logged in a transactionally safe manner. You *must* enable GTID consistency (by using `--enforce-gtid-consistency`) before you can start the server with `--gtid-mode=ON`; otherwise, enabling GTID mode fails with an error. You *can* (and *should*) enable GTID consistency *prior* to using `--gtid-mode`, in order to test whether the system is ready to use GTIDs.

Since only transactionally safe statements can be logged when `enforce_gtid_consistency` is true, it follows that the operations listed here cannot be used when this is the case:

• `CREATE TABLE ... SELECT` statements

• `CREATE TEMPORARY TABLE` statements inside transactions

• Transactions or statements that update both transactional and nontransactional tables.

This variable is read-only. To set it, use the `--enforce-gtid-consistency` option on the command line or in an option file when starting the MySQL Server.

Prior to MySQL 5.6.9, this variable was named `disable_gtid_unsafe_statements`. (Bug #14775984)

• `gtid_executed`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>5.6.9</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>gtid_executed</code></td>

Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

When used with global scope, this variable contains a representation of the set of all transactions that are logged in the binary log. This is the same as the value of the `Executed_Gtid_Set` column in the output of `SHOW MASTER STATUS` and `SHOW SLAVE STATUS`.

When used with session scope, this variable contains a representation of the set of transactions that are written to the cache in the current session.

The set of transactions that can be found in the binary logs at any given time is equal to `GTID_SUBTRACT(@@GLOBAL.gtid_executed, @@GLOBAL.gtid_purged)`; that is, to all transactions in the binary log that have not yet been purged.

When the server starts, `@@GLOBAL.gtid_executed` is initialized to the union of the following two sets:

- The GTIDs listed in the `Previous_gtid_executed` of the newest binary log
- The GTIDs found in every `Gtid_log_event` in the newest binary log.

Thereafter, GTIDs are added to the set as transactions are executed.

Issuing `RESET MASTER` causes the global value (but not the session value) of this variable to be reset to an empty string. GTIDs are not otherwise removed from this set other than when the set is cleared due to `RESET MASTER`. The set is also cleared if the server is shut down and all binary logs are removed.

Prior to MySQL 5.6.9, this variable was known as `gtid_done`.

- `gtid_lost`  

<table>

- **gtid_next**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>5.6.5</td>
</tr>
<tr>
<td>System Variable</td>
<td>gtid_next</td>
</tr>
<tr>
<td>Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>AUTOMATIC</td>
</tr>
</tbody>
</table>
| Valid Values | AUTOMATIC
 | ANONYMOUS
 | UUID:NUMBER

This variable is used to specify whether and how the next GTID is obtained.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 5.1.8.1, “System Variable Privileges”.

**gtid_next** can take any of the following values:

- **AUTOMATIC**: Use the next automatically-generated global transaction ID.
- **ANONYMOUS**: Transactions do not have global identifiers, and are identified by file and position only.
- A global transaction ID in **UUID:NUMBER** format.

Setting this variable has no effect if **gtid_mode** is OFF.

Prior to MySQL 5.6.20, when GTIDs were enabled but **gtid_next** was not AUTOMATIC, **DROP TABLE** did not work correctly when used on a combination of nontemporary tables with temporary tables, or of temporary tables using transactional storage engines with temporary tables using nontransactional storage engines. In MySQL 5.6.20 and later, **DROP TABLE** or **DROP TEMPORARY TABLE** fails with an explicit error when used with either of these combinations of tables. (Bug #17620053)

In MySQL 5.6.11 only, you cannot execute any of the statements **CHANGE MASTER TO, START SLAVE, STOP SLAVE, REPAIR TABLE, OPTIMIZE TABLE, ANALYZE TABLE, CHECK TABLE, CREATE SERVER, ALTER SERVER, DROP SERVER, CACHE INDEX, LOAD INDEX INTO CACHE, FLUSH**, or **RESET** when **gtid_next** is set to any value other than **AUTOMATIC**; in such cases, the statement fails with an error. Such statements are **not** disallowed in MySQL 5.6.12 and later. (Bug #16062608, Bug #16715809, Bug #69045)
Replication and Binary Logging Options and Variables

• **gtid_owned**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>5.6.5</td>
</tr>
<tr>
<td>System Variable</td>
<td>gtid_owned</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

This read-only variable holds a list whose contents depend on its scope. When used with session scope, the list holds all GTIDs that are owned by this client; when used with global scope, it holds a list of all GTIDs along with their owners.

• **gtid_purged**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>5.6.9</td>
</tr>
<tr>
<td>System Variable</td>
<td>gtid_purged</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

The set of all transactions that have been purged from the binary log. This is a subset of the set of transactions in `gtid_executed`.

When the server starts, the global value of `gtid_purged` is initialized to the set of GTIDs contained by the `Previous_gtid_log_event` of the oldest binary log. When a binary log is purged, `gtid_purged` is re-read from the binary log that has now become the oldest one.

Prior to MySQL 5.6.9, this variable was known as `gtid_lost`, and was read-only. In MySQL 5.6.9 and later, it is possible to update the value of this variable. (Bug #14797808)

To update the value of this variable, `gtid_mode` must be `ON`, `gtid_executed` must be the empty string, and therefore `gtid_purged` will also be the empty string. This can occur either when replication has not been started previously, or when replication was not previously using GTIDs.

After executing `SET gtid_purged`, you should note down the current binary log filename, which can be checked using `SHOW MASTER STATUS`. If the server is restarted before this file has been purged, then you should use `binlog_gtid_simple_recovery=0` (the default in 5.6) to avoid `gtid_purged` or `gtid_executed` being computed incorrectly.

Issuing `RESET MASTER` causes the value of this variable to be reset to an empty string.

### 17.1.5 Common Replication Administration Tasks

Once replication has been started it should execute without requiring much regular administration. Depending on your replication environment, you will want to check the replication status of each slave periodically, daily, or even more frequently.

#### 17.1.5.1 Checking Replication Status

The most common task when managing a replication process is to ensure that replication is taking place and that there have been no errors between the slave and the master. The primary statement for this is `SHOW SLAVE STATUS`, which you must execute on each slave:

```sql
mysql> SHOW SLAVE STATUS\G
*************************** 1. row ***************************
Slave_IO_State: Waiting for master to send event
Master_Host: master1
Master_User: root
Master_Port: 3306
Connect_Retry: 60
Master_Log_File: mysql-bin.000004
Read_Master_Log_Pos: 931
Relay_Log_File: slave1-relay-bin.000056
Relay_Log_Pos: 950
Relay_Master_Log_File: mysql-bin.000004
Slave_IO_Running: Yes
Slave_SQL_Running: Yes
Replicate_Do_DB:
Replicate_Ignore_DB:
Replicate_Do_Table:
Replicate_Ignore_Table:
Replicate_Wild_Do_Table:
Replicate_Wild_Ignore_Table:
Last_Errno: 0
Last_Error:
Skip_Counter: 0
Exec_Master_Log_Pos: 931
Relay_Log_Space: 1365
Until_Condition: None
Until_Log_File:
Until_Log_Pos: 0
Master_SSL_Allowed: No
Master_SSL_CA_File:
Master_SSL_CA_Path:
Master_SSL_Cert:
Master_SSL_CIPHER:
Master_SSL_Cipher:
Master_SSL_Key:
Seconds_Behind_Master: 0
Master_SSL_Verify_Server_Cert: No
Last_IO_Errno: 0
```
Common Replication Administration Tasks

<table>
<thead>
<tr>
<th>Last_IO_Error:</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Last_SQL_Errno:</td>
<td>0</td>
</tr>
<tr>
<td>Last_SQL_Error:</td>
<td>0</td>
</tr>
<tr>
<td>Replicate_Ignore_Server_Ids:</td>
<td>0</td>
</tr>
</tbody>
</table>

The key fields from the status report to examine are:

- **Slave_IO_State**: The current status of the slave. See Section 8.14.6, “Replication Slave I/O Thread States”, and Section 8.14.7, “Replication Slave SQL Thread States”, for more information.

- **Slave_IO_Running**: Whether the I/O thread for reading the master's binary log is running. Normally, you want this to be **Yes** unless you have not yet started replication or have explicitly stopped it with **STOP SLAVE**.

- **Slave_SQL_Running**: Whether the SQL thread for executing events in the relay log is running. As with the I/O thread, this should normally be **Yes**.

- **Last_IO_Error, Last_SQL_Error**: The last errors registered by the I/O and SQL threads when processing the relay log. Ideally these should be blank, indicating no errors.

- **Seconds_Behind_Master**: The number of seconds that the slave SQL thread is behind processing the master binary log. A high number (or an increasing one) can indicate that the slave is unable to handle events from the master in a timely fashion.

A value of 0 for **Seconds_Behind_Master** can usually be interpreted as meaning that the slave has caught up with the master, but there are some cases where this is not strictly true. For example, this can occur if the network connection between master and slave is broken but the slave I/O thread has not yet noticed this—that is, **slave_net_timeout** has not yet elapsed.

It is also possible that transient values for **Seconds_Behind_Master** may not reflect the situation accurately. When the slave SQL thread has caught up on I/O, **Seconds_Behind_Master** displays 0; but when the slave I/O thread is still queuing up a new event, **Seconds_Behind_Master** may show a large value until the SQL thread finishes executing the new event. This is especially likely when the events have old timestamps; in such cases, if you execute **SHOW SLAVE STATUS** several times in a relatively short period, you may see this value change back and forth repeatedly between 0 and a relatively large value.

Several pairs of fields provide information about the progress of the slave in reading events from the master binary log and processing them in the relay log:

- **(Master_Log_file, Read_Master_Log_Pos)**: Coordinates in the master binary log indicating how far the slave I/O thread has read events from that log.

- **(Relay_Master_Log_File, Exec_Master_Log_Pos)**: Coordinates in the master binary log indicating how far the slave SQL thread has executed events received from that log.

- **(Relay_Log_File, Relay_Log_Pos)**: Coordinates in the slave relay log indicating how far the slave SQL thread has executed the relay log. These correspond to the preceding coordinates, but are expressed in slave relay log coordinates rather than master binary log coordinates.

The **SHOW STATUS** statement also provides some information relating specifically to replication slaves. The replication heartbeat information displayed by **SHOW STATUS** lets you check that the replication connection is active even if the master has not sent events to the slave recently. The master sends a heartbeat signal to a slave if there are no updates to, and no unsent events in, the binary log for a longer period than the heartbeat interval. The **MASTER_HEARTBEAT_PERIOD** setting on the master (set by the **CHANGE MASTER TO** statement) specifies the frequency of the heartbeat, which defaults to half of the connection timeout interval for the slave (**slave_net_timeout**) when the **Slave_last_heartbeat** variable for **SHOW STATUS** shows when the replication slave last received a heartbeat signal.
On the master, you can check the status of connected slaves using `SHOW PROCESSLIST` to examine the list of running processes. Slave connections have `Binlog Dump` in the `Command` field:

```sql
mysql> SHOW PROCESSLIST \G;
*************************** 4. row ***************************
  Id: 10
  User: root
  Host: slave1:58371
  db: NULL
  Command: Binlog Dump
  Time: 777
  State: Has sent all binlog to slave; waiting for binlog to be updated
  Info: NULL
```

Because it is the slave that drives the replication process, very little information is available in this report.

For slaves that were started with the `--report-host` option and are connected to the master, the `SHOW SLAVE HOSTS` statement on the master shows basic information about the slaves. The output includes the ID of the slave server, the value of the `--report-host` option, the connecting port, and master ID:

```sql
mysql> SHOW SLAVE HOSTS;
+-----------+--------+------+-------------------+-----------+
<table>
<thead>
<tr>
<th>Server_id</th>
<th>Host</th>
<th>Port</th>
<th>Rpl_recovery_rank</th>
<th>Master_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>slave1</td>
<td>3306</td>
<td>0</td>
<td>1</td>
</tr>
</tbody>
</table>
+-----------+--------+------+-------------------+-----------+
1 row in set (0.00 sec)
```

### 17.1.5.2 Pausing Replication on the Slave

You can stop and start the replication of statements on the slave using the `STOP SLAVE` and `START SLAVE` statements.

To stop processing of the binary log from the master, use `STOP SLAVE`:

```sql
mysql> STOP SLAVE;
```

When replication is stopped, the slave I/O thread stops reading events from the master binary log and writing them to the relay log, and the SQL thread stops reading events from the relay log and executing them. You can pause the I/O or SQL thread individually by specifying the thread type:

```sql
mysql> STOP SLAVE IO_THREAD;
mysql> STOP SLAVE SQL_THREAD;
```

To start execution again, use the `START SLAVE` statement:

```sql
mysql> START SLAVE;
```

To start a particular thread, specify the thread type:

```sql
mysql> START SLAVE IO_THREAD;
mysql> START SLAVE SQL_THREAD;
```

For a slave that performs updates only by processing events from the master, stopping only the SQL thread can be useful if you want to perform a backup or other task. The I/O thread will continue to read events from the master but they are not executed. This makes it easier for the slave to catch up when you restart the SQL thread.
Stopping only the I/O thread enables the events in the relay log to be executed by the SQL thread up to the point where the relay log ends. This can be useful when you want to pause execution to catch up with events already received from the master, when you want to perform administration on the slave but also ensure that it has processed all updates to a specific point. This method can also be used to pause event receipt on the slave while you conduct administration on the master. Stopping the I/O thread but permitting the SQL thread to run helps ensure that there is not a massive backlog of events to be executed when replication is started again.

17.2 Replication Implementation

Replication is based on the master server keeping track of all changes to its databases (updates, deletes, and so on) in its binary log. The binary log serves as a written record of all events that modify database structure or content (data) from the moment the server was started. Typically, `SELECT` statements are not recorded because they modify neither database structure nor content.

Each slave that connects to the master requests a copy of the binary log. That is, it pulls the data from the master, rather than the master pushing the data to the slave. The slave also executes the events from the binary log that it receives. This has the effect of repeating the original changes just as they were made on the master. Tables are created or their structure modified, and data is inserted, deleted, and updated according to the changes that were originally made on the master.

Because each slave is independent, the replaying of the changes from the master's binary log occurs independently on each slave that is connected to the master. In addition, because each slave receives a copy of the binary log only by requesting it from the master, the slave is able to read and update the copy of the database at its own pace and can start and stop the replication process at will without affecting the ability to update to the latest database status on either the master or slave side.

For more information on the specifics of the replication implementation, see Section 17.2.1, “Replication Implementation Details”.

Masters and slaves report their status in respect of the replication process regularly so that you can monitor them. See Section 8.14, “Examining Thread Information”, for descriptions of all replicated-related states.

The master binary log is written to a local relay log on the slave before it is processed. The slave also records information about the current position with the master's binary log and the local relay log. See Section 17.2.2, “Replication Relay and Status Logs”.

Database changes are filtered on the slave according to a set of rules that are applied according to the various configuration options and variables that control event evaluation. For details on how these rules are applied, see Section 17.2.3, “How Servers Evaluate Replication Filtering Rules”.

17.2.1 Replication Implementation Details

MySQL replication capabilities are implemented using three threads, one on the master server and two on the slave:

- **Binlog dump thread.** The master creates a thread to send the binary log contents to a slave when the slave connects. This thread can be identified in the output of `SHOW PROCESSLIST` on the master as the Binlog Dump thread.

The binary log dump thread acquires a lock on the master's binary log for reading each event that is to be sent to the slave. As soon as the event has been read, the lock is released, even before the event is sent to the slave.
• **Slave I/O thread.** When a `START SLAVE` statement is issued on a slave server, the slave creates an I/O thread, which connects to the master and asks it to send the updates recorded in its binary logs.

The slave I/O thread reads the updates that the master’s Binlog Dump thread sends (see previous item) and copies them to local files that comprise the slave’s relay log.

The state of this thread is shown as `Slave_IO_running` in the output of `SHOW SLAVE STATUS` or as `Slave_running` in the output of `SHOW STATUS`.

• **Slave SQL thread.** The slave creates an SQL thread to read the relay log that is written by the slave I/O thread and execute the events contained therein.

In the preceding description, there are three threads per master/slave connection. A master that has multiple slaves creates one binary log dump thread for each currently connected slave, and each slave has its own I/O and SQL threads.

A slave uses two threads to separate reading updates from the master and executing them into independent tasks. Thus, the task of reading statements is not slowed down if statement execution is slow. For example, if the slave server has not been running for a while, its I/O thread can quickly fetch all the binary log contents from the master when the slave starts, even if the SQL thread lags far behind. If the slave stops before the SQL thread has executed all the fetched statements, the I/O thread has at least fetched everything so that a safe copy of the statements is stored locally in the slave’s relay logs, ready for execution the next time that the slave starts.

The `SHOW PROCESSLIST` statement provides information that tells you what is happening on the master and on the slave regarding replication. For information on master states, see Section 8.14.5, “Replication Master Thread States”. For slave states, see Section 8.14.6, “Replication Slave I/O Thread States”, and Section 8.14.7, “Replication Slave SQL Thread States”.

The following example illustrates how the three threads show up in the output from `SHOW PROCESSLIST`.

On the master server, the output from `SHOW PROCESSLIST` looks like this:

```plaintext
mysql> SHOW PROCESSLIST\G
*************************** 1. row ***************************
    Id: 2
    User: root
    Host: localhost:32931
    db: NULL
    Command: Binlog Dump
    Time: 94
    State: Has sent all binlog to slave; waiting for binlog to be updated
    Info: NULL
```

Here, thread 2 is a Binlog Dump replication thread that services a connected slave. The State information indicates that all outstanding updates have been sent to the slave and that the master is waiting for more updates to occur. If you see no Binlog Dump threads on a master server, this means that replication is not running; that is, no slaves are currently connected.

On a slave server, the output from `SHOW PROCESSLIST` looks like this:

```plaintext
mysql> SHOW PROCESSLIST\G
*************************** 1. row ***************************
    Id: 10
    User: system user
    Host: NULL
    db: NULL
    Command: Connect
```
Replication Relay and Status Logs

The `SHOW PROCESSLIST` was run, both threads were idle, waiting for further updates.

The value in the `Time` column can show how late the slave is compared to the master. See Section A.13, “MySQL 5.6 FAQ: Replication”. If sufficient time elapses on the master side without activity on the `Binlog Dump` thread, the master determines that the slave is no longer connected. As for any other client connection, the timeouts for this depend on the values of `net_write_timeout` and `net_retry_count`; for more information about these, see Section 5.1.7, “Server System Variables”.

The `SHOW SLAVE STATUS` statement provides additional information about replication processing on a slave server. See Section 17.1.5.1, “Checking Replication Status”.

17.2.2 Replication Relay and Status Logs

During replication, a slave server creates several logs that hold the binary log events relayed from the master to the slave, and to record information about the current status and location within the relay log. There are three types of logs used in the process, listed here:

- The **relay log** consists of the events read from the binary log of the master and written by the slave I/O thread. Events in the relay log are executed on the slave as part of the SQL thread.

- The **master info log** contains status and current configuration information for the slave's connection to the master. This log holds information on the master host name, login credentials, and coordinates indicating how far the slave has read from the master's binary log.

  Prior to MySQL 5.6, this log was always a file (`master.info`), but in MySQL 5.6 and later, this log can be written to the `mysql.slave_master_info` table instead of a file, by starting the slave with `--master-info-repository=TABLE`.

- The **relay log info log** holds status information about the execution point within the slave's relay log.

  Prior to MySQL 5.6, this log was always a file (`relay-log.info`), but in MySQL 5.6 and later, this log can be written to the `mysql.slave_relay_log_info` table instead of a file by starting the slave with `--relay-log-info-repository=TABLE`.

When tables are used for the slave status logs, a warning is given if `mysqld` is unable to initialize the replication logging tables, but the slave is allowed to continue starting. This situation is most likely to occur when upgrading from a version of MySQL that does not support slave logging tables to one in which they are supported.

In MySQL 5.6.5 and earlier, the `slave_master_info` and `slave_relay_log_info` tables used MyISAM by default, which meant that it was necessary before starting replication to change the storage engine used by these tables by issuing `ALTER TABLE ... ENGINE=InnoDB`, as shown here:
ALTER TABLE mysql.slave_master_info ENGINE=InnoDB;
ALTER TABLE mysql.slave_relay_log_info ENGINE=InnoDB;

The ALTER TABLE statements must be executed by the MySQL root or other user account with the appropriate privileges on the mysql system database. You should not attempt to do this while replication is running; beginning with MySQL 5.6.3, trying to execute an ALTER TABLE on either these tables while replication is ongoing is disallowed. Starting with MySQL 5.6.4, execution of any statement requiring a write lock on either or both of these tables is disallowed while replication is ongoing, while statements that perform only reads are permitted at any time.

Important
Do not attempt to update or insert rows in the slave_master_info or slave_relay_log_info table manually. Doing so can cause undefined behavior, and is not supported.

If you set master_info_repository and relay_log_info_repository to TABLE, the mysql.slave_master_info and mysql.slave_relay_log_info tables are created using the transactional storage engine InnoDB. As a table, updates to the relay log info log are committed together with the transactions, meaning that the slave's progress information recorded in that log is always consistent with what has been applied to the database, even in the event of an unexpected server halt. The --relay-log-recovery option must be enabled on the slave to guarantee resilience. For more details, see Section 17.3.2, “Handling an Unexpected Halt of a Replication Slave”.

17.2.2.1 The Slave Relay Log

The relay log, like the binary log, consists of a set of numbered files containing events that describe database changes, and an index file that contains the names of all used relay log files.

The term “relay log file” generally denotes an individual numbered file containing database events. The term “relay log” collectively denotes the set of numbered relay log files plus the index file.

Relay log files have the same format as binary log files and can be read using mysqlbinlog (see Section 4.6.8, “mysqlbinlog — Utility for Processing Binary Log Files”).

By default, relay log file names have the form host_name-relay-bin.nnnnnn in the data directory, where host_name is the name of the slave server host and nnnnnn is a sequence number. Successive relay log files are created using successive sequence numbers, beginning with 000001. The slave uses an index file to track the relay log files currently in use. The default relay log index file name is host_name-relay-bin.index in the data directory.

The default relay log file and relay log index file names can be overridden with, respectively, the --relay-log and --relay-log-index server options (see Section 17.1.4, “Replication and Binary Logging Options and Variables”).

If a slave uses the default host-based relay log file names, changing a slave’s host name after replication has been set up can cause replication to fail with the errors Failed to open the relay log and Could not find target log during relay log initialization. This is a known issue (see Bug #2122). If you anticipate that a slave’s host name might change in the future (for example, if networking is set up on the slave such that its host name can be modified using DHCP), you can avoid this issue entirely by using the --relay-log and --relay-log-index options to specify relay log file names explicitly when you initially set up the slave. This will make the names independent of server host name changes.

If you encounter the issue after replication has already begun, one way to work around it is to stop the slave server, prepend the contents of the old relay log index file to the new one, and then restart the slave. On a Unix system, this can be done as shown here:
Replication Relay and Status Logs

```
shell> cat new_relay_log_name.index >> old_relay_log_name.index
shell> mv old_relay_log_name.index new_relay_log_name.index
```

A slave server creates a new relay log file under the following conditions:

- Each time the I/O thread starts.
- When the logs are flushed (for example, with `FLUSH LOGS` or `mysqladmin flush-logs`).
- When the size of the current relay log file becomes “too large,” determined as follows:
  - If the value of `max_relay_log_size` is greater than 0, that is the maximum relay log file size.
  - If the value of `max_relay_log_size` is 0, `max_binlog_size` determines the maximum relay log file size.

The SQL thread automatically deletes each relay log file after it has executed all events in the file and no longer needs it. There is no explicit mechanism for deleting relay logs because the SQL thread takes care of doing so. However, `FLUSH LOGS` rotates relay logs, which influences when the SQL thread deletes them.

### 17.2.2.2 Slave Status Logs

A replication slave server creates two logs. By default, these logs are files named `master.info` and `relay-log.info` and created in the data directory. The names and locations of these files can be changed by using the `--master-info-file` and `--relay-log-info-file` options, respectively. In MySQL 5.6 and later, either or both of these logs can also be written to tables in the `mysql` system database by starting the server with the appropriate option: use `--master-info-repository` to have the master info log written to the `mysql.slave_master_info` table, and use `--relay-log-info-repository` to have the relay log info log written to the `mysql.slave_relay_log_info` table. See Section 17.1.4, “Replication and Binary Logging Options and Variables”.

The two status logs contain information similar to that shown in the output of the `SHOW SLAVE STATUS` statement, which is discussed in Section 13.4.2, “SQL Statements for Controlling Slave Servers”. Because the status logs are stored on disk, they survive a slave server's shutdown. The next time the slave starts up, it reads the two logs to determine how far it has proceeded in reading binary logs from the master and in processing its own relay logs.

Access to the master info log file or table should be restricted because it contains the password for connecting to the master. See Section 6.1.2.3, “Passwords and Logging”.

If you set `master_info_repository` and `relay_log_info_repository` to `TABLE`, the `mysql.slave_master_info` and `mysql.slave_relay_log_info` tables are created using the InnoDB transactional storage engine. As a table, updates to the relay log info log are committed together with the transactions, meaning that the slave’s progress information recorded in that log is always consistent with what has been applied to the database, even in the event of an unexpected server halt. The `--relay-log-recovery` option must be enabled on the slave to guarantee resilience. For more details, see Section 17.3.2, “Handling an Unexpected Halt of a Replication Slave”.

One additional slave status log is created primarily for internal use, and holds status information about worker threads on a multithreaded replication slave. This slave worker log includes the names and positions for the relay log file and master binary log file for each worker thread. If the relay log info log for the slave is created as a table, the slave worker log is written to the `mysql.slave_worker_info` table. If the relay log info log is written to a file, the slave worker log is written to the `worker-relay-log.info` file.
The slave I/O thread updates the master info log. The following table shows the correspondence between the lines in the `master.info` file, the columns in the `mysql.slave_master_info` table, and the columns displayed by `SHOW SLAVE STATUS`.

<td>The equivalent position within the master's binary log file of events that have already been executed</td>
</tr>
</tbody>
</table>

**Note**

If you downgrade a slave server to a version older than MySQL 5.6, the older server does not read the `relay-log.info` file correctly. To address this, modify the file in a text editor by deleting the initial line containing the number of lines.

The contents of the `relay-log.info` file and the states shown by the `SHOW SLAVE STATUS` statement might not match if the `relay-log.info` file has not been flushed to disk. Ideally, you should only view `relay-log.info` on a slave that is offline (that is, `mysqld` is not running). For a running system, you can use `SHOW SLAVE STATUS`, or query the `slave_master_info` and `slave_relay_log_info` tables if you are writing the status logs to tables.

When you back up the slave's data, you should back up these two status logs, along with the relay log files. The status logs are needed to resume replication after you restore the data from the slave. If you lose the relay logs but still have the relay log info log, you can check it to determine how far the SQL thread has executed in the master binary logs. Then you can use `CHANGE MASTER TO` with the `MASTER_LOG_FILE` and `MASTER_LOG_POS` options to tell the slave to re-read the binary logs from that point. Of course, this requires that the binary logs still exist on the master.

### 17.2.3 How Servers Evaluate Replication Filtering Rules

If a master server does not write a statement to its binary log, the statement is not replicated. If the server does log the statement, the statement is sent to all slaves and each slave determines whether to execute it or ignore it.

On the master, you can control which databases to log changes for by using the `--binlog-do-db` and `--binlog-ignore-db` options to control binary logging. For a description of the rules that servers use in evaluating these options, see Section 17.2.3.1, “Evaluation of Database-Level Replication and Binary Logging Options”. You should not use these options to control which databases and tables are replicated. Instead, use filtering on the slave to control the events that are executed on the slave.

On the slave side, decisions about whether to execute or ignore statements received from the master are made according to the `--replicate-*` options that the slave was started with. (See Section 17.1.4, “Replication and Binary Logging Options and Variables”.)

In the simplest case, when there are no `--replicate-*` options, the slave executes all statements that it receives from the master. Otherwise, the result depends on the particular options given.

Database-level options (`--replicate-do-db`, `--replicate-ignore-db`) are checked first; see Section 17.2.3.1, “Evaluation of Database-Level Replication and Binary Logging Options”, for a description of this process. If no database-level options are used, option checking proceeds to any table-level options that may be in use (see Section 17.2.3.2, “Evaluation of Table-Level Replication Options”, for a discussion of these). If one or more database-level options are used but none are matched, the statement is not replicated.

For statements affecting databases only (that is, `CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE`), database-level options always take precedence over any `--replicate-wild-do-table`
options. In other words, for such statements, \texttt{--replicate-wild-do-table} options are checked if and only if there are no database-level options that apply. This is a change in behavior from previous versions of MySQL, where the statement \texttt{CREATE DATABASE dbx} was not replicated if the slave had been started with \texttt{--replicate-do-db=dbx --replicate-wild-do-table=db%.t1}. (Bug \#46110)

To make it easier to determine what effect an option set will have, it is recommended that you avoid mixing “do” and “ignore” options, or wildcard and nonwildcard options.

If any \texttt{--replicate-rewrite-db} options were specified, they are applied before the \texttt{--replicate-*} filtering rules are tested.

\begin{itemize}
\item \textbf{Note}
\end{itemize}

In MySQL 5.6, all replication filtering options follow the same rules for case sensitivity that apply to names of databases and tables elsewhere in the MySQL server, including the effects of the \texttt{lower_case_table_names} system variable.

This is a change from previous versions of MySQL. (Bug \#51639)

\subsection*{17.2.3.1 Evaluation of Database-Level Replication and Binary Logging Options}

When evaluating replication options, the slave begins by checking to see whether there are any \texttt{--replicate-do-db} or \texttt{--replicate-ignore-db} options that apply. When using \texttt{--binlog-do-db} or \texttt{--binlog-ignore-db}, the process is similar, but the options are checked on the master.

The database that is checked for a match depends on the binary log format of the statement that is being handled. If the statement has been logged using the row format, the database where data is to be changed is the database that is checked. If the statement has been logged using the statement format, the default database (specified with a \texttt{USE} statement) is the database that is checked.

\begin{itemize}
\item \textbf{Note}
\end{itemize}

Only DML statements can be logged using the row format. DDL statements are always logged as statements, even when \texttt{binlog_format=ROW}. All DDL statements are therefore always filtered according to the rules for statement-based replication. This means that you must select the default database explicitly with a \texttt{USE} statement in order for a DDL statement to be applied.

For replication, the steps involved are listed here:

1. Which logging format is used?
   \begin{itemize}
   \item \textbf{STATEMENT.} Test the default database.
   \item \textbf{ROW.} Test the database affected by the changes.
   \end{itemize}

2. Are there any \texttt{--replicate-do-db} options?
   \begin{itemize}
   \item \textbf{Yes.} Does the database match any of them?
   \begin{itemize}
   \item Yes. Continue to Step 4.
   \item No. Ignore the update and exit.
   \end{itemize}
   \item \textbf{No.} Continue to step 3.
   \end{itemize}

3. Are there any \texttt{--replicate-ignore-db} options?
• **Yes.**  Does the database match any of them?
  
  • **Yes.**  Ignore the update and exit.
  
  • **No.**  Continue to step 4.
  
  • **No.**  Continue to step 4.

4. Proceed to checking the table-level replication options, if there are any. For a description of how these options are checked, see Section 17.2.3.2, “Evaluation of Table-Level Replication Options”.

---

**Important**

A statement that is still permitted at this stage is not yet actually executed. The statement is not executed until all table-level options (if any) have also been checked, and the outcome of that process permits execution of the statement.

For binary logging, the steps involved are listed here:

1. Are there any `--binlog-do-db` or `--binlog-ignore-db` options?
   
   • **Yes.**  Continue to step 2.
   
   • **No.**  Log the statement and exit.

2. Is there a default database (has any database been selected by `USE`)?
   
   • **Yes.**  Continue to step 3.
   
   • **No.**  Ignore the statement and exit.

3. There is a default database. Are there any `--binlog-do-db` options?
   
   • **Yes.**  Do any of them match the database?
     
     • **Yes.**  Log the statement and exit.
     
     • **No.**  Ignore the statement and exit.
   
   • **No.**  Continue to step 4.

4. Do any of the `--binlog-ignore-db` options match the database?
   
   • **Yes.**  Ignore the statement and exit.
   
   • **No.**  Log the statement and exit.

---

**Important**

For statement-based logging, an exception is made in the rules just given for the `CREATE DATABASE`, `ALTER DATABASE`, and `DROP DATABASE` statements. In those cases, the database being `created`, `altered`, or `dropped` replaces the default database when determining whether to log or ignore updates.

`--binlog-do-db` can sometimes mean “ignore other databases”. For example, when using statement-based logging, a server running with only `--binlog-do-db=sales` does not write to the binary log statements for which the default database differs from `sales`. When using row-based logging with the same option, the server logs only those updates that change data in `sales`. 
17.2.3.2 Evaluation of Table-Level Replication Options

The slave checks for and evaluates table options only if either of the following two conditions is true:

- No matching database options were found.
- One or more database options were found, and were evaluated to arrive at an “execute” condition according to the rules described in the previous section (see Section 17.2.3.1, “Evaluation of Database-Level Replication and Binary Logging Options”).

First, as a preliminary condition, the slave checks whether statement-based replication is enabled. If so, and the statement occurs within a stored function, the slave executes the statement and exits. If row-based replication is enabled, the slave does not know whether a statement occurred within a stored function on the master, so this condition does not apply.

**Note**

For statement-based replication, replication events represent statements (all changes making up a given event are associated with a single SQL statement); for row-based replication, each event represents a change in a single table row (thus a single statement such as `UPDATE mytable SET mycol = 1` may yield many row-based events). When viewed in terms of events, the process of checking table options is the same for both row-based and statement-based replication.

Having reached this point, if there are no table options, the slave simply executes all events. If there are any `--replicate-do-table` or `--replicate-wild-do-table` options, the event must match one of these if it is to be executed; otherwise, it is ignored. If there are any `--replicate-ignore-table` or `--replicate-wild-ignore-table` options, all events are executed except those that match any of these options.

The following steps describe this evaluation in more detail. The starting point is the end of the evaluation of the database-level options, as described in Section 17.2.3.1, “Evaluation of Database-Level Replication and Binary Logging Options”:

1. Are there any table replication options?
   - **Yes.** Continue to step 2.
   - **No.** Execute the update and exit.

2. Which logging format is used?
   - **STATEMENT.** Carry out the remaining steps for each statement that performs an update.
   - **ROW.** Carry out the remaining steps for each update of a table row.

3. Are there any `--replicate-do-table` options?
   - **Yes.** Does the table match any of them?
     - **Yes.** Execute the update and exit.
     - **No.** Continue to step 4.
   - **No.** Continue to step 4.

4. Are there any `--replicate-ignore-table` options?
How Servers Evaluate Replication Filtering Rules

- Yes. Does the table match any of them?
- Yes. Ignore the update and exit.
- No. Continue to step 5.
- No. Continue to step 5.

5. Are there any `--replicate-wild-do-table` options?
- Yes. Does the table match any of them?
- Yes. Execute the update and exit.
- No. Continue to step 6.
- No. Continue to step 6.

6. Are there any `--replicate-wild-ignore-table` options?
- Yes. Does the table match any of them?
- Yes. Ignore the update and exit.
- No. Continue to step 7.
- No. Continue to step 7.

7. Is there another table to be tested?
- Yes. Go back to step 3.
- No. Continue to step 8.

8. Are there any `--replicate-do-table` or `--replicate-wild-do-table` options?
- Yes. Ignore the update and exit.
- No. Execute the update and exit.

Note

Statement-based replication stops if a single SQL statement operates on both a table that is included by a `--replicate-do-table` or `--replicate-wild-do-table` option, and another table that is ignored by a `--replicate-ignore-table` or `--replicate-wild-ignore-table` option. The slave must either execute or ignore the complete statement (which forms a replication event), and it cannot logically do this. This also applies to row-based replication for DDL statements, because DDL statements are always logged as statements, without regard to the logging format in effect. The only type of statement that can update both an included and an ignored table and still be replicated successfully is a DML statement that has been logged with `binlog_format=ROW`.

17.2.3.3 Replication Rule Application

This section provides additional explanation and examples of usage for different combinations of replication filtering options.
Some typical combinations of replication filter rule types are given in the following table:

<table>
<thead>
<tr>
<th>Condition (Types of Options)</th>
<th>Outcome</th>
</tr>
</thead>
<tbody>
<tr>
<td>No <code>--replicate-*</code> options at all:</td>
<td>The slave executes all events that it receives from the master.</td>
</tr>
<tr>
<td><code>--replicate-*-db</code> options, but no table options:</td>
<td>The slave accepts or ignores events using the database options. It executes all events permitted by those options because there are no table restrictions.</td>
</tr>
<tr>
<td><code>--replicate-*-table</code> options, but no database options:</td>
<td>All events are accepted at the database-checking stage because there are no database conditions. The slave executes or ignores events based solely on the table options.</td>
</tr>
<tr>
<td>A combination of database and table options:</td>
<td>The slave accepts or ignores events using the database options. Then it evaluates all events permitted by those options according to the table options. This can sometimes lead to results that seem counterintuitive, and that may be different depending on whether you are using statement-based or row-based replication; see the text for an example.</td>
</tr>
</tbody>
</table>

A more complex example follows, in which we examine the outcomes for both statement-based and row-based settings.

Suppose that we have two tables `mytbl1` in database `db1` and `mytbl2` in database `db2` on the master, and the slave is running with the following options (and no other replication filtering options):

```
replicate-ignore-db = db1
replicate-do-table  = db2.tbl2
```

Now we execute the following statements on the master:

```
USE db1;
INSERT INTO db2.tbl2 VALUES (1);
```

The results on the slave vary considerably depending on the binary log format, and may not match initial expectations in either case.

**Statement-based replication.** The `USE` statement causes `db1` to be the default database. Thus the `--replicate-ignore-db` option matches, and the `INSERT` statement is ignored. The table options are not checked.

**Row-based replication.** The default database has no effect on how the slave reads database options when using row-based replication. Thus, the `USE` statement makes no difference in how the `--replicate-ignore-db` option is handled: the database specified by this option does not match the database where the `INSERT` statement changes data, so the slave proceeds to check the table options. The table specified by `--replicate-do-table` matches the table to be updated, and the row is inserted.

### 17.3 Replication Solutions

Replication can be used in many different environments for a range of purposes. This section provides general notes and advice on using replication for specific solution types.

For information on using replication in a backup environment, including notes on the setup, backup procedure, and files to back up, see Section 17.3.1, “Using Replication for Backups”.
For advice and tips on using different storage engines on the master and slaves, see Section 17.3.3, “Using Replication with Different Master and Slave Storage Engines”.

Using replication as a scale-out solution requires some changes in the logic and operation of applications that use the solution. See Section 17.3.4, “Using Replication for Scale-Out”.

For performance or data distribution reasons, you may want to replicate different databases to different replication slaves. See Section 17.3.5, “Replicating Different Databases to Different Slaves”

As the number of replication slaves increases, the load on the master can increase and lead to reduced performance (because of the need to replicate the binary log to each slave). For tips on improving your replication performance, including using a single secondary server as a replication master, see Section 17.3.6, “Improving Replication Performance”.

For guidance on switching masters, or converting slaves into masters as part of an emergency failover solution, see Section 17.3.7, “Switching Masters During Failover”.

To secure your replication communication, you can encrypt the communication channel. For step-by-step instructions, see Section 17.3.8, “Setting Up Replication to Use Encrypted Connections”.

17.3.1 Using Replication for Backups

To use replication as a backup solution, replicate data from the master to a slave, and then back up the data slave. The slave can be paused and shut down without affecting the running operation of the master, so you can produce an effective snapshot of “live” data that would otherwise require the master to be shut down.

How you back up a database depends on its size and whether you are backing up only the data, or the data and the replication slave state so that you can rebuild the slave in the event of failure. There are therefore two choices:

• If you are using replication as a solution to enable you to back up the data on the master, and the size of your database is not too large, the `mysqldump` tool may be suitable. See Section 17.3.1.1, “Backing Up a Slave Using mysqldump”.

• For larger databases, where `mysqldump` would be impractical or inefficient, you can back up the raw data files instead. Using the raw data files option also means that you can back up the binary and relay logs that will enable you to recreate the slave in the event of a slave failure. For more information, see Section 17.3.1.2, “Backing Up Raw Data from a Slave”.

Another backup strategy, which can be used for either master or slave servers, is to put the server in a read-only state. The backup is performed against the read-only server, which then is changed back to its usual read/write operational status. See Section 17.3.1.3, “Backing Up a Master or Slave by Making It Read Only”.

17.3.1.1 Backing Up a Slave Using mysqldump

Using `mysqldump` to create a copy of a database enables you to capture all of the data in the database in a format that enables the information to be imported into another instance of MySQL Server (see Section 4.5.4, "mysqldump — A Database Backup Program"). Because the format of the information is SQL statements, the file can easily be distributed and applied to running servers in the event that you need access to the data in an emergency. However, if the size of your data set is very large, `mysqldump` may be impractical.

When using `mysqldump`, you should stop replication on the slave before starting the dump process to ensure that the dump contains a consistent set of data:
1. Stop the slave from processing requests. You can stop replication completely on the slave using `mysqladmin`:

```
shell> mysqladmin stop-slave
```

Alternatively, you can stop only the slave SQL thread to pause event execution:

```
shell> mysql -e 'STOP SLAVE SQL_THREAD;'
```

This enables the slave to continue to receive data change events from the master's binary log and store them in the relay logs using the I/O thread, but prevents the slave from executing these events and changing its data. Within busy replication environments, permitting the I/O thread to run during backup may speed up the catch-up process when you restart the slave SQL thread.

2. Run `mysqldump` to dump your databases. You may either dump all databases or select databases to be dumped. For example, to dump all databases:

```
shell> mysqldump --all-databases > fulldb.dump
```

3. Once the dump has completed, start slave operations again:

```
shell> mysqladmin start-slave
```

In the preceding example, you may want to add login credentials (user name, password) to the commands, and bundle the process up into a script that you can run automatically each day.

If you use this approach, make sure you monitor the slave replication process to ensure that the time taken to run the backup does not affect the slave's ability to keep up with events from the master. See Section 17.1.5.1, “Checking Replication Status”. If the slave is unable to keep up, you may want to add another slave and distribute the backup process. For an example of how to configure this scenario, see Section 17.3.5, “Replicating Different Databases to Different Slaves”.

### 17.3.1.2 Backing Up Raw Data from a Slave

To guarantee the integrity of the files that are copied, backing up the raw data files on your MySQL replication slave should take place while your slave server is shut down. If the MySQL server is still running, background tasks may still be updating the database files, particularly those involving storage engines with background processes such as InnoDB. With InnoDB, these problems should be resolved during crash recovery, but since the slave server can be shut down during the backup process without affecting the execution of the master it makes sense to take advantage of this capability.

To shut down the server and back up the files:

1. Shut down the slave MySQL server:

```
shell> mysqladmin shutdown
```

2. Copy the data files. You can use any suitable copying or archive utility, including `cp`, `tar` or `WinZip`. For example, assuming that the data directory is located under the current directory, you can archive the entire directory as follows:

```
shell> tar cf /tmp/dbbackup.tar ./data
```

3. Start the MySQL server again. Under Unix:

```
shell> mysqld_safe &
```

Under Windows:
Normally you should back up the entire data directory for the slave MySQL server. If you want to be able to restore the data and operate as a slave (for example, in the event of failure of the slave), then in addition to the slave's data, you should also back up the slave status files, the master info and relay log info repositories, and the relay log files. These files are needed to resume replication after you restore the slave's data.

If you lose the relay logs but still have the `relay-log.info` file, you can check it to determine how far the SQL thread has executed in the master binary logs. Then you can use `CHANGE MASTER TO` with the `MASTER_LOG_FILE` and `MASTER_LOG_POS` options to tell the slave to re-read the binary logs from that point. This requires that the binary logs still exist on the master server.

If your slave is replicating `LOAD DATA` statements, you should also back up any `SQL_LOAD-*` files that exist in the directory that the slave uses for this purpose. The slave needs these files to resume replication of any interrupted `LOAD DATA` operations. The location of this directory is the value of the `--slave-load-tmpdir` option. If the server was not started with that option, the directory location is the value of the `tmpdir` system variable.

### 17.3.1.3 Backing Up a Master or Slave by Making It Read Only

It is possible to back up either master or slave servers in a replication setup by acquiring a global read lock and manipulating the `read_only` system variable to change the read-only state of the server to be backed up:

1. Make the server read-only, so that it processes only retrievals and blocks updates.

2. Perform the backup.

3. Change the server back to its normal read/write state.

**Note**

The instructions in this section place the server to be backed up in a state that is safe for backup methods that get the data from the server, such as `mysqldump` (see [Section 4.5.4, “mysqldump — A Database Backup Program”](#)). You should not attempt to use these instructions to make a binary backup by copying files directly because the server may still have modified data cached in memory and not flushed to disk.

The following instructions describe how to do this for a master server and for a slave server. For both scenarios discussed here, suppose that you have the following replication setup:

- A master server M1
- A slave server S1 that has M1 as its master
- A client C1 connected to M1
- A client C2 connected to S1

In either scenario, the statements to acquire the global read lock and manipulate the `read_only` variable are performed on the server to be backed up and do not propagate to any slaves of that server.

**Scenario 1: Backup with a Read-Only Master**
Using Replication for Backups

Put the master M1 in a read-only state by executing these statements on it:

```
mysql> FLUSH TABLES WITH READ LOCK;
mysql> SET GLOBAL read_only = ON;
```

While M1 is in a read-only state, the following properties are true:

- Requests for updates sent by C1 to M1 will block because the server is in read-only mode.
- Requests for query results sent by C1 to M1 will succeed.
- Making a backup on M1 is safe.
- Making a backup on S1 is not safe. This server is still running, and might be processing the binary log or update requests coming from client C2.

While M1 is read only, perform the backup. For example, you can use `mysqldump`.

After the backup operation on M1 completes, restore M1 to its normal operational state by executing these statements:

```
mysql> SET GLOBAL read_only = OFF;
mysql> UNLOCK TABLES;
```

Although performing the backup on M1 is safe (as far as the backup is concerned), it is not optimal for performance because clients of M1 are blocked from executing updates.

This strategy applies to backing up a master server in a replication setup, but can also be used for a single server in a nonreplication setting.

**Scenario 2: Backup with a Read-Only Slave**

Put the slave S1 in a read-only state by executing these statements on it:

```
mysql> FLUSH TABLES WITH READ LOCK;
mysql> SET GLOBAL read_only = ON;
```

While S1 is in a read-only state, the following properties are true:

- The master M1 will continue to operate, so making a backup on the master is not safe.
- The slave S1 is stopped, so making a backup on the slave S1 is safe.

These properties provide the basis for a popular backup scenario: Having one slave busy performing a backup for a while is not a problem because it does not affect the entire network, and the system is still running during the backup. In particular, clients can still perform updates on the master server, which remains unaffected by backup activity on the slave.

While S1 is read only, perform the backup. For example, you can use `mysqldump`.

After the backup operation on S1 completes, restore S1 to its normal operational state by executing these statements:

```
mysql> SET GLOBAL read_only = OFF;
```
Handling an Unexpected Halt of a Replication Slave

2514

mysql> UNLOCK TABLES;

After the slave is restored to normal operation, it again synchronizes to the master by catching up with any outstanding updates from the binary log of the master.

17.3.2 Handling an Unexpected Halt of a Replication Slave

In order for replication to be resilient to unexpected halts of the server (sometimes described as crash-safe) it must be possible for the slave to recover its state before halting. This section describes the impact of an unexpected halt of a slave during replication and how to configure a slave for the best chance of recovery to continue replication.

After an unexpected halt of a replication slave, upon restart the slave's SQL thread must recover which transactions have been executed already. The information required for recovery is stored in the slave's relay log info log. In older MySQL Server versions, this log could only be created as a file in the data directory that was updated after the transaction had been applied. This held the risk of losing synchrony with the master depending at which stage of processing a transaction the slave halted at, or even corruption of the file itself. In MySQL 5.6 you can instead use an InnoDB table to store the relay log info log. By using this transactional storage engine the information is always recoverable upon restart. As a table, updates to the relay log info log are committed together with the transactions, meaning that the slave’s progress information recorded in that log is always consistent with what has been applied to the database, even in the event of an unexpected server halt.

To configure MySQL 5.6 to store the relay log info log as an InnoDB table, set the system variable relay_log_info_repository to TABLE. The server then stores information required for the recovery of the slave’s SQL thread in the mysql.slave_relay_log_info table. For further information on the slave logs, see Section 17.2.2, “Replication Relay and Status Logs”.

Exactly how a replication slave recovers from an unexpected halt is influenced by the chosen method of replication, whether the slave is single-threaded or multithreaded, the setting of variables such as relay_log_recovery, and whether features such as MASTER_AUTO_POSITION are being used.

The following table shows the impact of these different factors on how a single-threaded slave recovers from an unexpected halt.

Table 17.1 Factors Influencing Single-threaded Replication Slave Recovery

</tbody>
</table>
As the table shows, when using a single-threaded slave the following configurations are most resilient to unexpected halts:

- When using GTIDs and `MASTER_AUTO_POSITION`, set `relay_log_recovery=1`. With this configuration the setting of `relay_log_info_repository` and other variables does not impact on recovery. Note that to guarantee recovery, `sync_binlog=1` must also be set on the slave, so that the slave's binary log is synchronized to disk at each write. Otherwise, committed transactions might not be present in the slave's binary log.

- When using file position based replication, set `relay_log_recovery=1` and `relay_log_info_repository=TABLE`.

  **Note**
  
  During recovery the relay log is lost.

The following table shows the impact of these different factors on how a multithreaded slave recovers from an unexpected halt.

**Table 17.2 Factors Influencing Multithreaded Replication Slave Recovery**

As the table shows, when using a multithreaded slave the following configurations are most resilient to unexpected halts:

- When using GTIDs and `MASTER_AUTO_POSITION`, set `relay_log_recovery=1`. With this configuration the setting of `relay_log_info_repository` and other variables does not impact on recovery.

- When using file position based replication, set `relay_log_recovery=1`, `sync_relay_log=1`, and `relay_log_info_repository=TABLE`.
Note

During recovery the relay log is lost.

It is important to note the impact of `sync_relay_log=1`, which requires a write of to the relay log per transaction. Although this setting is the most resilient to an unexpected halt, with at most one unwritten transaction being lost, it also has the potential to greatly increase the load on storage. Without `sync_relay_log=1`, the effect of an unexpected halt depends on how the relay log is handled by the operating system. Also note that when `relay_log_recovery=0`, the next time the slave is started after an unexpected halt the relay log is processed as part of recovery. After this process completes, the relay log is deleted.

An unexpected halt of a multithreaded replication slave using the recommended file position based replication configuration above may result in a relay log with transaction inconsistencies (gaps in the sequence of transactions) caused by the unexpected halt. See Replication and Transaction Inconsistencies. In MySQL 5.7.13 and later, if the relay log recovery process encounters such transaction inconsistencies they are filled and the recovery process continues automatically. In MySQL versions prior to MySQL 5.7.13, this process is not automatic and requires starting the server with `relay_log_recovery=0`, starting the slave with `START_SLAVE_UPTIL_SQL_AFTER_MTS_GAPS` to fix any transaction inconsistencies and then restarting the slave with `relay_log_recovery=1`.

When you are using multi-source replication and `relay_log_recovery=1`, after restarting due to an unexpected halt all replication channels go through the relay log recovery process. Any inconsistencies found in the relay log due to an unexpected halt of a multithreaded slave are filled.

17.3.3 Using Replication with Different Master and Slave Storage Engines

It does not matter for the replication process whether the source table on the master and the replicated table on the slave use different engine types. In fact, the `default_storage_engine` and `storage_engine` system variables are not replicated.

This provides a number of benefits in the replication process in that you can take advantage of different engine types for different replication scenarios. For example, in a typical scale-out scenario (see Section 17.3.4, “Using Replication for Scale-Out”), you want to use InnoDB tables on the master to take advantage of the transactional functionality, but use MyISAM on the slaves where transaction support is not required because the data is only read. When using replication in a data-logging environment you may want to use the Archive storage engine on the slave.

Configuring different engines on the master and slave depends on how you set up the initial replication process:

- If you used `mysqldump` to create the database snapshot on your master, you could edit the dump file text to change the engine type used on each table.

  Another alternative for `mysqldump` is to disable engine types that you do not want to use on the slave before using the dump to build the data on the slave. For example, you can add the `--skip-federated` option on your slave to disable the FEDERATED engine. If a specific engine does not exist for a table to be created, MySQL will use the default engine type, usually MyISAM. (This requires that the NO_ENGINE_SUBSTITUTION SQL mode is not enabled.) If you want to disable additional engines in this way, you may want to consider building a special binary to be used on the slave that only supports the engines you want.

- If you are using raw data files (a binary backup) to set up the slave, you will be unable to change the initial table format. Instead, use `ALTER TABLE` to change the table types after the slave has been started.
Using Replication for Scale-Out

- For new master/slave replication setups where there are currently no tables on the master, avoid specifying the engine type when creating new tables.

If you are already running a replication solution and want to convert your existing tables to another engine type, follow these steps:

1. Stop the slave from running replication updates:

```bash
mysql> STOP SLAVE;
```

This will enable you to change engine types without interruptions.

2. Execute an `ALTER TABLE ... ENGINE='engine_type'` for each table to be changed.

3. Start the slave replication process again:

```bash
mysql> START SLAVE;
```

Although the `default_storage_engine` variable is not replicated, be aware that `CREATE TABLE` and `ALTER TABLE` statements that include the engine specification will be correctly replicated to the slave. For example, if you have a CSV table and you execute:

```bash
mysql> ALTER TABLE csvtable Engine='MyISAM';
```

The above statement will be replicated to the slave and the engine type on the slave will be converted to `MyISAM`, even if you have previously changed the table type on the slave to an engine other than CSV. If you want to retain engine differences on the master and slave, you should be careful to use the `default_storage_engine` variable on the master when creating a new table. For example, instead of:

```bash
mysql> CREATE TABLE tablea (columna int) Engine=MyISAM;
```

Use this format:

```bash
mysql> SET default_storage_engine=MyISAM;
mysql> CREATE TABLE tablea (columna int);
```

When replicated, the `default_storage_engine` variable will be ignored, and the `CREATE TABLE` statement will execute on the slave using the slave's default engine.

### 17.3.4 Using Replication for Scale-Out

You can use replication as a scale-out solution; that is, where you want to split up the load of database queries across multiple database servers, within some reasonable limitations.

Because replication works from the distribution of one master to one or more slaves, using replication for scale-out works best in an environment where you have a high number of reads and low number of writes/updates. Most websites fit into this category, where users are browsing the website, reading articles, posts, or viewing products. Updates only occur during session management, or when making a purchase or adding a comment/message to a forum.

Replication in this situation enables you to distribute the reads over the replication slaves, while still enabling your web servers to communicate with the replication master when a write is required. You can see a sample replication layout for this scenario in Figure 17.1, “Using Replication to Improve Performance During Scale-Out”.
If the part of your code that is responsible for database access has been properly abstracted/modularized, converting it to run with a replicated setup should be very smooth and easy. Change the implementation of your database access to send all writes to the master, and to send reads to either the master or a slave. If your code does not have this level of abstraction, setting up a replicated system gives you the opportunity and motivation to clean it up. Start by creating a wrapper library or module that implements the following functions:

- `safe_writer_connect()`
- `safe_reader_connect()`
- `safe_reader_statement()`
- `safe_writer_statement()`

`safe_` in each function name means that the function takes care of handling all error conditions. You can use different names for the functions. The important thing is to have a unified interface for connecting for reads, connecting for writes, doing a read, and doing a write.

Then convert your client code to use the wrapper library. This may be a painful and scary process at first, but it pays off in the long run. All applications that use the approach just described are able to take advantage of a master/slave configuration, even one involving multiple slaves. The code is much easier to maintain, and adding troubleshooting options is trivial. You need modify only one or two functions (for example, to log how long each statement took, or which statement among those issued gave you an error).

If you have written a lot of code, you may want to automate the conversion task by using the `replace` utility that comes with standard MySQL distributions, or write your own conversion script. Ideally, your code uses consistent programming style conventions. If not, then you are probably better off rewriting it anyway, or at least going through and manually regularizing it to use a consistent style.

### 17.3.5 Replicating Different Databases to Different Slaves

There may be situations where you have a single master and want to replicate different databases to different slaves. For example, you may want to distribute different sales data to different departments to help spread the load during data analysis. A sample of this layout is shown in Figure 17.2, “Using Replication to Replicate Databases to Separate Replication Slaves”. 
You can achieve this separation by configuring the master and slaves as normal, and then limiting the binary log statements that each slave processes by using the `--replicate-wild-do-table` configuration option on each slave.

**Important**

You should *not* use `--replicate-do-db` for this purpose when using statement-based replication, since statement-based replication causes this option's affects to vary according to the database that is currently selected. This applies to mixed-format replication as well, since this enables some updates to be replicated using the statement-based format.

However, it should be safe to use `--replicate-do-db` for this purpose if you are using row-based replication only, since in this case the currently selected database has no effect on the option's operation.

For example, to support the separation as shown in Figure 17.2, “Using Replication to Replicate Databases to Separate Replication Slaves”, you should configure each replication slave as follows, before executing `START SLAVE`:

- Replication slave 1 should use `--replicate-wild-do-table=databaseA.%`.
- Replication slave 2 should use `--replicate-wild-do-table=databaseB.%`.
- Replication slave 3 should use `--replicate-wild-do-table=databaseC.%`.

Each slave in this configuration receives the entire binary log from the master, but executes only those events from the binary log that apply to the databases and tables included by the `--replicate-wild-do-table` option in effect on that slave.

If you have data that must be synchronized to the slaves before replication starts, you have a number of choices:

- Synchronize all the data to each slave, and delete the databases, tables, or both that you do not want to keep.
- Use `mysqldump` to create a separate dump file for each database and load the appropriate dump file on each slave.
- Use a raw data file dump and include only the specific files and databases that you need for each slave.

**Note**

This does not work with InnoDB databases unless you use `innodb_file_per_table`. 
17.3.6 Improving Replication Performance

As the number of slaves connecting to a master increases, the load, although minimal, also increases, as each slave uses a client connection to the master. Also, as each slave must receive a full copy of the master binary log, the network load on the master may also increase and create a bottleneck.

If you are using a large number of slaves connected to one master, and that master is also busy processing requests (for example, as part of a scale-out solution), then you may want to improve the performance of the replication process.

One way to improve the performance of the replication process is to create a deeper replication structure that enables the master to replicate to only one slave, and for the remaining slaves to connect to this primary slave for their individual replication requirements. A sample of this structure is shown in Figure 17.3, “Using an Additional Replication Host to Improve Performance”.

![Figure 17.3 Using an Additional Replication Host to Improve Performance](image)

For this to work, you must configure the MySQL instances as follows:

- Master 1 is the primary master where all changes and updates are written to the database. Binary logging should be enabled on this machine.

- Master 2 is the slave to the Master 1 that provides the replication functionality to the remainder of the slaves in the replication structure. Master 2 is the only machine permitted to connect to Master 1. Master 2 also has binary logging enabled, and the --log-slave-updates option so that replication instructions from Master 1 are also written to Master 2's binary log so that they can then be replicated to the true slaves.

- Slave 1, Slave 2, and Slave 3 act as slaves to Master 2, and replicate the information from Master 2, which actually consists of the upgrades logged on Master 1.

The above solution reduces the client load and the network interface load on the primary master, which should improve the overall performance of the primary master when used as a direct database solution.

If your slaves are having trouble keeping up with the replication process on the master, there are a number of options available:

- If possible, put the relay logs and the data files on different physical drives. To do this, use the --relay-log option to specify the location of the relay log.

- If the slaves are significantly slower than the master, you may want to divide up the responsibility for replicating different databases to different slaves. See Section 17.3.5, “Replicating Different Databases to Different Slaves”.

- If your master makes use of transactions and you are not concerned about transaction support on your slaves, use MyISAM or another nontransactional engine on the slaves. See Section 17.3.3, “Using Replication with Different Master and Slave Storage Engines”.
• If your slaves are not acting as masters, and you have a potential solution in place to ensure that you can bring up a master in the event of failure, then you can switch off `--log-slave-updates`. This prevents “dumb” slaves from also logging events they have executed into their own binary log.

### 17.3.7 Switching Masters During Failover

You can tell a slave to change to a new master using the `CHANGE MASTER TO` statement. The slave does not check whether the databases on the master are compatible with those on the slave; it simply begins reading and executing events from the specified coordinates in the new master's binary log. In a failover situation, all the servers in the group are typically executing the same events from the same binary log file, so changing the source of the events should not affect the structure or integrity of the database, provided that you exercise care in making the change.

Slaves should be run with the `--log-bin` option, and if not using GTIDs then they should also be run without `--log-slave-updates`. In this way, the slave is ready to become a master without restarting the slave `mysqld`. Assume that you have the structure shown in Figure 17.4, “Redundancy Using Replication, Initial Structure”.

**Figure 17.4 Redundancy Using Replication, Initial Structure**

![Diagram of redundancy using replication, initial structure](image)

In this diagram, the MySQL Master holds the master database, the MySQL Slave hosts are replication slaves, and the Web Client machines are issuing database reads and writes. Web clients that issue only reads (and would normally be connected to the slaves) are not shown, as they do not need to switch to a new server in the event of failure. For a more detailed example of a read/write scale-out replication structure, see Section 17.3.4, “Using Replication for Scale-Out”.

Each MySQL Slave (Slave 1, Slave 2, and Slave 3) is a slave running with `--log-bin` and without `--log-slave-updates`. Because updates received by a slave from the master are not logged in the binary log unless `--log-slave-updates` is specified, the binary log on each slave is empty initially. If for some reason MySQL Master becomes unavailable, you can pick one of the slaves to become the new master. For example, if you pick Slave 1, all Web Clients should be redirected to Slave 1, which writes the updates to its binary log. Slave 2 and Slave 3 should then replicate from Slave 1.

The reason for running the slave without `--log-slave-updates` is to prevent slaves from receiving updates twice in case you cause one of the slaves to become the new master. If Slave 1 has `--log-slave-updates` enabled, it writes any updates that it receives from Master in its own binary log. This
Switching Masters During Failover

means that, when Slave 2 changes from Master to Slave 1 as its master, it may receive updates from Slave 1 that it has already received from Master.

Make sure that all slaves have processed any statements in their relay log. On each slave, issue `STOP SLAVE IO_THREAD`, then check the output of `SHOW PROCESSLIST` until you see `Has read all relay log`. When this is true for all slaves, they can be reconfigured to the new setup. On the slave Slave 1 being promoted to become the master, issue `STOP SLAVE` and `RESET MASTER`.

On the other slaves Slave 2 and Slave 3, use `STOP SLAVE` and `CHANGE MASTER TO MASTER_HOST='Slave1'` (where 'Slave1' represents the real host name of Slave 1). To use `CHANGE MASTER TO`, add all information about how to connect to Slave 1 from Slave 2 or Slave 3 (user, password, port). When issuing the `CHANGE MASTER TO` statement in this, there is no need to specify the name of the Slave 1 binary log file or log position to read from, since the first binary log file and position 4, are the defaults. Finally, execute `START SLAVE` on Slave 2 and Slave 3.

Once the new replication setup is in place, you need to tell each Web Client to direct its statements to Slave 1. From that point on, all updates statements sent by Web Client to Slave 1 are written to the binary log of Slave 1, which then contains every update statement sent to Slave 1 since Master died.

The resulting server structure is shown in Figure 17.5, "Redundancy Using Replication, After Master Failure".

**Figure 17.5 Redundancy Using Replication, After Master Failure**

When Master becomes available again, you should make it a slave of Slave 1. To do this, issue on Master the same `CHANGE MASTER TO` statement as that issued on Slave 2 and Slave 3 previously. Master then becomes a slave of Slave 1 and picks up the Web Client writes that it missed while it was offline.

To make Master a master again, use the preceding procedure as if Slave 1 was unavailable and Master was to be the new master. During this procedure, do not forget to run `RESET MASTER` on Master before making Slave 1, Slave 2, and Slave 3 slaves of Master. If you fail to do this, the slaves may
pick up stale writes from the Web Client applications dating from before the point at which Master became unavailable.

You should be aware that there is no synchronization between slaves, even when they share the same master, and thus some slaves might be considerably ahead of others. This means that in some cases the procedure outlined in the previous example might not work as expected. In practice, however, relay logs on all slaves should be relatively close together.

One way to keep applications informed about the location of the master is to have a dynamic DNS entry for the master. With bind you can use nsupdate to update the DNS dynamically.

### 17.3.8 Setting Up Replication to Use Encrypted Connections

To use an encrypted connection for the transfer of the binary log required during replication, both the master and the slave servers must support encrypted network connections. If either server does not support encrypted connections (because it has not been compiled or configured for them), replication through an encrypted connection is not possible.

Setting up encrypted connections for replication is similar to doing so for client/server connections. You must obtain (or create) a suitable security certificate that you can use on the master, and a similar certificate (from the same certificate authority) on each slave. You must also obtain suitable key files.

For more information on setting up a server and client for encrypted connections, see Section 6.3.1, “Configuring MySQL to Use Encrypted Connections”.

To enable encrypted connections on the master, you must create or obtain suitable certificate and key files, and then add the following configuration options to the master's configuration within the [mysqld] section of the master's my.cnf file, changing the file names as necessary:

```
[mysqld]
ssl-ca=cacert.pem
ssl-cert=server-cert.pem
ssl-key=server-key.pem
```

The paths to the files may be relative or absolute; we recommend that you always use complete paths for this purpose.

The options are as follows:

- **--ssl-ca**: The path name of the Certificate Authority (CA) certificate file. (**--ssl-capath** is similar but specifies the path name of a directory of CA certificate files.)

- **--ssl-cert**: The path name of the server public key certificate file. This certificate can be sent to the client and authenticated against the CA certificate that it has.

- **--ssl-key**: The path name of the server private key file.

On the slave, there are two ways to specify the information required for connecting using encryption to the master. You can either name the slave certificate and key files in the [client] section of the slave's my.cnf file, or you can explicitly specify that information using the CHANGE MASTER TO statement:

- To name the slave certificate and key files using an option file, add the following lines to the [client] section of the slave's my.cnf file, changing the file names as necessary:

```
[client]
ssl-ca=cacert.pem
ssl-cert=client-cert.pem
```
Restart the slave server, using the `--skip-slave-start` option to prevent the slave from connecting to the master. Use `CHANGE MASTER TO` to specify the master configuration, using the `MASTER_SSL` option to connect using encryption:

```sql
mysql> CHANGE MASTER TO
       -> MASTER_HOST='master_hostname',
       -> MASTER_USER='replicate',
       -> MASTER_PASSWORD='password',
       -> MASTER_SSL=1;
```

- To specify the certificate and key names using the `CHANGE MASTER TO` statement, append the appropriate `MASTER_SSL_xxx` options:

```sql
mysql> CHANGE MASTER TO
       -> MASTER_HOST='master_hostname',
       -> MASTER_USER='replicate',
       -> MASTER_PASSWORD='password',
       -> MASTER_SSL=1,
       -> MASTER_SSL_CA = 'ca_file_name',
       -> MASTER_SSL_CAPATH = 'ca_directory_name',
       -> MASTER_SSL_CERT = 'cert_file_name',
       -> MASTER_SSL_KEY = 'key_file_name';
```

After the master information has been updated, start the slave replication process:

```sql
mysql> START SLAVE;
```

You can use the `SHOW SLAVE STATUS` statement to confirm that an encrypted connection was established successfully.

For more information on the `CHANGE MASTER TO` statement, see Section 13.4.2.1, “CHANGE MASTER TO Syntax”.

If you want to enforce the use of encrypted connections during replication, create a user with the `REPLICATION SLAVE` privilege and use the `REQUIRE SSL` option for that user. For example:

```sql
mysql> CREATE USER 'repl'@'%.example.com' IDENTIFIED BY 'password';
mysql> GRANT REPLICATION SLAVE ON *.* TO 'repl'@'%.example.com' REQUIRE SSL;
```

If the account already exists, you can add `REQUIRE SSL` to it with this statement:

```sql
mysql> GRANT USAGE ON *.* TO 'repl'@'%.example.com' REQUIRE SSL;
```

### 17.3.9 Semisynchronous Replication

In addition to the built-in asynchronous replication, MySQL 5.6 supports an interface to semisynchronous replication that is implemented by plugins. This section discusses what semisynchronous replication is and how it works. The following sections cover the administrative interface to semisynchronous replication and how to install, configure, and monitor it.

MySQL replication by default is asynchronous. The master writes events to its binary log but does not know whether or when a slave has retrieved and processed them. With asynchronous replication, if the master crashes, transactions that it has committed might not have been transmitted to any slave.
Consequently, failover from master to slave in this case may result in failover to a server that is missing transactions relative to the master.

Semisynchronous replication can be used as an alternative to asynchronous replication:

- A slave indicates whether it is semisynchronous-capable when it connects to the master.

- If semisynchronous replication is enabled on the master side and there is at least one semisynchronous slave, a thread that performs a transaction commit on the master blocks after the commit is done and waits until at least one semisynchronous slave acknowledges that it has received all events for the transaction, or until a timeout occurs.

- The slave acknowledges receipt of a transaction's events only after the events have been written to its relay log and flushed to disk.

- If a timeout occurs without any slave having acknowledged the transaction, the master reverts to asynchronous replication. When at least one semisynchronous slave catches up, the master returns to semisynchronous replication.

- Semisynchronous replication must be enabled on both the master and slave sides. If semisynchronous replication is disabled on the master, or enabled on the master but on no slaves, the master uses asynchronous replication.

While the master is blocking (waiting for acknowledgment from a slave after having performed a commit), it does not return to the session that performed the transaction. When the block ends, the master returns to the session, which then can proceed to execute other statements. At this point, the transaction has committed on the master side, and receipt of its events has been acknowledged by at least one slave.

Blocking also occurs after rollbacks that are written to the binary log, which occurs when a transaction that modifies nontransactional tables is rolled back. The rolled-back transaction is logged even though it has no effect for transactional tables because the modifications to the nontransactional tables cannot be rolled back and must be sent to slaves.

For statements that do not occur in transactional context (that is, when no transaction has been started with `START TRANSACTION` or `SET autocommit = 0`), autocommit is enabled and each statement commits implicitly. With semisynchronous replication, the master blocks after committing each such statement, just as it does for explicit transaction commits.

To understand what the “semi” in “semisynchronous replication” means, compare it with asynchronous and fully synchronous replication:

- With asynchronous replication, the master writes events to its binary log and slaves request them when they are ready. There is no guarantee that any event will ever reach any slave.

- With fully synchronous replication, when a master commits a transaction, all slaves also will have committed the transaction before the master returns to the session that performed the transaction. The drawback of this is that there might be a lot of delay to complete a transaction.

- Semisynchronous replication falls between asynchronous and fully synchronous replication. The master waits after commit only until at least one slave has received and logged the events. It does not wait for all slaves to acknowledge receipt, and it requires only receipt, not that the events have been fully executed and committed on the slave side.

Compared to asynchronous replication, semisynchronous replication provides improved data integrity. When a commit returns successfully, it is known that the data exists in at least two places (on the master and at least one slave). If the master commits but a crash occurs while the master is waiting for acknowledgment from a slave, it is possible that the transaction may not have reached any slave.
Semisynchronous replication also places a rate limit on busy sessions by constraining the speed at which binary log events can be sent from master to slave. When one user is too busy, this will slow it down, which is useful in some deployment situations.

Semisynchronous replication does have some performance impact because commits are slower due to the need to wait for slaves. This is the tradeoff for increased data integrity. The amount of slowdown is at least the TCP/IP roundtrip time to send the commit to the slave and wait for the acknowledgment of receipt by the slave. This means that semisynchronous replication works best for close servers communicating over fast networks, and worst for distant servers communicating over slow networks.

17.3.9.1 Semisynchronous Replication Administrative Interface

The administrative interface to semisynchronous replication has several components:

- Two plugins implement semisynchronous capability. There is one plugin for the master side and one for the slave side.

- System variables control plugin behavior. Some examples:
  - `rpl_semi_sync_master_enabled`
    Controls whether semisynchronous replication is enabled on the master. To enable or disable the plugin, set this variable to 1 or 0, respectively. The default is 0 (off).
  - `rpl_semi_sync_master_timeout`
    A value in milliseconds that controls how long the master waits on a commit for acknowledgment from a slave before timing out and reverting to asynchronous replication. The default value is 10000 (10 seconds).
  - `rpl_semi_sync_slave_enabled`
    Similar to `rpl_semi_sync_master_enabled`, but controls the slave plugin.

  All `rpl_semi_sync_` system variables are described at Section 5.1.7, “Server System Variables”.

- Status variables enable semisynchronous replication monitoring. Some examples:
  - `Rpl_semi_sync_master_clients`
    The number of semisynchronous slaves.
  - `Rpl_semi_sync_master_status`
    Whether semisynchronous replication currently is operational on the master. The value is 1 if the plugin has been enabled and a commit acknowledgment has not occurred. It is 0 if the plugin is not enabled or the master has fallen back to asynchronous replication due to commit acknowledgment timeout.
  - `Rpl_semi_sync_master_no_tx`
    The number of commits that were not acknowledged successfully by a slave.
  - `Rpl_semi_sync_master_yes_tx`
    The number of commits that were acknowledged successfully by a slave.
Whether semisynchronous replication currently is operational on the slave. This is 1 if the plugin has been enabled and the slave I/O thread is running, 0 otherwise.

All `rpl_semi_sync_***` status variables are described at Section 5.1.9, “Server Status Variables”.

The system and status variables are available only if the appropriate master or slave plugin has been installed with `INSTALL PLUGIN`.

17.3.9.2 Semisynchronous Replication Installation and Configuration

Semisynchronous replication is implemented using plugins, so the plugins must be installed into the server to make them available. After a plugin has been installed, you control it by means of the system variables associated with it. These system variables are unavailable until the associated plugin has been installed.

This section describes how to install the semisynchronous replication plugins. For general information about installing plugins, see Section 5.5.1, “Installing and Uninstalling Plugins”.

To use semisynchronous replication, the following requirements must be satisfied:

- The capability of installing plugins requires a MySQL server that supports dynamic loading. To verify this, check that the value of the `have_dynamic_loading` system variable is `YES`. Binary distributions should support dynamic loading.

- Replication must already be working, see Section 17.1, “Replication Configuration”.

To set up semisynchronous replication, use the following instructions. The `INSTALL PLUGIN`, `SET GLOBAL`, `STOP SLAVE`, and `START SLAVE` statements mentioned here require the `SUPER` privilege.

MySQL distributions include semisynchronous replication plugin files for the master side and the slave side.

To be usable by a master or slave server, the appropriate plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

The plugin library file base names are `semisync_master` and `semisync_slave`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

The master plugin library file must be present in the plugin directory of the master server. The slave plugin library file must be present in the plugin directory of each slave server.

To load the plugins, use the `INSTALL PLUGIN` statement on the master and on each slave that is to be semisynchronous (adjust the `.so` suffix for your platform as necessary).

On the master:

```
INSTALL PLUGIN rpl_semi_sync_master SONAME 'semisync_master.so';
```

On each slave:

```
INSTALL PLUGIN rpl_semi_sync_slave SONAME 'semisync_slave.so';
```

If an attempt to install a plugin results in an error on Linux similar to that shown here, you must install `libimf`:

```
mysql> INSTALL PLUGIN rpl_semi_sync_master SONAME 'semisync_master.so';
ERROR 1126 (HY000): Can't open shared library
```
Semisynchronous Replication

'/usr/local/mysql/lib/plugin/semisync_master.so'
(errno: 22 libimf.so: cannot open shared object file:
No such file or directory)

You can obtain libimf from https://dev.mysql.com/downloads/os-linux.html.

To see which plugins are installed, use the SHOW PLUGINS statement, or query the INFORMATION_SCHEMA.PLUGINS table.

To verify plugin installation, examine the INFORMATION_SCHEMA.PLUGINS table or use the SHOW PLUGINS statement (see Section 5.5.2, "Obtaining Server Plugin Information"). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
    FROM INFORMATION_SCHEMA.PLUGINS
    WHERE PLUGIN_NAME LIKE '%semi%';
```

<table>
<thead>
<tr>
<th>PLUGIN_NAME</th>
<th>PLUGIN_STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>rpl_semi_sync_master</td>
<td>ACTIVE</td>
</tr>
</tbody>
</table>

If the plugin fails to initialize, check the server error log for diagnostic messages.

After a semisynchronous replication plugin has been installed, it is disabled by default. The plugins must be enabled both on the master side and the slave side to enable semisynchronous replication. If only one side is enabled, replication will be asynchronous.

To control whether an installed plugin is enabled, set the appropriate system variables. You can set these variables at runtime using SET GLOBAL, or at server startup on the command line or in an option file.

At runtime, these master-side system variables are available:

```
SET GLOBAL rpl_semi_sync_master_enabled = {0|1};
SET GLOBAL rpl_semi_sync_master_timeout = \N;
```

On the slave side, this system variable is available:

```
SET GLOBAL rpl_semi_sync_slave_enabled = {0|1};
```

For `rpl_semi_sync_master_enabled` or `rpl_semi_sync_slave_enabled`, the value should be 1 to enable semisynchronous replication or 0 to disable it. By default, these variables are set to 0.

For `rpl_semi_sync_master_timeout`, the value `\N` is given in milliseconds. The default value is 10000 (10 seconds).

If you enable semisynchronous replication on a slave at runtime, you must also start the slave I/O thread (stopping it first if it is already running) to cause the slave to connect to the master and register as a semisynchronous slave:

```
STOP SLAVE IO_THREAD;
START SLAVE IO_THREAD;
```

If the I/O thread is already running and you do not restart it, the slave continues to use asynchronous replication.

At server startup, the variables that control semisynchronous replication can be set as command-line options or in an option file. A setting listed in an option file takes effect each time the server starts. For example, you can set the variables in `my.cnf` files on the master and slave sides as follows.
Delayed Replication

On the master:

```
[mysqld]
rpl_semi_sync_master_enabled=1
rpl_semi_sync_master_timeout=1000 # 1 second
```

On each slave:

```
[mysqld]
rpl_semi_sync_slave_enabled=1
```

### 17.3.9.3 Semisynchronous Replication Monitoring

The plugins for the semisynchronous replication capability expose several system and status variables that you can examine to determine its configuration and operational state.

The system variables reflect how semisynchronous replication is configured. To check their values, use `SHOW VARIABLES`:

```
mysql> SHOW VARIABLES LIKE 'rpl_semi_sync%';
```

The status variables enable you to monitor the operation of semisynchronous replication. To check their values, use `SHOW STATUS`:

```
mysql> SHOW STATUS LIKE 'Rpl_semi_sync%';
```

When the master switches between asynchronous or semisynchronous replication due to commit-blocking timeout or a slave catching up, it sets the value of the `Rpl_semi_sync_master_status` status variable appropriately. Automatic fallback from semisynchronous to asynchronous replication on the master means that it is possible for the `rpl_semi_sync_master_enabled` system variable to have a value of 1 on the master side even when semisynchronous replication is in fact not operational at the moment. You can monitor the `Rpl_semi_sync_master_status` status variable to determine whether the master currently is using asynchronous or semisynchronous replication.

To see how many semisynchronous slaves are connected, check `Rpl_semi_sync_master_clients`.

The number of commits that have been acknowledged successfully or unsuccessfully by slaves are indicated by the `Rpl_semi_sync_master_yes_tx` and `Rpl_semi_sync_master_no_tx` variables.

On the slave side, `Rpl_semi_sync_slave_status` indicates whether semisynchronous replication currently is operational.

### 17.3.10 Delayed Replication

MySQL 5.6 supports delayed replication such that a slave server deliberately lags behind the master by at least a specified amount of time. The default delay is 0 seconds. Use the `MASTER_DELAY` option for `CHANGE MASTER TO` to set the delay to \( N \) seconds:

```
CHANGE MASTER TO MASTER_DELAY = \( N \);
```

An event received from the master is not executed until at least \( N \) seconds later than its execution on the master. The exceptions are that there is no delay for format description events or log file rotation events, which affect only the internal state of the SQL thread.

Delayed replication can be used for several purposes:
• To protect against user mistakes on the master. A DBA can roll back a delayed slave to the time just before the disaster.

• To test how the system behaves when there is a lag. For example, in an application, a lag might be caused by a heavy load on the slave. However, it can be difficult to generate this load level. Delayed replication can simulate the lag without having to simulate the load. It can also be used to debug conditions related to a lagging slave.

• To inspect what the database looked like long ago, without having to reload a backup. For example, if the delay is one week and the DBA needs to see what the database looked like before the last few days’ worth of development, the delayed slave can be inspected.

START_SLAVE and STOP_SLAVE take effect immediately and ignore any delay. RESET_SLAVE resets the delay to 0.

SHOW_SLAVE_STATUS has three fields that provide information about the delay:

• SQL_Delay: A nonnegative integer indicating the number of seconds that the slave must lag the master.

• SQL_Remaining_Delay: When Slave_SQL_Running_State is Waiting until MASTER_DELAY seconds after master executed event, this field contains an integer indicating the number of seconds left of the delay. At other times, this field is NULL.

• Slave_SQL_Running_State: A string indicating the state of the SQL thread (analogous to Slave_IO_State). The value is identical to the State value of the SQL thread as displayed by SHOW_PROCESSLIST.

When the slave SQL thread is waiting for the delay to elapse before executing an event, SHOW_PROCESSLIST displays its State value as Waiting until MASTER_DELAY seconds after master executed event.

The relay-log.info file now contains the delay value, so the file format has changed. See Section 17.2.2.2, "Slave Status Logs". In particular, the first line of the file now indicates how many lines are in the file. If you downgrade a slave server to a version older than MySQL 5.6, the older server will not read the file correctly. To address this, modify the file in a text editor to delete the initial line containing the number of lines.

17.4 Replication Notes and Tips

17.4.1 Replication Features and Issues

The following sections provide information about what is supported and what is not in MySQL replication, and about specific issues and situations that may occur when replicating certain statements.

Statement-based replication depends on compatibility at the SQL level between the master and slave. In other words, successful SBR requires that any SQL features used be supported by both the master and the slave servers. For example, if you use a feature on the master server that exists in MySQL 5.6 but was removed in MySQL 5.7, errors will occur if you replicate to a slave that uses MySQL 5.7. Such incompatibilities also can occur within a release series when using pre-production releases of MySQL.

For this reason, use Generally Available (GA) releases of MySQL for statement-based replication in a production setting, since we do not introduce new SQL statements or change their behavior within a given release series once that series reaches GA release status.

If you are planning to use statement-based replication between MySQL 5.6 and a previous MySQL release series, it is also a good idea to consult the edition of the MySQL Reference Manual corresponding to the earlier release series for information regarding the replication characteristics of that series.
With MySQL's statement-based replication, there may be issues with replicating stored routines or triggers. You can avoid these issues by using MySQL's row-based replication instead. For a detailed list of issues, see Section 20.7, "Stored Program Binary Logging". For more information about row-based logging and row-based replication, see Section 5.4.1, "Binary Logging Formats", and Section 17.1.2, "Replication Formats".

For additional information specific to replication and InnoDB, see Section 14.19, "InnoDB and MySQL Replication". For information relating to replication with NDB Cluster, see Section 18.6, "NDB Cluster Replication".

### 17.4.1.1 Replication and AUTO_INCREMENT

Statement-based replication of `AUTO_INCREMENT`, `LAST_INSERT_ID()`, and `TIMESTAMP` values is done correctly, subject to the following exceptions:

- When using statement-based replication prior to MySQL 5.6.10, `AUTO_INCREMENT` columns in tables on the slave must match the same columns on the master; that is, `AUTO_INCREMENT` columns must be replicated to `AUTO_INCREMENT` columns. (Bug #12669186)

- A statement invoking a trigger or function that causes an update to an `AUTO_INCREMENT` column is not replicated correctly using statement-based replication. In MySQL 5.6, such statements are marked as unsafe. (Bug #45677)

- An `INSERT` into a table that has a composite primary key that includes an `AUTO_INCREMENT` column that is not the first column of this composite key is not safe for statement-based logging or replication. Beginning with MySQL 5.6.6, such statements are marked as unsafe. (Bug #11754117, Bug #45670)

This issue does not affect tables using the InnoDB storage engine, since an InnoDB table with an `AUTO_INCREMENT` column requires at least one key where the auto-increment column is the only or leftmost column.

- Adding an `AUTO_INCREMENT` column to a table with `ALTER TABLE` might not produce the same ordering of the rows on the slave and the master. This occurs because the order in which the rows are numbered depends on the specific storage engine used for the table and the order in which the rows were inserted. If it is important to have the same order on the master and slave, the rows must be ordered before assigning an `AUTO_INCREMENT` number. Assuming that you want to add an `AUTO_INCREMENT` column to a table `t1` that has columns `col1` and `col2`, the following statements produce a new table `t2` identical to `t1` but with an `AUTO_INCREMENT` column:

```sql
CREATE TABLE t2 LIKE t1;
ALTER TABLE t2 ADD id INT AUTO_INCREMENT PRIMARY KEY;
INSERT INTO t2 SELECT * FROM t1 ORDER BY col1, col2;
```

#### Important

To guarantee the same ordering on both master and slave, the `ORDER BY` clause must name all columns of `t1`.

The instructions just given are subject to the limitations of `CREATE TABLE ... LIKE`: Foreign key definitions are ignored, as are the `DATA DIRECTORY` and `INDEX DIRECTORY` table options. If a table definition includes any of those characteristics, create `t2` using a `CREATE TABLE` statement that is identical to the one used to create `t1`, but with the addition of the `AUTO_INCREMENT` column.

Regardless of the method used to create and populate the copy having the `AUTO_INCREMENT` column, the final step is to drop the original table and then rename the copy:
DROP t1;
ALTER TABLE t2 RENAME t1;

See also Section B.4.6.1, “Problems with ALTER TABLE”.

17.4.1.2 Replication and BLACKHOLE Tables

The BLACKHOLE storage engine accepts data but discards it and does not store it. When performing binary logging, all inserts to such tables are always logged, regardless of the logging format in use. Updates and deletes are handled differently depending on whether statement based or row based logging is in use. With the statement based logging format, all statements affecting BLACKHOLE tables are logged, but their effects ignored. When using row-based logging, updates and deletes to such tables are simply skipped—they are not written to the binary log. In MySQL 5.6.12 and later, a warning is logged whenever this occurs (Bug #13004581)

For this reason we recommend when you replicate to tables using the BLACKHOLE storage engine that you have the binlog_format server variable set to STATEMENT, and not to either ROW or MIXED.

17.4.1.3 Replication and Character Sets

The following applies to replication between MySQL servers that use different character sets:

• If the master has databases with a character set different from the global character_set_server value, you should design your CREATE TABLE statements so that they do not implicitly rely on the database default character set. A good workaround is to state the character set and collation explicitly in CREATE TABLE statements.

17.4.1.4 Replication and CHECKSUM TABLE

CHECKSUM TABLE returns a checksum that is calculated row by row, using a method that depends on the table row storage format. The storage format is not guaranteed to remain the same between MySQL versions, so the checksum value might change following an upgrade.

17.4.1.5 Replication of CREATE SERVER, ALTER SERVER, and DROP SERVER

In MySQL 5.6, the statements CREATE SERVER, ALTER SERVER, and DROP SERVER are not written to the binary log, regardless of the binary logging format that is in use.

17.4.1.6 Replication of CREATE ... IF NOT EXISTS Statements

MySQL applies these rules when various CREATE ... IF NOT EXISTS statements are replicated:

• Every CREATE DATABASE IF NOT EXISTS statement is replicated, whether or not the database already exists on the master.

• Similarly, every CREATE TABLE IF NOT EXISTS statement without a SELECT is replicated, whether or not the table already exists on the master. This includes CREATE TABLE IF NOT EXISTS ... LIKE. Replication of CREATE TABLE IF NOT EXISTS ... SELECT follows somewhat different rules; see Section 17.4.1.7, “Replication of CREATE TABLE ... SELECT Statements”, for more information.

• CREATE EVENT IF NOT EXISTS is always replicated in MySQL 5.6, whether or not the event named in the statement already exists on the master.

See also Bug #45574.

17.4.1.7 Replication of CREATE TABLE ... SELECT Statements
MySQL applies these rules when `CREATE TABLE ... SELECT` statements are replicated:

- `CREATE TABLE ... SELECT` always performs an implicit commit (Section 13.3.3, “Statements That Cause an Implicit Commit”).

- If the destination table does not exist, logging occurs as follows. It does not matter whether `IF NOT EXISTS` is present.
  - `STATEMENT` or `MIXED` format: The statement is logged as written.
  - `ROW` format: The statement is logged as a `CREATE TABLE` statement followed by a series of insert-row events.

- If the statement fails, nothing is logged. This includes the case that the destination table exists and `IF NOT EXISTS` is not given.

- If the destination table exists and `IF NOT EXISTS` is given, MySQL ignores the statement completely; nothing is inserted or logged.

MySQL 5.6 does not allow a `CREATE TABLE ... SELECT` statement to make any changes in tables other than the table that is created by the statement. This is a change in behavior from previous versions of MySQL, which permitted these statements to do so. This means that, when using statement-based replication between a MySQL 5.6 or later slave and a master running a previous version of MySQL, a `CREATE TABLE ... SELECT` statement causing changes in other tables on the master fails on the slave, causing replication to stop. To keep this from happening, you should use row-based replication, rewrite the offending statement before running it on the master, or upgrade the master to MySQL 5.6 (or later). (If you choose to upgrade the master, keep in mind that such a `CREATE TABLE ... SELECT` statement will fail following the upgrade unless it is rewritten to remove any side effects on other tables.) This is not an issue when using row-based replication, because the statement is logged as a `CREATE TABLE` statement with any changes to table data logged as row-insert events, rather than as the entire `CREATE TABLE ... SELECT`.

17.4.1.8 Replication of CURRENT_USER()

The following statements support use of the `CURRENT_USER()` function to take the place of the name of, and possibly the host for, an affected user or a definer:

- `DROP USER`
- `RENAME USER`
- `GRANT`
- `REVOKE`
- `CREATE FUNCTION`
- `CREATE PROCEDURE`
- `CREATE TRIGGER`
- `CREATE EVENT`
- `CREATE VIEW`
- `ALTER EVENT`
- `ALTER VIEW`
Replication Features and Issues

• **SET PASSWORD**

When binary logging is enabled and `CURRENT_USER()` or `CURRENT_USER` is used as the definer in any of these statements, MySQL Server ensures that the statement is applied to the same user on both the master and the slave when the statement is replicated. In some cases, such as statements that change passwords, the function reference is expanded before it is written to the binary log, so that the statement includes the user name. For all other cases, the name of the current user on the master is replicated to the slave as metadata, and the slave applies the statement to the current user named in the metadata, rather than to the current user on the slave.

### 17.4.1.9 Replication with Differing Table Definitions on Master and Slave

Source and target tables for replication do not have to be identical. A table on the master can have more or fewer columns than the slave’s copy of the table. In addition, corresponding table columns on the master and the slave can use different data types, subject to certain conditions.

**Note**

Replication between tables which are partitioned differently from one another is not supported. See Section 17.4.1.23, “Replication and Partitioning”.

In all cases where the source and target tables do not have identical definitions, the database and table names must be the same on both the master and the slave. Additional conditions are discussed, with examples, in the following two sections.

**Replication with More Columns on Master or Slave**

You can replicate a table from the master to the slave such that the master and slave copies of the table have differing numbers of columns, subject to the following conditions:

- Columns common to both versions of the table must be defined in the same order on the master and the slave.

  (This is true even if both tables have the same number of columns.)

- Columns common to both versions of the table must be defined before any additional columns.

  This means that executing an `ALTER TABLE` statement on the slave where a new column is inserted into the table within the range of columns common to both tables causes replication to fail, as shown in the following example:

  Suppose that a table `t`, existing on the master and the slave, is defined by the following `CREATE TABLE` statement:

  ```sql
  CREATE TABLE t {
      c1 INT,
      c2 INT,
      c3 INT
  };
  ```

  Suppose that the `ALTER TABLE` statement shown here is executed on the slave:

  ```sql
  ALTER TABLE t ADD COLUMN cnew1 INT AFTER c3;
  ```

  The previous `ALTER TABLE` is permitted on the slave because the columns `c1`, `c2`, and `c3` that are common to both versions of table `t` remain grouped together in both versions of the table, before any columns that differ.
However, the following `ALTER TABLE` statement cannot be executed on the slave without causing replication to break:

```
ALTER TABLE t ADD COLUMN cnew2 INT AFTER c2;
```

Replication fails after execution on the slave of the `ALTER TABLE` statement just shown, because the new column `cnew2` comes between columns common to both versions of `t`.

- Each “extra” column in the version of the table having more columns must have a default value.

A column's default value is determined by a number of factors, including its type, whether it is defined with a `DEFAULT` option, whether it is declared as `NULL`, and the server SQL mode in effect at the time of its creation; for more information, see Section 11.6, “Data Type Default Values”).

In addition, when the slave's copy of the table has more columns than the master's copy, each column common to the tables must use the same data type in both tables.

**Examples.** The following examples illustrate some valid and invalid table definitions:

**More columns on the master.** The following table definitions are valid and replicate correctly:

```sql
master> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
slave> CREATE TABLE t1 (c1 INT, c2 INT);
```

The following table definitions would raise an error because the definitions of the columns common to both versions of the table are in a different order on the slave than they are on the master:

```sql
master> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
slave> CREATE TABLE t1 (c2 INT, c1 INT);
```

The following table definitions would also raise an error because the definition of the extra column on the master appears before the definitions of the columns common to both versions of the table:

```sql
master> CREATE TABLE t1 (c3 INT, c1 INT, c2 INT);
slave> CREATE TABLE t1 (c1 INT, c2 INT);
```

**More columns on the slave.** The following table definitions are valid and replicate correctly:

```sql
master> CREATE TABLE t1 (c1 INT, c2 INT);
slave> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
```

The following definitions raise an error because the columns common to both versions of the table are not defined in the same order on both the master and the slave:

```sql
master> CREATE TABLE t1 (c1 INT, c2 INT);
slave> CREATE TABLE t1 (c2 INT, c1 INT, c3 INT);
```

The following table definitions also raise an error because the definition for the extra column in the slave's version of the table appears before the definitions for the columns which are common to both versions of the table:

```sql
master> CREATE TABLE t1 (c1 INT, c2 INT);
slave> CREATE TABLE t1 (c3 INT, c1 INT, c2 INT);
```
The following table definitions fail because the slave's version of the table has additional columns compared to the master's version, and the two versions of the table use different data types for the common column `c2`:

```
master> CREATE TABLE t1 (c1 INT, c2 BIGINT);
slave> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
```

## Replication of Columns Having Different Data Types

Corresponding columns on the master's and the slave's copies of the same table ideally should have the same data type. However, beginning with MySQL 5.1.21, this is not always strictly enforced, as long as certain conditions are met.

All other things being equal, it is always possible to replicate from a column of a given data type to another column of the same type and same size or width, where applicable, or larger. For example, you can replicate from a `CHAR(10)` column to another `CHAR(10)`, or from a `CHAR(10)` column to a `CHAR(25)` column without any problems. In certain cases, it is also possible to replicate from a column having one data type (on the master) to a column having a different data type (on the slave); when the data type of the master's version of the column is promoted to a type that is the same size or larger on the slave, this is known as attribute promotion.

Attribute promotion can be used with both statement-based and row-based replication, and is not dependent on the storage engine used by either the master or the slave. However, the choice of logging format does have an effect on the type conversions that are permitted; the particulars are discussed later in this section.

---

**Important**

Whether you use statement-based or row-based replication, the slave's copy of the table cannot contain more columns than the master's copy if you wish to employ attribute promotion.

**Statement-based replication.** When using statement-based replication, a simple rule of thumb to follow is, “If the statement run on the master would also execute successfully on the slave, it should also replicate successfully”. In other words, if the statement uses a value that is compatible with the type of a given column on the slave, the statement can be replicated. For example, you can insert any value that fits in a `TINYINT` column into a `BIGINT` column as well; it follows that, even if you change the type of a `TINYINT` column in the slave's copy of a table to `BIGINT`, any insert into that column on the master that succeeds should also succeed on the slave, since it is impossible to have a legal `TINYINT` value that is large enough to exceed a `BIGINT` column.

Prior to MySQL 5.6.10, when using statement-based replication, `AUTO_INCREMENT` columns were required to be the same on both the master and the slave; otherwise, updates could be applied to the wrong table on the slave. (Bug #12669186)

**Row-based replication: attribute promotion and demotion.** Row-based replication in MySQL 5.6 supports attribute promotion and demotion between smaller data types and larger types. It is also possible to specify whether or not to permit lossy (truncated) or non-lossy conversions of demoted column values, as explained later in this section.

**Lossy and non-lossy conversions.** In the event that the target type cannot represent the value being inserted, a decision must be made on how to handle the conversion. If we permit the conversion but truncate (or otherwise modify) the source value to achieve a “fit” in the target column, we make what is known as a *lossy conversion*. A conversion which does not require truncation or similar modifications to fit the source column value in the target column is a *non-lossy* conversion.
**Type conversion modes (slave_type_conversions variable).** The setting of the `slave_type_conversions` global server variable controls the type conversion mode used on the slave. This variable takes a set of values from the following table, which shows the effects of each mode on the slave’s type-conversion behavior:

<table>
<thead>
<tr>
<th>Mode</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>ALL_LOSSY</strong></td>
<td>In this mode, type conversions that would mean loss of information are permitted. This does not imply that non-lossy conversions are permitted, merely that only cases requiring either lossy conversions or no conversion at all are permitted; for example, enabling only this mode permits an <code>INT</code> column to be converted to <code>TINYINT</code> (a lossy conversion), but not a <code>TINYINT</code> column to an <code>INT</code> column (non-lossy). Attempting the latter conversion in this case would cause replication to stop with an error on the slave.</td>
</tr>
<tr>
<td><strong>ALL_NON_LOSSY</strong></td>
<td>This mode permits conversions that do not require truncation or other special handling of the source value; that is, it permits conversions where the target type has a wider range than the source type. Setting this mode has no bearing on whether lossy conversions are permitted; this is controlled with the <strong>ALL_LOSSY</strong> mode. If only <code>ALL_NON_LOSSY</code> is set, but not <strong>ALL_LOSSY</strong>, then attempting a conversion that would result in the loss of data (such as <code>INT</code> to <code>TINYINT</code>, or <code>CHAR(25)</code> to <code>VARCHAR(20)</code>) causes the slave to stop with an error.</td>
</tr>
<tr>
<td><strong>ALL_LOSSY, ALL_NON_LOSSY</strong></td>
<td>When this mode is set, all supported type conversions are permitted, whether or not they are lossy conversions.</td>
</tr>
<tr>
<td><strong>ALL_SIGNED</strong></td>
<td>Treat promoted integer types as signed values (the default behavior).</td>
</tr>
<tr>
<td><strong>ALL_UNSIGNED</strong></td>
<td>Treat promoted integer types as unsigned values.</td>
</tr>
<tr>
<td><strong>ALL_SIGNED, ALL_UNSIGNED</strong></td>
<td>Treat promoted integer types as signed if possible, otherwise as unsigned.</td>
</tr>
<tr>
<td>[empty]</td>
<td>When <code>slave_type_conversions</code> is not set, no attribute promotion or demotion is permitted; this means that all columns in the source and target tables must be of the same types. This mode is the default.</td>
</tr>
</tbody>
</table>

When an integer type is promoted, its signedness is not preserved. By default, the slave treats all such values as signed. Beginning with MySQL 5.6.13, you can control this behavior using **ALL_SIGNED**, **ALL_UNSIGNED**, or both. (Bug#15831300) **ALL_SIGNED** tells the slave to treat all promoted integer types as signed; **ALL_UNSIGNED** instructs it to treat these as unsigned. Specifying both causes the slave to treat the value as signed if possible, otherwise to treat it as unsigned; the order in which they are listed is not significant. Neither **ALL_SIGNED** nor **ALL_UNSIGNED** has any effect if at least one of **ALL_LOSSY** or **ALL_NONLOSSY** is not also used.

Changing the type conversion mode requires restarting the slave with the new `slave_type_conversions` setting.

**Supported conversions.** Supported conversions between different but similar data types are shown in the following list:
• Between any of the integer types TINYINT, SMALLINT, MEDIUMINT, INT, and BIGINT.

This includes conversions between the signed and unsigned versions of these types.

Lossy conversions are made by truncating the source value to the maximum (or minimum) permitted by the target column. For ensuring non-lossy conversions when going from unsigned to signed types, the target column must be large enough to accommodate the range of values in the source column. For example, you can demote TINYINT UNSIGNED non-lossily to SMALLINT, but not to TINYINT.

• Between any of the decimal types DECIMAL, FLOAT, DOUBLE, and NUMERIC.

FLOAT to DOUBLE is a non-lossy conversion; DOUBLE to FLOAT can only be handled lossily. A conversion from DECIMAL \((M, D)\) to DECIMAL \((M', D')\) where \(D' \geq D\) and \((M' - D') \geq (M - D)\) is non-lossy; for any case where \(M' < M\), \(D' < D\), or both, only a lossy conversion can be made.

For any of the decimal types, if a value to be stored cannot be fit in the target type, the value is rounded down according to the rounding rules defined for the server elsewhere in the documentation. See Section 12.21.4, “Rounding Behavior”, for information about how this is done for decimal types.

• Between any of the string types CHAR, VARCHAR, and TEXT, including conversions between different widths.

Conversion of a CHAR, VARCHAR, or TEXT to a CHAR, VARCHAR, or TEXT column the same size or larger is never lossy. Lossy conversion is handled by inserting only the first \(N\) characters of the string on the slave, where \(N\) is the width of the target column.

![Important]

Replication between columns using different character sets is not supported.

• Between any of the binary data types BINARY, VARBINARY, and BLOB, including conversions between different widths.

Conversion of a BINARY, VARBINARY, or BLOB to a BINARY, VARBINARY, or BLOB column the same size or larger is never lossy. Lossy conversion is handled by inserting only the first \(N\) bytes of the string on the slave, where \(N\) is the width of the target column.

• Between any 2 BIT columns of any 2 sizes.

When inserting a value from a BIT \((M)\) column into a BIT \((M')\) column, where \(M' > M\), the most significant bits of the BIT \((M')\) columns are cleared (set to zero) and the \(M\) bits of the BIT \((M)\) value are set as the least significant bits of the BIT \((M')\) column.

When inserting a value from a source BIT \((M)\) column into a target BIT \((M')\) column, where \(M' < M\), the maximum possible value for the BIT \((M')\) column is assigned; in other words, an “all-set” value is assigned to the target column.

Conversions between types not in the previous list are not permitted.

17.4.1.10 Replication and DIRECTORY Table Options

If a DATA DIRECTORY or INDEX DIRECTORY table option is used in a CREATE TABLE statement on the master server, the table option is also used on the slave. This can cause problems if no corresponding directory exists in the slave host file system or if it exists but is not accessible to the slave server. This can be overridden by using the NO_DIR_IN_CREATE server SQL mode on the slave, which causes the slave to ignore the DATA DIRECTORY and INDEX DIRECTORY table options when replicating CREATE TABLE statements. The result is that MyISAM data and index files are created in the table’s database directory.
Replication Features and Issues

For more information, see Section 5.1.10, “Server SQL Modes”.

17.4.1.11 Replication of DROP ... IF EXISTS Statements

The DROP DATABASE IF EXISTS, DROP TABLE IF EXISTS, and DROP VIEW IF EXISTS statements are always replicated, even if the database, table, or view to be dropped does not exist on the master. This is to ensure that the object to be dropped no longer exists on either the master or the slave, once the slave has caught up with the master.

DROP ... IF EXISTS statements for stored programs (stored procedures and functions, triggers, and events) are also replicated, even if the stored program to be dropped does not exist on the master.

17.4.1.12 Replication and Floating-Point Values

With statement-based replication, values are converted from decimal to binary. Because conversions between decimal and binary representations of them may be approximate, comparisons involving floating-point values are inexact. This is true for operations that use floating-point values explicitly, or that use values that are converted to floating-point implicitly. Comparisons of floating-point values might yield different results on master and slave servers due to differences in computer architecture, the compiler used to build MySQL, and so forth. See Section 12.2, “Type Conversion in Expression Evaluation”, and Section B.4.4.8, “Problems with Floating-Point Values”.

17.4.1.13 Replication and FLUSH

Some forms of the FLUSH statement are not logged because they could cause problems if replicated to a slave: FLUSH LOGS and FLUSH TABLES WITH READ LOCK. For a syntax example, see Section 13.7.6.3, “FLUSH Syntax”. The FLUSH TABLES, ANALYZE TABLE, OPTIMIZE TABLE, and REPAIR TABLE statements are written to the binary log and thus replicated to slaves. This is not normally a problem because these statements do not modify table data.

However, this behavior can cause difficulties under certain circumstances. If you replicate the privilege tables in the mysql database and update those tables directly without using GRANT, you must issue a FLUSH PRIVILEGES on the slaves to put the new privileges into effect. In addition, if you use FLUSH TABLES when renaming a MyISAM table that is part of a MERGE table, you must issue FLUSH TABLES manually on the slaves. These statements are written to the binary log unless you specify NO_WRITE_TO_BINLOG or its alias LOCAL.

17.4.1.14 Replication and Fractional Seconds Support

MySQL 5.6.4 and up permits fractional seconds for TIME, DATETIME, and TIMESTAMP values, with up to microseconds (6 digits) precision. See Section 11.3.6, “Fractional Seconds in Time Values”.

There may be problems replicating from a master server that understands fractional seconds to an older slave that does not:

- For CREATE TABLE statements containing columns that have an fsp (fractional seconds precision) value greater than 0, replication will fail due to parser errors.

- Statements that use temporal data types with an fsp value of 0 will work for with statement-based logging but not row-based logging. In the latter case, the data types have binary formats and type codes on the master that differ from those on the slave.

- Some expression results will differ on master and slave. Examples: On the master, the timestamp system variable returns a value that includes a microseconds fractional part; on the slave, it returns an integer. On the master, functions that return a result that includes the current time (such as CURTIME()).
SYSDATE(), or UTC_TIMESTAMP()) interpret an argument as an fsp value and the return value includes a fractional seconds part of that many digits. On the slave, these functions permit an argument but ignore it.

17.4.1.15 Replication and System Functions

Certain functions do not replicate well under some conditions:

- The USER(), CURRENT_USER() (or CURRENT_USER), UUID(), VERSION(), and LOAD_FILE() functions are replicated without change and thus do not work reliably on the slave unless row-based replication is enabled. (See Section 17.1.2, “Replication Formats”.)

- USER() and CURRENT_USER() are automatically replicated using row-based replication when using MIXED mode, and generate a warning in STATEMENT mode. (See also Section 17.4.1.8, “Replication of CURRENT_USER()”.) This is also true for VERSION() and RAND().

- For NOW(), the binary log includes the timestamp. This means that the value as returned by the call to this function on the master is replicated to the slave. To avoid unexpected results when replicating between MySQL servers in different time zones, set the time zone on both master and slave. See also Section 17.4.1.31, “Replication and Time Zones”

To explain the potential problems when replicating between servers which are in different time zones, suppose that the master is located in New York, the slave is located in Stockholm, and both servers are using local time. Suppose further that, on the master, you create a table mytable, perform an INSERT statement on this table, and then select from the table, as shown here:

```
mysql> CREATE TABLE mytable (mycol TEXT);
Query OK, 0 rows affected (0.06 sec)

mysql> INSERT INTO mytable VALUES ( NOW() );
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM mytable;
+---------------------+
| mycol               |
+---------------------+
| 2009-09-01 12:00:00  |
+---------------------+
1 row in set (0.00 sec)
```

Local time in Stockholm is 6 hours later than in New York; so, if you issue SELECT NOW() on the slave at that exact same instant, the value 2009-09-01 18:00:00 is returned. For this reason, if you select from the slave’s copy of mytable after the CREATE TABLE and INSERT statements just shown have been replicated, you might expect mycol to contain the value 2009-09-01 18:00:00. However, this is not the case; when you select from the slave’s copy of mytable, you obtain exactly the same result as on the master:

```
mysql> SELECT * FROM mytable;
+---------------------+
| mycol               |
+---------------------+
| 2009-09-01 12:00:00  |
+---------------------+
1 row in set (0.00 sec)
```

Unlike NOW(), the SYSDATE() function is not replication-safe because it is not affected by SET TIMESTAMP statements in the binary log and is nondeterministic if statement-based logging is used. This is not a problem if row-based logging is used.
An alternative is to use the --sysdate-is-now option to cause SYSDATE() to be an alias for NOW(). This must be done on the master and the slave to work correctly. In such cases, a warning is still issued by this function, but can safely be ignored as long as --sysdate-is-now is used on both the master and the slave.

SYSDATE() is automatically replicated using row-based replication when using MIXED mode, and generates a warning in STATEMENT mode.

See also Section 17.4.1.31, “Replication and Time Zones”.

The following restriction applies to statement-based replication only, not to row-based replication. The GET_LOCK(), RELEASE_LOCK(), IS_FREE_LOCK(), and IS_USED_LOCK() functions that handle user-level locks are replicated without the slave knowing the concurrency context on the master. Therefore, these functions should not be used to insert into a master table because the content on the slave would differ. For example, do not issue a statement such as INSERT INTO mytable VALUES(GET_LOCK(...)). These functions are automatically replicated using row-based replication when using MIXED mode, and generate a warning in STATEMENT mode.

As a workaround for the preceding limitations when statement-based replication is in effect, you can use the strategy of saving the problematic function result in a user variable and referring to the variable in a later statement. For example, the following single-row INSERT is problematic due to the reference to the UUID() function:

```
INSERT INTO t VALUES(UUID());
```

To work around the problem, do this instead:

```
SET @my_uuid = UUID();
INSERT INTO t VALUES(@my_uuid);
```

That sequence of statements replicates because the value of @my_uuid is stored in the binary log as a user-variable event prior to the INSERT statement and is available for use in the INSERT.

The same idea applies to multiple-row inserts, but is more cumbersome to use. For a two-row insert, you can do this:

```
SET @my_uuid1 = UUID(); @my_uuid2 = UUID();
INSERT INTO t VALUES(@my_uuid1),(@my_uuid2);
```

However, if the number of rows is large or unknown, the workaround is difficult or impracticable. For example, you cannot convert the following statement to one in which a given individual user variable is associated with each row:

```
INSERT INTO t2 SELECT UUID(), * FROM t1;
```

Within a stored function, RAND() replicates correctly as long as it is invoked only once during the execution of the function. (You can consider the function execution timestamp and random number seed as implicit inputs that are identical on the master and slave.)

The FOUND_ROWS() and ROW_COUNT() functions are not replicated reliably using statement-based replication. A workaround is to store the result of the function call in a user variable, and then use that in the INSERT statement. For example, if you wish to store the result in a table named mytable, you might normally do so like this:
Replication Features and Issues

SELECT SQL_CALC_FOUND_ROWS FROM mytable LIMIT 1;
INSERT INTO mytable VALUES( FOUND_ROWS() );

However, if you are replicating `mytable`, you should use `SELECT ... INTO`, and then store the variable in the table, like this:

SELECT SQL_CALC_FOUND_ROWS INTO @found_rows FROM mytable LIMIT 1;
INSERT INTO mytable VALUES(@found_rows);

In this way, the user variable is replicated as part of the context, and applied on the slave correctly.

These functions are automatically replicated using row-based replication when using `MIXED` mode, and generate a warning in `STATEMENT` mode. (Bug #12092, Bug #30244)

Prior to MySQL 5.6.15, the value of `LAST_INSERT_ID()` was not replicated correctly if any filtering options such as `--replicate-ignore-db` and `--replicate-do-table` were enabled on the slave. (Bug #17234370, BUG# 69861)

17.4.1.16 Replication of Invoked Features

Replication of invoked features such as user-defined functions (UDFs) and stored programs (stored procedures and functions, triggers, and events) provides the following characteristics:

- The effects of the feature are always replicated.
- The following statements are replicated using statement-based replication:
  - `CREATE EVENT`
  - `ALTER EVENT`
  - `DROP EVENT`
  - `CREATE PROCEDURE`
  - `DROP PROCEDURE`
  - `CREATE FUNCTION`
  - `DROP FUNCTION`
  - `CREATE TRIGGER`
  - `DROP TRIGGER`

However, the effects of features created, modified, or dropped using these statements are replicated using row-based replication.

Note

Attempting to replicate invoked features using statement-based replication produces the warning `Statement is not safe to log in statement format`. For example, trying to replicate a UDF with statement-based replication generates this warning because it currently cannot be determined by the MySQL server whether the UDF is deterministic. If you are absolutely certain that the invoked feature's effects are deterministic, you can safely disregard such warnings.
• In the case of `CREATE EVENT` and `ALTER EVENT`:

  • The status of the event is set to `SLAVESIDE_DISABLED` on the slave regardless of the state specified (this does not apply to `DROP EVENT`).

  • The master on which the event was created is identified on the slave by its server ID. The `ORIGINATOR` column in `INFORMATION_SCHEMA.EVENTS` and the `originator` column in `mysql.event` store this information. See Section 21.8, “The INFORMATION_SCHEMA EVENTS Table”, and Section 13.7.5.19, “SHOW EVENTS Syntax”, for more information.

  • The feature implementation resides on the slave in a renewable state so that if the master fails, the slave can be used as the master without loss of event processing.

To determine whether there are any scheduled events on a MySQL server that were created on a different server (that was acting as a replication master), query the `INFORMATION_SCHEMA.EVENTS` table in a manner similar to what is shown here:

```sql
SELECT EVENT_SCHEMA, EVENT_NAME
FROM INFORMATION_SCHEMA.EVENTS
WHERE STATUS = 'SLAVESIDE_DISABLED';
```

Alternatively, you can use the `SHOW EVENTS` statement, like this:

```sql
SHOW EVENTS
WHERE STATUS = 'SLAVESIDE_DISABLED';
```

When promoting a replication slave having such events to a replication master, you must enable each event using `ALTER EVENT event_name ENABLE`, where `event_name` is the name of the event.

If more than one master was involved in creating events on this slave, and you wish to identify events that were created only on a given master having the server ID `master_id`, modify the previous query on the `EVENTS` table to include the `ORIGINATOR` column, as shown here:

```sql
SELECT EVENT_SCHEMA, EVENT_NAME, ORIGINATOR
FROM INFORMATION_SCHEMA.EVENTS
WHERE STATUS = 'SLAVESIDE_DISABLED'
AND   ORIGINATOR = 'master_id'
```

You can employ `ORIGINATOR` with the `SHOW EVENTS` statement in a similar fashion:

```sql
SHOW EVENTS
WHERE STATUS = 'SLAVESIDE_DISABLED'
AND   ORIGINATOR = 'master_id'
```

Before enabling events that were replicated from the master, you should disable the MySQL Event Scheduler on the slave (using a statement such as `SET GLOBAL event_scheduler = OFF;`), run any necessary `ALTER EVENT` statements, restart the server, then re-enable the Event Scheduler on the slave afterward (using a statement such as `SET GLOBAL event_scheduler = ON;`).

If you later demote the new master back to being a replication slave, you must disable manually all events enabled by the `ALTER EVENT` statements. You can do this by storing in a separate table the event names from the `SELECT` statement shown previously, or using `ALTER EVENT` statements to rename the events with a common prefix such as `replicated_` to identify them.

If you rename the events, then when demoting this server back to being a replication slave, you can identify the events by querying the `EVENTS` table, as shown here:
SELECT CONCAT(EVENT_SCHEMA, '.', EVENT_NAME) AS 'Db.Event' FROM INFORMATION_SCHEMA.EVENTS WHERE INSTR(EVENT_NAME, 'replicated_') = 1;

17.4.1.17 Replication and LIMIT

Statement-based replication of `LIMIT` clauses in `DELETE`, `UPDATE`, and `INSERT ... SELECT` statements is unsafe since the order of the rows affected is not defined. (Such statements can be replicated correctly with statement-based replication only if they also contain an `ORDER BY` clause.) When such a statement is encountered:

- When using `STATEMENT` mode, a warning that the statement is not safe for statement-based replication is now issued.
- When using `STATEMENT` mode, warnings are issued for DML statements containing `LIMIT` even when they also have an `ORDER BY` clause (and so are made deterministic). This is a known issue. (Bug #42851)
- When using `MIXED` mode, the statement is now automatically replicated using row-based mode.

17.4.1.18 Replication and LOAD DATA

`LOAD DATA` is considered unsafe for statement-based logging (see Section 17.1.2.3, “Determination of Safe and Unsafe Statements in Binary Logging”). When `binlog_format=MIXED` is set, the statement is logged in row-based format. When `binlog_format=STATEMENT` is set, note that `LOAD DATA` does not generate a warning, unlike other unsafe statements.

When `mysqlbinlog` reads log events for `LOAD DATA` statements logged in statement-based format, a generated local file is created in a temporary directory. These temporary files are not automatically removed by `mysqlbinlog` or any other MySQL program. If you do use `LOAD DATA` statements with statement-based binary logging, you should delete the temporary files yourself after you no longer need the statement log. For more information, see Section 4.6.8, "mysqlbinlog — Utility for Processing Binary Log Files".

17.4.1.19 Replication and `max_allowed_packet`

`max_allowed_packet` sets an upper limit on the size of any single message between the MySQL server and clients, including replication slaves. If you are replicating large column values (such as might be found in `TEXT` or `BLOB` columns) and `max_allowed_packet` is too small on the master, the master fails with an error, and the slave shuts down the I/O thread. If `max_allowed_packet` is too small on the slave, this also causes the slave to stop the I/O thread.

Row-based replication currently sends all columns and column values for updated rows from the master to the slave, including values of columns that were not actually changed by the update. This means that, when you are replicating large column values using row-based replication, you must take care to set `max_allowed_packet` large enough to accommodate the largest row in any table to be replicated, even if you are replicating updates only, or you are inserting only relatively small values.

17.4.1.20 Replication and MEMORY Tables

When a master server shuts down and restarts, its `MEMORY` tables become empty. To replicate this effect to slaves, the first time that the master uses a given `MEMORY` table after startup, it logs an event that notifies slaves that the table must be emptied by writing a `DELETE` statement for that table to the binary log.

When a slave server shuts down and restarts, its `MEMORY` tables become empty. This causes the slave to be out of synchrony with the master and may lead to other failures or cause the slave to stop:
Replication Features and Issues

- Row-format updates and deletes received from the master may fail with *Can't find record in 'memory_table'*.

- Statements such as `INSERT INTO ... SELECT FROM memory_table` may insert a different set of rows on the master and slave.

The safe way to restart a slave that is replicating `MEMORY` tables is to first drop or delete all rows from the `MEMORY` tables on the master and wait until those changes have replicated to the slave. Then it is safe to restart the slave.

An alternative restart method may apply in some cases. When `binlog_format=ROW`, you can prevent the slave from stopping if you set `slave_exec_mode=IDEMPOTENT` before you start the slave again. This allows the slave to continue to replicate, but its `MEMORY` tables will still be different from those on the master. This can be okay if the application logic is such that the contents of `MEMORY` tables can be safely lost (for example, if the `MEMORY` tables are used for caching). `slave_exec_mode=IDEMPOTENT` applies globally to all tables, so it may hide other replication errors in non-`MEMORY` tables.

(The method just described is not applicable in NDB Cluster, where `slave_exec_mode` is always `IDEMPOTENT`, and cannot be changed.)

The size of `MEMORY` tables is limited by the value of the `max_heap_table_size` system variable, which is not replicated (see Section 17.4.1.35, “Replication and Variables”). A change in `max_heap_table_size` takes effect for `MEMORY` tables that are created or updated using `ALTER TABLE ... ENGINE = MEMORY` or `TRUNCATE TABLE` following the change, or for all `MEMORY` tables following a server restart. If you increase the value of this variable on the master without doing so on the slave, it becomes possible for a table on the master to grow larger than its counterpart on the slave, leading to inserts that succeed on the master but fail on the slave with *Table is full* errors. This is a known issue (Bug #48666). In such cases, you must set the global value of `max_heap_table_size` on the slave as well as on the master, then restart replication. It is also recommended that you restart both the master and slave MySQL servers, to insure that the new value takes complete (global) effect on each of them.

See Section 15.3, “The MEMORY Storage Engine”, for more information about `MEMORY` tables.

17.4.1.21 Replication of the mysql System Database

Data modification statements made to tables in the `mysql` database are replicated according to the value of `binlog_format`; if this value is `MIXED`, these statements are replicated using row-based format. However, statements that would normally update this information indirectly—such as `GRANT`, `REVOKE`, and statements manipulating triggers, stored routines, and views—are replicated to slaves using statement-based replication.

17.4.1.22 Replication and the Query Optimizer

It is possible for the data on the master and slave to become different if a statement is written in such a way that the data modification is nondeterministic; that is, left up the query optimizer. (In general, this is not a good practice, even outside of replication.) Examples of nondeterministic statements include `DELETE` or `UPDATE` statements that use `LIMIT` with no `ORDER BY` clause; see Section 17.4.1.17, “Replication and LIMIT”, for a detailed discussion of these.

17.4.1.23 Replication and Partitioning

Replication is supported between partitioned tables as long as they use the same partitioning scheme and otherwise have the same structure except where an exception is specifically allowed (see Section 17.4.1.9, “Replication with Differing Table Definitions on Master and Slave”).
Replication between tables having different partitioning is generally not supported. This because statements (such as `ALTER TABLE ... DROP PARTITION`) acting directly on partitions in such cases may produce different results on master and slave. In the case where a table is partitioned on the master but not on the slave, any statements operating on partitions on the master's copy of the slave fail on the slave. When the slave's copy of the table is partitioned but the master's copy is not, statements acting on partitions cannot be run on the master without causing errors there.

Due to these dangers of causing replication to fail entirely (on account of failed statements) and of inconsistencies (when the result of a partition-level SQL statement produces different results on master and slave), we recommend that insure that the partitioning of any tables to be replicated from the master is matched by the slave's versions of these tables.

### 17.4.1.24 Replication and REPAIR TABLE

When used on a corrupted or otherwise damaged table, it is possible for the `REPAIR TABLE` statement to delete rows that cannot be recovered. However, any such modifications of table data performed by this statement are not replicated, which can cause master and slave to lose synchronization. For this reason, in the event that a table on the master becomes damaged and you use `REPAIR TABLE` to repair it, you should first stop replication (if it is still running) before using `REPAIR TABLE`, then afterward compare the master's and slave's copies of the table and be prepared to correct any discrepancies manually, before restarting replication.

### 17.4.1.25 Replication and Reserved Words

You can encounter problems when you attempt to replicate from an older master to a newer slave and you make use of identifiers on the master that are reserved words in the newer MySQL version running on the slave. An example of this is using a table column named `range` on a 5.0 master that is replicating to a 5.1 or higher slave because `RANGE` is a reserved word beginning in MySQL 5.1. Replication can fail in such cases with Error 1064 `You have an error in your SQL syntax...`, even if a database or table named using the reserved word or a table having a column named using the reserved word is excluded from replication. This is due to the fact that each SQL event must be parsed by the slave prior to execution, so that the slave knows which database object or objects would be affected; only after the event is parsed can the slave apply any filtering rules defined by `--replicate-do-db`, `--replicate-do-table`, `--replicate-ignore-db`, and `--replicate-ignore-table`.

To work around the problem of database, table, or column names on the master which would be regarded as reserved words by the slave, do one of the following:

- Use one or more `ALTER TABLE` statements on the master to change the names of any database objects where these names would be considered reserved words on the slave, and change any SQL statements that use the old names to use the new names instead.

- In any SQL statements using these database object names, write the names as quoted identifiers using backtick characters (``).

For listings of reserved words by MySQL version, see `Reserved Words`, in the `MySQL Server Version Reference`. For identifier quoting rules, see Section 9.2, “Schema Object Names”.

### 17.4.1.26 Replication and Master or Slave Shutdowns

It is safe to shut down a master server and restart it later. When a slave loses its connection to the master, the slave tries to reconnect immediately and retries periodically if that fails. The default is to retry every 60 seconds. This may be changed with the `CHANGE MASTER TO` statement. A slave also is able to deal with network connectivity outages. However, the slave notices the network outage only after receiving no data from the master for `slave_net_timeout` seconds. If your outages are short, you may want to decrease `slave_net_timeout`. See Section 5.1.7, “Server System Variables”.

2546
An unclean shutdown (for example, a crash) on the master side can result in the master binary log having a final position less than the most recent position read by the slave, due to the master binary log file not being flushed. This can cause the slave not to be able to replicate when the master comes back up. Setting `sync_binlog=1` in the master `my.cnf` file helps to minimize this problem because it causes the master to flush its binary log more frequently. For the greatest possible durability and consistency in a replication setup using InnoDB with transactions, you should also set `innodb_flush_log_at_trx_commit=1`. With this setting, the contents of the InnoDB redo log buffer are written out to the log file at each transaction commit and the log file is flushed to disk. Note that the durability of transactions is still not guaranteed with this setting, because operating systems or disk hardware may tell `mysqld` that the flush-to-disk operation has taken place, even though it has not.

Shutting down a slave cleanly is safe because it keeps track of where it left off. However, be careful that the slave does not have temporary tables open; see Section 17.4.1.29, “Replication and Temporary Tables”. Unclean shutdowns might produce problems, especially if the disk cache was not flushed to disk before the problem occurred:

- For transactions, the slave commits and then updates `relay-log.info`. If a crash occurs between these two operations, relay log processing will have proceeded further than the information file indicates and the slave will re-execute the events from the last transaction in the relay log after it has been restarted.

- A similar problem can occur if the slave updates `relay-log.info` but the server host crashes before the write has been flushed to disk. To minimize the chance of this occurring, set `sync_relay_log_info=1` in the slave `my.cnf` file. The default value of `sync_relay_log_info` is 0, which does not cause writes to be forced to disk; the server relies on the operating system to flush the file from time to time.

The fault tolerance of your system for these types of problems is greatly increased if you have a good uninterruptible power supply.

17.4.1.27 Slave Errors During Replication

If a statement produces the same error (identical error code) on both the master and the slave, the error is logged, but replication continues.

If a statement produces different errors on the master and the slave, the slave SQL thread terminates, and the slave writes a message to its error log and waits for the database administrator to decide what to do about the error. This includes the case that a statement produces an error on the master or the slave, but not both. To address the issue, connect to the slave manually and determine the cause of the problem. `SHOW SLAVE STATUS` is useful for this. Then fix the problem and run `START SLAVE`. For example, you might need to create a nonexistent table before you can start the slave again.

**Note**

If a temporary error is recorded in the slave’s error log, you do not necessarily have to take any action suggested in the quoted error message. Temporary errors should be handled by the client retrying the transaction. For example, if the slave SQL thread records a temporary error relating to a deadlock, you do not need to restart the transaction manually on the slave, unless the slave SQL thread subsequently terminates with a nontemporary error message.

If this error code validation behavior is not desirable, some or all errors can be masked out (ignored) with the `--slave-skip-errors` option.

For nontransactional storage engines such as MyISAM, it is possible to have a statement that only partially updates a table and returns an error code. This can happen, for example, on a multiple-row insert that has
one row violating a key constraint, or if a long update statement is killed after updating some of the rows. If that happens on the master, the slave expects execution of the statement to result in the same error code. If it does not, the slave SQL thread stops as described previously.

If you are replicating between tables that use different storage engines on the master and slave, keep in mind that the same statement might produce a different error when run against one version of the table, but not the other, or might cause an error for one version of the table, but not the other. For example, since MyISAM ignores foreign key constraints, an INSERT or UPDATE statement accessing an InnoDB table on the master might cause a foreign key violation but the same statement performed on a MyISAM version of the same table on the slave would produce no such error, causing replication to stop.

17.4.1.28 Replication and Server SQL Mode

Using different server SQL mode settings on the master and the slave may cause the same INSERT statements to be handled differently on the master and the slave, leading the master and slave to diverge. For best results, you should always use the same server SQL mode on the master and on the slave. This advice applies whether you are using statement-based or row-based replication.

If you are replicating partitioned tables, using different SQL modes on the master and the slave is likely to cause issues. At a minimum, this is likely to cause the distribution of data among partitions to be different in the master's and slave's copies of a given table. It may also cause inserts into partitioned tables that succeed on the master to fail on the slave.

For more information, see Section 5.1.10, “Server SQL Modes”.

17.4.1.29 Replication and Temporary Tables

The discussion in the following paragraphs does not apply when binlog_format=ROW because, in that case, temporary tables are not replicated; this means that there are never any temporary tables on the slave to be lost in the event of an unplanned shutdown by the slave. The remainder of this section applies only when using statement-based or mixed-format replication. Loss of replicated temporary tables on the slave can be an issue, whenever binlog_format is STATEMENT or MIXED, for statements involving temporary tables that can be logged safely using statement-based format. For more information about row-based replication and temporary tables, see Row-based logging of temporary tables.

Safe slave shutdown when using temporary tables. Temporary tables are replicated except in the case where you stop the slave server (not just the slave threads) and you have replicated temporary tables that are open for use in updates that have not yet been executed on the slave. If you stop the slave server, the temporary tables needed by those updates are no longer available when the slave is restarted. To avoid this problem, do not shut down the slave while it has temporary tables open. Instead, use the following procedure:

1. Issue a DROP SLAVE SQL_THREAD statement.

2. Use SHOW STATUS to check the value of the Slave_open_temp_tables variable.

3. If the value is not 0, restart the slave SQL thread with START SLAVE SQL_THREAD and repeat the procedure later.

4. When the value is 0, issue a mysqladmin shutdown command to stop the slave.

Temporary tables and replication options. By default, all temporary tables are replicated; this happens whether or not there are any matching --replicate-do-db, --replicate-do-table, or --replicate-wild-do-table options in effect. However, the --replicate-ignore-table and --replicate-wild-ignore-table options are honored for temporary tables. The exception is that to
enable correct removal of temporary tables at the end of a session, a replication slave always replicates a \texttt{DROP TEMPORARY TABLE IF EXISTS} statement, regardless of any exclusion rules that would normally apply for the specified table.

A recommended practice when using statement-based or mixed-format replication is to designate a prefix for exclusive use in naming temporary tables that you do not want replicated, then employ a \texttt{--replicate-wild-ignore-table} option to match that prefix. For example, you might give all such tables names beginning with \texttt{norep} (such as \texttt{norepmytable}, \texttt{norepyourtable}, and so on), then use \texttt{--replicate-wild-ignore-table=norep\%} to prevent them from being replicated.

### 17.4.1.30 Replication Retries and Timeouts

The global system variable \texttt{slave_transaction_retries} affects replication as follows:

If the slave SQL thread fails to execute a transaction because of an InnoDB deadlock or because it exceeded the \texttt{InnoDB innodb_lock_wait_timeout} value, or the NDB \texttt{TransactionDeadlockDetectionTimeout} or \texttt{TransactionInactiveTimeout} value, the slave automatically retries the transaction \texttt{slave_transaction_retries} times before stopping with an error. The default value is 10. The total retry count can be seen in the output of \texttt{SHOW STATUS}; see Section 5.1.9, “Server Status Variables”.

### 17.4.1.31 Replication and Time Zones

By default, master and slave servers assume that they are in the same time zone. If you are replicating between servers in different time zones, the time zone must be set on both master and slave. Otherwise, statements depending on the local time on the master are not replicated properly, such as statements that use the \texttt{NOW()} or \texttt{FROM_UNIXTIME()} functions. Set the time zone in which MySQL server runs by using the \texttt{--timezone=timezone\_name} option of the \texttt{mysqld\_safe} script or by setting the \texttt{TZ} environment variable. See also Section 17.4.1.15, “Replication and System Functions”.

### 17.4.1.32 Replication and Transactions

**Mixing transactional and nontransactional statements within the same transaction.**  In general, you should avoid transactions that update both transactional and nontransactional tables in a replication environment. You should also avoid using any statement that accesses both transactional (or temporary) and nontransactional tables and writes to any of them.

The MySQL server uses these rules for binary logging:

- If the initial statements in a transaction are nontransactional, they are written to the binary log immediately. The remaining statements in the transaction are cached and not written to the binary log until the transaction is committed. (If the transaction is rolled back, the cached statements are written to the binary log only if they make nontransactional changes that cannot be rolled back. Otherwise, they are discarded.)

- For statement-based logging, logging of nontransactional statements is affected by the \texttt{binlog\_direct\_non\_transactional\_updates} system variable. When this variable is \texttt{OFF} (the default), logging is as just described. When this variable is \texttt{ON}, logging occurs immediately for nontransactional statements occurring anywhere in the transaction (not just initial nontransactional statements). Other statements are kept in the transaction cache and logged when the transaction commits. \texttt{binlog\_direct\_non\_transactional\_updates} has no effect for row-format or mixed-format binary logging.

**Transactional, nontransactional, and mixed statements.**  To apply those rules, the server considers a statement nontransactional if it changes only nontransactional tables, and transactional if it changes only transactional tables. In MySQL 5.6, a statement that references
both nontransactional and transactional tables and updates any of the tables involved, is considered a “mixed” statement. (In previous MySQL release series, a statement that changed both nontransactional and transactional tables was considered mixed.) Mixed statements, like transactional statements, are cached and logged when the transaction commits.

A mixed statement that updates a transactional table is considered unsafe if the statement also performs either of the following actions:

- Updates or reads a temporary table
- Reads a nontransactional table and the transaction isolation level is less than REPEATABLE_READ

A mixed statement following the update of a transactional table within a transaction is considered unsafe if it performs either of the following actions:

- Updates any table and reads from any temporary table
- Updates a nontransactional table and binlog_direct_non_transactional_updates is OFF

For more information, see Section 17.1.2.3, “Determination of Safe and Unsafe Statements in Binary Logging”.

Note
A mixed statement is unrelated to mixed binary logging format.

In situations where transactions mix updates to transactional and nontransactional tables, the order of statements in the binary log is correct, and all needed statements are written to the binary log even in case of a ROLLBACK. However, when a second connection updates the nontransactional table before the first connection transaction is complete, statements can be logged out of order because the second connection update is written immediately after it is performed, regardless of the state of the transaction being performed by the first connection.

**Using different storage engines on master and slave.** It is possible to replicate transactional tables on the master using nontransactional tables on the slave. For example, you can replicate an InnoDB master table as a MyISAM slave table. However, if you do this, there are problems if the slave is stopped in the middle of a BEGIN ... COMMIT block because the slave restarts at the beginning of the BEGIN block.

In MySQL 5.6, it is also safe to replicate transactions from MyISAM tables on the master to transactional tables—such as tables that use the InnoDB storage engine—on the slave. In such cases, an AUTOCOMMIT=1 statement issued on the master is replicated, thus enforcing AUTOCOMMIT mode on the slave.

When the storage engine type of the slave is nontransactional, transactions on the master that mix updates of transactional and nontransactional tables should be avoided because they can cause inconsistency of the data between the master transactional table and the slave nontransactional table. That is, such transactions can lead to master storage engine-specific behavior with the possible effect of replication going out of synchrony. MySQL does not issue a warning about this currently, so extra care should be taken when replicating transactional tables from the master to nontransactional tables on the slaves.

**Changing the binary logging format within transactions.** The binlog_format system variable is read-only as long as a transaction is in progress. (Bug #47863)

Every transaction (including autocommit transactions) is recorded in the binary log as though it starts with a BEGIN statement, and ends with either a COMMIT or a ROLLBACK statement. In MySQL 5.6, this true is even for statements affecting tables that use a nontransactional storage engine (such as MyISAM).
17.4.1.33 Replication and Triggers

With statement-based replication, triggers executed on the master also execute on the slave. With row-based replication, triggers executed on the master do not execute on the slave. Instead, the row changes on the master resulting from trigger execution are replicated and applied on the slave.

This behavior is by design. If under row-based replication the slave applied the triggers as well as the row changes caused by them, the changes would in effect be applied twice on the slave, leading to different data on the master and the slave.

If you want triggers to execute on both the master and the slave—perhaps because you have different triggers on the master and slave—you must use statement-based replication. However, to enable slave-side triggers, it is not necessary to use statement-based replication exclusively. It is sufficient to switch to statement-based replication only for those statements where you want this effect, and to use row-based replication the rest of the time.

A statement invoking a trigger (or function) that causes an update to an AUTO_INCREMENT column is not replicated correctly using statement-based replication. MySQL 5.6 marks such statements as unsafe. (Bug #45677)

17.4.1.34 Replication and TRUNCATE TABLE

TRUNCATE TABLE is normally regarded as a DML statement, and so would be expected to be logged and replicated using row-based format when the binary logging mode is ROW or MIXED. However this caused issues when logging or replicating, in STATEMENT or MIXED mode, tables that used transactional storage engines such as InnoDB when the transaction isolation level was READ COMMITTED or READ UNCOMMITTED, which precludes statement-based logging.

TRUNCATE TABLE is treated for purposes of logging and replication as DDL rather than DML so that it can be logged and replicated as a statement. However, the effects of the statement as applicable to InnoDB and other transactional tables on replication slaves still follow the rules described in Section 13.1.33, “TRUNCATE TABLE Syntax” governing such tables. (Bug #36763)

17.4.1.35 Replication and Variables

System variables are not replicated correctly when using STATEMENT mode, except for the following variables when they are used with session scope:

- auto_increment_increment
- auto_increment_offset
- character_set_client
- character_set_connection
- character_set_database
- character_set_server
- collation_connection
- collation_database
- collation_server
- foreign_key_checks
Replication Features and Issues

- identity
- last_insert_id
- lc_time_names
- pseudo_thread_id
- sql_auto_is_null
- time_zone
- timestamp
- unique_checks

When MIXED mode is used, the variables in the preceding list, when used with session scope, cause a switch from statement-based to row-based logging. See Section 5.4.4.3, “Mixed Binary Logging Format”. sql_mode is also replicated except for the NO_DIR_IN_CREATE mode; the slave always preserves its own value for NO_DIR_IN_CREATE, regardless of changes to it on the master. This is true for all replication formats.

However, when mysqlbinlog parses a SET @@sql_mode = mode statement, the full mode value, including NO_DIR_IN_CREATE, is passed to the receiving server. For this reason, replication of such a statement may not be safe when STATEMENT mode is in use.

The default_storage_engine and storage_engine system variables are not replicated, regardless of the logging mode; this is intended to facilitate replication between different storage engines.

The read_only system variable is not replicated. In addition, the enabling this variable has different effects with regard to temporary tables, table locking, and the SET PASSWORD statement in different MySQL versions.

The max_heap_table_size system variable is not replicated. Increasing the value of this variable on the master without doing so on the slave can lead eventually to Table is full errors on the slave when trying to execute INSERT statements on a MEMORY table on the master that is thus permitted to grow larger than its counterpart on the slave. For more information, see Section 17.4.1.20, “Replication and MEMORY Tables”.

In statement-based replication, session variables are not replicated properly when used in statements that update tables. For example, the following sequence of statements will not insert the same data on the master and the slave:

```
SET max_join_size=1000;
INSERT INTO mytable VALUES(@@max_join_size);
```

This does not apply to the common sequence:

```
SET time_zone=...;
INSERT INTO mytable VALUES(CONVERT_TZ(..., ..., @@time_zone));
```

Replication of session variables is not a problem when row-based replication is being used, in which case, session variables are always replicated safely. See Section 17.1.2, “Replication Formats”.

In MySQL 5.6, the following session variables are written to the binary log and honored by the replication slave when parsing the binary log, regardless of the logging format:
• sql_mode
• foreign_key_checks
• unique_checks
• character_set_client
• collation_connection
• collation_database
• collation_server
• sql_auto_is_null

Important

Even though session variables relating to character sets and collations are written to the binary log, replication between different character sets is not supported.

To help reduce possible confusion, we recommend that you always use the same setting for the lower_case_table_names system variable on both master and slave, especially when you are running MySQL on platforms with case-sensitive file systems.

Note

In previous versions of MySQL, when a case-sensitive file system was in use, setting this variable to 1 on the slave and to a different value on the master could lead to replication failure. This issue is fixed in MySQL 5.6.1. (Bug #37656)

17.4.1.36 Replication and Views

Views are always replicated to slaves. Views are filtered by their own name, not by the tables they refer to. This means that a view can be replicated to the slave even if the view contains a table that would normally be filtered out by replication-ignore-table rules. Care should therefore be taken to ensure that views do not replicate table data that would normally be filtered for security reasons.

Replication from a table to a same-named view is supported using statement-based logging, but not when using row-based logging. In MySQL 5.6.11 and later, trying to do so when row-based logging is in effect causes an error. (Bug #11752707, Bug #43975)

17.4.2 Replication Compatibility Between MySQL Versions

MySQL supports replication from one release series to the next higher release series. For example, you can replicate from a master running MySQL 5.6 to a slave running MySQL 5.7, from a master running MySQL 5.7 to a slave running MySQL 8.0, and so on. However, you may encounter difficulties when replicating from an older master to a newer slave if the master uses statements or relies on behavior no longer supported in the version of MySQL used on the slave. For example, foreign key names longer than 64 characters are no longer supported from MySQL 8.0.

The use of more than two MySQL Server versions is not supported in replication setups involving multiple masters, regardless of the number of master or slave MySQL servers. This restriction applies not only to release series, but to version numbers within the same release series as well. For example, if you are using a chained or circular replication setup, you cannot use MySQL 5.6.39, MySQL 5.6.40, and MySQL 5.6.41 concurrently, although you could use any two of these releases together.
Important

It is strongly recommended to use the most recent release available within a given MySQL release series because replication (and other) capabilities are continually being improved. It is also recommended to upgrade masters and slaves that use early releases of a release series of MySQL to GA (production) releases when the latter become available for that release series.

Replication from newer masters to older slaves may be possible, but is generally not supported. This is due to a number of factors:

• **Binary log format changes.** The binary log format can change between major releases. While we attempt to maintain backward compatibility, this is not always possible. For example, the binary log format implemented in MySQL 5.0 changed considerably from that used in previous versions, especially with regard to handling of character sets, LOAD DATA, and time zones. This means that replication from a MySQL 5.0 (or later) master to a MySQL 4.1 (or earlier) slave is generally not supported.

This also has significant implications for upgrading replication servers; see Section 17.4.3, “Upgrading a Replication Setup”, for more information.

• **Use of row-based replication.** Row-based replication was implemented in MySQL 5.1.5, so you cannot replicate using row-based replication from any MySQL 5.6 or later master to a slave older than MySQL 5.1.5.

For more information about row-based replication, see Section 17.1.2, “Replication Formats”.

• **SQL incompatibilities.** You cannot replicate from a newer master to an older slave using statement-based replication if the statements to be replicated use SQL features available on the master but not on the slave.

However, if both the master and the slave support row-based replication, and there are no data definition statements to be replicated that depend on SQL features found on the master but not on the slave, you can use row-based replication to replicate the effects of data modification statements even if the DDL run on the master is not supported on the slave.

• **Important Variables in MySQL 5.6.** Features have been added to MySQL 5.6 which need to be disabled when replicating to earlier MySQL versions. To avoid incompatibilities, set the following variables on the MySQL 5.6 master:

  • `binlog_checksum=None`
  • `binlog_row_image=FULL`
  • `binlog_rows_query_log_events=OFF`
  • `log_bin_use_v1_row_events=1` (NDB Cluster only)
  • `gtid_mode=OFF`

For more information on potential replication issues, see Section 17.4.1, “Replication Features and Issues”.

### 17.4.3 Upgrading a Replication Setup

When you upgrade servers that participate in a replication setup, the procedure for upgrading depends on the current server versions and the version to which you are upgrading. This section provides information about how upgrading affects replication. For general information about upgrading MySQL, see Section 2.11, “Upgrading MySQL”
When you upgrade a master to 5.6 from an earlier MySQL release series, you should first ensure that all the slaves of this master are using the same 5.6.x release. If this is not the case, you should first upgrade the slaves. To upgrade each slave, shut it down, upgrade it to the appropriate 5.6.x version, restart it, and restart replication. Relay logs created by the slave after the upgrade are in 5.6 format.

Changes affecting operations in strict SQL mode may result in replication failure on an updated slave. For example, as of MySQL 5.6.13, the server restricts insertion of a DEFAULT value of 0 for temporal data types in strict mode (STRICT_TRANS_TABLES or STRICT_ALL_TABLES). A resulting incompatibility for replication if you use statement-based logging (binlog_format=STATEMENT) is that if a slave is upgraded, a nonupgraded master will execute statements without error that may fail on the slave and replication will stop. To deal with this, stop all new statements on the master and wait until the slaves catch up. Then upgrade the slaves. Alternatively, if you cannot stop new statements, temporarily change to row-based logging on the master (binlog_format=ROW) and wait until all slaves have processed all binary logs produced up to the point of this change. Then upgrade the slaves.

After the slaves have been upgraded, shut down the master, upgrade it to the same 5.6.x release as the slaves, and restart it. If you had temporarily changed the master to row-based logging, change it back to statement-based logging. The 5.6 master is able to read the old binary logs written prior to the upgrade and to send them to the 5.6 slaves. The slaves recognize the old format and handle it properly. Binary logs created by the master subsequent to the upgrade are in 5.6 format. These too are recognized by the 5.6 slaves.

In other words, when upgrading to MySQL 5.6, the slaves must be MySQL 5.6 before you can upgrade the master to 5.6. Note that downgrading from 5.6 to older versions does not work so simply: You must ensure that any 5.6 binary log or relay log has been fully processed, so that you can remove it before proceeding with the downgrade.

Some upgrades may require that you drop and re-create database objects when you move from one MySQL series to the next. For example, collation changes might require that table indexes be rebuilt. Such operations, if necessary, are detailed at Section 2.11.3, “Changes in MySQL 5.6”. It is safest to perform these operations separately on the slaves and the master, and to disable replication of these operations from the master to the slave. To achieve this, use the following procedure:

1. Stop all the slaves and upgrade them. Restart them with the --skip-slave-start option so that they do not connect to the master. Perform any table repair or rebuilding operations needed to re-create database objects, such as use of REPAIR TABLE or ALTER TABLE, or dumping and reloading tables or triggers.

2. Disable the binary log on the master. To do this without restarting the master, execute a SET sql_log_bin = OFF statement. Alternatively, stop the master and restart it without the --log-bin option. If you restart the master, you might also want to disallow client connections. For example, if all clients connect using TCP/IP, use the --skip-networking option when you restart the master.

3. With the binary log disabled, perform any table repair or rebuilding operations needed to re-create database objects. The binary log must be disabled during this step to prevent these operations from being logged and sent to the slaves later.

4. Re-enable the binary log on the master. If you set sql_log_bin to OFF earlier, execute a SET sql_log_bin = ON statement. If you restarted the master to disable the binary log, restart it with --log-bin, and without --skip-networking so that clients and slaves can connect.

5. Restart the slaves, this time without the --skip-slave-start option.

Replication with global transaction identifiers was introduced in MySQL 5.6.7. If you are upgrading an existing replication setup from a version of MySQL that does not support GTIDs to a version that does, you should not enable GTIDs on either the master or the slave before making sure that the setup meets all
the requirements for GTID-based replication. See Section 17.1.3.2, “Setting Up Replication Using GTIDs”, which contains information about converting existing replication setups to use GTID-based replication.

When the server is running with global transaction identifiers (GTIDs) enabled (gtid_mode=ON), do not enable binary logging by mysql_upgrade.

It is not recommended to load a dump file when GTIDs are enabled on the server (gtid_mode=ON), if your dump file includes system tables. mysqldump issues DML instructions for the system tables which use the non-transactional MyISAM storage engine, and this combination is not permitted when GTIDs are enabled. Also be aware that loading a dump file from a server with GTIDs enabled, into another server with GTIDs enabled, causes different transaction identifiers to be generated.

17.4.4 Troubleshooting Replication

If you have followed the instructions but your replication setup is not working, the first thing to do is check the error log for messages. Many users have lost time by not doing this soon enough after encountering problems.

If you cannot tell from the error log what the problem was, try the following techniques:

• Verify that the master has binary logging enabled by issuing a SHOW MASTER STATUS statement. If logging is enabled, Position is nonzero. If binary logging is not enabled, verify that you are running the master with the --log-bin option.

• Verify that the master and slave both were started with the --server-id option and that the ID value is unique on each server.

• Verify that the slave is running. Use SHOW SLAVE STATUS to check whether the Slave_IO_Running and Slave_SQL_Running values are both Yes. If not, verify the options that were used when starting the slave server. For example, --skip-slave-start prevents the slave threads from starting until you issue a START SLAVE statement.

• If the slave is running, check whether it established a connection to the master. Use SHOW PROCESSLIST, find the I/O and SQL threads and check their State column to see what they display. See Section 17.2.1, “Replication Implementation Details”. If the I/O thread state says Connecting to master, check the following:

  • Verify the privileges for the user being used for replication on the master.
  
  • Check that the host name of the master is correct and that you are using the correct port to connect to the master. The port used for replication is the same as used for client network communication (the default is 3306). For the host name, ensure that the name resolves to the correct IP address.
  
  • Check that networking has not been disabled on the master or slave. Look for the skip-networking option in the configuration file. If present, comment it out or remove it.
  
  • If the master has a firewall or IP filtering configuration, ensure that the network port being used for MySQL is not being filtered.
  
  • Check that you can reach the master by using ping or traceroute/tracert to reach the host.
  
  • If the slave was running previously but has stopped, the reason usually is that some statement that succeeded on the master failed on the slave. This should never happen if you have taken a proper snapshot of the master, and never modified the data on the slave outside of the slave thread. If the slave stops unexpectedly, it is a bug or you have encountered one of the known replication limitations described in Section 17.4.1, “Replication Features and Issues”. If it is a bug, see Section 17.4.5, “How to Report Replication Bugs or Problems”, for instructions on how to report it.
• If a statement that succeeded on the master refuses to run on the slave, try the following procedure if it is not feasible to do a full database resynchronization by deleting the slave’s databases and copying a new snapshot from the master:

1. Determine whether the affected table on the slave is different from the master table. Try to understand how this happened. Then make the slave’s table identical to the master’s and run `START SLAVE`.

2. If the preceding step does not work or does not apply, try to understand whether it would be safe to make the update manually (if needed) and then ignore the next statement from the master.

3. If you decide that the slave can skip the next statement from the master, issue the following statements:

```
mysql> SET GLOBAL sql_slave_skip_counter = N;
mysql> START SLAVE;
```

The value of \( N \) should be 1 if the next statement from the master does not use `AUTO_INCREMENT` or `LAST_INSERT_ID()`. Otherwise, the value should be 2. The reason for using a value of 2 for statements that use `AUTO_INCREMENT` or `LAST_INSERT_ID()` is that they take two events in the binary log of the master.

See also Section 13.4.2.4, “SET GLOBAL sql_slave_skip_counter Syntax”.

4. If you are sure that the slave started out perfectly synchronized with the master, and that no one has updated the tables involved outside of the slave thread, then presumably the discrepancy is the result of a bug. If you are running the most recent version of MySQL, please report the problem. If you are running an older version, try upgrading to the latest production release to determine whether the problem persists.

### 17.4.5 How to Report Replication Bugs or Problems

When you have determined that there is no user error involved, and replication still either does not work at all or is unstable, it is time to send us a bug report. We need to obtain as much information as possible from you to be able to track down the bug. Please spend some time and effort in preparing a good bug report.

If you have a repeatable test case that demonstrates the bug, please enter it into our bugs database using the instructions given in Section 1.6, “How to Report Bugs or Problems”. If you have a “phantom” problem (one that you cannot duplicate at will), use the following procedure:

1. Verify that no user error is involved. For example, if you update the slave outside of the slave thread, the data goes out of synchrony, and you can have unique key violations on updates. In this case, the slave thread stops and waits for you to clean up the tables manually to bring them into synchrony. This is not a replication problem. It is a problem of outside interference causing replication to fail.

2. Run the slave with the `--log-slave-updates` and `--log-bin` options. These options cause the slave to log the updates that it receives from the master into its own binary logs.

3. Save all evidence before resetting the replication state. If we have no information or only sketchy information, it becomes difficult or impossible for us to track down the problem. The evidence you should collect is:
   - All binary log files from the master
   - All binary log files from the slave
• The output of `SHOW MASTER STATUS` from the master at the time you discovered the problem
• The output of `SHOW SLAVE STATUS` from the slave at the time you discovered the problem
• Error logs from the master and the slave

4. Use `mysqlbinlog` to examine the binary logs. The following should be helpful to find the problem statement. `log_file` and `log_pos` are the `Master_Log_File` and `Read_Master_Log_Pos` values from `SHOW SLAVE STATUS`.

```shell
shell> mysqlbinlog --start-position=log_pos log_file | head
```

After you have collected the evidence for the problem, try to isolate it as a separate test case first. Then enter the problem with as much information as possible into our bugs database using the instructions at Section 1.6, “How to Report Bugs or Problems”.
Chapter 18 MySQL NDB Cluster 7.3 and NDB Cluster 7.4

Table of Contents

18.1 NDB Cluster Overview .......................................................... 2563

    18.4.25 ndb_setup.py — Start browser-based Auto-Installer for NDB Cluster 2919

2559
MySQL NDB Cluster is a high-availability, high-redundancy version of MySQL adapted for the distributed computing environment. Recent NDB Cluster release series use version 7 of the NDB storage engine (also known as NDBCLUSTER) to enable running several computers with MySQL servers and other software in a cluster. NDB Cluster 7.6, now available as a General Availability (GA) release beginning with version 7.6.6, incorporates version 7.6 of the NDB storage engine. NDB Cluster 7.5, still available as a GA release, uses version 7.5 of NDB. Previous GA releases still available for use in production, NDB Cluster 7.3 and NDB Cluster 7.4, incorporate NDB versions 7.3 and 7.4, respectively. NDB Cluster 7.2, which uses version 7.2 of the NDB storage engine, is a previous GA release that is currently still maintained; 7.2 users are encouraged to upgrade to NDB 7.5 or NDB 7.6.

Support for the NDB storage engine is not included in standard MySQL Server 5.6 binaries built by Oracle. Instead, users of NDB Cluster binaries from Oracle should upgrade to the most recent binary release of NDB Cluster for supported platforms—these include RPMs that should work with most Linux distributions. NDB Cluster users who build from source should use the sources provided for NDB Cluster. (Locations where the sources can be obtained are listed later in this section.)

This chapter contains information about NDB Cluster 7.3 releases through 5.6.45-ndb-7.3.26 as well as NDB Cluster 7.4 releases through 5.6.45-ndb-7.4.25. NDB Cluster 7.6 is now available as a General
Availability release, and recommended for new deployments; for information about NDB Cluster 7.6, see What is New in NDB Cluster 7.6. NDB Cluster 7.5, 7.4, and 7.3 are previous GA releases still supported in production. NDB Cluster 7.2 is a previous GA release series which is still supported, although we recommend that new deployments for production use NDB Cluster 7.6 (see MySQL NDB Cluster 7.5 and NDB Cluster 7.6). For more information about NDB Cluster 7.2, see MySQL NDB Cluster 7.2.

NDB Cluster 8.0 is now available as a Developer Preview release for evaluation and testing of new features in the NDBCLUSTER storage engine; for more information, see MySQL NDB Cluster 8.0.

Supported Platforms. NDB Cluster is currently available and supported on a number of platforms. For exact levels of support available for on specific combinations of operating system versions, operating system distributions, and hardware platforms, please refer to https://www.mysql.com/support/supportedplatforms/cluster.html.

Availability. NDB Cluster binary and source packages are available for supported platforms from https://dev.mysql.com/downloads/cluster/.

NDB Cluster release numbers. NDB Cluster follows a somewhat different release pattern from the mainline MySQL Server 5.6 series of releases. In this Manual and other MySQL documentation, we identify these and later NDB Cluster releases employing a version number that begins with “NDB”. This version number is that of the NDBCLUSTER storage engine used in the release, and not of the MySQL server version on which the NDB Cluster release is based.

Version strings used in NDB Cluster software. The version string displayed by NDB Cluster programs uses this format:

```
mysql=mysql_server_version-ndb-ndb_engine_version
```

`mysql_server_version` represents the version of the MySQL Server on which the NDB Cluster release is based. For all NDB Cluster 7.3 and current NDB Cluster 7.4 releases, this is “5.6”. `ndb_engine_version` is the version of the NDB storage engine used by this release of the NDB Cluster software. You can see this format used in the mysql client, as shown here:

```
shell> mysql
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 2
Server version: 5.6.45-ndb-7.4.25 Source distribution
Type 'help;' or '\h' for help. Type '\c' to clear the buffer.
mysql> SELECT VERSION()\G
*************************** 1. row ***************************
VERSION(): 5.6.45-ndb-7.4.25
1 row in set (0.00 sec)
```

This version string is also displayed in the output of the SHOW command in the ndb_mgm client:

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
---------------------
[nbdb(NDB)] 2 node(s)
id=1    @10.0.10.6  (5.6.45-ndb-7.4.25, Nodegroup: 0, *)
id=2    @10.0.10.8  (5.6.45-ndb-7.4.25, Nodegroup: 0)

[nbdb_mgmd(MGM)] 1 node(s)
id=3    @10.0.10.2  (5.6.45-ndb-7.4.25)
```
The version string identifies the mainline MySQL version from which the NDB Cluster release was branched and the version of the NDB storage engine used. For example, the full version string for NDB 7.4.4 (the first NDB Cluster 7.4 GA release) is `mysql-5.6.23-ndb-7.4.4`. From this we can determine the following:

- Since the portion of the version string preceding `-ndb-` is the base MySQL Server version, this means that NDB 7.4.4 derives from MySQL 5.6.23, and contains all feature enhancements and bug fixes from MySQL 5.6 up to and including MySQL 5.6.23.

- Since the portion of the version string following `-ndb-` represents the version number of the NDB (or NDBCLUSTER) storage engine, NDB 7.4.4 uses version 7.4.4 of the NDBCLUSTER storage engine.

New NDB Cluster releases are numbered according to updates in the NDB storage engine, and do not necessarily correspond in a one-to-one fashion with mainline MySQL Server releases. For example, NDB 7.4.4 (as previously noted) is based on MySQL 5.6.23, while NDB 7.4.3 was based on MySQL 5.6.22 (version string: `mysql-5.6.22-ndb-7.4.3`).

**Compatibility with standard MySQL 5.6 releases.** While many standard MySQL schemas and applications can work using NDB Cluster, it is also true that unmodified applications and database schemas may be slightly incompatible or have suboptimal performance when run using NDB Cluster (see Section 18.1.7, “Known Limitations of NDB Cluster”). Most of these issues can be overcome, but this also means that you are very unlikely to be able to switch an existing application datastore—that currently uses, for example, MyISAM or InnoDB—to use the NDB storage engine without allowing for the possibility of changes in schemas, queries, and applications. In addition, the MySQL Server and NDB Cluster codebases diverge considerably, so that the standard mysqld cannot function as a drop-in replacement for the version of mysqld supplied with NDB Cluster.

**NDB Cluster development source trees.** NDB Cluster development trees can also be accessed from https://github.com/mysql/mysql-server.

The NDB Cluster development sources maintained at https://github.com/mysql/mysql-server are licensed under the GPL. For information about obtaining MySQL sources using Git and building them yourself, see Section 2.9.3, “Installing MySQL Using a Development Source Tree”.

**Note**

As with MySQL Server 5.6, NDB Cluster 7.3 and NDB Cluster 7.4 releases are built using CMake.

NDB Cluster 7.3 and NDB Cluster 7.4 are previous General Availability (GA) releases still supported in production. We recommend that new deployments for production use NDB Cluster 7.6 (see MySQL NDB Cluster 7.5 and NDB Cluster 7.6). NDB Cluster 7.5, 7.4, and 7.3 are previous General Availability (GA) releases. For an overview of major features added in NDB Cluster 7.6, see What is New in NDB Cluster 7.6. For similar information about NDB Cluster 7.5, see What is New in NDB Cluster 7.5. NDB Cluster 7.2 is a previous GA release that is still maintained (NDB Cluster 7.1 and earlier versions are no longer in active development); for information about NDB 7.2, see MySQL NDB Cluster 7.2.

This chapter represents a work in progress, and its contents are subject to revision as NDB Cluster continues to evolve. Additional information regarding NDB Cluster can be found on the MySQL website at http://www.mysql.com/products/cluster/.

**Additional Resources.** More information about NDB Cluster can be found in the following places:
18.1 NDB Cluster Overview

NDB Cluster is a technology that enables clustering of in-memory databases in a shared-nothing system. The shared-nothing architecture enables the system to work with very inexpensive hardware, and with a minimum of specific requirements for hardware or software.

NDB Cluster is designed not to have any single point of failure. In a shared-nothing system, each component is expected to have its own memory and disk, and the use of shared storage mechanisms such as network shares, network file systems, and SANs is not recommended or supported.

NDB Cluster integrates the standard MySQL server with an in-memory clustered storage engine called NDB (which stands for “Network DataBase”). In our documentation, the term NDB refers to the part of the setup that is specific to the storage engine, whereas “MySQL NDB Cluster” refers to the combination of one or more MySQL servers with the NDB storage engine.

An NDB Cluster consists of a set of computers, known as hosts, each running one or more processes. These processes, known as nodes, may include MySQL servers (for access to NDB data), data nodes (for storage of the data), one or more management servers, and possibly other specialized data access programs. The relationship of these components in an NDB Cluster is shown here:

![Figure 18.1 NDB Cluster Components](image)

All these programs work together to form an NDB Cluster (see Section 18.4, “NDB Cluster Programs”). When data is stored by the NDB storage engine, the tables (and table data) are stored in the data nodes. Such tables are directly accessible from all other MySQL servers (SQL nodes) in the cluster. Thus, in a payroll application storing data in a cluster, if one application updates the salary of an employee, all other MySQL servers that query this data can see this change immediately.
Although an NDB Cluster SQL node uses the `mysqld` server daemon, it differs in a number of critical respects from the `mysqld` binary supplied with the MySQL 5.6 distributions, and the two versions of `mysqld` are not interchangeable.

In addition, a MySQL server that is not connected to an NDB Cluster cannot use the NDB storage engine and cannot access any NDB Cluster data.

The data stored in the data nodes for NDB Cluster can be mirrored; the cluster can handle failures of individual data nodes with no other impact than that a small number of transactions are aborted due to losing the transaction state. Because transactional applications are expected to handle transaction failure, this should not be a source of problems.

Individual nodes can be stopped and restarted, and can then rejoin the system (cluster). Rolling restarts (in which all nodes are restarted in turn) are used in making configuration changes and software upgrades (see Section 18.5.5, “Performing a Rolling Restart of an NDB Cluster”). Rolling restarts are also used as part of the process of adding new data nodes online (see Section 18.5.14, “Adding NDB Cluster Data Nodes Online”). For more information about data nodes, how they are organized in an NDB Cluster, and how they handle and store NDB Cluster data, see Section 18.1.2, “NDB Cluster Nodes, Node Groups, Replicas, and Partitions”.

Backing up and restoring NDB Cluster databases can be done using the NDB-native functionality found in the NDB Cluster management client and the `ndb_restore` program included in the NDB Cluster distribution. For more information, see Section 18.5.3, “Online Backup of NDB Cluster”, and Section 18.4.22, “`ndb_restore` — Restore an NDB Cluster Backup”. You can also use the standard MySQL functionality provided for this purpose in `mysqldump` and the MySQL server. See Section 4.5.4, “`mysqldump` — A Database Backup Program”, for more information.

NDB Cluster nodes can employ different transport mechanisms for inter-node communications; TCP/IP over standard 100 Mbps or faster Ethernet hardware is used in most real-world deployments.

### 18.1.1 NDB Cluster Core Concepts

NDBCLUSTER (also known as NDB) is an in-memory storage engine offering high-availability and data-persistence features.

The NDBCLUSTER storage engine can be configured with a range of failover and load-balancing options, but it is easiest to start with the storage engine at the cluster level. NDB Cluster's NDB storage engine contains a complete set of data, dependent only on other data within the cluster itself.

The “Cluster” portion of NDB Cluster is configured independently of the MySQL servers. In an NDB Cluster, each part of the cluster is considered to be a node.

**Note**

In many contexts, the term “node” is used to indicate a computer, but when discussing NDB Cluster it means a process. It is possible to run multiple nodes on a single computer; for a computer on which one or more cluster nodes are being run we use the term cluster host.

There are three types of cluster nodes, and in a minimal NDB Cluster configuration, there will be at least three nodes, one of each of these types:

- **Management node**: The role of this type of node is to manage the other nodes within the NDB Cluster, performing such functions as providing configuration data, starting and stopping nodes, and running backups. Because this node type manages the configuration of the other nodes, a node of this type should be started first, before any other node. An MGM node is started with the command `ndb_mgmd`.
**NDB Cluster Core Concepts**

- **Data node**: This type of node stores cluster data. There are as many data nodes as there are replicas, times the number of fragments (see Section 18.1.2, “NDB Cluster Nodes, Node Groups, Replicas, and Partitions”). For example, with two replicas, each having two fragments, you need four data nodes. One replica is sufficient for data storage, but provides no redundancy; therefore, it is recommended to have 2 (or more) replicas to provide redundancy, and thus high availability. A data node is started with the command `ndbd` (see Section 18.4.1, “ndbd — The NDB Cluster Data Node Daemon”) or `ndbmtd` (see Section 18.4.3, “ndbmtd — The NDB Cluster Data Node Daemon (Multi-Threaded)”).

NDB Cluster tables are normally stored completely in memory rather than on disk (this is why we refer to NDB Cluster as an *in-memory* database). However, some NDB Cluster data can be stored on disk; see Section 18.5.12, “NDB Cluster Disk Data Tables”, for more information.

- **SQL node**: This is a node that accesses the cluster data. In the case of NDB Cluster, an SQL node is a traditional MySQL server that uses the `NDBCLUSTER` storage engine. An SQL node is a `mysqld` process started with the `--ndbcluster` and `--ndb-connectstring` options, which are explained elsewhere in this chapter, possibly with additional MySQL server options as well.

An SQL node is actually just a specialized type of *API node*, which designates any application which accesses NDB Cluster data. Another example of an API node is the `ndb_restore` utility that is used to restore a cluster backup. It is possible to write such applications using the NDB API. For basic information about the NDB API, see *Getting Started with the NDB API*.

**Important**

It is not realistic to expect to employ a three-node setup in a production environment. Such a configuration provides no redundancy; to benefit from NDB Cluster’s high-availability features, you must use multiple data and SQL nodes. The use of multiple management nodes is also highly recommended.

For a brief introduction to the relationships between nodes, node groups, replicas, and partitions in NDB Cluster, see Section 18.1.2, “NDB Cluster Nodes, Node Groups, Replicas, and Partitions”.

Configuration of a cluster involves configuring each individual node in the cluster and setting up individual communication links between nodes. NDB Cluster is currently designed with the intention that data nodes are homogeneous in terms of processor power, memory space, and bandwidth. In addition, to provide a single point of configuration, all configuration data for the cluster as a whole is located in one configuration file.

The management server manages the cluster configuration file and the cluster log. Each node in the cluster retrieves the configuration data from the management server, and so requires a way to determine where the management server resides. When interesting events occur in the data nodes, the nodes transfer information about these events to the management server, which then writes the information to the cluster log.

In addition, there can be any number of cluster client processes or applications. These include standard MySQL clients, *NDB*-specific API programs, and management clients. These are described in the next few paragraphs.

**Standard MySQL clients.** NDB Cluster can be used with existing MySQL applications written in PHP, Perl, C, C++, Java, Python, Ruby, and so on. Such client applications send SQL statements to and receive responses from MySQL servers acting as NDB Cluster SQL nodes in much the same way that they interact with standalone MySQL servers.

MySQL clients using an NDB Cluster as a data source can be modified to take advantage of the ability to connect with multiple MySQL servers to achieve load balancing and failover. For example, Java
clients using Connector/J 5.0.6 and later can use \texttt{jdbc:mysql:loadbalance://} URLs (improved in Connector/J 5.1.7) to achieve load balancing transparently; for more information about using Connector/J with NDB Cluster, see Using Connector/J with NDB Cluster.

**NDB client programs.** Client programs can be written that access NDB Cluster data directly from the NDBCLUSTER storage engine, bypassing any MySQL Servers that may be connected to the cluster, using the NDB API, a high-level C++ API. Such applications may be useful for specialized purposes where an SQL interface to the data is not needed. For more information, see The NDB API.

NDB-specific Java applications can also be written for NDB Cluster using the NDB Cluster Connector for Java. This NDB Cluster Connector includes ClusterJ, a high-level database API similar to object-relational mapping persistence frameworks such as Hibernate and JPA that connect directly to NDBCLUSTER, and so does not require access to a MySQL Server. Support is also provided in NDB Cluster for ClusterJPA, an OpenJPA implementation for NDB Cluster that leverages the strengths of ClusterJ and JDBC; ID lookups and other fast operations are performed using ClusterJ (bypassing the MySQL Server), while more complex queries that can benefit from MySQL’s query optimizer are sent through the MySQL Server, using JDBC. See Java and NDB Cluster, and The ClusterJ API and Data Object Model, for more information.

NDB Cluster 7.3 and later also supports applications written in JavaScript using Node.js. The MySQL Connector for JavaScript includes adapters for direct access to the NDB storage engine and as well as for the MySQL Server. Applications using this Connector are typically event-driven and use a domain object model similar in many ways to that employed by ClusterJ. For more information, see MySQL NoSQL Connector for JavaScript.

The Memcache API for NDB Cluster, implemented as the loadable ndbmemcache storage engine for memcached version 1.6 and later, can be used to provide a persistent NDB Cluster data store, accessed using the memcache protocol.

The standard memcached caching engine is included in NDB Cluster 7.3 and later distributions. Each memcached server has direct access to data stored in NDB Cluster, but is also able to cache data locally and to serve (some) requests from this local cache.

For more information, see ndbmemcache—Memcache API for NDB Cluster.

**Management clients.** These clients connect to the management server and provide commands for starting and stopping nodes gracefully, starting and stopping message tracing (debug versions only), showing node versions and status, starting and stopping backups, and so on. An example of this type of program is the \texttt{ndb_mgm} management client supplied with NDB Cluster (see Section 18.4.5, “ndb_mgm — The NDB Cluster Management Client”). Such applications can be written using the MGM API, a C-language API that communicates directly with one or more NDB Cluster management servers. For more information, see The MGM API.

Oracle also makes available MySQL Cluster Manager, which provides an advanced command-line interface simplifying many complex NDB Cluster management tasks, such as restarting an NDB Cluster with a large number of nodes. The MySQL Cluster Manager client also supports commands for getting and setting the values of most node configuration parameters as well as mysqld server options and variables relating to NDB Cluster. See MySQL™ Cluster Manager 1.4.7 User Manual, for more information.

**Event logs.** NDB Cluster logs events by category (startup, shutdown, errors, checkpoints, and so on), priority, and severity. A complete listing of all reportable events may be found in Section 18.5.6, “Event Reports Generated in NDB Cluster”. Event logs are of the two types listed here:

- **Cluster log:** Keeps a record of all desired reportable events for the cluster as a whole.
- **Node log:** A separate log which is also kept for each individual node.
Note
Under normal circumstances, it is necessary and sufficient to keep and examine only the cluster log. The node logs need be consulted only for application development and debugging purposes.

Checkpoint. Generally speaking, when data is saved to disk, it is said that a checkpoint has been reached. More specific to NDB Cluster, a checkpoint is a point in time where all committed transactions are stored on disk. With regard to the NDB storage engine, there are two types of checkpoints which work together to ensure that a consistent view of the cluster's data is maintained. These are shown in the following list:

- *Local Checkpoint (LCP)*: This is a checkpoint that is specific to a single node; however, LCPs take place for all nodes in the cluster more or less concurrently. An LCP involves saving all of a node’s data to disk, and so usually occurs every few minutes. The precise interval varies, and depends upon the amount of data stored by the node, the level of cluster activity, and other factors.

- *Global Checkpoint (GCP)*: A GCP occurs every few seconds, when transactions for all nodes are synchronized and the redo-log is flushed to disk.

For more information about the files and directories created by local checkpoints and global checkpoints, see NDB Cluster Data Node File System Directory Files.

### 18.1.2 NDB Cluster Nodes, Node Groups, Replicas, and Partitions

This section discusses the manner in which NDB Cluster divides and duplicates data for storage.

A number of concepts central to an understanding of this topic are discussed in the next few paragraphs.

**Data node.** An `ndbd` or `ndbmtd` process, which stores one or more replicas—that is, copies of the partitions (discussed later in this section) assigned to the node group of which the node is a member.

Each data node should be located on a separate computer. While it is also possible to host multiple data node processes on a single computer, such a configuration is not usually recommended.

It is common for the terms “node” and “data node” to be used interchangeably when referring to an `ndbd` or `ndbmtd` process; where mentioned, management nodes (`ndb_mgmd` processes) and SQL nodes (`mysqld` processes) are specified as such in this discussion.

**Node group.** A node group consists of one or more nodes, and stores partitions, or sets of replicas (see next item).

The number of node groups in an NDB Cluster is not directly configurable; it is a function of the number of data nodes and of the number of replicas (`NoOfReplicas` configuration parameter), as shown here:

\[
[# \text{ of node groups}] = [# \text{ of data nodes}] / \text{NoOfReplicas}
\]

Thus, an NDB Cluster with 4 data nodes has 4 node groups if `NoOfReplicas` is set to 1 in the `config.ini` file, 2 node groups if `NoOfReplicas` is set to 2, and 1 node group if `NoOfReplicas` is set to 4. Replicas are discussed later in this section; for more information about `NoOfReplicas`, see Section 18.3.3.6, “Defining NDB Cluster Data Nodes”.

Note
All node groups in an NDB Cluster must have the same number of data nodes.
You can add new node groups (and thus new data nodes) online, to a running NDB Cluster; see Section 18.5.14, “Adding NDB Cluster Data Nodes Online”, for more information.

**Partition.** This is a portion of the data stored by the cluster. Each node is responsible for keeping at least one copy of any partitions assigned to it (that is, at least one replica) available to the cluster.

The number of partitions used by default by NDB Cluster depends on the number of data nodes and the number of LDM threads in use by the data nodes, as shown here:

$$\text{[# of partitions]} = \text{[# of data nodes]} \times \text{[# of LDM threads]}$$

When using data nodes running *ndbmtd*, the number of LDM threads is controlled by the setting for *MaxNoOfExecutionThreads*. When using *ndbd* there is a single LDM thread, which means that there are as many cluster partitions as nodes participating in the cluster. This is also the case when using *ndbmtd* with *MaxNoOfExecutionThreads* set to 3 or less. (You should be aware that the number of LDM threads increases with the value of this parameter, but not in a strictly linear fashion, and that there are additional constraints on setting it; see the description of *MaxNoOfExecutionThreads* for more information.)

**NDB and user-defined partitioning.** NDB Cluster normally partitions *NDBCLUSTER* tables automatically. However, it is also possible to employ user-defined partitioning with *NDBCLUSTER* tables. This is subject to the following limitations:

1. Only the **KEY** and **LINEAR KEY** partitioning schemes are supported in production with *NDB* tables.

2. The maximum number of partitions that may be defined explicitly for any *NDB* table is $8 \times \text{MaxNoOfExecutionThreads} \times \text{[number of node groups]}$, the number of node groups in an NDB Cluster being determined as discussed previously in this section. When using *ndbd* for data node processes, setting *MaxNoOfExecutionThreads* has no effect; in such a case, it can be treated as though it were equal to 1 for purposes of performing this calculation.

See Section 18.4.3, “*ndbmtd* — The NDB Cluster Data Node Daemon (Multi-Threaded)”, for more information.

For more information relating to NDB Cluster and user-defined partitioning, see Section 18.1.7, “Known Limitations of NDB Cluster”, and Section 19.6.2, “Partitioning Limitations Relating to Storage Engines”.

**Replica.** This is a copy of a cluster partition. Each node in a node group stores a replica. Also sometimes known as a **partition replica**. The number of replicas is equal to the number of nodes per node group.

A replica belongs entirely to a single node; a node can (and usually does) store several replicas.

The following diagram illustrates an NDB Cluster with four data nodes running *ndbd*, arranged in two node groups of two nodes each; nodes 1 and 2 belong to node group 0, and nodes 3 and 4 belong to node group 1.

---

**Note**

Only data nodes are shown here; although a working NDB Cluster requires an *ndb_mgmd* process for cluster management and at least one SQL node to access the data stored by the cluster, these have been omitted from the figure for clarity.
The data stored by the cluster is divided into four partitions, numbered 0, 1, 2, and 3. Each partition is stored—in multiple copies—on the same node group. Partitions are stored on alternate node groups as follows:

- Partition 0 is stored on node group 0; a primary replica (primary copy) is stored on node 1, and a backup replica (backup copy of the partition) is stored on node 2.

- Partition 1 is stored on the other node group (node group 1); this partition's primary replica is on node 3, and its backup replica is on node 4.

- Partition 2 is stored on node group 0. However, the placing of its two replicas is reversed from that of Partition 0; for Partition 2, the primary replica is stored on node 2, and the backup on node 1.

- Partition 3 is stored on node group 1, and the placement of its two replicas are reversed from those of partition 1. That is, its primary replica is located on node 4, with the backup on node 3.

What this means regarding the continued operation of an NDB Cluster is this: so long as each node group participating in the cluster has at least one node operating, the cluster has a complete copy of all data and remains viable. This is illustrated in the next diagram.
In this example, the cluster consists of two node groups each consisting of two data nodes. Each data node is running an instance of ndbd. Any combination of at least one node from node group 0 and at least one node from node group 1 is sufficient to keep the cluster “alive”. However, if both nodes from a single node group fail, the combination consisting of the remaining two nodes in the other node group is not sufficient. In this situation, the cluster has lost an entire partition and so can no longer provide access to a complete set of all NDB Cluster data.

18.1.3 NDB Cluster Hardware, Software, and Networking Requirements

One of the strengths of NDB Cluster is that it can be run on commodity hardware and has no unusual requirements in this regard, other than for large amounts of RAM, due to the fact that all live data storage is done in memory. (It is possible to reduce this requirement using Disk Data tables—see Section 18.5.12, “NDB Cluster Disk Data Tables”, for more information about these.) Naturally, multiple and faster CPUs can enhance performance. Memory requirements for other NDB Cluster processes are relatively small.

The software requirements for NDB Cluster are also modest. Host operating systems do not require any unusual modules, services, applications, or configuration to support NDB Cluster. For supported operating systems, a standard installation should be sufficient. The MySQL software requirements are simple: all that is needed is a production release of NDB Cluster. It is not strictly necessary to compile MySQL yourself merely to be able to use NDB Cluster. We assume that you are using the binaries appropriate to your platform, available from the NDB Cluster software downloads page at https://dev.mysql.com/downloads/cluster/.

For communication between nodes, NDB Cluster supports TCP/IP networking in any standard topology, and the minimum expected for each host is a standard 100 Mbps Ethernet card, plus a switch, hub, or router to provide network connectivity for the cluster as a whole. We strongly recommend that an NDB Cluster be run on its own subnet which is not shared with machines not forming part of the cluster for the following reasons:

• **Security.** Communications between NDB Cluster nodes are not encrypted or shielded in any way. The only means of protecting transmissions within an NDB Cluster is to run your NDB Cluster on a protected network. If you intend to use NDB Cluster for Web applications, the cluster should definitely reside behind your firewall and not in your network's De-Militarized Zone (DMZ) or elsewhere.
What is New in MySQL NDB Cluster

See Section 18.5.11.1, “NDB Cluster Security and Networking Issues”, for more information.

- **Efficiency.** Setting up an NDB Cluster on a private or protected network enables the cluster to make exclusive use of bandwidth between cluster hosts. Using a separate switch for your NDB Cluster not only helps protect against unauthorized access to NDB Cluster data, it also ensures that NDB Cluster nodes are shielded from interference caused by transmissions between other computers on the network. For enhanced reliability, you can use dual switches and dual cards to remove the network as a single point of failure; many device drivers support failover for such communication links.

**Network communication and latency.** NDB Cluster requires communication between data nodes and API nodes (including SQL nodes), as well as between data nodes and other data nodes, to execute queries and updates. Communication latency between these processes can directly affect the observed performance and latency of user queries. In addition, to maintain consistency and service despite the silent failure of nodes, NDB Cluster uses heartbeating and timeout mechanisms which treat an extended loss of communication from a node as node failure. This can lead to reduced redundancy. Recall that, to maintain data consistency, an NDB Cluster shuts down when the last node in a node group fails. Thus, to avoid increasing the risk of a forced shutdown, breaks in communication between nodes should be avoided wherever possible.

The failure of a data or API node results in the abort of all uncommitted transactions involving the failed node. Data node recovery requires synchronization of the failed node's data from a surviving data node, and re-establishment of disk-based redo and checkpoint logs, before the data node returns to service. This recovery can take some time, during which the Cluster operates with reduced redundancy.

Heartbeating relies on timely generation of heartbeat signals by all nodes. This may not be possible if the node is overloaded, has insufficient machine CPU due to sharing with other programs, or is experiencing delays due to swapping. If heartbeat generation is sufficiently delayed, other nodes treat the node that is slow to respond as failed.

This treatment of a slow node as a failed one may or may not be desirable in some circumstances, depending on the impact of the node's slowed operation on the rest of the cluster. When setting timeout values such as `HeartbeatIntervalDbDb` and `HeartbeatIntervalDbApi` for NDB Cluster, care must be taken to achieve quick detection, failover, and return to service, while avoiding potentially expensive false positives.

Where communication latencies between data nodes are expected to be higher than would be expected in a LAN environment (on the order of 100 µs), timeout parameters must be increased to ensure that any allowed periods of latency periods are well within configured timeouts. Increasing timeouts in this way has a corresponding effect on the worst-case time to detect failure and therefore time to service recovery.

LAN environments can typically be configured with stable low latency, and such that they can provide redundancy with fast failover. Individual link failures can be recovered from with minimal and controlled latency visible at the TCP level (where NDB Cluster normally operates). WAN environments may offer a range of latencies, as well as redundancy with slower failover times. Individual link failures may require route changes to propagate before end-to-end connectivity is restored. At the TCP level this can appear as large latencies on individual channels. The worst-case observed TCP latency in these scenarios is related to the worst-case time for the IP layer to reroute around the failures.

**SCI support.** It is also possible to use the high-speed Scalable Coherent Interface (SCI) with NDB Cluster, but this is not a requirement. See Section 18.3.4, “Using High-Speed Interconnects with NDB Cluster”, for more about this protocol and its use with NDB Cluster.

### 18.1.4 What is New in MySQL NDB Cluster
This section lists changes in the implementation of NDB Cluster in MySQL NDB Cluster 7.3 and NDB Cluster 7.4, as compared to NDB Cluster 7.2 and earlier releases. Changes and features most likely to be of interest in NDB 7.3 are shown in the following list:

- NDB Cluster 7.3 is based on MySQL 5.6. For more information about new features in MySQL Server 5.6, see Section 1.4, “What Is New in MySQL 5.6”.

- NDB Cluster 7.3 supports foreign key constraints on tables. See Section 1.7.3.2, “FOREIGN KEY Constraints”, and Section 13.1.17.6, “Using FOREIGN KEY Constraints”, for more information.

- NDB Cluster 7.3 provides support for Node.js using the MySQL NoSQL Connector for JavaScript. See MySQL NoSQL Connector for JavaScript, for more information.

Changes and features in NDB Cluster 7.4 that are most likely to be of interest are shown in the following list:

- NDB Cluster 7.4 is based on MySQL 5.6 (For more information about new features in MySQL Server 5.6, see Section 1.4, “What Is New in MySQL 5.6”)

- NDB Cluster Replication conflict detection and resolution enhancements, including extensions to conflict exceptions tables (see Section 18.6.11, “NDB Cluster Replication Conflict Resolution”)

- Improvements in the management of circular (“active-active”) replication; primary/secondary assignment with ndb_slave_conflict_role

- Per-fragment memory usage reporting in the memory_per_fragment table

- A number of performance improvements, including the following enhancements:
  - Faster initial allocation of memory
  - Increased parallelization of local checkpoints (LCPs now support 32 fragments rather than 2)

    A group of configuration parameters (MaxDiskWriteSpeed, MaxDiskWriteSpeedOtherNoderestart, MaxDiskWriteSpeedOwnRestart) introduced in this version provides improved control over disk writes during LCPs

    Information about recent disk writes is available in the disk_write_speed_base, disk_write_speed_aggregate, and disk_write_speed_aggregate_node tables added to the ndbinfo database in this version

  - Faster times for restoring an NDB Cluster from backup
  - Optimization of the NDB receive thread
  - Improved error and other reporting during node restarts

This section contains information about NDB Cluster 7.3 releases through 5.6.45-ndb-7.3.26 as well as NDB Cluster 7.4 releases through 5.6.45-ndb-7.4.25. NDB Cluster 7.6 is now available as a General Availability release, and recommended for new deployments; for information about NDB Cluster 7.6, see What is New in NDB Cluster 7.6. NDB Cluster 7.5, 7.4, and 7.3 are previous GA releases still supported in production. NDB Cluster 7.2 is a previous GA release series which is still supported, although we recommend that new deployments for production use NDB Cluster 7.6 (see MySQL NDB Cluster 7.5 and NDB Cluster 7.6). For more information about NDB Cluster 7.2, see MySQL NDB Cluster 7.2.

NDB Cluster 8.0 is now available as a Developer Preview release for evaluation and testing of new features in the NDBCLUSTER storage engine; for more information, see MySQL NDB Cluster 8.0.
18.1.4.1 What is New in NDB Cluster 7.3

The following improvements to NDB Cluster have been made in NDB Cluster 7.3:

• **Based on MySQL Server 5.6.** NDB Cluster 7.3 is based on MySQL Server 5.6, so that NDB Cluster users can benefit from MySQL 5.6's improvements in scalability and performance monitoring. As with MySQL 5.6, NDB Cluster 7.3 uses CMake for configuring and building from source. For more information about changes and improvements in MySQL 5.6, see Section 1.4, "What Is New in MySQL 5.6".

• **Foreign keys.** Tables created using the NDB storage engine version 7.3.0 and later provide support for foreign key constraints. (This includes all NDB Cluster 7.3 releases.) For general information about how MySQL 5.6 and NDB Cluster 7.3 handle foreign keys, see Section 1.7.3.2, "FOREIGN KEY Constraints". For syntax and related information, see Section 13.1.17, “CREATE TABLE Syntax”, and Section 13.1.17.6, “Using FOREIGN KEY Constraints”.

• **Node.js support.** NDB Cluster 7.3 also supports applications written in JavaScript using Node.js. The MySQL Connector for JavaScript includes adapters for direct access to the NDB storage engine and as well as for the MySQL Server. Applications using this Connector are typically event-driven and use a domain object model similar in many ways to that employed by ClusterJ. For more information, see MySQL NoSQL Connector for JavaScript.

NDB Cluster 7.3 is also supported by MySQL Cluster Manager, which provides an advanced command-line interface that can simplify many complex NDB Cluster management tasks. See MySQL™ Cluster Manager 1.4.7 User Manual, for more information.

18.1.4.2 What is New in NDB Cluster 7.4

The following improvements to NDB Cluster have been made in NDB Cluster 7.4:

• **Conflict detection and resolution enhancements.** A reserved column name namespace NDB$ is now employed for exceptions table metacolumns, allowing an arbitrary subset of main table columns to be recorded, even if they are not part of the original table’s primary key.

  Recording the complete original primary key is no longer required, due to the fact that matching against exceptions table columns is now done by name and type only. It is now also possible for you to record values of columns which not are part of the main table’s primary key in the exceptions table.

  Read conflict detection is now possible. All rows read by the conflicting transaction are flagged, and logged in the exceptions table. Rows inserted in the same transaction are not included among the rows read or logged. This read tracking depends on the slave having an exclusive read lock which requires setting ndb_log_exclusive_reads in advance. See Read conflict detection and resolution, for more information and examples.

  Existing exceptions tables remain supported. For more information, see Section 18.6.11, “NDB Cluster Replication Conflict Resolution”.

• **Circular (“active-active”) replication improvements.** When using a circular or “active-active” NDB Cluster Replication topology, you can assign one of the roles of primary of secondary to a given NDB Cluster using the ndb_slave_conflict_role server system variable, which can be employed when failing over from an NDB Cluster acting as primary, or when using conflict detection and resolution with NDB$EPOCH2() and NDB$EPOCH2_TRANS() (NDB 7.4.2 and later), which support delete-delete conflict handling.

  See the description of the ndb_slave_conflict_role variable, as well as NDB$EPOCH2(), for more information. See also Section 18.6.11, “NDB Cluster Replication Conflict Resolution”.
What is New in MySQL NDB Cluster

- **Per-fragment memory usage reporting.** You can now obtain data about memory usage by individual NDB Cluster fragments from the `memory_per_fragment` view, added in NDB 7.4.1 to the `ndbinfo` information database. For more information, see Section 18.5.10.17, “The ndbinfo memory_per_fragment Table”.

- **Node restart improvements.** NDB Cluster 7.4 includes a number of improvements which decrease the time needed for data nodes to be restarted. These are described in the following list:

  - Memory allocated that is allocated on node startup cannot be used until it has been touched, which causes the operating system to set aside the actual physical memory required. In previous versions of NDB Cluster, the process of touching each page of memory that was allocated was singlethreaded, which made it relatively time-consuming. This process has now been reimplemented with multithreading. In tests with 16 threads, touch times on the order of 3 times shorter than with a single thread were observed.

  - Increased parallelization of local checkpoints; in NDB Cluster 7.4, LCPs now support 32 fragments rather than 2 as before. This greatly increases utilization of CPU power that would otherwise go unused, and can make LCPs faster by up to a factor of 10; this speedup in turn can greatly improve node restart times.

  The degree of parallelization used for the node copy phase during node and system restarts can be controlled in NDB 7.4.3 and later by setting the `MaxParallelCopyInstances` data node configuration parameter to a nonzero value.

  - Reporting on disk writes is provided by new `ndbinfo` tables `disk_write_speed_base`, `disk_write_speed_aggregate`, and `disk_write_speed_aggregate_node`, which provide information about the speed of disk writes for each LDM thread that is in use.

  This release also adds the data node configuration parameters `MinDiskWriteSpeed`, `MaxDiskWriteSpeed`, `MaxDiskWriteSpeedOtherNodeRestart`, and `MaxDiskWriteSpeedOwnRestart` to control write speeds for LCPs and backups when the present node, another node, or no node is currently restarting.

  These changes are intended to supersede configuration of disk writes using the `DiskCheckpointSpeed` and `DiskCheckpointSpeedInRestart` configuration parameters. These 2 parameters have now been deprecated, and are subject to removal in a future NDB Cluster release.

  - Faster times for restoring an NDB Cluster from backup have been obtained by replacing delayed signals found at a point which was found to be critical to performance with normal (undelayed) signals. The elimination or replacement of these unnecessary delayed signals should noticeably reduce the amount of time required to back up an NDB Cluster, or to restore an NDB Cluster from backup.

  - Several internal methods relating to the NDB receive thread have been optimized, to increase the efficiency of SQL processing by NDB. The receiver thread at time may have to process several million received records per second, so it is critical that it not perform unnecessary work or waste resources when retrieving records from NDB Cluster data nodes.

  - **Improved reporting of NDB Cluster restarts and start phases.** The `restart_info` table (included in the `ndbinfo` information database beginning with NDB 7.4.2) provides current status and timing information about node and system restarts.

  Reporting and logging of NDB Cluster start phases also provides more frequent and specific printouts during startup than previously. See Section 18.5.1, “Summary of NDB Cluster Start Phases”, for more information.
• **NDB API: new Event API.** NDB 7.4.3 introduces an epoch-driven Event API that supersedes the earlier GCI-based model. The new version of the API also simplifies error detection and handling. These changes are realized in the NDB API by implementing a number of new methods for `Ndb` and `NdbEventOperation`, deprecating several other methods of both classes, and adding new type values to `Event::TableEvent`.

The event handling methods added to `Ndb` in NDB 7.4.3 are `pollEvents2()`, `nextEvent2()`, `getHighestQueuedEpoch()`, and `getNextEventOpInEpoch2()`. The `Ndb` methods `pollEvents()`, `nextEvent()`, `getLatestGCI()`, `getGCIEventOperations()`, `isConsistent()`, and `isConsistentGCI()` are deprecated beginning with the same release.

NDB 7.4.3 adds the `NdbEventOperation` event handling methods `getEventType2()`, `getEpoch()`, `isEmptyEpoch()`, and `isErrorEpoch`; it obsoletes `getEventType()`, `getGCI()`, `getLatestGCI()`, `isOverrun()`, `hasError()`, and `clearError()`.

While some (but not all) of the new methods are direct replacements for deprecated methods, not all of the deprecated methods map to new ones. The Event Class, provides information as to which old methods correspond to new ones.

Error handling using the new API is no longer handled using dedicated `hasError()` and `clearError()` methods, which are now deprecated (and thus subject to removal in a future release of NDB Cluster). To support this change, the list of `TableEvent` types now includes the values `TE_EMPTY` (empty epoch), `TE_INCONSISTENT` (inconsistent epoch), and `TE_OUT_OF_MEMORY` (inconsistent data).

Improvements in event buffer management have also been made by implementing new `get_eventbuffer_free_percent()`, `set_eventbuffer_free_percent()`, and `get_event_buffer_memory_usage()` methods. Memory buffer usage can now be represented in application code using `EventBufferMemoryUsage`. The `ndb_eventbuffer_free_percent` system variable, also implemented in NDB Cluster 7.4, makes it possible for event buffer memory usage to be checked from MySQL client applications.

For more information, see the detailed descriptions for the `Ndb` and `NdbEventOperation` methods listed. See also `Event::TableEvent`, as well as The EventBufferMemoryUsage Structure.

• **Per-fragment operations information.** In NDB 7.4.3 and later, counts of various types of operations on a given fragment or fragment replica can obtained easily using the `operations_per_fragment` table in the `ndbinfo` information database. This includes read, write, update, and delete operations, as well as scan and index operations performed by these. Information about operations refused, and about rows scanned and returned from a given fragment replica, is also shown in `operations_per_fragment`. This table also provides information about interpreted programs used as attribute values, and values returned by them.

NDB Cluster 7.4 is also supported by MySQL Cluster Manager, which provides an advanced command-line interface that can simplify many complex NDB Cluster management tasks. See MySQL™ Cluster Manager 1.4.7 User Manual, for more information.

### 18.1.5 NDB: Added, Deprecated, and Removed Options, Variables, and Parameters

The next few sections contain information about NDB configuration parameters and NDB-specific `mysqld` options and variables that have been added to, deprecated in, or removed from NDB 7.3 and NDB 7.4.

### 18.1.5.1 Options, Variables, and Parameters Added, Deprecated, or Removed in NDB 7.5

• **Node Configuration Parameters Introduced in NDB 7.3**
This section contains information about NDB configuration parameters and \texttt{mysqld} options and variables that have been added to, deprecated in, or removed from NDB 7.3.

### Node Configuration Parameters Introduced in NDB 7.3

The following node configuration parameters have been added in NDB 7.3.

- **ConnectBackoffMaxTime**: Specifies longest time in milliseconds (~100ms resolution) to allow between connection attempts to any given data node by this API node. Excludes time elapsed while connection attempts are ongoing, which in worst case can take several seconds. Disable by setting to 0. If no data nodes are currently connected to this API node, StartConnectBackoffMaxTime is used instead. Added in NDB 7.3.7.

- **DiskPageBufferEntries**: Number of 32K page entries to allocate in DiskPageBufferMemory. Very large disk transactions may require increasing this value. Added in NDB 7.3.8.

- **HeartbeatIntervalMgmdMgmd**: Time between management-node-to-management-node heartbeats; connection between management nodes is considered lost after 3 missed heartbeats. Added in NDB 7.3.3.

- **LcpScanProgressTimeout**: Maximum time that local checkpoint fragment scan can be stalled before node is shut down to ensure systemwide LCP progress. Use 0 to disable. Added in NDB 7.3.3.

- **RestartSubscriberConnectTimeout**: Amount of time for data node to wait for subscribing API nodes to connect. Set to 0 to disable timeout, which is always resolved to nearest full second. Added in NDB 7.3.6.

- **StartConnectBackoffMaxTime**: Same as ConnectBackoffMaxTime except that this parameter is used in its place if no data nodes are connected to this API node. Added in NDB 7.3.7.

- **TimeBetweenGlobalCheckpointsTimeout**: Minimum timeout for group commit of transactions to disk. Added in NDB 7.3.9.

### Node Configuration Parameters Deprecated in NDB 7.3

No node configuration parameters have been deprecated in NDB 7.3.

### Node Configuration Parameters Removed in NDB 7.3

No node configuration parameters have been removed from NDB 7.3.

### MySQL Server Options and Variables Introduced in NDB 7.3

The following \texttt{mysqld} system variables, status variables, and options have been added in NDB 7.3.

- **Ndb_slave_max_replicated_epoch**: The most recently committed NDB epoch on this slave. When this value is greater than or equal to Ndb\_conflict\_last\_conflict\_epoch, no conflicts have yet been detected.. Added in NDB 7.3.8.
- **create_old_temporals**: Use pre-5.6.4 storage format for temporal types when creating tables. Intended for use in replication and upgrades/downgrades between NDB 7.2 and NDB 7.3/7.4. Added in NDB 7.3.10.

- **ndb_recv_thread-activation-threshold**: Activation threshold when receive thread takes over the polling of the cluster connection (measured in concurrently active threads). Added in NDB 7.3.1.

- **ndb_recv_thread-cpu-mask**: CPU mask for locking receiver threads to specific CPUs; specified as hexadecimal. See documentation for details. Added in NDB 7.3.1.

- **ndb_eventbuffer_max_alloc**: Maximum memory that can be allocated for buffering events by the NDB API. Defaults to 0 (no limit). Added in NDB 7.3.3.

- **ndb_eventbuffer_max_alloc**: Maximum memory that can be allocated for buffering events by the NDB API. Defaults to 0 (no limit). Added in NDB 7.3.3.

**MySQL Server Options and Variables Deprecated in NDB 7.3**

The following *mysqld* system variables, status variables, and options have been deprecated in NDB 7.3.

- **create_old_temporals**: Use pre-5.6.4 storage format for temporal types when creating tables. Intended for use in replication and upgrades/downgrades between NDB 7.2 and NDB 7.3/7.4. Deprecated as of NDB 7.3.10.

**MySQL Server Options and Variables Removed in NDB 7.3**

The following *mysqld* system variables, status variables, and options have been removed in NDB 7.3.

- **ndb_index_stat_cache_entries**: Sets the granularity of the statistics by determining the number of starting and ending keys. Removed in NDB 7.3.5.

- **ndb_index_stat_update_freq**: How often to query data nodes instead of the statistics cache. Removed in NDB 7.3.5.

**18.1.5.2 Options, Variables, and Parameters Added, Deprecated, or Removed in NDB 8.0**

- MySQL Server Options and Variables Introduced in NDB 7.4
- MySQL Server Options and Variables Deprecated in NDB 7.4
- MySQL Server Options and Variables Removed in NDB 7.4
- Node Configuration Parameters Introduced in NDB 7.4
- Node Configuration Parameters Deprecated in NDB 7.4
- Node Configuration Parameters Removed in NDB 7.4

This section contains information about NDB configuration parameters and *mysqld* options and variables that have been added to, deprecated in, or removed from NDB 7.4.

**MySQL Server Options and Variables Introduced in NDB 7.4**

The following *mysqld* system variables, status variables, and options have been added in NDB 7.4.
• **Ndb_conflict_delete_delete_count**: Number of delete-delete conflicts detected (delete operation is applied, but row does not exist). Added in NDB 7.4.2.

• **Ndb_conflict_fn_epoch2**: Number of rows that have been found in conflict by the NDB$EPOCH2() conflict detection function. Added in NDB 7.4.2.

• **Ndb_conflict_fn_epoch2_trans**: Number of rows that have been found in conflict by the NDB$EPOCH2_TRANS() conflict detection function. Added in NDB 7.4.2.

• **Ndb_conflict_fn_max_del_win**: Number of times that conflict resolution based on outcome of NDB$MAX_DELETE_WIN() has been applied. Added in NDB 7.4.1.

• **Ndb_conflict_last_conflict_epoch**: Most recent NDB epoch on this slave in which a conflict was detected. Added in NDB 7.4.2.

• **Ndb_conflict_last_stable_epoch**: Number of rows found to be in conflict by a transactional conflict function. Added in NDB 7.4.2.

• **Ndb_conflict_reflected_op_discard_count**: Number of reflected operations that were not applied due an error during execution. Added in NDB 7.4.2.

• **Ndb_conflict_reflected_op_prepare_count**: Number of reflected operations received that have been prepared for execution. Added in NDB 7.4.2.

• **Ndb_conflict_refresh_op_count**: Number of refresh operations that have been prepared. Added in NDB 7.4.2.

• **Ndb_conflict_trans_row_conflict_count**: Number of rows found in conflict by a transactional conflict function. Includes any rows included in or dependent on conflicting transactions. Added in NDB 7.4.2.

• **Ndb_slave_max_replicated_epoch**: The most recently committed NDB epoch on this slave. When this value is greater than or equal to Ndb_conflict_last_conflict_epoch, no conflicts have yet been detected. Added in NDB 7.4.1.

• **create_old_temporals**: Use pre-5.6.4 storage format for temporal types when creating tables. Intended for use in replication and upgrades/downgrades between NDB 7.2 and NDB 7.3/7.4. Added in NDB 7.4.7.

• **ndb-log-exclusive-reads**: Log primary key reads with exclusive locks; allow conflict resolution based on read conflicts. Added in NDB 7.4.1.

• **ndb-log-update-minimal**: Log updates in a minimal format. Added in NDB 7.4.16.

• **ndb_clear_apply_status**: Causes RESET SLAVE to clear all rows from the ndb_apply_status table; ON by default. Added in NDB 7.4.9.

• **ndb_eventbuffer_free_percent**: Percentage of free memory that should be available in event buffer before resumption of buffering, after reaching limit set by ndb_eventbuffer_max_alloc. Added in NDB 7.4.3.

• **ndb_log_exclusive_reads**: Log primary key reads with exclusive locks; allow conflict resolution based on read conflicts. Added in NDB 7.4.1.

• **ndb_slave_conflict_role**: Role for slave to play in conflict detection and resolution. Value is one of PRIMARY, SECONDARY, PASS, or NONE (default). Can be changed only when slave SQL thread is stopped. See documentation for further information. Added in NDB 7.4.1.
MySQL Server Options and Variables Deprecated in NDB 7.4

The following `mysqld` system variables, status variables, and options have been deprecated in NDB 7.4.

- `create_old_temporals`: Use pre-5.6.4 storage format for temporal types when creating tables. Intended for use in replication and upgrades/downgrades between NDB 7.2 and NDB 7.3/7.4. Deprecated as of NDB 7.4.7.

MySQL Server Options and Variables Removed in NDB 7.4

No system variables, status variables, or options have been removed from NDB 7.4.

Node Configuration Parameters Introduced in NDB 7.4

The following node configuration parameters have been added in NDB 7.4.

- `ApiVerbose`: Enable NDB API debugging; for NDB development. Added in NDB 7.4.12.
- `BackupDiskWriteSpeedPct`: Sets percentage of data node's allocated maximum write speed (MaxDiskWriteSpeed) to reserve for LCPs when starting a backup. Added in NDB 7.4.8.
- `ConnectBackoffMaxTime`: Specifies longest time in milliseconds (~100ms resolution) to allow between connection attempts to any given data node by this API node. Excludes time elapsed while connection attempts are ongoing, which in worst case can take several seconds. Disable by setting to 0. If no data nodes are currently connected to this API node, `StartConnectBackoffMaxTime` is used instead. Added in NDB 7.4.2.
- `DiskPageBufferEntries`: Number of 32K page entries to allocate in DiskPageBufferMemory. Very large disk transactions may require increasing this value. Added in NDB 7.4.3.
- `MaxDiskWriteSpeed`: Maximum number of bytes per second that can be written by LCP and backup when no restarts are ongoing. Added in NDB 7.4.1.
- `MaxDiskWriteSpeedOtherNodeRestart`: Maximum number of bytes per second that can be written by LCP and backup when another node is restarting. Added in NDB 7.4.1.
- `MaxDiskWriteSpeedOwnRestart`: Maximum number of bytes per second that can be written by LCP and backup when this node is restarting. Added in NDB 7.4.1.
- `MaxParallelCopyInstances`: Number of parallel copies during node restarts. Default is 0, which uses number of LDMs on both nodes, to a maximum of 16. Added in NDB 7.4.3.
- `MinDiskWriteSpeed`: Minimum number of bytes per second that can be written by LCP and backup. Added in NDB 7.4.1.
- `SchedulerResponsiveness`: Set NDB scheduler response optimization 0-10; higher values provide better response time but lower throughput. Added in NDB 7.4.9.
- `StartConnectBackoffMaxTime`: Same as `ConnectBackoffMaxTime` except that this parameter is used in its place if no data nodes are connected to this API node. Added in NDB 7.4.2.
- `TimeBetweenGlobalCheckpointsTimeout`: Minimum timeout for group commit of transactions to disk. Added in NDB 7.4.5.

Node Configuration Parameters Deprecated in NDB 7.4

The following node configuration parameters have been deprecated in NDB 7.4.
MySQL Server Using InnoDB Compared with NDB Cluster

- **BackupMemory**: Total memory allocated for backups per node (in bytes). Deprecated as of NDB 7.4.8.
- **DiskCheckpointSpeed**: Bytes allowed to be written by checkpoint, per second. Deprecated as of NDB 7.4.1.
- **DiskCheckpointSpeedInRestart**: Bytes allowed to be written by checkpoint during restart, per second. Deprecated as of NDB 7.4.1.

**Node Configuration Parameters Removed in NDB 7.4**

No node configuration parameters have been removed from NDB 7.4.

### 18.1.6 MySQL Server Using InnoDB Compared with NDB Cluster

MySQL Server offers a number of choices in storage engines. Since both NDB and InnoDB can serve as transactional MySQL storage engines, users of MySQL Server sometimes become interested in NDB Cluster. They see NDB as a possible alternative or upgrade to the default InnoDB storage engine in MySQL 5.6. While NDB and InnoDB share common characteristics, there are differences in architecture and implementation, so that some existing MySQL Server applications and usage scenarios can be a good fit for NDB Cluster, but not all of them.

In this section, we discuss and compare some characteristics of the NDB storage engine used by NDB Cluster 7.3 and 7.4 with InnoDB used in MySQL 5.6. The next few sections provide a technical comparison. In many instances, decisions about when and where to use NDB Cluster must be made on a case-by-case basis, taking all factors into consideration. While it is beyond the scope of this documentation to provide specifics for every conceivable usage scenario, we also attempt to offer some very general guidance on the relative suitability of some common types of applications for NDB as opposed to InnoDB back ends.

NDB Cluster 7.3 and 7.4 use a mysqld based on MySQL 5.6, including support for InnoDB 1.1. While it is possible to use InnoDB tables with NDB Cluster, such tables are not clustered. It is also not possible to use programs or libraries from an NDB Cluster 7.3 or 7.4 distribution with MySQL Server 5.6, or the reverse.

While it is also true that some types of common business applications can be run either on NDB Cluster or on MySQL Server (most likely using the InnoDB storage engine), there are some important architectural and implementation differences. Section 18.1.6.1, “Differences Between the NDB and InnoDB Storage Engines”, provides a summary of the these differences. Due to the differences, some usage scenarios are clearly more suitable for one engine or the other; see Section 18.1.6.2, “NDB and InnoDB Workloads”. This in turn has an impact on the types of applications that better suited for use with NDB or InnoDB. See Section 18.1.6.3, “NDB and InnoDB Feature Usage Summary”, for a comparison of the relative suitability of each for use in common types of database applications.

For information about the relative characteristics of the NDB and MEMORY storage engines, see When to Use MEMORY or NDB Cluster.

See Chapter 15, Alternative Storage Engines, for additional information about MySQL storage engines.

### 18.1.6.1 Differences Between the NDB and InnoDB Storage Engines

The NDB storage engine is implemented using a distributed, shared-nothing architecture, which causes it to behave differently from InnoDB in a number of ways. For those unaccustomed to working with NDB, unexpected behaviors can arise due to its distributed nature with regard to transactions, foreign keys, table limits, and other characteristics. These are shown in the following table:
### Table 18.1 Feature differences between InnoDB and NDB storage engines.

<table>
<thead>
<tr>
<th>Feature</th>
<th>InnoDB 1.1</th>
<th>NDB 7.3, NDB 7.4</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL Server Version</td>

### 18.1.6.2 NDB and InnoDB Workloads

NDB Cluster has a range of unique attributes that make it ideal to serve applications requiring high availability, fast failover, high throughput, and low latency. Due to its distributed architecture and multi-node implementation, NDB Cluster also has specific constraints that may keep some workloads from performing well. A number of major differences in behavior between the NDB and InnoDB storage engines with regard to some common types of database-driven application workloads are shown in the following table:

<table>
<thead>
<tr>
<th>Workload</th>
<th>InnoDB</th>
<th>NDB Cluster (NDB)</th>

### 18.1.6.3 NDB and InnoDB Feature Usage Summary

When comparing application feature requirements to the capabilities of InnoDB with NDB, some are clearly more compatible with one storage engine than the other.

The following table lists supported application features according to the storage engine to which each feature is typically better suited.

<table>
<thead>
<tr>
<th>Preferred application requirements for InnoDB</th>
<th>Preferred application requirements for NDB</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Foreign keys</td>
<td>• Write scaling</td>
</tr>
</tbody>
</table>
Known Limitations of NDB Cluster

### 18.1.7 Known Limitations of NDB Cluster

In the sections that follow, we discuss known limitations in current releases of NDB Cluster as compared with the features available when using the **MyISAM** and **InnoDB** storage engines. If you check the “Cluster” category in the MySQL bugs database at [http://bugs.mysql.com](http://bugs.mysql.com), you can find known bugs in the following categories under “MySQL Server:” in the MySQL bugs database at [http://bugs.mysql.com](http://bugs.mysql.com), which we intend to correct in upcoming releases of NDB Cluster:

- NDB Cluster
- Cluster Direct API (NDBAPI)
- Cluster Disk Data
- Cluster Replication
- ClusterJ

This information is intended to be complete with respect to the conditions just set forth. You can report any discrepancies that you encounter to the MySQL bugs database using the instructions given in Section 1.6, “How to Report Bugs or Problems”. If we do not plan to fix the problem in NDB Cluster 7.3 or 7.4, we will add it to the list.

See Section 18.1.7.11, “Previous NDB Cluster Issues Resolved in NDB Cluster 7.3” for a list of issues in NDB Cluster 7.2 that have been resolved in NDB Cluster 7.3 or 7.4.

| ![Note](image) | Limitations and other issues specific to NDB Cluster Replication are described in Section 18.6.3, “Known Issues in NDB Cluster Replication”. |

### 18.1.7.1 Noncompliance with SQL Syntax in NDB Cluster

Some SQL statements relating to certain MySQL features produce errors when used with **NDB** tables, as described in the following list:

- **Temporary tables.** Temporary tables are not supported. Trying either to create a temporary table that uses the **NDB** storage engine or to alter an existing temporary table to use **NDB** fails with the error **Table storage engine 'ndbcluster' does not support the create option 'TEMPORARY'**.
Known Limitations of NDB Cluster

• **Indexes and keys in NDB tables.** Keys and indexes on NDB Cluster tables are subject to the following limitations:

  • **Column width.** Attempting to create an index on an NDB table column whose width is greater than 3072 bytes succeeds, but only the first 3072 bytes are actually used for the index. In such cases, a warning Specified key was too long; max key length is 3072 bytes is issued, and a SHOW CREATE TABLE statement shows the length of the index as 3072.

  • **TEXT and BLOB columns.** You cannot create indexes on NDB table columns that use any of the TEXT or BLOB data types.

  • **FULLTEXT indexes.** The NDB storage engine does not support FULLTEXT indexes, which are possible for MyISAM and (MySQL 5.6.4 and later) InnoDB tables only.

    However, you can create indexes on VARCHAR columns of NDB tables.

  • **USING HASH keys and NULL.** Using nullable columns in unique keys and primary keys means that queries using these columns are handled as full table scans. To work around this issue, make the column NOT NULL, or re-create the index without the USING HASH option.

  • **Prefixes.** There are no prefix indexes; only entire columns can be indexed. (The size of an NDB column index is always the same as the width of the column in bytes, up to and including 3072 bytes, as described earlier in this section. Also see Section 18.1.7.6, “Unsupported or Missing Features in NDB Cluster”, for additional information.)

  • **BIT columns.** A BIT column cannot be a primary key, unique key, or index, nor can it be part of a composite primary key, unique key, or index.

  • **AUTO_INCREMENT columns.** Like other MySQL storage engines, the NDB storage engine can handle a maximum of one AUTO_INCREMENT column per table, and this column must be indexed. However, in the case of an NDB table with no explicit primary key, an AUTO_INCREMENT column is automatically defined and used as a “hidden” primary key. For this reason, you cannot create an NDB table having an AUTO_INCREMENT column and no explicit primary key.

• **Restrictions on foreign keys.** Support for foreign key constraints in NDB Cluster 7.3 and 7.4 is comparable to that provided by InnoDB, subject to the following restrictions:

  • Every column referenced as a foreign key requires an explicit unique key, if it is not the table's primary key.

  • **ON UPDATE CASCADE** is not supported when the reference is to the parent table's primary key.

    This is because an update of a primary key is implemented as a delete of the old row (containing the old primary key) plus an insert of the new row (with a new primary key). This is not visible to the NDB kernel, which views these two rows as being the same, and thus has no way of knowing that this update should be cascaded.

  • **SET DEFAULT** is not supported. (Also not supported by InnoDB.)

  • The **NO ACTION** keywords are accepted but treated as **REQUIRE**. (Also the same as with InnoDB.)

  • Prior to NDB 7.3.5, when creating a table with foreign key referencing an index in another table, it sometimes appeared possible to create the foreign key even if the order of the columns in the indexes did not match, due to the fact that an appropriate error was not always returned internally. A partial fix for this issue in NDB 7.3.5 improves the error used internally to work in most cases; however, it
is still possible for this situation to occur in the event that the parent index is a unique index. (Bug #18094360)

• In NDB 7.3, when adding or dropping a foreign key using ALTER TABLE, the parent table’s metadata is not updated, which makes it possible subsequently to execute ALTER TABLE statements on the parent that should be invalid. This issue also affects NDB 7.4 releases prior to 7.4.15. To work around this issue, execute SHOW CREATE TABLE on the parent table immediately after adding or dropping the foreign key; this forces the parent's metadata to be reloaded.

This issue is fixed in NDB 7.4.15 and later. (Bug #82989, Bug #24666177)

For more information, see Section 13.1.17.6, “Using FOREIGN KEY Constraints”, and Section 1.7.3.2, “FOREIGN KEY Constraints”.

• NDB Cluster and geometry data types. Geometry data types (WKT and WKB) are supported for NDB tables. However, spatial indexes are not supported.

• Character sets and binary log files. Currently, the ndb_apply_status and ndb_binlog_index tables are created using the latin1 (ASCII) character set. Because names of binary logs are recorded in this table, binary log files named using non-Latin characters are not referenced correctly in these tables. This is a known issue, which we are working to fix. (Bug #50226)

To work around this problem, use only Latin-1 characters when naming binary log files or setting any the --basedir, --log-bin, or --log-bin-index options.

• Creating NDB tables with user-defined partitioning. Support for user-defined partitioning in NDB Cluster is restricted to [LINEAR] KEY partitioning. Using any other partitioning type with ENGINE=NDB or ENGINE=NDBCLUSTER in a CREATE TABLE statement results in an error.

It is possible to override this restriction, but doing so is not supported for use in production settings. For details, see User-defined partitioning and the NDB storage engine (NDB Cluster).

Default partitioning scheme. All NDB Cluster tables are by default partitioned by KEY using the table’s primary key as the partitioning key. If no primary key is explicitly set for the table, the “hidden” primary key automatically created by the NDB storage engine is used instead. For additional discussion of these and related issues, see Section 19.2.5, “KEY Partitioning”.

CREATE TABLE and ALTER TABLE statements that would cause a user-partitioned NDBCLUSTER table not to meet either or both of the following two requirements are not permitted, and fail with an error:

1. The table must have an explicit primary key.
2. All columns listed in the table's partitioning expression must be part of the primary key.

Exception. If a user-partitioned NDBCLUSTER table is created using an empty column-list (that is, using PARTITION BY [LINEAR] KEY()), then no explicit primary key is required.

Maximum number of partitions for NDBCLUSTER tables. The maximum number of partitions that can be defined for a NDBCLUSTER table when employing user-defined partitioning is 8 per node group. (See Section 18.1.2, “NDB Cluster Nodes, Node Groups, Replicas, and Partitions”, for more information about NDB Cluster node groups.

DROP PARTITION not supported. It is not possible to drop partitions from NDB tables using ALTER TABLE ... DROP PARTITION. The other partitioning extensions to ALTER TABLE—ADD PARTITION, REORGANIZE PARTITION, and COALESCE PARTITION—are supported for NDB tables,
but use copying and so are not optimized. See Section 19.3.1, “Management of RANGE and LIST Partitions” and Section 13.1.7, “ALTER TABLE Syntax”.

- **Row-based replication.**
  When using row-based replication with NDB Cluster, binary logging cannot be disabled. That is, the NDB storage engine ignores the value of `sql_log_bin`. (Bug #16680)

### 18.1.7.2 Limits and Differences of NDB Cluster from Standard MySQL Limits

In this section, we list limits found in NDB Cluster that either differ from limits found in, or that are not found in, standard MySQL.

**Memory usage and recovery.** Memory consumed when data is inserted into an NDB table is not automatically recovered when deleted, as it is with other storage engines. Instead, the following rules hold true:

- A `DELETE` statement on an NDB table makes the memory formerly used by the deleted rows available for re-use by inserts on the same table only. However, this memory can be made available for general re-use by performing `OPTIMIZE TABLE`.
- A rolling restart of the cluster also frees any memory used by deleted rows. See Section 18.5.5, “Performing a Rolling Restart of an NDB Cluster”.

- A `DROP TABLE` or `TRUNCATE TABLE` operation on an NDB table frees the memory that was used by this table for re-use by any NDB table, either by the same table or by another NDB table.

  **Note**
  Recall that `TRUNCATE TABLE` drops and re-creates the table. See Section 13.1.33, “TRUNCATE TABLE Syntax”.

- **Limits imposed by the cluster's configuration.**
  A number of hard limits exist which are configurable, but available main memory in the cluster sets limits. See the complete list of configuration parameters in Section 18.3.3, “NDB Cluster Configuration Files”. Most configuration parameters can be upgraded online. These hard limits include:

  - Database memory size and index memory size (`DataMemory` and `IndexMemory`, respectively).
    `DataMemory` is allocated as 32KB pages. As each `DataMemory` page is used, it is assigned to a specific table; once allocated, this memory cannot be freed except by dropping the table.
    See Section 18.3.3.6, “Defining NDB Cluster Data Nodes”, for more information.
  - The maximum number of operations that can be performed per transaction is set using the configuration parameters `MaxNoOfConcurrentOperations` and `MaxNoOfLocalOperations`.
    **Note**
    Bulk loading, `TRUNCATE TABLE`, and `ALTER TABLE` are handled as special cases by running multiple transactions, and so are not subject to this limitation.
  - Different limits related to tables and indexes. For example, the maximum number of ordered indexes in the cluster is determined by `MaxNoOfOrderedIndexes`, and the maximum number of ordered indexes per table is 16.
  - **Node and data object maximums.** The following limits apply to numbers of cluster nodes and metadata objects:
Known Limitations of NDB Cluster

- The maximum number of data nodes is 48.

  A data node must have a node ID in the range of 1 to 48, inclusive. (Management and API nodes may use node IDs in the range 1 to 255, inclusive.)

- The total maximum number of nodes in an NDB Cluster is 255. This number includes all SQL nodes (MySQL Servers), API nodes (applications accessing the cluster other than MySQL servers), data nodes, and management servers.

- The maximum number of metadata objects in current versions of NDB Cluster is 20320. This limit is hard-coded.

  See Section 18.1.7.11, “Previous NDB Cluster Issues Resolved in NDB Cluster 7.3”, for more information.

18.1.7.3 Limits Relating to Transaction Handling in NDB Cluster

A number of limitations exist in NDB Cluster with regard to the handling of transactions. These include the following:

- **Transaction isolation level.** The NDBCLUSTER storage engine supports only the READ COMMITTED transaction isolation level. (InnoDB, for example, supports READ COMMITTED, READ UNCOMMITTED, REPEATABLE READ, and SERIALIZABLE.) You should keep in mind that NDB implements READ COMMITTED on a per-row basis; when a read request arrives at the data node storing the row, what is returned is the last committed version of the row at that time.

  Uncommitted data is never returned, but when a transaction modifying a number of rows commits concurrently with a transaction reading the same rows, the transaction performing the read can observe “before” values, “after” values, or both, for different rows among these, due to the fact that a given row read request can be processed either before or after the commit of the other transaction.

  To ensure that a given transaction reads only before or after values, you can impose row locks using SELECT ... LOCK IN SHARE MODE. In such cases, the lock is held until the owning transaction is committed. Using row locks can also cause the following issues:

  - Increased frequency of lock wait timeout errors, and reduced concurrency
  - Increased transaction processing overhead due to reads requiring a commit phase
  - Possibility of exhausting the available number of concurrent locks, which is limited by MaxNoOfConcurrentOperations

  NDB uses READ COMMITTED for all reads unless a modifier such as LOCK IN SHARE MODE or FOR UPDATE is used. LOCK IN SHARE MODE causes shared row locks to be used; FOR UPDATE causes exclusive row locks to be used. Unique key reads have their locks upgraded automatically by NDB to ensure a self-consistent read; BLOB reads also employ extra locking for consistency.

  See Section 18.5.3.4, “NDB Cluster Backup Troubleshooting”, for information on how NDB Cluster's implementation of transaction isolation level can affect backup and restoration of NDB databases.

- **Transactions and BLOB or TEXT columns.** NDBCLUSTER stores only part of a column value that uses any of MySQL’s BLOB or TEXT data types in the table visible to MySQL; the remainder of the BLOB or TEXT is stored in a separate internal table that is not accessible to MySQL. This gives rise to two related issues of which you should be aware whenever executing SELECT statements on tables that contain columns of these types:
Known Limitations of NDB Cluster

1. For any `SELECT` from an NDB Cluster table: If the `SELECT` includes a `BLOB` or `TEXT` column, the `READ COMMITTED` transaction isolation level is converted to a read with read lock. This is done to guarantee consistency.

2. For any `SELECT` which uses a unique key lookup to retrieve any columns that use any of the `BLOB` or `TEXT` data types and that is executed within a transaction, a shared read lock is held on the table for the duration of the transaction—that is, until the transaction is either committed or aborted.

This issue does not occur for queries that use index or table scans, even against NDB tables having `BLOB` or `TEXT` columns.

For example, consider the table `t` defined by the following `CREATE TABLE` statement:

```sql
CREATE TABLE t (  
a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,  
b INT NOT NULL,  
c INT NOT NULL,  
d TEXT,  
INDEX i(b),  
UNIQUE KEY u(c)  
) ENGINE = NDB,
```

Either of the following queries on `t` causes a shared read lock, because the first query uses a primary key lookup and the second uses a unique key lookup:

```sql
SELECT * FROM t WHERE a = 1;
SELECT * FROM t WHERE c = 1;
```

However, none of the four queries shown here causes a shared read lock:

```sql
SELECT * FROM t WHERE b = 1;
SELECT * FROM t WHERE d = '1';
SELECT * FROM t;
SELECT b,c WHERE a = 1;
```

This is because, of these four queries, the first uses an index scan, the second and third use table scans, and the fourth, while using a primary key lookup, does not retrieve the value of any `BLOB` or `TEXT` columns.

You can help minimize issues with shared read locks by avoiding queries that use unique key lookups that retrieve `BLOB` or `TEXT` columns, or, in cases where such queries are not avoidable, by committing transactions as soon as possible afterward.

- **Rollbacks.** There are no partial transactions, and no partial rollbacks of transactions. A duplicate key or similar error causes the entire transaction to be rolled back.

  This behavior differs from that of other transactional storage engines such as InnoDB that may roll back individual statements.

- **Transactions and memory usage.** As noted elsewhere in this chapter, NDB Cluster does not handle large transactions well; it is better to perform a number of small transactions with a few operations each than to attempt a single large
transaction containing a great many operations. Among other considerations, large transactions require very large amounts of memory. Because of this, the transactional behavior of a number of MySQL statements is affected as described in the following list:

• **TRUNCATE TABLE** is not transactional when used on NDB tables. If a **TRUNCATE TABLE** fails to empty the table, then it must be re-run until it is successful.

• **DELETE FROM** (even with no **WHERE** clause) is transactional. For tables containing a great many rows, you may find that performance is improved by using several **DELETE FROM ... LIMIT ...** statements to “chunk” the delete operation. If your objective is to empty the table, then you may wish to use **TRUNCATE TABLE** instead.

• **LOAD DATA** statements. **LOAD DATA** is not transactional when used on NDB tables.

  **Important**

  When executing a **LOAD DATA** statement, the NDB engine performs commits at irregular intervals that enable better utilization of the communication network. It is not possible to know ahead of time when such commits take place.

• **ALTER TABLE and transactions.** When copying an NDB table as part of an **ALTER TABLE**, the creation of the copy is nontransactional. (In any case, this operation is rolled back when the copy is deleted.)

• **Transactions and the COUNT() function.** When using NDB Cluster Replication, it is not possible to guarantee the transactional consistency of the **COUNT()** function on the slave. In other words, when performing on the master a series of statements (**INSERT**, **DELETE**, or both) that changes the number of rows in a table within a single transaction, executing **SELECT COUNT(*) FROM table** queries on the slave may yield intermediate results. This is due to the fact that **SELECT COUNT(.)** may perform dirty reads, and is not a bug in the NDB storage engine. (See Bug #31321 for more information.)

### 18.1.7.4 NDB Cluster Error Handling

Starting, stopping, or restarting a node may give rise to temporary errors causing some transactions to fail. These include the following cases:

• **Temporary errors.** When first starting a node, it is possible that you may see Error 1204 Temporary failure, distribution changed and similar temporary errors.

• **Errors due to node failure.** The stopping or failure of any data node can result in a number of different node failure errors. (However, there should be no aborted transactions when performing a planned shutdown of the cluster.)

In either of these cases, any errors that are generated must be handled within the application. This should be done by retrying the transaction.

See also Section 18.1.7.2, “Limits and Differences of NDB Cluster from Standard MySQL Limits”.

### 18.1.7.5 Limits Associated with Database Objects in NDB Cluster

Some database objects such as tables and indexes have different limitations when using the NDB storage engine:

• **Database and table names.** When using the NDB storage engine, the maximum allowed length both for database names and for table names is 63 characters.

  In NDB 7.3.8 and later, a statement using a database name or table name longer than this limit fails with an appropriate error. (Bug #19550973)
Known Limitations of NDB Cluster

- **Number of database objects.** The maximum number of all NDB database objects in a single NDB Cluster—including databases, tables, and indexes—is limited to 20320.

- **Attributes per table.** The maximum number of attributes (that is, columns and indexes) that can belong to a given table is 512.

- **Attributes per key.** The maximum number of attributes per key is 32.

- **Row size.** The maximum permitted size of any one row is 14000 bytes. Each BLOB or TEXT column contributes 256 + 8 = 264 bytes to this total.

In addition, the maximum offset for a fixed-width column of an NDB table is 8188 bytes; attempting to create a table that violates this limitation fails with NDB error 851 *Maximum offset for fixed-size columns exceeded*. For memory-based columns, you can work around this limitation by using a variable-width column type such as VARCHAR or defining the column as COLUMN_FORMAT=DYNAMIC; this does not work with columns stored on disk. For disk-based columns, you may be able to do so by reordering one or more of the table's disk-based columns such that the combined width of all but the disk-based column defined last in the CREATE TABLE statement used to create the table does not exceed 8188 bytes, less any possible rounding performed for some data types such as CHAR or VARCHAR; otherwise it is necessary to use memory-based storage for one or more of the offending column or columns instead.

- **BIT column storage per table.** The maximum combined width for all BIT columns used in a given NDB table is 4096.

- **FIXED column storage.** NDB Cluster supports a maximum of 16 GB per fragment of data in FIXED columns.

### 18.1.7.6 Unsupported or Missing Features in NDB Cluster

A number of features supported by other storage engines are not supported for NDB tables. Trying to use any of these features in NDB Cluster does not cause errors in or of itself; however, errors may occur in applications that expects the features to be supported or enforced. Statements referencing such features, even if effectively ignored by NDB, must be syntactically and otherwise valid.

- **Index prefixes.** Prefixes on indexes are not supported for NDB tables. If a prefix is used as part of an index specification in a statement such as CREATE TABLE, ALTER TABLE, or CREATE INDEX, the prefix is not created by NDB.

A statement containing an index prefix, and creating or modifying an NDB table, must still be syntactically valid. For example, the following statement always fails with Error 1089 *Incorrect prefix key; the used key part isn't a string, the used length is longer than the key part, or the storage engine doesn't support unique prefix keys*, regardless of storage engine:

```sql
CREATE TABLE t1 (  c1 INT NOT NULL,  c2 VARCHAR(100),  INDEX ii (c2(500)))
```

This happens on account of the SQL syntax rule that no index may have a prefix larger than itself.

- **Savepoints and rollbacks.** Savepoints and rollbacks to savepoints are ignored as in MyISAM.

- **Durability of commits.** There are no durable commits on disk. Commits are replicated, but there is no guarantee that logs are flushed to disk on commit.
18.1.7.7 Limitations Relating to Performance in NDB Cluster

The following performance issues are specific to or especially pronounced in NDB Cluster:

- **Range scans.** There are query performance issues due to sequential access to the NDB storage engine; it is also relatively more expensive to do many range scans than it is with either MyISAM or InnoDB.

- **Reliability of Records in range.** The Records in range statistic is available but is not completely tested or officially supported. This may result in nonoptimal query plans in some cases. If necessary, you can employ USE INDEX or FORCE INDEX to alter the execution plan. See Section 8.9.3, “Index Hints”, for more information on how to do this.

- **Unique hash indexes.** Unique hash indexes created with USING HASH cannot be used for accessing a table if NULL is given as part of the key.

18.1.7.8 Issues Exclusive to NDB Cluster

The following are limitations specific to the NDB storage engine:

- **Machine architecture.** All machines used in the cluster must have the same architecture. That is, all machines hosting nodes must be either big-endian or little-endian, and you cannot use a mixture of both. For example, you cannot have a management node running on a PowerPC which directs a data node that is running on an x86 machine. This restriction does not apply to machines simply running mysql or other clients that may be accessing the cluster’s SQL nodes.

- **Binary logging.** NDB Cluster has the following limitations or restrictions with regard to binary logging:
  - sql_log_bin has no effect on data operations; however, it is supported for schema operations.
  - NDB Cluster cannot produce a binary log for tables having BLOB columns but no primary key.
  - Only the following schema operations are logged in a cluster binary log which is not on the mysql executing the statement:
    - CREATE TABLE
    - ALTER TABLE
    - DROP TABLE
    - CREATE DATABASE / CREATE SCHEMA
Known Limitations of NDB Cluster

- DROP DATABASE / DROP SCHEMA
- CREATE TABLESPACE
- ALTER TABLESPACE
- DROP TABLESPACE
- CREATE LOGFILE GROUP
- ALTER LOGFILE GROUP
- DROP LOGFILE GROUP

- Schema operations (DDL statements) are rejected while any data node restarts.

- **Number of replicas.** The number of replicas, as determined by the `NoOfReplicas` data node configuration parameter, is the number of copies of all data stored by NDB Cluster. Setting this parameter to 1 means there is only a single copy; in this case, no redundancy is provided, and the loss of a data node entails loss of data. To guarantee redundancy, and thus preservation of data even if a data node fails, set this parameter to 2, which is the default and recommended value in production.

  Setting `NoOfReplicas` to a value greater than 2 is possible (to a maximum of 4) but unnecessary to guard against loss of data. In addition, values greater than 2 for this parameter are not supported in production.

  See also Section 18.1.7.10, “Limitations Relating to Multiple NDB Cluster Nodes”.

### 18.1.7.9 Limitations Relating to NDB Cluster Disk Data Storage

- **Disk Data object maximums and minimums.** Disk data objects are subject to the following maximums and minimums:
  - Maximum number of tablespaces: $2^{32}$ (4294967296)
  - Maximum number of data files per tablespace: $2^{16}$ (65536)
  - The minimum and maximum possible sizes of extents for tablespace data files are 32K and 2G, respectively. See Section 13.1.18, “CREATE TABLESPACE Syntax”, for more information.

  In addition, when working with NDB Disk Data tables, you should be aware of the following issues regarding data files and extents:
  - Data files use `DataMemory`. Usage is the same as for in-memory data.
  - Data files use file descriptors. It is important to keep in mind that data files are always open, which means the file descriptors are always in use and cannot be re-used for other system tasks.
  - Extents require sufficient `DiskPageBufferMemory`; you must reserve enough for this parameter to account for all memory used by all extents (number of extents times size of extents).

- **Disk Data tables and diskless mode.** Use of Disk Data tables is not supported when running the cluster in diskless mode.

### 18.1.7.10 Limitations Relating to Multiple NDB Cluster Nodes

- **Multiple SQL nodes.**
The following are issues relating to the use of multiple MySQL servers as NDB Cluster SQL nodes, and are specific to the NDBCLUSTER storage engine:

- **No distributed table locks.** A `LOCK TABLES` works only for the SQL node on which the lock is issued; no other SQL node in the cluster "sees" this lock. This is also true for a lock issued by any statement that locks tables as part of its operations. (See next item for an example.)

- **ALTER TABLE operations.** `ALTER TABLE` is not fully locking when running multiple MySQL servers (SQL nodes). (As discussed in the previous item, NDB Cluster does not support distributed table locks.)

### Multiple management nodes.

When using multiple management servers:

- If any of the management servers are running on the same host, you must give nodes explicit IDs in connection strings because automatic allocation of node IDs does not work across multiple management servers on the same host. This is not required if every management server resides on a different host.

- When a management server starts, it first checks for any other management server in the same NDB Cluster, and upon successful connection to the other management server uses its configuration data. This means that the management server `--reload` and `--initial` startup options are ignored unless the management server is the only one running. It also means that, when performing a rolling restart of an NDB Cluster with multiple management nodes, the management server reads its own configuration file if (and only if) it is the only management server running in this NDB Cluster. See Section 18.5.5, “Performing a Rolling Restart of an NDB Cluster”, for more information.

### Multiple network addresses.

Multiple network addresses per data node are not supported. Use of these is liable to cause problems: In the event of a data node failure, an SQL node waits for confirmation that the data node went down but never receives it because another route to that data node remains open. This can effectively make the cluster inoperable.

**Note**

It is possible to use multiple network hardware *interfaces* (such as Ethernet cards) for a single data node, but these must be bound to the same address. This also means that it not possible to use more than one [tcp] section per connection in the `config.ini` file. See Section 18.3.3.9, “NDB Cluster TCP/IP Connections”, for more information.

### 18.1.7.11 Previous NDB Cluster Issues Resolved in NDB Cluster 7.3

A number of limitations and related issues that existed in earlier versions of NDB Cluster have been resolved in NDB Cluster 7.3. These are described briefly in the following list:

- **Support for foreign keys.** Foreign key constraints are now supported for NDB tables, similar to how these are supported by the InnoDB storage engine.

**Note**

Unlike the case with user-partitioned InnoDB tables, foreign keys are supported for NDB tables that are partitioned by KEY or LINEAR KEY.

Section 1.7.3.2, “FOREIGN KEY Constraints”, provides more information about foreign key support in MySQL. For more information about the syntax supported by MySQL for foreign keys, see Section 13.1.17.6, “Using FOREIGN KEY Constraints”.

### 18.2 NDB Cluster Installation
This section describes the basics for planning, installing, configuring, and running an NDB Cluster. Whereas the examples in Section 18.3, “Configuration of NDB Cluster” provide more in-depth information on a variety of clustering options and configuration, the result of following the guidelines and procedures outlined here should be a usable NDB Cluster which meets the minimum requirements for availability and safeguarding of data.

For information about upgrading or downgrading an NDB Cluster between release versions, see Section 18.2.8, “Upgrading and Downgrading NDB Cluster”.

This section covers hardware and software requirements; networking issues; installation of NDB Cluster; basic configuration issues; starting, stopping, and restarting the cluster; loading of a sample database; and performing queries.

NDB Cluster 7.3 and later also provides the NDB Cluster Auto-Installer, a web-based graphical installer, as part of the NDB Cluster distribution. The Auto-Installer can be used to perform basic installation and setup of an NDB Cluster on one (for testing) or more host computers. See Section 18.2.1, “The NDB Cluster Auto-Installer”, for more information.

Assumptions. The following sections make a number of assumptions regarding the cluster’s physical and network configuration. These assumptions are discussed in the next few paragraphs.

Cluster nodes and host computers. The cluster consists of four nodes, each on a separate host computer, and each with a fixed network address on a typical Ethernet network as shown here:

<table>
<thead>
<tr>
<th>Table 18.4 Network addresses of nodes in example cluster</th>
</tr>
</thead>
<tbody>
<tr>
<td>Node</td>
</tr>
<tr>
<td>Management node (mgmd)</td>
</tr>
<tr>
<td>SQL node (mysqld)</td>
</tr>
<tr>
<td>Data node &quot;A&quot; (ndbd)</td>
</tr>
<tr>
<td>Data node &quot;B&quot; (ndbd)</td>
</tr>
</tbody>
</table>

This setup is also shown in the following diagram:

**Figure 18.4 NDB Cluster Multi-Computer Setup**
Network addressing. In the interest of simplicity (and reliability), this How-To uses only numeric IP addresses. However, if DNS resolution is available on your network, it is possible to use host names in lieu of IP addresses in configuring Cluster. Alternatively, you can use the `hosts` file (typically `/etc/hosts` for Linux and other Unix-like operating systems, `C:\WINDOWS\system32\drivers\etc\hosts` on Windows, or your operating system’s equivalent) for providing a means to do host lookup if such is available.

Potential hosts file issues. A common problem when trying to use host names for Cluster nodes arises because of the way in which some operating systems (including some Linux distributions) set up the system's own host name in the `/etc/hosts` during installation. Consider two machines with the host names `ndb1` and `ndb2`, both in the `cluster` network domain. Red Hat Linux (including some derivatives such as CentOS and Fedora) places the following entries in these machines' `/etc/hosts` files:

```plaintext
# ndb1 /etc/hosts:
127.0.0.1   ndb1.cluster ndb1 localhost.localdomain localhost

# ndb2 /etc/hosts:
127.0.0.1   ndb2.cluster ndb2 localhost.localdomain localhost
```

SUSE Linux (including OpenSUSE) places these entries in the machines' `/etc/hosts` files:

```plaintext
# ndb1 /etc/hosts:
127.0.0.1       localhost
127.0.0.2       ndb1.cluster ndb1

# ndb2 /etc/hosts:
127.0.0.1       localhost
127.0.0.2       ndb2.cluster ndb2
```

In both instances, `ndb1` routes `ndb1.cluster` to a loopback IP address, but gets a public IP address from DNS for `ndb2.cluster`, while `ndb2` routes `ndb2.cluster` to a loopback address and obtains a public address for `ndb1.cluster`. The result is that each data node connects to the management server, but cannot tell when any other data nodes have connected, and so the data nodes appear to hang while starting.

Caution

You cannot mix `localhost` and other host names or IP addresses in `config.ini`. For these reasons, the solution in such cases (other than to use IP addresses for all `config.ini` `HostName` entries) is to remove the fully qualified host names from `/etc/hosts` and use these in `config.ini` for all cluster hosts.

Host computer type. Each host computer in our installation scenario is an Intel-based desktop PC running a supported operating system installed to disk in a standard configuration, and running no unnecessary services. The core operating system with standard TCP/IP networking capabilities should be sufficient. Also for the sake of simplicity, we also assume that the file systems on all hosts are set up identically. In the event that they are not, you should adapt these instructions accordingly.

Network hardware. Standard 100 Mbps or 1 gigabit Ethernet cards are installed on each machine, along with the proper drivers for the cards, and that all four hosts are connected through a standard-issue Ethernet networking appliance such as a switch. (All machines should use network cards with the same throughput. That is, all four machines in the cluster should have 100 Mbps cards or all four machines should have 1 Gbps cards.) NDB Cluster works in a 100 Mbps network; however, gigabit Ethernet provides better performance.
Important

NDB Cluster is not intended for use in a network for which throughput is less than 100 Mbps or which experiences a high degree of latency. For this reason (among others), attempting to run an NDB Cluster over a wide area network such as the Internet is not likely to be successful, and is not supported in production.

Sample data. We use the world database which is available for download from the MySQL website (see https://dev.mysql.com/doc/index-other.html). We assume that each machine has sufficient memory for running the operating system, required NDB Cluster processes, and (on the data nodes) storing the database.

For general information about installing MySQL, see Chapter 2, Installing and Upgrading MySQL. For information about installation of NDB Cluster on Linux and other Unix-like operating systems, see Section 18.2.2, “Installation of NDB Cluster on Linux”. For information about installation of NDB Cluster on Windows operating systems, see Section 18.2.3, “Installing NDB Cluster on Windows”.

For general information about NDB Cluster hardware, software, and networking requirements, see Section 18.1.3, “NDB Cluster Hardware, Software, and Networking Requirements”.

18.2.1 The NDB Cluster Auto-Installer

This section describes the web-based graphical configuration installer included as part of the NDB Cluster distribution beginning with NDB 7.3.1. Topics discussed include an overview of the installer and its parts, software and other requirements for running the installer, navigating the GUI, and using the installer to set up and start or stop an NDB Cluster on one or more host computers.

The NDB Cluster Auto-Installer is made up of two components. The front end is a GUI client implemented as a Web page that loads and runs in a standard Web browser such as Firefox or Microsoft Internet Explorer. The back end is a server process (ndb_setup.py) that runs on the local machine or on another host to which you have access.

These two components (client and server) communicate with each other using standard HTTP requests and responses. The back end can manage NDB Cluster software programs on any host where the back end user has granted access. If the NDB Cluster software is on a different host, the back end relies on SSH for access, using the Paramiko library for executing commands remotely (see Section 18.2.1.1, “NDB Cluster Auto-Installer Requirements”).

18.2.1.1 NDB Cluster Auto-Installer Requirements

This section provides information on supported operating platforms and software, required software, and other prerequisites for running the NDB Cluster Auto-Installer.

Supported platforms. The NDB Cluster Auto-Installer is available with most NDB Cluster 7.3 and later distributions for recent versions of Linux, Windows, Solaris, and MacOS X. For more detailed information about platform support for NDB Cluster and the NDB Cluster Auto-Installer, see https://www.mysql.com/support/supportedplatforms/cluster.html.

Supported Web browsers. The Web-based installer is supported with recent versions of Firefox and Microsoft Internet Explorer. It should also work with recent versions of Opera, Safari, and Chrome, although we have not thoroughly tested for compatibility with these browsers.

Required software—server. The following software must be installed on the host where the Auto-Installer is run:
• **Python 2.6 or higher.** The Auto-Installer requires the Python interpreter and standard libraries. If these are not already installed on the system, you may be able to add them using the system’s package manager. Otherwise, they can be downloaded from [http://python.org/download/](http://python.org/download/).

• **Paramiko 1.7.7.1 or higher.** This is required to communicate with remote hosts using SSH. You can download it from [http://www.lag.net/paramiko/](http://www.lag.net/paramiko/). Paramiko may also be available from your system’s package manager.

• **Pycrypto version 2.6 or higher.** This cryptography module is required by Paramiko. If it is not available using your system’s package manager, you can download it from [https://www.dlitz.net/software/pycrypto/](https://www.dlitz.net/software/pycrypto/).

All of the software in the preceding list is included in the Windows version of the configuration tool, and does not need to be installed separately.

The Paramiko and Pycrypto libraries are required only if you intend to deploy NDB Cluster nodes on remote hosts, and are not needed if all nodes are on the same host where the installer is run.

**Required software—remote hosts.** The only software required for remote hosts where you wish to deploy NDB Cluster nodes is the SSH server, which is usually installed by default on Linux and Solaris systems. Several alternatives are available for Windows; for an overview of these, see [http://en.wikipedia.org/wiki/Comparison_of_SSH_servers](http://en.wikipedia.org/wiki/Comparison_of_SSH_servers).

An additional requirement when using multiple hosts is that it is possible to authenticate to any of the remote hosts using SSH and the proper keys or user credentials, as discussed in the next few paragraphs:

**Authentication and security.** Three basic security or authentication mechanisms for remote access are available to the Auto-Installer, which we list and describe here:

• **SSH.** A secure shell connection is used to enable the back end to perform actions on remote hosts. For this reason, an SSH server must be running on the remote host. In addition, the operating system user running the installer must have access to the remote server, either with a user name and password, or by using public and private keys.

  **Important**
  You should never use the system `root` account for remote access, as this is extremely insecure. In addition, `mysqld` cannot normally be started by system `root`. For these and other reasons, you should provide SSH credentials for a regular user account on the target system, and not for system `root`. For more information about this issue, see Section 6.1.5, "How to Run MySQL as a Normal User".

• **HTTPS.** Remote communication between the Web browser front end and the back end is not encrypted by default, which means that information such as the user’s SSH password is transmitted as cleartext that is readable to anyone. For communication from a remote client to be encrypted, the back end must have a certificate, and the front end must communicate with the back end using HTTPS rather than HTTP. Enabling HTTPS is accomplished most easily through issuing a self-signed certificate. Once the certificate is issued, you must make sure that it is used. You can do this by starting `ndb_setup.py` from the command line with the `--use-https` and `--cert-file` options.

• **Certificate-based authentication.** The back end `ndb_setup.py` process can execute commands on the local host as well as remote hosts. This means that anyone connecting to the back end can take charge of how commands are executed. To reject unwanted connections to the back end, a certificate may be required for authentication of the client. In this case, a certificate must be issued by the user, installed in the browser, and made available to the back end for authentication purposes. You can enact
The NDB Cluster Auto-Installer

this requirement (together with or in place of password or key authentication) by starting \texttt{ndb\_setup.py} with the \texttt{--ca-certs-file} option.

There is no need or requirement for secure authentication when the client browser is running on the same host as the Auto-Installer back end.

See also Section 18.5.11, “NDB Cluster Security Issues”, which discusses security considerations to take into account when deploying NDB Cluster, as well as Chapter 6, \textit{Security}, for more general MySQL security information.

18.2.1.2 Using the NDB Cluster Auto-Installer

The NDB Cluster Auto-Installer consists of several pages, each corresponding to a step in the process used to configure and deploy an NDB Cluster, and listed here:

- **Welcome**: Begin using the Auto-Installer by choosing either to configure a new NDB Cluster, or to continue configuring an existing one.

- **Define Cluster**: Set basic information about the cluster as a whole, such as name, hosts, and load type. Here you can also set the SSH authentication type for accessing remote hosts, if needed.

- **Define Hosts**: Identify the hosts where you intend to run NDB Cluster processes.

- **Define Processes**: Assign one or more processes of a given type or types to each cluster host.

- **Define Attributes**: Set configuration attributes for processes or types of processes.

- **Deploy Cluster**: Deploy the cluster with the configuration set previously; start and stop the deployed cluster.

The following sections describe in greater detail the purpose and function of each of these pages, in the order just listed.

Starting the NDB Cluster Auto-Installer

The Auto-Installer is provided together with the NDB Cluster software. (See Section 18.2, “NDB Cluster Installation”.) The present section explains how to start the installer. You can do by invoking the \texttt{ndb\_setup.py} executable.

\textbf{Important}

You should run the \texttt{ndb\_setup.py} as a normal user; no special privileges are needed to do so. You should \textit{not} run this program as the \texttt{mysql} user, or using the system \texttt{root} or Administrator account; doing so may cause the installation to fail.

\texttt{ndb\_setup.py} is found in the \texttt{bin} within the NDB Cluster installation directory; a typical location might be \texttt{/usr/local/mysql/bin} on a Linux system or \texttt{C:\Program Files\MySQL\MySQL Server 5.6\bin} on a Windows system, but this can vary according to where the NDB Cluster software is installed on your system.

On Windows, you can also start the installer by running \texttt{setup.bat} in the NDB Cluster installation directory. When invoked from the command line, it accepts the same options as does \texttt{ndb\_setup.py}.

\texttt{ndb\_setup.py} can be started with any of several options that affect its operation, but it is usually sufficient to allow the default settings be used, in which case you can start \texttt{ndb\_setup.py} by either of the following two methods:

1. Navigate to the NDB Cluster \texttt{bin} directory in a terminal and invoke it from the command line, without any additional arguments or options, like this:
shell> ndb_setup

This works regardless of operating platform.

2. Navigate to the NDB Cluster `bin` directory in a file browser (such Windows Explorer on Windows, or Konqueror, Dolphin, or Nautilus on Linux) and activate (usually by double-clicking) the `ndb_setup.py` file icon. This works on Windows, and should work with most common Linux desktops as well.

On Windows, you can also navigate to the NDB Cluster installation directory and activate the `setup.bat` file icon.

In either case, once `ndb_setup.py` is invoked, the Auto-Installer's Welcome screen should open in the system's default Web browser.

In some cases, you may wish to use non-default settings for the installer, such as specifying a different port for the Auto-Installer's included Web server to run on, in which case you must invoke `ndb_setup.py` with one or more startup options with values overriding the necessary defaults. The same startup options can be used on Windows systems with the `setup.bat` file supplied for such platforms in the NDB Cluster software distribution. This can be done using the command line, but if you want or need to start the installer from a desktop or file browser while emplying one or more of these options, it is also possible to create a script or batch file containing the proper invocation, then to double-click its file icon in the file browser to start the installer. (On Linux systems, you might also need to make the script file executable first.) For information about advanced startup options for the NDB Cluster Auto-Installer, see Section 18.4.25, "ndb_setup.py — Start browser-based Auto-Installer for NDB Cluster".

NDB Cluster Auto-Installer Welcome Screen

The Welcome screen is loaded in the default browser when `ndb_setup.py` is invoked, as shown here:

Figure 18.5 The NDB Cluster Auto-Installer Welcome screen (Closeup)

This screen provides the following two choices for entering the installer, one of which must be selected to continue:
1. **Create New NDB Cluster**: Start the Auto-Installer with a completely new cluster to be set up and deployed.

2. **Continue Previous Cluster Configuration**: Start the Auto-Installer at the same point where the previous session ended, with all previous settings preserved.

The second option requires that the browser be able to access its cookies from the previous session, as these provide the mechanism by which configuration and other information generated during a session is stored. In other words, to continue the previous session with the Auto-Installer, you must use the same web browser running on the same host as you did for the previous session.

**NDB Cluster Auto-Installer Define Cluster Screen**

The **Define Cluster** screen is the first screen to appear following the choice made in the Welcome screen, and is used for setting general properties of the cluster. The layout of the Define Cluster screen is shown here:

![Figure 18.6 The NDB Cluster Auto-Installer Define Cluster screen](image)

The Define Cluster screen allows you to set a number of general properties for the cluster, as described in this list:

- **Cluster name**: A name that identifies the cluster. The default is `MyCluster`.

- **Host list**: A comma-delimited list of one or more hosts where cluster processes should run. By default, this is `127.0.0.1`. If you add remote hosts to the list, you must be able to connect to them using the SSH Credentials supplied.

- **Application type**: Choose one of the following:
  1. **Simple testing**: Minimal resource usage for small-scale testing. This the default. *Not intended for production environments.*
  2. **Web**: Maximize performance for the given hardware.
3. **Real-time**: Maximize performance while maximizing sensitivity to timeouts in order to minimize the time needed to detect failed cluster processes.

- **Write load**: Choose a level for the anticipated number of writes for the cluster as a whole. You can choose any one of the following levels:
  1. **Low**: The expected load includes fewer than 100 write transactions for second.
  2. **Medium**: The expected load includes 100 to 1000 write transactions per second.
  3. **High**: The expected load includes more than 1000 write transactions per second.

- **SSH Credentials**: Choose **Key-Based SSH** or enter **User** and **Password** credentials. The SSH key or a user name with password is required for connecting to any remote hosts specified in the **Host list**. By default, **Key-Based SSH** is selected, and the **User** and **Password** fields are blank.

**NDB Cluster Auto-Installer Define Hosts Screen**

The **Define Hosts** screen, shown here, provides a means of viewing and specifying several key properties of each cluster host:

**Figure 18.7 NDB Cluster Define Hosts screen**

The hosts currently entered are displayed in the grid with various pieces of information. You can add hosts by clicking the **Add hosts** button and entering a list of one or more comma-separated host names, IP addresses, or both (as when editing the host list on the **Define Cluster** screen).

Similarly, you can remove one or more hosts using the button labelled **Remove selected host(s)**. When you remove a host in this fashion, any process which was configured for that host is also removed.

If **Automatically get resource information for new hosts** is checked in the **Settings** menu, the Auto-Installer attempts to retrieve the platform name, amount of memory, and number of CPU cores and to fill
these in automatically. The status of this is displayed in the Resource info column. Fetching the information from remote hosts is not instantaneous and may take some time, particularly from remote hosts running Windows.

If the SSH user credentials on the Define Cluster screen are changed, the tool tries to refresh the hardware information from any hosts for which information is missing. However, if a given field has already been edited, the user-supplied information is not overwritten by any value fetched from that host.

The hardware resource information, platform name, installation directory, and data directory can be edited by the user by clicking the corresponding cell in the grid, by selecting one or more hosts and clicking the button labelled Edit selected host(s). This causes a dialog box to appear, in which these fields can be edited, as shown here:

**Figure 18.8 NDB Cluster Auto-Installer Edit Hosts dialog**

When more than one host is selected, any edited values are applied to all selected hosts.

**NDB Cluster Auto-Installer Define Processes Screen**

The Define Processes screen, shown here, provides a way to assign NDB Cluster processes (nodes) to cluster hosts:

**Figure 18.9 NDB Cluster Auto-Installer Define Processes dialog**
This screen contains a process tree showing cluster hosts and processes set up to run on each one, as well as a panel which displays information about the item currently selected in the tree.

When this screen is accessed for the first time for a given cluster, a default set of processes is defined for you, based on the number of hosts. If you later return to the Define Hosts screen, remove all hosts, and add new hosts, this also causes a new default set of processes to be defined.

NDB Cluster processes are of the following types:

- **Management node.** Performs administrative tasks such as stopping individual data nodes, querying node and cluster status, and making backups. Executable: `ndb_mgmd`.

- **Single-threaded data node.** Stores data and executes queries. Executable: `ndbd`.

- **Multi threaded data node.** Stores data and executes queries with multiple worker threads executing in parallel. Executable: `ndbmtd`.

- **SQL node.** MySQL server for executing SQL queries against NDB. Executable: `mysqld`.

- **API node.** A client accessing data in NDB by means of the NDB API or other low-level client API, rather than by using SQL. See MySQL NDB Cluster API Developer Guide, for more information.

For more information about process (node) types, see Section 18.1.1, “NDB Cluster Core Concepts”.

Processes shown in the tree are numbered sequentially by type, for each host—for example, SQL node 1, SQL node 2, and so on—to simplify identification.

Each management node, data node, or SQL process must be assigned to a specific host, and is not allowed to run on any other host. An API node may be assigned to a single host, but this is not required. Instead, you can assign it to the special Any host entry which the tree also contains in addition to any other hosts, and which acts as a placeholder for processes that are allowed to run on any host. Only API processes may use this Any host entry.

**Adding processes.** To add a new process to a given host, either right-click that host's entry in the tree, then select the Add process popup when it appears, or select a host in the process tree, and press the Add process button below the process tree. Performing either of these actions opens the add process dialog, as shown here:

![Add process dialog](image)
Here you can select from among the available process types described earlier this section; you can also enter an arbitrary process name to take the place of the suggested value, if desired.

**Removing processes.** To delete a process, right-click on a process in the tree and select delete process from the pop up menu that appears, or select a process, then use the delete process button below the process tree.

When a process is selected in the process tree, information about that process is displayed in the information panel, where you can change the process name and possibly its type. **Important:** Currently, you can change a single-threaded data node (ndbd) to a multithreaded data node (ndbmt.c), or the reverse, only; no other process type changes are allowed. If you want to make a change between any other process types, you must delete the original process first, then add a new process of the desired type.

**NDB Cluster Auto-Installer Define Attributes Screen**

This screen has a layout similar to that of the Define Processes screen, including a process tree. Unlike that screen’s tree, the Define Attributes process tree is organized by process or node type, with single-threaded and multithreaded data nodes considered to be of the same type for this purpose, in groups labelled Management Layer, Data Layer, SQL Layer, and API Layer. An information panel displays information regarding the item currently selected. The Define Attributes screen is shown here:

![Figure 18.11 NDB Cluster Auto-Installer Define Attributes screen](image)

The checkbox labelled Show advanced configuration, when checked, makes advanced options visible in the information pane. These options are set and used whether or not they are visible.

You can edit attributes for a single process by selecting that process from the tree, or for all processes of the same type in the cluster by selecting one of the Layer folders. A per-process value set for a given attribute overrides any per-group setting for that attribute that would otherwise apply to the process in question. An example of such an information panel (for an SQL process) is shown here:
For some of the attributes shown in the information panel, a button bearing a plus sign is displayed, which means that the value of the attribute can be overridden. This + button activates an input widget for the attribute, enabling you to change its value. When the value has been overridden, this button changes into a button showing an X, as shown here:

Clicking the X button next to an attribute undoes any changes made to it; it immediately reverts to the predefined value.

All configuration attributes have predefined values calculated by the installer, based such factors as host name, node ID, node type, and so on. In most cases, these values may be left as they are. If you are not familiar with it already, it is highly recommended that you read the applicable documentation before making changes to any of the attribute values. To make finding this information easier, each attribute name shown in the information panel is linked to its description in the online NDB Cluster documentation.

NDB Cluster Auto-Installer Deploy Cluster Screen

This screen allows you to perform the following tasks:

- Review process startup commands and configuration files to be applied
• Distribute configuration files by creating any necessary files and directories on all cluster hosts—that is, deploy the cluster as presently configured

• Start and stop the cluster

The **Deploy Cluster** screen is shown here:

---

**Figure 18.14 NDB Cluster Auto-Installer Deploy Cluster Configuration screen**

---

Like the **Define Attributes** screen, this screen features a process tree which is organized by process type. Next to each process in the tree is a status icon indicating the current status of the process: connected (CONNECTED), starting (STARTING), running (STARTED), stopping (STOPPING), or disconnected (NO_CONTACT). The icon shows green if the process is connected or running; yellow if it is starting or stopping; red if the process is stopped or cannot be contacted by the management server.

This screen also contains two information panels, one showing the startup command or commands needed to start the selected process. (For some processes, more than one command may be required—for example, if initialization is necessary.) The other panel shows the contents of the configuration file, if any, for the given process; currently, the management node process is only type of process having a configuration file. Other process types are configured using command-line parameters when starting the process, or by obtaining configuration information from the management nodes as needed in real time.

This screen also contains three buttons, labelled as and performing the functions described in the following list:

• **Deploy cluster**: Verify that the configuration is valid. Create any directories required on the cluster hosts, and distribute the configuration files onto the hosts. A progress bar shows how far the deployment has proceeded.

• **Start cluster**: The cluster is deployed as with **Deploy cluster**, after which all cluster processes are started in the correct order.
Starting these processes may take some time. If the estimated time to completion is too large, the installer provides an opportunity to cancel or to continue of the startup procedure. A progress bar indicates the current status of the startup procedure, as shown here:

**Figure 18.15 Progress Bar With Status of Node Startup Process**

![Progress Bar With Status of Node Startup Process](image)

The process status icons adjoining the process tree mentioned previously also update with the status of each process.

- **Stop cluster:** After the cluster has been started, you can stop it using this button. As with starting the cluster, cluster shutdown is not instantaneous, and may require some time complete. A progress bar, similar to that displayed during cluster startup, shows the approximate current status of the cluster shutdown procedure, as do the process status icons adjoining the process tree.

Prior to NDB 7.3.3, SQL nodes were started with all options employed on the command line. Beginning with NDB 7.3.3, the Auto-Installer generates a `my.cnf` file containing the appropriate options for each `mysqld` process in the cluster. (Bug #16994782)

### 18.2.2 Installation of NDB Cluster on Linux

This section covers installation methods for NDB Cluster on Linux and other Unix-like operating systems. While the next few sections refer to a Linux operating system, the instructions and procedures given there should be easily adaptable to other supported Unix-like platforms. For manual installation and setup instructions specific to Windows systems, see Section 18.2.3, “Installing NDB Cluster on Windows”.

Each NDB Cluster host computer must have the correct executable programs installed. A host running an SQL node must have installed on it a MySQL Server binary (`mysqld`). Management nodes require the management server daemon (`ndb_mgmd`); data nodes require the data node daemon (`ndbd` or `ndbmd`). It is not necessary to install the MySQL Server binary on management node hosts and data node hosts. It is recommended that you also install the management client (`ndb_mgm`) on the management server host.

Installation of NDB Cluster on Linux can be done using precompiled binaries from Oracle (downloaded as a `.tar.gz` archive), with RPM packages (also available from Oracle), or from source code. All three of these installation methods are described in the section that follow.

Regardless of the method used, it is still necessary following installation of the NDB Cluster binaries to create configuration files for all cluster nodes, before you can start the cluster. See Section 18.2.4, “Initial Configuration of NDB Cluster”.

#### 18.2.2.1 Installing an NDB Cluster Binary Release on Linux

This section covers the steps necessary to install the correct executables for each type of Cluster node from precompiled binaries supplied by Oracle.

For setting up a cluster using precompiled binaries, the first step in the installation process for each cluster host is to download the binary archive from the NDB Cluster downloads page. (For the most recent 64-bit NDB 7.4 release, this is `mysql-cluster-gpl-7.4.25-linux-glibc2.12-x86_64.tar.gz`.) We assume that you have placed this file in each machine's `/var/tmp` directory.
Installation of NDB Cluster on Linux

If you require a custom binary, see Section 2.9.3, “Installing MySQL Using a Development Source Tree”.

Note
After completing the installation, do not yet start any of the binaries. We show you how to do so following the configuration of the nodes (see Section 18.2.4, “Initial Configuration of NDB Cluster”).

SQL nodes. On each of the machines designated to host SQL nodes, perform the following steps as the system `root` user:

1. Check your `/etc/passwd` and `/etc/group` files (or use whatever tools are provided by your operating system for managing users and groups) to see whether there is already a `mysql` group and `mysql` user on the system. Some OS distributions create these as part of the operating system installation process. If they are not already present, create a new `mysql` user group, and then add a `mysql` user to this group:

   ```
   shell> groupadd mysql
   shell> useradd --g mysql -s /bin/false mysql
   ```

   The syntax for `useradd` and `groupadd` may differ slightly on different versions of Unix, or they may have different names such as `adduser` and `addgroup`.

2. Change location to the directory containing the downloaded file, unpack the archive, and create a symbolic link named `mysql` to the `mysql` directory.

   ```
   shell> cd /var/tmp
   shell> tar -C /usr/local -xzvf mysql-cluster-gpl-7.4.25-linux-glibc2.12-x86_64.tar.gz
   shell> ln -s /usr/local/mysql-cluster-gpl-7.4.25-linux-glibc2.12-x86_64 /usr/local/mysql
   ```

3. Change location to the `mysql` directory and run the supplied script for creating the system databases:

   ```
   shell> cd mysql
   shell> scripts/mysql_install_db --user=mysql
   ```

4. Set the necessary permissions for the MySQL server and data directories:

   ```
   shell> chown -R root .
   shell> chown -R mysql data
   shell> chgrp -R mysql .
   ```

5. Copy the MySQL startup script to the appropriate directory, make it executable, and set it to start when the operating system is booted up:

   ```
   shell> cp support-files/mysql.server /etc/rc.d/init.d/
   shell> chmod +x /etc/rc.d/init.d/mysql.server
   shell> chkconfig --add mysql.server
   ```

   (The startup scripts directory may vary depending on your operating system and version—for example, in some Linux distributions, it is `/etc/init.d/`.)
Here we use Red Hat's `chkconfig` for creating links to the startup scripts; use whatever means is appropriate for this purpose on your platform, such as `update-rc.d` on Debian.

Remember that the preceding steps must be repeated on each machine where an SQL node is to reside.

**Data nodes.** Installation of the data nodes does not require the `mysqld` binary. Only the NDB Cluster data node executable `ndbd` (single-threaded) or `ndbmtd` (multithreaded) is required. These binaries can also be found in the `.tar.gz` archive. Again, we assume that you have placed this archive in `/var/tmp`.

As system `root` (that is, after using `sudo`, `su root`, or your system's equivalent for temporarily assuming the system administrator account's privileges), perform the following steps to install the data node binaries on the data node hosts:

1. Change location to the `/var/tmp` directory, and extract the `ndbd` and `ndbmtd` binaries from the archive into a suitable directory such as `/usr/local/bin`:

   ```shell
   cd /var/tmp
   tar -zxvf mysql-cluster-gpl-7.4.25-linux-glibc2.12-x86_64.tar.gz
   cd mysql-cluster-gpl-7.4.25-linux-glibc2.12-x86_64
   cp bin/ndbd /usr/local/bin/ndbd
   cp bin/ndbmtd /usr/local/bin/ndbmtd
   ```

   (You can safely delete the directory created by unpacking the downloaded archive, and the files it contains, from `/var/tmp` once `ndb_mgm` and `ndb_mgmd` have been copied to the executables directory.)

2. Change location to the directory into which you copied the files, and then make both of them executable:

   ```shell
   cd /usr/local/bin
   chmod +x ndb*
   ```

   The preceding steps should be repeated on each data node host.

Although only one of the data node executables is required to run an NDB Cluster data node, we have shown you how to install both `ndbd` and `ndbmtd` in the preceding instructions. We recommend that you do this when installing or upgrading NDB Cluster, even if you plan to use only one of them, since this will save time and trouble in the event that you later decide to change from one to the other.

**Note**

The data directory on each machine hosting a data node is `/usr/local/mysql/data`. This piece of information is essential when configuring the management node. (See Section 18.2.4, "Initial Configuration of NDB Cluster").

**Management nodes.** Installation of the management node does not require the `mysqld` binary. Only the NDB Cluster management server (`ndb_mgmd`) is required; you most likely want to install the management client (`ndb_mgm`) as well. Both of these binaries also be found in the `.tar.gz` archive. Again, we assume that you have placed this archive in `/var/tmp`.

As system `root`, perform the following steps to install `ndb_mgm` and `ndb_mgmd` on the management node host:

1. Change location to the `/var/tmp` directory, and extract the `ndb_mgm` and `ndb_mgmd` from the archive into a suitable directory such as `/usr/local/bin`:
Installation of NDB Cluster on Linux

shell> cd /var/tmp
shell> tar -zxvf mysql-cluster-gpl-7.4.25-linux-glibc2.12-x86_64.tar.gz
shell> cd mysql-cluster-gpl-7.4.25-linux-glibc2.12-x86_64
shell> cp bin/ndb_mgm* /usr/local/bin

(You can safely delete the directory created by unpacking the downloaded archive, and the files it contains, from /var/tmp once ndb_mgm and ndb_mgmd have been copied to the executables directory.)

2. Change location to the directory into which you copied the files, and then make both of them executable:

shell> cd /usr/local/bin
shell> chmod +x ndb_mgm*

In Section 18.2.4, “Initial Configuration of NDB Cluster”, we create configuration files for all of the nodes in our example NDB Cluster.

18.2.2.2 Installing NDB Cluster from RPM

This section covers the steps necessary to install the correct executables for each type of NDB Cluster node using RPM packages supplied by Oracle.

RPMs are available for both 32-bit and 64-bit Linux platforms. The filenames for these RPMs use the following pattern:

MySQL-Cluster-component-producttype-ndbversion.distribution.architecture.rpm

**component**: {server | client [ | other]}

**producttype**: {gpl | advanced}

**ndbversion**: major.minor.release

**distribution**: {sles10 | rhel5 | el6}

**architecture**: {i386 | x86_64}

The **component** can be server or client. (Other values are possible, but since only the server and client components are required for a working NDB Cluster installation, we do not discuss them here.) The **producttype** for Community RPMs downloaded from [https://dev.mysql.com/downloads/cluster/](https://dev.mysql.com/downloads/cluster/) is always gpl; advanced is used to indicate commercial releases. **ndbversion** represents the three-part NDB storage engine version number in 7.3.x or 7.4.x format. The **distribution** can be one of sles11 (SUSE Enterprise Linux 11), rhel5 (Oracle Linux 5, Red Hat Enterprise Linux 4 and 5), or el6 (Oracle Linux 6, Red Hat Enterprise Linux 6). The **architecture** is i386 for 32-bit RPMs and x86_64 for 64-bit versions.

For an NDB Cluster, one and possibly two RPMs are required:

- The **server** RPM (for example, MySQL-Cluster-server-gpl-7.3.26-1.sles11.i386.rpm or MySQL-Cluster-server-gpl-7.4.25-1.sles11.i386.rpm), which supplies the core files needed to run a MySQL Server with NDBCLUSTER storage engine support (that is, as an NDB Cluster SQL node) as well as all NDB Cluster executables, including the management node, data node, and ndb_mgm client binaries. This RPM is always required for installing NDB Cluster.

- If you do not have your own client application capable of administering a MySQL server, you should also obtain and install the **client** RPM (for example, MySQL-Cluster-client-gpl-7.3.26-1.sles11.i386.rpm or MySQL-Cluster-client-gpl-7.4.25-1.sles11.i386.rpm), which supplies the mysql client
Installation of NDB Cluster on Linux

The NDB Cluster version number in the RPM file names (shown here as 7.3.26 or 7.4.25, depending on whether you are installing NDB Cluster 7.3 or NDB Cluster 7.4) can vary according to the version which you are actually using. It is very important that all of the Cluster RPMs to be installed have the same version number. The architecture designation should also be appropriate to the machine on which the RPM is to be installed; in particular, you should keep in mind that 64-bit RPMs cannot be used with 32-bit operating systems.

**Data nodes.** On a computer that is to host a cluster data node it is necessary to install only the server RPM. To do so, copy this RPM to the data node host, and run the following command as the system root user, replacing the name shown for the RPM as necessary to match that of the RPM downloaded from the MySQL website:

```
shell> rpm -Uhv MySQL-Cluster-server-gpl-7.3.26-1.sles11.i386.rpm
```

or

```
shell> rpm -Uhv MySQL-Cluster-server-gpl-7.4.25-1.sles11.i386.rpm
```

Although this installs all NDB Cluster binaries, only the program ndbd or ndbmtd (both in /usr/sbin) is actually needed to run an NDB Cluster data node.

**SQL nodes.** On each machine to be used for hosting a cluster SQL node, install the server RPM by executing the following command as the system root user, replacing the name shown for the RPM as necessary to match the name of the RPM downloaded from the MySQL website:

```
shell> rpm -Uhv MySQL-Cluster-server-gpl-7.3.26-1.sles11.i386.rpm
```

or

```
shell> rpm -Uhv MySQL-Cluster-server-gpl-7.4.25-1.sles11.i386.rpm
```

This installs the MySQL server binary (mysqld) with NDB storage engine support in the /usr/sbin directory, as well as all needed MySQL Server support files. It also installs the mysql.server and mysqld_safe startup scripts (in /usr/share/mysql and /usr/bin, respectively). The RPM installer should take care of general configuration issues (such as creating the mysql user and group, if needed) automatically.

To administer the SQL node (MySQL server), you should also install the client RPM, as shown here:

```
shell> rpm -Uhv MySQL-Cluster-client-gpl-7.3.26-1.sles11.i386.rpm
```

or

```
shell> rpm -Uhv MySQL-Cluster-client-gpl-7.4.25-1.sles11.i386.rpm
```

This installs the mysql client program.

**Management nodes.** To install the NDB Cluster management server, it is necessary only to use the server RPM. Copy this RPM to the computer intended to host the management node, and then install it by running the following command as the system root user (replace the name shown for the RPM as necessary to match that of the server RPM downloaded from the MySQL website):

```
shell> rpm -Uhv MySQL-Cluster-server-gpl-7.3.26-1.sles11.i386.rpm
```

or
Installation of NDB Cluster on Linux

shell> rpm -Uhv MySQL-Cluster-server-gpl-7.4.25-1.sles11.i386.rpm

Although this RPM installs many other files, only the management server binary `ndb_mgmd` (in the `/usr/sbin` directory) is actually required for running a management node. The server RPM also installs `ndb_mgm`, the NDB management client.

See Section 2.5.5, “Installing MySQL on Linux Using RPM Packages from Oracle”, for general information about installing MySQL using RPMs supplied by Oracle.

After installing from RPM, you still need to configure the cluster as discussed in Section 18.2.4, “Initial Configuration of NDB Cluster”.

**Note**

A number of RPMs used by NDB Cluster 7.1 were made obsolete and discontinued in NDB Cluster 7.3. These include the former MySQL-Cluster-clusterj, MySQL-Cluster-extra, MySQL-Cluster-management, MySQL-Cluster-storage, and NDB Cluster-tools RPMs. The former contents of all of these packages are now included in the MySQL-Cluster-server RPM.

### 18.2.2.3 Installing NDB Cluster Using .deb Files

The section provides information about installing NDB Cluster on Debian and related Linux distributions such as Ubuntu using the .deb files supplied by Oracle for this purpose.

Oracle provides .deb installer files for NDB Cluster 7.3 and NDB Cluster 7.4 for 32-bit and 64-bit platforms. For a Debian-based system, only a single installer file is necessary. This file is named using the pattern shown here, according to the applicable NDB Cluster version, Debian version, and architecture:

```
mysql-cluster-gpl-ndbver-debiandebianver-arch.deb
```

Here, `ndbver` is the 3-part NDB engine version number, `debianver` is the major version of Debian (6.0 or 7), and `arch` is one of i686 or x86_64. In the examples that follow, we assume you wish to install NDB 7.4.9 on a 64-bit Debian 7 system; in this case, the installer file is named `mysql-cluster-gpl-7.4.9-debian7-x86_64.deb`.

Once you have downloaded the appropriate .deb file, you can install it from the command line using `dpkg`, like this:

```
shell> dpkg -i mysql-cluster-gpl-7.4.9-debian7-i686.deb
```

You can also remove it using `dpkg` as shown here:

```
shell> dpkg -r mysql
```

The installer file should also be compatible with most graphical package managers that work with .deb files, such as GDebi for the Gnome desktop.

The .deb file installs NDB Cluster under `/opt/mysql/server-version/`, where `version` is the 2-part release series version for the included MySQL server. For both NDB Cluster 7.3 and NDB Cluster 7.4, this is always 5.6. The directory layout is the same as that for the generic Linux binary distribution (see Table 2.3, “MySQL Installation Layout for Generic Unix/Linux Binary Package”), with the exception that startup scripts and configuration files are found in `support-files` instead of `share`. All NDB Cluster executables, such as `ndb_mgm`, `ndbd`, and `ndb_mgmd`, are placed in the `bin` directory.

### 18.2.2.4 Building NDB Cluster from Source on Linux
This section provides information about compiling NDB Cluster on Linux and other Unix-like platforms. Building NDB Cluster from source is similar to building the standard MySQL Server, although it differs in a few key respects discussed here. For general information about building MySQL from source, see Section 2.9, “Installing MySQL from Source”. For information about compiling NDB Cluster on Windows platforms, see Section 18.2.3.2, “Compiling and Installing NDB Cluster from Source on Windows”.

Building NDB Cluster requires using the NDB Cluster sources. These are available from the NDB Cluster downloads page at https://dev.mysql.com/downloads/cluster/. The archived source file should have a name similar to mysql-cluster-gpl-7.3.26.tar.gz (NDB Cluster 7.3) or mysql-cluster-gpl-7.4.25.tar.gz (NDB Cluster 7.4). You can also obtain NDB Cluster sources from GitHub at https://github.com/mysql/mysql-server/tree/cluster-7.3 (NDB 7.3) and https://github.com/mysql/mysql-server/tree/cluster-7.4 (NDB 7.4). Building NDB Cluster 7.3 or 7.4 from standard MySQL Server 5.6 sources is not supported.

The WITH_NDB_CLUSTER_STORAGE_ENGINE option for CMake causes the binaries for the management nodes, data nodes, and other NDB Cluster programs to be built; it also causes mysqld to be compiled with NDB storage engine support. This option (or its alias WITH_NDB_CLUSTER) is required when building NDB Cluster.

Important

In NDB Cluster 7.3 and later, the WITH_NDB_JAVA option is enabled by default. This means that, by default, if CMake cannot find the location of Java on your system, the configuration process fails; if you do not wish to enable Java and ClusterJ support, you must indicate this explicitly by configuring the build using -DWITH_NDB_JAVA=OFF. Use WITH_CLASSPATH to provide the Java classpath if needed.

For more information about CMake options specific to building NDB Cluster, see Options for Compiling NDB Cluster.

After you have run make && make install (or your system's equivalent), the result is similar to what is obtained by unpacking a precompiled binary to the same location.

Management nodes. When building from source and running the default make install, the management server and management client binaries (ndb_mgmd and ndb_mgm) can be found in /usr/local/mysql/bin. Only ndb_mgmd is required to be present on a management node host; however, it is also a good idea to have ndb_mgm present on the same host machine. Neither of these executables requires a specific location on the host machine's file system.

Data nodes. The only executable required on a data node host is the data node binary ndbd or ndbmd. (mysqld, for example, does not have to be present on the host machine.) By default, when building from source, this file is placed in the directory /usr/local/mysql/bin. For installing on multiple data node hosts, only ndbd or ndbmd need be copied to the other host machine or machines. (This assumes that all data node hosts use the same architecture and operating system; otherwise you may need to compile separately for each different platform.) The data node binary need not be in any particular location on the host machine's file system, as long as the location is known.

When compiling NDB Cluster from source, no special options are required for building multithreaded data node binaries. Configuring the build with NDB storage engine support causes ndbmd to be built automatically; make install places the ndbmd binary in the installation bin directory along with mysqld, ndbd, and ndb_mgm.

SQL nodes. If you compile MySQL with clustering support, and perform the default installation (using make install as the system root user), mysqld is placed in /usr/local/mysql/bin. Follow the steps given in Section 2.9, “Installing MySQL from Source” to make mysqld ready for use. If you want to
run multiple SQL nodes, you can use a copy of the same `mysqld` executable and its associated support files on several machines. The easiest way to do this is to copy the entire `/usr/local/mysql` directory and all directories and files contained within it to the other SQL node host or hosts, then repeat the steps from Section 2.9, “Installing MySQL from Source” on each machine. If you configure the build with a nondefault `PREFIX` option, you must adjust the directory accordingly.

In Section 18.2.4, “Initial Configuration of NDB Cluster”, we create configuration files for all of the nodes in our example NDB Cluster.

### 18.2.3 Installing NDB Cluster on Windows

This section describes installation procedures for NDB Cluster on Windows hosts. NDB Cluster 7.3 and NDB Cluster 7.4 binaries for Windows can be obtained from [https://dev.mysql.com/downloads/cluster/](https://dev.mysql.com/downloads/cluster/). For information about installing NDB Cluster on Windows from a binary release provided by Oracle, see Section 18.2.3.1, “Installing NDB Cluster on Windows from a Binary Release”.

It is also possible to compile and install NDB Cluster from source on Windows using Microsoft Visual Studio. For more information, see Section 18.2.3.2, “Compiling and Installing NDB Cluster from Source on Windows”.

#### 18.2.3.1 Installing NDB Cluster on Windows from a Binary Release

This section describes a basic installation of NDB Cluster on Windows using a binary “no-install” NDB Cluster release provided by Oracle, using the same 4-node setup outlined in the beginning of this section (see Section 18.2, “NDB Cluster Installation”), as shown in the following table:

**Table 18.5 Network addresses of nodes in example cluster**

<table>
<thead>
<tr>
<th>Node</th>
<th>IP Address</th>
</tr>
</thead>
<tbody>
<tr>
<td>Management node (mgmd)</td>
<td>198.51.100.10</td>
</tr>
<tr>
<td>SQL node (mysqld)</td>
<td>198.51.100.20</td>
</tr>
<tr>
<td>Data node &quot;A&quot; (ndbd)</td>
<td>198.51.100.30</td>
</tr>
<tr>
<td>Data node &quot;B&quot; (ndbd)</td>
<td>198.51.100.40</td>
</tr>
</tbody>
</table>

As on other platforms, the NDB Cluster host computer running an SQL node must have installed on it a MySQL Server binary (`mysqld.exe`). You should also have the MySQL client (`mysql.exe`) on this host. For management nodes and data nodes, it is not necessary to install the MySQL Server binary; however, each management node requires the management server daemon (`ndb_mgmd.exe`); each data node requires the data node daemon (`ndbd.exe` or `ndbmtd.exe`). For this example, we refer to `ndbd.exe` as the data node executable, but you can install `ndbmtd.exe`, the multithreaded version of this program, instead, in exactly the same way. You should also install the management client (`ndb_mgm.exe`) on the management server host. This section covers the steps necessary to install the correct Windows binaries for each type of NDB Cluster node.

#### Note

As with other Windows programs, NDB Cluster executables are named with the `.exe` file extension. However, it is not necessary to include the `.exe` extension when invoking these programs from the command line. Therefore, we often simply refer to these programs in this documentation as `mysqld`, `mysql`, `ndb_mgmd`, and so on. You should understand that, whether we refer (for example) to `mysqld` or `mysql.exe`, either name means the same thing (the MySQL Server program).

For setting up an NDB Cluster using Oracle's "no-install" binaries, the first step in the installation process is to download the latest NDB Cluster Windows ZIP binary archive from [https://dev.mysql.com/](https://dev.mysql.com/)
Installing NDB Cluster on Windows

downloads/cluster/. This archive has a filename of the *mysql-cluster-gpl-ver-winarch.zip*, where *ver* is the NDB storage engine version (such as 7.4.25), and *arch* is the architecture (32 for 32-bit binaries, and 64 for 64-bit binaries). For example, the NDB Cluster 7.4.25 archive for 64-bit Windows systems is named *mysql-cluster-gpl-7.4.25-win64.zip*.

You can run 32-bit NDB Cluster binaries on both 32-bit and 64-bit versions of Windows; however, 64-bit NDB Cluster binaries can be used only on 64-bit versions of Windows. If you are using a 32-bit version of Windows on a computer that has a 64-bit CPU, then you must use the 32-bit NDB Cluster binaries.

To minimize the number of files that need to be downloaded from the Internet or copied between machines, we start with the computer where you intend to run the SQL node.

**SQL node.** We assume that you have placed a copy of the archive in the directory C:\Documents and Settings\username\My Documents\Downloads on the computer having the IP address 198.51.100.20, where *username* is the name of the current user. (You can obtain this name using ECHO %USERNAME% on the command line.) To install and run NDB Cluster executables as Windows services, this user should be a member of the Administrators group.

Extract all the files from the archive. The Extraction Wizard integrated with Windows Explorer is adequate for this task. (If you use a different archive program, be sure that it extracts all files and directories from the archive, and that it preserves the archive's directory structure.) When you are asked for a destination directory, enter C:\, which causes the Extraction Wizard to extract the archive to the directory C:\mysql-cluster-gpl-ver-winarch. Rename this directory to C:\mysql.

It is possible to install the NDB Cluster binaries to directories other than C:\mysql\bin; however, if you do so, you must modify the paths shown in this procedure accordingly. In particular, if the MySQL Server (SQL node) binary is installed to a location other than C:\mysql or C:\Program Files\MySQL\MySQL Server 5.6, or if the SQL node's data directory is in a location other than C:\mysql\data or C:\Program Files\MySQL\MySQL Server 5.6\data, extra configuration options must be used on the command line or added to the my.ini or my.cnf file when starting the SQL node. For more information about configuring a MySQL Server to run in a nonstandard location, see Section 2.3.5, “Installing MySQL on Microsoft Windows Using a noinstall ZIP Archive”.

For a MySQL Server with NDB Cluster support to run as part of an NDB Cluster, it must be started with the options `--ndbcluster` and `--ndb-connectstring`. While you can specify these options on the command line, it is usually more convenient to place them in an option file. To do this, create a new text file in Notepad or another text editor. Enter the following configuration information into this file:

```ini
[mysqld]
# Options for mysqld process:
ndbcluster                      # run NDB storage engine
ndb-connectstring=198.51.100.10  # location of management server
```

You can add other options used by this MySQL Server if desired (see Section 2.3.5.2, “Creating an Option File”), but the file must contain the options shown, at a minimum. Save this file as C:\mysql\my.ini. This completes the installation and setup for the SQL node.

**Data nodes.** An NDB Cluster data node on a Windows host requires only a single executable, one of either ndbd.exe or ndbmtd.exe. For this example, we assume that you are using ndbd.exe, but the same instructions apply when using ndbmtd.exe. On each computer where you wish to run a data node (the computers having the IP addresses 198.51.100.30 and 198.51.100.40), create the directories C:\mysql, C:\mysql\bin, and C:\mysql\cluster-data; then, on the computer where you downloaded and extracted the no-install archive, locate ndbd.exe in the C:\mysql\bin directory. Copy this file to the C:\mysql\bin directory on each of the two data node hosts.

To function as part of an NDB Cluster, each data node must be given the address or hostname of the management server. You can supply this information on the command line using the `--ndb-`
Installing NDB Cluster on Windows

connectstring or -c option when starting each data node process. However, it is usually preferable to put this information in an option file. To do this, create a new text file in Notepad or another text editor and enter the following text:

```ini
[mysql_cluster]
# Options for data node process:
ndb-connectstring=198.51.100.10  # location of management server
```

Save this file as C:\mysql\my.ini on the data node host. Create another text file containing the same information and save it on as C:\mysql\my.ini on the other data node host, or copy the my.ini file from the first data node host to the second one, making sure to place the copy in the second data node's C: \mysql directory. Both data node hosts are now ready to be used in the NDB Cluster, which leaves only the management node to be installed and configured.

**Management node.** The only executable program required on a computer used for hosting an NDB Cluster management node is the management server program ndb_mgmd.exe. However, in order to administer the NDB Cluster once it has been started, you should also install the NDB Cluster management client program ndb_mgm.exe on the same machine as the management server. Locate these two programs on the machine where you downloaded and extracted the no-install archive; this should be the directory C:\mysql\bin on the SQL node host. Create the directory C:\mysql\bin on the computer having the IP address 198.51.100.10, then copy both programs to this directory.

You should now create two configuration files for use by ndb_mgmd.exe:

1. A local configuration file to supply configuration data specific to the management node itself. Typically, this file needs only to supply the location of the NDB Cluster global configuration file (see item 2).

   To create this file, start a new text file in Notepad or another text editor, and enter the following information:

   ```ini
   [mysql_cluster]
   # Options for management node process
   config-file=C:/mysql/bin/config.ini
   ```

   Save this file as the text file C:\mysql\bin\my.ini.

2. A global configuration file from which the management node can obtain configuration information governing the NDB Cluster as a whole. At a minimum, this file must contain a section for each node in the NDB Cluster, and the IP addresses or hostnames for the management node and all data nodes (HostName configuration parameter). It is also advisable to include the following additional information:

   - The IP address or hostname of any SQL nodes
   - The data memory and index memory allocated to each data node (DataMemory and IndexMemory configuration parameters)
   - The number of replicas, using the NoOfReplicas configuration parameter (see Section 18.1.2, “NDB Cluster Nodes, Node Groups, Replicas, and Partitions”)
   - The directory where each data node stores its data and log file, and the directory where the management node keeps its log files (in both cases, the DataDir configuration parameter)

   Create a new text file using a text editor such as Notepad, and input the following information:

```
[ndbd default]
# Options affecting ndbd processes on all data nodes:
```
Installing NDB Cluster on Windows

NoOfReplicas=2                      # Number of replicas
DataDir=C:/mysql/cluster-data       # Directory for each data node's data files
                          # Forward slashes used in directory path,
                          # rather than backslashes. This is correct;
                          # see Important note in text
DataMemory=80M    # Memory allocated to data storage
IndexMemory=18M   # Memory allocated to index storage
                          # For DataMemory and IndexMemory, we have used the
                          # default values. Since the "world" database takes up
                          # only about 500KB, this should be more than enough for
                          # this example Cluster setup.
[ndb_mgmd]
  # Management process options:
  HostName=198.51.100.10              # Hostname or IP address of management node
  DataDir=C:/mysql/bin/cluster-logs   # Directory for management node log files
[ndbd]
  # Options for data node "A":
  HostName=198.51.100.30          # Hostname or IP address
[ndbd]
  # Options for data node "B":
  HostName=198.51.100.40          # Hostname or IP address
[mysqld]
  # SQL node options:
  HostName=198.51.100.20          # Hostname or IP address

Save this file as the text file C:\mysql\bin\config.ini.

Important

A single backslash character (\) cannot be used when specifying directory paths in program options or configuration files used by NDB Cluster on Windows. Instead, you must either escape each backslash character with a second backslash (\\), or replace the backslash with a forward slash character (/). For example, the following line from the [ndb_mgmd] section of an NDB Cluster config.ini file does not work:

```
DataDir=C:\mysql\bin\cluster-logs
```

Instead, you may use either of the following:

```
DataDir=C:\\mysql\bin\cluster-logs  # Escaped backslashes
DataDir=C:/mysql/bin/cluster-logs   # Forward slashes
```

For reasons of brevity and legibility, we recommend that you use forward slashes in directory paths used in NDB Cluster program options and configuration files on Windows.

18.2.3.2 Compiling and Installing NDB Cluster from Source on Windows

Oracle provides precompiled NDB Cluster binaries for Windows which should be adequate for most users. However, if you wish, it is also possible to compile NDB Cluster for Windows from source code. The procedure for doing this is almost identical to the procedure used to compile the standard MySQL Server binaries for Windows, and uses the same tools. However, there are two major differences:
Installing NDB Cluster on Windows

• Building NDB Cluster requires using the NDB Cluster sources. These are available from the NDB Cluster downloads page at https://dev.mysql.com/downloads/cluster/. The archived source file should have a name similar to mysql-cluster-gpl-7.3.26.tar.gz (NDB Cluster 7.3) or mysql-cluster-gpl-7.4.25.tar.gz (NDB Cluster 7.4). You can also obtain NDB Cluster sources from GitHub at https://github.com/mysql/mysql-server/tree/cluster-7.3 (NDB 7.3) and https://github.com/mysql/mysql-server/tree/cluster-7.4 (NDB 7.4). Building NDB Cluster 7.3 or 7.4 from standard MySQL Server 5.6 sources is not supported.

• You must configure the build using the WITH_NDBCLUSTER_STORAGE_ENGINE or WITH_NDBCLUSTER option in addition to any other build options you wish to use with CMake. (WITH_NDBCLUSTER is supported as an alias for WITH_NDBCLUSTER_STORAGE_ENGINE, and works in exactly the same way.)

Important
In NDB Cluster 7.3 and later, the WITH_NDB_JAVA option is enabled by default. This means that, by default, if CMake cannot find the location of Java on your system, the configuration process fails; if you do not wish to enable Java and ClusterJ support, you must indicate this explicitly by configuring the build using -DWITH_NDB_JAVA=OFF. (Bug #12379735) Use WITH_CLASSPATH to provide the Java classpath if needed.

For more information about CMake options specific to building NDB Cluster, see Options for Compiling NDB Cluster.

Once the build process is complete, you can create a Zip archive containing the compiled binaries; Section 2.9.2, “Installing MySQL Using a Standard Source Distribution” provides the commands needed to perform this task on Windows systems. The NDB Cluster binaries can be found in the bin directory of the resulting archive, which is equivalent to the no-install archive, and which can be installed and configured in the same manner. For more information, see Section 18.2.3.1, “Installing NDB Cluster on Windows from a Binary Release”.

18.2.3.3 Initial Startup of NDB Cluster on Windows

Once the NDB Cluster executables and needed configuration files are in place, performing an initial start of the cluster is simply a matter of starting the NDB Cluster executables for all nodes in the cluster. Each cluster node process must be started separately, and on the host computer where it resides. The management node should be started first, followed by the data nodes, and then finally by any SQL nodes.

1. On the management node host, issue the following command from the command line to start the management node process. The output should appear similar to what is shown here:

```
C:\mysql\bin> ndb_mgmd
2010-06-23 07:53:34 [MgmtSrvr] INFO -- Reading cluster configuration from 'config.ini'
```

The management node process continues to print logging output to the console. This is normal, because the management node is not running as a Windows service. (If you have used NDB Cluster on a Unix-like platform such as Linux, you may notice that the management node’s default behavior in this regard on Windows is effectively the opposite of its behavior on Unix systems, where it runs by default as a Unix daemon process. This behavior is also true of NDB Cluster data node processes running on Windows.) For this reason, do not close the window in which ndb_mgmd.exe is running; doing so kills the management node process. (See Section 18.2.3.4, “Installing NDB Cluster Processes as Windows Services”, where we show how to install and run NDB Cluster processes as Windows services.)

The required -f option tells the management node where to find the global configuration file (config.ini). The long form of this option is --config-file.
Installing NDB Cluster on Windows

---

**Important**

An NDB Cluster management node caches the configuration data that it reads from `config.ini`; once it has created a configuration cache, it ignores the `config.ini` file on subsequent starts unless forced to do otherwise. This means that, if the management node fails to start due to an error in this file, you must make the management node re-read `config.ini` after you have corrected any errors in it. You can do this by starting `ndb_mgmd.exe` with the `--reload` or `--initial` option on the command line. Either of these options works to refresh the configuration cache.

It is not necessary or advisable to use either of these options in the management node's `my.ini` file.

For additional information about options which can be used with `ndb_mgmd`, see Section 18.4.4, “ndb_mgmd — The NDB Cluster Management Server Daemon”, as well as Section 18.4.29, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

2. On each of the data node hosts, run the command shown here to start the data node processes:

   ```
   C:\mysql\bin> ndbd
   ```

   In each case, the first line of output from the data node process should resemble what is shown in the preceding example, and is followed by additional lines of logging output. As with the management node process, this is normal, because the data node is not running as a Windows service. For this reason, do not close the console window in which the data node process is running; doing so kills `ndbd.exe`. (For more information, see Section 18.2.3.4, “Installing NDB Cluster Processes as Windows Services”.)

3. Do not start the SQL node yet; it cannot connect to the cluster until the data nodes have finished starting, which may take some time. Instead, in a new console window on the management node host, start the NDB Cluster management client `ndb_mgm.exe`, which should be in `C:\mysql\bin` on the management node host. (Do not try to re-use the console window where `ndb_mgmd.exe` is running by typing `CTRL+C`, as this kills the management node.) The resulting output should look like this:

   ```
   C:\mysql\bin> ndb_mgm
   -- NDB Cluster -- Management Client --
   ndb_mgm>
   ```

   When the prompt `ndb_mgm>` appears, this indicates that the management client is ready to receive NDB Cluster management commands. You can observe the status of the data nodes as they start by entering `ALL STATUS` at the management client prompt. This command causes a running report of the data nodes's startup sequence, which should look something like this:

   ```
   ndb_mgm> ALL STATUS
   Connected to Management Server at: localhost:1186
   Node 2: starting (Last completed phase 3) (mysql-5.6.45-ndb-7.4.25)
   Node 3: starting (Last completed phase 3) (mysql-5.6.45-ndb-7.4.25)
   Node 2: starting (Last completed phase 4) (mysql-5.6.45-ndb-7.4.25)
   Node 3: starting (Last completed phase 4) (mysql-5.6.45-ndb-7.4.25)
   Node 2: Started (version 7.4.25)
   Node 3: Started (version 7.4.25)
   ndb_mgm>
   ```
Installing NDB Cluster on Windows

Note

Commands issued in the management client are not case-sensitive; we use uppercase as the canonical form of these commands, but you are not required to observe this convention when inputting them into the ndb_mgm client. For more information, see Section 18.5.2, “Commands in the NDB Cluster Management Client”.

The output produced by ALL STATUS is likely to vary from what is shown here, according to the speed at which the data nodes are able to start, the release version number of the NDB Cluster software you are using, and other factors. What is significant is that, when you see that both data nodes have started, you are ready to start the SQL node.

You can leave ndb_mgm.exe running; it has no negative impact on the performance of the NDB Cluster, and we use it in the next step to verify that the SQL node is connected to the cluster after you have started it.

4. On the computer designated as the SQL node host, open a console window and navigate to the directory where you unpacked the NDB Cluster binaries (if you are following our example, this is C:\mysql\bin).

Start the SQL node by invoking mysql.exe from the command line, as shown here:

C:\mysql\bin> mysql --console

The --console option causes logging information to be written to the console, which can be helpful in the event of problems. (Once you are satisfied that the SQL node is running in a satisfactory manner, you can stop it and restart it without the --console option, so that logging is performed normally.)

In the console window where the management client (ndb_mgm.exe) is running on the management node host, enter the SHOW command, which should produce output similar to what is shown here:

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
---------------------
[ndbd(NDB)]  2 node(s)
 id=2  @198.51.100.30  (Version: 5.6.45-ndb-7.4.25, Nodegroup: 0, *)
 id=3  @198.51.100.40  (Version: 5.6.45-ndb-7.4.25, Nodegroup: 0)

[ndb_mgmd(MGM)]  1 node(s)
 id=1  @198.51.100.10  (Version: 5.6.45-ndb-7.4.25)

[mysqld(API)]  1 node(s)
 id=4  @198.51.100.20  (Version: 5.6.45-ndb-7.4.25)
```

You can also verify that the SQL node is connected to the NDB Cluster in the mysql client (mysql.exe) using the SHOW ENGINE NDB STATUS statement.

You should now be ready to work with database objects and data using NDB Cluster's NDBCLUSTER storage engine. See Section 18.2.6, “NDB Cluster Example with Tables and Data”, for more information and examples.

You can also install ndb_mgmd.exe, ndbd.exe, and ndbmtd.exe as Windows services. For information on how to do this, see Section 18.2.3.4, “Installing NDB Cluster Processes as Windows Services”.

2620
18.2.3.4 Installing NDB Cluster Processes as Windows Services

Once you are satisfied that NDB Cluster is running as desired, you can install the management nodes and data nodes as Windows services, so that these processes are started and stopped automatically whenever Windows is started or stopped. This also makes it possible to control these processes from the command line with the appropriate `SC START` and `SC STOP` commands, or using the Windows graphical `Services` utility. `NET START` and `NET STOP` commands can also be used.

Installing programs as Windows services usually must be done using an account that has Administrator rights on the system.

To install the management node as a service on Windows, invoke `ndb_mgmd.exe` from the command line on the machine hosting the management node, using the `--install` option, as shown here:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --install
Installing service 'NDB Cluster Management Server' as '"C:\mysql\bin\ndbd.exe" "--service=ndb_mgmd"'
Service successfully installed.
```

**Important**

When installing an NDB Cluster program as a Windows service, you should always specify the complete path; otherwise the service installation may fail with the error `The system cannot find the file specified`.

The `--install` option must be used first, ahead of any other options that might be specified for `ndb_mgmd.exe`. However, it is preferable to specify such options in an options file instead. If your options file is not in one of the default locations as shown in the output of `ndb_mgmd.exe --help`, you can specify the location using the `--config-file` option.

Now you should be able to start and stop the management server like this:

```
C:\> SC START ndb_mgmd
C:\> SC STOP ndb_mgmd
```

**Note**

If using `NET` commands, you can also start or stop the management server as a Windows service using the descriptive name, as shown here:

```
C:\> NET START 'NDB Cluster Management Server'
The NDB Cluster Management Server service is starting.
The NDB Cluster Management Server service was started successfully.
C:\> NET STOP 'NDB Cluster Management Server'
The NDB Cluster Management Server service is stopping..
The NDB Cluster Management Server service was stopped successfully.
```

It is usually simpler to specify a short service name or to permit the default service name to be used when installing the service, and then reference that name when starting or stopping the service. To specify a service name other than `ndb_mgmd`, append it to the `--install` option, as shown in this example:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --install=mgmd1
Installing service 'NDB Cluster Management Server' as '"C:\mysql\bin\ndbd.exe" "--service=mgmd1"'
Service successfully installed.
```
Now you should be able to start or stop the service using the name you have specified, like this:

C:\> SC START mgmd1
C:\> SC STOP mgmd1

To remove the management node service, use \texttt{SC DELETE service\_name}:

C:\> SC DELETE mgmd1

Alternatively, invoke \texttt{ndb\_mgmd.exe} with the \texttt{--remove} option, as shown here:

C:\> C:\mysql\bin\ndb\_mgmd.exe --remove
Removing service 'NDB Cluster Management Server'
Service successfully removed.

If you installed the service using a service name other than the default, pass the service name as the value of the \texttt{ndb\_mgmd.exe --remove} option, like this:

C:\> C:\mysql\bin\ndb\_mgmd.exe --remove=mgmd1
Removing service 'mgmd1'
Service successfully removed.

Installation of an NDB Cluster data node process as a Windows service can be done in a similar fashion, using the \texttt{--install} option for \texttt{ndbd.exe} (or \texttt{ndbmtd.exe}), as shown here:

C:\> C:\mysql\bin\ndbd.exe --install
Installing service 'NDB Cluster Data Node Daemon' as '"C:\mysql\bin\ndbd.exe" "--service=ndbd"'
Service successfully installed.

Now you can start or stop the data node as shown in the following example:

C:\> SC START ndbd
C:\> SC STOP ndbd

To remove the data node service, use \texttt{SC DELETE service\_name}:

C:\> SC DELETE ndbd

Alternatively, invoke \texttt{ndbd.exe} with the \texttt{--remove} option, as shown here:

C:\> C:\mysql\bin\ndbd.exe --remove
Removing service 'NDB Cluster Data Node Daemon'
Service successfully removed.

As with \texttt{ndb\_mgmd.exe} (and \texttt{mysqld.exe}), when installing \texttt{ndbd.exe} as a Windows service, you can also specify a name for the service as the value of \texttt{--install}, and then use it when starting or stopping the service, like this:

C:\> C:\mysql\bin\ndbd.exe --install=dnode1
Installing service 'dnode1' as '"C:\mysql\bin\ndbd.exe" "--service=dnode1"'
Service successfully installed.

C:\> SC START dnode1
C:\> SC STOP dnode1
If you specified a service name when installing the data node service, you can use this name when removing it as well, as shown here:

C:\> SC DELETE dnode1

Alternatively, you can pass the service name as the value of the ndbd.exe --remove option, as shown here:

C:\> C:\mysql\bin\ndbd.exe --remove=dnode1
Removing service 'dnode1'
Service successfully removed.

Installation of the SQL node as a Windows service, starting the service, stopping the service, and removing the service are done in a similar fashion, using mysqld --install, SC START, SC STOP, and SC DELETE (or mysqld --remove). .NET commands can also be used to start or stop a service. For additional information, see Section 2.3.5.7, “Starting MySQL as a Windows Service”.

18.2.4 Initial Configuration of NDB Cluster

In this section, we discuss manual configuration of an installed NDB Cluster by creating and editing configuration files.

NDB Cluster (NDB versions 7.3 and later) also provides a GUI installer which can be used to perform the configuration without the need to edit text files in a separate application. For more information, see Section 18.2.1, “The NDB Cluster Auto-Installer”.

For our four-node, four-host NDB Cluster (see Cluster nodes and host computers), it is necessary to write four configuration files, one per node host.

• Each data node or SQL node requires a my.cnf file that provides two pieces of information: a connection string that tells the node where to find the management node, and a line telling the MySQL server on this host (the machine hosting the data node) to enable the NDBCLUSTER storage engine.

For more information on connection strings, see Section 18.3.3.3, “NDB Cluster Connection Strings”.

• The management node needs a config.ini file telling it how many replicas to maintain, how much memory to allocate for data and indexes on each data node, where to find the data nodes, where to save data to disk on each data node, and where to find any SQL nodes.

Configuring the data nodes and SQL nodes. The my.cnf file needed for the data nodes is fairly simple. The configuration file should be located in the /etc directory and can be edited using any text editor. (Create the file if it does not exist.) For example:

shell> vi /etc/my.cnf

![Note]

We show vi being used here to create the file, but any text editor should work just as well.

For each data node and SQL node in our example setup, my.cnf should look like this:

```
[mysqld]
# Options for mysqld process:
ndbcluster # run NDB storage engine
```

``````
Initial Configuration of NDB Cluster

# Options for NDB Cluster processes:
ndb-connectstring=198.51.100.10  # location of management server

After entering the preceding information, save this file and exit the text editor. Do this for the machines hosting data node “A”, data node “B”, and the SQL node.

Important

Once you have started a mysqld process with the ndbcluster and ndb-connectstring parameters in the [mysqld] and [mysql_cluster] sections of the my.cnf file as shown previously, you cannot execute any CREATE TABLE or ALTER TABLE statements without having actually started the cluster. Otherwise, these statements will fail with an error. This is by design.

Configuring the management node. The first step in configuring the management node is to create the directory in which the configuration file can be found and then to create the file itself. For example (running as root):

shell> mkdir /var/lib/mysql-cluster
shell> cd /var/lib/mysql-cluster
shell> vi config.ini

For our representative setup, the config.ini file should read as follows:

```
[nxdbd default]
# Options affecting ndbd processes on all data nodes:
NoOfReplicas=2    # Number of replicas
DataMemory=80M    # How much memory to allocate for data storage
IndexMemory=18M   # How much memory to allocate for index storage
# For DataMemory and IndexMemory, we have used the
# default values. Since the "world" database takes up
# only about 500KB, this should be more than enough for
# this example NDB Cluster setup.
ServerPort=2202   # This the default value; however, you can use any
# port that is free for all the hosts in the cluster
# Note1: It is recommended that you do not specify the port
# number at all and simply allow the default value to be used
# instead
# Note2: The port was formerly specified using the PortNumber
# TCP parameter; this parameter is no longer available in NDB
# Cluster 7.5.

[nxdbd_mgmd]
# Management process options:
HostName=198.51.100.10          # Hostname or IP address of MGM node
DataDir=/var/lib/mysql-cluster  # Directory for MGM node log files

[nxdbd]
# Options for data node "A":
HostName=198.51.100.30          # Hostname or IP address
NodeId=2                        # Node ID for this data node
DataDir=/usr/local/mysql/data   # Directory for this data node's data files

[nxdbd]
# Options for data node "B":
HostName=198.51.100.40          # Hostname or IP address
NodeId=3                        # Node ID for this data node
DataDir=/usr/local/mysql/data   # Directory for this data node's data files

[mysqld]
# SQL node options:
HostName=198.51.100.20          # Hostname or IP address
```
Initial Startup of NDB Cluster

# (additional mysqld connections can be
# specified for this node for various
# purposes such as running ndb_restore)

Note

The world database can be downloaded from https://dev.mysql.com/doc/index-other.html.

After all the configuration files have been created and these minimal options have been specified, you are ready to proceed with starting the cluster and verifying that all processes are running. We discuss how this is done in Section 18.2.5, “Initial Startup of NDB Cluster”.

For more detailed information about the available NDB Cluster configuration parameters and their uses, see Section 18.3.3, “NDB Cluster Configuration Files”, and Section 18.3, “Configuration of NDB Cluster”. For configuration of NDB Cluster as relates to making backups, see Section 18.5.3.3, “Configuration for NDB Cluster Backups”.

Note

The default port for Cluster management nodes is 1186; the default port for data nodes is 2202. However, the cluster can automatically allocate ports for data nodes from those that are already free.

18.2.5 Initial Startup of NDB Cluster

Starting the cluster is not very difficult after it has been configured. Each cluster node process must be started separately, and on the host where it resides. The management node should be started first, followed by the data nodes, and then finally by any SQL nodes:

1. On the management host, issue the following command from the system shell to start the management node process:

```
shell> ndb_mgmd -f /var/lib/mysql-cluster/config.ini
```

The first time that it is started, ndb_mgmd must be told where to find its configuration file, using the -f or --config-file option. (See Section 18.4.4, “ndb_mgmd — The NDB Cluster Management Server Daemon”, for details.)

For additional options which can be used with ndb_mgmd, see Section 18.4.29, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

2. On each of the data node hosts, run this command to start the ndbd process:

```
shell> ndbd
```

3. If you used RPM files to install MySQL on the cluster host where the SQL node is to reside, you can (and should) use the supplied startup script to start the MySQL server process on the SQL node.

If all has gone well, and the cluster has been set up correctly, the cluster should now be operational. You can test this by invoking the ndb_mgm management node client. The output should look like that shown here, although you might see some slight differences in the output depending upon the exact version of MySQL that you are using:

```
shell> ndb_mgm
```
The SQL node is referenced here as \[\text{[mysqld(API)]}\], which reflects the fact that the \text{mysqld} process is acting as an NDB Cluster API node.

You should now be ready to work with databases, tables, and data in NDB Cluster. See Section 18.2.6, “NDB Cluster Example with Tables and Data”, for a brief discussion.

18.2.6 NDB Cluster Example with Tables and Data

Working with database tables and data in NDB Cluster is not much different from doing so in standard MySQL. There are two key points to keep in mind:

- For a table to be replicated in the cluster, it must use the \text{NDBCLUSTER} storage engine. To specify this, use the \text{ENGINE=NDDBCLUSTER} or \text{ENGINE=ND} option when creating the table:

  \[
  \text{CREATE TABLE \textit{tbl_name} (col_name column_definitions) ENGINE=NDDBCLUSTER;}
  \]

  Alternatively, for an existing table that uses a different storage engine, use \text{ALTER TABLE} to change the table to use \text{NDDBCLUSTER}:

  \[
  \text{ALTER TABLE \textit{tbl_name} ENGINE=NDDBCLUSTER;}
  \]

- Every \text{NDDBCLUSTER} table has a primary key. If no primary key is defined by the user when a table is created, the \text{NDDBCLUSTER} storage engine automatically generates a hidden one. Such a key takes up space just as does any other table index. (It is not uncommon to encounter problems due to insufficient memory for accommodating these automatically created indexes.)

If you are importing tables from an existing database using the output of \text{mysqldump}, you can open the SQL script in a text editor and add the \text{ENGINE} option to any table creation statements, or replace any existing \text{ENGINE} options. Suppose that you have the \text{world} sample database on another MySQL server that does not support NDB Cluster, and you want to export the \text{City} table:

\[
\text{shell> mysqldump --add-drop-table world City > city_table.sql}
\]
The resulting `city_table.sql` file will contain this table creation statement (and the `INSERT` statements necessary to import the table data):

```sql
DROP TABLE IF EXISTS `City`;
CREATE TABLE `City` (
  `ID` int(11) NOT NULL auto_increment,
  `Name` char(35) NOT NULL default '',
  `CountryCode` char(3) NOT NULL default '',
  `District` char(20) NOT NULL default '',
  `Population` int(11) NOT NULL default '0',
  PRIMARY KEY  (`ID`)
) ENGINE=MyISAM DEFAULT CHARSET=latin1;

INSERT INTO `City` VALUES (1,'Kabul','AFG','Kabol',1780000);
INSERT INTO `City` VALUES (2,'Qandahar','AFG','Qandahar',237500);
INSERT INTO `City` VALUES (3,'Herat','AFG','Herat',186800);
(remaining INSERT statements omitted)
```

You need to make sure that MySQL uses the NDBCLUSTER storage engine for this table. There are two ways that this can be accomplished. One of these is to modify the table definition before importing it into the Cluster database. Using the `City` table as an example, modify the `ENGINE` option of the definition as follows:

```sql
DROP TABLE IF EXISTS `City`;
CREATE TABLE `City` (
  `ID` int(11) NOT NULL auto_increment,
  `Name` char(35) NOT NULL default '',
  `CountryCode` char(3) NOT NULL default '',
  `District` char(20) NOT NULL default '',
  `Population` int(11) NOT NULL default '0',
  PRIMARY KEY  (`ID`)
) ENGINE=NDBCLUSTER DEFAULT CHARSET=latin1;

INSERT INTO `City` VALUES (1,'Kabul','AFG','Kabol',1780000);
INSERT INTO `City` VALUES (2,'Qandahar','AFG','Qandahar',237500);
INSERT INTO `City` VALUES (3,'Herat','AFG','Herat',186800);
(remaining INSERT statements omitted)
```

This must be done for the definition of each table that is to be part of the clustered database. The easiest way to accomplish this is to do a search-and-replace on the file that contains the definitions and replace all instances of `TYPE=engine_name` or `ENGINE=engine_name` with `ENGINE=NDBCLUSTER`. If you do not want to modify the file, you can use the unmodified file to create the tables, and then use `ALTER TABLE` to change their storage engine. The particulars are given later in this section.

Assuming that you have already created a database named `world` on the SQL node of the cluster, you can then use the `mysql` command-line client to read `city_table.sql`, and create and populate the corresponding table in the usual manner:

```
shell> mysql world < city_table.sql
```

It is very important to keep in mind that the preceding command must be executed on the host where the SQL node is running (in this case, on the machine with the IP address `198.51.100.20`).

To create a copy of the entire `world` database on the SQL node, use `mysqldump` on the noncluster server to export the database to a file named `world.sql` (for example, in the `/tmp` directory). Then modify the table definitions as just described and import the file into the SQL node of the cluster like this:

```
shell> mysql world < /tmp/world.sql
```
If you save the file to a different location, adjust the preceding instructions accordingly.

Running \texttt{SELECT} queries on the SQL node is no different from running them on any other instance of a MySQL server. To run queries from the command line, you first need to log in to the MySQL Monitor in the usual way (specify the \texttt{root} password at the \texttt{Enter password:} prompt):

\begin{verbatim}
shell> mysql -u root -p
Enter password:
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 1 to server version: 5.6.45-ndb-7.4.25
Type 'help;' or '\h' for help. Type '\c' to clear the buffer.
mysql>
\end{verbatim}

We simply use the MySQL server's \texttt{root} account and assume that you have followed the standard security precautions for installing a MySQL server, including setting a strong \texttt{root} password. For more information, see Section 2.10.4, “Securing the Initial MySQL Accounts”.

It is worth taking into account that Cluster nodes do not make use of the MySQL privilege system when accessing one another. Setting or changing MySQL user accounts (including the \texttt{root} account) effects only applications that access the SQL node, not interaction between nodes. See Section 18.5.11.2, “NDB Cluster and MySQL Privileges”, for more information.

If you did not modify the \texttt{ENGINE} clauses in the table definitions prior to importing the SQL script, you should run the following statements at this point:

\begin{verbatim}
mysql> USE world;
mysql> ALTER TABLE City ENGINE=NDBCLUSTER;
mysql> ALTER TABLE Country ENGINE=NDBCLUSTER;
mysql> ALTER TABLE CountryLanguage ENGINE=NDBCLUSTER;
\end{verbatim}

Selecting a database and running a \texttt{SELECT} query against a table in that database is also accomplished in the usual manner, as is exiting the MySQL Monitor:

\begin{verbatim}
mysql> USE world;
mysql> SELECT Name, Population FROM City ORDER BY Population DESC LIMIT 5;
+-----------+------------+
| Name      | Population |
+-----------+------------+
| Bombay    |   10500000 |
| Seoul     |    9981619 |
| São Paulo |    9968485 |
| Shanghai  |    9696300 |
| Jakarta   |    9604900 |
+-----------+------------+
5 rows in set (0.34 sec)
mysql> \q
Bye
shell>
\end{verbatim}

Applications that use MySQL can employ standard APIs to access \texttt{NDB} tables. It is important to remember that your application must access the SQL node, and not the management or data nodes. This brief example shows how we might execute the \texttt{SELECT} statement just shown by using the PHP 5.X \texttt{mysqli} extension running on a Web server elsewhere on the network:

\begin{verbatim}
<!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 4.01 Transitional//EN"
"http://www.w3.org/TR/html4/loose.dtd">
\end{verbatim}
18.2.7 Safe Shutdown and Restart of NDB Cluster

To shut down the cluster, enter the following command in a shell on the machine hosting the management node:

shell> ndb_mgm -e shutdown
Upgrading and Downgrading NDB Cluster

The -e option here is used to pass a command to the ndb_mgm client from the shell. (See Section 18.4.29, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”, for more information about this option.) The command causes the ndb_mgm, ndb_mgmd, and any ndbd or ndbmtd processes to terminate gracefully. Any SQL nodes can be terminated using mysqladmin shutdown and other means. On Windows platforms, assuming that you have installed the SQL node as a Windows service, you can use SC STOP service_name or NET STOP service_name.

To restart the cluster on Unix platforms, run these commands:

- On the management host (198.51.100.10 in our example setup):
  
  shell> ndb_mgmd -f /var/lib/mysql-cluster/config.ini

- On each of the data node hosts (198.51.100.30 and 198.51.100.40):
  
  shell> ndbd

- Use the ndb_mgm client to verify that both data nodes have started successfully.

- On the SQL host (198.51.100.20):
  
  shell> mysqld_safe &

On Windows platforms, assuming that you have installed all NDB Cluster processes as Windows services using the default service names (see Section 18.2.3.4, “Installing NDB Cluster Processes as Windows Services”), you can restart the cluster as follows:

- On the management host (198.51.100.10 in our example setup), execute the following command:
  
  C:\> SC START ndb_mgmd

- On each of the data node hosts (198.51.100.30 and 198.51.100.40), execute the following command:
  
  C:\> SC START ndbd

- On the management node host, use the ndb_mgm client to verify that the management node and both data nodes have started successfully (see Section 18.2.3.3, “Initial Startup of NDB Cluster on Windows”).

- On the SQL node host (198.51.100.20), execute the following command:
  
  C:\> SC START mysql

In a production setting, it is usually not desirable to shut down the cluster completely. In many cases, even when making configuration changes, or performing upgrades to the cluster hardware or software (or both), which require shutting down individual host machines, it is possible to do so without shutting down the cluster as a whole by performing a rolling restart of the cluster. For more information about doing this, see Section 18.5.5, “Performing a Rolling Restart of an NDB Cluster”.

18.2.8 Upgrading and Downgrading NDB Cluster

This section provides information about NDB Cluster software and table file compatibility between different NDB Cluster 7.3 releases with regard to performing upgrades and downgrades as well as compatibility
matrices and notes. You are expected already to be familiar with installing and configuring an NDB Cluster prior to attempting an upgrade or downgrade. See Section 18.3, “Configuration of NDB Cluster”.

For information regarding the rolling restart procedure used to perform an online upgrade, see Section 18.5.5, “Performing a Rolling Restart of an NDB Cluster”.

Important

Only compatibility between MySQL versions with regard to NDBCLUSTER is taken into account in this section, and there are likely other issues to be considered. As with any other MySQL software upgrade or downgrade, you are strongly encouraged to review the relevant portions of the MySQL Manual for the MySQL versions from which and to which you intend to migrate, before attempting an upgrade or downgrade of the NDB Cluster software. See Section 2.11, “Upgrading MySQL”.

The tables shown here provide information on NDB Cluster upgrade and downgrade compatibility among different releases of NDB Cluster 7.3 and of NDB Cluster 7.4, respectively. Additional notes about upgrades and downgrades to, from, or within the NDB Cluster 7.3 and NDB Cluster 7.4 release series can be found following the tables.

Upgrades and Downgrades, NDB Cluster 7.4

Figure 18.16 NDB Cluster Upgrade and Downgrade Compatibility, NDB Cluster 7.4

Version support. The following versions of NDB Cluster are supported for upgrades to NDB Cluster 7.4 (7.4.4 and later):
Upgrading and Downgrading NDB Cluster

- NDB Cluster 7.3 GA releases (7.3.2 and later)
- NDB Cluster 7.2 GA releases (7.2.4 and later)
- NDB Cluster 7.1 GA releases (7.1.3 and later)
- NDB Cluster 7.0 GA releases (7.0.5 and later)

**NDB 7.4.10 Replacement Release.** Shortly after the release of NDB 7.4.9, a regression was discovered that adversely affected node and system restarts (Bug #22582233). This issue was known to affect NDB 7.4.8 as well. NDB 7.4.10—incorporating a fix for this regression, but otherwise identical to NDB 7.4.9—was released shortly thereafter as a replacement. *Users of the NDB 7.4 series are advised to bypass the 7.4.8 and 7.4.9 releases and to upgrade directly to NDB 7.4.10 (or later).*

**Known Issues—NDB 7.4**

- Prior to NDB 7.4.4, when upgrading from NDB 7.3 to NDB 7.4, the first new data node binary to be started caused the master node (still running NDB 7.3) to fail, then itself failed. (Bug #20608889)

- Prior to NDB 7.4.3, `mysql_upgrade` failed to drop and recreate `ndbinfo`. (Bug #74863, Bug #20031425) In addition, when running `mysql_upgrade` on an NDB Cluster SQL node, the expected drop of the `performance_schema` database on this node was instead performed on all SQL nodes connected to the cluster. (Bug #20032691)

**Upgrades and Downgrades, NDB Cluster 7.3**

---

### MySQL NDB Cluster 7.3

| 7.3.19 |
|---|---|
| 7.3.18 |
| 7.3.17 |
| 7.3.16 |
| 7.3.15 |
| 7.3.14 |
| 7.3.13 |
| 7.3.12 |
| 7.3.11 |
| 7.3.10 |
| 7.3.9 |
| 7.3.8 |
| 7.3.7 |
| 7.3.6 |
| 7.3.5 |
| 7.3.4 |
| 7.3.3 |
| 7.3.2 |
| 7.3.1 |

---

**KEY:**

- Online upgrades and downgrades possible
- Online downgrades not possible
Version support. The following versions of NDB Cluster are supported for upgrades to NDB Cluster 7.3 (7.3.2 and later):

- NDB Cluster 7.2 GA releases (7.2.4 and later)
- NDB Cluster 7.1 GA releases (7.1.3 and later)
- NDB Cluster 7.0 GA releases (7.0.5 and later)
- NDB Cluster 6.3 GA releases (6.3.8 and later) that can be upgraded to NDB Cluster 7.1

Known Issues—NDB 7.3

- Prior to NDB 7.3.8, `mysql_upgrade` failed to drop and recreate `ndbinfo`. (Bug #74863, Bug #20031425) In addition, when running `mysql_upgrade` on an NDB Cluster SQL node, the expected drop of the `performance_schema` database on this node was instead performed on all SQL nodes connected to the cluster. (Bug #200328691)

- NDB API, ClusterJ, and other applications used with recent releases of NDB Cluster 6.3 and later should continue to work with NDB 7.3.2 and later without rewriting or recompiling.

- It is not possible to downgrade online to NDB 7.3.2 or earlier from NDB 7.3.3 or later. Online upgrades from NDB 7.3.2 to later NDB Cluster 7.3 releases are supported.

18.3 Configuration of NDB Cluster

A MySQL server that is part of an NDB Cluster differs in one chief respect from a normal (nonclustered) MySQL server, in that it employs the NDB storage engine. This engine is also referred to sometimes as `NDBCLUSTER`, although `NDB` is preferred.

To avoid unnecessary allocation of resources, the server is configured by default with the NDB storage engine disabled. To enable NDB, you must modify the server's `my.cnf` configuration file, or start the server with the `--ndbcluster` option.

This MySQL server is a part of the cluster, so it also must know how to access a management node to obtain the cluster configuration data. The default behavior is to look for the management node on `localhost`. However, should you need to specify that its location is elsewhere, this can be done in `my.cnf`, or with the `mysql` client. Before the NDB storage engine can be used, at least one management node must be operational, as well as any desired data nodes.

For more information about `--ndbcluster` and other `mysqld` options specific to NDB Cluster, see MySQL Server Options for NDB Cluster.

In NDB 7.3.1 and later, you can use the NDB Cluster Auto-Installer to set up and deploy an NDB Cluster on one or more hosts using a browser-based GUI. For more information, see Section 18.2.1, “The NDB Cluster Auto-Installer”.

For general information about installing NDB Cluster, see Section 18.2, “NDB Cluster Installation”.

18.3.1 Quick Test Setup of NDB Cluster
Quick Test Setup of NDB Cluster

To familiarize you with the basics, we will describe the simplest possible configuration for a functional NDB Cluster. After this, you should be able to design your desired setup from the information provided in the other relevant sections of this chapter.

First, you need to create a configuration directory such as `/var/lib/mysql-cluster`, by executing the following command as the system root user:

```
shell> mkdir /var/lib/mysql-cluster
```

In this directory, create a file named `config.ini` that contains the following information. Substitute appropriate values for `HostName` and `DataDir` as necessary for your system.

```ini
# file "config.ini" - showing minimal setup consisting of 1 data node, # 1 management server, and 3 MySQL servers. # The empty default sections are not required, and are shown only for # the sake of completeness. # Data nodes must provide a hostname but MySQL Servers are not required # to do so. # If you don't know the hostname for your machine, use localhost. # The DataDir parameter also has a default value, but it is recommended to # set it explicitly. # Note: [db], [api], and [mgm] are aliases for [ndbd], [mysqld], and [ndb_mgmd], # respectively. [db] is deprecated and should not be used in new installations.

[ndbd default]
NoOfReplicas=1

[mysqld  default]

[ndb_mgmd default]
[tcp default]

[ndb_mgmd]
HostName= myhost.example.com

[ndbd]
HostName= myhost.example.com
DataDir= /var/lib/mysql-cluster

[mysqld]

[mysqld]

You can now start the `ndb_mgmd` management server. By default, it attempts to read the `config.ini` file in its current working directory, so change location into the directory where the file is located and then invoke `ndb_mgmd`:

```
shell> cd /var/lib/mysql-cluster
shell> ndb_mgmd
```

Then start a single data node by running `ndbd`:

```
shell> ndbd
```

For command-line options which can be used when starting `ndbd`, see Section 18.4.29, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

By default, `ndbd` looks for the management server at `localhost` on port 1186.
Quick Test Setup of NDB Cluster

Note
If you have installed MySQL from a binary tarball, you will need to specify the path of the ndb_mgmd and ndbd servers explicitly. (Normally, these will be found in /usr/local/mysql/bin.)

Finally, change location to the MySQL data directory (usually /var/lib/mysql or /usr/local/mysql/data), and make sure that the my.cnf file contains the option necessary to enable the NDB storage engine:

```
[mysqld]
dbcluster
```

You can now start the MySQL server as usual:

```
shell> mysqld_safe --user=mysql &
```

Wait a moment to make sure the MySQL server is running properly. If you see the notice `mysql ended`, check the server’s .err file to find out what went wrong.

If all has gone well so far, you now can start using the cluster. Connect to the server and verify that the NDBCLUSTER storage engine is enabled:

```
shell> mysql
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 1 to server version: 5.6.46
Type 'help;' or '\h' for help. Type '\c' to clear the buffer.
mysql> SHOW ENGINES\G
... **************************** 12. row ****************************
Engine: NDBCLUSTER
Support: YES
Comment: Clustered, fault-tolerant, memory-based tables
... **************************** 13. row ****************************
Engine: NDB
Support: YES
Comment: Alias for NDBCLUSTER
...
```

The row numbers shown in the preceding example output may be different from those shown on your system, depending upon how your server is configured.

Try to create an NDBCLUSTER table:

```
shell> mysql
mysql> USE test;
Database changed
mysql> CREATE TABLE ctest (i INT) ENGINE=NDBCLUSTER;
Query OK, 0 rows affected (0.09 sec)
mysql> SHOW CREATE TABLE ctest \G
*************************** 1. row ***************************
Table: ctest
Create Table: CREATE TABLE `ctest` ( `i` int(11) default NULL ) ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```
To check that your nodes were set up properly, start the management client:

```
shell> ndb_mgm
```

Use the `SHOW` command from within the management client to obtain a report on the cluster's status:

```
ndb_mgm> SHOW
            Cluster Configuration
                         -----------
        [ndbd(NDB)]  1 node(s)
                id=2    @127.0.0.1  (Version: 5.6.45-ndb-7.4.25, Nodegroup: 0, *)
        [ndb_mgmd(MGM)] 1 node(s)
                id=1    @127.0.0.1  (Version: 5.6.45-ndb-7.4.25)
        [mysqld(API)]   3 node(s)
                id=3    @127.0.0.1  (Version: 5.6.45-ndb-7.4.25)
                        id=4 (not connected, accepting connect from any host)
                        id=5 (not connected, accepting connect from any host)
```

At this point, you have successfully set up a working NDB Cluster. You can now store data in the cluster by using any table created with `ENGINE=NDBCLUSTER` or its alias `ENGINE=NDB`.

18.3.2 Overview of NDB Cluster Configuration Parameters, Options, and Variables

The next several sections provide summary tables of NDB Cluster node configuration parameters used in the `config.ini` file to govern various aspects of node behavior, as well as of options and variables read by `mysqld` from a `my.cnf` file or from the command line when run as an NDB Cluster process. Each of the node parameter tables lists the parameters for a given type (`ndbd`, `ndb_mgmd`, `mysqld`, `computer`, `tcp`, `shm`, or `sci`). All tables include the data type for the parameter, option, or variable, as well as its default, minimum, and maximum values as applicable.

Considerations when restarting nodes. For node parameters, these tables also indicate what type of restart is required (node restart or system restart)—and whether the restart must be done with `--initial`—to change the value of a given configuration parameter. When performing a node restart or an initial node restart, all of the cluster's data nodes must be restarted in turn (also referred to as a rolling restart). It is possible to update cluster configuration parameters marked as `node` online—that is, without shutting down the cluster—in this fashion. An initial node restart requires restarting each `ndbd` process with the `--initial` option.

A system restart requires a complete shutdown and restart of the entire cluster. An initial system restart requires taking a backup of the cluster, wiping the cluster file system after shutdown, and then restoring from the backup following the restart.

In any cluster restart, all of the cluster's management servers must be restarted for them to read the updated configuration parameter values.

---

**Important**

Values for numeric cluster parameters can generally be increased without any problems, although it is advisable to do so progressively, making such adjustments in relatively small increments. Many of these can be increased online, using a rolling restart.

However, decreasing the values of such parameters—whether this is done using a node restart, node initial restart, or even a complete system restart of the
Overview of NDB Cluster Configuration Parameters, Options, and Variables

cluster—is not to be undertaken lightly; it is recommended that you do so only after careful planning and testing. This is especially true with regard to those parameters that relate to memory usage and disk space, such as MaxNoOfTables, MaxNoOfOrderedIndexes, and MaxNoOfUniqueHashIndexes. In addition, it is generally the case that configuration parameters relating to memory and disk usage can be raised using a simple node restart, but they require an initial node restart to be lowered.

Because some of these parameters can be used for configuring more than one type of cluster node, they may appear in more than one of the tables.

**Note**

4294967039 often appears as a maximum value in these tables. This value is defined in the NDBCLUSTER sources as MAX_INT_RNIL and is equal to 0xFFFFFEFF, or $2^{32} - 2^8 - 1$.

### 18.3.2.1 NDB Cluster Data Node Configuration Parameters

The listings in this section provide information about parameters used in the [ndbd] or [ndbd default] sections of a config.ini file for configuring NDB Cluster data nodes. For detailed descriptions and other additional information about each of these parameters, see Section 18.3.3.6, “Defining NDB Cluster Data Nodes”.

These parameters also apply to ndbmtd, the multithreaded version of ndbd. For more information, see Section 18.4.3, "ndbmtd — The NDB Cluster Data Node Daemon (Multi-Threaded)".

- **Arbitration**: How arbitration should be performed to avoid split-brain issues in the event of node failure.
- **ArbitrationTimeout**: Maximum time (milliseconds) database partition waits for arbitration signal
- **BackupDataBufferSize**: Default size of databuffer for a backup (in bytes)
- **BackupDataDir**: Path to where to store backups. Note that the string /BACKUP is always appended to this setting, so that the *effective* default is FileSystemPath/BACKUP.
- **BackupDiskWriteSpeedPct**: Sets the percentage of the data node's allocated maximum write speed (MaxDiskWriteSpeed) to reserve for LCPs when starting a backup.
- **BackupLogBufferSize**: Default size of log buffer for a backup (in bytes)
- **BackupMaxWriteSize**: Maximum size of file system writes made by backup (in bytes)
- **BackupMemory**: Total memory allocated for backups per node (in bytes)
- **BackupReportFrequency**: Frequency of backup status reports during backup in seconds
- **BackupWriteSize**: Default size of file system writes made by backup (in bytes)
- **BatchSizePerLocalScan**: Used to calculate the number of lock records for scan with hold lock
- **BuildIndexThreads**: Number of threads to use for building ordered indexes during a system or node restart. Also applies when running ndb_restore --rebuild-indexes. Setting this parameter to 0 disables multithreaded building of ordered indexes.
- **CompressedBackup**: Use zlib to compress backups as they are written
- **CompressedLCP**: Write compressed LCPs using zlib
• **ConnectCheckIntervalDelay**: Time between data node connectivity check stages. Data node is considered suspect after 1 interval and dead after 2 intervals with no response.

• **CrashOnCorruptedTuple**: When enabled, forces node to shut down whenever it detects a corrupted tuple.

• **DataDir**: Data directory for this node

• **DataMemory**: Number of bytes on each data node allocated for storing data; subject to available system RAM and size of IndexMemory.

• **DefaultHashMapSize**: Set size (in buckets) to use for table hash maps. Three values are supported: 0, 240, and 3840. Intended primarily for upgrades and downgrades to and from NDB 7.2.7+; see the documentation before attempting to use.

• **DictTrace**: Enable DBDICT debugging; for NDB development

• **DiskCheckpointSpeed**: Bytes allowed to be written by checkpoint, per second

• **DiskCheckpointSpeedInRestart**: Bytes allowed to be written by checkpoint during restart, per second

• **DiskIOThreadPool**: Number of unbound threads for file access (currently only for Disk Data); known as IOThreadPool before MySQL Cluster NDB 6.4.3.

• **Diskless**: Run without using the disk

• **DiskPageBufferEntries**: Number of 32K page entries to allocate in DiskPageBufferMemory. Very large disk transactions may require increasing this value.

• **DiskPageBufferMemory**: Number of bytes on each data node allocated for the disk page buffer cache

• **DiskSyncSize**: Amount of data written to file before a synch is forced

• **EventLogBufferSize**: Size of circular buffer for NDB log events within data nodes.

• **ExecuteOnComputer**: String referencing an earlier defined COMPUTER

• **ExtraSendBufferMemory**: Memory to use for send buffers in addition to any allocated by TotalSendBufferMemory or SendBufferMemory. Default (0) allows up to 16MB.

• **FileSystemPath**: Path to directory where the data node stores its data (directory must exist)

• **FileSystemPathDataFiles**: Path to directory where the data node stores its Disk Data files. The default value is FilesystemPathDD, if set; otherwise, FilesystemPath is used if it is set; otherwise, the value of DataDir is used.

• **FileSystemPathDD**: Path to directory where the data node stores its Disk Data and undo files. The default value is FileSystemPath, if set; otherwise, the value of DataDir is used.

• **FileSystemPathUndoFiles**: Path to directory where the data node stores its undo files for Disk Data. The default value is FileSystemPathDD, if set; otherwise, FileSystemPath is used if it is set; otherwise, the value of DataDir is used.

• **FragmentLogFileSize**: Size of each redo log file

• **HeartbeatIntervalDbApi**: Time between API node-data node heartbeats. (API connection closed after 3 missed heartbeats)
### Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **HeartbeatIntervalDbDb**: Time between data node-to-data node heartbeats; data node considered dead after 3 missed heartbeats
- **HeartbeatOrder**: Sets the order in which data nodes check each others' heartbeats for determining whether a given node is still active and connected to the cluster. Must be zero for all data nodes or distinct nonzero values for all data nodes; see documentation for further guidance.
- **HostName**: Host name or IP address for this data node.
- **Id**: Number identifying the data node (Id). Now deprecated; use NodeId instead.
- **IndexMemory**: Number of bytes on each data node allocated for storing indexes; subject to available system RAM and size of DataMemory.
- **IndexStatAutoCreate**: Enable/disable automatic statistics collection when indexes are created.
- **IndexStatAutoUpdate**: Monitor indexes for changes and trigger automatic statistics updates
- **IndexStatSaveScale**: Scaling factor used in determining size of stored index statistics.
- **IndexStatSaveSize**: Maximum size in bytes for saved statistics per index.
- **IndexStatTriggerPct**: Threshold percent change in DML operations for index statistics updates. The value is scaled down by IndexStatTriggerScale.
- **IndexStatTriggerScale**: Scale down IndexStatTriggerPct by this amount, multiplied by the base 2 logarithm of the index size, for a large index. Set to 0 to disable scaling.
- **IndexStatUpdateDelay**: Minimum delay between automatic index statistics updates for a given index. 0 means no delay.
- **InitFragmentLogFiles**: Initialize fragment logfiles (sparse/full)
- **InitialLogFileGroup**: Describes a log file group that is created during an initial start. See documentation for format.
- **InitialNoOfOpenFiles**: Initial number of files open per data node. (One thread is created per file)
- **InitialTablespace**: Describes a tablespace that is created during an initial start. See documentation for format.
- **LateAlloc**: Allocate memory after the connection to the management server has been established.
- **LcpScanProgressTimeout**: Maximum time that local checkpoint fragment scan can be stalled before node is shut down to ensure systemwide LCP progress. Use 0 to disable.
- **LockExecuteThreadToCPU**: In NDB 6.3, the ID of the CPU to run the execution thread; in NDB 7.0 and later, a comma-delimited list of CPU IDs
- **LockMaintThreadsToCPU**: CPU ID indicating which CPU runs the maintenance threads
- **LockPagesInMainMemory**: Previously: If set to true/1, then NDB Cluster data is not swapped out to disk. In MySQL 5.0.36/5.1.15 and later: 0=disable locking, 1=lock after memory allocation, 2=lock before memory allocation
- **LogLevelCheckpoint**: Log level of local and global checkpoint information printed to stdout
- **LogLevelCongestion**: Level of congestion information printed to stdout
- **LogLevelConnection**: Level of node connect/disconnect information printed to stdout
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **LogLevelError**: Transporter, heartbeat errors printed to stdout
- **LogLevelInfo**: Heartbeat and log information printed to stdout
- **LogLevelNodeRestart**: Level of node restart and node failure information printed to stdout
- **LogLevelShutdown**: Level of node shutdown information printed to stdout
- **LogLevelStartup**: Level of node startup information printed to stdout
- **LogLevelStatistic**: Level of transaction, operation, and transporter information printed to stdout
- **LongMessageBuffer**: Number of bytes allocated on each data node for internal long messages
- **MaxAllocate**: Maximum size of allocation to use when allocating memory for tables
- **MaxBufferedEpochs**: Allowed number of epochs that a subscribing node can lag behind (unprocessed epochs). Exceeding will cause lagging subscribers to be disconnected.
- **MaxBufferedEpochBytes**: Total number of bytes allocated for buffering epochs.
- **MaxDiskWriteSpeed**: Maximum number of bytes per second that can be written by LCP and backup when no restarts are ongoing.
- **MaxDiskWriteSpeedOtherNodeRestart**: Maximum number of bytes per second that can be written by LCP and backup when another node is restarting.
- **MaxDiskWriteSpeedOwnRestart**: Maximum number of bytes per second that can be written by LCP and backup when this node is restarting.
- **MaxDMLOperationsPerTransaction**: Limit size of a transaction; aborts the transaction if it requires more than this many DML operations. Set to 0 to disable.
- **MaxLCPStartDelay**: Time in seconds that LCP polls for checkpoint mutex (to allow other data nodes to complete metadata synchronization), before putting itself in lock queue for parallel recovery of table data.
- **MaxNoOfAttributes**: Suggests a total number of attributes stored in database (sum over all tables)
- **MaxNoOfConcurrentIndexOperations**: Total number of index operations that can execute simultaneously on one data node
- **MaxNoOfConcurrentOperations**: Maximum number of operation records in transaction coordinator
- **MaxNoOfConcurrentScans**: Maximum number of scans executing concurrently on the data node
- **MaxNoOfConcurrentSubOperations**: Maximum number of concurrent subscriber operations
- **MaxNoOfConcurrentTransactions**: Maximum number of transactions executing concurrently on this data node, the total number of transactions that can be executed concurrently is this value times the number of data nodes in the cluster.
- **MaxNoOfFiredTriggers**: Total number of triggers that can fire simultaneously on one data node
- **MaxNoOfLocalOperations**: Maximum number of operation records defined on this data node
- **MaxNoOfLocalScans**: Maximum number of fragment scans in parallel on this data node
- **MaxNoOfOpenFiles**: Maximum number of files open per data node. (One thread is created per file)
- **MaxNoOfOrderedIndexes**: Total number of ordered indexes that can be defined in the system
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **MaxNoOfSavedMessages**: Maximum number of error messages to write in error log and maximum number of trace files to retain.
- **MaxNoOfSubscribers**: Maximum number of subscribers (default $0 = \text{MaxNoOfTables} * 2$).
- **MaxNoOfSubscriptions**: Maximum number of subscriptions (default $0 = \text{MaxNoOfTables}$).
- **MaxNoOfTables**: Suggests a total number of NDB tables stored in the database.
- **MaxNoOfTriggers**: Total number of triggers that can be defined in the system.
- **MaxNoOfUniqueHashIndexes**: Total number of unique hash indexes that can be defined in the system.
- **MaxParallelCopyInstances**: Number of parallel copies during node restarts. Default is 0, which uses number of LDMs on both nodes, to a maximum of 16.
- **MaxParallelScansPerFragment**: Maximum number of parallel scans per fragment. Once this limit is reached, scans are serialized.
- **MaxStartFailRetries**: Maximum retries when data node fails on startup, requires StopOnError = 0. Setting to 0 causes start attempts to continue indefinitely.
- **MemReportFrequency**: Frequency of memory reports in seconds; $0 = \text{report only when exceeding percentage limits}$.
- **MinDiskWriteSpeed**: Minimum number of bytes per second that can be written by LCP and backup.
- **MinFreePct**: The percentage of memory resources to keep in reserve for restarts.
- **NodeGroup**: Node group to which the data node belongs; used only during initial start of cluster.
- **NodeId**: Number uniquely identifying the data node among all nodes in the cluster.
- **NoOfFragmentLogFiles**: Number of 16 MB redo log files in each of 4 file sets belonging to the data node.
- **NoOfReplicas**: Number of copies of all data in database; recommended value is 2 (default). Values greater than 2 are not supported in production.
- **Numa**: (Linux only; requires libnuma) Controls NUMA support. Setting to 0 permits system to determine use of interleaving by data node process; 1 means that it is determined by data node.
- **ODirect**: Use O_DIRECT file reads and writes when possible.
- **RealtimeScheduler**: When true, data node threads are scheduled as real-time threads. Default is false.
- **RedoBuffer**: Number bytes on each data node allocated for writing redo logs.
- **RedoOverCommitCounter**: When RedoOverCommitLimit has been exceeded this many times, transactions are aborted, and operations are handled as specified by DefaultOperationRedoProblemAction.
- **RedoOverCommitLimit**: Each time that flushing the current redo buffer takes longer than this many seconds, the number of times that this has happened is compared to RedoOverCommitCounter.
- **ReservedSendBufferMemory**: This parameter is present in NDB code but is not enabled, and is now deprecated.
- **RestartOnErrorInsert**: Control the type of restart caused by inserting an error (when StopOnError is enabled).
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **SchedulerExecutionTimer**: Number of microseconds to execute in scheduler before sending
- **SchedulerResponsiveness**: Set NDB scheduler response optimization 0-10; higher values provide better response time but lower throughput
- **SchedulerSpinTimer**: Number of microseconds to execute in scheduler before sleeping
- **ServerPort**: Port used to set up transporter for incoming connections from API nodes
- **SharedGlobalMemory**: Total number of bytes on each data node allocated for any use
- **StartFailRetryDelay**: Delay in seconds after start failure prior to retry; requires StopOnError = 0.
- **StartFailureTimeout**: Milliseconds to wait before terminating. (0=Wait forever)
- **StartNoNodeGroupTimeout**: Time to wait for nodes without a nodegroup before trying to start (0=forever)
- **StartPartialTimeout**: Milliseconds to wait before trying to start without all nodes. (0=Wait forever)
- **StartPartitionedTimeout**: Milliseconds to wait before trying to start partitioned. (0=Wait forever)
- **StartupStatusReportFrequency**: Frequency of status reports during startup
- **StopOnError**: When set to 0, the data node automatically restarts and recovers following node failures
- **StringMemory**: Default size of string memory (0 to 100 = % of maximum, 101+ = actual bytes)
- **TcpBind_INADDR_ANY**: Bind IP_ADDR_ANY so that connections can be made from anywhere (for autogenerated connections)
- **TimeBetweenEpochs**: Time between epochs (synchronization used for replication)
- **TimeBetweenEpochsTimeout**: Timeout for time between epochs. Exceeding will cause node shutdown.
- **TimeBetweenGlobalCheckpoints**: Time between doing group commit of transactions to disk
- **TimeBetweenGlobalCheckpointsTimeout**: Minimum timeout for group commit of transactions to disk
- **TimeBetweenInactiveTransactionAbortCheck**: Time between checks for inactive transactions
- **TimeBetweenLocalCheckpoints**: Time between taking snapshots of the database (expressed in base-2 logarithm of bytes)
- **TimeBetweenWatchDogCheck**: Time between execution checks inside a data node
- **TimeBetweenWatchDogCheckInitial**: Time between execution checks inside a data node (early start phases when memory is allocated)
- **TotalSendBufferMemory**: Total memory to use for all transporter send buffers.
- **TransactionBufferMemory**: Dynamic buffer space (in bytes) for key and attribute data allocated for each data node
- **TransactionDeadlockDetectionTimeout**: Time transaction can spend executing within a data node. This is the time that the transaction coordinator waits for each data node participating in the transaction to execute a request. If the data node takes more than this amount of time, the transaction is aborted. Prior to MySQL Cluster NDB 6.2.18/6.3.24/7.0.5, values between 50 and 100 were possible, but were treated as 100.
• **TransactionInactiveTimeout**: Milliseconds that the application waits before executing another part of the transaction. This is the time the transaction coordinator waits for the application to execute or send another part (query, statement) of the transaction. If the application takes too much time, then the transaction is aborted. Timeout = 0 means that the application never times out.

• **TwoPassInitialNodeRestartCopy**: Copy data in 2 passes during initial node restart, which enables multithreaded building of ordered indexes for such restarts.

• **UndoDataBuffer**: Number of bytes on each data node allocated for writing data undo logs

• **UndoIndexBuffer**: Number of bytes on each data node allocated for writing index undo logs

The following parameters are specific to **ndbmtmd**:

• **MaxNoOfExecutionThreads**: For ndbmtmd only, specify maximum number of execution threads

• **NoOfFragmentLogParts**: Number of redo log file groups belonging to this data node; value must be an even multiple of 4.

• **ThreadConfig**: Used for configuration of multithreaded data nodes (ndbmtmd). Default is an empty string; see documentation for syntax and other information.

### 18.3.2.2 NDB Cluster Management Node Configuration Parameters

The listing in this section provides information about parameters used in the `[ndb_mgmd]` or `[mgm]` section of a `config.ini` file for configuring NDB Cluster management nodes. For detailed descriptions and other additional information about each of these parameters, see Section 18.3.3.5, “Defining an NDB Cluster Management Server”.

• **ArbitrationDelay**: When asked to arbitrate, arbitrator waits this long before voting (milliseconds)

• **ArbitrationRank**: If 0, then management node is not arbitrator. Kernel selects arbitrators in order 1, 2

• **DataDir**: Data directory for this node

• **ExecuteOnComputer**: String referencing an earlier defined COMPUTER

• **HeartbeatIntervalMgmdMgmd**: Time between management node-to-management node heartbeats; the connection between management node is considered lost after 3 missed heartbeats.

• **HeartbeatThreadPriority**: Set heartbeat thread policy and priority for management nodes; see manual for allowed values

• **HostName**: Host name or IP address for this management node.

• **Id**: Number identifying the management node (Id). Now deprecated; use NodeId instead.

• **LogDestination**: Where to send log messages: console, system log, or specified log file

• **MaxNoOfSavedEvents**: Not used

• **NodeId**: Number uniquely identifying the management node among all nodes in the cluster.

• **PortNumber**: Port number to send commands to and fetch configuration from management server

• **PortNumberStats**: Port number used to get statistical information from a management server

• **TotalSendBufferMemory**: Total memory to use for all transporter send buffers

• **wan**: Use WAN TCP setting as default
Overview of NDB Cluster Configuration Parameters, Options, and Variables

Note
After making changes in a management node’s configuration, it is necessary to perform a rolling restart of the cluster for the new configuration to take effect. See Section 18.3.3.5, “Defining an NDB Cluster Management Server”, for more information.

To add new management servers to a running NDB Cluster, it is also necessary perform a rolling restart of all cluster nodes after modifying any existing config.ini files. For more information about issues arising when using multiple management nodes, see Section 18.1.7.10, “Limitations Relating to Multiple NDB Cluster Nodes”.

18.3.2.3 NDB Cluster SQL Node and API Node Configuration Parameters

The listing in this section provides information about parameters used in the [mysqld] and [api] sections of a config.ini file for configuring NDB Cluster SQL nodes and API nodes. For detailed descriptions and other additional information about each of these parameters, see Section 18.3.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”.

- **ApiVerbose**: Enable NDB API debugging; for NDB development
- **ArbitrationDelay**: When asked to arbitrate, arbitrator waits this many milliseconds before voting
- **ArbitrationRank**: If 0, then API node is not arbitrator. Kernel selects arbitrators in order 1, 2
- **AutoReconnect**: Specifies whether an API node should reconnect fully when disconnected from the cluster
- **BatchByteSize**: The default batch size in bytes
- **BatchSize**: The default batch size in number of records
- **ConnectBackoffMaxTime**: Specifies longest time in milliseconds (~100ms resolution) to allow between connection attempts to any given data node by this API node. Excludes time elapsed while connection attempts are ongoing, which in worst case can take several seconds. Disable by setting to 0. If no data nodes are currently connected to this API node, StartConnectBackoffMaxTime is used instead.
- **ConnectionMap**: Specifies which data nodes to connect
- **DefaultHashMapSize**: Set size (in buckets) to use for table hash maps. Three values are supported: 0, 240, and 3840. Intended primarily for upgrades and downgrades to and from NDB 7.2.7+; see the documentation before attempting to use.
- **DefaultOperationRedoProblemAction**: How operations are handled in the event that RedoOverCommitCounter is exceeded
- **ExecuteOnComputer**: String referencing an earlier defined COMPUTER
- **ExtraSendBufferMemory**: Memory to use for send buffers in addition to any allocated by TotalSendBufferMemory or SendBufferMemory. Default (0) allows up to 16MB.
- **HeartbeatThreadPriority**: Set heartbeat thread policy and priority for API nodes; see manual for allowed values
- **HostName**: Host name or IP address for this SQL or API node.
- **Id**: Number identifying MySQL server or API node (Id). Now deprecated; use NodeId instead.
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **MaxScanBatchSize**: The maximum collective batch size for one scan
- **NodeId**: Number uniquely identifying the SQL node or API node among all nodes in the cluster.
- **StartConnectBackoffMaxTime**: Same as ConnectBackoffMaxTime except that this parameter is used in its place if no data nodes are connected to this API node.
- **TotalSendBufferMemory**: Total memory to use for all transporter send buffers
- **wan**: Use WAN TCP setting as default

For a discussion of MySQL server options for NDB Cluster, see [MySQL Server Options for NDB Cluster](#).
For information about MySQL server system variables relating to NDB Cluster, see [NDB Cluster System Variables](#).

**Note**

To add new SQL or API nodes to the configuration of a running NDB Cluster, it is necessary to perform a rolling restart of all cluster nodes after adding new [mysqld] or [api] sections to the config.ini file (or files, if you are using more than one management server). This must be done before the new SQL or API nodes can connect to the cluster.

It is **not** necessary to perform any restart of the cluster if new SQL or API nodes can employ previously unused API slots in the cluster configuration to connect to the cluster.

### 18.3.2.4 Other NDB Cluster Configuration Parameters

The listings in this section provide information about parameters used in the [computer], [tcp], [shm], and [sci] sections of a config.ini file for configuring NDB Cluster. For detailed descriptions and additional information about individual parameters, see Section 18.3.3.9, "NDB Cluster TCP/IP Connections", Section 18.3.3.11, "NDB Cluster Shared-Memory Connections", or Section 18.3.3.12, "SCI Transport Connections in NDB Cluster", as appropriate.

The following parameters apply to the config.ini file's [computer] section:

- **HostName**: Host name or IP address of this computer.
- **Id**: A unique identifier for this computer.

The following parameters apply to the config.ini file's [tcp] section:

- **Checksum**: If checksum is enabled, all signals between nodes are checked for errors
- **Group**: Used for group proximity; smaller value is interpreted as being closer
- **NodeId1**: ID of node (data node, API node, or management node) on one side of the connection
- **NodeId2**: ID of node (data node, API node, or management node) on one side of the connection
- **NodeIdServer**: Set server side of TCP connection
- **OverloadLimit**: When more than this many unsent bytes are in the send buffer, the connection is considered overloaded.
- **PortNumber**: Port used for this transporter (DEPRECATED)
- **Proxy**: 

---

2645
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **ReceiveBufferMemory**: Bytes of buffer for signals received by this node
- **SendBufferMemory**: Bytes of TCP buffer for signals sent from this node
- **SendSignalId**: Sends ID in each signal. Used in trace files. Defaults to true in debug builds.
- **TCP_MAXSEG_SIZE**: Value used for TCP_MAXSEG
- **TCP_RCV_BUF_SIZE**: Value used for SO_RCVBUF
- **TCP_SND_BUF_SIZE**: Value used for SO_SNDBUF
- **TcpBind_INADDR_ANY**: Bind InAddrAny instead of host name for server part of connection

The following parameters apply to the `config.ini` file's `[shm]` section:

- **Checksum**: If checksum is enabled, all signals between nodes are checked for errors
- **Group**:
  - **NodeId1**: ID of node (data node, API node, or management node) on one side of the connection
  - **NodeId2**: ID of node (data node, API node, or management node) on one side of the connection
  - **NodeIdServer**: Set server side of SHM connection
  - **OverloadLimit**: When more than this many unsent bytes are in the send buffer, the connection is considered overloaded.
- **PortNumber**: Port used for this transporter (DEPRECATED)
- **SendSignalId**: Sends ID in each signal. Used in trace files.
- **ShmKey**: A shared memory key; when set to 1, this is calculated by NDB
- **ShmSize**: Size of shared memory segment
- **Signum**: Signal number to be used for signalling

The following parameters apply to the `config.ini` file's `[sci]` section:

- **Checksum**: If checksum is enabled, all signals between nodes are checked for errors
- **Group**:
  - **Host1SciId0**: SCI-node ID for adapter 0 on Host1 (a computer can have two adapters)
  - **Host1SciId1**: SCI-node ID for adapter 1 on Host1 (a computer can have two adapters)
  - **Host2SciId0**: SCI-node ID for adapter 0 on Host2 (a computer can have two adapters)
  - **Host2SciId1**: SCI-node ID for adapter 1 on Host2 (a computer can have two adapters)
  - **NodeId1**: ID of node (data node, API node, or management node) on one side of the connection
  - **NodeId2**: ID of node (data node, API node, or management node) on one side of the connection
  - **NodeIdServer**:
  - **OverloadLimit**: When more than this many unsent bytes are in the send buffer, the connection is considered overloaded.
- **PortNumber**: Port used for this transporter (DEPRECATED)
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **SendLimit**: Transporter send buffer contents are sent when this number of bytes is buffered.
- **SendSignalId**: Sends ID in each signal. Used in trace files.
- **SharedBufferSize**: Size of shared memory segment.

### 18.3.2.5 NDB Cluster mysqld Option and Variable Reference

The following table provides a list of the command-line options, server and status variables applicable within `mysqld` when it is running as an SQL node in an NDB Cluster. For a table showing all command-line options, server and status variables available for use with `mysqld`, see Section 5.1.3, “Server Option, System Variable, and Status Variable Reference”.

- **Com_show_ndb_status**: Count of SHOW NDB STATUS statements.
- **create_old_temporals**: Use pre-5.6.4 storage format for temporal types when creating tables. Intended for use in replication and upgrades/downgrades between NDB 7.2 and NDB 7.3/7.4.
- **Handler_discover**: Number of times that tables have been discovered.
- **have_ndbcluster**: Whether mysqld supports NDB Cluster tables (set by --ndbcluster option).
- **ndb-batch-size**: Size (in bytes) to use for NDB transaction batches.
- **ndb-blob-read-batch-bytes**: Specifies size in bytes that large BLOB reads should be batched into. 0 = no limit.
- **ndb-blob-write-batch-bytes**: Specifies size in bytes that large BLOB writes should be batched into. 0 = no limit.
- **ndb-cluster-connection-pool**: Number of connections to the cluster used by MySQL.
- **ndb-connectstring**: Point to the management server that distributes the cluster configuration.
- **ndb-deferred-constraints**: Specifies that constraint checks on unique indexes (where these are supported) should be deferred until commit time. Not normally needed or used; for testing purposes only.
- **ndb-distribution**: Default distribution for new tables in NDBCLUSTER (KEYHASH or LINHASH, default is KEYHASH).
- **ndb-log-apply-status**: Cause a MySQL server acting as a slave to log mysql.ndb_apply_status updates received from its immediate master in its own binary log, using its own server ID. Effective only if the server is started with the --ndbcluster option.
- **ndb-log-empty-epochs**: When enabled, causes epochs in which there were no changes to be written to the ndb_apply_status and ndb_binlog_index tables, even when --log-slave-updates is enabled.
- **ndb-log-empty-update**: When enabled, causes updates that produced no changes to be written to the ndb_apply_status and ndb_binlog_index tables, even when --log-slave-updates is enabled.
- **ndb-log-exclusive-reads**: Log primary key reads with exclusive locks; allow conflict resolution based on read conflicts.
- **ndb-log-orig**: Log originating server id and epoch in mysql.ndb_binlog_index table.
- **ndb-log-transaction-id**: Write NDB transaction IDs in the binary log. Requires --log-bin-v1-events=OFF.
- **ndb-log-update-as-write**: Toggles logging of updates on the master between updates (OFF) and writes (ON).
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **ndb-mgmd-host**: Set the host (and port, if desired) for connecting to management server
- **ndb-nodeid**: NDB Cluster node ID for this MySQL server
- **ndb-rev-thread-activation-threshold**: Activation threshold when receive thread takes over the polling of the cluster connection (measured in concurrently active threads)
- **ndb-rev-thread-cpu-mask**: CPU mask for locking receiver threads to specific CPUs; specified as hexadecimal. See documentation for details.
- **ndb-transid-mysql-connection-map**: Enable or disable the ndb_transid_mysql_connection_map plugin; that is, enable or disable the INFORMATION_SCHEMA table having that name
- **ndb-wait-connected**: Time (in seconds) for the MySQL server to wait for connection to cluster management and data nodes before accepting MySQL client connections
- **ndb-wait-setup**: Time (in seconds) for the MySQL server to wait for NDB engine setup to complete
- **Ndb_api_bytes_received_count**: Amount of data (in bytes) received from the data nodes by this MySQL Server (SQL node)
- **Ndb_api_bytes_received_count_session**: Amount of data (in bytes) received from the data nodes in this client session
- **Ndb_api_bytes_received_count_slave**: Amount of data (in bytes) received from the data nodes by this slave
- **Ndb_api_bytes_sent_count**: Amount of data (in bytes) sent to the data nodes by this MySQL Server (SQL node)
- **Ndb_api_bytes_sent_count_session**: Amount of data (in bytes) sent to the data nodes in this client session
- **Ndb_api_bytes_sent_count_slave**: Amount of data (in bytes) sent to the data nodes by this slave
- **Ndb_api_event_bytes_count**: Number of bytes of events received by this MySQL Server (SQL node)
- **Ndb_api_event_bytes_count_injector**: Number of bytes of events received by the NDB binary log injector thread
- **Ndb_api_event_data_count**: Number of row change events received by this MySQL Server (SQL node)
- **Ndb_api_event_data_count_injector**: Number of row change events received by the NDB binary log injector thread
- **Ndb_api_event_nondata_count**: Number of events received, other than row change events, by this MySQL Server (SQL node)
- **Ndb_api_event_nondata_count_injector**: Number of events received, other than row change events, by the NDB binary log injector thread
- **Ndb_api_pk_op_count**: Number of operations based on or using primary keys by this MySQL Server (SQL node)
- **Ndb_api_pk_op_count_session**: Number of operations based on or using primary keys in this client session
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **Ndb_api_pk_op_count_slave**: Number of operations based on or using primary keys by this slave
- **Ndb_api_pruned_scan_count**: Number of scans that have been pruned to a single partition by this MySQL Server (SQL node)
- **Ndb_api_pruned_scan_count_session**: Number of scans that have been pruned to a single partition in this client session
- **Ndb_api_pruned_scan_count_slave**: Number of scans that have been pruned to a single partition by this slave
- **Ndb_api_range_scan_count**: Number of range scans that have been started by this MySQL Server (SQL node)
- **Ndb_api_range_scan_count_session**: Number of range scans that have been started in this client session
- **Ndb_api_range_scan_count_slave**: Number of range scans that have been started by this slave
- **Ndb_api_read_row_count**: Total number of rows that have been read by this MySQL Server (SQL node)
- **Ndb_api_read_row_count_session**: Total number of rows that have been read in this client session
- **Ndb_api_read_row_count_slave**: Total number of rows that have been read by this slave
- **Ndb_api_scan_batch_count**: Number of batches of rows received by this MySQL Server (SQL node)
- **Ndb_api_scan_batch_count_session**: Number of batches of rows received in this client session
- **Ndb_api_scan_batch_count_slave**: Number of batches of rows received by this slave
- **Ndb_api_table_scan_count**: Number of table scans that have been started, including scans of internal tables, by this MySQL Server (SQL node)
- **Ndb_api_table_scan_count_session**: Number of table scans that have been started, including scans of internal tables, in this client session
- **Ndb_api_table_scan_count_slave**: Number of table scans that have been started, including scans of internal tables, by this slave
- **Ndb_api_trans_abort_count**: Number of transactions aborted by this MySQL Server (SQL node)
- **Ndb_api_trans_abort_count_session**: Number of transactions aborted in this client session
- **Ndb_api_trans_abort_count_slave**: Number of transactions aborted by this slave
- **Ndb_api_trans_close_count**: Number of transactions aborted (may be greater than the sum of TransCommitCount and TransAbortCount) by this MySQL Server (SQL node)
- **Ndb_api_trans_close_count_session**: Number of transactions aborted (may be greater than the sum of TransCommitCount and TransAbortCount) in this client session
- **Ndb_api_trans_close_count_slave**: Number of transactions aborted (may be greater than the sum of TransCommitCount and TransAbortCount) by this slave
- **Ndb_api_trans_commit_count**: Number of transactions committed by this MySQL Server (SQL node)
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **Ndb_api_trans_commit_count_session**: Number of transactions committed in this client session
- **Ndb_api_trans_commit_count_slave**: Number of transactions committed by this slave
- **Ndb_api_trans_local_read_row_count**: Total number of rows that have been read by this MySQL Server (SQL node)
- **Ndb_api_trans_local_read_row_count_session**: Total number of rows that have been read in this client session
- **Ndb_api_trans_local_read_row_count_slave**: Total number of rows that have been read by this slave
- **Ndb_api_trans_start_count**: Number of transactions started by this MySQL Server (SQL node)
- **Ndb_api_trans_start_count_session**: Number of transactions started in this client session
- **Ndb_api_trans_start_count_slave**: Number of transactions started by this slave
- **Ndb_api_uk_op_count**: Number of operations based on or using unique keys by this MySQL Server (SQL node)
- **Ndb_api_uk_op_count_session**: Number of operations based on or using unique keys in this client session
- **Ndb_api_uk_op_count_slave**: Number of operations based on or using unique keys by this slave
- **Ndb_api_wait_exec_complete_count**: Number of times thread has been blocked while waiting for execution of an operation to complete by this MySQL Server (SQL node)
- **Ndb_api_wait_exec_complete_count_session**: Number of times thread has been blocked while waiting for execution of an operation to complete in this client session
- **Ndb_api_wait_exec_complete_count_slave**: Number of times thread has been blocked while waiting for execution of an operation to complete by this slave
- **Ndb_api_wait_meta_request_count**: Number of times thread has been blocked waiting for a metadata-based signal by this MySQL Server (SQL node)
- **Ndb_api_wait_meta_request_count_session**: Number of times thread has been blocked waiting for a metadata-based signal in this client session
- **Ndb_api_wait_meta_request_count_slave**: Number of times thread has been blocked waiting for a metadata-based signal by this slave
- **Ndb_api_wait_nanos_count**: Total time (in nanoseconds) spent waiting for some type of signal from the data nodes by this MySQL Server (SQL node)
- **Ndb_api_wait_nanos_count_session**: Total time (in nanoseconds) spent waiting for some type of signal from the data nodes in this client session
- **Ndb_api_wait_nanos_count_slave**: Total time (in nanoseconds) spent waiting for some type of signal from the data nodes by this slave
- **Ndb_api_wait_scan_result_count**: Number of times thread has been blocked while waiting for a scan-based signal by this MySQL Server (SQL node)
- **Ndb_api_wait_scan_result_count_session**: Number of times thread has been blocked while waiting for a scan-based signal in this client session
Overview of NDB Cluster Configuration Parameters, Options, and Variables

• **Ndb_api_wait_scan_result_count_slave**: Number of times thread has been blocked while waiting for a scan-based signal by this slave

• **ndb_autoincrement_prefetch_sz**: NDB auto-increment prefetch size

• **ndb_cache_check_time**: Number of milliseconds between checks of cluster SQL nodes made by the MySQL query cache

• **ndb_clear_apply_status**: Causes RESET SLAVE to clear all rows from the ndb_apply_status table; ON by default

• **Ndb_cluster_node_id**: If the server is acting as an NDB Cluster node, then the value of this variable is its node ID in the cluster

• **Ndb_config_from_host**: The host name or IP address of the Cluster management server. Formerly Ndb_connected_host

• **Ndb_config_from_port**: The port for connecting to Cluster management server. Formerly Ndb_connected_port

• **Ndb_conflict_fn_epoch**: Number of rows that have been found in conflict by the NDB$EPOCH() conflict detection function

• **Ndb_conflict_fn_epoch2**: Number of rows that have been found in conflict by the NDB$EPOCH2() conflict detection function

• **Ndb_conflict_fn_epoch2_trans**: Number of rows that have been found in conflict by the NDB$EPOCH2_TRANS() conflict detection function

• **Ndb_conflict_fn_epoch_trans**: Number of rows that have been found in conflict by the NDB$EPOCH_TRANS() conflict detection function

• **Ndb_conflict_fn_max**: If the server is part of an NDB Cluster involved in cluster replication, the value of this variable indicates the number of times that conflict resolution based on "greater timestamp wins" has been applied

• **Ndb_conflict_fn_max_del_win**: Number of times that conflict resolution based on outcome of NDB$MAX_DELETE_WIN() has been applied

• **Ndb_conflict_fn_old**: If the server is part of an NDB Cluster involved in cluster replication, the value of this variable indicates the number of times that "same timestamp wins" conflict resolution has been applied

• **Ndb_conflict_last_conflict_epoch**: Most recent NDB epoch on this slave in which a conflict was detected

• **Ndb_conflict_last_stable_epoch**: Number of rows found to be in conflict by a transactional conflict function

• **Ndb_conflict_reflected_op_discard_count**: Number of reflected operations that were not applied due an error during execution

• **Ndb_conflict_reflected_op_prepare_count**: Number of reflected operations received that have been prepared for execution

• **Ndb_conflict_refresh_op_count**: Number of refresh operations that have been prepared

• **Ndb_conflict_trans_conflict_commit_count**: Number of epoch transactions committed after requiring transactional conflict handling
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **Ndb_conflict_trans_detect_iter_count**: Number of internal iterations required to commit an epoch transaction. Should be (slightly) greater than or equal to Ndb_conflict_trans_conflict_commit_count

- **Ndb_conflict_trans_reject_count**: Number of transactions rejected after being found in conflict by a transactional conflict function

- **Ndb_conflict_trans_row_conflict_count**: Number of rows found in conflict by a transactional conflict function. Includes any rows included in or dependent on conflicting transactions.

- **Ndb_conflict_trans_row_reject_count**: Total number of rows realigned after being found in conflict by a transactional conflict function. Includes Ndb_conflict_trans_row_conflict_count and any rows included in or dependent on conflicting transactions.

- **ndb_deferred_constraints**: Specifies that constraint checks should be deferred (where these are supported). Not normally needed or used; for testing purposes only.

- **ndb_distribution**: Default distribution for new tables in NDBCLUSTER (KEYHASH or LINHASH, default is KEYHASH)

- **Ndb_conflict_delete_delete_count**: Number of delete-delete conflicts detected (delete operation is applied, but row does not exist)

- **ndb_eventbuffer_free_percent**: Percentage of free memory that should be available in event buffer before resumption of buffering, after reaching limit set by ndb_eventbuffer_max_alloc

- **ndb_eventbuffer_max_alloc**: Maximum memory that can be allocated for buffering events by the NDB API. Defaults to 0 (no limit).

- **Ndb_execute_count**: Provides the number of round trips to the NDB kernel made by operations

- **ndb_extra_logging**: Controls logging of NDB Cluster schema, connection, and data distribution events in the MySQL error log

- **ndb_force_send**: Forces sending of buffers to NDB immediately, without waiting for other threads

- **ndb_index_stat_cache_entries**: Sets the granularity of the statistics by determining the number of starting and ending keys

- **ndb_index_stat_enable**: Use NDB index statistics in query optimization

- **ndb_index_stat_option**: Comma-separated list of tunable options for NDB index statistics; the list should contain no spaces

- **ndb_index_stat_update_freq**: How often to query data nodes instead of the statistics cache

- **ndb_join_pushdown**: Enables pushing down of joins to data nodes

- **ndb_log_apply_status**: Whether or not a MySQL server acting as a slave logs mysql.ndb_apply_status updates received from its immediate master in its own binary log, using its own server ID

- **ndb_log_bin**: Write updates to NDB tables in the binary log. Effective only if binary logging is enabled with --log-bin.

- **ndb_log_binlog_index**: Insert mapping between epochs and binary log positions into the ndb_binlog_index table. Defaults to ON. Effective only if binary logging is enabled on the server.

- **ndb_log_empty_epochs**: When enabled, epochs in which there were no changes are written to the ndb_apply_status and ndb_binlog_index tables, even when log_slave_updates is enabled
Overview of NDB Cluster Configuration Parameters, Options, and Variables

- **ndb_log_empty_update**: When enabled, updates which produce no changes are written to the ndb_apply_status and ndb_binlog_index tables, even when log_slave_updates is enabled.

- **ndb_log_exclusive_reads**: Log primary key reads with exclusive locks; allow conflict resolution based on read conflicts.

- **ndb_log_orig**: Whether the id and epoch of the originating server are recorded in the mysql.ndb_binlog_index table. Set using the --ndb-log-orig option when starting mysqld.

- **ndb_log_transaction_id**: Whether NDB transaction IDs are written into the binary log (Read-only.)

- **ndb-log-update-minimal**: Log updates in a minimal format.

- **ndb_log_updated_only**: Log complete rows (ON) or updates only (OFF)

- **Ndb_number_of_data_nodes**: If the server is part of an NDB Cluster, the value of this variable is the number of data nodes in the cluster.

- **ndb-optimization-delay**: Sets the number of milliseconds to wait between processing sets of rows by OPTIMIZE TABLE on NDB tables.

- **ndb_optimized_node_selection**: Determines how an SQL node chooses a cluster data node to use as transaction coordinator.

- **Ndb_pruned_scan_count**: Number of scans executed by NDB since the cluster was last started where partition pruning could be used.

- **Ndb_pushed_queries_defined**: Number of joins that API nodes have attempted to push down to the data nodes.

- **Ndb_pushed_queries_dropped**: Number of joins that API nodes have tried to push down, but failed.

- **Ndb_pushed_queries_executed**: Number of joins successfully pushed down and executed on the data nodes.

- **Ndb_pushed_reads**: Number of reads executed on the data nodes by pushed-down joins.

- **ndb_recv_thread_activation_threshold**: Activation threshold when receive thread takes over the polling of the cluster connection (measured in concurrently active threads).

- **ndb_recv_thread_cpu_mask**: CPU mask for locking receiver threads to specific CPUs; specified as hexadecimal. See documentation for details.

- **ndb_report_thresh_binlog_epoch_slip**: NDB 7.5.4 and later: Threshold for number of epochs completely buffered, but not yet consumed by binlog injector thread which when exceeded generates BUFFERED_EPOCHS_OVER_THRESHOLD event buffer status message; prior to NDB 7.5.4: Threshold for number of epochs to lag behind before reporting binary log status.

- **ndb_report_thresh_binlog_mem_usage**: This is a threshold on the percentage of free memory remaining before reporting binary log status.

- **Ndb_scan_count**: The total number of scans executed by NDB since the cluster was last started.

- **ndb_show_foreign_key_mock_tables**: Show the mock tables used to support foreign_key_checks=0.

- **ndb_slave_conflict_role**: Role for slave to play in conflict detection and resolution. Value is one of PRIMARY, SECONDARY, PASS, or NONE (default). Can be changed only when slave SQL thread is stopped. See documentation for further information.
• **Ndb_slave_max_replicated_epoch**: The most recently committed NDB epoch on this slave. When this value is greater than or equal to Ndb_conflict_last_conflict_epoch, no conflicts have yet been detected.

• **ndb_table_no_logging**: NDB tables created when this setting is enabled are not checkpointed to disk (although table schema files are created). The setting in effect when the table is created with or altered to use NDBCLUSTER persists for the lifetime of the table.

• **ndb_table_temporary**: NDB tables are not persistent on disk: no schema files are created and the tables are not logged

• **ndb_use_exact_count**: Use exact row count when planning queries

• **ndb_use_transactions**: Forces NDB to use a count of records during SELECT COUNT(‘) query planning to speed up this type of query

• **ndb_version**: Shows build and NDB engine version as an integer

• **ndb_version_string**: Shows build information including NDB engine version in ndb-x.y.z format

• **ndbcluster**: Enable NDB Cluster (if this version of MySQL supports it) Disabled by `--skip-ndbcluster`

• **ndbinfo_database**: The name used for the NDB information database; read only

• **ndbinfo_max_bytes**: Used for debugging only

• **ndbinfo_max_rows**: Used for debugging only

• **ndbinfo_offline**: Put the ndbinfo database into offline mode, in which no rows are returned from tables or views

• **ndbinfo_show_hidden**: Whether to show ndbinfo internal base tables in the mysql client. The default is OFF.

• **ndbinfo_table_prefix**: The prefix to use for naming ndbinfo internal base tables

• **ndbinfo_version**: The version of the ndbinfo engine; read only

• **server-id-bits**: Sets the number of least significant bits in the server_id actually used for identifying the server, permitting NDB API applications to store application data in the most significant bits. server_id must be less than 2 to the power of this value.

• **slave_allow_batching**: Turns update batching on and off for a replication slave

• **transaction_allow_batching**: Allows batching of statements within a transaction. Disable AUTOCOMMIT to use.

### 18.3.3 NDB Cluster Configuration Files

Configuring NDB Cluster requires working with two files:

• **my.cnf**: Specifies options for all NDB Cluster executables. This file, with which you should be familiar with from previous work with MySQL, must be accessible by each executable running in the cluster.

• **config.ini**: This file, sometimes known as the *global configuration file*, is read only by the NDB Cluster management server, which then distributes the information contained therein to all processes participating in the cluster. `config.ini` contains a description of each node involved in the cluster. This includes configuration parameters for data nodes and configuration parameters for connections between
all nodes in the cluster. For a quick reference to the sections that can appear in this file, and what sorts of configuration parameters may be placed in each section, see Sections of the config.ini File.

Caching of configuration data. In NDB Cluster 7.3 and later, NDB uses stateful configuration. Rather than reading the global configuration file every time the management server is restarted, the management server caches the configuration the first time it is started, and thereafter, the global configuration file is read only when one of the following conditions is true:

• **The management server is started using the --initial option.** When --initial is used, the global configuration file is re-read, any existing cache files are deleted, and the management server creates a new configuration cache.

• **The management server is started using the --reload option.** The --reload option causes the management server to compare its cache with the global configuration file. If they differ, the management server creates a new configuration cache; any existing configuration cache is preserved, but not used. If the management server's cache and the global configuration file contain the same configuration data, then the existing cache is used, and no new cache is created.

• **The management server is started using --config-cache=FALSE.** This disables --config-cache (enabled by default), and can be used to force the management server to bypass configuration caching altogether. In this case, the management server ignores any configuration files that may be present, always reading its configuration data from the config.ini file instead.

• **No configuration cache is found.** In this case, the management server reads the global configuration file and creates a cache containing the same configuration data as found in the file.

Configuration cache files. The management server by default creates configuration cache files in a directory named mysql-cluster in the MySQL installation directory. (If you build NDB Cluster from source on a Unix system, the default location is /usr/local/mysql-cluster.) This can be overridden at runtime by starting the management server with the --configdir option. Configuration cache files are binary files named according to the pattern ndb_node_id_config.bin.seq_id, where node_id is the management server's node ID in the cluster, and seq_id is a cache identifier. Cache files are numbered sequentially using seq_id, in the order in which they are created. The management server uses the latest cache file as determined by the seq_id.

Note

It is possible to roll back to a previous configuration by deleting later configuration cache files, or by renaming an earlier cache file so that it has a higher seq_id. However, since configuration cache files are written in a binary format, you should not attempt to edit their contents by hand.

For more information about the --configdir, --config-cache, --initial, and --reload options for the NDB Cluster management server, see Section 18.4.4, "ndb_mgmd — The NDB Cluster Management Server Daemon".

We are continuously making improvements in Cluster configuration and attempting to simplify this process. Although we strive to maintain backward compatibility, there may be times when introduce an incompatible change. In such cases we will try to let Cluster users know in advance if a change is not backward compatible. If you find such a change and we have not documented it, please report it in the MySQL bugs database using the instructions given in Section 1.6, “How to Report Bugs or Problems”.

18.3.3.1 NDB Cluster Configuration: Basic Example

To support NDB Cluster, you will need to update my.cnf as shown in the following example. You may also specify these parameters on the command line when invoking the executables.
The options shown here should not be confused with those that are used in config.ini global configuration files. Global configuration options are discussed later in this section.

---

### Note

Important

Once you have started a mysqld process with the NDDBCLUSTER and ndb-connectstring parameters in the [mysqld] in the my.cnf file as shown previously, you cannot execute any CREATE TABLE or ALTER TABLE statements without having actually started the cluster. Otherwise, these statements will fail with an error. This is by design.

You may also use a separate [mysql_cluster] section in the cluster my.cnf file for settings to be read and used by all executables:

For additional NDB variables that can be set in the my.cnf file, see NDB Cluster System Variables.

The NDB Cluster global configuration file is by convention named config.ini (but this is not required). If needed, it is read by ndb_mgmd at startup and can be placed in any location that can be read by it. The location and name of the configuration are specified using --config-file=path_name with ndb_mgmd.
on the command line. This option has no default value, and is ignored if ndb_mgmd uses the configuration cache.

The global configuration file for NDB Cluster uses INI format, which consists of sections preceded by section headings (surrounded by square brackets), followed by the appropriate parameter names and values. One deviation from the standard INI format is that the parameter name and value can be separated by a colon (:) as well as the equal sign (=); however, the equal sign is preferred. Another deviation is that sections are not uniquely identified by section name. Instead, unique sections (such as two different nodes of the same type) are identified by a unique ID specified as a parameter within the section.

Default values are defined for most parameters, and can also be specified in config.ini. To create a default value section, simply add the word default to the section name. For example, an [ndbd] section contains parameters that apply to a particular data node, whereas an [ndbd default] section contains parameters that apply to all data nodes. Suppose that all data nodes should use the same data memory size. To configure them all, create an [ndbd default] section that contains a DataMemory line to specify the data memory size.

Note
In some older releases of NDB Cluster, there was no default value for NoOfReplicas, which always had to be specified explicitly in the [ndbd default] section. Although this parameter now has a default value of 2, which is the recommended setting in most common usage scenarios, it is still recommended practice to set this parameter explicitly.

The global configuration file must define the computers and nodes involved in the cluster and on which computers these nodes are located. An example of a simple configuration file for a cluster consisting of one management server, two data nodes and two MySQL servers is shown here:

```
# file "config.ini" - 2 data nodes and 2 SQL nodes
# This file is placed in the startup directory of ndb_mgmd (the management server)
# The first MySQL Server can be started from any host. The second can be started only on the host mysqld_5.mysql.com

[ndbd default]
NoOfReplicas= 2
DataDir= /var/lib/mysql-cluster

[ndb_mgmd]
Hostname= ndb_mgmd.mysql.com
DataDir= /var/lib/mysql-cluster

[ndbd]
HostName= ndbd_2.mysql.com

[ndbd]
HostName= ndbd_3.mysql.com

[mysqld]
[mysqld]
HostName= mysqld_5.mysql.com
```

Note
The preceding example is intended as a minimal starting configuration for purposes of familiarization with NDB Cluster, and is almost certain not to be sufficient for production settings. See Section 18.3.3.2, “Recommended Starting Configuration for NDB Cluster”, which provides a more complete example starting configuration.
Each node has its own section in the config.ini file. For example, this cluster has two data nodes, so the preceding configuration file contains two [ndbd] sections defining these nodes.

Note
Do not place comments on the same line as a section heading in the config.ini file; this causes the management server not to start because it cannot parse the configuration file in such cases.

Sections of the config.ini File

There are six different sections that you can use in the config.ini configuration file, as described in the following list:

- [computer]: Defines cluster hosts. This is not required to configure a viable NDB Cluster, but be may used as a convenience when setting up a large cluster. See Section 18.3.3.4, “Defining Computers in an NDB Cluster”, for more information.

- [ndbd]: Defines a cluster data node (ndbd process). See Section 18.3.3.6, “Defining NDB Cluster Data Nodes”, for details.

- [mysqld]: Defines the cluster’s MySQL server nodes (also called SQL or API nodes). For a discussion of SQL node configuration, see Section 18.3.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”.

- [mgm] or [ndb_mgmd]: Defines a cluster management server (MGM) node. For information concerning the configuration of management nodes, see Section 18.3.3.5, “Defining an NDB Cluster Management Server”.

- [tcp]: Defines a TCP/IP connection between cluster nodes, with TCP/IP being the default connection protocol. Normally, [tcp] or [tcp default] sections are not required to set up an NDB Cluster, as the cluster handles this automatically; however, it may be necessary in some situations to override the defaults provided by the cluster. See Section 18.3.3.9, “NDB Cluster TCP/IP Connections”, for information about available TCP/IP configuration parameters and how to use them. (You may also find Section 18.3.3.10, “NDB Cluster TCP/IP Connections Using Direct Connections” to be of interest in some cases.)

- [shm]: Defines shared-memory connections between nodes. In MySQL 5.6, it is enabled by default, but should still be considered experimental. For a discussion of SHM interconnects, see Section 18.3.3.11, “NDB Cluster Shared-Memory Connections”.

- [sci]: Defines Scalable Coherent Interface connections between cluster data nodes. Not supported in NDB 7.2 or later.

You can define default values for each section. NDB Cluster parameter names are case-insensitive, unless specified in MySQL Server my.cnf or my.ini files.

18.3.3.2 Recommended Starting Configuration for NDB Cluster

Achieving the best performance from an NDB Cluster depends on a number of factors including the following:

- NDB Cluster software version
- Numbers of data nodes and SQL nodes
- Hardware
- Operating system
• Amount of data to be stored

• Size and type of load under which the cluster is to operate

Therefore, obtaining an optimum configuration is likely to be an iterative process, the outcome of which can vary widely with the specifics of each NDB Cluster deployment. Changes in configuration are also likely to be indicated when changes are made in the platform on which the cluster is run, or in applications that use the NDB Cluster's data. For these reasons, it is not possible to offer a single configuration that is ideal for all usage scenarios. However, in this section, we provide a recommended base configuration.

Starting config.ini file. The following config.ini file is a recommended starting point for configuring a cluster running NDB Cluster 7.3 or later:

```ini
# TCP PARAMETERS
ttpd default
SendBufferMemory=2M
ReceiveBufferMemory=2M

# Increasing the sizes of these 2 buffers beyond the default values helps prevent bottlenecks due to slow disk I/O.

# MANAGEMENT NODE PARAMETERS
ndb_mgmd default
DataDir=path/to/management/server/data/directory

It is possible to use a different data directory for each management server, but for ease of administration it is preferable to be consistent.

[ndbd]
DataDir=ndbd/data/directory

# Using 2 management servers helps guarantee that there is always an arbitrator in the event of network partitioning, and so is recommended for high availability. Each management server must be identified by a HostName. You may for the sake of convenience specify a NodeId for any management server, although one will be allocated for it automatically; if you do so, it must be in the range 1-255 inclusive and must be unique among all IDs specified for cluster nodes.

# DATA NODE PARAMETERS
ndbd default
NoOfReplicas=2

# Using 2 replicas is recommended to guarantee availability of data; using only 1 replica does not provide any redundancy, which means that the failure of a single data node causes the entire cluster to shut down. We do not recommend using more than 2 replicas, since 2 is sufficient to provide high availability, and we do not currently test with greater values for this parameter.

LockPagesInMainMemory=1

On Linux and Solaris systems, setting this parameter locks data node processes into memory. Doing so prevents them from swapping to disk,
# which can severely degrade cluster performance.

DataMemory=3072M
IndexMemory=384M

# The values provided for DataMemory and IndexMemory assume 4 GB RAM per data node. However, for best results, you should first calculate the memory that would be used based on the data you actually plan to store (you may find the ndb_size.pl utility helpful in estimating this), then allow an extra 20% over the calculated values. Naturally, you should ensure that each data node host has at least as much physical memory as the sum of these two values.

# ODirect=1

# Enabling this parameter causes NDBCLUSTER to try using O DIRECT writes for local checkpoints and redo logs; this can reduce load on CPUs. We recommend doing so when using NDB Cluster on systems running Linux kernel 2.6 or later.

NoOfFragmentLogFiles=300
DataDir=path/to/data/node/data/directory
MaxNoOfConcurrentOperations=100000

SchedulerSpinTimer=400
SchedulerExecutionTimer=100
RealTimeScheduler=1

# Setting these parameters allows you to take advantage of real-time scheduling of NDB threads to achieve increased throughput when using ndbd. They are not needed when using ndbmtd; in particular, you should not set RealTimeScheduler for ndbmtd data nodes.

TimeBetweenGlobalCheckpoints=1000
TimeBetweenEpochs=200
DiskCheckpointSpeed=10M
DiskCheckpointSpeedInRestart=100M

# The two parameters just listed are deprecated in NDB 7.4.1 and later, where setting either or both of them has no effect; see Section 18.3.3.6, “Defining NDB Cluster Data Nodes”, for more information

RedoBuffer=32M

# CompressedLCP=1
# CompressedBackup=1

# Enabling CompressedLCP and CompressedBackup causes, respectively, local checkpoint files and backup files to be compressed, which can result in a space savings of up to 50% over noncompressed LCPs and backups.

MaxNoOfLocalScans=64
MaxNoOfTables=1024
MaxNoOfOrderedIndexes=256

[nbdb]
HostName=data-node-A-hostname
# NodeId=data-node-A-nodeid
LockExecuteThreadToCPU=1
LockMaintThreadsToCPU=0

# On systems with multiple CPUs, these parameters can be used to lock NDBCLUSTER threads to specific CPUs

[nbdb]
HostName=data-node-B-hostname
# NodeId=data-node-B-nodeid
LockExecuteThreadToCPU=1
LockMaintThreadsToCPU=0
You must have an [ndbd] section for every data node in the cluster; each of these sections must include a HostName. Each section may optionally include a NodeId for convenience, but in most cases, it is sufficient to allow the cluster to allocate node IDs dynamically. If you do specify the node ID for a data node, it must be in the range 1 to 48 inclusive and must be unique among all IDs specified for cluster nodes.

SQL NODE / API NODE PARAMETERS

[mysqld]
HostName=sql-node-A-hostname
NodeId=sql-node-A-nodeid

Each API or SQL node that connects to the cluster requires a [mysqld] or [api] section of its own. Each such section defines a connection "slot"; you should have at least as many of these sections in the config.ini file as the total number of API nodes and SQL nodes that you wish to have connected to the cluster at any given time. There is no performance or other penalty for having extra slots available in case you find later that you want or need more API or SQL nodes to connect to the cluster at the same time.

If no HostName is specified for a given [mysqld] or [api] section, then any API or SQL node may use that slot to connect to the cluster. You may wish to use an explicit HostName for one connection slot to guarantee that an API or SQL node from that host can always connect to the cluster. If you wish to prevent API or SQL nodes from connecting from other than a desired host or hosts, then use a HostName for every [mysqld] or [api] section in the config.ini file. You can if you wish define a node ID (NodeId parameter) for any API or SQL node, but this is not necessary; if you do so, it must be in the range 1 to 255 inclusive and must be unique among all IDs specified for cluster nodes.

Recommended my.cnf options for SQL nodes. MySQL Servers acting as NDB Cluster SQL nodes must always be started with the --ndbcluster and --ndb-connectstring options, either on the command line or in my.cnf. In addition, set the following options for all mysqld processes in the cluster, unless your setup requires otherwise:

- --ndb-use-exact-count=0
- --ndb-index-stat-enable=0
- --ndb-force-send=1
- --engine-condition-pushdown=1

18.3.3.3 NDB Cluster Connection Strings

With the exception of the NDB Cluster management server (ndb_mgmd), each node that is part of an NDB Cluster requires a connection string that points to the management server’s location. This connection string is used in establishing a connection to the management server as well as in performing other tasks depending on the node’s role in the cluster. The syntax for a connection string is as follows:

[nodeid=node_id, ]host-definition[, host-definition[, ...]]

host-definition:
  host_name[:port_number]
node_id is an integer greater than or equal to 1 which identifies a node in config.ini. host_name is a string representing a valid Internet host name or IP address. port_number is an integer referring to a TCP/IP port number.

example 1 (long): "nodeid=2,myhost1:1100,myhost2:1100,198.51.100.3:1200"
example 2 (short): "myhost1"

localhost:1186 is used as the default connection string value if none is provided. If port_num is omitted from the connection string, the default port is 1186. This port should always be available on the network because it has been assigned by IANA for this purpose (see http://www.iana.org/assignments/port-numbers for details).

By listing multiple host definitions, it is possible to designate several redundant management servers. An NDB Cluster data or API node attempts to contact successive management servers on each host in the order specified, until a successful connection has been established.

It is also possible to specify in a connection string one or more bind addresses to be used by nodes having multiple network interfaces for connecting to management servers. A bind address consists of a hostname or network address and an optional port number. This enhanced syntax for connection strings is shown here:

```
[nodeid=node_id, ]
[bind-address=host-definition, ]
  host-definition[; bind-address=host-definition]
  host-definition[; bind-address=host-definition]
  [, ...]

host-definition:
  host_name[:port_number]
```

If a single bind address is used in the connection string prior to specifying any management hosts, then this address is used as the default for connecting to any of them (unless overridden for a given management server; see later in this section for an example). For example, the following connection string causes the node to use 198.51.100.242 regardless of the management server to which it connects:

```
bind-address=198.51.100.242, poseidon:1186, perch:1186
```

If a bind address is specified following a management host definition, then it is used only for connecting to that management node. Consider the following connection string:

```
poseidon:1186;bind-address=localhost, perch:1186;bind-address=198.51.100.242
```

In this case, the node uses localhost to connect to the management server running on the host named poseidon and 198.51.100.242 to connect to the management server running on the host named perch.

You can specify a default bind address and then override this default for one or more specific management hosts. In the following example, localhost is used for connecting to the management server running on host poseidon; since 198.51.100.242 is specified first (before any management server definitions), it is the default bind address and so is used for connecting to the management servers on hosts perch and orca:

```
bind-address=198.51.100.242,poseidon:1186;bind-address=localhost, perch:1186,orca:2200
```

There are a number of different ways to specify the connection string:
Each executable has its own command-line option which enables specifying the management server at startup. (See the documentation for the respective executable.)

It is also possible to set the connection string for all nodes in the cluster at once by placing it in a `[mysql_cluster]` section in the management server's `my.cnf` file.

For backward compatibility, two other options are available, using the same syntax:

1. Set the `NDB_CONNECTSTRING` environment variable to contain the connection string.
2. Write the connection string for each executable into a text file named `Ndb.cfg` and place this file in the executable's startup directory.

However, these are now deprecated and should not be used for new installations.

The recommended method for specifying the connection string is to set it on the command line or in the `my.cnf` file for each executable.

### 18.3.3.4 Defining Computers in an NDB Cluster

The `[computer]` section has no real significance other than serving as a way to avoid the need of defining host names for each node in the system. All parameters mentioned here are required.

**Restart types.** Information about the restart types used by the parameter descriptions in this section is shown in the following table:

#### Table 18.6 NDB Cluster restart types

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Restart Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
<td>Node</td>
<td>The parameter can be updated using a rolling restart (see Section 18.5.5, &quot;Performing a Rolling Restart of an NDB Cluster&quot;)</td>
</tr>
<tr>
<td>S</td>
<td>System</td>
<td>All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter</td>
</tr>
<tr>
<td>I</td>
<td>Initial</td>
<td>Data nodes must be restarted using the <code>--initial</code> option</td>
</tr>
</tbody>
</table>

**Id**

#### Table 18.7 This table provides type and value information for the Id computer configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>string</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IS</td>
</tr>
</tbody>
</table>

This is a unique identifier, used to refer to the host computer elsewhere in the configuration file.

**Important**

The computer ID is *not* the same as the node ID used for a management, API, or data node. Unlike the case with node IDs, you cannot use `Node Id` in place of `Id` in the `[computer]` section of the `config.ini` file.
• HostName

Table 18.8 This table provides type and value information for the HostName computer configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>

<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This is the computer's hostname or IP address.

### 18.3.3.5 Defining an NDB Cluster Management Server

The [ndb_mgmd] section is used to configure the behavior of the management server. If multiple management servers are employed, you can specify parameters common to all of them in an [ndb_mgmd default] section. [mgm] and [mgm default] are older aliases for these, supported for backward compatibility.

All parameters in the following list are optional and assume their default values if omitted.

Note

If neither the ExecuteOnComputer nor the HostName parameter is present, the default value localhost will be assumed for both.

**Restart types.** Information about the restart types used by the parameter descriptions in this section is shown in the following table:

Table 18.9 NDB Cluster restart types

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Restart Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
<td>Node</td>
<td>The parameter can be updated using a rolling restart (see Section 18.5.5, “Performing a Rolling Restart of an NDB Cluster”)</td>
</tr>
<tr>
<td>S</td>
<td>System</td>
<td>All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter</td>
</tr>
<tr>
<td>I</td>
<td>Initial</td>
<td>Data nodes must be restarted using the --initial option</td>
</tr>
</tbody>
</table>

• Id

Table 18.10 This table provides type and value information for the Id management node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 255</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IS</td>
</tr>
</tbody>
</table>
Each node in the cluster has a unique identity. For a management node, this is represented by an integer value in the range 1 to 255, inclusive. This ID is used by all internal cluster messages for addressing the node, and so must be unique for each NDB Cluster node, regardless of the type of node.

Note

Data node IDs must be less than 49. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for management nodes (and API nodes) to values greater than 48.

The use of the `Id` parameter for identifying management nodes is deprecated in favor of `NodeId`. Although `Id` continues to be supported for backward compatibility, it now generates a warning and is subject to removal in a future version of NDB Cluster.

- **NodeId**

Table 18.11 This table provides type and value information for the `NodeId` management node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 255</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IS</td>
</tr>
</tbody>
</table>

Each node in the cluster has a unique identity. For a management node, this is represented by an integer value in the range 1 to 255 inclusive. This ID is used by all internal cluster messages for addressing the node, and so must be unique for each NDB Cluster node, regardless of the type of node.

Note

Data node IDs must be less than 49. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for management nodes (and API nodes) to values greater than 48.

- **NodeId** is the preferred parameter name to use when identifying management nodes. Although the older `Id` continues to be supported for backward compatibility, it is now deprecated and generates a warning when used; it is also subject to removal in a future NDB Cluster release.

- **ExecuteOnComputer**

Table 18.12 This table provides type and value information for the `ExecuteOnComputer` management node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>name</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

2665
This refers to the Id set for one of the computers defined in a [computer] section of the config.ini file.

- **PortNumber**

  Table 18.13 This table provides type and value information for the PortNumber management node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>1186</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 64K</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>S</td>
</tr>
</tbody>
</table>

This is the port number on which the management server listens for configuration requests and management commands.

- **HostName**

  Table 18.14 This table provides type and value information for the HostName management node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>name or IP address</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

Specifying this parameter defines the hostname of the computer on which the management node is to reside. To specify a hostname other than localhost, either this parameter or ExecuteOnComputer is required.

- **LogDestination**

  Table 18.15 This table provides type and value information for the LogDestination management node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>{CONSOLE</td>
</tr>
<tr>
<td>Default</td>
<td>[see text]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter specifies where to send cluster logging information. There are three options in this regard—CONSOLE, SYSLOG, and FILE—with FILE being the default:

- **CONSOLE** outputs the log to stdout:
SYSLOG sends the log to a syslog facility, possible values being one of auth, authpriv, cron, daemon, ftp, kern, lpr, mail, news, syslog, user, uucp, local0, local1, local2, local3, local4, local5, local6, or local7.

Note
Not every facility is necessarily supported by every operating system.

SYSLOG:facility=syslog

FILE pipes the cluster log output to a regular file on the same machine. The following values can be specified:

- **filename**: The name of the log file.

  In NDB Cluster 7.3 and later, the default log file name used in such cases is `ndb_nodeid_cluster.log` (in some older versions, the log file's default name, used if `FILE` was specified without also setting `filename`, was `logger.log`).

- **maxsize**: The maximum size (in bytes) to which the file can grow before logging rolls over to a new file. When this occurs, the old log file is renamed by appending `.N` to the file name, where `N` is the next number not yet used with this name.

- **maxfiles**: The maximum number of log files.

FILE:filename=cluster.log,maxsize=1000000,maxfiles=6

The default value for the `FILE` parameter is

**FILE:filename=ndb_nodeid_cluster.log,maxsize=1000000,maxfiles=6, where node_id is the ID of the node.**

It is possible to specify multiple log destinations separated by semicolons as shown here:

CONSOLE;SYSLOG:facility=local0;FILE:filename=/var/log/mgmd

- **ArbitrationRank**

  **Table 18.16 This table provides type and value information for the ArbitrationRank management node configuration parameter**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>0-2</td>
</tr>
<tr>
<td>Default</td>
<td>1</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 2</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is used to define which nodes can act as arbitrators. Only management nodes and SQL nodes can be arbitrators. `ArbitrationRank` can take one of the following values:
NDB Cluster Configuration Files

- **0**: The node will never be used as an arbitrator.
- **1**: The node has high priority; that is, it will be preferred as an arbitrator over low-priority nodes.
- **2**: Indicates a low-priority node which be used as an arbitrator only if a node with a higher priority is not available for that purpose.

Normally, the management server should be configured as an arbitrator by setting its `ArbitrationRank` to 1 (the default for management nodes) and those for all SQL nodes to 0 (the default for SQL nodes).

You can disable arbitration completely either by setting `ArbitrationRank` to 0 on all management and SQL nodes, or by setting the `Arbitration` parameter in the `[ndbd default]` section of the `config.ini` global configuration file. Setting `Arbitration` causes any settings for `ArbitrationRank` to be disregarded.

- **ArbitrationDelay**

  **Table 18.17** This table provides type and value information for the ArbitrationDelay management node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

An integer value which causes the management server’s responses to arbitration requests to be delayed by that number of milliseconds. By default, this value is 0; it is normally not necessary to change it.

- **DataDir**

  **Table 18.18** This table provides type and value information for the DataDir management node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>path</td>
</tr>
<tr>
<td>Default</td>
<td>.</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This specifies the directory where output files from the management server will be placed. These files include cluster log files, process output files, and the daemon’s process ID (PID) file. (For log files, this location can be overridden by setting the `FILE` parameter for `LogDestination` as discussed previously in this section.)

The default value for this parameter is the directory in which `ndb_mgmd` is located.

- **PortNumberStats**
Table 18.19 This table provides type and value information for the PortNumberStats management node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 64K</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter specifies the port number used to obtain statistical information from an NDB Cluster management server. It has no default value.

- **Wan**

Table 18.20 This table provides type and value information for the wan management node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Use WAN TCP setting as default.

- **HeartbeatThreadPriority**

Table 18.21 This table provides type and value information for the HeartbeatThreadPriority management node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>string</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

Set the scheduling policy and priority of heartbeat threads for management and API nodes.

The syntax for setting this parameter is shown here:

```
HeartbeatThreadPriority = policy[, priority]

policy:
  {FIFO | RR}
```
When setting this parameter, you must specify a policy. This is one of **FIFO** (first in, first out) or **RR** (round robin). The policy value is followed optionally by the priority (an integer).

- **TotalSendBufferMemory**

Table 18.22 This table provides type and value information for the TotalSendBufferMemory management node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>256K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

If this parameter is set, its minimum permitted value is 256KB; 0 indicates that the parameter has not been set. For more detailed information, see Section 18.3.3.13, “Configuring NDB Cluster Send Buffer Parameters”.

- **HeartbeatIntervalMgmdMgmd**

Table 18.23 This table provides type and value information for the HeartbeatIntervalMgmdMgmd management node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.3</td>
</tr>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>1500</td>
</tr>
<tr>
<td>Range</td>
<td>100 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Specify the interval between heartbeat messages used to determine whether another management node is on contact with this one. The management node waits after 3 of these intervals to declare the connection dead; thus, the default setting of 1500 milliseconds causes the management node to wait for approximately 1600 ms before timing out.

This parameter was added in NDB 7.3.3. (Bug #16426805)

![Note]

After making changes in a management node's configuration, it is necessary to perform a rolling restart of the cluster for the new configuration to take effect.

To add new management servers to a running NDB Cluster, it is also necessary to perform a rolling restart of all cluster nodes after modifying any existing config.ini files. For more information about issues arising when using multiple management nodes, see Section 18.1.7.10, “Limitations Relating to Multiple NDB Cluster Nodes”.
18.3.3.6 Defining NDB Cluster Data Nodes

The [ndbd] and [ndbd default] sections are used to configure the behavior of the cluster’s data nodes.

[ndbd] and [ndbd default] are always used as the section names whether you are using ndbd or ndbmtd binaries for the data node processes.

There are many parameters which control buffer sizes, pool sizes, timeouts, and so forth. The only mandatory parameter is either one of ExecuteOnComputer or HostName; this must be defined in the local [ndbd] section.

The parameter NoOfReplicas should be defined in the [ndbd default] section, as it is common to all Cluster data nodes. It is not strictly necessary to set NoOfReplicas, but it is good practice to set it explicitly.

Most data node parameters are set in the [ndbd default] section. Only those parameters explicitly stated as being able to set local values are permitted to be changed in the [ndbd] section. Where present, HostName, NodeId and ExecuteOnComputer must be defined in the local [ndbd] section, and not in any other section of config.ini. In other words, settings for these parameters are specific to one data node.

For those parameters affecting memory usage or buffer sizes, it is possible to use K, M, or G as a suffix to indicate units of 1024, 1024×1024, or 1024×1024×1024. (For example, 100K means 100 × 1024 = 102400.)

Parameter names and values are case-insensitive, unless used in a MySQL Server my.cnf or my.ini file, in which case they are case sensitive.

Information about configuration parameters specific to NDB Cluster Disk Data tables can be found later in this section (see Disk Data Configuration Parameters).

All of these parameters also apply to ndbmtd (the multithreaded version of ndbd). Three additional data node configuration parameters—MaxNoOfExecutionThreads, ThreadConfig, and NoOfFragmentLogParts—apply to ndbmtd only; these have no effect when used with ndbd. For more information, see Multi-Threading Configuration Parameters (ndbmtd). See also Section 18.4.3, “ndbmtd — The NDB Cluster Data Node Daemon (Multi-Threaded)”.

Restart types. Information about the restart types used by the parameter descriptions in this section is shown in the following table:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Restart Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
<td>Node</td>
<td>The parameter can be updated using a rolling restart (see Section 18.5.5, “Performing a Rolling Restart of an NDB Cluster”)</td>
</tr>
<tr>
<td>S</td>
<td>System</td>
<td>All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter</td>
</tr>
<tr>
<td>I</td>
<td>Initial</td>
<td>Data nodes must be restarted using the --initial option</td>
</tr>
</tbody>
</table>

Identifying data nodes. The NodeId or Id value (that is, the data node identifier) can be allocated on the command line when the node is started or in the configuration file.

- Id
Table 18.25 This table provides type and value information for the Id data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 48</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IS</td>
</tr>
</tbody>
</table>

A unique node ID is used as the node's address for all cluster internal messages. For data nodes, this is an integer in the range 1 to 48 inclusive. Each node in the cluster must have a unique identifier.

NodeId is the preferred parameter name to use when identifying data nodes. Although the older Id is still supported for backward compatibility, it is now deprecated, and generates a warning when used. Id is also subject to removal in a future NDB Cluster release.

- **NodeId**

Table 18.26 This table provides type and value information for the NodeId data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 48</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IS</td>
</tr>
</tbody>
</table>

A unique node ID is used as the node's address for all cluster internal messages. For data nodes, this is an integer in the range 1 to 48 inclusive. Each node in the cluster must have a unique identifier.

NodeId is the preferred parameter name to use when identifying data nodes. Although Id continues to be supported for backward compatibility, it is now deprecated, generates a warning when used, and is subject to removal in a future version of NDB Cluster.

- **ExecuteOnComputer**

Table 18.27 This table provides type and value information for the ExecuteOnComputer data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>name</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

This refers to the Id set for one of the computers defined in a [computer] section.
NDB Cluster Configuration Files

- **HostName**

  Table 18.28 This table provides type and value information for the HostName data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>name or IP address</td>
</tr>
<tr>
<td>Default</td>
<td>localhost</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td><strong>N</strong></td>
</tr>
</tbody>
</table>

Specifying this parameter defines the hostname of the computer on which the data node is to reside. To specify a hostname other than `localhost`, either this parameter or `ExecuteOnComputer` is required.

- **ServerPort**

  Table 18.29 This table provides type and value information for the ServerPort data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 64K</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td><strong>S</strong></td>
</tr>
</tbody>
</table>

Each node in the cluster uses a port to connect to other nodes. By default, this port is allocated dynamically in such a way as to ensure that no two nodes on the same host computer receive the same port number, so it should normally not be necessary to specify a value for this parameter.

However, if you need to be able to open specific ports in a firewall to permit communication between data nodes and API nodes (including SQL nodes), you can set this parameter to the number of the desired port in an `[ndbd]` section or (if you need to do this for multiple data nodes) the `[ndbd default]` section of the `config.ini` file, and then open the port having that number for incoming connections from SQL nodes, API nodes, or both.

- **TcpBind_INADDR_ANY**

  Setting this parameter to `TRUE` or `1` binds `IP_ADDR_ANY` so that connections can be made from anywhere (for autogenerated connections). The default is `FALSE (0)`.

- **NodeGroup**
Table 18.30 This table provides type and value information for the NodeGroup data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td></td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 65536</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IS</td>
</tr>
</tbody>
</table>

This parameter can be used to assign a data node to a specific node group. It is read only when the cluster is started for the first time, and cannot be used to reassign a data node to a different node group online. It is generally not desirable to use this parameter in the [ndbd default] section of the config.ini file, and care must be taken not to assign nodes to node groups in such a way that an invalid numbers of nodes are assigned to any node groups.

The NodeGroup parameter is chiefly intended for use in adding a new node group to a running NDB Cluster without having to perform a rolling restart. For this purpose, you should set it to 65536 (the maximum value). You are not required to set a NodeGroup value for all cluster data nodes, only for those nodes which are to be started and added to the cluster as a new node group at a later time. For more information, see Section 18.5.14.3, “Adding NDB Cluster Data Nodes Online: Detailed Example”.

- NoOfReplicas

Table 18.31 This table provides type and value information for the NoOfReplicas data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>2</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 4</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IS</td>
</tr>
</tbody>
</table>

This global parameter can be set only in the [ndbd default] section, and defines the number of replicas for each table stored in the cluster. This parameter also specifies the size of node groups. A node group is a set of nodes all storing the same information.

Node groups are formed implicitly. The first node group is formed by the set of data nodes with the lowest node IDs, the next node group by the set of the next lowest node identities, and so on. By way of example, assume that we have 4 data nodes and that NoOfReplicas is set to 2. The four data nodes have node IDs 2, 3, 4 and 5. Then the first node group is formed from nodes 2 and 3, and the second node group by nodes 4 and 5. It is important to configure the cluster in such a manner that nodes in the same node groups are not placed on the same computer because a single hardware failure would cause the entire cluster to fail.

If no node IDs are provided, the order of the data nodes will be the determining factor for the node group. Whether or not explicit assignments are made, they can be viewed in the output of the management client's SHOW command.
The default value for `NoOfReplicas` is 2. *This is the recommended value for most production environments.*

Important

While the maximum *possible* value for this parameter is 4, *setting* `NoOfReplicas` to a value greater than 2 is *not supported in production.*

Warning

Setting `NoOfReplicas` to 1 means that there is only a single copy of all Cluster data; in this case, the loss of a single data node causes the cluster to fail because there are no additional copies of the data stored by that node.

The value for this parameter must divide evenly into the number of data nodes in the cluster. For example, if there are two data nodes, then `NoOfReplicas` must be equal to either 1 or 2, since 2/3 and 2/4 both yield fractional values; if there are four data nodes, then `NoOfReplicas` must be equal to 1, 2, or 4.

- **DataDir**

  Table 18.32 This table provides type and value information for the DataDir data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>path</td>
</tr>
<tr>
<td>Default</td>
<td>.</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IN</td>
</tr>
</tbody>
</table>

This parameter specifies the directory where trace files, log files, pid files and error logs are placed.

The default is the data node process working directory.

- **FileSystemPath**

  Table 18.33 This table provides type and value information for the FileSystemPath data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>path</td>
</tr>
<tr>
<td>Default</td>
<td>DataDir</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IN</td>
</tr>
</tbody>
</table>

This parameter specifies the directory where all files created for metadata, REDO logs, UNDO logs (for Disk Data tables), and data files are placed. The default is the directory specified by `DataDir`.  

2675
NDB Cluster Configuration Files

Note
This directory must exist before the \texttt{ndbd} process is initiated.

The recommended directory hierarchy for NDB Cluster includes \texttt{/var/lib/mysql-cluster}, under which a directory for the node's file system is created. The name of this subdirectory contains the node ID. For example, if the node ID is 2, this subdirectory is named \texttt{ndb\_2\_fs}.

- \textbf{BackupDataDir}

\textbf{Table 18.34} This table provides type and value information for the BackupDataDir data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>

This parameter specifies the directory in which backups are placed.

\textbf{Important}

The string '\texttt{/BACKUP}' is always appended to this value. For example, if you set the value of \texttt{BackupDataDir} to \texttt{/var/lib/cluster-data}, then all backups are stored under \texttt{/var/lib/cluster-data/BACKUP}. This also means that the \textit{effective} default backup location is the directory named \texttt{BACKUP} under the location specified by the \texttt{FileSystemPath} parameter.

Data Memory, Index Memory, and String Memory

\texttt{DataMemory} and \texttt{IndexMemory} are \texttt{[ndbd]} parameters specifying the size of memory segments used to store the actual records and their indexes. In setting values for these, it is important to understand how \texttt{DataMemory} and \texttt{IndexMemory} are used, as they usually need to be updated to reflect actual usage by the cluster:

- \textbf{DataMemory}

\textbf{Table 18.35} This table provides type and value information for the DataMemory data node configuration parameter

<table>

<td>1M - 1T</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>
This parameter defines the amount of space (in bytes) available for storing database records. The entire amount specified by this value is allocated in memory, so it is extremely important that the machine has sufficient physical memory to accommodate it.

The memory allocated by DataMemory is used to store both the actual records and indexes. There is a 16-byte overhead on each record; an additional amount for each record is incurred because it is stored in a 32KB page with 128 byte page overhead (see below). There is also a small amount wasted per page due to the fact that each record is stored in only one page.

For variable-size table attributes, the data is stored on separate data pages, allocated from DataMemory. Variable-length records use a fixed-size part with an extra overhead of 4 bytes to reference the variable-size part. The variable-size part has 2 bytes overhead plus 2 bytes per attribute.

The maximum record size is 14000 bytes.

The memory space defined by DataMemory is also used to store ordered indexes, which use about 10 bytes per record. Each table row is represented in the ordered index. A common error among users is to assume that all indexes are stored in the memory allocated by IndexMemory, but this is not the case: Only primary key and unique hash indexes use this memory; ordered indexes use the memory allocated by DataMemory. However, creating a primary key or unique hash index also creates an ordered index on the same keys, unless you specify USING HASH in the index creation statement. This can be verified by running ndb_desc -d db_name table_name in the management client.

NDB Cluster can use a maximum of 512 MB for hash indexes per partition, which means in some cases it is possible to get Table is full errors in MySQL client applications even when ndb_mgm -e "ALL REPORT MEMORYUSAGE" shows significant free DataMemory. This can also pose a problem with data node restarts on nodes that are heavily loaded with data.

You can force NDB to create extra partitions for NDB Cluster tables and thus have more memory available for hash indexes by using the MAX_ROWS option for CREATE TABLE. In general, setting MAX_ROWS to twice the number of rows that you expect to store in the table should be sufficient.

You can also use the MinFreePct configuration parameter to help avoid problems with node restarts.

The memory space allocated by DataMemory consists of 32KB pages, which are allocated to table fragments. Each table is normally partitioned into the same number of fragments as there are data nodes in the cluster. Thus, for each node, there are the same number of fragments as are set in NoOfReplicas.

Once a page has been allocated, it is currently not possible to return it to the pool of free pages, except by deleting the table. (This also means that DataMemory pages, once allocated to a given table, cannot be used by other tables.) Performing a data node recovery also compresses the partition because all records are inserted into empty partitions from other live nodes.

The DataMemory memory space also contains UNDO information: For each update, a copy of the unaltered record is allocated in the DataMemory. There is also a reference to each copy in the ordered table indexes. Unique hash indexes are updated only when the unique index columns are updated, in which case a new entry in the index table is inserted and the old entry is deleted upon commit. For this reason, it is also necessary to allocate enough memory to handle the largest transactions performed by applications using the cluster. In any case, performing a few large transactions holds no advantage over using many smaller ones, for the following reasons:

• Large transactions are not any faster than smaller ones
• Large transactions increase the number of operations that are lost and must be repeated in event of transaction failure

• Large transactions use more memory

The default value for DataMemory is 80MB; the minimum is 1MB. There is no maximum size, but in reality the maximum size has to be adapted so that the process does not start swapping when the limit is reached. This limit is determined by the amount of physical RAM available on the machine and by the amount of memory that the operating system may commit to any one process. 32-bit operating systems are generally limited to 2−4GB per process; 64-bit operating systems can use more. For large databases, it may be preferable to use a 64-bit operating system for this reason.

• IndexMemory

Table 18.36 This table provides type and value information for the IndexMemory data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>

<td>N</td>
</tr>
</tbody>
</table>

This parameter controls the amount of storage used for hash indexes in NDB Cluster. Hash indexes are always used for primary key indexes, unique indexes, and unique constraints. When defining a primary key or a unique index, two indexes are created, one of which is a hash index used for all tuple accesses as well as lock handling. This index is also used to enforce unique constraints.

You can estimate the size of a hash index using this formula:

\[
\text{size} = (\text{fragments} \times 32K) + (\text{rows} \times 18) \times \text{replicas}
\]

fragments is the number of fragments, replicas is the number of replicas (normally 2), and rows is the number of rows. If a table has one million rows, 8 fragments, and 2 replicas, the expected index memory usage is calculated as shown here:

\[
\begin{align*}
((8 \times 32K) + (1000000 \times 18)) \times 2 &= ((8 \times 32768) + (1000000 \times 18)) \times 2 \\
&= (262144 + 18000000) \times 2 \\
&= 18262144 \times 2 = 36524288 \text{ bytes} = \sim 35\text{MB}
\end{align*}
\]

In NDB Cluster 7.2 and later, index statistics (when enabled) for ordered indexes are stored in the mysql.ndb_index_stat_sample table. Since this table has a hash index, this adds to index memory usage. An upper bound to the number of rows for a given ordered index can be calculated as follows:

\[
\begin{align*}
\text{sample_size} &= \text{key_size} + ((\text{key_attributes} + 1) \times 4) \\
\text{sample_rows} &= \text{IndexStatSaveSize} \times ((0.01 \times \text{IndexStatSaveScale} \times \log_2(\text{rows} \times \text{sample_size})) + 1) / \text{sample_size}
\end{align*}
\]
In the preceding formula, \(key\_size\) is the size of the ordered index key in bytes, \(key\_attributes\) is the number of attributes in the ordered index key, and \(rows\) is the number of rows in the base table.

Assume that table \(t1\) has 1 million rows and an ordered index named \(ix1\) on two four-byte integers. Assume in addition that \(IndexStatSaveSize\) and \(IndexStatSaveScale\) are set to their default values (32K and 100, respectively). Using the previous 2 formulas, we can calculate as follows:

\[
sample\_size = 8 + ((1 + 2) \times 4) = 20 \text{ bytes}
\]

\[
sample\_rows = 32K \times \left(\frac{0.01 \times 100 \times \log_2(1000000 \times 20)) + 1}{20}\right)
\]

\[
= 32768 \times \left(\frac{1 \times 16.811}{20}\right)
\]

\[
= 32768 \times \sim17.811 / 20
\]

\[
= \sim29182 \text{ rows}
\]

The expected index memory usage is thus \(2 \times 18 \times 29182 = \sim1050550\) bytes.

The default value for \(IndexMemory\) is 18MB. The minimum is 1MB.

- **StringMemory**

Table 18.37 This table provides type and value information for the StringMemory data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>

<tr>
<td>Type or units</td>
<td>% or bytes</td>
</tr>
<tr>
<td>Default</td>
<td>25</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

This parameter determines how much memory is allocated for strings such as table names, and is specified in an [ndbd] or [ndbd default] section of the config.ini file. A value between 0 and 100 inclusive is interpreted as a percent of the maximum default value, which is calculated based on a number of factors including the number of tables, maximum table name size, maximum size of .FRM files, MaxNoOfTriggers, maximum column name size, and maximum default column value.

A value greater than 100 is interpreted as a number of bytes.

The default value is 25—that is, 25 percent of the default maximum.

Under most circumstances, the default value should be sufficient, but when you have a great many Cluster tables (1000 or more), it is possible to get Error 773 Out of string memory, please modify StringMemory config parameter: Permanent error: Schema error, in which case you should increase this value. 25 (25 percent) is not excessive, and should prevent this error from recurring in all but the most extreme conditions.

The following example illustrates how memory is used for a table. Consider this table definition:

```sql
CREATE TABLE example (  
a INT NOT NULL,  
b INT NOT NULL,  
c INT NOT NULL,
```
For each record, there are 12 bytes of data plus 12 bytes overhead. Having no nullable columns saves 4 bytes of overhead. In addition, we have two ordered indexes on columns a and b consuming roughly 10 bytes each per record. There is a primary key hash index on the base table using roughly 29 bytes per record. The unique constraint is implemented by a separate table with b as primary key and a as a column. This other table consumes an additional 29 bytes of index memory per record in the example table as well 8 bytes of record data plus 12 bytes of overhead.

Thus, for one million records, we need 58MB for index memory to handle the hash indexes for the primary key and the unique constraint. We also need 64MB for the records of the base table and the unique index table, plus the two ordered index tables.

You can see that hash indexes takes up a fair amount of memory space; however, they provide very fast access to the data in return. They are also used in NDB Cluster to handle uniqueness constraints.

The only partitioning algorithm is hashing and ordered indexes are local to each node. Thus, ordered indexes cannot be used to handle uniqueness constraints in the general case.

An important point for both IndexMemory and DataMemory is that the total database size is the sum of all data memory and all index memory for each node group. Each node group is used to store replicated information, so if there are four nodes with two replicas, there will be two node groups. Thus, the total data memory available is 2 x DataMemory for each data node.

It is highly recommended that DataMemory and IndexMemory be set to the same values for all nodes. Data distribution is even over all nodes in the cluster, so the maximum amount of space available for any node can be no greater than that of the smallest node in the cluster.

DataMemory and IndexMemory can be changed, but decreasing either of these can be risky; doing so can easily lead to a node or even an entire NDB Cluster that is unable to restart due to there being insufficient memory space. Increasing these values should be acceptable, but it is recommended that such upgrades are performed in the same manner as a software upgrade, beginning with an update of the configuration file, and then restarting the management server followed by restarting each data node in turn.

MinFreePct. A proportion (5% by default) of data node resources including DataMemory and IndexMemory is kept in reserve to insure that the data node does not exhaust its memory when performing a restart. This can be adjusted using the MinFreePct data node configuration parameter (default 5).

#### Table 18.38 This table provides type and value information for the MinFreePct data node configuration parameter

</tbody>
</table>

Updates do not increase the amount of index memory used. Inserts take effect immediately; however, rows are not actually deleted until the transaction is committed.

**Transaction parameters.** The next few [ndbd] parameters that we discuss are important because they affect the number of parallel transactions and the sizes of transactions that can be handled by the
system. **MaxNoOfConcurrentTransactions** sets the number of parallel transactions possible in a node. **MaxNoOfConcurrentOperations** sets the number of records that can be in update phase or locked simultaneously.

Both of these parameters (especially **MaxNoOfConcurrentOperations**) are likely targets for users setting specific values and not using the default value. The default value is set for systems using small transactions, to ensure that these do not use excessive memory.

**MaxDMLOperationsPerTransaction** sets the maximum number of DML operations that can be performed in a given transaction.

- **MaxNoOfConcurrentTransactions**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>4096</td>
</tr>
<tr>

<td>32 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Each cluster data node requires a transaction record for each active transaction in the cluster. The task of coordinating transactions is distributed among all of the data nodes. The total number of transaction records in the cluster is the number of transactions in any given node times the number of nodes in the cluster.

Transaction records are allocated to individual MySQL servers. Each connection to a MySQL server requires at least one transaction record, plus an additional transaction object per table accessed by that connection. This means that a reasonable minimum for the total number of transactions in the cluster can be expressed as

\[
\text{TotalNoOfConcurrentTransactions} = (\text{maximum number of tables accessed in any single transaction} + 1) 
\times \text{number of SQL nodes}
\]

Suppose that there are 10 SQL nodes using the cluster. A single join involving 10 tables requires 11 transaction records; if there are 10 such joins in a transaction, then 10 \(\times\) 11 = 110 transaction records are required for this transaction, per MySQL server, or 110 \(\times\) 10 = 1100 transaction records total. Each data node can be expected to handle TotalNoOfConcurrentTransactions / number of data nodes. For an NDB Cluster having 4 data nodes, this would mean setting MaxNoOfConcurrentTransactions on each data node to 1100 / 4 = 275. In addition, you should provide for failure recovery by ensuring that a single node group can accommodate all concurrent transactions; in other words, that each data node's MaxNoOfConcurrentTransactions is sufficient to cover a number of transactions equal to TotalNoOfConcurrentTransactions / number of node groups. If this cluster has a single node group, then MaxNoOfConcurrentTransactions should be set to 1100 (the same as the total number of concurrent transactions for the entire cluster).

In addition, each transaction involves at least one operation; for this reason, the value set for MaxNoOfConcurrentTransactions should always be no more than the value of MaxNoOfConcurrentOperations.
This parameter must be set to the same value for all cluster data nodes. This is due to the fact that, when a data node fails, the oldest surviving node re-creates the transaction state of all transactions that were ongoing in the failed node.

It is possible to change this value using a rolling restart, but the amount of traffic on the cluster must be such that no more transactions occur than the lower of the old and new levels while this is taking place.

The default value is 4096.

- MaxNoOfConcurrentOperations

### Table 18.40 This table provides type and value information for the MaxNoOfConcurrentOperations data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>32K</td>
</tr>
<tr>
<td>Range</td>
<td>32 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

It is a good idea to adjust the value of this parameter according to the size and number of transactions. When performing transactions which involve only a few operations and records, the default value for this parameter is usually sufficient. Performing large transactions involving many records usually requires that you increase its value.

Records are kept for each transaction updating cluster data, both in the transaction coordinator and in the nodes where the actual updates are performed. These records contain state information needed to find UNDO records for rollback, lock queues, and other purposes.

This parameter should be set at a minimum to the number of records to be updated simultaneously in transactions, divided by the number of cluster data nodes. For example, in a cluster which has four data nodes and which is expected to handle one million concurrent updates using transactions, you should set this value to 1000000 / 4 = 250000. To help provide resiliency against failures, it is suggested that you set this parameter to a value that is high enough to permit an individual data node to handle the load for its node group. In other words, you should set the value equal to `total number of concurrent operations / number of node groups`. (In the case where there is a single node group, this is the same as the total number of concurrent operations for the entire cluster.)

Because each transaction always involves at least one operation, the value of `MaxNoOfConcurrentOperations` should always be greater than or equal to the value of `MaxNoOfConcurrentTransactions`.

Read queries which set locks also cause operation records to be created. Some extra space is allocated within individual nodes to accommodate cases where the distribution is not perfect over the nodes.

When queries make use of the unique hash index, there are actually two operation records used per record in the transaction. The first record represents the read in the index table and the second handles the operation on the base table.

The default value is 32768.
This parameter actually handles two values that can be configured separately. The first of these specifies how many operation records are to be placed with the transaction coordinator. The second part specifies how many operation records are to be local to the database.

A very large transaction performed on an eight-node cluster requires as many operation records in the transaction coordinator as there are reads, updates, and deletes involved in the transaction. However, the operation records of the are spread over all eight nodes. Thus, if it is necessary to configure the system for one very large transaction, it is a good idea to configure the two parts separately. `MaxNoOfConcurrentOperations` will always be used to calculate the number of operation records in the transaction coordinator portion of the node.

It is also important to have an idea of the memory requirements for operation records. These consume about 1KB per record.

- **MaxNoOfLocalOperations**

Table 18.41 This table provides type and value information for the MaxNoOfLocalOperations data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>UNDEFINED</td>
</tr>
<tr>
<td>Range</td>
<td>32 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

By default, this parameter is calculated as 1.1 × `MaxNoOfConcurrentOperations`. This fits systems with many simultaneous transactions, none of them being very large. If there is a need to handle one very large transaction at a time and there are many nodes, it is a good idea to override the default value by explicitly specifying this parameter.

- **MaxDMLOperationsPerTransaction**

Table 18.42 This table provides type and value information for the MaxDMLOperationsPerTransaction data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>operations (DML)</td>
</tr>
<tr>
<td>Default</td>
<td>4294967295</td>
</tr>
<tr>
<td>Range</td>
<td>32 - 4294967295</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter limits the size of a transaction. The transaction is aborted if it requires more than this many DML operations. The minimum number of operations per transaction is 32; however, you can set `MaxDMLOperationsPerTransaction` to 0 to disable any limitation on the number of DML operations per transaction. The maximum (and default) is 4294967295.

**Transaction temporary storage.** The next set of `[ndbd]` parameters is used to determine temporary storage when executing a statement that is part of a Cluster transaction. All records are released when the statement is completed and the cluster is waiting for the commit or rollback.
The default values for these parameters are adequate for most situations. However, users with a need to support transactions involving large numbers of rows or operations may need to increase these values to enable better parallelism in the system, whereas users whose applications require relatively small transactions can decrease the values to save memory.

- **MaxNoOfConcurrentIndexOperations**

Table 18.43 This table provides type and value information for the MaxNoOfConcurrentIndexOperations data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>8K</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

For queries using a unique hash index, another temporary set of operation records is used during a query's execution phase. This parameter sets the size of that pool of records. Thus, this record is allocated only while executing a part of a query. As soon as this part has been executed, the record is released. The state needed to handle aborts and commits is handled by the normal operation records, where the pool size is set by the parameter MaxNoOfConcurrentOperations.

The default value of this parameter is 8192. Only in rare cases of extremely high parallelism using unique hash indexes should it be necessary to increase this value. Using a smaller value is possible and can save memory if the DBA is certain that a high degree of parallelism is not required for the cluster.

- **MaxNoOfFiredTriggers**

Table 18.44 This table provides type and value information for the MaxNoOfFiredTriggers data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>4000</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

The default value of MaxNoOfFiredTriggers is 4000, which is sufficient for most situations. In some cases it can even be decreased if the DBA feels certain the need for parallelism in the cluster is not high.

A record is created when an operation is performed that affects a unique hash index. Inserting or deleting a record in a table with unique hash indexes or updating a column that is part of a unique hash index fires an insert or a delete in the index table. The resulting record is used to represent this index table operation while waiting for the original operation that fired it to complete. This operation is short-lived but can still require a large number of records in its pool for situations with many parallel write operations on a base table containing a set of unique hash indexes.

- **TransactionBufferMemory**
Table 18.45 This table provides type and value information for the TransactionBufferMemory data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>1M</td>
</tr>
<tr>
<td>Range</td>
<td>1K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

The memory affected by this parameter is used for tracking operations fired when updating index tables and reading unique indexes. This memory is used to store the key and column information for these operations. It is only very rarely that the value for this parameter needs to be altered from the default.

The default value for TransactionBufferMemory is 1MB.

Normal read and write operations use a similar buffer, whose usage is even more short-lived. The compile-time parameter ZATTRBUF_FILESIZE (found in ndb/src/kernel/blocks/Dbtc/Dbtc.hpp) set to 4000 × 128 bytes (500KB). A similar buffer for key information, ZDATABUF_FILESIZE (also in Dbtc.hpp) contains 4000 × 16 = 62.5KB of buffer space. Dbtc is the module that handles transaction coordination.

Scans and buffering. There are additional [ndbd] parameters in the Dblqh module (in ndb/src/kernel/blocks/Dblqh/Dblqh.hpp) that affect reads and updates. These include ZATTRINBUF_FILESIZE, set by default to 10000 × 128 bytes (1250KB) and ZDATABUF_FILE_SIZE, set by default to 10000*16 bytes (roughly 156KB) of buffer space. To date, there have been neither any reports from users nor any results from our own extensive tests suggesting that either of these compile-time limits should be increased.

- MaxNoOfConcurrentScans

Table 18.46 This table provides type and value information for the MaxNoOfConcurrentScans data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>256</td>
</tr>
<tr>
<td>Range</td>
<td>2 - 500</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is used to control the number of parallel scans that can be performed in the cluster. Each transaction coordinator can handle the number of parallel scans defined for this parameter. Each scan query is performed by scanning all partitions in parallel. Each partition scan uses a scan record in the node where the partition is located, the number of records being the value of this parameter times the number of nodes. The cluster should be able to sustain MaxNoOfConcurrentScans scans concurrently from all nodes in the cluster.

Scans are actually performed in two cases. The first of these cases occurs when no hash or ordered indexes exists to handle the query, in which case the query is executed by performing a full table scan. The second case is encountered when there is no hash index to support the query but there is an
ordered index. Using the ordered index means executing a parallel range scan. The order is kept on the local partitions only, so it is necessary to perform the index scan on all partitions.

The default value of `MaxNoOfConcurrentScans` is 256. The maximum value is 500.

- **MaxNoOfLocalScans**

  Table 18.47 This table provides type and value information for the `MaxNoOfLocalScans` data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>

<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>256</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 992</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is used to calculate the number of lock records used to handle concurrent scan operations.

`BatchSizePerLocalScan` has a strong connection to the `BatchSize` defined in the SQL nodes.

- **LongMessageBuffer**

  Table 18.49 This table provides type and value information for the `LongMessageBuffer` data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>64M</td>
</tr>
<tr>
<td>Range</td>
<td>512K - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>
This is an internal buffer used for passing messages within individual nodes and between nodes. The default is 64MB. (Prior to NDB 7.3.5, this was 4MB.)

This parameter seldom needs to be changed from the default.

• **MaxParallelCopyInstances**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.4.3</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 64</td>
</tr>
</tbody>
</table>

This parameter sets the parallelization used in the copy phase of a node restart or system restart, when a node that is currently just starting is synchronised with a node that already has current data by copying over any changed records from the node that is up to date. Because full parallelism in such cases can lead to overload situations, **MaxParallelCopyInstances** was introduced in NDB 7.4.3 to provide a means to decrease it. This parameter’s default value 0. This value means that the effective parallelism is equal to the number of LDM instances in the node just starting as well as the node updating it.

• **MaxParallelScansPerFragment**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>256</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>
It is possible to configure the maximum number of parallel scans (TUP scans and TUX scans) allowed before they begin queuing for serial handling. You can increase this to take advantage of any unused CPU when performing large number of scans in parallel and improve their performance.

The default value for this parameter in NDB Cluster and later 7.3 is 256.

## Memory Allocation

### MaxAllocate

**Table 18.52 This table provides type and value information for the MaxAllocate data node configuration parameter**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>32M</td>
</tr>
<tr>
<td>Range</td>
<td>1M - 1G</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This is the maximum size of the memory unit to use when allocating memory for tables. In cases where NDB gives Out of memory errors, but it is evident by examining the cluster logs or the output of DUMP 1000 that all available memory has not yet been used, you can increase the value of this parameter (or MaxNoOfTables, or both) to cause NDB to make sufficient memory available.

## Hash Map Size

### DefaultHashMapSize

**Table 18.53 This table provides type and value information for the DefaultHashMapSize data node configuration parameter**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>LDM threads</td>
</tr>
<tr>
<td>Default</td>
<td>3840</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 3840</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

NDB 7.2.7 and later use a larger default table hash map size (3840) than in previous releases (240). Beginning with NDB 7.2.11, the size of the table hash maps used by NDB is configurable using this parameter; previously this value was hard-coded. DefaultHashMapSize can take any of three possible values (0, 240, 3840). These values and their effects are described in the following table:

**Table 18.54 DefaultHashMapSize parameters**

<table>
<thead>
<tr>
<th>Value</th>
<th>Description / Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Use the lowest value set, if any, for this parameter among all data nodes and API nodes in the cluster; if it is not set on any data or API node, use the default value.</td>
</tr>
</tbody>
</table>
NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Value</th>
<th>Description / Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>240</td>
<td>Original hash map size (used by default in all NDB Cluster releases prior to NDB 7.2.7)</td>
</tr>
<tr>
<td>3840</td>
<td>Larger hash map size (used by default beginning with NDB 7.2.7)</td>
</tr>
</tbody>
</table>

The primary intended use for this parameter is to facilitate upgrades and especially downgrades between NDB 7.2.7 and later NDB Cluster versions, in which the larger hash map size (3840) is the default, and earlier releases (in which the default was 240), due to the fact that this change is not otherwise backward compatible (Bug #14800539). By setting this parameter to 240 prior to performing an upgrade from an older version where this value is in use, you can cause the cluster to continue using the smaller size for table hash maps, in which case the tables remain compatible with earlier versions following the upgrade. `DefaultHashMapSize` can be set for individual data nodes, API nodes, or both, but setting it once only, in the `[ndbd default]` section of the `config.ini` file, is the recommended practice.

After increasing this parameter, to have existing tables to take advantage of the new size, you can run `ALTER TABLE ... REORGANIZE PARTITION` on them, after which they can use the larger hash map size. This is in addition to performing a rolling restart, which makes the larger hash maps available to new tables, but does not enable existing tables to use them.

Decreasing this parameter online after any tables have been created or modified with `DefaultHashMapSize` equal to 3840 is not currently supported.

Logging and checkpointing. The following `[ndbd]` parameters control log and checkpoint behavior.

- `NoOfFragmentLogFiles` Table 18.55 This table provides type and value information for the `NoOfFragmentLogFiles` data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>16</td>
</tr>
<tr>
<td>Range</td>
<td>3 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IN</td>
</tr>
</tbody>
</table>

This parameter sets the number of REDO log files for the node, and thus the amount of space allocated to REDO logging. Because the REDO log files are organized in a ring, it is extremely important that the first and last log files in the set (sometimes referred to as the “head” and “tail” log files, respectively) do not meet. When these approach one another too closely, the node begins aborting all transactions encompassing updates due to a lack of room for new log records.

A REDO log record is not removed until the required number of local checkpoints has been completed since that log record was inserted. (In NDB Cluster 7.3 and later, only 2 local checkpoints are necessary). Checkpointing frequency is determined by its own set of configuration parameters discussed elsewhere in this chapter.

The default parameter value is 16, which by default means 16 sets of 4 16MB files for a total of 1024MB. The size of the individual log files is configurable using the `FragmentLogFileSize` parameter. In scenarios requiring a great many updates, the value for `NoOfFragmentLogFiles` may need to be set as high as 300 or even higher to provide sufficient space for REDO logs.
If the checkpointing is slow and there are so many writes to the database that the log files are full and the log tail cannot be cut without jeopardizing recovery, all updating transactions are aborted with internal error code 410 (**Out of log file space temporarily**). This condition prevails until a checkpoint has completed and the log tail can be moved forward.

![Important]

This parameter cannot be changed “on the fly”; you must restart the node using `--initial`. If you wish to change this value for all data nodes in a running cluster, you can do so using a rolling node restart (using `--initial` when starting each data node).

- **FragmentLogFileSize**

Table 18.56 This table provides type and value information for the FragmentLogFileSize data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>16M</td>
</tr>
<tr>
<td>Range</td>
<td>4M - 1G</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IN</td>
</tr>
</tbody>
</table>

Setting this parameter enables you to control directly the size of redo log files. This can be useful in situations when NDB Cluster is operating under a high load and it is unable to close fragment log files quickly enough before attempting to open new ones (only 2 fragment log files can be open at one time); increasing the size of the fragment log files gives the cluster more time before having to open each new fragment log file. The default value for this parameter is 16M.

For more information about fragment log files, see the description for `NoOfFragmentLogFiles`.

- **InitFragmentLogFiles**

Table 18.57 This table provides type and value information for the InitFragmentLogFiles data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>[see values]</td>
</tr>
<tr>
<td>Default</td>
<td>SPARSE</td>
</tr>
<tr>
<td>Range</td>
<td>SPARSE, FULL</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IN</td>
</tr>
</tbody>
</table>

By default, fragment log files are created sparsely when performing an initial start of a data node—that is, depending on the operating system and file system in use, not all bytes are necessarily written to disk. However, it is possible to override this behavior and force all bytes to be written, regardless of the platform and file system type being used, by means of this parameter. `InitFragmentLogFiles` takes either of two values:

- **SPARSE**. Fragment log files are created sparsely. This is the default value.
• **FULL.** Force all bytes of the fragment log file to be written to disk.

Depending on your operating system and file system, setting `InitFragmentLogFiles=FULL` may help eliminate I/O errors on writes to the REDO log.

• **MaxNoOfOpenFiles**

Table 18.58 This table provides type and value information for the MaxNoOfOpenFiles data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>20 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter sets a ceiling on how many internal threads to allocate for open files. *Any situation requiring a change in this parameter should be reported as a bug.*

The default value is 0. However, the minimum value to which this parameter can be set is 20.

• **InitialNoOfOpenFiles**

Table 18.59 This table provides type and value information for the InitialNoOfOpenFiles data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>files</td>
</tr>
<tr>
<td>Default</td>
<td>27</td>
</tr>
<tr>
<td>Range</td>
<td>20 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter sets the initial number of internal threads to allocate for open files.

The default value is 27.

• **MaxNoOfSavedMessages**

Table 18.60 This table provides type and value information for the MaxNoOfSavedMessages data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>25</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>
This parameter sets the maximum number of errors written to the error log as well as the maximum number of trace files that are kept before overwriting the existing ones. Trace files are generated when, for whatever reason, the node crashes.

The default is 25, which sets these maximums to 25 error messages and 25 trace files.

- **MaxLCPStartDelay**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>seconds</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 600</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

  In parallel data node recovery, only table data is actually copied and synchronized in parallel; synchronization of metadata such as dictionary and checkpoint information is done in a serial fashion. In addition, recovery of dictionary and checkpoint information cannot be executed in parallel with performing of local checkpoints. This means that, when starting or restarting many data nodes concurrently, data nodes may be forced to wait while a local checkpoint is performed, which can result in longer node recovery times.

  It is possible to force a delay in the local checkpoint to permit more (and possibly all) data nodes to complete metadata synchronization; once each data node's metadata synchronization is complete, all of the data nodes can recover table data in parallel, even while the local checkpoint is being executed. To force such a delay, set `MaxLCPStartDelay`, which determines the number of seconds the cluster can wait to begin a local checkpoint while data nodes continue to synchronize metadata. This parameter should be set in the `[ndbd default]` section of the `config.ini` file, so that it is the same for all data nodes. The maximum value is 600; the default is 0.

- **LcpScanProgressTimeout**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.3</td>
</tr>
<tr>
<td>Type or units</td>
<td>second</td>
</tr>
<tr>
<td>Default</td>
<td>60</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

  A local checkpoint fragment scan watchdog checks periodically for no progress in each fragment scan performed as part of a local checkpoint, and shuts down the node if there is no progress after a given amount of time has elapsed. Prior to NDB 7.3.3, this interval is always 60 seconds (Bug #16630410). In NDB 7.3.3 and later, this interval can be set using the `LcpScanProgressTimeout` data node configuration parameter, which sets the maximum time for which the local checkpoint can be stalled before the LCP fragment scan watchdog shuts down the node.
The default value is 60 seconds (providing compatibility with previous releases). Setting this parameter to 0 disables the LCP fragment scan watchdog altogether.

**Metadata objects.** The next set of [ndbd] parameters defines pool sizes for metadata objects, used to define the maximum number of attributes, tables, indexes, and trigger objects used by indexes, events, and replication between clusters.

- **MaxNoOfAttributes**

Table 18.63 This table provides type and value information for the MaxNoOfAttributes data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>1000</td>
</tr>
<tr>
<td>Range</td>
<td>32 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter sets a suggested maximum number of attributes that can be defined in the cluster; like MaxNoOfTables, it is not intended to function as a hard upper limit.

(In older NDB Cluster releases, this parameter was sometimes treated as a hard limit for certain operations. This caused problems with NDB Cluster Replication, when it was possible to create more tables than could be replicated, and sometimes led to confusion when it was possible [or not possible, depending on the circumstances] to create more than MaxNoOfAttributes attributes.)

The default value is 1000, with the minimum possible value being 32. The maximum is 4294967039. Each attribute consumes around 200 bytes of storage per node due to the fact that all metadata is fully replicated on the servers.

When setting MaxNoOfAttributes, it is important to prepare in advance for any ALTER TABLE statements that you might want to perform in the future. This is due to the fact, during the execution of ALTER TABLE on a Cluster table, 3 times the number of attributes as in the original table are used, and a good practice is to permit double this amount. For example, if the NDB Cluster table having the greatest number of attributes (greatest_number_of_attributes) has 100 attributes, a good starting point for the value of MaxNoOfAttributes would be 6 * greatest_number_of_attributes = 600.

You should also estimate the average number of attributes per table and multiply this by MaxNoOfTables. If this value is larger than the value obtained in the previous paragraph, you should use the larger value instead.

Assuming that you can create all desired tables without any problems, you should also verify that this number is sufficient by trying an actual ALTER TABLE after configuring the parameter. If this is not successful, increase MaxNoOfAttributes by another multiple of MaxNoOfTables and test it again.

- **MaxNoOfTables**
Table 18.64 This table provides type and value information for the MaxNoOfTables data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>128</td>
</tr>
<tr>
<td>Range</td>
<td>8 - 20320</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

A table object is allocated for each table and for each unique hash index in the cluster. This parameter sets a suggested maximum number of table objects for the cluster as a whole; like \texttt{MaxNoOfAttributes}, it is not intended to function as a hard upper limit.

(In older NDB Cluster releases, this parameter was sometimes treated as a hard limit for certain operations. This caused problems with NDB Cluster Replication, when it was possible to create more tables than could be replicated, and sometimes led to confusion when it was possible [or not possible, depending on the circumstances] to create more than \texttt{MaxNoOfTables} tables.)

For each attribute that has a \texttt{BLOB} data type an extra table is used to store most of the \texttt{BLOB} data. These tables also must be taken into account when defining the total number of tables.

The default value of this parameter is 128. The minimum is 8 and the maximum is 20320. Each table object consumes approximately 20KB per node.

Note

The sum of \texttt{MaxNoOfTables}, \texttt{MaxNoOfOrderedIndexes}, and \texttt{MaxNoOfUniqueHashIndexes} must not exceed $2^{32} - 2$ (4294967294).

- \texttt{MaxNoOfOrderedIndexes}

Table 18.65 This table provides type and value information for the MaxNoOfOrderedIndexes data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>128</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

For each ordered index in the cluster, an object is allocated describing what is being indexed and its storage segments. By default, each index so defined also defines an ordered index. Each unique index and primary key has both an ordered index and a hash index. \texttt{MaxNoOfOrderedIndexes} sets the total number of ordered indexes that can be in use in the system at any one time.

The default value of this parameter is 128. Each index object consumes approximately 10KB of data per node.
Note
The sum of MaxNoOfTables, MaxNoOfOrderedIndexes, and MaxNoOfUniqueHashIndexes must not exceed $2^{32} - 2$ (4294967294).

- **MaxNoOfUniqueHashIndexes**

Table 18.66 This table provides type and value information for the MaxNoOfUniqueHashIndexes data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>64</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

For each unique index that is not a primary key, a special table is allocated that maps the unique key to the primary key of the indexed table. By default, an ordered index is also defined for each unique index. To prevent this, you must specify the **USING HASH** option when defining the unique index.

The default value is 64. Each index consumes approximately 15KB per node.

Note
The sum of MaxNoOfTables, MaxNoOfOrderedIndexes, and MaxNoOfUniqueHashIndexes must not exceed $2^{32} - 2$ (4294967294).

- **MaxNoOfTriggers**

Table 18.67 This table provides type and value information for the MaxNoOfTriggers data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>768</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Internal update, insert, and delete triggers are allocated for each unique hash index. (This means that three triggers are created for each unique hash index.) However, an **ordered** index requires only a single trigger object. Backups also use three trigger objects for each normal table in the cluster.

Replication between clusters also makes use of internal triggers.

This parameter sets the maximum number of trigger objects in the cluster.

The default value is 768.

- **MaxNoOfIndexes**
This parameter is deprecated in NDB 7.4 and is no longer available in NDB Cluster 7.5. You should use `MaxNoOfOrderedIndexes` and `MaxNoOfUniqueHashIndexes` instead.

This parameter is used only by unique hash indexes. There needs to be one record in this pool for each unique hash index defined in the cluster.

The default value of this parameter is 128.

- **MaxNoOfSubscriptions**

  Table 18.68 This table provides type and value information for the MaxNoOfSubscriptions data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFFFFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Each NDB table in an NDB Cluster requires a subscription in the NDB kernel. For some NDB API applications, it may be necessary or desirable to change this parameter. However, for normal usage with MySQL servers acting as SQL nodes, there is not any need to do so.

The default value for `MaxNoOfSubscriptions` is 0, which is treated as equal to `MaxNoOfTables`. Each subscription consumes 108 bytes.

- **MaxNoOfSubscribers**

  Table 18.69 This table provides type and value information for the MaxNoOfSubscribers data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFFFFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is of interest only when using NDB Cluster Replication. The default value is 0, which is treated as `2 * MaxNoOfTables`; that is, there is one subscription per NDB table for each of two MySQL servers (one acting as the replication master and the other as the slave). Each subscriber uses 16 bytes of memory.

When using circular replication, multi-master replication, and other replication setups involving more than 2 MySQL servers, you should increase this parameter to the number of `mysqld` processes included in replication (this is often, but not always, the same as the number of clusters). For example, if you have a circular replication setup using three NDB Clusters, with one `mysqld` attached to each cluster, and each of these `mysqld` processes acts as a master and as a slave, you should set `MaxNoOfSubscribers` equal to `3 * MaxNoOfTables`.  

2696
For more information, see Section 18.6, “NDB Cluster Replication”.

- **MaxNoOfConcurrentSubOperations**

Table 18.70 This table provides type and value information for the MaxNoOfConcurrentSubOperations data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>256</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter sets a ceiling on the number of operations that can be performed by all API nodes in the cluster at one time. The default value (256) is sufficient for normal operations, and might need to be adjusted only in scenarios where there are a great many API nodes each performing a high volume of operations concurrently.

**Boolean parameters.** The behavior of data nodes is also affected by a set of [ndbd] parameters taking on boolean values. These parameters can each be specified as TRUE by setting them equal to 1 or Y, and as FALSE by setting them equal to 0 or N.

- **LateAlloc**

Table 18.71 This table provides type and value information for the LateAlloc data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>

<td>N</td>
</tr>
</tbody>
</table>
For a number of operating systems, including Solaris and Linux, it is possible to lock a process into memory and so avoid any swapping to disk. This can be used to help guarantee the cluster’s real-time characteristics.

This parameter takes one of the integer values 0, 1, or 2, which act as shown in the following list:

- 0: Disables locking. This is the default value.
- 1: Performs the lock after allocating memory for the process.
- 2: Performs the lock before memory for the process is allocated.

If the operating system is not configured to permit unprivileged users to lock pages, then the data node process making use of this parameter may have to be run as system root. (LockPagesInMainMemory uses the mlockall function. From Linux kernel 2.6.9, unprivileged users can lock memory as limited by max locked memory. For more information, see ulimit -l.)

**Note**

In older NDB Cluster releases, this parameter was a Boolean. 0 or false was the default setting, and disabled locking. 1 or true enabled locking of the process after its memory was allocated. NDB Cluster 7.3 and later treats using true or false for the value of this parameter as an error.

**Important**

Beginning with glibc 2.10, glibc uses per-thread arenas to reduce lock contention on a shared pool, which consumes real memory. In general, a data node process does not need per-thread arenas, since it does not perform any memory allocation after startup. (This difference in allocators does not appear to affect performance significantly.)

The glibc behavior is intended to be configurable via the MALLOC_ARENA_MAX environment variable, but a bug in this mechanism prior to glibc 2.16 meant that this variable could not be set to less than 8, so that the wasted memory could not be reclaimed. (Bug #15907219; see also http://sourceware.org/bugzilla/show_bug.cgi?id=13137 for more information concerning this issue.)

One possible workaround for this problem is to use the LD_PRELOAD environment variable to preload a jemalloc memory allocation library to take the place of that supplied with glibc.

- **StopOnError**

**Table 18.73** This table provides type and value information for the StopOnError data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>1</td>
</tr>
<tr>
<td>Range</td>
<td>0, 1</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>
This parameter specifies whether a data node process should exit or perform an automatic restart when an error condition is encountered.

This parameter's default value is 1; this means that, by default, an error causes the data node process to halt.

When an error is encountered and `StopOnError` is 0, the data node process is restarted.

Prior to NDB Cluster 7.4.14, if the data node process exits in an uncontrolled fashion (due, for example, to performing `kill -9` on the data node process while performing a query, or to a segmentation fault), and `StopOnError` is set to 0, the angel process attempts to restart it in exactly the same way as it was started previously—that is, using the same startup options that were employed the last time the node was started. Thus, if the data node process was originally started using the `--initial` option, it is also restarted with `--initial`. This means that, in such cases, if the failure occurs on a sufficient number of data nodes in a very short interval, the effect is the same as if you had performed an initial restart of the entire cluster, leading to loss of all data. This issue is resolved in NDB Cluster 7.4.14 and later NDB 7.4 releases (Bug #83510, Bug #24945638).

Users of MySQL Cluster Manager should note that, when `StopOnError` equals 1, this prevents the MySQL Cluster Manager agent from restarting any data nodes after it has performed its own restart and recovery. See Starting and Stopping the Agent on Linux, for more information.

- **CrashOnCorruptedTuple**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>true</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
</tbody>
</table>

When this parameter is enabled, it forces a data node to shut down whenever it encounters a corrupted tuple. In NDB Cluster 7.3 and later, it is enabled by default.

- **Diskless**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>true</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
</tbody>
</table>

It is possible to specify NDB Cluster tables as _diskless_, meaning that tables are not checkpointed to disk and that no logging occurs. Such tables exist only in main memory. A consequence of using diskless
tables is that neither the tables nor the records in those tables survive a crash. However, when operating in diskless mode, it is possible to run `ndbd` on a diskless computer.

**Important**

This feature causes the *entire* cluster to operate in diskless mode.

When this feature is enabled, Cluster online backup is disabled. In addition, a partial start of the cluster is not possible.

*Diskless* is disabled by default.

- **ODirect**

  **Table 18.76 This table provides type and value information for the ODirect data node configuration parameter**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

Enabling this parameter causes NDB to attempt using `O_DIRECT` writes for LCP, backups, and redo logs, often lowering `kswapd` and CPU usage. When using NDB Cluster on Linux, enable `ODirect` if you are using a 2.6 or later kernel.

*ODirect* is disabled by default.

- **RestartOnErrorInsert**

  **Table 18.77 This table provides type and value information for the RestartOnErrorInsert data node configuration parameter**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>error code</td>
</tr>
<tr>
<td>Default</td>
<td>2</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

This feature is accessible only when building the debug version where it is possible to insert errors in the execution of individual blocks of code as part of testing.

This feature is disabled by default.

- **CompressedBackup**
Table 18.78 This table provides type and value information for the CompressedBackup data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Enabling this parameter causes backup files to be compressed. The compression used is equivalent to `gzip --fast`, and can save 50% or more of the space required on the data node to store uncompressed backup files. Compressed backups can be enabled for individual data nodes, or for all data nodes (by setting this parameter in the `[ndbd default]` section of the `config.ini` file).

Important

You cannot restore a compressed backup to a cluster running a MySQL version that does not support this feature.

The default value is 0 (disabled).

- **CompressedLCP**

Table 18.79 This table provides type and value information for the CompressedLCP data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Setting this parameter to 1 causes local checkpoint files to be compressed. The compression used is equivalent to `gzip --fast`, and can save 50% or more of the space required on the data node to store uncompressed checkpoint files. Compressed LCPs can be enabled for individual data nodes, or for all data nodes (by setting this parameter in the `[ndbd default]` section of the `config.ini` file).

Important

You cannot restore a compressed local checkpoint to a cluster running a MySQL version that does not support this feature.

The default value is 0 (disabled).

**Controlling Timeouts, Intervals, and Disk Paging**

There are a number of `[ndbd]` parameters specifying timeouts and intervals between various actions in Cluster data nodes. Most of the timeout values are specified in milliseconds. Any exceptions to this are mentioned where applicable.
• **TimeBetweenWatchDogCheck**

Table 18.80 This table provides type and value information for the TimeBetweenWatchDogCheck data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>6000</td>
</tr>
<tr>
<td>Range</td>
<td>70 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

To prevent the main thread from getting stuck in an endless loop at some point, a “watchdog” thread checks the main thread. This parameter specifies the number of milliseconds between checks. If the process remains in the same state after three checks, the watchdog thread terminates it.

This parameter can easily be changed for purposes of experimentation or to adapt to local conditions. It can be specified on a per-node basis although there seems to be little reason for doing so.

The default timeout is 6000 milliseconds (6 seconds).

• **TimeBetweenWatchDogCheckInitial**

Table 18.81 This table provides type and value information for the TimeBetweenWatchDogCheckInitial data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>6000</td>
</tr>
<tr>
<td>Range</td>
<td>70 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This is similar to the **TimeBetweenWatchDogCheck** parameter, except that **TimeBetweenWatchDogCheckInitial** controls the amount of time that passes between execution checks inside a storage node in the early start phases during which memory is allocated.

The default timeout is 6000 milliseconds (6 seconds).

• **StartPartialTimeout**

Table 18.82 This table provides type and value information for the StartPartialTimeout data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>30000</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>
This parameter specifies how long the Cluster waits for all data nodes to come up before the cluster initialization routine is invoked. This timeout is used to avoid a partial Cluster startup whenever possible.

This parameter is overridden when performing an initial start or initial restart of the cluster.

The default value is 30000 milliseconds (30 seconds). 0 disables the timeout, in which case the cluster may start only if all nodes are available.

- **StartPartitionedTimeout**

Table 18.83 This table provides type and value information for the StartPartitionedTimeout data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>60000</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

If the cluster is ready to start after waiting for StartPartialTimeout milliseconds but is still possibly in a partitioned state, the cluster waits until this timeout has also passed. If StartPartitionedTimeout is set to 0, the cluster waits indefinitely.

This parameter is overridden when performing an initial start or initial restart of the cluster.

The default timeout is 60000 milliseconds (60 seconds).

- **StartFailureTimeout**

Table 18.84 This table provides type and value information for the StartFailureTimeout data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

If a data node has not completed its startup sequence within the time specified by this parameter, the node startup fails. Setting this parameter to 0 (the default value) means that no data node timeout is applied.

For nonzero values, this parameter is measured in milliseconds. For data nodes containing extremely large amounts of data, this parameter should be increased. For example, in the case of a data node containing several gigabytes of data, a period as long as 10–15 minutes (that is, 600000 to 1000000 milliseconds) might be required to perform a node restart.

- **StartNoNodeGroupTimeout**
Table 18.85 This table provides type and value information for the StartNoNodeGroupTimeout data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>15000</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

When a data node is configured with Nodegroup = 65536, is regarded as not being assigned to any node group. When that is done, the cluster waits StartNoNodeGroupTimeout milliseconds, then treats such nodes as though they had been added to the list passed to the --nowait-nodes option, and starts. The default value is 15000 (that is, the management server waits 15 seconds). Setting this parameter equal to 0 means that the cluster waits indefinitely.

StartNoNodeGroupTimeout must be the same for all data nodes in the cluster; for this reason, you should always set it in the [ndbd default] section of the config.ini file, rather than for individual data nodes.

See Section 18.5.14, “Adding NDB Cluster Data Nodes Online”, for more information.

- HeartbeatIntervalDbDb

Table 18.86 This table provides type and value information for the HeartbeatIntervalDbDb data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>5000</td>
</tr>
<tr>
<td>Range</td>
<td>10 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

One of the primary methods of discovering failed nodes is by the use of heartbeats. This parameter states how often heartbeat signals are sent and how often to expect to receive them. Heartbeats cannot be disabled.

After missing four heartbeat intervals in a row, the node is declared dead. Thus, the maximum time for discovering a failure through the heartbeat mechanism is five times the heartbeat interval.

In NDB Cluster 7.3 and later, the default heartbeat interval is 5000 milliseconds (5 seconds). This parameter must not be changed drastically and should not vary widely between nodes. If one node uses 5000 milliseconds and the node watching it uses 1000 milliseconds, obviously the node will be declared dead very quickly. This parameter can be changed during an online software upgrade, but only in small increments.

See also Network communication and latency, as well as the description of the ConnectCheckIntervalDelay configuration parameter.

- HeartbeatIntervalDbApi
Table 18.87 This table provides type and value information for the HeartbeatIntervalDbApi data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>1500</td>
</tr>
<tr>
<td>Range</td>
<td>100 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Each data node sends heartbeat signals to each MySQL server (SQL node) to ensure that it remains in contact. If a MySQL server fails to send a heartbeat in time it is declared “dead,” in which case all ongoing transactions are completed and all resources released. The SQL node cannot reconnect until all activities initiated by the previous MySQL instance have been completed. The three-heartbeat criteria for this determination are the same as described for HeartbeatIntervalDbDb.

The default interval is 1500 milliseconds (1.5 seconds). This interval can vary between individual data nodes because each data node watches the MySQL servers connected to it, independently of all other data nodes.

For more information, see Network communication and latency.

• HeartbeatOrder

Table 18.88 This table provides type and value information for the HeartbeatOrder data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 65535</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

Data nodes send heartbeats to one another in a circular fashion whereby each data node monitors the previous one. If a heartbeat is not detected by a given data node, this node declares the previous data node in the circle “dead” (that is, no longer accessible by the cluster). The determination that a data node is dead is done globally; in other words; once a data node is declared dead, it is regarded as such by all nodes in the cluster.

It is possible for heartbeats between data nodes residing on different hosts to be too slow compared to heartbeats between other pairs of nodes (for example, due to a very low heartbeat interval or temporary connection problem), such that a data node is declared dead, even though the node can still function as part of the cluster.

In this type of situation, it may be that the order in which heartbeats are transmitted between data nodes makes a difference as to whether or not a particular data node is declared dead. If this declaration occurs unnecessarily, this can in turn lead to the unnecessary loss of a node group and as thus to a failure of the cluster.
Consider a setup where there are 4 data nodes A, B, C, and D running on 2 host computers host1 and host2, and that these data nodes make up 2 node groups, as shown in the following table:

<table>
<thead>
<tr>
<th>Node</th>
<th>HeartbeatOrder Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>10</td>
</tr>
<tr>
<td>B</td>
<td>20</td>
</tr>
<tr>
<td>C</td>
<td>30</td>
</tr>
<tr>
<td>D</td>
<td>25</td>
</tr>
</tbody>
</table>

Suppose the heartbeats are transmitted in the order A->B->C->D->A. In this case, the loss of the heartbeat between the hosts causes node B to declare node A dead and node C to declare node B dead. This results in loss of Node Group 0, and so the cluster fails. On the other hand, if the order of transmission is A->B->D->C->A (and all other conditions remain as previously stated), the loss of the heartbeat causes nodes A and D to be declared dead; in this case, each node group has one surviving node, and the cluster survives.

The HeartbeatOrder configuration parameter makes the order of heartbeat transmission user-configurable. The default value for HeartbeatOrder is zero; allowing the default value to be used on all data nodes causes the order of heartbeat transmission to be determined by NDB. If this parameter is used, it must be set to a nonzero value (maximum 65535) for every data node in the cluster, and this value must be unique for each data node; this causes the heartbeat transmission to proceed from data node to data node in the order of their HeartbeatOrder values from lowest to highest (and then directly from the data node having the highest HeartbeatOrder to the data node having the lowest value, to complete the circle). The values need not be consecutive. For example, to force the heartbeat transmission order A->B->D->C->A in the scenario outlined previously, you could set the HeartbeatOrder values as shown here:

<table>
<thead>
<tr>
<th>Node</th>
<th>HeartbeatOrder Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>10</td>
</tr>
<tr>
<td>B</td>
<td>20</td>
</tr>
<tr>
<td>C</td>
<td>30</td>
</tr>
<tr>
<td>D</td>
<td>25</td>
</tr>
</tbody>
</table>

To use this parameter to change the heartbeat transmission order in a running NDB Cluster, you must first set HeartbeatOrder for each data node in the cluster in the global configuration (config.ini) file (or files). To cause the change to take effect, you must perform either of the following:

- A complete shutdown and restart of the entire cluster.
- 2 rolling restarts of the cluster in succession. All nodes must be restarted in the same order in both rolling restarts.

You can use DUMP 908 to observe the effect of this parameter in the data node logs.

- ConnectCheckIntervalDelay
Table 18.91 This table provides type and value information for the ConnectCheckIntervalDelay data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter enables connection checking between data nodes after one of them has failed heartbeat checks for 5 intervals of up to HeartbeatIntervalDbDb milliseconds.

Such a data node that further fails to respond within an interval of ConnectCheckIntervalDelay milliseconds is considered suspect, and is considered dead after two such intervals. This can be useful in setups with known latency issues.

The default value for this parameter is 0 (disabled).

- TimeBetweenLocalCheckpoints

Table 18.92 This table provides type and value information for the TimeBetweenLocalCheckpoints data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>number of 4-byte words, as a base-2 logarithm</td>
</tr>
<tr>
<td>Default</td>
<td>20</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 31</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is an exception in that it does not specify a time to wait before starting a new local checkpoint; rather, it is used to ensure that local checkpoints are not performed in a cluster where relatively few updates are taking place. In most clusters with high update rates, it is likely that a new local checkpoint is started immediately after the previous one has been completed.

The size of all write operations executed since the start of the previous local checkpoints is added. This parameter is also exceptional in that it is specified as the base-2 logarithm of the number of 4-byte words, so that the default value 20 means 4MB (4 × 2²⁰) of write operations, 21 would mean 8MB, and so on up to a maximum value of 31, which equates to 8GB of write operations.

All the write operations in the cluster are added together. Setting TimeBetweenLocalCheckpoints to 6 or less means that local checkpoints will be executed continuously without pause, independent of the cluster’s workload.

- TimeBetweenGlobalCheckpoints
Table 18.93 This table provides type and value information for the TimeBetweenGlobalCheckpoints data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>2000</td>
</tr>
<tr>
<td>Range</td>
<td>20 - 32000</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

When a transaction is committed, it is committed in main memory in all nodes on which the data is mirrored. However, transaction log records are not flushed to disk as part of the commit. The reasoning behind this behavior is that having the transaction safely committed on at least two autonomous host machines should meet reasonable standards for durability.

It is also important to ensure that even the worst of cases—a complete crash of the cluster—is handled properly. To guarantee that this happens, all transactions taking place within a given interval are put into a global checkpoint, which can be thought of as a set of committed transactions that has been flushed to disk. In other words, as part of the commit process, a transaction is placed in a global checkpoint group. Later, this group's log records are flushed to disk, and then the entire group of transactions is safely committed to disk on all computers in the cluster.

This parameter defines the interval between global checkpoints. The default is 2000 milliseconds.

- TimeBetweenGlobalCheckpointsTimeout

Table 18.94 This table provides type and value information for the TimeBetweenGlobalCheckpointsTimeout data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.4.5</td>
</tr>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>120000</td>
</tr>
<tr>
<td>Range</td>
<td>10 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.9</td>
</tr>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>120000</td>
</tr>
<tr>
<td>Range</td>
<td>10 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter defines the minimum timeout between global checkpoints. The default is 120000 milliseconds.

This parameter was added in NDB 7.3.9 and NDB 7.4.5. (Bug #20069617)

- TimeBetweenEpochs
Table 18.95 This table provides type and value information for the `TimeBetweenEpochs` data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>100</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 32000</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter defines the interval between synchronization epochs for NDB Cluster Replication. The default value is 100 milliseconds.

`TimeBetweenEpochs` is part of the implementation of “micro-GCPs”, which can be used to improve the performance of NDB Cluster Replication.

- `TimeBetweenEpochsTimeout`

Table 18.96 This table provides type and value information for the `TimeBetweenEpochsTimeout` data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 256000</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter defines a timeout for synchronization epochs for NDB Cluster Replication. If a node fails to participate in a global checkpoint within the time determined by this parameter, the node is shut down. In NDB Cluster 7.3 and later, the default value is 0; in other words, the timeout is disabled.

`TimeBetweenEpochsTimeout` is part of the implementation of “micro-GCPs”, which can be used to improve the performance of NDB Cluster Replication.

The current value of this parameter and a warning are written to the cluster log whenever a GCP save takes longer than 1 minute or a GCP commit takes longer than 10 seconds.

Setting this parameter to zero has the effect of disabling GCP stops caused by save timeouts, commit timeouts, or both. The maximum possible value for this parameter is 256000 milliseconds.

- `MaxBufferedEpochs`

Table 18.97 This table provides type and value information for the `MaxBufferedEpochs` data node configuration parameter

<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Range</td>
<td>0 - 100000</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

The number of unprocessed epochs by which a subscribing node can lag behind. Exceeding this number causes a lagging subscriber to be disconnected.

The default value of 100 is sufficient for most normal operations. If a subscribing node does lag enough to cause disconnections, it is usually due to network or scheduling issues with regard to processes or threads. (In rare circumstances, the problem may be due to a bug in the NDB client.) It may be desirable to set the value lower than the default when epochs are longer.

Disconnection prevents client issues from affecting the data node service, running out of memory to buffer data, and eventually shutting down. Instead, only the client is affected as a result of the disconnect (by, for example gap events in the binary log), forcing the client to reconnect or restart the process.

- MaxBufferedEpochBytes

Table 18.98 This table provides type and value information for the MaxBufferedEpochBytes data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>

<td>1000 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Timeout handling is performed by checking a timer on each transaction once for every interval specified by this parameter. Thus, if this parameter is set to 1000 milliseconds, every transaction will be checked for timing out once per second.

The default value is 1000 milliseconds (1 second).

- TransactionInactiveTimeout
This parameter states the maximum time that is permitted to lapse between operations in the same transaction before the transaction is aborted.

The default for this parameter is 4G (also the maximum). For a real-time database that needs to ensure that no transaction keeps locks for too long, this parameter should be set to a relatively small value. Setting it to 0 means that the application never times out. The unit is milliseconds.

- **TransactionDeadlockDetectionTimeout**

When a node executes a query involving a transaction, the node waits for the other nodes in the cluster to respond before continuing. This parameter sets the amount of time that the transaction can spend executing within a data node, that is, the time that the transaction coordinator waits for each data node participating in the transaction to execute a request.

A failure to respond can occur for any of the following reasons:

- The node is “dead”
- The operation has entered a lock queue
- The node requested to perform the action could be heavily overloaded.

This timeout parameter states how long the transaction coordinator waits for query execution by another node before aborting the transaction, and is important for both node failure handling and deadlock detection.

The default timeout value is 1200 milliseconds (1.2 seconds).

The minimum for this parameter is 50 milliseconds.

- **DiskSyncSize**
Table 18.102 This table provides type and value information for the DiskSyncSize data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>

<td>4M</td>
</tr>
<tr>
<td>Range</td>
<td>32K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This is the maximum number of bytes to store before flushing data to a local checkpoint file. This is done to prevent write buffering, which can impede performance significantly. This parameter is not intended to take the place of TimeBetweenLocalCheckpoints.

Note

When ODirect is enabled, it is not necessary to set DiskSyncSize; in fact, in such cases its value is simply ignored.

The default value is 4M (4 megabytes).

- DiskCheckpointSpeed

Table 18.103 This table provides type and value information for the DiskCheckpointSpeed data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>

<tr>
<td>Default</td>
<td>10M</td>
</tr>
<tr>
<td>Range</td>
<td>1M - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

The amount of data, in bytes per second, that is sent to disk during a local checkpoint. This allocation is shared by DML operations and backups (but not backup logging), which means that backups started during times of intensive DML may be impaired by flooding of the redo log buffer and may fail altogether if the contention is sufficiently severe.

The default value is 10M (10 megabytes per second).

This parameter is deprecated in NDB 7.4.1 and later, where setting it has no effect, and removed in NDB 7.5. Instead, use the configuration parameters MinDiskWriteSpeed, MaxDiskWriteSpeed, MaxDiskWriteSpeedOtherNodeRestart, and MaxDiskWriteSpeedOwnRestart to control write speeds for LCPs and backups.

- DiskCheckpointSpeedInRestart
Table 18.104 This table provides type and value information for the DiskCheckpointSpeedInRestart data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>

</tr>
<tr>
<td>Range</td>
<td>1M - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

The amount of data, in bytes per second, that is sent to disk during a local checkpoint as part of a restart operation.

The default value is 100M (100 megabytes per second).

This parameter is deprecated in NDB 7.4.1 and later, where setting it has no effect, and removed in NDB 7.5. Instead, use the configuration parameters MinDiskWriteSpeed, MaxDiskWriteSpeed, MaxDiskWriteSpeedOtherNodeRestart, and MaxDiskWriteSpeedOwnRestart to control write speeds for LCPs and backups.

- NoOfDiskPagesToDiskAfterRestartTUP

This parameter is deprecated and subject to removal in a future version of NDB Cluster. Use DiskCheckpointSpeedInRestart and DiskSyncSize instead. Beginning with NDB 7.4.1, you should instead use the configuration parameters MinDiskWriteSpeed, MaxDiskWriteSpeed, MaxDiskWriteSpeedOtherNodeRestart, and MaxDiskWriteSpeedOwnRestart introduced in that release.

• MaxDiskWriteSpeed

Table 18.105 This table provides type and value information for the MaxDiskWriteSpeed data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>

<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

Set the maximum rate for writing to disk, in bytes per second, by local checkpoints and backup operations when no restarts (by this data node or any other data node) are taking place in this NDB Cluster.

For setting the maximum rate of disk writes allowed while this data node is restarting, use MaxDiskWriteSpeedOwnRestart. For setting the maximum rate of disk writes allowed while other data nodes are restarting, use MaxDiskWriteSpeedOtherNodeRestart. The minimum speed for disk writes by all LCPs and backup operations can be adjusted by setting MinDiskWriteSpeed.

MaxDiskWriteSpeed was added in NDB 7.4.1.

• MaxDiskWriteSpeedOtherNodeRestart
Table 18.106 This table provides type and value information for the MaxDiskWriteSpeedOtherNodeRestart data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>

<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

Set the maximum rate for writing to disk, in bytes per second, by local checkpoints and backup operations when one or more data nodes in this NDB Cluster are restarting, other than this node.

For setting the maximum rate of disk writes allowed while this data node is restarting, use MaxDiskWriteSpeedOwnRestart. For setting the maximum rate of disk writes allowed when no data nodes are restarting anywhere in the cluster, use MaxDiskWriteSpeed. The minimum speed for disk writes by all LCPs and backup operations can be adjusted by setting MinDiskWriteSpeed.

MaxDiskWriteSpeedOtherNodeRestart was added in NDB 7.4.1.

- MaxDiskWriteSpeedOwnRestart

Table 18.107 This table provides type and value information for the MaxDiskWriteSpeedOwnRestart data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>

</tr>
<tr>
<td>Range</td>
<td>1M - 1024G</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>S</td>
</tr>
</tbody>
</table>

Set the minimum rate for writing to disk, in bytes per second, by local checkpoints and backup operations.

The maximum rates of disk writes allowed for LCPs and backups under various conditions are adjustable using the parameters `MaxDiskWriteSpeed`, `MaxDiskWriteSpeedOwnRestart`, and `MaxDiskWriteSpeedOtherNodeRestart`. See the descriptions of these parameters for more information.

*MinDiskWriteSpeed* was added in NDB 7.4.1.

- **NoOfDiskPagesToDiskAfterRestartACC**

  This parameter is deprecated and subject to removal in a future version of NDB Cluster. In NDB Cluster 7.3, use `DiskCheckpointSpeedInRestart` and `DiskSyncSize` instead. In NDB 7.4.1 and later, you should use the parameters `MinDiskWriteSpeed`, `MaxDiskWriteSpeed`, `MaxDiskWriteSpeedOtherNodeRestart`, and `MaxDiskWriteSpeedOwnRestart`.

- **NoOfDiskPagesToDiskDuringRestartTUP** (DEPRECATED)

  This parameter is deprecated and subject to removal in a future version of NDB Cluster. In NDB Cluster 7.3, use `DiskCheckpointSpeedInRestart` and `DiskSyncSize` instead. In NDB 7.4.1 and later, you should use the parameters `MinDiskWriteSpeed`, `MaxDiskWriteSpeed`, `MaxDiskWriteSpeedOtherNodeRestart`, and `MaxDiskWriteSpeedOwnRestart`.

- **NoOfDiskPagesToDiskDuringRestartACC** (DEPRECATED)

  This parameter is deprecated and subject to removal in a future version of NDB Cluster. In NDB Cluster 7.3, use `DiskCheckpointSpeedInRestart` and `DiskSyncSize` instead. In NDB 7.4.1 and later, you should use the parameters `MinDiskWriteSpeed`, `MaxDiskWriteSpeed`, `MaxDiskWriteSpeedOtherNodeRestart`, and `MaxDiskWriteSpeedOwnRestart`.

- **ArbitrationTimeout**

  *Table 18.109* This table provides type and value information for the *ArbitrationTimeout* data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>7500</td>
</tr>
<tr>
<td>Range</td>
<td>10 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter specifies how long data nodes wait for a response from the arbitrator to an arbitration message. If this is exceeded, the network is assumed to have split.

In NDB Cluster 7.3 and later, the default value is 7500 milliseconds (7.5 seconds).
**Arbitration**

Table 18.110 This table provides type and value information for the Arbitration data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>enumeration</td>
</tr>
<tr>
<td>Default</td>
<td>Default</td>
</tr>
<tr>
<td>Range</td>
<td>Default, Disabled, WaitExternal</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

The **Arbitration** parameter enables a choice of arbitration schemes, corresponding to one of 3 possible values for this parameter:

- **Default.** This enables arbitration to proceed normally, as determined by the **ArbitrationRank** settings for the management and API nodes. This is the default value.

- **Disabled.** Setting **Arbitration = Disabled** in the `[ndbd default]` section of the `config.ini` file to accomplishes the same task as setting **ArbitrationRank** to 0 on all management and API nodes. When **Arbitration** is set in this way, any **ArbitrationRank** settings are ignored.

- **WaitExternal.** The **Arbitration** parameter also makes it possible to configure arbitration in such a way that the cluster waits until after the time determined by **ArbitrationTimeout** has passed for an external cluster manager application to perform arbitration instead of handling arbitration internally. This can be done by setting **Arbitration = WaitExternal** in the `[ndbd default]` section of the `config.ini` file. For best results with the **WaitExternal** setting, it is recommended that **ArbitrationTimeout** be 2 times as long as the interval required by the external cluster manager to perform arbitration.

**Important**

This parameter should be used only in the `[ndbd default]` section of the cluster configuration file. The behavior of the cluster is unspecified when **Arbitration** is set to different values for individual data nodes.

**RestartSubscriberConnectTimeout**

Table 18.111 This table provides type and value information for the RestartSubscriberConnectTimeout data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.6</td>
</tr>
<tr>
<td>Type or units</td>
<td>ms</td>
</tr>
<tr>
<td>Default</td>
<td>12000</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>S</td>
</tr>
</tbody>
</table>

This parameter determines the time that a data node waits for subscribing API nodes to connect. Once this timeout expires, any “missing” API nodes are disconnected from the cluster. To disable this timeout, set **RestartSubscriberConnectTimeout** to 0.
While this parameter is specified in milliseconds, the timeout itself is resolved to the next-greatest whole second.

**RestartSubscriberConnectTimeout** was added in NDB 7.3.6.

**Buffering and logging.** Several [ndbd] configuration parameters enable the advanced user to have more control over the resources used by node processes and to adjust various buffer sizes at need.

These buffers are used as front ends to the file system when writing log records to disk. If the node is running in diskless mode, these parameters can be set to their minimum values without penalty due to the fact that disk writes are “faked” by the NDB storage engine’s file system abstraction layer.

- **UndoIndexBuffer**

**Table 18.112 This table provides type and value information for the UndoIndexBuffer data node configuration parameter**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>

<td>2M</td>
</tr>
<tr>
<td>Range</td>
<td>1M - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

The UNDO index buffer, whose size is set by this parameter, is used during local checkpoints. The NDB storage engine uses a recovery scheme based on checkpoint consistency in conjunction with an operational REDO log. To produce a consistent checkpoint without blocking the entire system for writes, UNDO logging is done while performing the local checkpoint. UNDO logging is activated on a single table fragment at a time. This optimization is possible because tables are stored entirely in main memory.

The UNDO index buffer is used for the updates on the primary key hash index. Inserts and deletes rearrange the hash index; the NDB storage engine writes UNDO log records that map all physical changes to an index page so that they can be undone at system restart. It also logs all active insert operations for each fragment at the start of a local checkpoint.

Reads and updates set lock bits and update a header in the hash index entry. These changes are handled by the page-writing algorithm to ensure that these operations need no UNDO logging.

This buffer is 2MB by default. The minimum value is 1MB, which is sufficient for most applications. For applications doing extremely large or numerous inserts and deletes together with large transactions and large primary keys, it may be necessary to increase the size of this buffer. If this buffer is too small, the NDB storage engine issues internal error code 677 (Index UNDO buffers overloaded).

- **Important**

It is not safe to decrease the value of this parameter during a rolling restart.

- **UndoDataBuffer**
Table 18.113 This table provides type and value information for the UndoDataBuffer data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>16M</td>
</tr>
<tr>
<td>Range</td>
<td>1M - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter sets the size of the UNDO data buffer, which performs a function similar to that of the UNDO index buffer, except the UNDO data buffer is used with regard to data memory rather than index memory. This buffer is used during the local checkpoint phase of a fragment for inserts, deletes, and updates.

Because UNDO log entries tend to grow larger as more operations are logged, this buffer is also larger than its index memory counterpart, with a default value of 16MB.

This amount of memory may be unnecessarily large for some applications. In such cases, it is possible to decrease this size to a minimum of 1MB.

It is rarely necessary to increase the size of this buffer. If there is such a need, it is a good idea to check whether the disks can actually handle the load caused by database update activity. A lack of sufficient disk space cannot be overcome by increasing the size of this buffer.

If this buffer is too small and gets congested, the NDB storage engine issues internal error code 891 (Data UNDO buffers overloaded).

─ Important ─

It is not safe to decrease the value of this parameter during a rolling restart.

• RedoBuffer

Table 18.114 This table provides type and value information for the RedoBuffer data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>32M</td>
</tr>
<tr>
<td>Range</td>
<td>1M - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

All update activities also need to be logged. The REDO log makes it possible to replay these updates whenever the system is restarted. The NDB recovery algorithm uses a “fuzzy” checkpoint of the data together with the UNDO log, and then applies the REDO log to play back all changes up to the restoration point.

RedoBuffer sets the size of the buffer in which the REDO log is written. The default value is 32MB; the minimum value is 1MB.
If this buffer is too small, the NDB storage engine issues error code 1221 (REDO log buffers overloaded). For this reason, you should exercise care if you attempt to decrease the value of RedoBuffer as part of an online change in the cluster's configuration.

ndbmtc allocates a separate buffer for each LDM thread (see ThreadConfig). For example, with 4 LDM threads, an ndbmtc data node actually has 4 buffers and allocates RedoBuffer bytes to each one, for a total of $4 \times \text{RedoBuffer}$ bytes.

- EventLogBufferSize

Table 18.115 This table provides type and value information for the EventLogBufferSize data node configuration parameter

<table>
<thead>

<td>S</td>
</tr>
</tbody>
</table>

Controls the size of the circular buffer used for NDB log events within data nodes.

Controlling log messages. In managing the cluster, it is very important to be able to control the number of log messages sent for various event types to stdout. For each event category, there are 16 possible event levels (numbered 0 through 15). Setting event reporting for a given event category to level 15 means all event reports in that category are sent to stdout; setting it to 0 means that there will be no event reports made in that category.

By default, only the startup message is sent to stdout, with the remaining event reporting level defaults being set to 0. The reason for this is that these messages are also sent to the management server's cluster log.

An analogous set of levels can be set for the management client to determine which event levels to record in the cluster log.

- LogLevelStartup

Table 18.116 This table provides type and value information for the LogLevelStartup data node configuration parameter

</tr>
</tbody>
</table>

This parameter controls how often data node memory usage reports are recorded in the cluster log; it is an integer value representing the number of seconds between reports.

Each data node's data memory and index memory usage is logged as both a percentage and a number of 32 KB pages of the `DataMemory` and `IndexMemory`, respectively, set in the `config.ini` file. For
example, if \texttt{DataMemory} is equal to 100 MB, and a given data node is using 50 MB for data memory storage, the corresponding line in the cluster log might look like this:

\begin{verbatim}
2006-12-24 01:18:16 [MgmSrvr] INFO -- Node 2: Data usage is 50\% (1280 32K pages of total 2560)
\end{verbatim}

\texttt{MemReportFrequency} is not a required parameter. If used, it can be set for all cluster data nodes in the \texttt{[ndbd default]} section of \texttt{config.ini}, and can also be set or overridden for individual data nodes in the corresponding \texttt{[ndbd]} sections of the configuration file. The minimum value—which is also the default value—is 0, in which case memory reports are logged only when memory usage reaches certain percentages (80\%, 90\%, and 100\%), as mentioned in the discussion of statistics events in Section 18.5.6.2, “NDB Cluster Log Events”.

- \textbf{StartupStatusReportFrequency}

\textbf{Table 18.126} This table provides type and value information for the \texttt{StartupStatusReportFrequency} data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>seconds</td>
</tr>
<tr>

<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

When a data node is started with the \texttt{--initial}, it initializes the redo log file during Start Phase 4 (see Section 18.5.1, “Summary of NDB Cluster Start Phases”). When very large values are set for \texttt{NoOfFragmentLogFiles}, \texttt{FragmentLogFileSize}, or both, this initialization can take a long time. You can force reports on the progress of this process to be logged periodically, by means of the \texttt{StartupStatusReportFrequency} configuration parameter. In this case, progress is reported in the cluster log, in terms of both the number of files and the amount of space that have been initialized, as shown here:

\begin{verbatim}
#Total files: 80, Completed: 60
#Total MBytes: 20480, Completed: 15557
#Total files: 80, Completed: 60
#Total MBytes: 20480, Completed: 15570
\end{verbatim}

These reports are logged each \texttt{StartupStatusReportFrequency} seconds during Start Phase 4. If \texttt{StartupStatusReportFrequency} is 0 (the default), then reports are written to the cluster log only when at the beginning and at the completion of the redo log file initialization process.

\textbf{Data Node Debugging Parameters.} In NDB Cluster 7.3 and later, it is possible to cause logging of traces for events generated by creating and dropping tables using \texttt{DictTrace}. This parameter is useful only in debugging NDB kernel code. \texttt{DictTrace} takes an integer value. 0 (default - no logging) and 1 (logging enabled) are the only supported values prior to NDB 7.4.12. In NDB 7.4.12 and later, setting this parameter to 2 enables logging of additional \texttt{DBDICT} debugging output (Bug #20368450).

\textbf{Backup parameters.} The \texttt{[ndbd]} parameters discussed in this section define memory buffers set aside for execution of online backups.

- \texttt{BackupDataBufferSize}
Table 18.127 This table provides type and value information for the BackupDataBufferSize data node configuration parameter

</tr>
</tbody>
</table>

In creating a backup, there are two buffers used for sending data to the disk. The backup data buffer is used to fill in data recorded by scanning a node’s tables. Once this buffer has been filled to the level specified as `BackupWriteSize`, the pages are sent to disk. While flushing data to disk, the backup process can continue filling this buffer until it runs out of space. When this happens, the backup process pauses the scan and waits until some disk writes have completed freeing up memory so that scanning may continue.

The default value for this parameter is 16MB. The minimum was raised to 2M in NDB 7.4.8, then lowered to 512K in NDB 7.4.11. (Bug #22749509)

- **BackupDiskWriteSpeedPct**

Table 18.128 This table provides type and value information for the BackupDiskWriteSpeedPct data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>

<td>50</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 90</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

During normal operation, data nodes attempt to maximize the disk write speed used for local checkpoints and backups while remaining within the bounds set by `MinDiskWriteSpeed` and `MaxDiskWriteSpeed`. In NDB Cluster 7.4, the implementation of disk write throttling has been changed to give each LDM thread an equal share of the total budget. This allows parallel LCPs to take place without exceeding the disk I/O budget. Because a backup is executed by only one LDM thread, this...
effectively caused a budget cut, resulting in longer backup completion times, and—if the rate of change is sufficiently high—in failure to complete the backup when the backup log buffer fill rate is higher than the achievable write rate.

This problem is addressed in NDB 7.4.8 and later by the addition of the `BackupDiskWriteSpeedPct` configuration parameter (Bug #20204854). This parameter takes a value in the range 0-90 (inclusive) which is interpreted as the percentage of the node's maximum write rate budget that is reserved prior to sharing out the remainder of the budget among LDM threads for LCPs. The LDM thread running the backup receives the whole write rate budget for the backup, plus its (reduced) share of the write rate budget for local checkpoints. This makes the disk write rate budget in NDB 7.4.8 and later behave similarly to how it is handled in NDB Cluster 7.3 and previous NDB Cluster release series.

The default value for this parameter is 50 (interpreted as 50%).

- **BackupLogBufferSize**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>

</tr>
<tr>
<td>Version (or later)</td>
<td>NDB 7.4.8</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>16M</td>
</tr>
<tr>
<td>Range</td>
<td>2M - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

The backup log buffer fulfills a role similar to that played by the backup data buffer, except that it is used for generating a log of all table writes made during execution of the backup. The same principles apply for writing these pages as with the backup data buffer, except that when there is no more space in the backup log buffer, the backup fails. For that reason, the size of the backup log buffer must be large enough to handle the load caused by write activities while the backup is being made. See Section 18.5.3.3, “Configuration for NDB Cluster Backups”.

The default value for this parameter should be sufficient for most applications. In fact, it is more likely for a backup failure to be caused by insufficient disk write speed than it is for the backup log buffer to become full. If the disk subsystem is not configured for the write load caused by applications, the cluster is unlikely to be able to perform the desired operations.

It is preferable to configure cluster nodes in such a manner that the processor becomes the bottleneck rather than the disks or the network connections.

The default value for this parameter is 16MB.

- **BackupMemory**
Table 18.130 This table provides type and value information for the BackupMemory data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>

</tr>
<tr>
<td>Default</td>
<td>32M</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

This parameter is deprecated, and is subject to removal in a future version of NDB Cluster. In NDB Cluster 7.5 and later, it is ignored.

- **BackupReportFrequency**

Table 18.131 This table provides type and value information for the BackupReportFrequency data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>

</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

This parameter controls how often backup status reports are issued in the management client during a backup, as well as how often such reports are written to the cluster log (provided cluster event logging is configured to permit it—see Logging and checkpointing). BackupReportFrequency represents the time in seconds between backup status reports.

The default value is 0.

- **BackupWriteSize**

Table 18.132 This table provides type and value information for the BackupWriteSize data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
</tbody>
</table>

Version (or later)  
NDB 7.4.8  
Type or units       bytes  
Default             256K  
Range               32K - 4294967039 (0xFFFFFEFF)
NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter specifies the default size of messages written to disk by the backup log and backup data buffers.

The default value for this parameter is 256KB.

- **BackupMaxWriteSize**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>

<td>2K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
<tr>
<td>Version (or later)</td>
<td>NDB 7.4.8</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>1M</td>
</tr>
<tr>
<td>Range</td>
<td>256K - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

This parameter specifies the maximum size of messages written to disk by the backup log and backup data buffers.

The default value for this parameter is 1MB.

**Note**

The location of the backup files is determined by the `BackupDataDir` data node configuration parameter.

**Additional requirements.** When specifying these parameters, the following relationships must hold true. Otherwise, the data node will be unable to start.

- `BackupDataBufferSize >= BackupWriteSize + 188KB`
- `BackupLogBufferSize >= BackupWriteSize + 16KB`
- `BackupMaxWriteSize >= BackupWriteSize`

**NDB Cluster Realtime Performance Parameters**

The `[ndbd]` parameters discussed in this section are used in scheduling and locking of threads to specific CPUs on multiprocessor data node hosts.

**Note**

To make use of these parameters, the data node process must be run as system root.
• **LockExecuteThreadToCPU**

Table 18.134 This table provides type and value information for the LockExecuteThreadToCPU data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>set of CPU IDs</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

When used with `ndbd`, this parameter (now a string) specifies the ID of the CPU assigned to handle the `NDBCLUSTER` execution thread. When used with `ndbmtd`, the value of this parameter is a comma-separated list of CPU IDs assigned to handle execution threads. Each CPU ID in the list should be an integer in the range 0 to 65535 (inclusive).

The number of IDs specified should match the number of execution threads determined by `MaxNoOfExecutionThreads`. However, there is no guarantee that threads are assigned to CPUs in any given order when using this parameter. You can obtain more finely-grained control of this type using `ThreadConfig`.

**LockExecuteThreadToCPU** has no default value.

• **LockMaintThreadsToCPU**

Table 18.135 This table provides type and value information for the LockMaintThreadsToCPU data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>CPU ID</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 64K</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter specifies the ID of the CPU assigned to handle `NDBCLUSTER` maintenance threads.

The value of this parameter is an integer in the range 0 to 65535 (inclusive). In NDB Cluster 7.3 and later, there is no default value.

• **RealtimeScheduler**

Table 18.136 This table provides type and value information for the RealtimeScheduler data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
</tbody>
</table>
Setting this parameter to 1 enables real-time scheduling of data node threads.

Prior to NDB 7.3.3, this parameter did not work correctly with data nodes running `ndbmtd`. (Bug #16961971)

The default is 0 (scheduling disabled).

- **SchedulerExecutionTimer**

  **Table 18.137** This table provides type and value information for the SchedulerExecutionTimer data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>µs</td>
</tr>
<tr>
<td>Default</td>
<td>50</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 11000</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter specifies the time in microseconds for threads to be executed in the scheduler before being sent. Setting it to 0 minimizes the response time; to achieve higher throughput, you can increase the value at the expense of longer response times.

The default is 50 µsec, which our testing shows to increase throughput slightly in high-load cases without materially delaying requests.

- **SchedulerResponsiveness**

  **Table 18.138** This table provides type and value information for the SchedulerResponsiveness data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.4.9</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>5</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 10</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

Set the balance in the NDB scheduler between speed and throughput. This parameter takes an integer whose value is in the range 0-10 inclusive, with 5 as the default. (This is the same as the previous hard-coded value for this parameter.) Higher values provide better response times relative to throughput. Lower values provide increased throughput at the expense of longer response times.

The **SchedulerResponsiveness** parameter was added in NDB 7.4.9, but did not become effective until NDB 7.4.11 (Bug #80341, Bug #22712481).

- **SchedulerSpinTimer**
Table 18.139 This table provides type and value information for the SchedulerSpinTimer data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>µs</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 500</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter specifies the time in microseconds for threads to be executed in the scheduler before sleeping.

The default value is 0.

• **BuildIndexThreads**

Table 18.140 This table provides type and value information for the BuildIndexThreads data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 128</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

This parameter determines the number of threads to create when rebuilding ordered indexes during a system or node start, as well as when running `ndb_restore --rebuild-indexes`. It is supported only when there is more than one fragment for the table per data node (for example, when the `MAX_ROWS` option has been used with `CREATE TABLE`).

Setting this parameter to 0 (the default) disables multithreaded building of ordered indexes.

This parameter is supported when using `ndbd` or `ndbmtd`.

You can enable multithreaded builds during data node initial restarts by setting the `TwoPassInitialNodeRestartCopy` data node configuration parameter to `TRUE`.

• **TwoPassInitialNodeRestartCopy**

Table 18.141 This table provides type and value information for the TwoPassInitialNodeRestartCopy data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
</tbody>
</table>
Multithreaded building of ordered indexes can be enabled for initial restarts of data nodes by setting this configuration parameter to `TRUE`, which enables two-pass copying of data during initial node restarts.

You must also set `BuildIndexThreads` to a nonzero value.

- **Numa**

  Table 18.142 This table provides type and value information for the Numa data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>1</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter determines whether Non-Uniform Memory Access (NUMA) is controlled by the operating system or by the data node process, whether the data node uses `ndbd` or `ndbmtd`. By default, NDB attempts to use an interleaved NUMA memory allocation policy on any data node where the host operating system provides NUMA support.

Setting `Numa = 0` means that the datanode process does not itself attempt to set a policy for memory allocation, and permits this behavior to be determined by the operating system, which may be further guided by the separate `numactl` tool. That is, `Numa = 0` yields the system default behavior, which can be customised by `numactl`. For many Linux systems, the system default behavior is to allocate socket-local memory to any given process at allocation time. This can be problematic when using `ndbmtd`; this is because `ndbmtd` allocates all memory at startup, leading to an imbalance, giving different access speeds for different sockets, especially when locking pages in main memory.

Setting `Numa = 1` means that the data node process uses `libnuma` to request interleaved memory allocation. (This can also be accomplished manually, on the operating system level, using `numactl`.) Using interleaved allocation in effect tells the data node process to ignore non-uniform memory access but does not attempt to take any advantage of fast local memory; instead, the data node process tries to avoid imbalances due to slow remote memory. If interleaved allocation is not desired, set `Numa` to 0 so that the desired behavior can be determined on the operating system level.

The `Numa` configuration parameter is supported only on Linux systems where `libnuma.so` is available.

**Multi-Threading Configuration Parameters (ndbmtd).** `ndbmtd` runs by default as a single-threaded process and must be configured to use multiple threads, using either of two methods, both of which require setting configuration parameters in the `config.ini` file. The first method is simply to set an appropriate value for the `MaxNoOfExecutionThreads` configuration parameter. NDB Cluster 7.3 and later also support a second method, whereby it is possible to set up more complex rules for `ndbmtd` multithreading using `ThreadConfig`. The next few paragraphs provide information about these parameters and their use with multithreaded data nodes.

- **MaxNoOfExecutionThreads**
### Table 18.143
This table provides type and value information for the MaxNoOfExecutionThreads multi-threaded data node configuration parameter.

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>Restart Type</td>
<td>IS</td>
</tr>
</tbody>
</table>

This parameter directly controls the number of execution threads used by ndbmt, up to a maximum of 72 (previous to NDB 7.3.3, this was 36). Although this parameter is set in [ndbd] or [ndbd default] sections of the config.ini file, it is exclusive to ndbmt and does not apply to ndbd.

Setting `MaxNoOfExecutionThreads` sets the number of threads for each type as determined by a matrix in the file `storage/ndb/src/kernel/vm/mt_thr_config.cpp`. This table shows these numbers of threads for possible values of `MaxNoOfExecutionThreads` in NDB 7.4.3 and later (Bug #75220, Bug #20215689). (A table with information about the matrix applicable in previous versions of NDB Cluster follows this one.) Rows containing values which changed in NDB 7.4.3 are shown in emphasized text.

</table>
The following table shows how the number of threads for each type is obtained for values of `MaxNoOfExecutionThreads` in NDB 7.4.2 and earlier. This table can be also used with NDB 7.3.2 and earlier, except that in these versions the maximum value for `MaxNoOfExecutionThreads` is 36, and thus rows from this table which correspond to values greater than 36 do not apply in versions prior to NDB 7.3.3.

</tbody>
</table>
In NDB Cluster 7.3 and later, there is always one SUMA (replication) thread.

NoOfFragmentLogParts should be set equal to the number of LDM threads used by ndbmtd as determined by the setting for MaxNoOfExecutionThreads. This ratio should not be any greater than 4:1; beginning with NDB 7.4.16, a configuration in which this is the case is specifically disallowed. (Bug #25333414)

The number of LDM threads also determines the number of partitions used by an NDB table that is not explicitly partitioned; this is the number of LDM threads times the number of data nodes in the cluster. (If ndbd is used on the data nodes rather than ndbmtd, then there is always a single LDM thread; in this case, the number of partitions created automatically is simply equal to the number of data nodes. See Section 18.1.2, “NDB Cluster Nodes, Node Groups, Replicas, and Partitions”, for more information.

Adding large tablespaces for Disk Data tables when using more than the default number of LDM threads may cause issues with resource and CPU usage if the disk page buffer is insufficiently large; see the description of the DiskPageBufferMemory configuration parameter, for more information.

The thread types are described later in this section (see ThreadConfig).

Setting this parameter outside the permitted range of values causes the management server to abort on startup with the error **Error line number: Illegal value value for parameter MaxNoOfExecutionThreads**.

For MaxNoOfExecutionThreads, a value of 0 or 1 is rounded up internally by NDB to 2, so that 2 is considered this parameter's default and minimum value.
MaxNoOfExecutionThreads is generally intended to be set equal to the number of CPU threads available, and to allocate a number of threads of each type suitable to typical workloads. It does not assign particular threads to specified CPUs. For cases where it is desirable to vary from the settings provided, or to bind threads to CPUs, you should use ThreadConfig instead, which allows you to allocate each thread directly to a desired type, CPU, or both.

The multithreaded data node process always spawns, at a minimum, the threads listed here:

- 1 local query handler (LDM) thread
- 1 receive thread
- 1 subscription manager (SUMA or replication) thread

For a MaxNoOfExecutionThreads value of 8 or less, no TC threads are created, and TC handling is instead performed by the main thread.

Changing the number of LDM threads always requires a system restart, whether it is changed using this parameter or ThreadConfig. If the cluster's IndexMemory usage is greater than 50%, changing this requires an initial restart of the cluster. (A maximum of 30-35% IndexMemory usage is recommended in such cases.) Otherwise, resource usage and LDM thread allocation cannot be balanced between nodes, which can result in underutilized and overutilized LDM threads, and ultimately data node failures.

- NoOfFragmentLogParts

Table 18.146 This table provides type and value information for the NoOfFragmentLogParts multithreaded data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>

</tr>
</tbody>
</table>

Set the number of log file groups for redo logs belonging to this ndbmtd. Prior to NDB 7.3.3, this value must be an even multiple of 4 between 4 and 16, inclusive. In NDB 7.3.3 and later, the maximum is 32; the value must, as before, be an even multiple of 4.

NoOfFragmentLogParts should be set equal to the number of LDM threads used by ndbmtd as determined by the setting for MaxNoOfExecutionThreads. Beginning with NDB 7.4.16, a configuration where this number is any greater than 4 is disallowed. (Bug #25333414)

See the description of MaxNoOfExecutionThreads for more information.

- ThreadConfig
Table 18.147 This table provides type and value information for the ThreadConfig multi-threaded data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>string</td>
</tr>
<tr>
<td>Default</td>
<td>&quot;</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IS</td>
</tr>
</tbody>
</table>

This parameter is used with `ndbmtd` to assign threads of different types to different CPUs. Its value is a string whose format has the following syntax:

```
ThreadConfig := entry[,entry[,...]]
entry := type={param[,param[,...,]]}

type := ldm | main | recv | send | rep | io | tc | watchdog

param := count=number
   | cpubind=cpu_list
   | cpuset=cpu_list
   | spintime=number
   | realtime={0|1}
```

The curly braces (`{...}`) surrounding the list of parameters are required, even if there is only one parameter in the list.

A `param` (parameter) specifies any or all of the following information:

- The number of threads of the given type (`count`).
- The set of CPUs to which the threads of the given type are to be nonexclusively bound. This is determined by either one of `cpubind` or `cpuset`. `cpubind` causes each thread to be bound (nonexclusively) to a CPU in the set; `cpuset` means that each thread is bound (nonexclusively) to the set of CPUs specified.

Only one of `cpubind` or `cpuset` can be provided in a single configuration.

- `spintime` determines the wait time in microseconds the thread spins before going to sleep.

  The default value for `spintime` is the value of the `SchedulerSpinTimer` data node configuration parameter.

  `spintime` does not apply to I/O threads or watchdog threads and so cannot be set for these thread types.

- `realtime` can be set to 0 or 1. If it is set to 1, the threads run with real-time priority. This also means that `thread_prio` cannot be set.

  The `realtime` parameter is set by default to the value of the `RealtimeScheduler` data node configuration parameter.
The `type` attribute represents an NDB thread type. The thread types supported in NDB Cluster 7.3 and later, and the range of permitted count values for each, are provided in the following list:

- **ldm**: Local query handler (DBLQH kernel block) that handles data. The more LDM threads that are used, the more highly partitioned the data becomes. Each LDM thread maintains its own sets of data and index partitions, as well as its own redo log. The value set for ldm must be one of the values 1, 2, 4, 6, 8, 12, 16, 24, or 32. (Prior to NDB 7.3.3, the maximum value was 16.)

Changing the number of LDM threads requires a system restart to be effective and safe for cluster operations. (This is also true when this is done using MaxNoOfExecutionThreads.) If IndexMemory usage is in excess of 50%, an initial restart of the cluster is required; a maximum of 30-35% IndexMemory usage is recommended in such cases. Otherwise, IndexMemory and DataMemory usage as well as the allocation of LDM threads cannot be balanced between nodes, which can ultimately lead to data node failures.

Adding large tablespaces (hundreds of gigabytes or more) for Disk Data tables when using more than the default number of LDMs may cause issues with resource and CPU usage if DiskPageBufferMemory is not sufficiently large.

- **tc**: Transaction coordinator thread (DBTC kernel block) containing the state of an ongoing transaction. In NDB Cluster 7.3 and later, the number of TC threads is configurable; a total of 32 is possible in NDB 7.3.3 and later; previously this was 16.

Optimally, every new transaction can be assigned to a new TC thread. In most cases 1 TC thread per 2 LDM threads is sufficient to guarantee that this can happen. In cases where the number of writes is relatively small when compared to the number of reads, it is possible that only 1 TC thread per 4 LQH threads is required to maintain transaction states. Conversely, in applications that perform a great many updates, it may be necessary for the ratio of TC threads to LDM threads to approach 1 (for example, 3 TC threads to 4 LDM threads).

Setting tc to 0 causes TC handling to be done by the main thread. In most cases, this is effectively the same as setting it to 1.

Range: (NDB 7.3.3 and later) 0 - 32; (NDB 7.3.2 and earlier) 0 - 16.

- **main**: Data dictionary and transaction coordinator (DBDIH and DBTC kernel blocks), providing schema management. This is always handled by a single dedicated thread.

Range: 1 only.

- **recv**: Receive thread (CMVMI kernel block). Each receive thread handles one or more sockets for communicating with other nodes in an NDB Cluster, with one socket per node. NDB Cluster 7.3 and later support multiple receive threads. In NDB 7.3.2 and earlier, the maximum is 8 such threads; in NDB 7.3.3 and later, the maximum is 16.

Range: (NDB 7.3.3 and later) 1 - 16; (NDB 7.3.2 and earlier) 1 - 8.

- **send**: Send thread (CMVMI kernel block). To increase throughput, it is possible to perform sends from one or more separate, dedicated threads (maximum 8).

Previously, all threads handled their own sending directly; this can still be made to happen by setting the number of send threads to 0 (this also happens when MaxNoOfExecutionThreads is set less than 10). While doing so can have an adverse impact on throughput, it can also in some cases provide decreased latency.
NDB Cluster Configuration Files

Range: *(NDB 7.3.3 and later)* 0 - 16; *(NDB 7.3.2 and earlier)* 0 - 8.

- **rep**: Replication thread *(SUMA* kernel block). Asynchronous replication operations are always handled by a single, dedicated thread.
  
  Range: 1 only.

- **io**: File system and other miscellaneous operations. These are not demanding tasks, and are always handled as a group by a single, dedicated I/O thread.
  
  Range: 1 only.

- **watchdog**: Settings to this parameter are actually applied to several threads of this type having specific uses. These threads include the *SocketServer* thread which receives connection setups from other nodes, the *SocketClient* thread which attempts to set up connections to other nodes, and the thread watchdog thread that checks that threads are progressing.
  
  Range: 1 only.

Simple examples:

```plaintext
# Example 1.
ThreadConfig=ldm={count=2,cpubind=1,2},main={cpubind=12},rep={cpubind=11}

# Example 2.
Threadconfig=main={cpubind=0},ldm={count=4,cpubind=1,2,5,6},io={cpubind=3}
```

It is usually desirable when configuring thread usage for a data node host to reserve one or more number of CPUs for operating system and other tasks. Thus, for a host machine with 24 CPUs, you might want to use 20 CPU threads (leaving 4 for other uses), with 8 LDM threads, 4 TC threads (half the number of LDM threads), 3 send threads, 3 receive threads, and 1 thread each for schema management, asynchronous replication, and I/O operations. (This is almost the same distribution of threads used when *MaxNoOfExecutionThreads* is set equal to 20.) The following *ThreadConfig* setting performs these assignments, additionally binding all of these threads to specific CPUs:

```plaintext
ThreadConfig=ldm{count=8,cpubind=1,2,3,4,5,6,7,8},main={cpubind=9},io={cpubind=9}, rep={cpubind=10},tc{count=4,cpubind=11,12,13,14},recv={count=3,cpubind=15,16,17}, 
 send={count=3,cpubind=18,19,20}
```

It should be possible in most cases to bind the main (schema management) thread and the I/O thread to the same CPU, as we have done in the example just shown.

In order to take advantage of the enhanced stability that the use of *ThreadConfig* offers, it is necessary to insure that CPUs are isolated, and that they not subject to interrupts, or to being scheduled for other tasks by the operating system. On many Linux systems, you can do this by setting *IRQBALANCE_BANNED_CPUS* in `/etc/sysconfig/irqbalance` to `0xFFFFFFFF`, and by using the *isolcpus* boot option in *grub.conf*. For specific information, see your operating system or platform documentation.

**Disk Data Configuration Parameters.** Configuration parameters affecting Disk Data behavior include the following:

- **DiskPageBufferEntries**
Table 18.148 This table provides type and value information for the DiskPageBufferEntries data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.8</td>
</tr>
<tr>
<td>Type or units</td>
<td>32K pages</td>
</tr>
<tr>
<td>Default</td>
<td>10</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 1000</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This is the number of page entries (page references) to allocate. It is specified as a number of 32K pages in DiskPageBufferMemory. The default is sufficient for most cases but you may need to increase the value of this parameter if you encounter problems with very large transactions on Disk Data tables. Each page entry requires approximately 100 bytes.

• DiskPageBufferMemory

Table 18.149 This table provides type and value information for the DiskPageBufferMemory data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>64M</td>
</tr>
<tr>
<td>Range</td>
<td>4M - 1T</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This determines the amount of space used for caching pages on disk, and is set in the [ndbd] or [ndbd default] section of the config.ini file. It is measured in bytes. Each page takes up 32 KB. This means that NDB Cluster Disk Data storage always uses \( N \times 32 \) KB memory where \( N \) is some nonnegative integer.

The default value for this parameter is 64M (2000 pages of 32 KB each).

If the value for DiskPageBufferMemory is set too low in conjunction with using more than the default number of LDM threads in ThreadConfig (for example \{ldm=6...\}), problems can arise when trying to add a large (for example 500G) data file to a disk-based NDB table, wherein the process takes indefinitely long while occupying one of the CPU cores.

This is due to the fact that, as part of adding a data file to a tablespace, extent pages are locked into memory in an extra PGMAN worker thread, for quick metadata access. When adding a large file, this worker has insufficient memory for all of the data file metadata. In such cases, you should either increase DiskPageBufferMemory, or add smaller tablespace files. You may also need to adjust DiskPageBufferEntries.
You can query the `ndbinfo.diskpagebuffer` table to help determine whether the value for this parameter should be increased to minimize unnecessary disk seeks. See Section 18.5.10.12, “The ndbinfo diskpagebuffer Table”, for more information.

- **SharedGlobalMemory**

**Table 18.150 This table provides type and value information for the SharedGlobalMemory data node configuration parameter**

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

This parameter determines the amount of memory that is used for log buffers, disk operations (such as page requests and wait queues), and metadata for tablespaces, log file groups, UNDO files, and data files. The shared global memory pool also provides memory used for satisfying the memory requirements of the `UNDO_BUFFER_SIZE` option used with `CREATE LOGFILE GROUP` and `ALTER LOGFILE GROUP` statements, including any default value implied for this options by the setting of the `InitialLogFileGroup` data node configuration parameter. SharedGlobalMemory can be set in the `[ndbd]` or `[ndbd default]` section of the `config.ini` configuration file, and is measured in bytes.

The default value is **128M**.

- **DiskIOThreadPool**

**Table 18.151 This table provides type and value information for the DiskIOThreadPool data node configuration parameter**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>

</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter determines the number of unbound threads used for Disk Data file access. Before `DiskIOThreadPool` was introduced, exactly one thread was spawned for each Disk Data file, which could lead to performance issues, particularly when using very large data files. With `DiskIOThreadPool`, you can—for example—access a single large data file using several threads working in parallel.

This parameter applies to Disk Data I/O threads only.

The optimum value for this parameter depends on your hardware and configuration, and includes these factors:

- **Physical distribution of Disk Data files.** You can obtain better performance by placing data files, undo log files, and the data node file system on separate physical disks. If you do this with some or
all of these sets of files, then you can set `DiskIOThreadPool` higher to enable separate threads to handle the files on each disk.

- **Disk performance and types.** The number of threads that can be accommodated for Disk Data file handling is also dependent on the speed and throughput of the disks. Faster disks and higher throughput allow for more disk I/O threads. Our test results indicate that solid-state disk drives can handle many more disk I/O threads than conventional disks, and thus higher values for `DiskIOThreadPool`.

The default value for this parameter is 2.

- **Disk Data file system parameters.** The parameters in the following list make it possible to place NDB Cluster Disk Data files in specific directories without the need for using symbolic links.

  - **FileSystemPathDD**

    | Property                  | Value                  |
    |---------------------------|------------------------|
    | **Version (or later)**    | NDB 7.3.1              |
    | **Type or units**         | filename               |
    | **Default**               | [see text]             |
    | **Range**                 | ...                    |
    | **Restart Type**          | IN                     |

If this parameter is specified, then NDB Cluster Disk Data data files and undo log files are placed in the indicated directory. This can be overridden for data files, undo log files, or both, by specifying values for `FileSystemPathDataFiles`, `FileSystemPathUndoFiles`, or both, as explained for these parameters. It can also be overridden for data files by specifying a path in the `ADD DATAFILE` clause of a `CREATE TABLESPACE` or `ALTER TABLESPACE` statement, and for undo log files by specifying a path in the `ADD UNDOFILE` clause of a `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP` statement. If `FileSystemPathDD` is not specified, then `FileSystemPath` is used.

If a `FileSystemPathDD` directory is specified for a given data node (including the case where the parameter is specified in the `[ndbd default]` section of the `config.ini` file), then starting that data node with `--initial` causes all files in the directory to be deleted.

- **FileSystemPathDataFiles**

    | Property                  | Value                  |
    |---------------------------|------------------------|
    | **Version (or later)**    | NDB 7.3.1              |
    | **Type or units**         | filename               |
    | **Default**               | [see text]             |
    | **Range**                 | ...                    |
    | **Restart Type**          | IN                     |

If this parameter is specified, then NDB Cluster Disk Data data files are placed in the indicated directory. This overrides any value set for `FileSystemPathDD`. This parameter can be overridden.
for a given data file by specifying a path in the ADD DATAFILE clause of a CREATE TABLESPACE or ALTER TABLESPACE statement used to create that data file. If FileSystemPathDataFiles is not specified, then FileSystemPathDD is used (or FileSystemPath, if FileSystemPathDD has also not been set).

If a FileSystemPathDataFiles directory is specified for a given data node (including the case where the parameter is specified in the [ndbd default] section of the config.ini file), then starting that data node with --initial causes all files in the directory to be deleted.

• FileSystemPathUndoFiles

Table 18.154 This table provides type and value information for the FileSystemPathUndoFiles data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>filename</td>
</tr>
<tr>
<td>Default</td>
<td>[see text]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td><strong>IN</strong></td>
</tr>
</tbody>
</table>

If this parameter is specified, then NDB Cluster Disk Data undo log files are placed in the indicated directory. This overrides any value set for FileSystemPathDD. This parameter can be overridden for a given data file by specifying a path in the ADD UNDO clause of a CREATE LOGFILE GROUP or ALTER LOGFILE GROUP statement used to create that data file. If FileSystemPathUndoFiles is not specified, then FileSystemPathDD is used (or FileSystemPath, if FileSystemPathDD has also not been set).

If a FileSystemPathUndoFiles directory is specified for a given data node (including the case where the parameter is specified in the [ndbd default] section of the config.ini file), then starting that data node with --initial causes all files in the directory to be deleted.

For more information, see Section 18.5.12.1, “NDB Cluster Disk Data Objects”.

• Disk Data object creation parameters. The next two parameters enable you—when starting the cluster for the first time—to cause a Disk Data log file group, tablespace, or both, to be created without the use of SQL statements.

• InitialLogFileGroup

Table 18.155 This table provides type and value information for the InitialLogFileGroup data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>string</td>
</tr>
<tr>
<td>Default</td>
<td>[see text]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td><strong>S</strong></td>
</tr>
</tbody>
</table>

This parameter can be used to specify a log file group that is created when performing an initial start of the cluster. InitialLogFileGroup is specified as shown here:
InitialLogFileGroup = [name=name;] [undo_buffer_size=size;] file-specification-list

file-specification-list:
  file-specification; file-specification[; ...]

file-specification:
  filename:size

The name of the log file group is optional and defaults to DEFAULT-LG. The undo_buffer_size is also optional; if omitted, it defaults to 64M. Each file-specification corresponds to an undo log file, and at least one must be specified in the file-specification-list. Undo log files are placed according to any values that have been set for FileSystemPath, FileSystemPathDD, and FileSystemPathUndoFiles, just as if they had been created as the result of a CREATE LOGFILE GROUP or ALTER LOGFILE GROUP statement.

Consider the following:

InitialLogFileGroup = name=LG1; undo_buffer_size=128M; undo1.log:250M; undo2.log:150M

This is equivalent to the following SQL statements:

```
CREATE LOGFILE GROUP LG1
  ADD UNDOFILE 'undo1.log'
  INITIAL_SIZE 250M
  UNDO_BUFFER_SIZE 128M
  ENGINE NDBCLUSTER;

ALTER LOGFILE GROUP LG1
  ADD UNDOFILE 'undo2.log'
  INITIAL_SIZE 150M
  ENGINE NDBCLUSTER;
```

This logfile group is created when the data nodes are started with --initial.

Prior to NDB 7.3.6, resources for the initial log file group are taken from the global memory pool whose size is determined by the value of the SharedGlobalMemory data node configuration parameter; in these versions, if this parameter is set too low and the values set in InitialLogFileGroup for the logfile group’s initial size or undo buffer size are too high, the cluster may fail to create the default log file group when starting, or fail to start altogether. In NDB 7.3.6 and later, resources for the initial log file group are added to the global memory pool along with those indicated by the value of SharedGlobalMemory (Bug #11762867).

This parameter, if used, should always be set in the [ndbd default] section of the config.ini file. The behavior of an NDB Cluster when different values are set on different data nodes is not defined.

* InitialTablespace

**Table 18.156** This table provides type and value information for the InitialTablespace data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>string</td>
</tr>
<tr>
<td>Default</td>
<td>[see text]</td>
</tr>
</tbody>
</table>
NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

This parameter can be used to specify an NDB Cluster Disk Data tablespace that is created when performing an initial start of the cluster. `InitialTablespace` is specified as shown here:

```
InitialTablespace = [name=name]; [extent_size=size]; file-specification-list
```

The `name` of the tablespace is optional and defaults to `DEFAULT-TS`. The `extent_size` is also optional; it defaults to 1M. The `file-specification-list` uses the same syntax as shown with the `InitialLogfileGroup` parameter, the only difference being that each `file-specification` used with `InitialTablespace` corresponds to a data file. At least one must be specified in the `file-specification-list`. Data files are placed according to any values that have been set for `FileSystemPath`, `FileSystemPathDD`, and `FileSystemPathDataFiles`, just as if they had been created as the result of a `CREATE TABLESPACE` or `ALTER TABLESPACE` statement.

For example, consider the following line specifying `InitialTablespace` in the `[ndbd default]` section of the `config.ini` file (as with `InitialLogfileGroup`, this parameter should always be set in the `[ndbd default]` section, as the behavior of an NDB Cluster when different values are set on different data nodes is not defined):

```
InitialTablespace = name=TS1; extent_size=8M; data1.dat:2G; data2.dat:4G
```

This is equivalent to the following SQL statements:

```
CREATE TABLESPACE TS1
  ADD DATAFILE 'data1.dat'
  EXTENT_SIZE 8M
  INITIAL_SIZE 2G
  ENGINE NDBCLUSTER;

ALTER TABLESPACE TS1
  ADD DATAFILE 'data2.dat'
  INITIAL_SIZE 4G
  ENGINE NDBCLUSTER;
```

This tablespace is created when the data nodes are started with `--initial`, and can be used whenever creating NDB Cluster Disk Data tables thereafter.

**Disk Data and GCP Stop errors.** Errors encountered when using Disk Data tables such as `Node nodeid killed this node because GCP stop was detected (error 2303)` are often referred to as “GCP stop errors”. Such errors occur when the redo log is not flushed to disk quickly enough; this is usually due to slow disks and insufficient disk throughput.

You can help prevent these errors from occurring by using faster disks, and by placing Disk Data files on a separate disk from the data node file system. Reducing the value of `TimeBetweenGlobalCheckpoints` tends to decrease the amount of data to be written for each global checkpoint, and so may provide some protection against redo log buffer overflows when trying to write a global checkpoint; however, reducing this value also permits less time in which to write the GCP, so this must be done with caution.

In addition to the considerations given for `DiskPageBufferMemory` as explained previously, it is also very important that the `DiskIOThreadPool` configuration parameter be set correctly; having `DiskIOThreadPool` set too high is very likely to cause GCP stop errors (Bug #37227).
GCP stops can be caused by save or commit timeouts; the `TimeBetweenEpochsTimeout` data node configuration parameter determines the timeout for commits. However, it is possible to disable both types of timeouts by setting this parameter to 0.

**Parameters for configuring send buffer memory allocation.** Send buffer memory is allocated dynamically from a memory pool shared between all transporters, which means that the size of the send buffer can be adjusted as necessary. (Previously, the NDB kernel used a fixed-size send buffer for every node in the cluster, which was allocated when the node started and could not be changed while the node was running.) The `TotalSendBufferMemory` and `OverLoadLimit` data node configuration parameters permit the setting of limits on this memory allocation. For more information about the use of these parameters (as well as `SendBufferMemory`), see Section 18.3.3.13, “Configuring NDB Cluster Send Buffer Parameters”.

- **ExtraSendBufferMemory**
  This parameter specifies the amount of transporter send buffer memory to allocate in addition to any set using `TotalSendBufferMemory`, `SendBufferMemory`, or both.

- **TotalSendBufferMemory**
  This parameter is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

  If this parameter is set, its minimum permitted value is 256KB; 0 indicates that the parameter has not been set. For more detailed information, see Section 18.3.3.13, “Configuring NDB Cluster Send Buffer Parameters”.

- **ReservedSendBufferMemory**
  This parameter is present in `NDBCLUSTER` source code beginning with NDB 6.4.0. However, it is not currently enabled.

  This parameter was deprecated in NDB Cluster 7.2, and is subject to removal in a future release of NDB Cluster (Bug #11760629, Bug #53053). For more detailed information about the behavior and use of `TotalSendBufferMemory` and `ReservedSendBufferMemory`, and about configuring send buffer memory parameters in NDB Cluster, see Section 18.3.3.13, “Configuring NDB Cluster Send Buffer Parameters”.

  See also Section 18.5.14, “Adding NDB Cluster Data Nodes Online”.

**Redo log over-commit handling.** It is possible to control a data node’s handling of operations when too much time is taken flushing redo logs to disk. This occurs when a given redo log flush takes longer than `RedoOverCommitLimit` seconds, more than `RedoOverCommitCounter` times, causing any pending transactions to be aborted. When this happens, the API node that sent the transaction can handle the operations that should have been committed either by queuing the operations and re-trying them, or by aborting them, as determined by `DefaultOperationRedoProblemAction`. The data node configuration parameters for setting the timeout and number of times it may be exceeded before the API node takes this action are described in the following list:

- **RedoOverCommitCounter**

  This table provides type and value information for the `RedoOverCommitCounter` data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
</tbody>
</table>
When `RedoOverCommitLimit` is exceeded when trying to write a given redo log to disk this many times or more, any transactions that were not committed as a result are aborted, and an API node where any of these transactions originated handles the operations making up those transactions according to its value for `DefaultOperationRedoProblemAction` (by either queuing the operations to be re-tried, or aborting them).

`RedoOverCommitCounter` defaults to 3. Set it to 0 to disable the limit.

- `RedoOverCommitLimit`

Table 18.158 This table provides type and value information for the `RedoOverCommitLimit` data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>seconds</td>
</tr>
<tr>
<td>Default</td>
<td>20</td>
</tr>
<tr>
<td>Range</td>
<td>0-4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter sets an upper limit in seconds for trying to write a given redo log to disk before timing out. The number of times the data node tries to flush this redo log, but takes longer than `RedoOverCommitLimit`, is kept and compared with `RedoOverCommitCounter`, and when flushing takes too long more times than the value of that parameter, any transactions that were not committed as a result of the flush timeout are aborted. When this occurs, the API node where any of these transactions originated handles the operations making up those transactions according to its `DefaultOperationRedoProblemAction` setting (it either queues the operations to be re-tried, or aborts them).

By default, `RedoOverCommitLimit` is 20 seconds. Set to 0 to disable checking for redo log flush timeouts. This parameter was added in NDB 7.1.10.

**Controlling restart attempts.** It is possible to exercise finely-grained control over restart attempts by data nodes when they fail to start using the `MaxStartFailRetries` and `StartFailRetryDelay` data node configuration parameters.

`MaxStartFailRetries` limits the total number of retries made before giving up on starting the data node, `StartFailRetryDelay` sets the number of seconds between retry attempts. These parameters are listed here:

- `StartFailRetryDelay`
NDB Cluster Configuration Files

Table 18.159 This table provides type and value information for the StartFailRetryDelay data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Use this parameter to set the number of seconds between restart attempts by the data node in the event of failure on startup. The default is 0 (no delay).

Both this parameter and MaxStartFailRetries are ignored unless StopOnError is equal to 0.

• MaxStartFailRetries

Table 18.160 This table provides type and value information for the MaxStartFailRetries data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>3</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Use this parameter to limit the number restart attempts made by the data node in the event that it fails on startup. The default is 3 attempts.

Both this parameter and StartFailRetryDelay are ignored unless StopOnError is equal to 0.

NDB index statistics parameters. The parameters in the following list relate to NDB index statistics generation, which was introduced in NDB 7.2.1.

• IndexStatAutoCreate

Table 18.161 This table provides type and value information for the IndexStatAutoCreate data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0, 1</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

Enable (set equal to 1) or disable (set equal to 0) automatic statistics collection when indexes are created. Disabled by default.
This parameter was added in NDB 7.2.1.

- **IndexStatAutoUpdate**

  Table 18.162 This table provides type and value information for the IndexStatAutoUpdate data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0, 1</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>S</td>
</tr>
</tbody>
</table>

Enable (set equal to 1) or disable (set equal to 0) monitoring of indexes for changes and trigger automatic statistics updates these are detected. The amount and degree of change needed to trigger the updates are determined by the settings for the **IndexStatTriggerPct** and **IndexStatTriggerScale** options.

This parameter was added in NDB 7.2.1.

- **IndexStatSaveSize**

  Table 18.163 This table provides type and value information for the IndexStatSaveSize data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>32768</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>IN</td>
</tr>
</tbody>
</table>

Maximum space in bytes allowed for the saved statistics of any given index in the NDB system tables and in the **mysqld** memory cache. This consumes **IndexMemory**.

At least one sample is always produced, regardless of any size limit. This size is scaled by **IndexStatSaveScale**.

This parameter was added in NDB 7.2.1.

The size specified by **IndexStatSaveSize** is scaled by the value of **IndexStatTriggerPct** for a large index, times 0.01. This is further multiplied by the logarithm to the base 2 of the index size. Setting **IndexStatTriggerPct** equal to 0 disables the scaling effect.

- **IndexStatSaveScale**
Table 18.164 This table provides type and value information for the IndexStatSaveScale data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>percentage</td>
</tr>
<tr>
<td>Default</td>
<td>100</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IN</td>
</tr>
</tbody>
</table>

The size specified by `IndexStatSaveSize` is scaled by the value of `IndexStatTriggerPct` for a large index, times 0.01. This is further multiplied by the logarithm to the base 2 of the index size. Setting `IndexStatTriggerPct` equal to 0 disables the scaling effect.

- `IndexStatTriggerPct`

Table 18.165 This table provides type and value information for the `IndexStatTriggerPct` data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>percentage</td>
</tr>
<tr>
<td>Default</td>
<td>100</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IN</td>
</tr>
</tbody>
</table>

Percentage change in updates that triggers an index statistics update. The value is scaled by `IndexStatTriggerScale`. You can disable this trigger altogether by setting `IndexStatTriggerPct` to 0.

This parameter was added in NDB 7.2.1.

- `IndexStatTriggerScale`

Table 18.166 This table provides type and value information for the `IndexStatTriggerScale` data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>percentage</td>
</tr>
<tr>
<td>Default</td>
<td>100</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IN</td>
</tr>
</tbody>
</table>

Scale `IndexStatTriggerPct` by this amount times 0.01 for a large index. A value of 0 disables scaling.

This parameter was added in NDB 7.2.1.

- `IndexStatUpdateDelay`
Table 18.167 This table provides type and value information for the `IndexStatUpdateDelay` data node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>seconds</td>
</tr>
<tr>
<td>Default</td>
<td>60</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>IN</td>
</tr>
</tbody>
</table>

Minimum delay in seconds between automatic index statistics updates for a given index. Setting this variable to 0 disables any delay. The default is 60 seconds.

This parameter was added in NDB 7.2.1.

### 18.3.3.7 Defining SQL and Other API Nodes in an NDB Cluster

The `[mysqld]` and `[api]` sections in the `config.ini` file define the behavior of the MySQL servers (SQL nodes) and other applications (API nodes) used to access cluster data. None of the parameters shown is required. If no computer or host name is provided, any host can use this SQL or API node.

Generally speaking, a `[mysqld]` section is used to indicate a MySQL server providing an SQL interface to the cluster, and an `[api]` section is used for applications other than `mysqld` processes accessing cluster data, but the two designations are actually synonymous; you can, for instance, list parameters for a MySQL server acting as an SQL node in an `[api]` section.

**Note**

For a discussion of MySQL server options for NDB Cluster, see MySQL Server Options for NDB Cluster. For information about MySQL server system variables relating to NDB Cluster, see NDB Cluster System Variables.

**Restart types.** Information about the restart types used by the parameter descriptions in this section is shown in the following table:

Table 18.168 NDB Cluster restart types

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Restart Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
<td>Node</td>
<td>The parameter can be updated using a rolling restart (see Section 18.5.5, “Performing a Rolling Restart of an NDB Cluster”)</td>
</tr>
<tr>
<td>S</td>
<td>System</td>
<td>All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter</td>
</tr>
<tr>
<td>I</td>
<td>Initial</td>
<td>Data nodes must be restarted using the <code>--initial</code> option</td>
</tr>
</tbody>
</table>

- **Id**

Table 18.169 This table provides type and value information for the `Id` API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
</tbody>
</table>
The **Id** is an integer value used to identify the node in all cluster internal messages. The permitted range of values is 1 to 255 inclusive. This value must be unique for each node in the cluster, regardless of the type of node.

**Note**

Data node IDs must be less than 49, regardless of the NDB Cluster version used. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for API nodes (and management nodes) to values greater than 48.

**NodeId** is the preferred parameter name to use when identifying API nodes. (**id** continues to be supported for backward compatibility, but is now deprecated and generates a warning when used. It is also subject to future removal.)

- **ConnectionMap**

**Table 18.170** This table provides type and value information for the ConnectionMap API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>string</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

Specifies which data nodes to connect.

- **NodeId**

**Table 18.171** This table provides type and value information for the NodeId API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 255</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>IS</td>
</tr>
</tbody>
</table>

The **NodeId** is an integer value used to identify the node in all cluster internal messages. The permitted range of values is 1 to 255 inclusive. This value must be unique for each node in the cluster, regardless of the type of node.
NDB Cluster Configuration Files

Note

Data node IDs must be less than 49, regardless of the NDB Cluster version used. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for API nodes (and management nodes) to values greater than 48.

NodeId is the preferred parameter name to use when identifying management nodes. An alias, Id, was used for this purpose in very old versions of NDB Cluster, and continues to be supported for backward compatibility; it is now deprecated and generates a warning when used, and is subject to removal in a future release of NDB Cluster.

• ExecuteOnComputer

Table 18.172 This table provides type and value information for the ExecuteOnComputer API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>name</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

This refers to the Id set for one of the computers (hosts) defined in a [computer] section of the configuration file.

• HostName

Table 18.173 This table provides type and value information for the HostName API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>name or IP address</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Specifying this parameter defines the hostname of the computer on which the SQL node (API node) is to reside. To specify a hostname, either this parameter or ExecuteOnComputer is required.

If no HostName or ExecuteOnComputer is specified in a given [mysql] or [api] section of the config.ini file, then an SQL or API node may connect using the corresponding “slot” from any host which can establish a network connection to the management server host machine. This differs from the default behavior for data nodes, where localhost is assumed for HostName unless otherwise specified.

• ArbitrationRank
Table 18.174 This table provides type and value information for the ArbitrationRank API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>0-2</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 2</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter defines which nodes can act as arbitrators. Both management nodes and SQL nodes can be arbitrators. A value of 0 means that the given node is never used as an arbitrator, a value of 1 gives the node high priority as an arbitrator, and a value of 2 gives it low priority. A normal configuration uses the management server as arbitrator, setting its `ArbitrationRank` to 1 (the default for management nodes) and those for all SQL nodes to 0 (the default for SQL nodes).

By setting `ArbitrationRank` to 0 on all management and SQL nodes, you can disable arbitration completely. You can also control arbitration by overriding this parameter; to do so, set the `Arbitration` parameter in the `[ndbd default]` section of the `config.ini` global configuration file.

- **ArbitrationDelay**

Table 18.175 This table provides type and value information for the ArbitrationDelay API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>milliseconds</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Setting this parameter to any other value than 0 (the default) means that responses by the arbitrator to arbitration requests will be delayed by the stated number of milliseconds. It is usually not necessary to change this value.

- **BatchByteSize**

Table 18.176 This table provides type and value information for the BatchByteSize API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>16K</td>
</tr>
<tr>
<td>Range</td>
<td>1K - 1M</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>
For queries that are translated into full table scans or range scans on indexes, it is important for best performance to fetch records in properly sized batches. It is possible to set the proper size both in terms of number of records (BatchSize) and in terms of bytes (BatchByteSize). The actual batch size is limited by both parameters.

The speed at which queries are performed can vary by more than 40% depending upon how this parameter is set.

This parameter is measured in bytes. The default value in NDB Cluster 7.3 and later is 16K.

- **BatchSize**

  Table 18.177 This table provides type and value information for the BatchSize API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>records</td>
</tr>
<tr>
<td>Default</td>
<td>256</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 992</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is measured in number of records and is by default set to 256. The maximum size is 992.

- **ExtraSendBufferMemory**

  Table 18.178 This table provides type and value information for the ExtraSendBufferMemory API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter specifies the amount of transporter send buffer memory to allocate in addition to any that has been set using TotalSendBufferMemory, SendBufferMemory, or both.

- **HeartbeatThreadPriority**

  Table 18.179 This table provides type and value information for the HeartbeatThreadPriority API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>string</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>
Use this parameter to set the scheduling policy and priority of heartbeat threads for management and API nodes. The syntax for setting this parameter is shown here:

```
HeartbeatThreadPriority = policy[, priority]
```

policy: `{FIFO | RR}`

When setting this parameter, you must specify a policy. This is one of **FIFO** (first in, first in) or **RR** (round robin). This followed optionally by the priority (an integer).

- **MaxScanBatchSize**

**Table 18.180** This table provides type and value information for the MaxScanBatchSize API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>256K</td>
</tr>
<tr>
<td>Range</td>
<td>32K - 16M</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

The batch size is the size of each batch sent from each data node. Most scans are performed in parallel to protect the MySQL Server from receiving too much data from many nodes in parallel; this parameter sets a limit to the total batch size over all nodes.

The default value of this parameter is set to 256KB. Its maximum size is 16MB.

- **TotalSendBufferMemory**

**Table 18.181** This table provides type and value information for the TotalSendBufferMemory API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>256K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

If this parameter is set, its minimum permitted value is 256KB; 0 indicates that the parameter has not been set. For more detailed information, see Section 18.3.3.13, “Configuring NDB Cluster Send Buffer Parameters”.

- **AutoReconnect**
Table 18.182 This table provides type and value information for the AutoReconnect API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is false by default. This forces disconnected API nodes (including MySQL Servers acting as SQL nodes) to use a new connection to the cluster rather than attempting to re-use an existing one, as re-use of connections can cause problems when using dynamically-allocated node IDs. (Bug #45921)

**Note**

This parameter can be overridden using the NDB API. For more information, see `Ndb_cluster_connection::set_auto_reconnect()` and `Ndb_cluster_connection::get_auto_reconnect()`.

- DefaultOperationRedoProblemAction

Table 18.183 This table provides type and value information for the DefaultOperationRedoProblemAction API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>enumeration</td>
</tr>
<tr>
<td>Default</td>
<td>QUEUE</td>
</tr>
<tr>
<td>Range</td>
<td>ABORT, QUEUE</td>
</tr>
<tr>
<td>Restart Type</td>
<td>S</td>
</tr>
</tbody>
</table>

This parameter (along with RedoOverCommitLimit and RedoOverCommitCounter) controls the data node’s handling of operations when too much time is taken flushing redo logs to disk. This occurs when a given redo log flush takes longer than RedoOverCommitLimit seconds, more than RedoOverCommitCounter times, causing any pending transactions to be aborted.

When this happens, the node can respond in either of two ways, according to the value of DefaultOperationRedoProblemAction, listed here:

- **ABORT**: Any pending operations from aborted transactions are also aborted.

- **QUEUE**: Pending operations from transactions that were aborted are queued up to be re-tried. This the default. In NDB 7.3.10 and later as well as NDB 7.4.7 and later, pending operations are still aborted when the redo log runs out of space—that is, when P_TAIL_PROBLEM errors occur. (Bug #20782580)

- DefaultHashMapSize
Table 18.184 This table provides type and value information for the DefaultHashMapSize API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>buckets</td>
</tr>
<tr>
<td>Default</td>
<td>3840</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 3840</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

NDB 7.2.7 and later use a larger default table hash map size (3840) than in previous releases (240). Beginning with NDB 7.2.11, the size of the table hash maps used by NDB is configurable using this parameter; previously this value was hard-coded. DefaultHashMapSize can take any of three possible values (0, 240, 3840). These values and their effects are described in the following table.

Table 18.185 DefaultHashMapSize parameter values

<table>
<thead>
<tr>
<th>Value</th>
<th>Description / Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Use the lowest value set, if any, for this parameter among all data nodes and API nodes in the cluster; if it is not set on any data or API node, use the default value.</td>
</tr>
<tr>
<td>240</td>
<td>Original hash map size (used by default prior to NDB 7.2.7.</td>
</tr>
<tr>
<td>3840</td>
<td>Larger hash map size as (used by default in NDB 7.2.7 and later</td>
</tr>
</tbody>
</table>

The primary intended use for this parameter is to facilitate upgrades and especially downgrades between NDB 7.2.7 and later NDB Cluster versions, in which the larger hash map size (3840) is the default, and earlier releases (in which the default was 240), due to the fact that this change is not otherwise backward compatible (Bug #14800539). By setting this parameter to 240 prior to performing an upgrade from an older version where this value is in use, you can cause the cluster to continue using the smaller size for table hash maps, in which case the tables remain compatible with earlier versions following the upgrade. DefaultHashMapSize can be set for individual data nodes, API nodes, or both, but setting it once only, in the [ndbd default] section of the config.ini file, is the recommended practice.

After increasing this parameter, to have existing tables to take advantage of the new size, you can run ALTER TABLE ... REORGANIZE PARTITION on them, after which they can use the larger hash map size. This is in addition to performing a rolling restart, which makes the larger hash maps available to new tables, but does not enable existing tables to use them.

Decreasing this parameter online after any tables have been created or modified with DefaultHashMapSize equal to 3840 is not currently supported.

- Wan

Table 18.186 This table provides type and value information for the wan API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>

<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
</tbody>
</table>
Use WAN TCP setting as default.

- **ConnectBackoffMaxTime**

**Table 18.187** This table provides type and value information for the ConnectBackoffMaxTime API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.7</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFFFF)</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
<tr>
<td>Version (or later)</td>
<td>NDB 7.4.2</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFFFF)</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

Starting with NDB 7.3.7 and NDB 7.4.2, in an NDB Cluster with many unstarted data nodes, the value of this parameter can be raised to circumvent connection attempts to data nodes which have not yet begun to function in the cluster, as well as moderate high traffic to management nodes. As long as the API node is not connected to any new data nodes, the value of the **StartConnectBackoffMaxTime** parameter is applied; otherwise, **ConnectBackoffMaxTime** is used to determine the length of time in milliseconds to wait between connection attempts.

Time elapsed *during* node connection attempts is not taken into account when calculating elapsed time for this parameter. The timeout is applied with approximately 100 ms resolution, starting with a 100 ms delay; for each subsequent attempt, the length of this period is doubled until it reaches **ConnectBackoffMaxTime** milliseconds, up to a maximum of 100000 ms (100s).

Once the API node is connected to a data node and that node reports (in a heartbeat message) that it has connected to other data nodes, connection attempts to those data nodes are no longer affected by this parameter, and are made every 100 ms thereafter until connected. Once a data node has started, it can take up **HeartbeatIntervalDbApi** for the API node to be notified that this has occurred.

- **StartConnectBackoffMaxTime**

**Table 18.188** This table provides type and value information for the StartConnectBackoffMaxTime API node configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.7</td>
</tr>
<tr>
<td>Type or units</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFFFF)</td>
</tr>
<tr>
<td>Property</td>
<td>Value</td>
</tr>
<tr>
<td>------------------------------</td>
<td>----------------------</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
<tr>
<td><strong>Version (or later)</strong></td>
<td>NDB 7.4.2</td>
</tr>
<tr>
<td><strong>Type or units</strong></td>
<td>integer</td>
</tr>
<tr>
<td><strong>Default</strong></td>
<td>0</td>
</tr>
<tr>
<td><strong>Range</strong></td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

Starting with NDB 7.3.7 and NDB 7.4.2, in an NDB Cluster with many unstarted data nodes, the value of this parameter can be raised to circumvent connection attempts to data nodes which have not yet begun to function in the cluster, as well as moderate high traffic to management nodes. As long as the API node is not connected to any new data nodes, the value of the `StartConnectBackoffMaxTime` parameter is applied; otherwise, `ConnectBackoffMaxTime` is used to determine the length of time in milliseconds to wait between connection attempts.

Time elapsed during node connection attempts is not taken into account when calculating elapsed time for this parameter. The timeout is applied with approximately 100 ms resolution, starting with a 100 ms delay; for each subsequent attempt, the length of this period is doubled until it reaches `StartConnectBackoffMaxTime` milliseconds, up to a maximum of 100000 ms (100s).

Once the API node is connected to a data node and that node reports (in a heartbeat message) that it has connected to other data nodes, connection attempts to those data nodes are no longer affected by this parameter, and are made every 100 ms thereafter until connected. Once a data node has started, it can take up `HeartbeatIntervalDbApi` for the API node to be notified that this has occurred.

**API Node Debugging Parameters.** Beginning with NDB 7.4.12, you can use the `ApiVerbose` configuration parameter to enable debugging output from a given API node. This parameter takes an integer value. 0 is the default, and disables such debugging; 1 enables debugging output to the cluster log; 2 adds `DBDICT` debugging output as well. (Bug #20638450) See also DUMP 1229.

You can also obtain information from a MySQL server running as an NDB Cluster SQL node using `SHOW STATUS` in the `mysql` client, as shown here:

```
mysql> SHOW STATUS LIKE 'ndb';
+-----------------------------+----------------+
<table>
<thead>
<tr>
<th>Variable_name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ndb_cluster_node_id</td>
<td>5</td>
</tr>
<tr>
<td>Ndb_config_from_host</td>
<td>198.51.100.112</td>
</tr>
<tr>
<td>Ndb_config_from_port</td>
<td>1186</td>
</tr>
<tr>
<td>Ndb_number_of_storage_nodes</td>
<td>4</td>
</tr>
</tbody>
</table>
+-----------------------------+----------------+
4 rows in set (0.02 sec)
```

For information about the status variables appearing in the output from this statement, see NDB Cluster Status Variables.

**Note**

To add new SQL or API nodes to the configuration of a running NDB Cluster, it is necessary to perform a rolling restart of all cluster nodes after adding new `[mysqld]` or `[api]` sections to the `config.ini` file (or files, if you are using more than one management server). This must be done before the new SQL or API nodes can connect to the cluster.
It is not necessary to perform any restart of the cluster if new SQL or API nodes can employ previously unused API slots in the cluster configuration to connect to the cluster.

### 18.3.3.8 MySQL Server Options and Variables for NDB Cluster

This section provides information about MySQL server options, server and status variables that are specific to NDB Cluster. For general information on using these, and for other options and variables not specific to NDB Cluster, see Section 5.1, “The MySQL Server”.

For NDB Cluster configuration parameters used in the cluster configuration file (usually named `config.ini`), see Section 18.3, “Configuration of NDB Cluster”.

### MySQL Server Options for NDB Cluster

This section provides descriptions of `mysqld` server options relating to NDB Cluster. For information about `mysqld` options not specific to NDB Cluster, and for general information about the use of options with `mysqld`, see Section 5.1.6, “Server Command Options”.

For information about command-line options used with other NDB Cluster processes (`ndbd`, `ndb_mgmd`, and `ndb_mgm`), see Section 18.4.29, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”. For information about command-line options used with NDB utility programs (such as `ndb_desc`, `ndb_size.pl`, and `ndb_show_tables`), see Section 18.4, “NDB Cluster Programs”.

- `--ndbcluster`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td><code>ndbcluster</code></td>
</tr>
<tr>
<td>Command Line</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>No</td>
</tr>
<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>Yes</td>
</tr>
<tr>
<td>Scope</td>
<td>No</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td></td>
</tr>
<tr>
<td>Default, Range</td>
<td>FALSE (Version: NDB 7.3-7.4)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Enable NDB Cluster (if this version of MySQL supports it)</td>
</tr>
<tr>
<td></td>
<td>Disabled by <code>--skip-ndbcluster</code>.</td>
</tr>
</tbody>
</table>

The `NDBCLUSTER` storage engine is necessary for using NDB Cluster. If a `mysqld` binary includes support for the `NDBCLUSTER` storage engine, the engine is disabled by default. Use the `--ndbcluster` option to enable it. Use `--skip-ndbcluster` to explicitly disable the engine.

- `--ndb-batch-size=#`
### Table 18.190 Type and value information for ndb-batch-size

<table>
<thead>
<tr>

<tr>
<td>Type</td>
<td>Default, Range 1 / 1 - 63 (Version: NDB 7.3-7.4)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Number of connections to the cluster used by MySQL</td>
</tr>
</tbody>
</table>

By setting this option to a value greater than 1 (the default), a `mysqld` process can use multiple connections to the cluster, effectively mimicking several SQL nodes. Each connection requires its own [api] or [mysqld] section in the cluster configuration (config.ini) file, and counts against the maximum number of API connections supported by the cluster.

Suppose that you have 2 cluster host computers, each running an SQL node whose `mysqld` process was started with `--ndb-cluster-connection-pool=4`; this means that the cluster must have 8 API slots available for these connections (instead of 2). All of these connections are set up when the SQL node connects to the cluster, and are allocated to threads in a round-robin fashion.

This option is useful only when running `mysqld` on host machines having multiple CPUs, multiple cores, or both. For best results, the value should be smaller than the total number of cores available on the host machine. Setting it to a value greater than this is likely to degrade performance severely.
Important
Because each SQL node using connection pooling occupies multiple API node slots—each slot having its own node ID in the cluster—you must not use a node ID as part of the cluster connection string when starting any mysqld process that employs connection pooling.

Setting a node ID in the connection string when using the --ndb-cluster-connection-pool option causes node ID allocation errors when the SQL node attempts to connect to the cluster.

- `--ndb-blob-read-batch-bytes=bytes`

<td>Default, Range: 65536 / 0 - 4294967295 (Version: NDB 7.3-7.4) Notes: DESCRIPTION: Specifies size in bytes that large BLOB reads should be batched into. 0 = no limit.</td>
</tr>
</tbody>
</table>

This option can be used to set the size (in bytes) for batching of BLOB data reads in NDB Cluster applications. When this batch size is exceeded by the amount of BLOB data to be read within the current transaction, any pending BLOB read operations are immediately executed.

The maximum value for this option is 4294967295; the default is 65536. Setting it to 0 has the effect of disabling BLOB read batching.

**Note**
In NDB API applications, you can control BLOB write batching with the setMaxPendingBlobReadBytes() and getMaxPendingBlobReadBytes() methods.

<tr>
<td>Type</td>
<td>Default, Range</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Cause a MySQL server acting as a slave to log mysql.ndb_apply_status updates received from its immediate master in its own binary log, using its own server ID. Effective only if the server is started with the --ndbcluster option.</td>
</tr>
</tbody>
</table>

Causes a slave `mysqld` to log any updates received from its immediate master to the `mysql.ndb_apply_status` table in its own binary log using its own server ID rather than the server ID of the master. In a circular or chain replication setting, this allows such updates to propagate to the `mysql.ndb_apply_status` tables of any MySQL servers configured as slaves of the current `mysqld`.

In a chain replication setup, using this option allows downstream (slave) clusters to be aware of their positions relative to all of their upstream contributors (masters).

In a circular replication setup, this option causes changes to `ndb_apply_status` tables to complete the entire circuit, eventually propagating back to the originating NDB Cluster. This also allows a cluster acting as a master to see when its changes (epochs) have been applied to the other clusters in the circle.

This option has no effect unless the MySQL server is started with the `--ndbcluster` option.

- `--ndb-log-empty-epochs=[ON|OFF]`

### Table 18.198 Type and value information for ndb-log-empty-epochs

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td><code>ndb-log-empty-epochs</code></td>

<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td></td>
</tr>
<tr>
<td>Default, Range</td>
<td>OFF (Version: NDB 7.3-7.4)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: When enabled, causes epochs in which there were no changes to be written to the <code>ndb_apply_status</code> and <code>ndb_binlog_index</code> tables, even when <code>--log-slave-updates</code> is enabled.</td>
</tr>
</tbody>
</table>
Causes epochs during which there were no changes to be written to the `ndb_apply_status` and `ndb_binlog_index` tables, even when `--log-slave-updates` is enabled.

By default this option is disabled. Disabling `--ndb-log-empty-epochs` causes epoch transactions with no changes not to be written to the binary log, although a row is still written even for an empty epoch in `ndb_binlog_index`.

Because `--ndb-log-empty-epochs=1` causes the size of the `ndb_binlog_index` table to increase independently of the size of the binary log, users should be prepared to manage the growth of this table, even if they expect the cluster to be idle a large part of the time.

- `--ndb-log-empty-update=[ON|OFF]`

**Table 18.199** Type and value information for `ndb-log-empty-update`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td><code>ndb-log-empty-update</code></td>

<tr>
<td>Type</td>
<td></td>
</tr>
<tr>
<td>Default, Range</td>
<td>OFF (Version: NDB 7.3-7.4)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: When enabled, causes updates that produced no changes to be written to the <code>ndb_apply_status</code> and <code>ndb_binlog_index</code> tables, even when <code>--log-slave-updates</code> is enabled.</td>
</tr>
</tbody>
</table>

Causes updates that produced no changes to be written to the `ndb_apply_status` and `ndb_binlog_index` tables, even when `--log-slave-updates` is enabled.

By default this option is disabled (OFF). Disabling `--ndb-log-empty-update` causes updates with no changes not to be written to the binary log.

- `--ndb-log-exclusive-reads=[0|1]`

**Table 18.200** Type and value information for `ndb-log-exclusive-reads`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td><code>ndb-log-exclusive-reads</code></td>
</tr>
<tr>
<td>Command Line</td>
<td>Yes</td>

<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>Yes</td>
</tr>
<tr>
<td>Scope</td>
<td>Both</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
</tbody>
</table>
In NDB 7.4.1 and later, starting the server with this option causes primary key reads to be logged with exclusive locks, which allows for NDB Cluster Replication conflict detection and resolution based on read conflicts. You can also enable and disable these locks at runtime by setting the value of the `ndb_log_exclusive_reads` system variable to 1 or 0, respectively. 0 (disable locking) is the default.

For more information, see Read conflict detection and resolution.

- `--ndb-log-orig`

**Table 18.201  Type and value information for ndb-log-orig**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td><code>ndb-log-orig</code></td>

<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>Yes</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Default, Range 0 (Version: NDB 7.3-7.4)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Log originating server id and epoch in <code>mysql.ndb_binlog_index</code> table</td>
</tr>
</tbody>
</table>

Log the originating server ID and epoch in the `ndb_binlog_index` table.

**Note**

This makes it possible for a given epoch to have multiple rows in `ndb_binlog_index`, one for each originating epoch.

For more information, see Section 18.6.4, "NDB Cluster Replication Schema and Tables".

- `--ndb-log-transaction-id`

**Table 18.202  Type and value information for ndb-log-transaction-id**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td><code>ndb-log-transaction-id</code></td>
</tr>
<tr>
<td>Command Line</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>Yes</td>
</tr>
</tbody>
</table>
Causes a slave `mysql` to write the NDB transaction ID in each row of the binary log. Such logging requires the use of the Version 2 event format for the binary log; thus, `--log-bin-v1-events=OFF`.

This option is not supported in mainline MySQL Server 5.6. It is required to enable NDB Cluster Replication conflict detection and resolution using the `NDB$EPOCH_TRANS()` function (see `NDB$EPOCH_TRANS()`).

The default value is `FALSE`.

For more information, see Section 18.6.11, “NDB Cluster Replication Conflict Resolution”.

- `--ndb-log-update-minimal`

**Table 18.203 Type and value information for ndb-log-update-minimal**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td><code>ndb-log-update-minimal</code></td>
</tr>
<tr>
<td>Command Line</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>Yes</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td></td>
</tr>
<tr>
<td>Default, Range</td>
<td>OFF (Version: 5.6.36-ndb-7.4.16)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Log updates in a minimal format.</td>
</tr>
</tbody>
</table>

Log updates in a minimal fashion, by writing only the primary key values in the before image, and only the changed columns in the after image. This may cause compatibility problems if replicating to storage engines other than NDB.

- `--ndb-mgmd-host=host[:port]`

**Table 18.204 Type and value information for ndb-mgmd-host**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td><code>ndb-mgmd-host</code></td>
</tr>
<tr>
<td>Command Line</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>No</td>
</tr>
</tbody>
</table>
Can be used to set the host and port number of a single management server for the program to connect to. If the program requires node IDs or references to multiple management servers (or both) in its connection information, use the `--ndb-connectstring` option instead.

- `--ndb-nodeid=##`

### Table 18.205 Type and value information for ndb-nodeid

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>ndb-nodeid</td>

<tr>
<td>Type</td>
<td>Default, Range / 1 - 63 (Version: 5.0.45)</td>
</tr>
<tr>
<td></td>
<td>Default, Range / 1 - 255 (Version: 5.1.5)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: NDB Cluster node ID for this MySQL server</td>
</tr>
</tbody>
</table>

Set this MySQL server’s node ID in an NDB Cluster.

The `--ndb-nodeid` option overrides any node ID set with `--ndb-connectstring`, regardless of the order in which the two options are used.

In addition, if `--ndb-nodeid` is used, then either a matching node ID must be found in a `[mysqld]` or `[api]` section of `config.ini`, or there must be an “open” `[mysqld]` or `[api]` section in the file (that is, a section without a `NodeId` or `Id` parameter specified). This is also true if the node ID is specified as part of the connection string.

Regardless of how the node ID is determined, its is shown as the value of the global status variable `Ndb_cluster_node_id` in the output of `SHOW STATUS`, and as `cluster_node_id` in the `connection row` of the output of `SHOW ENGINE NDDBCLUSTER STATUS`.

For more information about node IDs for NDB Cluster SQL nodes, see Section 18.3.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”.

<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Default, Range \texttt{ON / ON, OFF, FORCE} (Version: NDB 7.3-7.4)</td>
</tr>
</tbody>
</table>

Notes: DESCRIPTION: Enable or disable the ndb_transid_mysql_connection_map plugin; that is, enable or disable the INFORMATION_SCHEMA table having that name.

Enables or disables the plugin that handles the \texttt{ndb_transid_mysql_connection_map} table in the INFORMATION_SCHEMA database. Takes one of the values \texttt{ON}, \texttt{OFF}, or \texttt{FORCE}. \texttt{ON} (the default) enables the plugin. \texttt{OFF} disables the plugin, which makes \texttt{ndb_transid_mysql_connection_map} inaccessible. \texttt{FORCE} keeps the MySQL Server from starting if the plugin fails to load and start.

You can see whether the \texttt{ndb_transid_mysql_connection_map} table plugin is running by checking the output of \texttt{SHOW PLUGINS}.

- \texttt{--ndb-wait-connected=seconds}
Table 18.210  Type and value information for ndb-wait-connected

</tr>
<tr>
<td></td>
<td>Default, Range 30 / 0 - 31536000 (Version: 5.1.56-ndb-7.1.16)</td>
</tr>
</tbody>
</table>
This variable shows the period of time that the MySQL server waits for the NDB storage engine to complete setup before timing out and treating NDB as unavailable. The time is specified in seconds. The default value is 30.

- `--server-id-bits=`

### Table 18.212 Type and value information for server-id-bits

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>server-id-bits</td>
</tr>
<tr>
<td>Command Line</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>Yes</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Default, Range (32 / 7 - 32 (Version: NDB 7.3-7.4))</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Sets the number of least significant bits in the server_id actually used for identifying the server, permitting NDB API applications to store application data in the most significant bits. server_id must be less than 2 to the power of this value.</td>
</tr>
</tbody>
</table>

This option indicates the number of least significant bits within the 32-bit server_id which actually identify the server. Indicating that the server is actually identified by fewer than 32 bits makes it possible for some of the remaining bits to be used for other purposes, such as storing user data generated by applications using the NDB API's Event API within the AnyValue of an OperationOptions structure (NDB Cluster uses the AnyValue to store the server ID).

When extracting the effective server ID from server_id for purposes such as detection of replication loops, the server ignores the remaining bits. The `--server-id-bits` option is used to mask out any irrelevant bits of server_id in the IO and SQL threads when deciding whether an event should be ignored based on the server ID.

This data can be read from the binary log by mysqlbinlog, provided that it is run with its own `--server-id-bits` option set to 32 (the default).

The value of server_id must be less than $2^{server_id_bits}$; otherwise, mysqld refuses to start.

This system variable is supported only by NDB Cluster. It is not supported in the standard MySQL 5.6 Server.

- `--skip-ndbcluster`
### Table 18.213 Type and value information for skip-ndbcluster

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td><code>skip-ndbcluster</code></td>
</tr>
<tr>
<td>Command Line</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>No</td>
</tr>
<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>

<td>Yes</td>
</tr>
<tr>
<td>Scope</td>
<td></td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td></td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Disable the NDB Cluster storage engine</td>
</tr>
</tbody>
</table>

Disable the `NDBCLUSTER` storage engine. This is the default for binaries that were built with `NDBCLUSTER` storage engine support; the server allocates memory and other resources for this storage engine only if the `--ndbcluster` option is given explicitly. See Section 18.3.1, “Quick Test Setup of NDB Cluster”, for an example.

### NDB Cluster System Variables

This section provides detailed information about MySQL server system variables that are specific to NDB Cluster and the NDB storage engine. For system variables not specific to NDB Cluster, see Section 5.1.7, “Server System Variables”. For general information on using system variables, see Section 5.1.8, “Using System Variables”.

- `create_old_temporals`

### Table 18.214 Type and value information for create_old_temporals

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td><code>create_old_temporals</code></td>
</tr>
<tr>
<td>Command Line</td>
<td>Yes</td>

<td>No</td>
</tr>
<tr>
<td>Type</td>
<td></td>
</tr>
<tr>
<td>Default, Range</td>
<td>false (Version: NDB 7.3-7.4)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Use pre-5.6.4 storage format for temporal types when creating tables. Intended for use in replication and upgrades/downgrades between NDB 7.2 and NDB 7.3/7.4.</td>
</tr>
</tbody>
</table>

Causes `mysqld` to use the storage formats for temporal data types that were used in the MySQL server prior to MySQL 5.6.4; that is, `TIME`, `DATETIME`, and `TIMESTAMP` columns are created without support for fractional seconds. This affects all `CREATE TABLE` and `ALTER TABLE` statements.
The `create_old_temporals` system variable is read-only, with a default value of `false`; to enable it, use the `--create-old-temporals` option on the command line or in the server configuration file.

**Important**

`avoid_temporal_upgrade` must also be enabled for this feature to work properly. It is also strongly recommended that you enable `show_old_temporals` as well. See the descriptions of these variables for more information, as well as Date and Time Type Storage Requirements.

This variable was added in NDB 7.3.10 and NDB 7.4.7; it is specific to NDB Cluster and is not available in standard MySQL Server releases. It is intended to facilitate upgrades from NDB Cluster 7.2 to NDB Cluster 7.3 and 7.4; following this, table columns of the affected types can be upgraded to the new storage format. `create_old_temporals` is deprecated and scheduled for removal in a future version of NDB Cluster.

- **have_ndbcluster**

  **Table 18.215 Type and value information for have_ndbcluster**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>have_ndbcluster</td>

### ndb_cluster_configuration_files

**Property** | **Value**
--- | ---
Dynamic | Yes
Type | Default, Range
Default, Range | 32 / 1 - 256 (Version: NDB 7.3-7.4)
Default, Range | 1 / 1 - 256 (Version: 5.0.56)
Default, Range | 32 / 1 - 256 (Version: 5.1.1)
Default, Range | 1 / 1 - 256 (Version: 5.1.23)
Default, Range | 32 / 1 - 256 (Version: 5.1.16-ndb-6.2.0)
Default, Range | 1 / 1 - 256 (Version: 5.1.23-ndb-6.2.10)
Default, Range | 32 / 1 - 256 (Version: 5.1.19-ndb-6.3.0)
Default, Range | 1 / 1 - 256 (Version: 5.1.23-ndb-6.3.7)
Default, Range | 1 / 1 - 65536 (Version: 5.1.41-ndb-6.3.31)
Default, Range | 32 / 1 - 256 (Version: 5.1.30-ndb-6.4.0)
Default, Range | 1 / 1 - 65536 (Version: 5.1.41-ndb-7.0.11)
Default, Range | 1 / 1 - 65536 (Version: 5.5.15-ndb-7.2.1)
Notes | DESCRIPTION: NDB auto-increment prefetch size

Determines the probability of gaps in an autoincremented column. Set it to 1 to minimize this. Setting it to a high value for optimization makes inserts faster, but decreases the likelihood that consecutive autoincrement numbers will be used in a batch of inserts. The minimum and default value is 1. The maximum value for `ndb_autoincrement_prefetch_sz` is 65536.

This variable affects only the number of `AUTO_INCREMENT` IDs that are fetched between statements; within a given statement, at least 32 IDs are obtained at a time. The default value is 1.

**Important**

This variable does not affect inserts performed using `INSERT ... SELECT`.

- `ndb_cache_check_time`

**Table 18.217 Type and value information for ndb_cache_check_time**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td><code>ndb_cache_check_time</code></td>
</tr>
<tr>
<td>Command Line</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>Yes</td>

<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td></td>
</tr>
<tr>
<td>Default, Range</td>
<td>0 / - (Version: NDB 7.3-7.4)</td>
</tr>
</tbody>
</table>
### NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Number of milliseconds between checks of cluster SQL nodes made by the MySQL query cache</td>
</tr>
</tbody>
</table>

The number of milliseconds that elapse between checks of NDB Cluster SQL nodes by the MySQL query cache. Setting this to 0 (the default and minimum value) means that the query cache checks for validation on every query.

The recommended maximum value for this variable is 1000, which means that the check is performed once per second. A larger value means that the check is performed and possibly invalidated due to updates on different SQL nodes less often. It is generally not desirable to set this to a value greater than 2000.

- **ndb_clear_apply_status**

**Table 18.218 Type and value information for ndb_clear_apply_status**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>ndb_clear_apply_status</td>
</tr>
<tr>
<td>Command Line</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>No</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td></td>
</tr>
<tr>
<td>Default, Range</td>
<td>ON (Version: NDB 7.3-7.4)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Causes RESET SLAVE to clear all rows from the ndb_apply_status table; ON by default</td>
</tr>
</tbody>
</table>

By the default, executing `RESET SLAVE` causes an NDB Cluster replication slave to purge all rows from its `ndb_apply_status` table. In NDB 7.4.9 and later you can disable this by setting `ndb_clear_apply_status=OFF`.

- **ndb_deferred_constraints**

**Table 18.219 Type and value information for ndb_deferred_constraints**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>

<td>Yes</td>
</tr>
<tr>
<td>Scope</td>
<td>Both</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td></td>
</tr>
</tbody>
</table>
Controls whether or not constraint checks are deferred, where these are supported. 0 is the default.

This variable is not normally needed for operation of NDB Cluster or NDB Cluster Replication, and is intended primarily for use in testing.

- **ndb_distribution**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>ndb_distribution</td>
</tr>
<tr>
<td>Command Line</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>Yes</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Type</td>
<td>KEYHASH / LINHASH, KEYHASH (Version: NDB 7.3-7.4)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Default distribution for new tables in NDBCLUSTER (KEYHASH or LINHASH, default is KEYHASH)</td>
</tr>
</tbody>
</table>

Controls the default distribution method for NDB tables. Can be set to either of **KEYHASH** (key hashing) or **LINHASH** (linear hashing). **KEYHASH** is the default.

- **ndb_eventbuffer_free_percent**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>ndb_eventbuffer_free_percent</td>
</tr>
<tr>

<td>DESCRIPTION: Maximum memory that can be allocated for buffering events by the NDB API. Defaults to 0 (no limit).</td>
</tr>
<tr>
<td></td>
<td>0 / 0 - 4294967295 (Version: NDB 7.3-7.4)</td>
</tr>
</tbody>
</table>

Sets the maximum amount memory (in bytes) that can be allocated for buffering events by the NDB API. 0 means that no limit is imposed, and is the default.

This variable was added in NDB 7.3.3.

- *ndb_extra_logging*

### Table 18.223 Type and value information for ndb_extra_logging

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>

</tr>
<tr>
<td></td>
<td>1 / - (Version: 5.1.19-ndb-6.3.0)</td>
</tr>
</tbody>
</table>
This variable enables recording in the MySQL error log of information specific to the NDB storage engine.

When this variable is set to 0, the only information specific to NDB that is written to the MySQL error log relates to transaction handling. If it set to a value greater than 0 but less than 10, NDB table schema and connection events are also logged, as well as whether or not conflict resolution is in use, and other NDB errors and information. If the value is set to 10 or more, information about NDB internals, such as the progress of data distribution among cluster nodes, is also written to the MySQL error log. The default is 1.

- **ndb_force_send**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>ndb_force_send</td>
</tr>
<tr>
<td>Command Line</td>

<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>Yes</td>
</tr>
<tr>
<td>Scope</td>
<td>Both</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Default, Range: 32 / 0 - 4294967295 (Version: NDB 7.3-7.4)</td>
</tr>
</tbody>
</table>
Sets the granularity of the statistics by determining the number of starting and ending keys to store in the statistics memory cache. Zero means no caching takes place; in this case, the data nodes are always queried directly. Default value: 32.

**Note**

If `ndb_index_stat_enable` is OFF, then setting this variable has no effect.

This variable was deprecated in MySQL 5.1, and is removed from NDB 7.3.5 and later.

- `ndb_index_stat_enable`

### Table 18.226 Type and value information for ndb_index_stat_enable

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>

</tbody>
</table>
This variable is used for providing tuning options for NDB index statistics generation. The list consists of comma-separated name-value pairs of option names and values, and this list must not contain any space characters.

Options not used when setting `ndb_index_stat_option` are not changed from their default values. For example, you can set `ndb_index_stat_option = 'loop_idle=1000ms,cache_limit=32M'`.

Time values can be optionally suffixed with `h` (hours), `m` (minutes), or `s` (seconds). Millisecond values can optionally be specified using `ms`; millisecond values cannot be specified using `h`, `m`, or `s`.) Integer values can be suffixed with `K`, `M`, or `G`.

The names of the options that can be set using this variable are shown in the table that follows. The table also provides brief descriptions of the options, their default values, and (where applicable) their minimum and maximum values.

<table>

<td>Default, Range 20 / 0 - 4294967295 (Version: NDB 7.3-7.4)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: How often to query data nodes instead of the statistics cache</td>
</tr>
</tbody>
</table>

How often to query data nodes instead of the statistics cache. For example, a value of 20 (the default) means to direct every 20\textsuperscript{th} query to the data nodes.

**Note**

If ndb_index_stat_cache_entries is 0, then setting this variable has no effect; in this case, every query is sent directly to the data nodes.

This variable was deprecated in MySQL 5.1, and is removed from NDB 7.3.5 and later.

• **ndb_join_pushdown**
Table 18.230 Type and value information for ndb_join_pushdown

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>ndb_join_pushdown</td>
</tr>
<tr>
<td>Command Line</td>
<td>No</td>

<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Default, Range: TRUE (Version: 5.1.51-ndb-7.2.0)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Enables pushing down of joins to data nodes</td>
</tr>
</tbody>
</table>

This variable controls whether joins on NDB tables are pushed down to the NDB kernel (data nodes). Previously, a join was handled using multiple accesses of NDB by the SQL node; however, when ndb_join_pushdown is enabled, a pushable join is sent in its entirety to the data nodes, where it can be distributed among the data nodes and executed in parallel on multiple copies of the data, with a single, merged result being returned to mysqld. This can reduce greatly the number of round trips between an SQL node and the data nodes required to handle such a join.

By default, ndb_join_pushdown is enabled.

**Conditions for NDB pushdown joins.** In order for a join to be pushable, it must meet the following conditions:

1. Only columns can be compared, and all columns to be joined must use exactly the same data type.

   This means that expressions such as `t1.a = t2.a + constant` cannot be pushed down, and that (for example) a join on an INT column and a BIGINT column also cannot be pushed down.

2. Queries referencing BLOB or TEXT columns are not supported.

3. Explicit locking is not supported; however, the NDB storage engine’s characteristic implicit row-based locking is enforced.

   This means that a join using FOR UPDATE cannot be pushed down.

4. In order for a join to be pushed down, child tables in the join must be accessed using one of the ref, eq_ref, or const access methods, or some combination of these methods.

   Outer joined child tables can only be pushed using eq_ref.

   If the root of the pushed join is an eq_ref or const, only child tables joined by eq_ref can be appended. (A table joined by ref is likely to become the root of another pushed join.)

   If the query optimizer decides on Using join cache for a candidate child table, that table cannot be pushed as a child. However, it may be the root of another set of pushed tables.

5. Joins referencing tables explicitly partitioned by [LINEAR] HASH, LIST, or RANGE currently cannot be pushed down.
You can see whether a given join can be pushed down by checking it with `EXPLAIN`; when the join can be pushed down, you can see references to the `pushed join` in the `Extra` column of the output, as shown in this example:

```sql
mysql> EXPLAIN
    -> SELECT e.first_name, e.last_name, t.title, d.dept_name
    -> FROM employees e
    -> JOIN dept_emp de ON e.emp_no=de.emp_no
    -> JOIN departments d ON d.dept_no=de.dept_no
    -> JOIN titles t ON e.emp_no=t.emp_no
```

```
*************************** 1. row ***************************

```

4 rows in set (0.00 sec)

**Note**

If inner joined child tables are joined by `ref, and` the result is ordered or grouped by a sorted index, this index cannot provide sorted rows, which forces writing to a sorted tempfile.

Two additional sources of information about pushed join performance are available:
1. The status variables `Ndb_pushed_queries_defined`, `Ndb_pushed_queries_dropped`, `Ndb_pushed_queries_executed`, and `Ndb_pushed_reads`.

2. The counters in the `ndbinfocounters` table that belong to the DBSPJ kernel block. See Section 18.5.10.7, “The ndbinfocounters Table”, for information about these counters. See also The DBSPJ Block, in the NDB Cluster API Developer Guide.

- `ndb_log_apply_status`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td><code>ndb_log_apply_status</code></td>
</tr>
<tr>
<td>Command Line</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>Yes</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Default, Range OFF (Version: NDB 7.3-7.4)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Whether or not a MySQL server acting as a slave logs mysql.ndb_apply_status updates received from its immediate master in its own binary log, using its own server ID</td>
</tr>
</tbody>
</table>

A read-only variable which shows whether the server was started with the `--ndb-log-apply-status` option.

- `ndb_log_bin`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td><code>ndb_log_bin</code></td>
</tr>
<tr>
<td>Command Line</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>No</td>
</tr>
<tr>
<td>Scope</td>
<td>Both</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Default, Range ON (Version: NDB 7.3-7.4)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Write updates to NDB tables in the binary log. Effective only if binary logging is enabled with <code>--log-bin</code>.</td>
</tr>
</tbody>
</table>
Causes updates to NDB tables to be written to the binary log. Setting this variable has no effect if binary logging is not already enabled for the server using log_bin. ndb_log_bin defaults to 1 (ON); normally, there is never any need to change this value in a production environment.

- **ndb_log_binlog_index**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>ndb_log_binlog_index</td>
</tr>
<tr>
<td>Command Line</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>No</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Default, Range: ON (Version: NDB 7.3-7.4)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Insert mapping between epochs and binary log positions into the ndb_binlog_index table. Defaults to ON. Effective only if binary logging is enabled on the server.</td>
</tr>
</tbody>
</table>

Causes a mapping of epochs to positions in the binary log to be inserted into the ndb_binlog_index table. Setting this variable has no effect if binary logging is not already enabled for the server using log_bin. (In addition, ndb_log_bin must not be disabled.) ndb_log_binlog_index defaults to 1 (ON); normally, there is never any need to change this value in a production environment.

- **ndb_log_empty_epochs**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>ndb_log_empty_epochs</td>
</tr>
<tr>
<td>Command Line</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>Yes</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Default, Range: OFF (Version: NDB 7.3-7.4)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: When enabled, epochs in which there were no changes are written to the ndb_apply_status and ndb_binlog_index tables, even when log_slave_updates is enabled</td>
</tr>
</tbody>
</table>

When this variable is set to 0, epoch transactions with no changes are not written to the binary log, although a row is still written even for an empty epoch in ndb_binlog_index.
• `ndb_log_empty_update`

Table 18.235 Type and value information for `ndb_log_empty_update`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td><code>ndb_log_empty_update</code></td>
</tr>
<tr>
<td>Command Line</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>Yes</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Default, Range</td>
</tr>
<tr>
<td>Default, Range</td>
<td>OFF (Version: NDB 7.3-7.4)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: When enabled, updates which produce no changes are written to the ndb_apply_status and ndb_binlog_index tables, even when log_slave_updates is enabled</td>
</tr>
</tbody>
</table>

When this variable is set to `ON` (1), update transactions with no changes are written to the binary log, even when `--log-slave-updates` is enabled.

• `ndb_log_exclusive_reads`

Table 18.236 Type and value information for `ndb_log_exclusive_reads`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td><code>ndb_log_exclusive_reads</code></td>

<tr>
<td>Option File</td>
<td>Yes</td>
</tr>
<tr>
<td>Scope</td>
<td>Both</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Default, Range</td>
</tr>
<tr>
<td>Default, Range</td>
<td>0 (Version: NDB 7.3-7.4)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Log primary key reads with exclusive locks; allow conflict resolution based on read conflicts</td>
</tr>
</tbody>
</table>

In NDB 7.4.1 and later, this variable determines whether primary key reads are logged with exclusive locks, which allows for NDB Cluster Replication conflict detection and resolution based on read conflicts. To enable these locks, set the value of `ndb_log_exclusive_reads` to 1. 0, which disables such locking, is the default.

For more information, see Read conflict detection and resolution.

• `ndb_log_orig`
### Table 18.237 Type and value information for ndb_log_orig

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>

<td>Yes</td>
</tr>
<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>Yes</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td></td>
</tr>
<tr>
<td>Default, Range</td>
<td>OFF (Version: NDB 7.3-7.4)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Whether the id and epoch of the originating server are recorded in the mysql.ndb_binlog_index table. Set using the --ndb-log-orig option when starting mysqld.</td>
</tr>
</tbody>
</table>

Shows whether the originating server ID and epoch are logged in the `ndb_binlog_index` table. Set using the `--ndb-log-orig` server option.

- `ndb_log_transaction_id`

### Table 18.238 Type and value information for ndb_log_transaction_id

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>ndb_log_transaction_id</td>
</tr>
<tr>
<td>Command Line</td>
<td>No</td>
</tr>
<tr>
<td>System Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>No</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td></td>
</tr>
<tr>
<td>Default, Range</td>
<td>OFF (Version: NDB 7.3-7.4)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Whether NDB transaction IDs are written into the binary log (Read-only.)</td>
</tr>
</tbody>
</table>

This read-only, Boolean system variable shows whether a slave `mysqld` writes NDB transaction IDs in the binary log (required to use “active-active” NDB Cluster Replication with `NDB$EPOCH_TRANS()` conflict detection). To change the setting, use the `--ndb-log-transaction-id` option.

`ndb_log_transaction_id` is not supported in mainline MySQL Server 5.6.

For more information, see Section 18.6.11, “NDB Cluster Replication Conflict Resolution”.

- `ndb_optimized_node_selection`
<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>ndb_optimized_node_selection</td>
</tr>
<tr>
<td>Command Line</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>Yes</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Default, Range: ON (Version: NDB 7.3-7.4) Default, Range: 3 / 0 - 3 (Version: 5.1.22-ndb-6.3.4) Notes: DESCRIPTION: Determines how an SQL node chooses a cluster data node to use as transaction coordinator</td>
</tr>
</tbody>
</table>

There are two forms of optimized node selection, described here:

1. The SQL node uses *proximity* to determine the transaction coordinator; that is, the “closest” data node to the SQL node is chosen as the transaction coordinator. For this purpose, a data node having a shared memory connection with the SQL node is considered to be “closest” to the SQL node; the next closest (in order of decreasing proximity) are: TCP connection to `localhost`; SCI connection; TCP connection from a host other than `localhost`.

2. The SQL thread uses *distribution awareness* to select the data node. That is, the data node housing the cluster partition accessed by the first statement of a given transaction is used as the transaction coordinator for the entire transaction. (This is effective only if the first statement of the transaction accesses no more than one cluster partition.)

This option takes one of the integer values 0, 1, 2, or 3. 3 is the default. These values affect node selection as follows:

- **0**: Node selection is not optimized. Each data node is employed as the transaction coordinator 8 times before the SQL thread proceeds to the next data node.

- **1**: Proximity to the SQL node is used to determine the transaction coordinator.

- **2**: Distribution awareness is used to select the transaction coordinator. However, if the first statement of the transaction accesses more than one cluster partition, the SQL node reverts to the round-robin behavior seen when this option is set to 0.

- **3**: If distribution awareness can be employed to determine the transaction coordinator, then it is used; otherwise proximity is used to select the transaction coordinator. (This is the default behavior.)

Proximity is determined as follows:

1. Start with the value set for the `Group` parameter (default 55).

2. For an API node sharing the same host with other API nodes, decrement the value by 1. Assuming the default value for `Group`, the effective value for data nodes on same host as the API node is 54, and for remote data nodes 55.
• **ndb_recv_thread_activation_threshold**

**Table 18.240 Type and value information for ndb_recv_thread_activation_threshold**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>ndb_recv_thread_activation_threshold</td>
</tr>
<tr>
<td>Command Line</td>
<td>No</td>

<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>No</td>
</tr>
<tr>
<td>Scope</td>
<td>Dynamic No</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Default, Range [8 / 0 (MIN_ACTIVATION_THRESHOLD) - 16 (MAX_ACTIVATION_THRESHOLD)] (Version: 5.6.10-ndb-7.3.1)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Activation threshold when receive thread takes over the polling of the cluster connection (measured in concurrently active threads)</td>
</tr>
</tbody>
</table>

When this number of concurrently active threads is reached, the receive thread takes over polling of the cluster connection.

This variable is global in scope. It can also be set on startup using the `--ndb-recv-thread-activation-threshold` option.

• **ndb_recv_thread_cpu_mask**

**Table 18.241 Type and value information for ndb_recv_thread_cpu_mask**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>ndb_recv_thread_cpu_mask</td>
</tr>
<tr>
<td>Command Line</td>
<td>No</td>
</tr>
<tr>
<td>System Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Status Variable</td>
<td>No</td>

<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Default, Range [empty] (Version: NDB 7.3-7.4)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: CPU mask for locking receiver threads to specific CPUs; specified as hexadecimal. See documentation for details.</td>
</tr>
</tbody>
</table>

CPU mask for locking receiver threads to specific CPUs. This is specified as a hexadecimal bitmask. For example, `0x33` means that one CPU is used per receiver thread. An empty string is the default; setting `ndb_recv_thread_cpu_mask` to this value removes any receiver thread locks previously set.

This variable is global in scope. It can also be set on startup using the `--ndb-recv-thread-cpu-mask` option.
• **ndb_report_thresh_binlog_epoch_slip**

**Table 18.242 Type and value information for ndb_report_thresh_binlog_epoch_slip**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>ndb_report_thresh_binlog_epoch_slip</td>
</tr>
<tr>
<td>Command Line</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>Yes</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Default, Range</td>
</tr>
<tr>
<td></td>
<td>3 / 0 - 256 (Version: NDB 7.3-7.4)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: NDB 7.5.4 and later: Threshold for number of epochs completely buffered, but not yet consumed by binlog injector thread which when exceeded generates BUFFERED_EPOCHS_OVER_THRESHOLD event buffer status message; prior to NDB 7.5.4: Threshold for number of epochs to lag behind before reporting binary log status</td>
</tr>
</tbody>
</table>

This is a threshold on the number of epochs to be behind before reporting binary log status. For example, a value of 3 (the default) means that if the difference between which epoch has been received from the storage nodes and which epoch has been applied to the binary log is 3 or more, a status message is sent to the cluster log.

• **ndb_report_thresh_binlog_mem_usage**

**Table 18.243 Type and value information for ndb_report_thresh_binlog_mem_usage**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>ndb_report_thresh_binlog_mem_usage</td>
</tr>
<tr>
<td>Command Line</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>Yes</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Default, Range</td>
</tr>
<tr>
<td></td>
<td>10 / 0 - 10 (Version: NDB 7.3-7.4)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: This is a threshold on the percentage of free memory remaining before reporting binary log status</td>
</tr>
</tbody>
</table>

This is a threshold on the percentage of free memory remaining before reporting binary log status. For example, a value of 10 (the default) means that if the amount of available memory for receiving binary log data from the data nodes falls below 10%, a status message is sent to the cluster log.

• **slave_allow_batching**
Table 18.244 Type and value information for slave_allow batching

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>slave_allow batching</td>
</tr>
<tr>
<td>Command Line</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>Yes</td>
</tr>
<tr>

<tr>
<td>Option File</td>
<td>Yes</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Default, Range off (Version: NDB 7.3-7.4)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Turns update batching on and off for a replication slave</td>
</tr>
</tbody>
</table>

Whether or not batched updates are enabled on NDB Cluster replication slaves.

Setting this variable has an effect only when using replication with the NDB storage engine; in MySQL Server 5.6, it is present but does nothing. For more information, see Section 18.6.6, “Starting NDB Cluster Replication (Single Replication Channel)”.

• ndb_show_foreign_key_mock_tables

Table 18.245 Type and value information for ndb_show_foreign_key_mock_tables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>ndb_show_foreign_key_mock_tables</td>
</tr>
<tr>
<td>Command Line</td>
<td>Yes</td>

<td>Default, Range OFF (Version: NDB 7.3-7.4)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Show the mock tables used to support foreign_key_checks=0</td>
</tr>
</tbody>
</table>

Show the mock tables used by NDB to support foreign_key_checks=0. When this is enabled, extra warnings are shown when creating and dropping the tables. The real (internal) name of the table can be seen in the output of SHOW CREATE TABLE.

• ndb_slave_conflict_role
Table 18.246  Type and value information for ndb_slave_conflict_role

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>ndb_slave_conflict_role</td>
</tr>
<tr>
<td>Command Line</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>Yes</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Default, Range: NONE / NONE, PRIMARY, SECONDARY, PASS (Version: NDB 7.3-7.4)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Role for slave to play in conflict detection and resolution. Value is one of PRIMARY, SECONDARY, PASS, or NONE (default). Can be changed only when slave SQL thread is stopped. See documentation for further information.</td>
</tr>
</tbody>
</table>

Determine the role of this SQL node (and NDB Cluster) in a circular ("active-active") replication setup. ndb_slave_conflict_role can take any one of the values PRIMARY, SECONDARY, PASS, or NULL (the default). The slave SQL thread must be stopped before you can change ndb_slave_conflict_role. In addition, it is not possible to change directly between PASS and either of PRIMARY or SECONDARY directly; in such cases, you must ensure that the SQL thread is stopped, then execute `SET @@GLOBAL.ndb_slave_conflict_role = 'NONE'` first.

This variable was added in NDB 7.4.1. For more information, see Section 18.6.11, “NDB Cluster Replication Conflict Resolution”.

• ndb_table_no_logging

Table 18.247  Type and value information for ndb_table_no_logging

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>ndb_table_no_logging</td>
</tr>
<tr>
<td>Command Line</td>
<td>No</td>
</tr>
<tr>
<td>System Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>No</td>
</tr>
<tr>
<td>Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Default, Range: FALSE (Version: NDB 7.3-7.4)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: NDB tables created when this setting is enabled are not checkpointed to disk (although table schema files are created). The setting in effect when the table is created with or altered to use NDBCLUSTER persists for the lifetime of the table.</td>
</tr>
</tbody>
</table>
When this variable is set to ON or 1, it causes NDB tables not to be checkpointed to disk. More specifically, this setting applies to tables which are created or altered using ENGINE NDB when ndb_table_no_logging is enabled, and continues to apply for the lifetime of the table, even if ndb_table_no_logging is later changed. Suppose that A, B, C, and D are tables that we create (and perhaps also alter), and that we also change the setting for ndb_table_no_logging as shown here:

```
SET @@ndb_table_no_logging = 1;
CREATE TABLE A ... ENGINE NDB;
CREATE TABLE B ... ENGINE MYISAM;
CREATE TABLE C ... ENGINE MYISAM;
ALTER TABLE B ENGINE NDB;
SET @@ndb_table_no_logging = 0;
CREATE TABLE D ... ENGINE NDB;
ALTER TABLE C ENGINE NDB;
SET @@ndb_table_no_logging = 1;
```

After the previous sequence of events, tables A and B are not checkpointed; A was created with ENGINE NDB and B was altered to use NDB, both while ndb_table_no_logging was enabled. However, tables C and D are logged; C was altered to use NDB and D was created using ENGINE NDB, both while ndb_table_no_logging was disabled. Setting ndb_table_no_logging back to 1 or ON does not cause table C or D to be checkpointed.

**Note**

ndb_table_no_logging has no effect on the creation of NDB table schema files; to suppress these, use ndb_table_temporary instead.

- ndb_table_temporary

### Table 18.248 Type and value information for ndb_table_temporary

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>ndb_table_temporary</td>

<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td></td>
</tr>
<tr>
<td>Default, Range</td>
<td>FALSE (Version: NDB 7.3-7.4)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: NDB tables are not persistent on disk: no schema files are created and the tables are not logged</td>
</tr>
</tbody>
</table>

When set to ON or 1, this variable causes NDB tables not to be written to disk: This means that no table schema files are created, and that the tables are not logged.
Note

Setting this variable currently has no effect in NDB Cluster 7.0 and later. This is a known issue; see Bug #34036.

- `ndb_use_copying_alter_table`

Table 18.249  Type and value information for `ndb_use_copying_alter_table`

<table>

</tbody>
</table>

Forces NDB to use a count of records during `SELECT COUNT(*)` query planning to speed up this type of query. The default value is `OFF`, which allows for faster queries overall.

- `ndb_use_transactions`
### Table 18.251 Type and value information for ndb_use_transactions

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>ndb_use_transactions</td>

<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Default, Range: 32 / 7 - 32 (Version: NDB 7.3-7.4)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: The effective value of <code>server_id</code> if the server was started with the <code>--server-id-bits</code> option set to a nondefault value</td>
</tr>
</tbody>
</table>

The effective value of `server_id` if the server was started with the `--server-id-bits` option set to a nondefault value.

If the value of `server_id` greater than or equal to 2 to the power of `server_id_bits`, `mysqld` refuses to start.

This system variable is supported only by NDB Cluster. `server_id_bits` is not supported by the standard MySQL Server.

- **transaction_allow_batching**

**Table 18.255** Type and value information for `transaction_allow_batching`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>

### NDB Cluster Configuration Files

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option File</td>
<td>No</td>
</tr>
<tr>
<td>Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td></td>
</tr>
<tr>
<td>Default, Range</td>
<td>FALSE (Version: NDB 7.3-7.4)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Allows batching of statements within a transaction. Disable AUTOCOMMIT to use.</td>
</tr>
</tbody>
</table>

When set to 1 or ON, this variable enables batching of statements within the same transaction. To use this variable, `autocommit` must first be disabled by setting it to 0 or OFF; otherwise, setting `transaction_allow_batching` has no effect.

It is safe to use this variable with transactions that performs writes only, as having it enabled can lead to reads from the “before” image. You should ensure that any pending transactions are committed (using an explicit `COMMIT` if desired) before issuing a `SELECT`.

**Important**

`transaction_allow_batching` should not be used whenever there is the possibility that the effects of a given statement depend on the outcome of a previous statement within the same transaction.

This variable is currently supported for NDB Cluster only.

The system variables in the following list all relate to the `ndbinfo` information database.

- `ndbinfo_database`

**Table 18.256  Type and value information for ndbinfo_database**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td><code>ndbinfo_database</code></td>
</tr>
<tr>
<td>Command Line</td>
<td>No</td>
</tr>
<tr>
<td>System Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>No</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td></td>
</tr>
<tr>
<td>Default, Range</td>
<td>ndbinfo (Version: NDB 7.3-7.4)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: The name used for the NDB information database; read only</td>
</tr>
</tbody>
</table>

Shows the name used for the NDB information database; the default is `ndbinfo`. This is a read-only variable whose value is determined at compile time; you can set it by starting the server using `--ndbinfo-database=name`, which sets the value shown for this variable but does not actually change the name used for the NDB information database.
• `ndbinfo_max_bytes`

Table 18.257 Type and value information for ndbinfo_max_bytes

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td><code>ndbinfo_max_bytes</code></td>
</tr>
<tr>
<td>Command Line</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>No</td>
</tr>
<tr>
<td>Scope</td>
<td>Both</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Default, Range: 0 / - (Version: NDB 7.3-7.4)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Used for debugging only</td>
</tr>
</tbody>
</table>

Used in testing and debugging only.

• `ndbinfo_max_rows`

Table 18.258 Type and value information for ndbinfo_max_rows

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td><code>ndbinfo_max_rows</code></td>
</tr>
<tr>
<td>Command Line</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>Yes</td>

<tr>
<td>Option File</td>
<td>No</td>
</tr>
<tr>
<td>Scope</td>
<td>Both</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Default, Range: 10 / - (Version: NDB 7.3-7.4)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Used for debugging only</td>
</tr>
</tbody>
</table>

Used in testing and debugging only.

• `ndbinfo_offline`

Table 18.259 Type and value information for ndbinfo_offline

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td><code>ndbinfo_offline</code></td>
</tr>
<tr>
<td>Command Line</td>
<td>No</td>
</tr>
<tr>
<td>System Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>No</td>
</tr>
</tbody>
</table>
Place the `ndbinfo` database into offline mode, in which tables and views can be opened even when they do not actually exist, or when they exist but have different definitions in NDB. No rows are returned from such tables (or views).

- **ndbinfo_show_hidden**

  **Table 18.260 Type and value information for ndbinfo_show_hidden**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td><code>ndbinfo_show_hidden</code></td>
</tr>
<tr>
<td>Command Line</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>No</td>
</tr>
<tr>
<td>Scope</td>
<td>Both</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Default, Range <code>OFF</code> (Version: NDB 7.3-7.4)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Whether to show ndbinfo internal base tables in the mysql client. The default is OFF.</td>
</tr>
</tbody>
</table>

Whether or not the `ndbinfo` database's underlying internal tables are shown in the mysql client. The default is OFF.

- **ndbinfo_table_prefix**

  **Table 18.261 Type and value information for ndbinfo_table_prefix**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td><code>ndbinfo_table_prefix</code></td>
</tr>
<tr>
<td>Command Line</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>No</td>
</tr>
<tr>
<td>Scope</td>
<td>Both</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Default, Range <code>ndb$</code> (Version: NDB 7.3-7.4)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: Put the ndbinfo database into offline mode, in which no rows are returned from tables or views</td>
</tr>
</tbody>
</table>
The prefix used in naming the ndbinfo database's base tables (normally hidden, unless exposed by setting `ndbinfo_show_hidden`). This is a read-only variable whose default value is `ndb$.` You can start the server with the `--ndbinfo-table-prefix` option, but this merely sets the variable and does not change the actual prefix used to name the hidden base tables; the prefix itself is determined at compile time.

- **ndbinfo_version**

  **Table 18.262  Type and value information for ndbinfo_version**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td><code>ndbinfo_version</code></td>
</tr>
<tr>
<td>Command Line</td>
<td>No</td>
</tr>
<tr>
<td>System Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Status Variable</td>
<td>No</td>
</tr>
<tr>
<td>Option File</td>
<td>No</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td></td>
</tr>
<tr>
<td>Default, Range</td>
<td>(Version: NDB 7.3-7.4)</td>
</tr>
<tr>
<td>Notes</td>
<td>DESCRIPTION: The version of the ndbinfo engine; read only</td>
</tr>
</tbody>
</table>

Shows the version of the ndbinfo engine in use; read-only.

**NDB Cluster Status Variables**

This section provides detailed information about MySQL server status variables that relate to NDB Cluster and the NDB storage engine. For status variables not specific to NDB Cluster, and for general information on using status variables, see Section 5.1.9, "Server Status Variables".

- **Handler_discover**

  The MySQL server can ask the NDBCLUSTER storage engine if it knows about a table with a given name. This is called discovery. `Handler_discover` indicates the number of times that tables have been discovered using this mechanism.

- **Ndb_api_bytes_sent_count_session**

  Amount of data (in bytes) sent to the data nodes in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.

- **Ndb_api_bytes_sent_count_slave**

  Amount of data (in bytes) sent to the data nodes by this slave.
Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.

- **Ndb_api_bytes_sent_count**
  
  Amount of data (in bytes) sent to the data nodes by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.

- **Ndb_api_bytes_received_count_session**
  
  Amount of data (in bytes) received from the data nodes in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.

- **Ndb_api_bytes_received_count_slave**
  
  Amount of data (in bytes) received from the data nodes by this slave.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.

- **Ndb_api_bytes_received_count**
  
  Amount of data (in bytes) received from the data nodes by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.

- **Ndb_api_event_data_count.injector**
  
  The number of row change events received by the NDB binlog injector thread.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.

- **Ndb_api_event_data_count**
  
  The number of row change events received by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.
For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.

- **Ndb_api_event_nondata_count_injector**
  The number of events received, other than row change events, by the NDB binary log injector thread.
  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.
  For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.

- **Ndb_api_event_nondata_count**
  The number of events received, other than row change events, by this MySQL Server (SQL node).
  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.
  For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.

- **Ndb_api_event_bytes_count_injector**
  The number of bytes of events received by the NDB binlog injector thread.
  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.
  For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.

- **Ndb_api_event_bytes_count**
  The number of bytes of events received by this MySQL Server (SQL node).
  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.
  For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.

- **Ndb_api_pk_op_count_session**
  The number of operations in this client session based on or using primary keys. This includes operations on blob tables, implicit unlock operations, and auto-increment operations, as well as user-visible primary key operations.
  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.
  For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.

- **Ndb_api_pk_op_count_slave**
  The number of operations by this slave based on or using primary keys. This includes operations on blob tables, implicit unlock operations, and auto-increment operations, as well as user-visible primary key operations.
  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.
For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_pk_op_count**

  The number of operations by this MySQL Server (SQL node) based on or using primary keys. This includes operations on blob tables, implicit unlock operations, and auto-increment operations, as well as user-visible primary key operations.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_pruned_scan_count_session**

  The number of scans in this client session that have been pruned to a single partition.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_pruned_scan_count_slave**

  The number of scans by this slave that have been pruned to a single partition.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_pruned_scan_count**

  The number of scans by this MySQL Server (SQL node) that have been pruned to a single partition.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_range_scan_count_session**

  The number of range scans that have been started in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_range_scan_count_slave**

  The number of range scans that have been started by this slave.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.
For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_range_scan_count**

  The number of range scans that have been started by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_read_row_count_session**

  The total number of rows that have been read in this client session. This includes all rows read by any primary key, unique key, or scan operation made in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqlld`.

  For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_read_row_count_slave**

  The total number of rows that have been read by this slave. This includes all rows read by any primary key, unique key, or scan operation made by this slave.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_read_row_count**

  The total number of rows that have been read by this MySQL Server (SQL node). This includes all rows read by any primary key, unique key, or scan operation made by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_scan_batch_count_session**

  The number of batches of rows received in this client session. 1 batch is defined as 1 set of scan results from a single fragment.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqlld`.

  For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_scan_batch_count_slave**

  The number of batches of rows received by this slave. 1 batch is defined as 1 set of scan results from a single fragment.
Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_scan_batch_count**

  The number of batches of rows received by this MySQL Server (SQL node). 1 batch is defined as 1 set of scan results from a single fragment.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_table_scan_count_session**

  The number of table scans that have been started in this client session, including scans of internal tables.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_table_scan_count_slave**

  The number of table scans that have been started by this slave, including scans of internal tables.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_table_scan_count**

  The number of table scans that have been started by this MySQL Server (SQL node), including scans of internal tables.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_transAbort_count_session**

  The number of transactions aborted in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_transAbort_count_slave**

  The number of transactions aborted by this slave.
Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.

- **Ndb_api_trans_abort_count**

  The number of transactions aborted by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.

- **Ndb_api_trans_close_count_session**

  The number of transactions closed in this client session. This value may be greater than the sum of `Ndb_api_trans_commit_count_session` and `Ndb_api_trans_abort_count_session`, since some transactions may have been rolled back.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.

- **Ndb_api_trans_close_count_slave**

  The number of transactions closed by this slave. This value may be greater than the sum of `Ndb_api_trans_commit_count_slave` and `Ndb_api_trans_abort_count_slave`, since some transactions may have been rolled back.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.

- **Ndb_api_trans_close_count**

  The number of transactions closed by this MySQL Server (SQL node). This value may be greater than the sum of `Ndb_api_trans_commit_count` and `Ndb_api_trans_abort_count`, since some transactions may have been rolled back.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.

- **Ndb_api_trans_commit_count_session**

  The number of transactions committed in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.

- **Ndb_api_trans_commit_count**

  The number of transactions committed in this MySQL Server (SQL node). This value may be greater than the sum of `Ndb_api_trans_commit` and `Ndb_api_trans_abort_count`, since some transactions may have been rolled back.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.
• **Ndb_api_trans_commit_count_slave**

  The number of transactions committed by this slave.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  For more information, see [Section 18.5.16, “NDB API Statistics Counters and Variables”](#).

• **Ndb_api_trans_commit_count**

  The number of transactions committed by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see [Section 18.5.16, “NDB API Statistics Counters and Variables”](#).

• **Ndb_api_trans_local_read_row_count_session**

  The total number of rows that have been read in this client session. This includes all rows read by any primary key, unique key, or scan operation made in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see [Section 18.5.16, “NDB API Statistics Counters and Variables”](#).

• **Ndb_api_trans_local_read_row_count_slave**

  The total number of rows that have been read by this slave. This includes all rows read by any primary key, unique key, or scan operation made by this slave.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  For more information, see [Section 18.5.16, “NDB API Statistics Counters and Variables”](#).

• **Ndb_api_trans_local_read_row_count**

  The total number of rows that have been read by this MySQL Server (SQL node). This includes all rows read by any primary key, unique key, or scan operation made by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see [Section 18.5.16, “NDB API Statistics Counters and Variables”](#).

• **Ndb_api_trans_start_count_session**

  The number of transactions started in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see [Section 18.5.16, “NDB API Statistics Counters and Variables”](#).
• **Ndb_api_trans_start_count_slave**

The number of transactions started by this slave.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_trans_start_count**

The number of transactions started by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_uk_op_count_session**

The number of operations in this client session based on or using unique keys.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_uk_op_count_slave**

The number of operations by this slave based on or using unique keys.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_uk_op_count**

The number of operations by this MySQL Server (SQL node) based on or using unique keys.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_wait_exec_complete_count_session**

The number of times a thread has been blocked in this client session while waiting for execution of an operation to complete. This includes all `execute()` calls as well as implicit executes for blob and auto-increment operations not visible to clients.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.

• **Ndb_api_wait_exec_complete_count_slave**
The number of times a thread has been blocked by this slave while waiting for execution of an operation to complete. This includes all `execute()` calls as well as implicit executes for blob and auto-increment operations not visible to clients.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.

- **Ndb_api_wait_exec_complete_count**

  The number of times a thread has been blocked by this MySQL Server (SQL node) while waiting for execution of an operation to complete. This includes all `execute()` calls as well as implicit executes for blob and auto-increment operations not visible to clients.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.

- **Ndb_api_wait_meta_request_count_session**

  The number of times a thread has been blocked in this client session waiting for a metadata-based signal, such as is expected for DDL requests, new epochs, and seizure of transaction records.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.

- **Ndb_api_wait_meta_request_count_slave**

  The number of times a thread has been blocked by this slave waiting for a metadata-based signal, such as is expected for DDL requests, new epochs, and seizure of transaction records.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.

- **Ndb_api_wait_meta_request_count**

  The number of times a thread has been blocked by this MySQL Server (SQL node) waiting for a metadata-based signal, such as is expected for DDL requests, new epochs, and seizure of transaction records.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.

- **Ndb_api_wait_nanos_count_session**

  Total time (in nanoseconds) spent in this client session waiting for any type of signal from the data nodes.
Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.

- **Ndb_api_wait_nanos_count_slave**

  Total time (in nanoseconds) spent by this slave waiting for any type of signal from the data nodes.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.

- **Ndb_api_wait_nanos_count**

  Total time (in nanoseconds) spent by this MySQL Server (SQL node) waiting for any type of signal from the data nodes.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.

- **Ndb_api_wait_scan_result_count_session**

  The number of times a thread has been blocked in this client session while waiting for a scan-based signal, such as when waiting for more results from a scan, or when waiting for a scan to close.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.

- **Ndb_api_wait_scan_result_count_slave**

  The number of times a thread has been blocked by this slave while waiting for a scan-based signal, such as when waiting for more results from a scan, or when waiting for a scan to close.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.

- **Ndb_api_wait_scan_result_count**

  The number of times a thread has been blocked by this MySQL Server (SQL node) while waiting for a scan-based signal, such as when waiting for more results from a scan, or when waiting for a scan to close.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  For more information, see Section 18.5.16, “NDB API Statistics Counters and Variables”.
NDB Cluster Configuration Files

- **Ndb_cluster_node_id**
  
  If the server is acting as an NDB Cluster node, then the value of this variable its node ID in the cluster.
  
  If the server is not part of an NDB Cluster, then the value of this variable is 0.

- **Ndb_config_from_host**
  
  If the server is part of an NDB Cluster, the value of this variable is the host name or IP address of the Cluster management server from which it gets its configuration data.
  
  If the server is not part of an NDB Cluster, then the value of this variable is an empty string.

- **Ndb_config_from_port**
  
  If the server is part of an NDB Cluster, the value of this variable is the number of the port through which it is connected to the Cluster management server from which it gets its configuration data.
  
  If the server is not part of an NDB Cluster, then the value of this variable is 0.

- **Ndb_conflict_fn_max_del_win**
  
  Shows the number of times that a row was rejected on the current SQL node due to NDB Cluster Replication conflict resolution using `NDB$MAX_DELETE_WIN()`, since the last time that this `mysqld` was started.
  
  For more information, see Section 18.6.11, “NDB Cluster Replication Conflict Resolution”.

- **Ndb_conflict_fn_max**
  
  Used in NDB Cluster Replication conflict resolution, this variable shows the number of times that a row was not applied on the current SQL node due to “greatest timestamp wins” conflict resolution since the last time that this `mysqld` was started.
  
  For more information, see Section 18.6.11, “NDB Cluster Replication Conflict Resolution”.

- **Ndb_conflict_fn_old**
  
  Used in NDB Cluster Replication conflict resolution, this variable shows the number of times that a row was not applied as the result of “same timestamp wins” conflict resolution on a given `mysqld` since the last time it was restarted.
  
  For more information, see Section 18.6.11, “NDB Cluster Replication Conflict Resolution”.

- **Ndb_conflict_fn_epoch**
  
  Used in NDB Cluster Replication conflict resolution, this variable shows the number of rows found to be in conflict using `NDB$EPOCH()` conflict resolution on a given `mysqld` since the last time it was restarted.
  
  For more information, see Section 18.6.11, “NDB Cluster Replication Conflict Resolution”.

- **Ndb_conflict_fn_epoch2**
  
  Shows the number of rows found to be in conflict in NDB Cluster Replication conflict resolution, when using `NDB$EPOCH2()`, on the master designated as the primary since the last time it was restarted.
  
  Added in NDB 7.4.2.
  
  For more information, see `NDB$EPOCH2()`.
Ndb_conflict_fn_epoch_trans

Used in NDB Cluster Replication conflict resolution, this variable shows the number of rows found to be in conflict using NDB$EPOCH_TRANS() conflict resolution on a given mysqld since the last time it was restarted.

For more information, see Section 18.6.11, “NDB Cluster Replication Conflict Resolution”.

Ndb_conflict_fn_epoch2_trans

Used in NDB Cluster Replication conflict resolution, this variable shows the number of rows found to be in conflict using NDB$EPOCH_TRANS2() conflict resolution on a given mysqld since the last time it was restarted.

Added in NDB 7.4.2.

For more information, see NDB$EPOCH2_TRANS().

Ndb_conflict_last_conflict_epoch

The most recent epoch in which a conflict was detected on this slave. You can compare this value with Ndb_slave_max_replicated_epoch; if Ndb_slave_max_replicated_epoch is greater than Ndb_conflict_last_conflict_epoch, no conflicts have yet been detected.

This variable was added in NDB 7.4.2.

See Section 18.6.11, “NDB Cluster Replication Conflict Resolution”, for more information.

Ndb_conflict_reflected_op_discard_count

When using NDB Cluster Replication conflict resolution, this is the number of reflected operations that were not applied on the secondary, due to encountering an error during execution.

This variable was added in NDB 7.4.2.

See Section 18.6.11, “NDB Cluster Replication Conflict Resolution”, for more information.

Ndb_conflict_reflected_op_prepare_count

When using conflict resolution with NDB Cluster Replication, this status variable contains the number of reflected operations that have been defined (that is, prepared for execution on the secondary).

This variable was added in NDB 7.4.2.

See Section 18.6.11, “NDB Cluster Replication Conflict Resolution”.

Ndb_conflict_refresh_op_count

When using conflict resolution with NDB Cluster Replication, this gives the number of refresh operations that have been prepared for execution on the secondary.

This variable was added in NDB 7.4.2.

See Section 18.6.11, “NDB Cluster Replication Conflict Resolution”, for more information.

Ndb_conflict_last_stable_epoch

Number of rows found to be in conflict by a transactional conflict function
This variable was added in NDB 7.4.2.

See Section 18.6.11, “NDB Cluster Replication Conflict Resolution”, for more information.

- **Ndb_conflict_trans_row_conflict_count**

  Used in NDB Cluster Replication conflict resolution, this status variable shows the number of rows found to be directly in-conflict by a transactional conflict function on a given mysqld since the last time it was restarted.

  Currently, the only transactional conflict detection function supported by NDB Cluster is NDB$EPOCH_TRANS(), so this status variable is effectively the same as Ndb_conflict_fn_epoch_trans.

  For more information, see Section 18.6.11, “NDB Cluster Replication Conflict Resolution”.

- **Ndb_conflict_trans_row_reject_count**

  Used in NDB Cluster Replication conflict resolution, this status variable shows the total number of rows realigned due to being determined as conflicting by a transactional conflict detection function. This includes not only Ndb_conflict_trans_row_conflict_count, but any rows in or dependent on conflicting transactions.

  For more information, see Section 18.6.11, “NDB Cluster Replication Conflict Resolution”.

- **Ndb_conflict_trans_reject_count**

  Used in NDB Cluster Replication conflict resolution, this status variable shows the number of transactions found to be in conflict by a transactional conflict detection function.

  For more information, see Section 18.6.11, “NDB Cluster Replication Conflict Resolution”.

- **Ndb_conflict_trans_detect_iter_count**

  Used in NDB Cluster Replication conflict resolution, this shows the number of internal iterations required to commit an epoch transaction. Should be (slightly) greater than or equal to Ndb_conflict_trans_conflict_commit_count.

  For more information, see Section 18.6.11, “NDB Cluster Replication Conflict Resolution”.

- **Ndb_conflict_trans_conflict_commit_count**

  Used in NDB Cluster Replication conflict resolution, this shows the number of epoch transactions committed after they required transactional conflict handling.

  For more information, see Section 18.6.11, “NDB Cluster Replication Conflict Resolution”.

- **Ndb_epoch_delete_delete_count**

  When using delete-delete conflict detection, this is the number of delete-delete conflicts detected, where a delete operation is applied, but the indicated row does not exist.

  Added in NDB 7.4.2.

- **Ndb_execute_count**

  Provides the number of round trips to the NDB kernel made by operations.
• **Ndb_last_commit_epoch_server**

The epoch most recently committed by NDB.

This variable was added in NDB 7.3.8 and NDB 7.4.1.

• **Ndb_last_commit_epoch_session**

The epoch most recently committed by this NDB client.

This variable was added in NDB 7.3.8 and NDB 7.4.1.

• **Ndb_number_of_data_nodes**

If the server is part of an NDB Cluster, the value of this variable is the number of data nodes in the cluster.

If the server is not part of an NDB Cluster, then the value of this variable is 0.

• **Ndb_pushed_queries_defined**

The total number of joins pushed down to the NDB kernel for distributed handling on the data nodes.

**Note**

Joins tested using `EXPLAIN` that can be pushed down contribute to this number.

• **Ndb_pushed_queries_dropped**

The number of joins that were pushed down to the NDB kernel but that could not be handled there.

• **Ndb_pushed_queries_executed**

The number of joins successfully pushed down to NDB and executed there.

• **Ndb_pushed_reads**

The number of rows returned to `mysqld` from the NDB kernel by joins that were pushed down.

**Note**

Executing `EXPLAIN` on joins that can be pushed down to NDB does not add to this number.

• **Ndb_pruned_scan_count**

This variable holds a count of the number of scans executed by `NDBCLUSTER` since the NDB Cluster was last started where `NDBCLUSTER` was able to use partition pruning.

Using this variable together with `Ndb_scan_count` can be helpful in schema design to maximize the ability of the server to prune scans to a single table partition, thereby involving only a single data node.

• **Ndb_scan_count**

This variable holds a count of the total number of scans executed by `NDBCLUSTER` since the NDB Cluster was last started.

• **Ndb_slave_max_replicated_epoch**
The most recently committed epoch on this slave. In NDB 7.4.1 and later, you can compare this value with `Ndb_conflict_last_conflict_epoch`; if `Ndb_slave_max_replicated_epoch` is the greater of the two, no conflicts have yet been detected.

This variable was added in NDB 7.3.8 and NDB 7.4.1.

For more information, see Section 18.6.11, “NDB Cluster Replication Conflict Resolution”.

### 18.3.3.9 NDB Cluster TCP/IP Connections

TCP/IP is the default transport mechanism for all connections between nodes in an NDB Cluster. Normally it is not necessary to define TCP/IP connections; NDB Cluster automatically sets up such connections for all data nodes, management nodes, and SQL or API nodes.

**Note**

For an exception to this rule, see Section 18.3.3.10, “NDB Cluster TCP/IP Connections Using Direct Connections”.

To override the default connection parameters, it is necessary to define a connection using one or more `[tcp]` sections in the `config.ini` file. Each `[tcp]` section explicitly defines a TCP/IP connection between two NDB Cluster nodes, and must contain at a minimum the parameters `NodeId1` and `NodeId2`, as well as any connection parameters to override.

It is also possible to change the default values for these parameters by setting them in the `[tcp default]` section.

**Important**

Any `[tcp]` sections in the `config.ini` file should be listed last, following all other sections in the file. However, this is not required for a `[tcp default]` section. This requirement is a known issue with the way in which the `config.ini` file is read by the NDB Cluster management server.

Connection parameters which can be set in `[tcp]` and `[tcp default]` sections of the `config.ini` file are listed here:

**Restart types.** Information about the restart types used by the parameter descriptions in this section is shown in the following table:

**Table 18.263 NDB Cluster restart types**

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Restart Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
<td>Node</td>
<td>The parameter can be updated using a rolling restart (see Section 18.5.5, “Performing a Rolling Restart of an NDB Cluster”)</td>
</tr>
<tr>
<td>S</td>
<td>System</td>
<td>All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter</td>
</tr>
<tr>
<td>I</td>
<td>Initial</td>
<td>Data nodes must be restarted using the <code>--initial</code> option</td>
</tr>
</tbody>
</table>

- `NodeId1`
Table 18.264 This table provides type and value information for the NodeId1 TCP configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 255</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

To identify a connection between two nodes it is necessary to provide their node IDs in the [tcp] section of the configuration file as the values of `NodeId1` and `NodeId2`. These are the same unique `Id` values for each of these nodes as described in Section 18.3.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”.

- **NodeId2**

Table 18.265 This table provides type and value information for the NodeId2 TCP configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 255</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

To identify a connection between two nodes it is necessary to provide their node IDs in the [tcp] section of the configuration file as the values of `NodeId1` and `NodeId2`. These are the same unique `Id` values for each of these nodes as described in Section 18.3.3.7, “Defining SQL and Other API Nodes in an NDB Cluster”.

- **HostName1**

Table 18.266 This table provides type and value information for the HostName1 TCP configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>name or IP address</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

The `HostName1` and `HostName2` parameters can be used to specify specific network interfaces to be used for a given TCP connection between two nodes. The values used for these parameters can be host names or IP addresses.

- **HostName2**
Table 18.267 This table provides type and value information for the HostName1 TCP configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>name or IP address</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

The HostName1 and HostName2 parameters can be used to specify specific network interfaces to be used for a given TCP connection between two nodes. The values used for these parameters can be host names or IP addresses.

- **OverloadLimit**

Table 18.268 This table provides type and value information for the OverloadLimit TCP configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

When more than this many unsent bytes are in the send buffer, the connection is considered overloaded.

This parameter can be used to determine the amount of unsent data that must be present in the send buffer before the connection is considered overloaded. See Section 18.3.3.13, “Configuring NDB Cluster Send Buffer Parameters”, and Section 18.5.10.27, “The ndbinfo transporters Table”, for more information.

- **SendBufferMemory**

Table 18.269 This table provides type and value information for the SendBufferMemory TCP configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>2M</td>
</tr>
<tr>
<td>Range</td>
<td>256K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

TCP transporters use a buffer to store all messages before performing the send call to the operating system. When this buffer reaches 64KB its contents are sent; these are also sent when a round of messages have been executed. To handle temporary overload situations it is also possible to define a bigger send buffer.
If this parameter is set explicitly, then the memory is not dedicated to each transporter; instead, the value used denotes the hard limit for how much memory (out of the total available memory—that is, \texttt{TotalSendBufferMemory}) that may be used by a single transporter. For more information about configuring dynamic transporter send buffer memory allocation in NDB Cluster, see Section 18.3.3.13, “Configuring NDB Cluster Send Buffer Parameters”.

The default size of the send buffer is 2MB, which is the size recommended in most situations. The minimum size is 64 KB; the theoretical maximum is 4 GB.

- \texttt{SendSignalId}

Table 18.270 This table provides type and value information for the \texttt{SendSignalId} TCP configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>[see text]</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

To be able to retrace a distributed message datagram, it is necessary to identify each message. When this parameter is set to \texttt{Y}, message IDs are transported over the network. This feature is disabled by default in production builds, and enabled in \texttt{-debug} builds.

- \texttt{Checksum}

Table 18.271 This table provides type and value information for the \texttt{Checksum} TCP configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is a boolean parameter (enabled by setting it to \texttt{Y} or \texttt{1}, disabled by setting it to \texttt{N} or \texttt{0}). It is disabled by default. When it is enabled, checksums for all messages are calculated before they placed in the send buffer. This feature ensures that messages are not corrupted while waiting in the send buffer, or by the transport mechanism.

- \texttt{PortNumber (OBSOLETE / REMOVED)}

This parameter formerly specified the port number to be used for listening for connections from other nodes, and was removed in NDB 7.5.1; use the \texttt{ServerPort} data node configuration parameter for this purpose instead (Bug #77405, Bug #21280456).

- \texttt{ReceiveBufferMemory}
Table 18.272 This table provides type and value information for the ReceiveBufferMemory TCP configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>2M</td>
</tr>
<tr>
<td>Range</td>
<td>16K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Specifies the size of the buffer used when receiving data from the TCP/IP socket.

The default value of this parameter is 2MB. The minimum possible value is 16KB; the theoretical maximum is 4GB.

- **TCP_RCV_BUF_SIZE**

Table 18.273 This table provides type and value information for the TCP_RCV_BUF_SIZE TCP configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>70080</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 2G</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 2G</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Determines the size of the receive buffer set during TCP transporter initialization. Prior to NDB 7.3.1, the default was 70080 and the minimum was 1. In NDB 7.3.1 and later, the default and minimum value is 0, which allows the operating system or platform to set this value. The default is recommended for most common usage cases.

- **TCP_SND_BUF_SIZE**

Table 18.274 This table provides type and value information for the TCP_SND_BUF_SIZE TCP configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>71540</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 2G</td>
</tr>
</tbody>
</table>
Determines the size of the send buffer set during TCP transporter initialization. Prior to NDB 7.3.1, the default was 71540 and the minimum was 1. In NDB 7.3.1 and later, the default and minimum value is 0, which allows the operating system or platform to set this value. The default is recommended for most common usage cases.

- **TCP_MAXSEG_SIZE**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 2G</td>
</tr>
</tbody>
</table>

Determines the size of the memory set during TCP transporter initialization. The default is recommended for most common usage cases.

- **TcpBind_INADDR_ANY**

  Setting this parameter to TRUE or 1 binds IP_ADDR_ANY so that connections can be made from anywhere (for autogenerated connections). The default is FALSE (0).

- **Group**

  When ndb_optimized_node_selection is enabled, node proximity is used in some cases to select which node to connect to. This parameter can be used to influence proximity by setting it to a lower value, which is interpreted as “closer”. See the description of the system variable for more information.

18.3.3.10 NDB Cluster TCP/IP Connections Using Direct Connections

Setting up a cluster using direct connections between data nodes requires specifying explicitly the crossover IP addresses of the data nodes so connected in the [tcp] section of the cluster config.ini file.
In the following example, we envision a cluster with at least four hosts, one each for a management server, an SQL node, and two data nodes. The cluster as a whole resides on the 172.23.72.* subnet of a LAN. In addition to the usual network connections, the two data nodes are connected directly using a standard crossover cable, and communicate with one another directly using IP addresses in the 1.1.0.* address range as shown:

```
# Management Server
[ndb_mgmd]
Id=1
HostName=172.23.72.20

# SQL Node
[mysqld]
Id=2
HostName=172.23.72.21

# Data Nodes
[ndbd]
Id=3
HostName=172.23.72.22
[ndbd]
Id=4
HostName=172.23.72.23

# TCP/IP Connections
[tcp]
NodeId1=3
NodeId2=4
HostName1=1.1.0.1
HostName2=1.1.0.2
```

The `HostName1` and `HostName2` parameters are used only when specifying direct connections.

The use of direct TCP connections between data nodes can improve the cluster's overall efficiency by enabling the data nodes to bypass an Ethernet device such as a switch, hub, or router, thus cutting down on the cluster's latency.

**Note**

To take the best advantage of direct connections in this fashion with more than two data nodes, you must have a direct connection between each data node and every other data node in the same node group.

### 18.3.3.11 NDB Cluster Shared-Memory Connections

NDB Cluster attempts to use the shared memory transporter and configure it automatically where possible. `[shm]` sections in the `config.ini` file explicitly define shared-memory connections between nodes in the cluster. When explicitly defining shared memory as the connection method, it is necessary to define at least `NodeId1`, `NodeId2`, and `ShmKey`. All other parameters have default values that should work well in most cases.

**Important**

*SHM functionality is considered experimental only.* It is not officially supported in any current NDB Cluster release, and testing results indicate that SHM performance is not appreciably greater than when using TCP/IP for the transporter.
For these reasons, you must determine for yourself or by using our free resources (forums, mailing lists) whether SHM can be made to work correctly in your specific case.

**Restart types.** Information about the restart types used by the parameter descriptions in this section is shown in the following table:

### Table 18.276 NDB Cluster restart types

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Restart Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
<td>Node</td>
<td>The parameter can be updated using a rolling restart (see Section 18.5.5, “Performing a Rolling Restart of an NDB Cluster”)</td>
</tr>
<tr>
<td>S</td>
<td>System</td>
<td>All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter</td>
</tr>
<tr>
<td>I</td>
<td>Initial</td>
<td>Data nodes must be restarted using the <code>--initial</code> option</td>
</tr>
</tbody>
</table>

- **Checksum**

  **Table 18.277 This table provides type and value information for the Checksum shared memory configuration parameter**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>true</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is a boolean (Y/N) parameter which is disabled by default. When it is enabled, checksums for all messages are calculated before being placed in the send buffer.

This feature prevents messages from being corrupted while waiting in the send buffer. It also serves as a check against data being corrupted during transport.

- **HostName1**

  **Table 18.278 This table provides type and value information for the HostName1 shared memory configuration parameter**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>name or IP address</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

The `HostName1` and `HostName2` parameters can be used to specify specific network interfaces to be used for a given SHM connection between two nodes. The values used for these parameters can be host names or IP addresses.
• HostName2

Table 18.279 This table provides type and value information for the HostName1 shared memory configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>name or IP address</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

The HostName1 and HostName2 parameters can be used to specify specific network interfaces to be used for a given SHM connection between two nodes. The values used for these parameters can be host names or IP addresses.

• NodeId1

Table 18.280 This table provides type and value information for the NodeId1 shared memory configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 255</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as NodeId1 and NodeId2.

• NodeId2

Table 18.281 This table provides type and value information for the NodeId2 shared memory configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 255</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as NodeId1 and NodeId2.

• NodeIdServer
Table 18.282 This table provides type and value information for the NodeIdServer shared memory configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 63</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Identify the server end of a shared memory connection.

- **OverloadLimit**

Table 18.283 This table provides type and value information for the OverloadLimit shared memory configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

When more than this many unsent bytes are in the send buffer, the connection is considered overloaded.

This parameter can be used to determine the amount of unsent data that must be present in the send buffer before the connection is considered overloaded. See Section 18.3.3.13, "Configuring NDB Cluster Send Buffer Parameters", for more information.

- **SendSignalId**

Table 18.284 This table provides type and value information for the SendSignalId shared memory configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

To retrace the path of a distributed message, it is necessary to provide each message with a unique identifier. Setting this parameter to `Y` causes these message IDs to be transported over the network as well. This feature is disabled by default in production builds, and enabled in `-debug` builds.

- **ShmKey**
Table 18.285 This table provides type and value information for the ShmKey shared memory configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

When setting up shared memory segments, a node ID, expressed as an integer, is used to identify uniquely the shared memory segment to use for the communication. There is no default value.

• ShmSize

Table 18.286 This table provides type and value information for the ShmSize shared memory configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>1M</td>
</tr>
<tr>
<td>Range</td>
<td>64K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Each SHM connection has a shared memory segment where messages between nodes are placed by the sender and read by the reader. The size of this segment is defined by `ShmSize`. The default value is 1MB.

• SigNum

Table 18.287 This table provides type and value information for the Signum shared memory configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

When using the shared memory transporter, a process sends an operating system signal to the other process when there is new data available in the shared memory. Should that signal conflict with an existing signal, this parameter can be used to change it. This is a possibility when using SHM due to the fact that different operating systems use different signal numbers.

The default value of `SigNum` is 0; therefore, it must be set to avoid errors in the cluster log when using the shared memory transporter. Typically, this parameter is set to 10 in the `[shm default]` section of the `config.ini` file.
18.3.3.12 SCI Transport Connections in NDB Cluster

[sci] sections in the `config.ini` file explicitly define SCI (Scalable Coherent Interface) connections between cluster nodes. Using SCI transporters in NDB Cluster requires specialized hardware as well as specially-built MySQL binaries; compiling such binaries is not supported using an NDB 7.2 or later distribution.

**Restart types.** Information about the restart types used by the parameter descriptions in this section is shown in the following table:

**Table 18.288 NDB Cluster restart types**

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Restart Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
<td>Node</td>
<td>The parameter can be updated using a rolling restart (see Section 18.5.5, “Performing a Rolling Restart of an NDB Cluster”)</td>
</tr>
<tr>
<td>S</td>
<td>System</td>
<td>All cluster nodes must be shut down completely, then restarted, to effect a change in this parameter</td>
</tr>
<tr>
<td>I</td>
<td>Initial</td>
<td>Data nodes must be restarted using the <code>--initial</code> option</td>
</tr>
</tbody>
</table>

The following parameters are present in NDB source code as well as the output of `ndb_config` and other NDB programs, but are nonfunctional in NDB 7.2 and later.

- **NodeId1**

  **Table 18.289 This table provides type and value information for the NodeId1 SCI configuration parameter**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 255</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as `NodeId1` and `NodeId2`.

- **NodeId2**

  **Table 18.290 This table provides type and value information for the NodeId2 SCI configuration parameter**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>1 - 255</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as `NodeId1` and `NodeId2`.  

• **Host1SciId0**

**Table 18.291 This table provides type and value information for the Host1SciId0 SCI configuration parameter**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

This identifies the SCI node ID on the first Cluster node (identified by **NodeId1**).

• **Host1SciId1**

**Table 18.292 This table provides type and value information for the Host1SciId1 SCI configuration parameter**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

It is possible to set up SCI Transporters for failover between two SCI cards which then should use separate networks between the nodes. This identifies the node ID and the second SCI card to be used on the first node.

• **Host2SciId0**

**Table 18.293 This table provides type and value information for the Host2SciId0 SCI configuration parameter**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
<td>N</td>
</tr>
</tbody>
</table>

This identifies the SCI node ID on the second Cluster node (identified by **NodeId2**).

• **Host2SciId1**
Table 18.294 This table provides type and value information for the Host2SciId1 SCI configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

When using two SCI cards to provide failover, this parameter identifies the second SCI card to be used on the second node.

- **HostName1**

Table 18.295 This table provides type and value information for the HostName1 SCI configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>name or IP address</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

The **HostName1** and **HostName2** parameters can be used to specify specific network interfaces to be used for a given SCI connection between two nodes. The values used for these parameters can be host names or IP addresses.

- **HostName2**

Table 18.296 This table provides type and value information for the HostName1 SCI configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>name or IP address</td>
</tr>
<tr>
<td>Default</td>
<td>[none]</td>
</tr>
<tr>
<td>Range</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

The **HostName1** and **HostName2** parameters can be used to specify specific network interfaces to be used for a given SCI connection between two nodes. The values used for these parameters can be host names or IP addresses.

- **SharedBufferSize**
Table 18.297 This table provides type and value information for the SharedBufferSize SCI configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>10M</td>
</tr>
<tr>
<td>Range</td>
<td>64K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

Each SCI transporter has a shared memory segment used for communication between the two nodes. Setting the size of this segment to the default value of 1MB should be sufficient for most applications. Using a smaller value can lead to problems when performing many parallel inserts; if the shared buffer is too small, this can also result in a crash of the `ndbd` process.

- **SendLimit**

Table 18.298 This table provides type and value information for the SendLimit SCI configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>unsigned</td>
</tr>
<tr>
<td>Default</td>
<td>8K</td>
</tr>
<tr>
<td>Range</td>
<td>128 - 32K</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

A small buffer in front of the SCI media stores messages before transmitting them over the SCI network. By default, this is set to 8KB. Our benchmarks show that performance is best at 64KB but 16KB reaches within a few percent of this, and there was little if any advantage to increasing it beyond 8KB.

- **SendSignalId**

Table 18.299 This table provides type and value information for the SendSignalId SCI configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>true</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

To trace a distributed message it is necessary to identify each message uniquely. When this parameter is set to `Y`, message IDs are transported over the network. This feature is disabled by default in production builds, and enabled in `-debug` builds.

- **Checksum**
Table 18.300 This table provides type and value information for the Checksum SCI configuration
parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>Range</td>
<td>true, false</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is a boolean value, and is disabled by default. When Checksum is enabled, checksums
are calculated for all messages before they are placed in the send buffer. This feature prevents
messages from being corrupted while waiting in the send buffer. It also serves as a check against data
being corrupted during transport.

• OverloadLimit

Table 18.301 This table provides type and value information for the OverloadLimit SCI
configuration parameter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version (or later)</td>
<td>NDB 7.3.1</td>
</tr>
<tr>
<td>Type or units</td>
<td>bytes</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>Restart Type</td>
<td>N</td>
</tr>
</tbody>
</table>

When more than this many unsent bytes are in the send buffer, the connection is considered overloaded.
See Section 18.3.3.13, “Configuring NDB Cluster Send Buffer Parameters”, for more information.

18.3.3.13 Configuring NDB Cluster Send Buffer Parameters

Formerly, the NDB kernel employed a send buffer whose size was fixed at 2MB for each node in the
cluster, this buffer being allocated when the node started. Because the size of this buffer could not
be changed after the cluster was started, it was necessary to make it large enough in advance to
accommodate the maximum possible load on any transporter socket. However, this was an inefficient
use of memory, since much of it often went unused, and could result in large amounts of resources being
wasted when scaling up to many API nodes.

This problem was eventually solved (in NDB Cluster 7.0) by employing a unified send buffer whose
memory is allocated dynamically from a pool shared by all transporters. This means that the size of the
send buffer can be adjusted as necessary. Configuration of the unified send buffer can accomplished by
setting the following parameters:

• TotalSendBufferMemory. This parameter can be set for all types of NDB Cluster nodes—that
  is, it can be set in the [ndbd], [mgm], and [api] (or [mysql]) sections of the config.ini file. It
  represents the total amount of memory (in bytes) to be allocated by each node for which it is set for use
  among all configured transporters. If set, its minimum is 256KB; the maximum is 4294967039.
To be backward-compatible with existing configurations, this parameter takes as its default value the sum of the maximum send buffer sizes of all configured transporters, plus an additional 32KB (one page) per transporter. The maximum depends on the type of transporter, as shown in the following table:

**Table 18.302 Transporter types with maximum send buffer sizes**

<table>
<thead>
<tr>
<th>Transporter</th>
<th>Maximum Send Buffer Size (bytes)</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP</td>
<td><code>SendBufferMemory</code> (default = 2M)</td>
</tr>
<tr>
<td>SCI</td>
<td><code>SendLimit</code> (default = 8K) plus 16K</td>
</tr>
<tr>
<td>SHM</td>
<td>20K</td>
</tr>
</tbody>
</table>

This enables existing configurations to function in close to the same way as they did with NDB Cluster 6.3 and earlier, with the same amount of memory and send buffer space available to each transporter. However, memory that is unused by one transporter is not available to other transporters.

- **OverloadLimit.** This parameter is used in the `config.ini` file `[tcp]` section, and denotes the amount of unsent data (in bytes) that must be present in the send buffer before the connection is considered overloaded. When such an overload condition occurs, transactions that affect the overloaded connection fail with NDB API Error 1218 (*Send Buffers overloaded in NDB kernel*) until the overload status passes. The default value is 0, in which case the effective overload limit is calculated as `SendBufferMemory * 0.8` for a given connection. The maximum value for this parameter is 4G.

- **SendBufferMemory.** This value denotes a hard limit for the amount of memory that may be used by a single transporter out of the entire pool specified by `TotalSendBufferMemory`. However, the sum of `SendBufferMemory` for all configured transporters may be greater than the `TotalSendBufferMemory` that is set for a given node. This is a way to save memory when many nodes are in use, as long as the maximum amount of memory is never required by all transporters at the same time.

- **ReservedSendBufferMemory.** This optional data node parameter, if set, gives an amount of memory (in bytes) that is reserved for connections between data nodes; this memory is not allocated to send buffers used for communications with management servers or API nodes. This provides a way to protect the cluster against misbehaving API nodes that use excess send memory and thus cause failures in communications internally in the NDB kernel. If set, its the minimum permitted value for this parameters is 256KB; the maximum is 4294967039.

You can use the `ndbinfo.transporters` table to monitor send buffer memory usage, and to detect slowdown and overload conditions that can adversely affect performance.

### 18.3.4 Using High-Speed Interconnects with NDB Cluster

Even before design of NDBCLUSTER began in 1996, it was evident that one of the major problems to be encountered in building parallel databases would be communication between the nodes in the network. For this reason, NDBCLUSTER was designed from the very beginning to permit the use of a number of different data transport mechanisms. In this Manual, we use the term *transporter* for these.

The NDB Cluster codebase provides for four different transporters:

- **TCP/IP using 100 Mbps or gigabit Ethernet**, as discussed in Section 18.3.3.9, “NDB Cluster TCP/IP Connections”.
- **Direct (machine-to-machine) TCP/IP;** although this transporter uses the same TCP/IP protocol as mentioned in the previous item, it requires setting up the hardware differently and is configured differently as well. For this reason, it is considered a separate transport mechanism for NDB Cluster. See Section 18.3.3.10, “NDB Cluster TCP/IP Connections Using Direct Connections”, for details.
• **Shared memory (SHM).** For more information about SHM, see Section 18.3.3.11, “NDB Cluster Shared-Memory Connections”.

  **Note**  
  SHM is considered experimental only, and is not officially supported.

• **Scalable Coherent Interface (SCI).** For more information about SHM, see Section 18.3.3.12, “SCI Transport Connections in NDB Cluster”.

  **Note**  
  Using SCI transporters in NDB Cluster requires specialized hardware, software, and MySQL binaries not available using an NDB 7.2 or later distribution.

Most users today employ TCP/IP over Ethernet because it is ubiquitous. TCP/IP is also by far the best-tested transporter for use with NDB Cluster.

We are working to make sure that communication with the `ndbd` process is made in “chunks” that are as large as possible because this benefits all types of data transmission.

## 18.4 NDB Cluster Programs

Using and managing an NDB Cluster requires several specialized programs, which we describe in this chapter. We discuss the purposes of these programs in an NDB Cluster, how to use the programs, and what startup options are available for each of them.

These programs include the NDB Cluster data, management, and SQL node processes (`ndbd`, `ndbmtd`, `ndb_mgmd`, and `mysqld`) and the management client (`ndb_mgm`).

Information about the program `ndb_setup.py` (added in NDB 7.3.1), used to start the NDB Cluster Auto-Installer, is also included in this section. You should be aware that Section 18.4.25, “`ndb_setup.py` — Start browser-based Auto-Installer for NDB Cluster”, contains information about the command-line client only; for information about using the GUI installer spawned by this program to configure and deploy an NDB Cluster, see Section 18.2.1, “The NDB Cluster Auto-Installer”.

For information about using `mysqld` as an NDB Cluster process, see Section 18.5.4, “MySQL Server Usage for NDB Cluster”.

Other NDB utility, diagnostic, and example programs are included with the NDB Cluster distribution. These include `ndb_restore`, `ndb_show_tables`, and `ndb_config`. These programs are also covered in this section.

The final portion of this section contains tables of options that are common to all the various NDB Cluster programs.

### 18.4.1 `ndbd` — The NDB Cluster Data Node Daemon

`ndbd` is the process that is used to handle all the data in tables using the NDB Cluster storage engine. This is the process that empowers a data node to accomplish distributed transaction handling, node recovery, checkpointing to disk, online backup, and related tasks.

In an NDB Cluster, a set of `ndbd` processes cooperate in handling data. These processes can execute on the same computer (host) or on different computers. The correspondences between data nodes and Cluster hosts is completely configurable.
The following table includes command options specific to the NDB Cluster data node program `ndbd`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndbd`), see Section 18.4.29, "Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs".

Table 18.303 Command-line options for the `ndbd` program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--bind-address=name</code></td>
<td>Local bind address</td>
<td>All MySQL 5.6 based releases</td>
</tr>

<tr>
<td><code>--initial</code></td>
<td>Perform initial start of ndbd, including cleaning the file system. Consult the documentation before using this option</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td><code>--initial-start</code></td>
<td>Perform partial initial start (requires <code>--nowait-nodes</code>)</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td><code>--install[=name]</code></td>
<td>Used to install the data node process as a Windows service. Does not apply on non-Windows platforms.</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td><code>--nostart</code>, <code>-n</code></td>
<td>Don't start ndbd immediately; ndbd waits for command to start from ndb_mgmd</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td><code>--nodaemon</code></td>
<td>Do not start ndbd as daemon; provided for testing purposes</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td><code>--nowait-nodes=list</code></td>
<td>Do not wait for these data nodes to start (takes comma-separated list of node IDs). Also requires <code>--ndb-nodeid</code> to be used.</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td><code>--remove[=name]</code></td>
<td>Used to remove a data node process that was previously</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>Format</td>
<td>Description</td>
<td>Added, Deprecated, or Removed</td>
</tr>
<tr>
<td>------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>-----------------------------------------------</td>
</tr>
<tr>
<td>--verbose, -v</td>
<td>installed as a Windows service. Does not apply on non-Windows platforms.</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td></td>
<td>Causes the data log to write extra debugging information to the node log.</td>
<td></td>
</tr>
</tbody>
</table>

Note

All of these options also apply to the multithreaded version of this program (ndbmtd) and you may substitute “ndbmtd” for “ndbd” wherever the latter occurs in this section.

- **--bind-address**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--bind-address=name</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>

Causes ndbd to bind to a specific network interface (host name or IP address). This option has no default value.

- **--connect-delay=#**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--connect-delay=#</td>
</tr>
<tr>
<td>Deprecated</td>
<td>5.6.28-ndb-7.4.9</td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>5</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>3600</td>
</tr>
</tbody>
</table>

Determines the time to wait between attempts to contact a management server when starting (the number of attempts is controlled by the --connect-retries option). The default is 5 seconds.

This option is deprecated in NDB 7.4.9, and is subject to removal in a future release of NDB Cluster. Use --connect-retry-delay instead.

- **--connect-retries=#**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--connect-retries=#</td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>12</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>65535</td>
</tr>
</tbody>
</table>
Set the number of times to retry a connection before giving up; 0 means 1 attempt only (and no retries). The default is 12 attempts. The time to wait between attempts is controlled by the `--connect-retry-delay` option in MySQL NDB 7.4.9 and later (previously, this was `--connect-delay`).

```
• --connect-retry-delay=#
```

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--connect-retry-delay=#</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.28-ndb-7.4.9</td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>5</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Determines the time to wait between attempts to contact a management server when starting (the time between attempts is controlled by the `--connect-retries` option). The default is 5 seconds.

This option was added in NDB 7.4.9, and is intended to take the place of the `--connect-delay` option, which is now deprecated and subject to removal in a future release of NDB Cluster.

```
• --daemon, -d
```

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--daemon</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

Instructs `ndbd` or `ndbmtd` to execute as a daemon process. This is the default behavior. `--nodaemon` can be used to prevent the process from running as a daemon.

This option has no effect when running `ndbd` or `ndbmtd` on Windows platforms.

```
• --foreground
```

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--foreground</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Causes `ndbd` or `ndbmtd` to execute as a foreground process, primarily for debugging purposes. This option implies the `--nodaemon` option.

This option has no effect when running `ndbd` or `ndbmtd` on Windows platforms.

```
• --initial
```

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--initial</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
</tbody>
</table>
Instructs `ndbd` to perform an initial start. An initial start erases any files created for recovery purposes by earlier instances of `ndbd`. It also re-creates recovery log files. On some operating systems, this process can take a substantial amount of time.

An **--initial** start is to be used *only* when starting the `ndbd` process under very special circumstances; this is because this option causes all files to be removed from the NDB Cluster file system and all redo log files to be re-created. These circumstances are listed here:

- When performing a software upgrade which has changed the contents of any files.
- When restarting the node with a new version of `ndbd`.
- As a measure of last resort when for some reason the node restart or system restart repeatedly fails. In this case, be aware that this node can no longer be used to restore data due to the destruction of the data files.

**Warning**

To avoid the possibility of eventual data loss, it is recommended that you *not* use the **--initial** option together with `StopOnError = 0`. Instead, set `StopOnError` to 0 in `config.ini` only after the cluster has been started, then restart the data nodes normally—that is, without the **--initial** option. See the description of the `StopOnError` parameter for a detailed explanation of this issue. (Bug #24945638)

Use of this option prevents the `StartPartialTimeout` and `StartPartitionedTimeout` configuration parameters from having any effect.

**Important**

This option does *not* affect either of the following types of files:

- Backup files that have already been created by the affected node
- NDB Cluster Disk Data files (see Section 18.5.12, “NDB Cluster Disk Data Tables”).

This option also has no effect on recovery of data by a data node that is just starting (or restarting) from data nodes that are already running. This recovery of data occurs automatically, and requires no user intervention in an NDB Cluster that is running normally.

It is permissible to use this option when starting the cluster for the very first time (that is, before any data node files have been created); however, it is *not* necessary to do so.

**--initial-start**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><strong>--initial-start</strong></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>
This option is used when performing a partial initial start of the cluster. Each node should be started with this option, as well as --nowait-nodes.

Suppose that you have a 4-node cluster whose data nodes have the IDs 2, 3, 4, and 5, and you wish to perform a partial initial start using only nodes 2, 4, and 5—that is, omitting node 3:

```
shell> ndbd --ndb-nodeid=2 --nowait-nodes=3 --initial-start
shell> ndbd --ndb-nodeid=4 --nowait-nodes=3 --initial-start
shell> ndbd --ndb-nodeid=5 --nowait-nodes=3 --initial-start
```

When using this option, you must also specify the node ID for the data node being started with the --ndb-nodeid option.

---

**Important**

Do not confuse this option with the --nowait-nodes option for ndb_mgmd, which can be used to enable a cluster configured with multiple management servers to be started without all management servers being online.

---

- **--install[=name]**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--install[=name]</td>
</tr>
<tr>
<td>Platform Specific</td>
<td>Windows</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>ndbd</td>
</tr>
</tbody>
</table>

Causes ndbd to be installed as a Windows service. Optionally, you can specify a name for the service; if not set, the service name defaults to ndbd. Although it is preferable to specify other ndbd program options in a my.ini or my.cnf configuration file, it is possible to use together with --install. However, in such cases, the --install option must be specified first, before any other options are given, for the Windows service installation to succeed.

It is generally not advisable to use this option together with the --initial option, since this causes the data node file system to be wiped and rebuilt every time the service is stopped and started. Extreme care should also be taken if you intend to use any of the other ndbd options that affect the starting of data nodes—including --initial-start, --nostart, and --nowait-nodes—together with --install, and you should make absolutely certain you fully understand and allow for any possible consequences of doing so.

The --install option has no effect on non-Windows platforms.

- **--nodaemon**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--nodaemon</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Prevents ndbd or ndbmtd from executing as a daemon process. This option overrides the --daemon option. This is useful for redirecting output to the screen when debugging the binary.
The default behavior for `ndbd` and `ndbmtd` on Windows is to run in the foreground, making this option unnecessary on Windows platforms, where it has no effect.

- `--nostart, -n`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--nostart</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Instructs `ndbd` not to start automatically. When this option is used, `ndbd` connects to the management server, obtains configuration data from it, and initializes communication objects. However, it does not actually start the execution engine until specifically requested to do so by the management server. This can be accomplished by issuing the proper START command in the management client (see Section 18.5.2, "Commands in the NDB Cluster Management Client").

- `--nowait-nodes=node_id_1[, node_id_2[, ...]]`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--nowait-nodes=list</code></td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>

This option takes a list of data nodes which for which the cluster will not wait for before starting.

This can be used to start the cluster in a partitioned state. For example, to start the cluster with only half of the data nodes (nodes 2, 3, 4, and 5) running in a 4-node cluster, you can start each `ndbd` process with `--nowait-nodes=3,5`. In this case, the cluster starts as soon as nodes 2 and 4 connect, and does not wait `StartPartitionedTimeout` milliseconds for nodes 3 and 5 to connect as it would otherwise.

If you wanted to start up the same cluster as in the previous example without one `ndbd` (say, for example, that the host machine for node 3 has suffered a hardware failure) then start nodes 2, 4, and 5 with `--nowait-nodes=3`. Then the cluster will start as soon as nodes 2, 4, and 5 connect and will not wait for node 3 to start.

- `--remove[=name]`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--remove[=name]</code></td>
</tr>
<tr>
<td>Platform Specific</td>
<td>Windows</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>ndbd</code></td>
</tr>
</tbody>
</table>

Causes an `ndbd` process that was previously installed as a Windows service to be removed. Optionally, you can specify a name for the service to be uninstalled; if not set, the service name defaults to `ndbd`.

The `--remove` option has no effect on non-Windows platforms.

- `--verbose, -v`
ndbd — The NDB Cluster Data Node Daemon

Causes extra debug output to be written to the node log.

ndbd generates a set of log files which are placed in the directory specified by DataDir in the config.ini configuration file.

These log files are listed below. node_id is and represents the node's unique identifier. For example, ndb_2_error.log is the error log generated by the data node whose node ID is 2.

- ndb_node_id_error.log is a file containing records of all crashes which the referenced ndbd process has encountered. Each record in this file contains a brief error string and a reference to a trace file for this crash. A typical entry in this file might appear as shown here:

```
Date/Time: Saturday 30 July 2004 - 00:20:01
Type of error: error
Message: Internal program error (failed ndbrequire)
Fault ID: 2341
Problem data: DbtupFixAlloc.cpp
Object of reference: DBTUP (Line: 173)
ProgramName: NDB Kernel
ProcessID: 14909
TraceFile: ndb_2_trace.log.2
***EOM***
```

Listings of possible ndbd exit codes and messages generated when a data node process shuts down prematurely can be found in Data Node Error Messages.

Important
---

*The last entry in the error log file is not necessarily the newest one* (nor is it likely to be). Entries in the error log are *not* listed in chronological order; rather, they correspond to the order of the trace files as determined in the ndb_node_id_trace.log.next file (see below). Error log entries are thus overwritten in a cyclical and not sequential fashion.

- ndb_node_id_trace.log.trace_id is a trace file describing exactly what happened just before the error occurred. This information is useful for analysis by the NDB Cluster development team.

It is possible to configure the number of these trace files that will be created before old files are overwritten. trace_id is a number which is incremented for each successive trace file.

- ndb_node_id_trace.log.next is the file that keeps track of the next trace file number to be assigned.

- ndb_node_id_out.log is a file containing any data output by the ndbd process. This file is created only if ndbd is started as a daemon, which is the default behavior.

- ndb_node_id.pid is a file containing the process ID of the ndbd process when started as a daemon. It also functions as a lock file to avoid the starting of nodes with the same identifier.

- ndb_node_id_signal.log is a file used only in debug versions of ndbd, where it is possible to trace all incoming, outgoing, and internal messages with their data in the ndbd process.

It is recommended not to use a directory mounted through NFS because in some environments this can cause problems whereby the lock on the .pid file remains in effect even after the process has terminated.

To start ndbd, it may also be necessary to specify the host name of the management server and the port on which it is listening. Optionally, one may also specify the node ID that the process is to use.
When \texttt{ndbd} starts, it actually initiates two processes. The first of these is called the “angel process”; its only job is to discover when the execution process has been completed, and then to restart the \texttt{ndbd} process if it is configured to do so. Thus, if you attempt to kill \texttt{ndbd} using the Unix \texttt{kill} command, it is necessary to kill both processes, beginning with the angel process. The preferred method of terminating an \texttt{ndbd} process is to use the management client and stop the process from there.

The execution process uses one thread for reading, writing, and scanning data, as well as all other activities. This thread is implemented asynchronously so that it can easily handle thousands of concurrent actions. In addition, a watch-dog thread supervises the execution thread to make sure that it does not hang in an endless loop. A pool of threads handles file I/O, with each thread able to handle one open file. Threads can also be used for transporter connections by the transporters in the \texttt{ndbd} process. In a multi-processor system performing a large number of operations (including updates), the \texttt{ndbd} process can consume up to 2 CPUs if permitted to do so.

For a machine with many CPUs it is possible to use several \texttt{ndbd} processes which belong to different node groups; however, such a configuration is still considered experimental and is not supported for MySQL 5.6 in a production setting. See Section 18.1.7, “Known Limitations of NDB Cluster”.

18.4.2 \texttt{ndbinfo_select_all} — Select From ndbinfo Tables

\texttt{ndbinfo_select_all} is a client program that selects all rows and columns from one or more tables in the \texttt{ndbinfo} database. It is included with the NDB Cluster distribution beginning with NDB 7.2.2.

Not all \texttt{ndbinfo} tables available in the \texttt{mysql} client can be read by this program. In addition, \texttt{ndbinfo_select_all} can show information about some tables internal to \texttt{ndbinfo} which cannot be accessed using SQL, including the \texttt{tables} and \texttt{columns} metadata tables.

To select from one or more \texttt{ndbinfo} tables using \texttt{ndbinfo_select_all}, it is necessary to supply the names of the tables when invoking the program as shown here:

\begin{verbatim}
shell> ndbinfo_select_all table_name1 [table_name2] [...]
\end{verbatim}

For example:

\begin{verbatim}
shell> ndbinfo_select_all logbuffers logspaces
== logbuffers ==
 node_id log_type log_id log_part total  used  high
  5     0     0     0 33554432 262144 0
  6     0     0     0 33554432 262144 0
  7     0     0     0 33554432 262144 0
  8     0     0     0 33554432 262144 0
== logspaces ==
 node_id log_type log_id log_part total  used  high
  5     0     0     0 268435456 0 0
  5     0     0     1 268435456 0 0
  5     0     0     2 268435456 0 0
  5     0     0     3 268435456 0 0
  6     0     0     0 268435456 0 0
  6     0     0     1 268435456 0 0
  6     0     0     2 268435456 0 0
\end{verbatim}
The following table includes options that are specific to `ndbinfo_select_all`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndbinfo_select_all`), see Section 18.4.29, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

Table 18.304 Command-line options for the `ndbinfo_select_all` program

• `--delay=seconds`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--delay=#</code></td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>5</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>MAX_INT</td>
</tr>
</tbody>
</table>

This option sets the number of seconds to wait between executing loops. Has no effect if `--loops` is set to 0 or 1.

• `--loops=number, -l number`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--loops=#</code></td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>MAX_INT</td>
</tr>
</tbody>
</table>
This option sets the number of times to execute the select. Use `--delay` to set the time between loops.

### 18.4.3 ndbmtd — The NDB Cluster Data Node Daemon (Multi-Threaded)

`ndbmtd` is a multithreaded version of `ndbd`, the process that is used to handle all the data in tables using the NDBCLUSTER storage engine. `ndbmtd` is intended for use on host computers having multiple CPU cores. Except where otherwise noted, `ndbmtd` functions in the same way as `ndbd`; therefore, in this section, we concentrate on the ways in which `ndbmtd` differs from `ndbd`, and you should consult Section 18.4.1, "ndbd — The NDB Cluster Data Node Daemon", for additional information about running NDB Cluster data nodes that apply to both the single-threaded and multithreaded versions of the data node process.

Command-line options and configuration parameters used with `ndbd` also apply to `ndbmtd`. For more information about these options and parameters, see Section 18.4.1, “ndbd — The NDB Cluster Data Node Daemon”, and Section 18.3.3.6, “Defining NDB Cluster Data Nodes”, respectively.

`ndbmtd` is also file system-compatible with `ndbd`. In other words, a data node running `ndbd` can be stopped, the binary replaced with `ndbmtd`, and then restarted without any loss of data. (However, when doing this, you must make sure that MaxNoOfExecutionThreads is set to an appropriate value before restarting the node if you wish for `ndbmtd` to run in multithreaded fashion.) Similarly, an `ndbmtd` binary can be replaced with `ndbd` simply by stopping the node and then starting `ndbd` in place of the multithreaded binary. It is not necessary when switching between the two to start the data node binary using `--initial`.

Using `ndbmtd` differs from using `ndbd` in two key respects:

1. Because `ndbmtd` runs by default in single-threaded mode (that is, it behaves like `ndbd`), you must configure it to use multiple threads. This can be done by setting an appropriate value in the `config.ini` file for the `MaxNoOfExecutionThreads` configuration parameter or the `ThreadConfig` configuration parameter. Using `MaxNoOfExecutionThreads` is simpler, but `ThreadConfig` offers more flexibility. For more information about these configuration parameters and their use, see Multi-Threading Configuration Parameters (`ndbmtd`).

2. Trace files are generated by critical errors in `ndbmtd` processes in a somewhat different fashion from how these are generated by `ndbd` failures. These differences are discussed in more detail in the next few paragraphs.

Like `ndbd`, `ndbmtd` generates a set of log files which are placed in the directory specified by `DataDir` in the `config.ini` configuration file. Except for trace files, these are generated in the same way and have the same names as those generated by `ndbd`.

In the event of a critical error, `ndbmtd` generates trace files describing what happened just prior to the error occurrence. These files, which can be found in the data node's `DataDir`, are useful for analysis of problems by the NDB Cluster Development and Support teams. One trace file is generated for each `ndbmtd` thread. The names of these files have the following pattern:

```
ndb_node_id_trace.log.trace_id_thread_id
```

In this pattern, `node_id` stands for the data node's unique node ID in the cluster, `trace_id` is a trace sequence number, and `thread_id` is the thread ID. For example, in the event of the failure of an `ndbmtd` process running as an NDB Cluster data node having the node ID 3 and with `MaxNoOfExecutionThreads` equal to 4, four trace files are generated in the data node's data directory. If the is the first time this node has failed, then these files are named `ndb_3_trace.log.1_t1`, `ndb_3_trace.log.1_t2`, `ndb_3_trace.log.1_t3`, and `ndb_3_trace.log.1_t4`. Internally, these trace files follow the same format as `ndbd` trace files.
The `ndbd` exit codes and messages that are generated when a data node process shuts down prematurely are also used by `ndbmtd`. See Data Node Error Messages, for a listing of these.

Note

It is possible to use `ndbd` and `ndbmtd` concurrently on different data nodes in the same NDB Cluster. However, such configurations have not been tested extensively; thus, we cannot recommend doing so in a production setting at this time.

18.4.4 ndb_mgmd — The NDB Cluster Management Server Daemon

The management server is the process that reads the cluster configuration file and distributes this information to all nodes in the cluster that request it. It also maintains a log of cluster activities. Management clients can connect to the management server and check the cluster's status.

The following table includes options that are specific to the NDB Cluster management server program `ndb_mgmd`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_mgmd`), see Section 18.4.29, "Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs".

<table>
<thead>

<td>Do not provide any node id checks.</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--nodaemon</td>
<td>Do not run ndb_mgmd as a daemon.</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--nowait-nodes=list</td>
<td>Do not wait for these management nodes when starting this management server. Also requires --ndb-nodeid to be used.</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--print-full-config, -P</td>
<td>Print full configuration and exit.</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--reload</td>
<td>Causes the management server to compare the configuration file with its configuration cache</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--remove[=name]</td>
<td>Used to remove a management server process that was previously installed as a Windows service, optionally specifying the name of the service to be removed. Does not apply on non-Windows platforms.</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--verbose, -v</td>
<td>Write additional information to the log.</td>
<td>All MySQL 5.6 based releases</td>
</tr>
</tbody>
</table>

#### --bind-address=host

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--bind-address=host</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Causes the management server to bind to a specific network interface (host name or IP address). This option has no default value.

#### --config-cache

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--config-cache[=TRUE</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>TRUE</td>
</tr>
</tbody>
</table>
This option, whose default value is 1 (or TRUE, or ON), can be used to disable the management server’s configuration cache, so that it reads its configuration from config.ini every time it starts (see Section 18.3.3, “NDB Cluster Configuration Files”). You can do this by starting the ndb_mgmd process with any one of the following options:

- --config-cache=0
- --config-cache=FALSE
- --config-cache=OFF
- --skip-config-cache

Using one of the options just listed is effective only if the management server has no stored configuration at the time it is started. If the management server finds any configuration cache files, then the --config-cache option or the --skip-config-cache option is ignored. Therefore, to disable configuration caching, the option should be used the first time that the management server is started. Otherwise—that is, if you wish to disable configuration caching for a management server that has already created a configuration cache—you must stop the management server, delete any existing configuration cache files manually, then restart the management server with --skip-config-cache (or with --config-cache set equal to 0, OFF, or FALSE).

Configuration cache files are normally created in a directory named mysql-cluster under the installation directory (unless this location has been overridden using the --configdir option). Each time the management server updates its configuration data, it writes a new cache file. The files are named sequentially in order of creation using the following format:

```
ndb_node-id_config.bin.seq-number
```

node-id is the management server’s node ID; seq-number is a sequence number, beginning with 1. For example, if the management server’s node ID is 5, then the first three configuration cache files would, when they are created, be named ndb_5_config.bin, ndb_5_config.bin.2, and ndb_5_config.bin.3.

If your intent is to purge or reload the configuration cache without actually disabling caching, you should start ndb_mgmd with one of the options --reload or --initial instead of --skip-config-cache.

To re-enable the configuration cache, simply restart the management server, but without the --config-cache or --skip-config-cache option that was used previously to disable the configuration cache.

ndb_mgmd does not check for the configuration directory (--configdir) or attempts to create one when --skip-config-cache is used. (Bug #13428853)

- --config-file=filename, -f filename

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--config-file=file</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Instructs the management server as to which file it should use for its configuration file. By default, the management server looks for a file named config.ini in the same directory as the ndb_mgmd executable; otherwise the file name and location must be specified explicitly.
This option has no default value, and is ignored unless the management server is forced to read the configuration file, either because `ndb_mgmd` was started with the `--reload` or `--initial` option, or because the management server could not find any configuration cache. This option is also read if `ndb_mgmd` was started with `--config-cache=OFF`. See Section 18.3.3, “NDB Cluster Configuration Files”, for more information.

Formerly, using this option together with `--initial` caused removal of the configuration cache even if the file was not found. This issue was resolved in NDB 7.3.2. (Bug #1299289)

- `--configdir=dir_name`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--configdir=directory</code></td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>$INSTALLDIR/mysql-cluster</code></td>
</tr>
</tbody>
</table>

Specifies the cluster management server’s configuration cache directory. `--config-dir` is an alias for this option.

- `--daemon, -d`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--daemon</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

Instructs `ndb_mgmd` to start as a daemon process. This is the default behavior.

This option has no effect when running `ndb_mgmd` on Windows platforms.

- `--initial`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--initial</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Configuration data is cached internally, rather than being read from the cluster global configuration file each time the management server is started (see Section 18.3.3, “NDB Cluster Configuration Files”). Using the `--initial` option overrides this behavior, by forcing the management server to delete any existing cache files, and then to re-read the configuration data from the cluster configuration file and to build a new cache.

This differs in two ways from the `--reload` option. First, `--reload` forces the server to check the configuration file against the cache and reload its data only if the contents of the file are different from the cache. Second, `--reload` does not delete any existing cache files.

If `ndb_mgmd` is invoked with `--initial` but cannot find a global configuration file, the management server cannot start.
When a management server starts, it checks for another management server in the same NDB Cluster and tries to use the other management server's configuration data. This behavior has implications when performing a rolling restart of an NDB Cluster with multiple management nodes. See Section 18.5.5, “Performing a Rolling Restart of an NDB Cluster”, for more information.

Formerly, using this option together with the --config-file option caused removal of the configuration cache even if the file was not found. Starting with NDB 7.3.2, the cache is cleared in such cases only if the configuration file is actually found. (Bug #1299289)

- **--install [=name]**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--install [=name]</td>
</tr>
<tr>
<td>Platform Specific</td>
<td>Windows</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>ndb_mgmd</td>
</tr>
</tbody>
</table>

Causes `ndb_mgmd` to be installed as a Windows service. Optionally, you can specify a name for the service; if not set, the service name defaults to `ndb_mgmd`. Although it is preferable to specify other `ndb_mgmd` program options in a `my.ini` or `my.cnf` configuration file, it is possible to use them together with `--install`. However, in such cases, the `--install` option must be specified first, before any other options are given, for the Windows service installation to succeed.

It is generally not advisable to use this option together with the `--initial` option, since this causes the configuration cache to be wiped and rebuilt every time the service is stopped and started. Care should also be taken if you intend to use any other `ndb_mgmd` options that affect the starting of the management server, and you should make absolutely certain you fully understand and allow for any possible consequences of doing so.

The `--install` option has no effect on non-Windows platforms.

- **--interactive**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--interactive</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Starts `ndb_mgmd` in interactive mode; that is, an `ndb_mgm` client session is started as soon as the management server is running. This option does not start any other NDB Cluster nodes.

- **--log-name=name**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--log-name=name</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>MgmtSrvr</td>
</tr>
</tbody>
</table>

Provides a name to be used for this node in the cluster log.

- **--mycnf**
ndb_mgmd — The NDB Cluster Management Server Daemon

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--mycnf</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Read configuration data from the `my.cnf` file.

- **--no-nodeid-checks**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--no-nodeid-checks</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Do not perform any checks of node IDs.

- **--nodaemon**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--nodaemon</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Instructs `ndb_mgmd` not to start as a daemon process.

The default behavior for `ndb_mgmd` on Windows is to run in the foreground, making this option unnecessary on Windows platforms.

- **--nowait-nodes**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--nowait-nodes=list</td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>255</td>
</tr>
</tbody>
</table>

When starting an NDB Cluster is configured with two management nodes, each management server normally checks to see whether the other `ndb_mgmd` is also operational and whether the other management server’s configuration is identical to its own. However, it is sometimes desirable to start the cluster with only one management node (and perhaps to allow the other `ndb_mgmd` to be started later). This option causes the management node to bypass any checks for any other management nodes whose node IDs are passed to this option, permitting the cluster to start as though configured to use only the management node that was started.

For purposes of illustration, consider the following portion of a `config.ini` file (where we have omitted most of the configuration parameters that are not relevant to this example):
Assume that you wish to start this cluster using only the management server having node ID 10 and running on the host having the IP address 198.51.100.150. (Suppose, for example, that the host computer on which you intend to the other management server is temporarily unavailable due to a hardware failure, and you are waiting for it to be repaired.) To start the cluster in this way, use a command line on the machine at 198.51.100.150 to enter the following command:

```
shell> ndb_mgmd --ndb-nodeid=10 --nowait-nodes=11
```

As shown in the preceding example, when using `--nowait-nodes`, you must also use the `--ndb-nodeid` option to specify the node ID of this `ndb_mgmd` process.

You can then start each of the cluster’s data nodes in the usual way. If you wish to start and use the second management server in addition to the first management server at a later time without restarting the data nodes, you must start each data node with a connection string that references both management servers, like this:

```
shell> ndbd -c 198.51.100.150,198.51.100.151
```

The same is true with regard to the connection string used with any `mysqld` processes that you wish to start as NDB Cluster SQL nodes connected to this cluster. See Section 18.3.3.3, “NDB Cluster Connection Strings”, for more information.

When used with `ndb_mgmd`, this option affects the behavior of the management node with regard to other management nodes only. Do not confuse it with the `--nowait-nodes` option used with `ndbd` or `ndbmtd` to permit a cluster to start with fewer than its full complement of data nodes; when used with data nodes, this option affects their behavior only with regard to other data nodes.
Multiple management node IDs may be passed to this option as a comma-separated list. Each node ID must be no less than 1 and no greater than 255. In practice, it is quite rare to use more than two management servers for the same NDB Cluster (or to have any need for doing so); in most cases you need to pass to this option only the single node ID for the one management server that you do not wish to use when starting the cluster.

**Note**

When you later start the “missing” management server, its configuration must match that of the management server that is already in use by the cluster. Otherwise, it fails the configuration check performed by the existing management server, and does not start.

- `--print-full-config, -P`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--print-full-config</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Shows extended information regarding the configuration of the cluster. With this option on the command line the `ndb_mgmd` process prints information about the cluster setup including an extensive list of the cluster configuration sections as well as parameters and their values. Normally used together with the `--config-file (-f)` option.

- `--reload`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--reload</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

NDB Cluster configuration data is stored internally rather than being read from the cluster global configuration file each time the management server is started (see Section 18.3.3, “NDB Cluster Configuration Files”). Using this option forces the management server to check its internal data store against the cluster configuration file and to reload the configuration if it finds that the configuration file does not match the cache. Existing configuration cache files are preserved, but not used.

This differs in two ways from the `--initial` option. First, `--initial` causes all cache files to be deleted. Second, `--initial` forces the management server to re-read the global configuration file and construct a new cache.

If the management server cannot find a global configuration file, then the `--reload` option is ignored.

When `--reload` is used, the management server must be able to communicate with data nodes and any other management servers in the cluster before it attempts to read the global configuration file; otherwise, the management server fails to start. This can happen due to changes in the networking environment, such as new IP addresses for nodes or an altered firewall configuration. In such cases, you must use `--initial` instead to force the existing cached configuration to be discarded and reloaded from the file. See Section 18.5.5, “Performing a Rolling Restart of an NDB Cluster”, for additional information.
• --remove=[name]

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--remove=[name]</td>
</tr>
<tr>
<td>Platform Specific</td>
<td>Windows</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>ndb_mgmd</td>
</tr>
</tbody>
</table>

Remove a management server process that has been installed as a Windows service, optionally specifying the name of the service to be removed. Applies only to Windows platforms.

• --verbose, -v

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--verbose</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Remove a management server process that has been installed as a Windows service, optionally specifying the name of the service to be removed. Applies only to Windows platforms.

It is not strictly necessary to specify a connection string when starting the management server. However, if you are using more than one management server, a connection string should be provided and each node in the cluster should specify its node ID explicitly.

See Section 18.3.3.3, “NDB Cluster Connection Strings”, for information about using connection strings. Section 18.4.4, “ndb_mgmd — The NDB Cluster Management Server Daemon”, describes other options for ndb_mgmd.

The following files are created or used by ndb_mgmd in its starting directory, and are placed in the DataDir as specified in the config.ini configuration file. In the list that follows, node_id is the unique node identifier.

• config.ini is the configuration file for the cluster as a whole. This file is created by the user and read by the management server. Section 18.3, “Configuration of NDB Cluster”, discusses how to set up this file.

• ndb_node_id_cluster.log is the cluster events log file. Examples of such events include checkpoint startup and completion, node startup events, node failures, and levels of memory usage. A complete listing of cluster events with descriptions may be found in Section 18.5, “Management of NDB Cluster”.

By default, when the size of the cluster log reaches one million bytes, the file is renamed to ndb_node_id_cluster.log.seq_id, where seq_id is the sequence number of the cluster log file. (For example: If files with the sequence numbers 1, 2, and 3 already exist, the next log file is named using the number 4.) You can change the size and number of files, and other characteristics of the cluster log, using the LogDestination configuration parameter.

• ndb_node_id_out.log is the file used for stdout and stderr when running the management server as a daemon.

• ndb_node_id.pid is the process ID file used when running the management server as a daemon.
The \texttt{ndb\_mgm} management client process is actually not needed to run the cluster. Its value lies in providing a set of commands for checking the cluster's status, starting backups, and performing other administrative functions. The management client accesses the management server using a C API. Advanced users can also employ this API for programming dedicated management processes to perform tasks similar to those performed by \texttt{ndb\_mgm}.

To start the management client, it is necessary to supply the host name and port number of the management server:

\begin{verbatim}
shell> ndb\_mgm [host\_name [port\_num]]
\end{verbatim}

For example:

\begin{verbatim}
shell> ndb\_mgm ndb\_mgmd.mysql.com 1186
\end{verbatim}

The default host name and port number are \texttt{localhost} and 1186, respectively.

The following table includes options that are specific to the NDB Cluster management client program \texttt{ndb\_mgm}. Additional descriptions follow the table. For options common to most NDB Cluster programs (including \texttt{ndb\_mgm}), see Section 18.4.29, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

Table 18.306 Command-line options for the \texttt{ndb\_mgm} program

<table>

  Property & Value & \\
  \hline
  Command-Line Format & \texttt{--connect-retries=\#} & \\
  Introduced & 5.6.28-ndb-7.4.9 & \\
  Type & Numeric & \\
  Default Value & 3 & \\
  Minimum Value & 0 & \\
  Maximum Value & 4294967295 & \\
  \hline
\end{tabular}
\end{table}

This option specifies the number of times following the first attempt to retry a connection before giving up (the client always tries the connection at least once). The length of time to wait per attempt is set using \texttt{--connect-retry-delay}.
This option was added in NDB 7.4.9, and is synonymous with the --try-reconnect option, which is now deprecated.

The default for this option this option differs from its default when used with other NDB programs. See Section 18.4.29, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”, for more information.

* --execute=command, -e command

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--execute=name</td>
</tr>
</tbody>
</table>

This option can be used to send a command to the NDB Cluster management client from the system shell. For example, either of the following is equivalent to executing SHOW in the management client:

```
shell> ndb_mgm -e "SHOW"
shell> ndb_mgm --execute=SHOW
```

This is analogous to how the --execute or -e option works with the mysql command-line client. See Section 4.2.2.1, “Using Options on the Command Line”.

Note

If the management client command to be passed using this option contains any space characters, then the command must be enclosed in quotation marks. Either single or double quotation marks may be used. If the management client command contains no space characters, the quotation marks are optional.

* --try-reconnect=number

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--try-reconnect=</td>
</tr>
<tr>
<td>Deprecated</td>
<td>5.6.28-ndb-7.4.9</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>3</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

If the connection to the management server is broken, the node tries to reconnect to it every 5 seconds until it succeeds. By using this option, it is possible to limit the number of attempts to number before giving up and reporting an error instead.

This option is deprecated in NDB 7.4.9 and later, and is superseded by --connect-retries.

Additional information about using ndb_mgm can be found in Section 18.5.2, “Commands in the NDB Cluster Management Client”.

18.4.6 ndb_blob_tool — Check and Repair BLOB and TEXT columns of NDB Cluster Tables
This tool can be used to check for and remove orphaned BLOB column parts from NDB tables, as well as to generate a file listing any orphaned parts. It is sometimes useful in diagnosing and repairing corrupted or damaged NDB tables containing BLOB or TEXT columns.

The basic syntax for ndb_blob_tool is shown here:

```
ndb_blob_tool [options] table [column, ...]
```

Unless you use the --help option, you must specify an action to be performed by including one or more of the options --check-orphans, --delete-orphans, or --dump-file. These options cause ndb_blob_tool to check for orphaned BLOB parts, remove any orphaned BLOB parts, and generate a dump file listing orphaned BLOB parts, respectively, and are described in more detail later in this section.

You must also specify the name of a table when invoking ndb_blob_tool. In addition, you can optionally follow the table name with the (comma-separated) names of one or more BLOB or TEXT columns from that table. If no columns are listed, the tool works on all of the table’s BLOB and TEXT columns. If you need to specify a database, use the --database (-d) option.

The --verbose option provides additional information in the output about the tool’s progress.

The following table includes options that are specific to ndb_blob_tool. Additional descriptions follow the table. For options common to most NDB Cluster programs (including ndb_blob_tool), see Section 18.4.29, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

Table 18.307 Command-line options for the ndb_blob_tool program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--check-orphans</td>
<td>Check for orphan blob parts</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--database=db_name, -d</td>
<td>Database to find the table in.</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--delete-orphans</td>
<td>Delete orphan blob parts</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--dump-file=file</td>
<td>Write orphan keys to specified file</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--verbose, -v</td>
<td>Verbose output</td>
<td>All MySQL 5.6 based releases</td>
</tr>
</tbody>
</table>

- **--check-orphans**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--check-orphans</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Check for orphaned BLOB parts in NDB Cluster tables.

- **--database=db_name, -d**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--database=db_name</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>
**ndb_blob_tool** — Check and Repair BLOB and TEXT columns of NDB Cluster Tables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Specify the database to find the table in.

- **--delete-orphans**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--delete-orphans</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Remove orphaned BLOB parts from NDB Cluster tables.

- **--dump-file=file**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--dump-file=file</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Writes a list of orphaned BLOB column parts to file. The information written to the file includes the table key and BLOB part number for each orphaned BLOB part.

- **--verbose**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--verbose</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Provide extra information in the tool's output regarding its progress.

**Example**

First we create an NDB table in the test database, using the CREATE TABLE statement shown here:

```sql
USE test;
CREATE TABLE btest (  
c0 BIGINT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,  
c1 TEXT,  
c2 BLOB  
) ENGINE=NDB;
```

Then we insert a few rows into this table, using a series of statements similar to this one:

```sql
INSERT INTO btest VALUES (NULL, 'x', REPEAT('x', 1000));
```

When run with --check-orphans against this table, ndb_blob_tool generates the following output:

```shell
shell> ndb_blob_tool --check-orphans --verbose -d test btest
```
The tool reports that there are no NDB BLOB column parts associated with column c1, even though c1 is a TEXT column. This is due to the fact that, in an NDB table, only the first 256 bytes of a BLOB or TEXT column value are stored inline, and only the excess, if any, is stored separately; thus, if there are no values using more than 256 bytes in a given column of one of these types, no BLOB column parts are created by NDB for this column. See Section 11.7, “Data Type Storage Requirements”, for more information.

18.4.7 ndb_config — Extract NDB Cluster Configuration Information

This tool extracts current configuration information for data nodes, SQL nodes, and API nodes from one of a number of sources: an NDB Cluster management node, or its config.ini or my.cnf file. By default, the management node is the source for the configuration data; to override the default, execute ndb_config with the --config-file or --mycnf option. It is also possible to use a data node as the source by specifying its node ID with --config_from_node=node_id.

ndb_config can also provide an offline dump of all configuration parameters which can be used, along with their default, maximum, and minimum values and other information. The dump can be produced in either text or XML format; for more information, see the discussion of the --configinfo and --xml options later in this section).

You can filter the results by section (DB, SYSTEM, or CONNECTIONS) using one of the options --nodes, --system, or --connections.

The following table includes options that are specific to ndb_config. Additional descriptions follow the table. For options common to most NDB Cluster programs (including ndb_config), see Section 18.4.29, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

Table 18.308 Command-line options for the ndb_config program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--config-file=file_name</td>
<td>Set the path to config.ini file</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--config_from_node=</td>
<td>Obtain configuration data from the node having this ID (must be a data node).</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--configinfo</td>
<td>Dumps information about all NDB configuration parameters in text</td>
<td>All MySQL 5.6 based releases</td>
</tr>
</tbody>
</table>
### ndb_config — Extract NDB Cluster Configuration Information

<table>

<td></td>
</tr>
<tr>
<td>-r</td>
<td>Use --xml with --configinfo to obtain a dump of all NDB configuration</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--system</td>
<td>format with default, maximum, and minimum values. Use with --xml to</td>
<td></td>
</tr>
<tr>
<td>--type=name</td>
<td>obtain XML output.</td>
<td></td>
</tr>
<tr>
<td>--configinfo --xml</td>
<td>All MySQL 5.6 based releases</td>
<td></td>
</tr>
</tbody>
</table>

- --configinfo
The `--configinfo` option causes `ndb_config` to dump a list of each NDB Cluster configuration parameter supported by the NDB Cluster distribution of which `ndb_config` is a part, including the following information:

- A brief description of each parameter's purpose, effects, and usage
- The section of the `config.ini` file where the parameter may be used
- The parameter's data type or unit of measurement
- Where applicable, the parameter's default, minimum, and maximum values
- NDB Cluster release version and build information

By default, this output is in text format. Part of this output is shown here:

```sql
shell> ndb_config --configinfo

******* SYSTEM *******
Name (String)
Name of system (NDB Cluster)
MANDATORY
PrimaryMGMNode (Non-negative Integer)
Node id of Primary ndb_mgmd(MGM) node
Default: 0 (Min: 0, Max: 4294967039)
ConfigGenerationNumber (Non-negative Integer)
Configuration generation number
Default: 0 (Min: 0, Max: 4294967039)

******* DB *******
MaxNoOfSubscriptions (Non-negative Integer)
Max no of subscriptions (default 0 == MaxNoOfTables)
Default: 0 (Min: 0, Max: 4294967039)
MaxNoOfSubscribers (Non-negative Integer)
Max no of subscribers (default 0 == 2 * MaxNoOfTables)
Default: 0 (Min: 0, Max: 4294967039)
```

Use this option together with the `--xml` option to obtain output in XML format.

- `--config-file=path-to-file`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--config-file=file_name</code></td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>

Gives the path to the management server's configuration file (`config.ini`). This may be a relative or absolute path. If the management node resides on a different host from the one on which `ndb_config` is invoked, then an absolute path must be used.

- `--config_from_node=\#`
## ndb_config — Extract NDB Cluster Configuration Information

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--config-from-node=1</td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>none</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>48</td>
</tr>
</tbody>
</table>

Obtain the cluster's configuration data from the data node that has this ID.

If the node having this ID is not a data node, ndb_config fails with an error. (To obtain configuration data from the management node instead, simply omit this option.)

- --connections

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--connections</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Tells ndb_config to print CONNECTIONS information only—that is, information about parameters found in the [tcp], [tcp default], [sci], [sci default], [shm], or [shm default] sections of the cluster configuration file (see Section 18.3.3.9, “NDB Cluster TCP/IP Connections”, Section 18.3.3.12, “SCI Transport Connections in NDB Cluster”, and Section 18.3.3.11, “NDB Cluster Shared-Memory Connections”, for more information).

This option is mutually exclusive with --nodes and --system; only one of these 3 options can be used.

- --diff-default

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--diff-default</td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.36-ndb-7.4.16</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Print only configuration parameters that have non-default values.

- --fields=delimiter, -f delimiter

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--fields=string</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>

Specifies a delimiter string used to separate the fields in the result. The default is , (the comma character).
**ndb_config** — Extract NDB Cluster Configuration Information

**Note**

If the delimiter contains spaces or escapes (such as \n for the linefeed character), then it must be quoted.

- **--host=hostname**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--host=name</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>

Specifies the host name of the node for which configuration information is to be obtained.

**Note**

While the hostname localhost usually resolves to the IP address 127.0.0.1, this may not necessarily be true for all operating platforms and configurations. This means that it is possible, when localhost is used in config.ini, for ndb_config --host=localhost to fail if ndb_config is run on a different host where localhost resolves to a different address (for example, on some versions of SUSE Linux, this is 127.0.0.2). In general, for best results, you should use numeric IP addresses for all NDB Cluster configuration values relating to hosts, or verify that all NDB Cluster hosts handle localhost in the same fashion.

- **--mycnf**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--mycnf</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Read configuration data from the my.cnf file.

- **--nodeid=node_id, --id=node_id**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--ndb-nodeid=#</td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
</tbody>
</table>

Specify the node ID of the node for which configuration information is to be obtained. --nodeid is the preferred form; --id is deprecated and subject to removal in a later version of NDB Cluster.

- **--nodes**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--nodes</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
</tbody>
</table>
ndb_config — Extract NDB Cluster Configuration Information

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Tells ndb_config to print information relating only to parameters defined in an [ndbd] or [ndbd default] section of the cluster configuration file (see Section 18.3.6, “Defining NDB Cluster Data Nodes”).

This option is mutually exclusive with --connections and --system; only one of these 3 options can be used.

- `--ndb-connectstring=connection_string, -c connection_string`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--ndb-connectstring=connectstring</code></td>
</tr>
<tr>
<td></td>
<td><code>--connect-string=connectstring</code></td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>localhost:1186</td>
</tr>
</tbody>
</table>

Specifies the connection string to use in connecting to the management server. The format for the connection string is the same as described in Section 18.3.3, “NDB Cluster Connection Strings”, and defaults to localhost:1186.

- `--query=query-options, - q query-options`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--query=string</code></td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>

This is a comma-delimited list of query options—that is, a list of one or more node attributes to be returned. These include nodeid (node ID), type (node type—that is, ndbd, mysqld, or ndb_mgmd), and any configuration parameters whose values are to be obtained.

For example, `--query=nodeid,type,datamemory,datadir` returns the node ID, node type, DataMemory, and DataDir for each node.

`id` is accepted as a synonym for nodeid, but is deprecated and subject to removal in a later version of NDB Cluster.

**Note**

If a given parameter is not applicable to a certain type of node, than an empty string is returned for the corresponding value. See the examples later in this section for more information.

- `--query-all, - a`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--query-all</code></td>
</tr>
</tbody>
</table>

Returns a comma-delimited list of all query options (node attributes; note that this list is a single string).
This option was introduced in NDB 7.4.16 (Bug #60095, Bug #11766869).

• `--rows=separator, -r separator`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--rows=string</code></td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>

Specifies a `separator` string used to separate the rows in the result. The default is a space character.

**Note**

If the `separator` contains spaces or escapes (such as `\n` for the linefeed character), then it must be quoted.

• `--system`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--system</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Tells `ndb_config` to print `SYSTEM` information only. This consists of system variables that cannot be changed at run time; thus, there is no corresponding section of the cluster configuration file for them. They can be seen (prefixed with `****** SYSTEM ******`) in the output of `ndb_config --configinfo`.

This option is mutually exclusive with `--nodes` and `--connections`; only one of these 3 options can be used.

• `--type=node_type`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--type=name</code></td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
<tr>
<td>Valid Values</td>
<td>ndbd</td>
</tr>
<tr>
<td></td>
<td>mysqlld</td>
</tr>
<tr>
<td></td>
<td>ndb_mgmd</td>
</tr>
</tbody>
</table>

Filters results so that only configuration values applying to nodes of the specified `node_type` (`ndbd`, `mysqlld`, or `ndb_mgmd`) are returned.

• `--usage, --help, or -?`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--help</code></td>
</tr>
</tbody>
</table>
### ndb_config — Extract NDB Cluster Configuration Information

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>--usage</td>
<td></td>
</tr>
</tbody>
</table>

Causes `ndb_config` to print a list of available options, and then exit.

- **--version, -V**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--version</td>
</tr>
</tbody>
</table>

Causes `ndb_config` to print a version information string, and then exit.

- **--configinfo --xml**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--configinfo --xml</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>false</td>
</tr>
</tbody>
</table>

Causes `ndb_config --configinfo` to provide output as XML by adding this option. A portion of such output is shown in this example:

```plaintext
shell> ndb_config --configinfo --xml

<configvariables protocolversion="1" ndbversionstring="5.6.45-ndb-7.3.26"
 ndbversion="458758" ndbversionmajor="7" ndbversionminor="0"
 ndbversionbuild="6">
 <section name="SYSTEM">
  <param name="Name" comment="Name of system (NDB Cluster)" type="string"
 mandatory="true"/>
  <param name="PrimaryMGMNode" comment="Node id of Primary ndb_mgmd (MGM) node" type="unsigned" default="0" min="0" max="4294967039"/>
  <param name="ConfigGenerationNumber" comment="Configuration generation number" type="unsigned" default="0" min="0" max="4294967039"/>
 </section>
 </section>
 <section name="NDBD">
  <param name="MaxNoOfSubscriptions" comment="Max no of subscriptions (default 0 == MaxNoOfTables)"
 type="unsigned" default="0" min="0" max="4294967039"/>
  <param name="MaxNoOfSubscribers" comment="Max no of subscribers (default 0 == 2 * MaxNoOfTables)"
 type="unsigned" default="0" min="0" max="4294967039"/>
  ...
 </section>
 ...</configvariables>
```

**Note**

Normally, the XML output produced by `ndb_config --configinfo --xml` is formatted using one line per element; we have added extra whitespace in the previous example, as well as the next one, for reasons of legibility. This should not make any difference to applications using this output, since most XML
processors either ignore nonessential whitespace as a matter of course, or can be instructed to do so.

The XML output also indicates when changing a given parameter requires that data nodes be restarted using the `--initial` option. This is shown by the presence of an `initial="true"` attribute in the corresponding `<param>` element. In addition, the restart type (system or node) is also shown; if a given parameter requires a system restart, this is indicated by the presence of a `restart="system"` attribute in the corresponding `<param>` element. For example, changing the value set for the Diskless parameter requires a system initial restart, as shown here (with the `restart` and `initial` attributes highlighted for visibility):

```xml
<param name="Diskless" comment="Run wo/ disk" type="bool" default="false"
    restart="system" initial="true"/>
```

Currently, no `initial` attribute is included in the XML output for `<param>` elements corresponding to parameters which do not require initial restarts; in other words, `initial="false"` is the default, and the value `false` should be assumed if the attribute is not present. Similarly, the default restart type is `node` (that is, an online or “rolling” restart of the cluster), but the `restart` attribute is included only if the restart type is `system` (meaning that all cluster nodes must be shut down at the same time, then restarted).

Beginning with NDB 7.4.7, deprecated parameters are indicated in the XML output with the addition of a `deprecated` attribute, as shown here:

```xml
<param name="NoOfDiskPagesToDiskAfterRestartACC" comment="DiskCheckpointSpeed"
    type="unsigned" default="20" min="1" max="4294967039" deprecated="true"/>
```

In such cases, the `comment` refers to one or more parameters that supersede the deprecated parameter. Similarly to `initial`, the `deprecated` attribute is indicated only when the parameter is deprecated, with `deprecated="true"`, and does not appear at all for parameters which are not deprecated. (Bug #21127135)

**Important**

The `--xml` option can be used only with the `--configinfo` option. Using `--xml` without `--configinfo` fails with an error.

Unlike the options used with this program to obtain current configuration data, `--configinfo` and `--xml` use information obtained from the NDB Cluster sources when `ndb_config` was compiled. For this reason, no connection to a running NDB Cluster or access to a `config.ini` or `my.cnf` file is required for these two options.

Combining other `ndb_config` options (such as `--query` or `--type`) with `--configinfo` (with or without the `--xml` option) is not supported. Currently, if you attempt to do so, the usual result is that all other options besides `--configinfo` or `--xml` are simply ignored. However, this behavior is not guaranteed and is subject to change at any time. In addition, since `ndb_config`, when used with the `--configinfo` option, does not access the NDB Cluster or read any files, trying to specify additional options such as `--ndb-connectstring` or `--config-file` with `--configinfo` serves no purpose.

**Examples**

1. To obtain the node ID and type of each node in the cluster:

```
shell> ./ndb_config -q nodeid,type --fields=':' --rows='\n'
1:ndbd
```
In this example, we used the **--fields** options to separate the node ID and type of each node with a colon character (:``), and the **--rows** options to place the values for each node on a new line in the output.

2. To produce a connection string that can be used by data, SQL, and API nodes to connect to the management server:

```shell
./ndb_config --config-file=usr/local/mysql/cluster-data/config.ini \  --query=hostname, portnumber --fields=:: --rows=, --type=ndb_mgmd
198.51.100.179:1186
```

3. This invocation of **ndb_config** checks only data nodes (using the **--type** option), and shows the values for each node's ID and host name, as well as the values set for its DataMemory, IndexMemory, and DataDir parameters:

```shell
./ndb_config --type=ndbd --query=nodeid, host, datamemory, indexmemory, datadir -f ' : ' -r '
1 : 198.51.100.193 : 83886080 : 18874368 : /usr/local/mysql/cluster-data
2 : 198.51.100.112 : 83886080 : 18874368 : /usr/local/mysql/cluster-data
4 : 198.51.100.119 : 83886080 : 18874368 : /usr/local/mysql/cluster-data
```

In this example, we used the short options **-f** and **-r** for setting the field delimiter and row separator, respectively, as well as the short option **-q** to pass a list of parameters to be obtained.

4. To exclude results from any host except one in particular, use the **--host** option:

```shell
./ndb_config --host=198.51.100.176 -f : -r '
3:ndbd
5:ndb_mgmd
```

In this example, we also used the short form **-q** to determine the attributes to be queried.

Similarly, you can limit results to a node with a specific ID using the **--nodeid** option.

---

**18.4.8 ndb_cpcd — Automate Testing for NDB Development**

A utility having this name was formerly part of an internal automated test framework used in testing and debugging NDB Cluster. It is no longer included in NDB Cluster distributions provided by Oracle.

**18.4.9 ndb_delete_all — Delete All Rows from an NDB Table**

**ndb_delete_all** deletes all rows from the given **NDB** table. In some cases, this can be much faster than **DELETE** or even **TRUNCATE TABLE**.

**Usage**

```
ndb_delete_all -c connection_string tbl_name -d db_name
```
This deletes all rows from the table named `tbl_name` in the database named `db_name`. It is exactly equivalent to executing `TRUNCATE db_name.tbl_name` in MySQL.

The following table includes options that are specific to `ndb_delete_all`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_delete_all`), see Section 18.4.29, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--database=dbname,</code></td>
<td>Name of the database in which the table is found</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td><code>-d</code></td>
<td>Perform the delete in a single transaction (may run out of operations)</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td><code>--transactional,</code></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>-t</code></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--tupscan</code></td>
<td>Run tup scan</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td><code>--diskscan</code></td>
<td>Run disk scan</td>
<td>All MySQL 5.6 based releases</td>
</tr>
</tbody>
</table>

- `--transactional, -t`

Use of this option causes the delete operation to be performed as a single transaction.

**Warning**

With very large tables, using this option may cause the number of operations available to the cluster to be exceeded.

### 18.4.10 ndb_desc — Describe NDB Tables

`ndb_desc` provides a detailed description of one or more NDB tables.

#### Usage

```
ndb_desc -c connection_string tbl_name -d db_name [options]
ndb_desc -c connection_string index_name -d db_name -t tbl_name
```

Additional options that can be used with `ndb_desc` are listed later in this section.

#### Sample Output

MySQL table creation and population statements:

```sql
USE test;

CREATE TABLE fish (  
    id INT(11) NOT NULL AUTO_INCREMENT,  
    name VARCHAR(20) NOT NULL,  
    length_mm INT(11) NOT NULL,  
    weight_gm INT(11) NOT NULL,  

    PRIMARY KEY pk (id),  
    UNIQUE KEY uk (name)
)```

) ENGINE=NDB;

INSERT INTO fish VALUES
('', 'guppy', 35, 2), ('', 'tuna', 2500, 150000),
('', 'shark', 3000, 110000), ('', 'manta ray', 1500, 50000),
('', 'grouper', 900, 125000), ('', 'puffer', 250, 2500);

Output from `ndb_desc`:

```
shell> ./ndb_desc -c localhost fish -d test -p
-- fish --
Version: 2
Fragment type: 9
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 4
Number of primary keys: 1
Length of frm data: 311
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
FragmentCount: 2
TableStatus: Retrieved
-- Attributes --
id Int PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY AUTO_INCR
name Varchar(20) latin1_swedish_ci NOT NULL AT=SHORT_VAR ST=MEMORY
length_mm Int NOT NULL AT=FIXED ST=MEMORY
weight_gm Int NOT NULL AT=FIXED ST=MEMORY
-- Indexes --
PRIMARY KEY(id) - UniqueHashIndex
PRIMARY(id) - OrderedIndex
uk$unique(name) - UniqueHashIndex
uk(name) - OrderedIndex
-- Per partition info --
0 2 2 32768 ...
1 4 4 32768 ...
... Frag varsized memory Extent_space Free extent_space
... 32768 0 0
... 32768 0 0
NDBT_ProgramExit: 0 - OK
```

Information about multiple tables can be obtained in a single invocation of `ndb_desc` by using their names, separated by spaces. All of the tables must be in the same database.

You can obtain additional information about a specific index using the `--table` (short form: `-t`) option and supplying the name of the index as the first argument to `ndb_desc`, as shown here:

```
shell> ./ndb_desc uk -d test -t fish
-- uk --
Version: 3
Base table: fish
Number of attributes: 1
Logging: 0
Index type: OrderedIndex
Index status: Retrieved
-- Attributes --
```
When an index is specified in this way, the `--extra-partition-info` and `--extra-node-info` options have no effect.

The `Version` column in the output contains the table's schema object version. For information about interpreting this value, see NDB Schema Object Versions.

The `Extent_space` and `Free extent_space` columns are applicable only to NDB tables having columns on disk; for tables having only in-memory columns, these columns always contain the value 0.

To illustrate their use, we modify the previous example. First, we must create the necessary Disk Data objects, as shown here:

```sql
CREATE LOGFILE GROUP lg_1
   ADD UNDOFILE 'undo_1.log'
   INITIAL_SIZE 16M
   UNDO_BUFFER_SIZE 2M
   ENGINE NDB;

ALTER LOGFILE GROUP lg_1
   ADD UNDOFILE 'undo_2.log'
   INITIAL_SIZE 12M
   ENGINE NDB;

CREATE TABLESPACE ts_1
   ADD DATAFILE 'data_1.dat'
   USE LOGFILE GROUP lg_1
   INITIAL_SIZE 32M
   ENGINE NDB;

ALTER TABLESPACE ts_1
   ADD DATAFILE 'data_2.dat'
   INITIAL_SIZE 48M
   ENGINE NDB;
```

(For more information on the statements just shown and the objects created by them, see Section 18.5.12.1, “NDB Cluster Disk Data Objects”, as well as Section 13.1.14, “CREATE LOGFILE GROUP Syntax”, and Section 13.1.18, “CREATE TABLESPACE Syntax”.)
Now we can create and populate a version of the `fish` table that stores 2 of its columns on disk (deleting the previous version of the table first, if it already exists):

```
CREATE TABLE fish (
  id INT(11) NOT NULL AUTO_INCREMENT,
  name VARCHAR(20) NOT NULL,
  length_mm INT(11) NOT NULL,
  weight_gm INT(11) NOT NULL,

  PRIMARY KEY pk (id),
  UNIQUE KEY uk (name)
) TABLESPACE ts_1 STORAGE DISK
ENGINE=NDB;

INSERT INTO fish VALUES
  ('', 'guppy', 35, 2), ('', 'tuna', 2500, 150000),
  ('', 'shark', 3000, 110000), ('', 'manta ray', 1500, 50000),
  ('', 'grouper', 900, 125000), ('', 'puffer', 250, 250);
```

When run against this version of the table, `ndb_desc` displays the following output:

```
shell> ./ndb_desc -c localhost fish -d test -p
-- fish --
Version: 3
Fragment type: 9
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 4
Number of primary keys: 1
Length of frm data: 321
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
FragmentCount: 2
TableStatus: Retrieved
-- Attributes --
id Int PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY AUTO_INCR
name VARCHAR(20) latin1_swedish_ci NOT NULL AT=SHORT_VAR ST=MEMORY
length_mm Int NOT NULL AT=FIXED ST=DISK
weight_gm Int NOT NULL AT=FIXED ST=DISK
-- Indexes --
PRIMARY KEY(id) - UniqueHashIndex
PRIMARY(id) - OrderedIndex
uk$unique(name) - UniqueHashIndex
uk(name) - OrderedIndex
-- Per partition info --
Partition Row count Commit count Frag fixed memory ...
0 2 2 32768 ...
1 4 4 32768 ...
... Frag varsized memory Extent_space Free extent_space
... 32768 0 0
... 32768 0 0
NDBT_ProgramExit: 0 - OK
```

This means that 1048576 bytes are allocated from the tablespace for this table on each partition, of which 1044440 bytes remain free for additional storage. In other words, 1048576 - 1044440 = 4136 bytes per partition is currently being used to store the data from this table’s disk-based columns. The number of
bytes shown as Free extent space is available for storing on-disk column data from the fish table only; for this reason, it is not visible when selecting from the INFORMATION_SCHEMA.FILES table.

The following table includes options that are specific to ndb_desc. Additional descriptions follow the table. For options common to most NDB Cluster programs (including ndb_desc), see Section 18.4.29, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

Table 18.310 Command-line options for the ndb_desc program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--blob-info, -b</td>
<td>Include partition information for BLOB tables in output. Requires that the -p option also be used</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--database=dbname, -d</td>
<td>Name of database containing table</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--extra-node-info, -n</td>
<td>Include partition-to-data-node mappings in output. Requires that the -p option also be used</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--extra-partition-info, -p</td>
<td>Display information about partitions</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--retries=#, -r</td>
<td>Number of times to retry the connection (once per second)</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--table=tbl_name, -t</td>
<td>Specify the table in which to find an index. When this option is used, -p and -n have no effect and are ignored.</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--unqualified, -u</td>
<td>Use unqualified table names</td>
<td>All MySQL 5.6 based releases</td>
</tr>
</tbody>
</table>

- --blob-info, -b
  Include information about subordinate BLOB and TEXT columns.

  Use of this option also requires the use of the --extra-partition-info (-p) option.

- --database=db_name, -d
  Specify the database in which the table should be found.

- --extra-node-info, -n
  Include information about the mappings between table partitions and the data nodes upon which they reside. This information can be useful for verifying distribution awareness mechanisms and supporting more efficient application access to the data stored in NDB Cluster.

  Use of this option also requires the use of the --extra-partition-info (-p) option.

- --extra-partition-info, -p
  Print additional information about the table’s partitions.
ndb_drop_index — Drop Index from an NDB Table

- **--retries=#, -r**
  Try to connect this many times before giving up. One connect attempt is made per second.
- **--table=tbl_name, -t**
  Specify the table in which to look for an index.
- **--unqualified, -u**
  Use unqualified table names.

### 18.4.11 ndb_drop_index — Drop Index from an NDB Table

ndb_drop_index drops the specified index from an NDB table. It is recommended that you use this utility only as an example for writing NDB API applications—see the Warning later in this section for details.

#### Usage

```shell
dbd_drop_index -c connection_string table_name index -d db_name
```

The statement shown above drops the index named `index` from the `table` in the `database`.

The following table includes options that are specific to ndb_drop_index. Additional descriptions follow the table. For options common to most NDB Cluster programs (including ndb_drop_index), see Section 18.4.29, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--database=dbname, -d</td>
<td>Name of the database in which the table is found</td>
<td>All MySQL 5.6 based releases</td>
</tr>
</tbody>
</table>

#### Warning

Operations performed on Cluster table indexes using the NDB API are not visible to MySQL and make the table unusable by a MySQL server. If you use this program to drop an index, then try to access the table from an SQL node, an error results, as shown here:

```shell
cshell> ./ndb_drop_index -c localhost dogs ix -d ctest1
Dropping index dogs/idx...OK
NDBT_ProgramExit: 0 - OK

cshell> ./mysql -u jon -p ctest1
Enter password: *******
Reading table information for completion of table and column names
You can turn off this feature for a quicker startup with -A
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 7 to server version: 5.6.45-ndb-7.3.26
```
In such a case, your only option for making the table available to MySQL again is to drop the table and re-create it. You can use either the SQL statement `DROP TABLE` or the `ndb_drop_table` utility (see Section 18.4.12, "ndb_drop_table — Drop an NDB Table") to drop the table.

### 18.4.12 ndb_drop_table — Drop an NDB Table

`ndb_drop_table` drops the specified NDB table. (If you try to use this on a table created with a storage engine other than NDB, the attempt fails with the error 723: No such table exists.) This operation is extremely fast; in some cases, it can be an order of magnitude faster than using a MySQL `DROP TABLE` statement on an NDB table.

**Usage**

```
ndb_drop_table -c connection_string tbl_name -d db_name
```

The following table includes options that are specific to `ndb_drop_table`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_drop_table`), see Section 18.4.29, "Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs".

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--database=dbname</code>, -d</td>
<td>Name of the database in which the table is found</td>
<td>All MySQL 5.6 based releases</td>
</tr>
</tbody>
</table>

### 18.4.13 ndb_error_reporter — NDB Error-Reporting Utility

`ndb_error_reporter` creates an archive from data node and management node log files that can be used to help diagnose bugs or other problems with a cluster. *It is highly recommended that you make use of this utility when filing reports of bugs in NDB Cluster.*

The following table includes command options specific to the NDB Cluster program `ndb_error_reporter`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_error_reporter`), see Section 18.4.29, "Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs".
ndb_error_reporter did not support the --help option prior to NDB 7.3.3 (Bug #11756666, Bug #48606). The --connection-timeout --dry-scp, and --skip-nodegroup options were also added in this release (Bug #16602002).

Table 18.313 Command-line options for the ndb_error_reporter program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--connection-timeout=timeout</td>
<td>Number of seconds to wait when connecting to nodes before timing out.</td>
<td>ADDED: NDB 7.3.3</td>
</tr>
<tr>
<td>--dry-scp</td>
<td>Disable scp with remote hosts; used only for testing.</td>
<td>ADDED: NDB 7.3.3</td>
</tr>
<tr>
<td>--fs</td>
<td>Include file system data in error report; can use a large amount of disk space</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--skip-nodegroup=nodegroup_id</td>
<td>Skip all nodes in the node group having this ID.</td>
<td>ADDED: NDB 7.3.3</td>
</tr>
</tbody>
</table>

Usage

ndb_error_reporter path/to/config-file [username] [options]

This utility is intended for use on a management node host, and requires the path to the management host configuration file (usually named config.ini). Optionally, you can supply the name of a user that is able to access the cluster's data nodes using SSH, to copy the data node log files. ndb_error_reporter then includes all of these files in archive that is created in the same directory in which it is run. The archive is named ndb_error_report_YYYYMMDDhhmmss.tar.bz2, where YYYYMMDDhhmmss is a datetime string.

ndb_error_reporter also accepts the options listed here:

- --connection-timeout=timeout

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--connection-timeout=timeout</td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.14-ndb-7.3.3</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
</tbody>
</table>

Wait this many seconds when trying to connect to nodes before timing out.

- --dry-scp

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--dry-scp</td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.14-ndb-7.3.3</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>TRUE</td>
</tr>
</tbody>
</table>
ndb_index_stat — NDB Index Statistics Utility

Run ndb_error_reporter without using scp from remote hosts. Used for testing only.

- --fs

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--fs</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Copy the data node file systems to the management host and include them in the archive.

Because data node file systems can be extremely large, even after being compressed, we ask that you please do not send archives created using this option to Oracle unless you are specifically requested to do so.

- --skip-nodegroup=nodegroup_id

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--connection-timeout=timeout</td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.14-ndb-7.3.3</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
</tbody>
</table>

Skip all nodes belong to the node group having the supplied node group ID.

18.4.14 ndb_index_stat — NDB Index Statistics Utility

ndb_index_stat provides per-fragment statistical information about indexes on NDB tables. This includes cache version and age, number of index entries per partition, and memory consumption by indexes.

Usage

To obtain basic index statistics about a given NDB table, invoke ndb_index_stat as shown here, with the name of the table as the first argument and the name of the database containing this table specified immediately following it, using the --database (-d) option:

```
ndb_index_stat table -d database
```

In this example, we use ndb_index_stat to obtain such information about an NDB table named mytable in the test database:

```
shell> ndb_index_stat -d test mytable
```

```
table:City index:PRIMARY fragCount:2
query cache: valid:1 sampleCount:1994 totalBytes:27916
times in ms: save: 7.133 sort: 1.974 sort per sample: 0.000
NDBT_ProgramExit: 0 - OK
```

sampleVersion is the version number of the cache from which the statistics data is taken. Running ndb_index_stat with the --update option causes sampleVersion to be incremented.
loadTime shows when the cache was last updated. This is expressed as seconds since the Unix Epoch.

sampleCount is the number of index entries found per partition. You can estimate the total number of entries by multiplying this by the number of fragments (shown as fragCount).

sampleCount can be compared with the cardinality of SHOW INDEX or INFORMATION_SCHEMA.STATISTICS, although the latter two provide a view of the table as a whole, while ndb_index_stat provides a per-fragment average.

keyBytes is the number of bytes used by the index. In this example, the primary key is an integer, which requires four bytes for each index, so keyBytes can be calculated in this case as shown here:

\[
\text{keyBytes} = \text{sampleCount} \times (4 \text{ bytes per index}) = 1994 \times 4 = 7976
\]

This information can also be obtained using the corresponding column definitions from INFORMATION_SCHEMA.COLUMNS (this requires a MySQL Server and a MySQL client application).

totalBytes is the total memory consumed by all indexes on the table, in bytes.

Timings shown in the preceding examples are specific to each invocation of ndb_index_stat.

The --verbose option provides some additional output, as shown here:

```shell
shell> ndb_index_stat -d test mytable --verbose
random seed 1337010518
connected
loop 1 of 1
table:mytable index:PRIMARY fragCount:4
sampleVersion:2 loadTime:1336751773 sampleCount:0 keyBytes:0
read stats
query cache created
query cache: valid:1 sampleCount:0 totalBytes:0
times in ms: save: 20.766 sort: 0.001
disconnected
NDBT_ProgramExit: 0 - OK
shell>
```

If the only output from the program is NDBT_ProgramExit: 0 - OK, this may indicate that no statistics yet exist. To force them to be created (or updated if they already exist), invoke ndb_index_stat with the --update option, or execute ANALYZE TABLE on the table in the mysql client.

**Options**

The following table includes options that are specific to the NDB Cluster ndb_index_stat utility. Additional descriptions are listed following the table. For options common to most NDB Cluster programs (including ndb_index_stat), see Section 18.4.29, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--database=name,</td>
<td>Name of the database containing the table.</td>
<td>All MySQL 5.6 based releases</td>
</tr>
</tbody>
</table>
### ndb_index_stat — NDB Index Statistics Utility

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--delete</td>
<td>Delete index statistics for the given table, stopping any auto-update previously configured.</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--update</td>
<td>Update index statistics for the given table, restarting any auto-update previously configured.</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--dump</td>
<td>Print the query cache.</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--query=#</td>
<td>Perform a number of random range queries on first key attr (must be int unsigned).</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--sys-drop</td>
<td>Drop any statistics tables and events in NDB kernel (all statistics are lost)</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--sys-create</td>
<td>Create all statistics tables and events in NDB kernel, if none of them already exist.</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--sys-create-if-not-exist</td>
<td>Create any statistics tables and events in NDB kernel that do not already exist.</td>

</table>

**ndb_index_stat statistics options.** The following options are used to generate index statistics. They work with a given table and database. They cannot be mixed with system options (see ndb_index_stat system options).

- `--database=name, -d name`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--database=name</code></td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
<tr>
<td>Minimum Value</td>
<td></td>
</tr>
<tr>
<td>Property</td>
<td>Value</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-------</td>
</tr>
<tr>
<td>Maximum Value</td>
<td></td>
</tr>
</tbody>
</table>

The name of the database that contains the table being queried.

- **--delete**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--delete</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>false</td>
</tr>
<tr>
<td>Minimum Value</td>
<td></td>
</tr>
<tr>
<td>Maximum Value</td>
<td></td>
</tr>
</tbody>
</table>

Delete the index statistics for the given table, stopping any auto-update that was previously configured.

- **--update**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--update</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>false</td>
</tr>
<tr>
<td>Minimum Value</td>
<td></td>
</tr>
<tr>
<td>Maximum Value</td>
<td></td>
</tr>
</tbody>
</table>

Update the index statistics for the given table, and restart any auto-update that was previously configured.

- **--dump**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--dump</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>false</td>
</tr>
<tr>
<td>Minimum Value</td>
<td></td>
</tr>
<tr>
<td>Maximum Value</td>
<td></td>
</tr>
</tbody>
</table>

Dump the contents of the query cache.

- **--query=#**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--query=#</td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
</tbody>
</table>
Perform random range queries on first key attribute (must be int unsigned).

ndb_index_stat system options. The following options are used to generate and update the statistics tables in the NDB kernel. None of these options can be mixed with statistics options (see ndb_index_stat statistics options):

- **--sys-drop**

  Drop all statistics tables and events in the NDB kernel. *This causes all statistics to be lost.*

- **--sys-create**

  Create all statistics tables and events in the NDB kernel. This works only if none of them exist previously.

- **sys-create-if-not-exist**

  Create any NDB system statistics tables or events (or both) that do not already exist when the program is invoked.

- **--sys-create-if-not-valid**

  -
# ndb_index_stat — NDB Index Statistics Utility

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>false</td>
</tr>
<tr>
<td>Minimum Value</td>
<td></td>
</tr>
<tr>
<td>Maximum Value</td>
<td></td>
</tr>
</tbody>
</table>

Create any NDB system statistics tables or events that do not already exist, after dropping any that are invalid.

- **--sys-check**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--sys-check</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>false</td>
</tr>
<tr>
<td>Minimum Value</td>
<td></td>
</tr>
<tr>
<td>Maximum Value</td>
<td></td>
</tr>
</tbody>
</table>

Verify that all required system statistics tables and events exist in the NDB kernel.

- **--sys-skip-tables**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--sys-skip-tables</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>false</td>
</tr>
<tr>
<td>Minimum Value</td>
<td></td>
</tr>
<tr>
<td>Maximum Value</td>
<td></td>
</tr>
</tbody>
</table>

Do not apply any **--sys-* options to any statistics tables.

- **--sys-skip-events**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--sys-skip-events</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>false</td>
</tr>
<tr>
<td>Minimum Value</td>
<td></td>
</tr>
<tr>
<td>Maximum Value</td>
<td></td>
</tr>
</tbody>
</table>

Do not apply any **--sys-* options to any events.

- **--verbose**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--verbose</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
</tbody>
</table>
ndb_move_data — NDB Data Copy Utility

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>false</td>
</tr>
<tr>
<td>Minimum Value</td>
<td></td>
</tr>
<tr>
<td>Maximum Value</td>
<td></td>
</tr>
</tbody>
</table>

Turn on verbose output.

- `--loops=#`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--loops=#</code></td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td><code>MAX_INT</code></td>
</tr>
</tbody>
</table>

Repeat commands this number of times (for use in testing).

18.4.15 ndb_move_data — NDB Data Copy Utility

ndb_move_data copies data from one NDB table to another.

Usage

The program is invoked with the names of the source and target tables; either or both of these may be qualified optionally with the database name. Both tables must use the NDB storage engine.

```
ndb_move_data options source target
```

The following table includes options that are specific to ndb_move_data. Additional descriptions follow the table. For options common to most NDB Cluster programs (including ndb_move_data), see Section 18.4.29, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

Table 18.315 Command-line options for the ndb_move_data program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--abort-on-error</code></td>
<td>Dump core on permanent error (debug option)</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td><code>--character-sets-dir=name</code></td>
<td>Directory where character sets are</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td><code>--database=dbname, -d</code></td>
<td>Name of the database in which the table is found</td>
<td>All MySQL 5.6 based releases</td>

</tbody>
</table>
### ndb_move_data — NDB Data Copy Utility

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--lossy-conversions, -l</code></td>
<td>Allow attribute data to be truncated when converted to a smaller type</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td><code>--promote-attributes, -A</code></td>
<td>Allow attribute data to be converted to a larger type</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td><code>--staging-tries=x[,y[,z]]</code></td>
<td>Specify tries on temporary errors. Format is x[,y[,z]] where x=max tries (0=no limit), y=min delay (ms), z=max delay (ms)</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td><code>--verbose</code></td>
<td>Enable verbose messages</td>
<td>All MySQL 5.6 based releases</td>
</tr>
</tbody>
</table>

- **--abort-on-error**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--abort-on-error</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Dump core on permanent error (debug option).

- **--character-sets-dir=name**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--character-sets-dir=name</code></td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Directory where character sets are.

- **--database=dbname, -d**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--database=dbname</code></td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>TEST_DB</td>
</tr>
</tbody>
</table>

Name of the database in which the table is found.

- **--drop-source**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--drop-source</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Drop source table after all rows have been moved.
• **--error-insert**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--error-insert</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Insert random temporary errors (testing option).

• **--exclude-missing-columns**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--exclude-missing-columns</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Ignore extra columns in source or target table.

• **--lossy-conversions, -l**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--lossy-conversions</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Allow attribute data to be truncated when converted to a smaller type.

• **--promote-attributes, -A**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--promote-attributes</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Allow attribute data to be converted to a larger type.

• **--staging-tries=x[,y[,z]]**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--staging-tries=x[,y[,z]]</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>0,1000,60000</td>
</tr>
</tbody>
</table>

Specify tries on temporary errors. Format is x,y,z] where x=max tries (0=no limit), y=min delay (ms), z=max delay (ms).

• **--verbose**
ndb_print_backup_file — Print NDB Backup File Contents

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--verbose</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Enable verbose messages.

18.4.16 ndb_print_backup_file — Print NDB Backup File Contents

ndb_print_backup_file obtains diagnostic information from a cluster backup file.

Usage

```bash
ndb_print_backup_file file_name
```

`file_name` is the name of a cluster backup file. This can be any of the files (.Data, .ctl, or .log file) found in a cluster backup directory. These files are found in the data node's backup directory under the subdirectory `BACKUP-#`, where `#` is the sequence number for the backup. For more information about cluster backup files and their contents, see Section 18.5.3.1, “NDB Cluster Backup Concepts”.

Like `ndb_print_schema_file` and `ndb_print_sys_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_backup_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

Additional Options

None.

18.4.17 ndb_print_file — Print NDB Disk Data File Contents

ndb_print_file obtains information from an NDB Cluster Disk Data file.

Usage

```bash
ndb_print_file [-v] [-q] file_name+
```

`file_name` is the name of an NDB Cluster Disk Data file. Multiple filenames are accepted, separated by spaces.

Like `ndb_print_schema_file` and `ndb_print_sys_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_file` must be run on an NDB Cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

Additional Options

`ndb_print_file` supports the following options:

- `-v`: Make output verbose.
ndb_print_frag_file — Print NDB Fragment List File Contents

-\q: Suppress output (quiet mode).

-\--help, -\h, -\?: Print help message.

This option did not work correctly prior to NDB 7.3.7. (Bug #17069285)

For more information, see Section 18.5.12, “NDB Cluster Disk Data Tables”.

18.4.18 ndb_print_frag_file — Print NDB Fragment List File Contents

ndb_print_frag_file obtains information from a cluster fragment list file. It is intended for use in helping to diagnose issues with data node restarts.

Usage

ndb_print_frag_file file_name

file_name is the name of a cluster fragment list file, which matches the pattern SX.FragList, where X is a digit in the range 2-9 inclusive, and are found in the data node file system of the data node having the node ID nodeid, in directories named ndb_nodeid_fs/DN/DBDIH/, where N is 1 or 2. Each fragment file contains records of the fragments belonging to each NDB table. For more information about cluster fragment files, see NDB Cluster Data Node File System Directory Files.

Like ndb_print_backup_file, ndb_print_sys_file, and ndb_print_schema_file (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server), ndb_print_frag_file must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

Additional Options

None.

Sample Output

shell> ndb_print_frag_file /usr/local/mysqld/data/ndb_3_fs/D1/DBDIH/S2.FragList
Filename: /usr/local/mysqld/data/ndb_3_fs/D1/DBDIH/S2.FragList with size 8192
noOfPages = 1 noOfWords = 182

LcpNo[1]: maxGciCompleted: 0 maxGciStarted: 0 lcpId: 0 lcpStatus: invalid

This program was added in MySQL NDB Cluster 7.4.3. (Bug #74594, Bug #19898269)

18.4.19 ndb_print_schema_file — Print NDB Schema File Contents

ndb_print_schema_file obtains diagnostic information from a cluster schema file.

Usage

```
ndb_print_schema_file file_name
```

`file_name` is the name of a cluster schema file. For more information about cluster schema files, see NDB Cluster Data Node File System Directory Files.

Like `ndb_print_backup_file` and `ndb_print_sys_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_schema_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

Additional Options

None.

18.4.20 ndb_print_sys_file — Print NDB System File Contents

ndb_print_sys_file obtains diagnostic information from an NDB Cluster system file.

Usage

```
ndb_print_sys_file file_name
```

`file_name` is the name of a cluster system file (sysfile). Cluster system files are located in a data node's data directory (DataDir); the path under this directory to system files matches the pattern `ndb_#.fs/D#/DBDIH/P#.sysfile`. In each case, the `#` represents a number (not necessarily the same number). For more information, see NDB Cluster Data Node File System Directory Files.

Like `ndb_print_backup_file` and `ndb_print_schema_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_sys_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

Additional Options

None.

18.4.21 ndb_redo_log_reader — Check and Print Content of Cluster Redo Log
Reads a redo log file, checking it for errors, printing its contents in a human-readable format, or both. `ndb_redo_log_reader` is intended for use primarily by NDB Cluster developers and Support personnel in debugging and diagnosing problems.

This utility remains under development, and its syntax and behavior are subject to change in future NDB Cluster releases.

![Note]
Prior to NDB 7.2, this utility was named `ndbd_redo_log_reader`.

The C++ source files for `ndb_redo_log_reader` can be found in the directory `/storage/ndb/src/kernel/blocks/dblqh/redoLogReader`.

The following table includes options that are specific to the NDB Cluster program `ndb_redo_log_reader`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_redo_log_reader`), see Section 18.4.29, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

**Table 18.316 Command-line options for the `ndb_redo_log_reader` program**

<table>
<thead>
<tr>
<th>Format</th>

<tr>
<td><code>-twiddle</code></td>
<td>Bit-shifted dump</td>
<td>All MySQL 5.6 based releases</td>
</tr>
</tbody>
</table>

**Usage**

```
ndb_redo_log_reader file_name [options]
```

`file_name` is the name of a cluster redo log file. Redo log files are located in the numbered directories under the data node’s data directory (`DataDir`); the path under this directory to the redo log files matches the pattern `ndb_nodeid_fs/D#/DBLQH/S#.FragLog.nodeid` is the data node’s node ID. The two instances of `#` each represent a number (not necessarily the same number); the number following `D` is in the range 8-39 inclusive; the range of the number following `S` varies according to the value of the `NoOfFragmentLogFiles` configuration parameter, whose default value is 16; thus, the default range of the number in the file name is 0-15 inclusive. For more information, see NDB Cluster Data Node File System Directory Files.
The name of the file to be read may be followed by one or more of the options listed here:

- `-dump`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>-dump</code></td>
</tr>
<tr>
<td>Type</td>

Bit-shifted dump.

Like `ndb_print_backup_file` and `ndb_print_schema_file` (and unlike most of the NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndb_redo_log_reader` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

## 18.4.22 ndb_restore — Restore an NDB Cluster Backup

The NDB Cluster restoration program is implemented as a separate command-line utility `ndb_restore`, which can normally be found in the MySQL `bin` directory. This program reads the files created as a result of the backup and inserts the stored information into the database.

### Note
Beginning with NDB 7.3.25 and 7.4.24, this program no longer prints `NDBT_ProgramExit: ...` when it finishes its run. Applications depending on this behavior should be modified accordingly when upgrading from earlier releases.

`ndb_restore` must be executed once for each of the backup files that were created by the `START BACKUP` command used to create the backup (see Section 18.5.3.2, “Using The NDB Cluster Management Client to Create a Backup”). This is equal to the number of data nodes in the cluster at the time that the backup was created.

### Note
Before using `ndb_restore`, it is recommended that the cluster be running in single user mode, unless you are restoring multiple data nodes in parallel. See Section 18.5.8, “NDB Cluster Single User Mode”, for more information.

The following table includes options that are specific to the NDB Cluster native backup restoration program `ndb_restore`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_restore`), see Section 18.4.29, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

### Table 18.317 Command-line options for the ndb_restore program

<td>Causes missing blob tables in the backup file to be ignored.</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--skip-table-check, -s</td>
<td>Skip table structure check during restoring of data</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--skip-unknown-objects</td>
<td>Causes schema objects not recognized by ndb_restore to be ignored when restoring a backup made from a newer MySQL Cluster version to an older version.</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--tab=dir_name, -T dir_name</td>
<td>Creates a tab-separated .txt file for each table in the given path</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--verbose=#</td>
<td>Level of verbosity in output</td>
<td>All MySQL 5.6 based releases</td>
</tr>
</tbody>
</table>

Typical options for this utility are shown here:

```
ndb_restore [-c connection_string] -n node_id -b backup_id \[
[-m] -r --backup_path=/path/to/backup/files
```

Normally, when restoring from an NDB Cluster backup, ndb_restore requires at a minimum the --nodeid (short form: -n), --backupid (short form: -b), and --backup_path options. In addition, when ndb_restore is used to restore any tables containing unique indexes, you must include --disable-indexes or --rebuild-indexes. (Bug #57782, Bug #11764893)

The --c option is used to specify a connection string which tells ndb_restore where to locate the cluster management server (see Section 18.3.3.3, “NDB Cluster Connection Strings”). If this option is not used, then ndb_restore attempts to connect to a management server on localhost:1186. This utility acts as a cluster API node, and so requires a free connection “slot” to connect to the cluster management.
server. This means that there must be at least one [api] or [mysqld] section that can be used by it in the cluster config.ini file. It is a good idea to keep at least one empty [api] or [mysqld] section in config.ini that is not being used for a MySQL server or other application for this reason (see Section 18.3.3.7, "Defining SQL and Other API Nodes in an NDB Cluster").

You can verify that ndb_restore is connected to the cluster by using the SHOW command in the ndb_mgm management client. You can also accomplish this from a system shell, as shown here:

```shell
shell> ndb_mgm -e "SHOW"
```

### Note

In NDB 7.3.11 and NDB 7.4.8 only, when ndb_restore is used to restore any tables containing unique indexes, you must include `--disable-indexes` or `--rebuild-indexes`. (Bug #57782, Bug #11764893) This is not a requirement in later versions. (Bug #22345748)

More detailed information about all options used by ndb_restore can be found in the following list:

- **--append**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--append</td>
</tr>
</tbody>
</table>

  When used with the `--tab` and `--print-data` options, this causes the data to be appended to any existing files having the same names.

- **--backup_path=dir_name**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--backup-path=dir_name</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
<tr>
<td>Default Value</td>
<td>./</td>
</tr>
</tbody>
</table>

The path to the backup directory is required; this is supplied to ndb_restore using the `--backup_path` option, and must include the subdirectory corresponding to the ID backup of the backup to be restored. For example, if the data node's DataDir is `/var/lib/mysql-cluster`, then the backup directory is `/var/lib/mysql-cluster/BACKUP`, and the backup files for the backup with the ID 3 can be found in `/var/lib/mysql-cluster/BACKUP/BACKUP-3`. The path may be absolute or relative to the directory in which the ndb_restore executable is located, and may be optionally prefixed with `backup_path=`.

It is possible to restore a backup to a database with a different configuration than it was created from. For example, suppose that a backup with backup ID 12, created in a cluster with two storage nodes having the node IDs 2 and 3, is to be restored to a cluster with four nodes. Then ndb_restore must be run twice—one for each storage node in the cluster where the backup was taken. However, ndb_restore cannot always restore backups made from a cluster running one version of MySQL to a cluster running a different MySQL version. See Section 18.2.8, "Upgrading and Downgrading NDB Cluster", for more information.

### Important

It is not possible to restore a backup made from a newer version of NDB Cluster using an older version of ndb_restore. You can restore a backup made from
ndb_restore — Restore an NDB Cluster Backup

a newer version of MySQL to an older cluster, but you must use a copy of
ndb_restore from the newer NDB Cluster version to do so.

For example, to restore a cluster backup taken from a cluster running NDB
Cluster 7.4.25 to a cluster running NDB Cluster 7.3.26, you must use the
ndb_restore that comes with the NDB Cluster 7.4.25 distribution.

For more rapid restoration, the data may be restored in parallel, provided that there is a sufficient
number of cluster connections available. That is, when restoring to multiple nodes in parallel, you must
have an [api] or [mysqld] section in the cluster config.ini file available for each concurrent
ndb_restore process. However, the data files must always be applied before the logs.

•  --backupid=#, -b

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--backupid=#</td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>none</td>
</tr>
</tbody>
</table>

This option is used to specify the ID or sequence number of the backup, and is the same number
shown by the management client in the Backup backup_id completed message displayed upon
completion of a backup. (See Section 18.5.3.2, “Using The NDB Cluster Management Client to Create a
Backup”.)

Important

When restoring cluster backups, you must be sure to restore all data nodes
from backups having the same backup ID. Using files from different backups
will at best result in restoring the cluster to an inconsistent state, and may fail
altogether.

•  --connect, -c

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--connect</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>localhost:1186</td>
</tr>
</tbody>
</table>

Alias for --ndb-connectstring.

•  --disable-indexes

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--disable-indexes</td>
</tr>
</tbody>
</table>

Disable restoration of indexes during restoration of the data from a native NDB backup. Afterwards, you
can restore indexes for all tables at once with multithreaded building of indexes using --rebuild-
indexes, which should be faster than rebuilding indexes concurrently for very large tables.

•  --dont-ignore-systab-0, -f
Normally, when restoring table data and metadata, `ndb_restore` ignores the copy of the NDB system table that is present in the backup. `--dont-ignore-systab-0` causes the system table to be restored. *This option is intended for experimental and development use only, and is not recommended in a production environment.*

- `--exclude-databases=db-list`

Comma-delimited list of one or more databases which should not be restored.

This option is often used in combination with `--exclude-tables`; see that option's description for further information and examples.

- `--exclude-intermediate-sql-tables[=TRUE|FALSE]`

When performing copying `ALTER TABLE` operations, `mysqld` creates intermediate tables (whose names are prefixed with `#sql-`). When TRUE, the `--exclude-intermediate-sql-tables` option keeps `ndb_restore` from restoring such tables that may have been left over from these operations. This option is TRUE by default.

This option was introduced in NDB 7.3.6. (Bug #17882305)

- `--exclude-missing-columns`

It is possible to restore only selected table columns using this option, which causes `ndb_restore` to ignore any columns missing from tables being restored as compared to the versions of those tables found in the backup. This option applies to all tables being restored. If you wish to apply this option only to selected tables or databases, you can use it in combination with one or more of the `--include-*` or `--exclude-*` options described elsewhere in this section to do so, then restore data to the remaining tables using a complementary set of these options.

- `--exclude-missing-tables`
It is possible to restore only selected tables using this option, which causes `ndb_restore` to ignore any tables from the backup that are not found in the target database.

This option was introduced in NDB 7.3.7.

- `--exclude-tables=table-list`

You can use these two options together. For example, the following causes all tables in all databases except for databases `db1` and `db2`, and tables `t1` and `t2` in database `db3`, to be restored:

```shell
shell> ndb_restore [...] --exclude-databases=db1,db2 --exclude-tables=db3.t1,db3.t2
```
You can use `--include-*` and `--exclude-*` options together, subject to the following rules:

- The actions of all `--include-*` and `--exclude-*` options are cumulative.
- All `--include-*` and `--exclude-*` options are evaluated in the order passed to ndb_restore, from right to left.
- In the event of conflicting options, the first (rightmost) option takes precedence. In other words, the first option (going from right to left) that matches against a given database or table “wins”.

For example, the following set of options causes `ndb_restore` to restore all tables from database `db1` except `db1.t1`, while restoring no other tables from any other databases:

```
--include-databases=db1 --exclude-tables=db1.t1
```

However, reversing the order of the options just given simply causes all tables from database `db1` to be restored (including `db1.t1`, but no tables from any other database), because the `--include-databases` option, being farthest to the right, is the first match against database `db1` and thus takes precedence over any other option that matches `db1` or any tables in `db1`:

```
--exclude-tables=db1.t1 --include-databases=db1
```

- `--fields-enclosed-by=char`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--fields-enclosed-by=char</code></td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>

Each column value is enclosed by the string passed to this option (regardless of data type; see the description of `--fields-optionally-enclosed-by`).

- `--fields-optionally-enclosed-by`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--fields-optionally-enclosed-by</code></td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>

The string passed to this option is used to enclose column values containing character data (such as `CHAR`, `VARCHAR`, `BINARY`, `TEXT`, or `ENUM`).

- `--fields-terminated-by=char`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--fields-terminated-by=char</code></td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>
### ndb_restore — Restore an NDB Cluster Backup

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>\t (tab)</td>
</tr>
</tbody>
</table>

The string passed to this option is used to separate column values. The default value is a tab character (\t).

- **--hex**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--hex</td>
</tr>
</tbody>
</table>

If this option is used, all binary values are output in hexadecimal format.

- **--include-databases=db-list**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--include-databases=db-list</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>

Comma-delimited list of one or more databases to restore. Often used together with **--include-tables**; see the description of that option for further information and examples.

- **--include-tables=table-list**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--include-tables=table-list</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>

Comma-delimited list of tables to restore; each table reference must include the database name.

When **--include-databases** or **--include-tables** is used, only those databases or tables named by the option are restored; all other databases and tables are excluded by **ndb_restore**, and are not restored.

The following table shows several invocations of **ndb_restore** using **--include-*** options (other options possibly required have been omitted for clarity), and the effects these have on restoring from an NDB Cluster backup:

**Table 18.319 Several invocations of ndb_restore using --include-* options, and their effects on restoring from an NDB Cluster backup.**

<table>
<thead>
<tr>
<th>Option</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>--include-databases=db1</strong></td>
<td>Only tables in database db1 are restored; all tables in all other databases are ignored</td>
</tr>
<tr>
<td><strong>--include-databases=db1,db2</strong></td>
<td>Only tables in databases db1 and db2 are restored; all tables in all other databases are ignored</td>
</tr>
<tr>
<td><strong>--include-tables=db1.t1</strong></td>
<td>Only table t1 in database db1 is restored; no other tables in db1 or in any other database are restored</td>
</tr>
</tbody>
</table>
ndb_restore — Restore an NDB Cluster Backup

<table>
<thead>
<tr>
<th>Option</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--include-tables=db1.t2,db2.t1</code> (or <code>--include-tables=db1.t2 --include-tables=db2.t1</code>)</td>
<td>Only the table <code>t2</code> in database <code>db1</code> and the table <code>t1</code> in database <code>db2</code> are restored; no other tables in <code>db1</code>, <code>db2</code>, or any other database are restored</td>
</tr>
</tbody>
</table>

You can also use these two options together. For example, the following causes all tables in databases `db1` and `db2`, together with the tables `t1` and `t2` in database `db3`, to be restored (and no other databases or tables):

```
shell> ndb_restore [...] --include-databases=db1,db2 --include-tables=db3.t1,db3.t2
```

(Again we have omitted other, possibly required, options in the example just shown.)

It also possible to restore only selected databases, or selected tables from a single database, without any `--include-*` (or `--exclude-*`) options, using the syntax shown here:

```shell
ndb_restore other_options db_name,[db_name[,...] | tbl_name[,tbl_name][,...]]
```

In other words, you can specify either of the following to be restored:

- All tables from one or more databases
- One or more tables from a single database
- `--lines-terminated-by=char`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--lines-terminated-by=char</code></td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>\n (linebreak)</td>
</tr>
</tbody>
</table>

Specifies the string used to end each line of output. The default is a linefeed character (`\n`).

- `--lossy-conversions`, `-L`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--lossy-conversions</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>FALSE</code> (If option is not used)</td>
</tr>
</tbody>
</table>

This option is intended to complement the `--promote-attributes` option. Using `--lossy-conversions` allows lossy conversions of column values (type demotions or changes in sign) when restoring data from backup. With some exceptions, the rules governing demotion are the same as for MySQL replication; see Replication of Columns Having Different Data Types, for information about specific type conversions currently supported by attribute demotion.

`ndb_restore` reports any truncation of data that it performs during lossy conversions once per attribute and column.

- `--no-binlog`
**ndb_restore** — Restore an NDB Cluster Backup

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--no-binlog</td>
</tr>
</tbody>
</table>

This option prevents any connected SQL nodes from writing data restored by `ndb_restore` to their binary logs.

- `--no-restore-disk-objects, -d`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--no-restore-disk-objects</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

This option stops `ndb_restore` from restoring any NDB Cluster Disk Data objects, such as tablespaces and log file groups; see Section 18.5.12, “NDB Cluster Disk Data Tables”, for more information about these.

- `--no-upgrade, -u`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--no-upgrade</td>
</tr>
</tbody>
</table>

When using `ndb_restore` to restore a backup, VARCHAR columns created using the old fixed format are resized and recreated using the variable-width format now employed. This behavior can be overridden by specifying `--no-upgrade`.

- `--ndb-nodegroup-map=map, -z`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--ndb-nodegroup-map=map</td>
</tr>
</tbody>
</table>

This option can be used to restore a backup taken from one node group to a different node group. Its argument is a list of the form `source_node_group, target_node_group`.

- `--nodeid=#, -n`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--nodeid=#</td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>none</td>
</tr>
</tbody>
</table>

Specify the node ID of the data node on which the backup was taken.

When restoring to a cluster with different number of data nodes from that where the backup was taken, this information helps identify the correct set or sets of files to be restored to a given node. (In such cases, multiple files usually need to be restored to a single data node.) See Section 18.4.22.1, “Restoring to a different number of data nodes”, for additional information and examples.

- `--parallelism=#, -p`
### ndb_restore — Restore an NDB Cluster Backup

**Property** | **Value**
--- | ---
**Command-Line Format** | `--parallelism=#`

**Type** | Numeric

**Default Value** | 128

**Minimum Value** | 1

**Maximum Value** | 1024

`ndb_restore` uses single-row transactions to apply many rows concurrently. This parameter determines the number of parallel transactions (concurrent rows) that an instance of `ndb_restore` tries to use. By default, this is 128; the minimum is 1, and the maximum is 1024.

The work of performing the inserts is parallelized across the threads in the data nodes involved. This mechanism is employed for restoring bulk data from the `.Data` file—that is, the fuzzy snapshot of the data; it is not used for building or rebuilding indexes. The change log is applied serially; index drops and builds are DDL operations and handled separately. There is no thread-level parallelism on the client side of the restore.

- **--preserve-trailing-spaces, -P**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td><code>--preserve-trailing-spaces</code></td>
</tr>
</tbody>
</table>

Cause trailing spaces to be preserved when promoting a fixed-width character data type to its variable-width equivalent—that is, when promoting a `CHAR` column value to `VARCHAR`, or a `BINARY` column value to `VARBINARY`. Otherwise, any trailing spaces are dropped from such column values when they are inserted into the new columns.

**Note**

Although you can promote `CHAR` columns to `VARCHAR` and `BINARY` columns to `VARBINARY`, you cannot promote `VARCHAR` columns to `CHAR` or `VARBINARY` columns to `BINARY`.

- **--print**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td><code>--print</code></td>
</tr>
</tbody>
</table>

**Type** | Boolean

**Default Value** | `FALSE`

Causes `ndb_restore` to print all data, metadata, and logs to `stdout`. Equivalent to using the `--print-data`, `--print-meta`, and `--print-log` options together.

**Note**

Use of `--print` or any of the `--print_*` options is in effect performing a dry run. Including one or more of these options causes any output to be redirected to `stdout`; in such cases, `ndb_restore` makes no attempt to restore data or metadata to an NDB Cluster.

- **--print-data**
ndb_restore — Restore an NDB Cluster Backup

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--print-data</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Cause `ndb_restore` to direct its output to stdout. Often used together with one or more of `--tab`, `--fields-enclosed-by`, `--fields-optionally-enclosed-by`, `--fields-terminated-by`, `--hex`, and `--append`.

* TEXT and BLOB column values are always truncated. In NDB 7.3.7 and earlier, such values are truncated to the first 240 bytes in the output; in NDB 7.3.8 and later, they are truncated to 256 bytes. (Bug #14571512, Bug #65467) This cannot currently be overridden when using `--print-data`.

* --print-log

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--print-log</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Cause `ndb_restore` to output its log to stdout.

* --print-meta

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--print-meta</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Print all metadata to stdout.

* --progress-frequency=N

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--progress-frequency=#</td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>65535</td>
</tr>
</tbody>
</table>

Print a status report each \( N \) seconds while the restore is in progress. 0 (the default) causes no status reports to be printed. The maximum is 65535.

* --promote-attributes, -A

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--promote-attributes</td>
</tr>
</tbody>
</table>
ndb_restore supports limited *attribute promotion* in much the same way that it is supported by MySQL replication; that is, data backed up from a column of a given type can generally be restored to a column using a “larger, similar” type. For example, data from a `CHAR(20)` column can be restored to a column declared as `VARCHAR(20)`, `VARCHAR(30)`, or `CHAR(30)`; data from a `MEDIUMINT` column can be restored to a column of type `INT` or `BIGINT`. See *Replication of Columns Having Different Data Types*, for a table of type conversions currently supported by attribute promotion.

Attribute promotion by *ndb_restore* must be enabled explicitly, as follows:

1. Prepare the table to which the backup is to be restored. *ndb_restore* cannot be used to re-create the table with a different definition from the original; this means that you must either create the table manually, or alter the columns which you wish to promote using *ALTER TABLE* after restoring the table metadata but before restoring the data.

2. Invoke *ndb_restore* with the `--promote-attributes` option (short form `-A`) when restoring the table data. Attribute promotion does not occur if this option is not used; instead, the restore operation fails with an error.

Prior to NDB 7.3.3, conversions between character data types and `TEXT` or `BLOB` were not handled correctly (Bug #17325051).

Prior to NDB 7.3.7, demotion of `TEXT` to `TINYTEXT` was not handled correctly (Bug #18875137).

When converting between character data types and `TEXT` or `BLOB`, only conversions between character types (`CHAR` and `VARCHAR`) and binary types (`BINARY` and `VARBINARY`) can be performed at the same time. For example, you cannot promote an `INT` column to `BIGINT` while promoting a `VARCHAR` column to `TEXT` in the same invocation of *ndb_restore*.

Converting between `TEXT` columns using different character sets is not supported. Beginning with NDB 7.3.7, it is expressly disallowed (Bug #18875137).

When performing conversions of character or binary types to `TEXT` or `BLOB` with *ndb_restore*, you may notice that it creates and uses one or more staging tables named `table_name$STnode_id`. These tables are not needed afterwards, and are normally deleted by *ndb_restore* following a successful restoration.

* --rebuild-indexes

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--rebuild-indexes</code></td>
</tr>
</tbody>
</table>

Enable multithreaded rebuilding of the ordered indexes while restoring a native NDB backup. The number of threads used for building ordered indexes by *ndb_restore* with this option is controlled by the `BuildIndexThreads` data node configuration parameter and the number of LDMs.

It is necessary to use this option only for the first run of *ndb_restore*; this causes all ordered indexes to be rebuilt without using `--rebuild-indexes` again when restoring subsequent nodes. You should use this option prior to inserting new rows into the database; otherwise, it is possible for a row to be inserted that later causes a unique constraint violation when trying to rebuild the indexes.

Building of ordered indices is parallelized with the number of LDMs by default. Offline index builds performed during node and system restarts can be made faster using the `BuildIndexThreads` data node configuration parameter; this parameter has no effect on dropping and rebuilding of indexes by *ndb_restore*, which is performed online.
Rebuilding of unique indexes uses disk write bandwidth for redo logging and local checkpointing. An insufficient amount of this bandwidth can lead to redo buffer overload or log overload errors. In such cases you can run `ndb_restore --rebuild-indexes` again; the process resumes at the point where the error occurred. You can also do this when you have encountered temporary errors. You can repeat execution of `ndb_restore --rebuild-indexes` indefinitely; you may be able to stop such errors by reducing the value of `--parallelism`. If the problem is insufficient space, you can increase the size of the redo log (`FragmentLogFileSize` node configuration parameter), or you can increase the speed at which LCPs are performed (`MaxDiskWriteSpeed` and related parameters), in order to free space more quickly.

- `--restore-data, -r`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--restore-data</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Output NDB table data and logs.

- `--restore-epoch, -e`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--restore-epoch</code></td>
</tr>
</tbody>
</table>

Add (or restore) epoch information to the cluster replication status table. This is useful for starting replication on an NDB Cluster replication slave. When this option is used, the row in the `mysql.ndb_apply_status` having 0 in the `id` column is updated if it already exists; such a row is inserted if it does not already exist. (See Section 18.6.9, “NDB Cluster Backups With NDB Cluster Replication”.)

- `--restore-meta, -m`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--restore-meta</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

This option causes `ndb_restore` to print NDB table metadata.

The first time you run the `ndb_restore` restoration program, you also need to restore the metadata. In other words, you must re-create the database tables—this can be done by running it with the `--restore-meta (-m)` option. Restoring the metadata need be done only on a single data node; this is sufficient to restore it to the entire cluster.

**Note**

The cluster should have an empty database when starting to restore a backup. (In other words, you should start the data nodes with `--initial` prior to performing the restore.)

- `--restore-privilege-tables`
**ndb_restore** — Restore an NDB Cluster Backup

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--restore-privilege-tables</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE (If option is not used)</td>
</tr>
</tbody>
</table>

`ndb_restore` does not by default restore distributed MySQL privilege tables. This option causes `ndb_restore` to restore the privilege tables.

This works only if the privilege tables were converted to **NDB** before the backup was taken. For more information, see Section 18.5.15, "Distributed MySQL Privileges for NDB Cluster".

- **--rewrite-database=olddb,newdb**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--rewrite-database=olddb,newdb</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>none</td>
</tr>
</tbody>
</table>

This option makes it possible to restore to a database having a different name from that used in the backup. For example, if a backup is made of a database named `products`, you can restore the data it contains to a database named `inventory`, use this option as shown here (omitting any other options that might be required):

```
shell> ndb_restore --rewrite-database=product,inventory
```

The option can be employed multiple times in a single invocation of `ndb_restore`. Thus it is possible to restore simultaneously from a database named `db1` to a database named `db2` and from a database named `db3` to one named `db4` using `--rewrite-database=db1,db2 --rewrite-database=db3,db4`. Other `ndb_restore` options may be used between multiple occurrences of `--rewrite-database`.

In the event of conflicts between multiple `--rewrite-database` options, the last `--rewrite-database` option used, reading from left to right, is the one that takes effect. For example, if `--rewrite-database=db1,db2 --rewrite-database=db1,db3` is used, only `--rewrite-database=db1,db3` is honored, and `--rewrite-database=db1,db2` is ignored. It is also possible to restore from multiple databases to a single database, so that `--rewrite-database=db1,db3 --rewrite-database=db2,db3` restores all tables and data from databases `db1` and `db2` into database `db3`.

**Important**

When restoring from multiple backup databases into a single target database using `--rewrite-database`, no check is made for collisions between table or other object names, and the order in which rows are restored is not guaranteed. This means that it is possible in such cases for rows to be overwritten and updates to be lost.

- **--skip-broken-objects**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--skip-broken-objects</td>
</tr>
</tbody>
</table>
This option causes `ndb_restore` to ignore corrupt tables while reading a native NDB backup, and to continue restoring any remaining tables (that are not also corrupted). Currently, the `--skip-broken-objects` option works only in the case of missing blob parts tables.

- `--skip-table-check`, `-s`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--skip-table-check</code></td>
</tr>
</tbody>
</table>

It is possible to restore data without restoring table metadata. By default when doing this, `ndb_restore` fails with an error if a mismatch is found between the table data and the table schema; this option overrides that behavior.

Some of the restrictions on mismatches in column definitions when restoring data using `ndb_restore` are relaxed; when one of these types of mismatches is encountered, `ndb_restore` does not stop with an error as it did previously, but rather accepts the data and inserts it into the target table while issuing a warning to the user that this is being done. This behavior occurs whether or not either of the options `--skip-table-check` or `--promote-attributes` is in use. These differences in column definitions are of the following types:

- Different `COLUMN_FORMAT` settings (`FIXED`, `DYNAMIC`, `DEFAULT`)
- Different `STORAGE` settings (`MEMORY`, `DISK`)
- Different default values
- Different distribution key settings

- `--skip-unknown-objects`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--skip-unknown-objects</code></td>
</tr>
</tbody>
</table>

This option causes `ndb_restore` to ignore any schema objects it does not recognize while reading a native NDB backup. This can be used for restoring a backup made from a cluster running (for example) NDB 7.4 to a cluster running NDB Cluster 7.3.

- `--tab=dir_name`, `-T dir_name`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--tab=dir_name</code></td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
</tbody>
</table>

Causes `--print-data` to create dump files, one per table, each named `tbl_name.txt`. It requires as its argument the path to the directory where the files should be saved; use `. ` for the current directory.

- `--verbose=#`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--verbose=#</code></td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
</tbody>
</table>
ndb_restore — Restore an NDB Cluster Backup

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>255</td>
</tr>
</tbody>
</table>

Sets the level for the verbosity of the output. The minimum is 0; the maximum is 255. The default value is 1.

**Error reporting.**

`ndb_restore` reports both temporary and permanent errors. In the case of temporary errors, it may be able to recover from them, and reports *Restore successful, but encountered temporary error, please look at configuration* in such cases.

---

**Important**

After using `ndb_restore` to initialize an NDB Cluster for use in circular replication, binary logs on the SQL node acting as the replication slave are not automatically created, and you must cause them to be created manually. To cause the binary logs to be created, issue a `SHOW TABLES` statement on that SQL node before running `START SLAVE`. This is a known issue in NDB Cluster.

### 18.4.22.1 Restoring to a different number of data nodes

It is possible to restore from an NDB backup to a cluster having a different number of data nodes than the original from which the backup was taken. The following two sections discuss, respectively, the cases where the target cluster has a lesser or greater number of data nodes than the source of the backup.

#### Restoring to Fewer Nodes Than the Original

You can restore to a cluster having fewer data nodes than the original provided that the larger number of nodes is an even multiple of the smaller number. In the following example, we use a backup taken on a cluster having four data nodes to restore to a cluster having two data nodes.

1. The management server for the original cluster is on host `host10`. The original cluster has four data nodes, with the node IDs and host names shown in the following extract from the management server’s `config.ini` file:

   ```ini
   [ndbd]
   NodeId=2
   HostName=host2
   
   [ndbd]
   NodeId=4
   HostName=host4
   
   [ndbd]
   NodeId=6
   HostName=host6
   
   [ndbd]
   NodeId=8
   HostName=host8
   ```

   We assume that each data node was originally started with `ndbmtd --ndb-connectstring=host10` or the equivalent.

2. Perform a backup in the normal manner. See Section 18.5.3.2, “Using The NDB Cluster Management Client to Create a Backup”, for information about how to do this.
3. The files created by the backup on each data node are listed here, where \( N \) is the node ID and \( B \) is the backup ID.

- BACKUP-B-0.N.Data
- BACKUP-B.N.ctl
- BACKUP-B.N.log

These files are found under `BackupDataDir/BACKUP/BACKUP-B`, on each data node. For the rest of this example, we assume that the backup ID is 1.

Have all of these files available for later copying to the new data nodes (where they can be accessed on the data node's local file system by `ndb_restore`). It is simplest to copy them all to a single location; we assume that this is what you have done.

4. The management server for the target cluster is on host `host20`, and the target has two data nodes, with the node IDs and host names shown, from the configuration server `config.ini` file on `host20`:

```ini
[ndbd]
NodeId=3
hostname=host3

[ndbd]
NodeId=5
hostname=host5
```

Each of the data node processes on `host3` and `host5` should be started with `ndbmtd -c host20 --initial` or the equivalent, so that the new (target) cluster starts with clean data node file systems.

5. Copy two different sets of two backup files to each of the target data nodes. For this example, copy the backup files from nodes 2 and 4 from the original cluster to node 3 in the target cluster. These files are listed here:

- BACKUP-1-0.2.Data
- BACKUP-1.2.ctl
- BACKUP-1.2.log
- BACKUP-1-0.6.Data
- BACKUP-1.6.ctl
- BACKUP-1.6.log

Then copy the backup files from nodes 6 and 8 to node 5; these files are shown in the following list:

- BACKUP-1-0.4.Data
- BACKUP-1.4.ctl
- BACKUP-1.4.log
- BACKUP-1-0.8.Data
- BACKUP-1.8.ctl
For the remainder of this example, we assume that the respective backup files have been saved to the directory `/BACKUP-1` on each of nodes 3 and 5.

6. On each of the two target data nodes, you must restore from both sets of backups. First, restore the backups from nodes 2 and 4 to node 3 by invoking `ndb_restore` on `host3` as shown here:

```shell
shell> ndb_restore -c host20 --nodeid=2 --backupid=1 --restore-data --backup_path=/BACKUP-1
shell> ndb_restore -c host20 --nodeid=4 --backupid=1 --restore-data --backup_path=/BACKUP-1
```

Then restore the backups from nodes 6 and 8 to node 5 by invoking `ndb_restore` on `host5`, like this:

```shell
shell> ndb_restore -c host20 --nodeid=6 --backupid=1 --restore-data --backup_path=/BACKUP-1
shell> ndb_restore -c host20 --nodeid=8 --backupid=1 --restore-data --backup_path=/BACKUP-1
```

**Restoring to More Nodes Than the Original**

The node ID specified for a given `ndb_restore` command is that of the node in the original backup and not that of the data node to restore it to. When performing a backup using the method described in this section, `ndb_restore` connects to the management server and obtains a list of data nodes in the cluster the backup is being restored to. The restored data is distributed accordingly, so that the number of nodes in the target cluster does not need to be to be known or calculated when performing the backup.

### Note

When changing the total number of LCP threads or LQH threads per node group, you should recreate the schema from backup created using `mysqldump`.

1. **Create the backup of the data.** You can do this by invoking the `ndb_mgm` client `START BACKUP` command from the system shell, like this:

   ```shell
   shell> ndb_mgm -e "START BACKUP 1"
   ```

   This assumes that the desired backup ID is 1.

2. **Create a backup of the schema** (see also below):

   ```shell
   shell> mysqldump --no-data --routines --events --triggers --databases > myschema.sql
   ```

   **Important**
   
   You must not make any schema changes between the first and second steps.

3. **Copy the backup directories from above to the new cluster.** For example if the backup you want to restore is has ID 1 and `BackupDataDir = /backups/node_nodeid`, then the path to the backup on this node is `/backups/node_1/BACKUP/BACKUP-1`. Inside this directory there are three files, listed here:

   - **BACKUP-1-0.1.Data**
   - **BACKUP-1.1.ctl**
You should copy the entire directory to the new node.

There is no requirement for the backup to be restored from a specific node or nodes.

To restore from the backup just created, perform the following steps:

1. **Restore the schema.** Import the schema file using the `mysql` client, as shown here:

   ```
   shell> mysql < myschema.sql
   ```

2. **Restore the data.** The following commands can be run in parallel:

   ```
   ndb_restore --nodeid=1 --backupid=1 --restore-data --backup_path=/backups/node_1/BACKUP/BACKUP-1 --disable-indexes
   ndb_restore --nodeid=2 --backupid=1 --restore-data --backup_path=/backups/node_2/BACKUP/BACKUP-1 --disable-indexes
   ndb_restore --nodeid=3 --backupid=1 --restore-data --backup_path=/backups/node_3/BACKUP/BACKUP-1 --disable-indexes
   ndb_restore --nodeid=4 --backupid=1 --restore-data --backup_path=/backups/node_4/BACKUP/BACKUP-1 --disable-indexes
   ndb_restore --nodeid=5 --backupid=1 --restore-data --backup_path=/backups/node_5/BACKUP/BACKUP-1 --disable-indexes
   ndb_restore --nodeid=6 --backupid=1 --restore-data --backup_path=/backups/node_6/BACKUP/BACKUP-1 --disable-indexes
   ndb_restore --nodeid=7 --backupid=1 --restore-data --backup_path=/backups/node_7/BACKUP/BACKUP-1 --disable-indexes
   ndb_restore --nodeid=8 --backupid=1 --restore-data --backup_path=/backups/node_8/BACKUP/BACKUP-1 --disable-indexes
   ```

   Add the `--ndb-connectstring` option as needed.

   If you in 3. for example copied the backups from the “old” nodes having node IDs 1 and 2 to a “new” node whose node ID is 1, you should perform the two invocations of `ndb_restore` with `--nodeid=1` and `--nodeid=2` on the new node that has 1 as its node ID.

3. **Rebuild the indexes.** These were disabled by the `--disable-indexes` option used in the commands just shown. Recreating the indexes avoids errors due to the restore not being consistent at all points. Rebuilding the indexes can also improve performance in some cases. To rebuild the indexes, execute the following command once, on a single node:

   ```
   shell> ndb_restore --nodeid=1 --backupid=1 --backup_path=/backups/node_1/BACKUP/BACKUP-1 --rebuild-indexes
   ```

---

**Important**

You should be aware that the supported number of partitions in each table depends on the number of data nodes, node groups, and LDM threads in the cluster. Other conditions (such as the values of `MaxNoOfExecutionThreads`, `ThreadConfig`, `NoOfReplicas`, and so on) being the same, a cluster with (for example) two data nodes supports fewer partitions than a cluster with eight data nodes supports.

This means that using `ndb_restore --restore-meta` to restore the schema does not always work since this restores a given table with the same number of partitions as in the original; it is safer to restore the schema from a backup written by `mysqldump`—as in the example shown previously—when restoring to a cluster having fewer data nodes, LDM threads, or both, than were used in the original cluster.

The support for fewer partitions when restoring to a smaller cluster also means the maximum number of rows per table is lower. However, with the larger hash maps available in MySQL Cluster 7.2.9 and later (used by default for new tables), this is not likely to be an issue.
**ndb_select_all** — Print Rows from an NDB Table

**ndb_select_all** prints all rows from an NDB table to stdout.

### Usage

```
ndb_select_all -c connection_string tbl_name -d db_name [> file_name]
```

The following table includes options that are specific to the NDB Cluster native backup restoration program **ndb_select_all**. Additional descriptions follow the table. For options common to most NDB Cluster programs (including **ndb_select_all**), see Section 18.4.29, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

**Table 18.320 Command-line options for the ndb_select_all program**

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--database=dbname, -d</td>
<td>Name of the database in which the table is found</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--parallelism=#, -p</td>
<td>Degree of parallelism</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--lock=#, -l</td>
<td>Lock type</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--order=index, -o</td>
<td>Sort resultset according to index whose name is supplied</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--descending, -z</td>
<td>Sort resultset in descending order (requires order flag)</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--header, -h</td>
<td>Print header (set to 0</td>
<td>FALSE to disable headers in output)</td>
</tr>
<tr>
<td>--useHexFormat, -x</td>
<td>Output numbers in hexadecimal format</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--delimiter=char, -D</td>
<td>Set a column delimiter</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--disk</td>
<td>Print disk references (useful only for Disk Data tables having nonindexed columns)</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--rowid</td>
<td>Print rowid</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--gci</td>
<td>Include GCI in output</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--gci64</td>
<td>Include GCI and row epoch in output</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--tupscan, -t</td>
<td>Scan in tup order</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--nodata</td>
<td>Do not print table column data</td>
<td>All MySQL 5.6 based releases</td>
</tr>
</tbody>
</table>

- **--database=dbname, -d dbname**
Name of the database in which the table is found. The default value is `TEST_DB`.

- `parallelism=#, -p #`
  Specifies the degree of parallelism.

- `--lock=lock_type, -l lock_type`
  Employs a lock when reading the table. Possible values for `lock_type` are:
  - 0: Read lock
  - 1: Read lock with hold
  - 2: Exclusive read lock
  There is no default value for this option.

- `--order=index_name, -o index_name`
  Orders the output according to the index named `index_name`.

  **Note**
  This is the name of an index, not of a column, and that the index must have been explicitly named when created.

- `--descending, -z`
  Sorts the output in descending order. This option can be used only in conjunction with the `-o (--order)` option.

- `--header=FALSE`
  Excludes column headers from the output.

- `--useHexFormat -x`
  Causes all numeric values to be displayed in hexadecimal format. This does not affect the output of numerals contained in strings or datetime values.

- `--delimiter=character, -D character`
  Causes the `character` to be used as a column delimiter. Only table data columns are separated by this delimiter.

  The default delimiter is the tab character.

- `--disk`
  Adds a disk reference column to the output. The column is nonempty only for Disk Data tables having nonindexed columns.

- `--rowid`
  Adds a ROWID column providing information about the fragments in which rows are stored.

- `--gci`
Adds a `GCI` column to the output showing the global checkpoint at which each row was last updated. See Section 18.1, “NDB Cluster Overview”, and Section 18.5.6.2, “NDB Cluster Log Events”, for more information about checkpoints.

- **--gci64**

  Adds a `ROW$GCI64` column to the output showing the global checkpoint at which each row was last updated, as well as the number of the epoch in which this update occurred.

- **--tupscan, -t**

  Scan the table in the order of the tuples.

- **--nodata**

  Causes any table data to be omitted.

**Sample Output**

Output from a MySQL `SELECT` statement:

```
mysql> SELECT * FROM ctest1.fish;
+----+-----------+
| id | name      |
+----+-----------+
|  3 | shark     |
|  6 | puffer    |
|  2 | tuna      |
|  4 | manta ray |
|  5 | grouper   |
|  1 | guppy     |
+----+-----------+
6 rows in set (0.04 sec)
```

Output from the equivalent invocation of `ndb_select_all`:

```
shell> ./ndb_select_all -c localhost fish -d ctest1
id      name
3       [shark]
6       [puffer]
2       [tuna]
4       [manta ray]
5       [grouper]
1       [guppy]
6 rows returned
NDBT_ProgramExit: 0 - OK
```

All string values are enclosed by square brackets (```...```)) in the output of `ndb_select_all`. Now consider the table created and populated as shown here:

```
CREATE TABLE dogs (  
  id INT(11) NOT NULL AUTO_INCREMENT,  
  name VARCHAR(25) NOT NULL,  
  breed VARCHAR(50) NOT NULL,  
  PRIMARY KEY pk (id),  
  KEY ix (name)  
)  
TABLESPACE ts STORAGE DISK
```
This demonstrates the use of several additional `ndb_select_all` options:

```
shell> .!/ndb_select_all -d ctest1 dogs -o ix -z --gci --disk
GCI     id name          breed        DISK_REF
834461  2  [Scooby-Doo]  [Great Dane] 
834878  4  [Rosscoe]     [Mutt]       
834463  3  [Rin-Tin-Tin] [Alsatian]   
835657  1  [Lassie]      [Collie]     
4 rows returned
NDBT_ProgramExit: 0 - OK
```

18.4.24 `ndb_select_count` — Print Row Counts for NDB Tables

`ndb_select_count` prints the number of rows in one or more NDB tables. With a single table, the result is equivalent to that obtained by using the MySQL statement `SELECT COUNT(*) FROM tbl_name`.

**Usage**

```
ndb_select_count [-c connection_string] -d db_name tbl_name[, tbl_name2[, ...]]
```

The following table includes options that are specific to the NDB Cluster native backup restoration program `ndb_select_count`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_select_count`), see Section 18.4.29, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

**Table 18.321 Command-line options for the `ndb_select_count` program**

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--database=dbname,</code></td>
<td>Name of the database in which the table is found</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td><code>-d</code></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--parallelism=#,</code></td>
<td>Degree of parallelism</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td><code>-p</code></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--lock=#,</code></td>
<td>Lock type</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td><code>-l</code></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

You can obtain row counts from multiple tables in the same database by listing the table names separated by spaces when invoking this command, as shown under **Sample Output**.

**Sample Output**

```
shell> .!/ndb_select_count -c localhost -d ctest1 fish dogs
6 records in table fish
4 records in table dogs
```
18.4.25 ndb_setup.py — Start browser-based Auto-Installer for NDB Cluster

ndb_setup.py starts the NDB Cluster Auto-Installer and opens the installer's Start page in the default Web browser.

Warning

This program is intended to be invoked as a normal user, and not with the mysql, system root, or other administrative account.

This section describes usage of and program options for the command-line tool only. For information about using the Auto-Installer GUI that is spawned when ndb_setup.py is invoked, see Section 18.2.1, “The NDB Cluster Auto-Installer”.

Usage

All platforms:

```
ndb_setup.py [options]
```

Additionally, on Windows platforms only:

```
setup.bat [options]
```

The following table includes all options that are supported by the NDB Cluster installation and configuration program ndb_setup.py. Additional descriptions follow the table.

Table 18.322 Command-line options for the ndb_setup.py program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--browser-start-page=filename, -s</td>
<td>Page that the web browser opens when starting.</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--ca-certs-file=filename, -a</td>
<td>File containing list of client certificates allowed to connect to the server</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--cert-file=filename, -c</td>
<td>File containing X509 certificate that identifies the server. (Default: cfg.pem)</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--debug-level=level, -d</td>
<td>Python logging module debug level. One of DEBUG, INFO, WARNING (default), ERROR, or CRITICAL.</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--help, -h</td>
<td>Print help message</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--key-file=file, --key-file=filename</td>
<td>Specify file containing private key (if not included in --cert-file)</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>Format</td>
<td>Description</td>
<td>Added, Deprecated, or Removed</td>
</tr>
<tr>
<td>---------------------------</td>
<td>-------------------------------------------------------</td>
<td>-------------------------------</td>
</tr>
<tr>
<td>--k</td>
<td>Do not open the start page in a browser, merely start the tool</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--no-browser,</td>
<td></td>
<td></td>
</tr>
<tr>
<td>-n</td>
<td>Specify the port used by the web server</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--port=#,</td>
<td></td>
<td></td>
</tr>
<tr>
<td>-p</td>
<td>Log requests to this file. Use '-' to force logging to stderr instead.</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--server-log-file=file,</td>
<td></td>
<td></td>
</tr>
<tr>
<td>o</td>
<td>The name of the server to connect with</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--server-name=name,</td>
<td></td>
<td></td>
</tr>
<tr>
<td>-N</td>
<td>Use encrypted (HTTPS) client/server connection</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--use-https,</td>
<td></td>
<td></td>
</tr>
<tr>
<td>-S</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- `--browser-start-page=filename, -s`  

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--browser-start-page=filename</code></td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>index.html</code></td>
</tr>
</tbody>
</table>

Specify the file to open in the browser as the installation and configuration Start page. The default is `index.html`.

- `--ca-certs-file=filename, -a`  

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--ca-certs-file=filename</code></td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>[none]</code></td>
</tr>
</tbody>
</table>

Specify a file containing a list of client certificates which are allowed to connect to the server. The default is an empty string, which means that no client authentication is used.

- `--cert-file=filename, -c`  

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--cert-file=filename</code></td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>/usr/share/mysql/mcc/cfg.pem</code></td>
</tr>
</tbody>
</table>

Specify a file containing an X.509 certificate which identifies the server. It is possible for the certificate to be self-signed. The default is `cfg.pem`.

- `--debug-level=level, -d`
### ndb_setup.py — Start browser-based Auto-Installer for NDB Cluster

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--debug-level=level</code></td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>WARNING</code></td>
</tr>
<tr>
<td>Valid Values</td>
<td><code>WARNING</code>, <code>DEBUG</code>, <code>INFO</code>, <code>ERROR</code>, <code>CRITICAL</code></td>
</tr>
</tbody>
</table>

Set the Python logging module debug level. This is one of `DEBUG`, `INFO`, `WARNING`, `ERROR`, or `CRITICAL`. `WARNING` is the default.

- `--help, -h`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--help</code></td>
</tr>
</tbody>
</table>

Print a help message.

- `--key-file=file, -d`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--key-file=file</code></td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>[none]</code></td>
</tr>
</tbody>
</table>

Specify a file containing the private key if this is not included in the X.509 certificate file (`--cert-file`). The default is an empty string, which means that no such file is used.

- `--no-browser, -n`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--no-browser</code></td>
</tr>
</tbody>
</table>

Start the installation and configuration tool, but do not open the Start page in a browser.

- `--port=#, -p`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--port=#</code></td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>8081</code></td>
</tr>
<tr>
<td>Minimum Value</td>
<td><code>1</code></td>
</tr>
<tr>
<td>Maximum Value</td>
<td><code>65535</code></td>
</tr>
</tbody>
</table>
Set the port used by the web server. The default is 8081.

- `--server-log-file=file`, `-o`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--server-log-file=file</code></td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>ndb_setup.log</code></td>
</tr>
<tr>
<td>Valid Values</td>
<td><code>ndb_setup.log</code></td>
</tr>
<tr>
<td></td>
<td>- (Log to stderr)</td>
</tr>
</tbody>
</table>

Log requests to this file. The default is `ndb_setup.log`. To specify logging to `stderr`, rather than to a file, use a `-` (dash character) for the file name.

- `--server-name=host`, `-N`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--server-name=name</code></td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>localhost</code></td>
</tr>
</tbody>
</table>

Specify the host name or IP address for the browser to use when connecting. The default is `localhost`.

- `--use-https`, `-S`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--use-https</code></td>
</tr>
</tbody>
</table>

Make the browser use a secure (HTTPS) connection with the server.

### 18.4.26 ndb_show_tables — Display List of NDB Tables

`ndb_show_tables` displays a list of all NDB database objects in the cluster. By default, this includes not only both user-created tables and NDB system tables, but NDB-specific indexes, internal triggers, and NDB Cluster Disk Data objects as well.

The following table includes options that are specific to the NDB Cluster native backup restoration program `ndb_show_tables`. Additional descriptions follow the table. For options common to most NDB Cluster programs (including `ndb_show_tables`), see Section 18.4.29, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

**Table 18.323 Command-line options for the ndb_show_tables program**

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--database=string</code>, <code>-d</code></td>
<td>Specifies the database in which the table is found</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td><code>--loops=#</code>, <code>-l</code></td>
<td>Number of times to repeat output</td>
<td>All MySQL 5.6 based releases</td>
</tr>
</tbody>
</table>
ndb_show_tables — Display List of NDB Tables

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--parsable, -p</td>
<td>Return output suitable for MySQL LOAD DATA INFILE statement</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--show-temp-status</td>
<td>Show table temporary flag</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--type=#, -t</td>
<td>Limit output to objects of this type</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--unqualified, -u</td>
<td>Do not qualify table names</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>-</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Usage

ndb_show_tables [-c connection_string]

- --database, -d
  Specifies the name of the database in which the tables are found. In NDB 7.4.8 and later, if this option has not been specified, and no tables are found in the TEST_DB database, ndb_show_tables issues a warning (Bug #50633, Bug #11758430).

- --loops, -l
  Specifies the number of times the utility should execute. This is 1 when this option is not specified, but if you do use the option, you must supply an integer argument for it.

- --parsable, -p
  Using this option causes the output to be in a format suitable for use with LOAD DATA.

- --show-temp-status
  If specified, this causes temporary tables to be displayed.

- --type, -t
  Can be used to restrict the output to one type of object, specified by an integer type code as shown here:
  - 1: System table
  - 2: User-created table
  - 3: Unique hash index
  Any other value causes all NDB database objects to be listed (the default).

- --unqualified, -u
  If specified, this causes unqualified object names to be displayed.

Note

Only user-created NDB Cluster tables may be accessed from MySQL; system tables such as SYSTAB_0 are not visible to mysqld. However, you can
examine the contents of system tables using NDB API applications such as
ndb_select_all (see Section 18.4.23, “ndb_select_all — Print Rows from
an NDB Table”).

18.4.27 ndb_size.pl — NDBCLUSTER Size Requirement Estimator

This is a Perl script that can be used to estimate the amount of space that would be required by a MySQL
database if it were converted to use the NDBCLUSTER storage engine. Unlike the other utilities discussed
in this section, it does not require access to an NDB Cluster (in fact, there is no reason for it to do so).
However, it does need to access the MySQL server on which the database to be tested resides.

Requirements

- A running MySQL server. The server instance does not have to provide support for NDB Cluster.
- A working installation of Perl.
- The DBI module, which can be obtained from CPAN if it is not already part of your Perl installation.
  (Many Linux and other operating system distributions provide their own packages for this library.)
- A MySQL user account having the necessary privileges. If you do not wish to use an existing account,
  then creating one using GRANT USAGE ON db_name.*—where db_name is the name of the database
to be examined—is sufficient for this purpose.

ndb_size.pl can also be found in the MySQL sources in storage/ndb/tools.

The following table includes options that are specific to the NDB Cluster program ndb_size.pl.
Additional descriptions follow the table. For options common to most NDB Cluster programs (including
ndb_size.pl), see Section 18.4.29, “Options Common to NDB Cluster Programs — Options Common to
NDB Cluster Programs”.

Table 18.324 Command-line options for the ndb_size.pl program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--database=dbname</td>
<td>The database or databases to examine; accepts a comma-delimited list; the default is ALL (use all databases found on the server)</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--hostname[:port]</td>
<td>Specify host and optional port as host[:port]</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--socket=file_name</td>
<td>Specify a socket to connect to</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--user=string</td>
<td>Specify a MySQL user name</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--password=string</td>
<td>Specify a MySQL user password</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--format=string</td>
<td>Set output format (text or HTML)</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--excludetables=tbl_list</td>
<td>Skip any tables in a comma-separated list of tables</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--excludedbs=db_list</td>
<td>Skip any databases in a comma-separated list of databases</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--savequeries=file</td>
<td>Saves all queries to the database into the file specified</td>
<td>All MySQL 5.6 based releases</td>
</tr>
</tbody>
</table>
Format | Description | Added, Deprecated, or Removed
--- | --- | ---
--loadqueries=file | Loads all queries from the file specified; does not connect to a database | All MySQL 5.6 based releases
--real_table_name=table | Designates a table to handle unique index size calculations | All MySQL 5.6 based releases

Usage

perl ndb_size.pl [--database={db_name|ALL}] [--hostname=host[:port]] [--socket=socket] \[--user=user] [--password=password] \[--help|-h] [--format={html|text}] \[--loadqueries=file_name] \[--savequeries=file_name]

By default, this utility attempts to analyze all databases on the server. You can specify a single database using the --database option; the default behavior can be made explicit by using ALL for the name of the database. You can also exclude one or more databases by using the --excludedbs option with a comma-separated list of the names of the databases to be skipped. Similarly, you can cause specific tables to be skipped by listing their names, separated by commas, following the optional --excludetables option. A host name can be specified using --hostname; the default is localhost. You can specify a port in addition to the host using host:port format for the value of --hostname. The default port number is 3306. If necessary, you can also specify a socket; the default is /var/lib/mysql.sock. A MySQL user name and password can be specified the corresponding options shown. It also possible to control the format of the output using the --format option; this can take either of the values html or text, with text being the default. An example of the text output is shown here:

shell> ndb_size.pl --database=test --socket=/tmp/mysql.sock
ndb_size.pl report for database: 'test' (1 tables)

</table>

Summary (for THIS table):
For debugging purposes, the Perl arrays containing the queries run by this script can be read from the file specified using can be saved to a file using `--savequeries`; a file containing such arrays to be read during script execution can be specified using `--loadqueries`. Neither of these options has a default value.

To produce output in HTML format, use the `--format` option and redirect the output to a file, as shown here:

```
shell> ndb_size.pl --database=test --socket=/tmp/mysql.sock --format=html > ndb_size.html
```

(Without the redirection, the output is sent to `stdout`.)

The output from this script includes the following information:

- Minimum values for the `DataMemory`, `IndexMemory`, `MaxNoOfTables`, `MaxNoOfAttributes`, `MaxNoOfOrderedIndexes`, `MaxNoOfUniqueHashIndexes`, and `MaxNoOfTriggers` configuration parameters required to accommodate the tables analyzed.

- Memory requirements for all of the tables, attributes, ordered indexes, and unique hash indexes defined in the database.

- The `IndexMemory` and `DataMemory` required per table and table row.

### 18.4.28 ndb_waiter — Wait for NDB Cluster to Reach a Given Status

`ndb_waiter` repeatedly (each 100 milliseconds) prints out the status of all cluster data nodes until either the cluster reaches a given status or the `--timeout` limit is exceeded, then exits. By default, it waits for the cluster to reach the status `Running`. You can specify a different status using `--targetstatus`. If the target status is not reached within the specified timeout period, the script exits with an error message.

Options:

- `--database` specifies the name of the database to analyze.
- `--socket` specifies the name of the socket to connect to.
- `--timeout` specifies the maximum time in milliseconds to wait for the target status to be reached.
- `--targetstatus` specifies the status to wait for. The default is `Running`.
- `--format` specifies the output format. The default is `text`.
- `--savequeries` specifies the name of the file to save the Perl arrays containing the queries run by this script.
- `--loadqueries` specifies the name of the file to load the Perl arrays containing the queries run by this script.

the cluster to achieve **STARTED** status, in which all nodes have started and connected to the cluster. This can be overridden using the **--no-contact** and **--not-started** options.

The node states reported by this utility are as follows:

* **NO_CONTACT**: The node cannot be contacted.
* **UNKNOWN**: The node can be contacted, but its status is not yet known. Usually, this means that the node has received a **START** or **RESTART** command from the management server, but has not yet acted on it.
* **NOT_STARTED**: The node has stopped, but remains in contact with the cluster. This is seen when restarting the node using the management client's **RESTART** command.
* **STARTING**: The node's ndbd process has started, but the node has not yet joined the cluster.
* **STARTED**: The node is operational, and has joined the cluster.
* **SHUTTING_DOWN**: The node is shutting down.
* **SINGLE_USER_MODE**: This is shown for all cluster data nodes when the cluster is in single user mode.

The following table includes options that are specific to the NDB Cluster native backup restoration program ndb_waiter. Additional descriptions follow the table. For options common to most NDB Cluster programs (including ndb_waiter), see Section 18.4.29, “Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs”.

### Table 18.325 Command-line options for the ndb_waiter program

<td>List of nodes not to be waited for.</td>
<td>All MySQL 5.6 based releases</td>
</tr>
<tr>
<td>--wait-nodes=list,</td>
<td>List of nodes to be waited for.</td>
<td>All MySQL 5.6 based releases</td>
</tr>
</tbody>
</table>

### Usage

```bash
ndb_waiter [-c connection_string]
```

### Additional Options

* **--no-contact, -n**

Instead of waiting for the **STARTED** state, `ndb_waiter` continues running until the cluster reaches **NO_CONTACT** status before exiting.
ndb_waiter — Wait for NDB Cluster to Reach a Given Status

- **--not-started**
  
  Instead of waiting for the **STARTED** state, **ndb_waiter** continues running until the cluster reaches **NOT_STARTED** status before exiting.

- **--timeout=seconds, -t seconds**
  
  Time to wait. The program exits if the desired state is not achieved within this number of seconds. The default is 120 seconds (1200 reporting cycles).

- **--single-user**
  
  The program waits for the cluster to enter single user mode.

- **--nowait-nodes=list**
  
  When this option is used, **ndb_waiter** does not wait for the nodes whose IDs are listed. The list is comma-delimited; ranges can be indicated by dashes, as shown here:

  ```
  shell> ndb_waiter --nowait-nodes=1,3,7-9
  ```

  **Important**

  Do **not** use this option together with the **--wait-nodes** option.

- **--wait-nodes=list, -w list**
  
  When this option is used, **ndb_waiter** waits only for the nodes whose IDs are listed. The list is comma-delimited; ranges can be indicated by dashes, as shown here:

  ```
  shell> ndb_waiter --wait-nodes=2,4-6,10
  ```

  **Important**

  Do **not** use this option together with the **--nowait-nodes** option.

**Sample Output.** Shown here is the output from **ndb_waiter** when run against a 4-node cluster in which two nodes have been shut down and then started again manually. Duplicate reports (indicated by ...) are omitted.

````
shell> ./ndb_waiter -c localhost

Connecting to mgmsrv at (localhost)

Note
If no connection string is specified, then ndb_waiter tries to connect to a management on localhost, and reports Connecting to mgmsrv at (null).

18.4.29 Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs

All NDB Cluster programs accept the options described in this section, with the following exceptions:

• mysqld
• ndb_print_backup_file
• ndb_print_schema_file
• ndb_print_sys_file

Note
Users of earlier NDB Cluster versions should note that some of these options have been changed to make them consistent with one another, and also with mysqld. You can use the --help option with any NDB Cluster program—with
The options in the following table are common to all NDB Cluster executables (except those noted previously in this section).

**Table 18.326 Command-line options common to all MySQL NDB Cluster programs**

<th>Added, Deprecated, or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--version, -V</td>
<td>Output version information and exit</td>
<td>All MySQL 5.6 based releases</td>
</tr>
</tbody>
</table>

For options specific to individual NDB Cluster programs, see Section 18.4, "NDB Cluster Programs".

See MySQL Server Options for NDB Cluster, for mysqld options relating to NDB Cluster.

- **--character-sets-dir=**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--character-sets-dir=dir_name</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
</tbody>
</table>

Tells the program where to find character set information.

- **--connect-retries=#**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--connect-retries=#</td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.28-ndb-7.4.9</td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>12</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

This option specifies the number of times following the first attempt to retry a connection before giving up (the client always tries the connection at least once). The length of time to wait per attempt is set using --connect-retry-delay.

Note

When used with ndb_mgm, this option has 3 as its default. See Section 18.4.5, "ndb_mgm — The NDB Cluster Management Client", for more information.

This option was added in NDB 7.4.9.

- **--connect-retry-delay=#**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--connect-retry-delay=#</td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.28-ndb-7.4.9</td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>5</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>
This option specifies the length of time to wait per attempt a connection before giving up. The number of times to try connecting is set by `--connect-retries`.

This option was added in NDB 7.4.9.

- **`--core-file`**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--core-file</code></td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Write a core file if the program dies. The name and location of the core file are system-dependent. (For NDB Cluster programs nodes running on Linux, the default location is the program's working directory—for a data node, this is the node's `DataDir`.) For some systems, there may be restrictions or limitations. For example, it might be necessary to execute `ulimit -c unlimited` before starting the server. Consult your system documentation for detailed information.

If NDB Cluster was built using the `--debug` option for `configure`, then `--core-file` is enabled by default. For regular builds, `--core-file` is disabled by default.

- **`--debug[=options]`**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--debug=options</code></td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>d:t:O,/tmp/ndb_restore.trace</code></td>
</tr>
</tbody>
</table>

This option can be used only for versions compiled with debugging enabled. It is used to enable output from debug calls in the same manner as for the `mysqld` process.

- **`--defaults-extra-file=filename`**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--defaults-extra-file=filename</code></td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>[none]</code></td>
</tr>
</tbody>
</table>

Read this file after global option files are read.

For additional information about this and other option-file options, see Section 4.2.2.3, "Command-Line Options that Affect Option-File Handling".

- **`--defaults-file=filename`**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--defaults-file=filename</code></td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>[none]</code></td>
</tr>
</tbody>
</table>
Read default options from this file.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--defaults-group-suffix**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--defaults-group-suffix</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Also read groups with names ending in this suffix.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--help, --usage, -?**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--help</td>
</tr>
<tr>
<td></td>
<td>--usage</td>
</tr>
</tbody>
</table>

Prints a short list with descriptions of the available command options.

- **--login-path=path**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--login-path=path</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>[none]</td>
</tr>
</tbody>
</table>

Read this path from the login file.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--ndb-connectstring=connection_string, --connect-string=connection_string, -c connection_string**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--ndb-connectstring=connectstring</td>
</tr>
<tr>
<td></td>
<td>--connect-string=connectstring</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>localhost:1186</td>
</tr>
</tbody>
</table>

This option takes an NDB Cluster connection string that specifies the management server for the application to connect to, as shown here:
Options Common to NDB Cluster Programs — Options Common to NDB Cluster Programs

shell> ndbd --ndb-connectstring="nodeid=2;host=ndb_mgmd.mysql.com:1186"

For more information, see Section 18.3.3.3, “NDB Cluster Connection Strings”.

- **--ndb-mgmd-host=host[:port]**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--ndb-mgmd-host=host[:port]</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>localhost:1186</td>
</tr>
</tbody>
</table>

Can be used to set the host and port number of a single management server for the program to connect to. If the program requires node IDs or references to multiple management servers (or both) in its connection information, use the **--ndb-connectstring** option instead.

- **--ndb-nodeid=#**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--ndb-nodeid=#</td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
</tbody>
</table>

Sets this node’s NDB Cluster node ID. The range of permitted values depends on the node’s type (data, management, or API) and the NDB Cluster software version. See Section 18.1.7.2, “Limits and Differences of NDB Cluster from Standard MySQL Limits”, for more information.

- **--no-defaults**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--no-defaults</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

Do not read default options from any option file other than login file.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- **--ndb-optimized-node-selection**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--ndb-optimized-node-selection</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

Optimize selection of nodes for transactions. Enabled by default.

- **--print-defaults**
### Property | Value
---|---
**Command-Line Format** | `--print-defaults`
**Type** | Boolean
**Default Value** | TRUE

Print the program argument list and exit.

For additional information about this and other option-file options, see Section 4.2.2.3, “Command-Line Options that Affect Option-File Handling”.

- `--version`, `-V`

### Property | Value
---|---
**Command-Line Format** | `--version`

Prints the NDB Cluster version number of the executable. The version number is relevant because not all versions can be used together, and the NDB Cluster startup process verifies that the versions of the binaries being used can co-exist in the same cluster. This is also important when performing an online (rolling) software upgrade or downgrade of NDB Cluster.

See Section 18.5.5, “Performing a Rolling Restart of an NDB Cluster”), for more information.

### 18.5 Management of NDB Cluster

Managing an NDB Cluster involves a number of tasks, the first of which is to configure and start NDB Cluster. This is covered in Section 18.3, “Configuration of NDB Cluster”, and Section 18.4, “NDB Cluster Programs”.

The next few sections cover the management of a running NDB Cluster.

For information about security issues relating to management and deployment of an NDB Cluster, see Section 18.5.11, “NDB Cluster Security Issues”.

There are essentially two methods of actively managing a running NDB Cluster. The first of these is through the use of commands entered into the management client whereby cluster status can be checked, log levels changed, backups started and stopped, and nodes stopped and started. The second method involves studying the contents of the cluster log `ndb_node_id_cluster.log`; this is usually found in the management server's `DataDir` directory, but this location can be overridden using the `LogDestination` option. (Recall that `node_id` represents the unique identifier of the node whose activity is being logged.) The cluster log contains event reports generated by `ndbd`. It is also possible to send cluster log entries to a Unix system log.

Some aspects of the cluster's operation can be also be monitored from an SQL node using the `SHOW ENGINE NDB STATUS` statement.

More detailed information about NDB Cluster operations is available in real time through an SQL interface using the `ndbinfo` database. For more information, see Section 18.5.10, “ndbinfo: The NDB Cluster Information Database”.

NDB statistics counters provide improved monitoring using the `mysql` client. These counters, implemented in the NDB kernel, relate to operations performed by or affecting `Ndb` objects, such as starting, closing, and aborting transactions; primary key and unique key operations; table, range, and pruned scans; blocked
threads waiting for various operations to complete; and data and events sent and received by NDB Cluster. The counters are incremented by the NDB kernel whenever NDB API calls are made or data is sent to or received by the data nodes.

\texttt{mysqld} exposes the NDB API statistics counters as system status variables, which can be identified from the prefix common to all of their names (\texttt{Ndb\_api\_}). The values of these variables can be read in the \texttt{mysql} client from the output of a \texttt{SHOW\_STATUS} statement, or by querying either the \texttt{SESSION\_STATUS} table or the \texttt{GLOBAL\_STATUS} table (in the \texttt{INFORMATION\_SCHEMA} database). By comparing the values of the status variables before and after the execution of an SQL statement that acts on NDB tables, you can observe the actions taken on the NDB API level that correspond to this statement, which can be beneficial for monitoring and performance tuning of NDB Cluster.

MySQL Cluster Manager provides an advanced command-line interface that simplifies many otherwise complex NDB Cluster management tasks, such as starting, stopping, or restarting an NDB Cluster with a large number of nodes. The MySQL Cluster Manager client also supports commands for getting and setting the values of most node configuration parameters as well as \texttt{mysqld} server options and variables relating to NDB Cluster. See MySQL™ Cluster Manager 1.4.7 User Manual, for more information.

### 18.5.1 Summary of NDB Cluster Start Phases

This section provides a simplified outline of the steps involved when NDB Cluster data nodes are started. More complete information can be found in NDB Cluster Start Phases, in the NDB Internals Guide.

These phases are the same as those reported in the output from the \texttt{node\_id\_STATUS} command in the management client (see Section 18.5.2, “Commands in the NDB Cluster Management Client”). These start phases are also reported in the \texttt{start\_phase} column of the \texttt{ndbinfo\_nodes} table.

**Start types.** There are several different startup types and modes, as shown in the following list:

- **Initial start.** The cluster starts with a clean file system on all data nodes. This occurs either when the cluster started for the very first time, or when all data nodes are restarted using the --initial option.

  \begin{itemize}
    \item\textbf{Note}\hfill Disk Data files are not removed when restarting a node using --initial.
  \end{itemize}

- **System restart.** The cluster starts and reads data stored in the data nodes. This occurs when the cluster has been shut down after having been in use, when it is desired for the cluster to resume operations from the point where it left off.

- **Node restart.** This is the online restart of a cluster node while the cluster itself is running.

- **Initial node restart.** This is the same as a node restart, except that the node is reinitialized and started with a clean file system.

**Setup and initialization (phase -1).** Prior to startup, each data node (\texttt{ndbd} process) must be initialized. Initialization consists of the following steps:

1. Obtain a node ID
2. Fetch configuration data
3. Allocate ports to be used for inter-node communications
4. Allocate memory according to settings obtained from the configuration file
When a data node or SQL node first connects to the management node, it reserves a cluster node ID. To make sure that no other node allocates the same node ID, this ID is retained until the node has managed to connect to the cluster and at least one ndbd reports that this node is connected. This retention of the node ID is guarded by the connection between the node in question and ndb_mgmd.

After each data node has been initialized, the cluster startup process can proceed. The stages which the cluster goes through during this process are listed here:

• **Phase 0.** The NDBFS and NDBCNTR blocks start (see NDB Kernel Blocks). Data node file systems are cleared on those data nodes that were started with --initial option.

• **Phase 1.** In this stage, all remaining NDB kernel blocks are started. NDB Cluster connections are set up, inter-block communications are established, and heartbeats are started. In the case of a node restart, API node connections are also checked.

  **Note**

  When one or more nodes hang in Phase 1 while the remaining node or nodes hang in Phase 2, this often indicates network problems. One possible cause of such issues is one or more cluster hosts having multiple network interfaces. Another common source of problems causing this condition is the blocking of TCP/IP ports needed for communications between cluster nodes. In the latter case, this is often due to a misconfigured firewall.

• **Phase 2.** The NDBCNTR kernel block checks the states of all existing nodes. The master node is chosen, and the cluster schema file is initialized.

• **Phase 3.** The DBLQH and DBTC kernel blocks set up communications between them. The startup type is determined; if this is a restart, the DBDIH block obtains permission to perform the restart.

• **Phase 4.** For an initial start or initial node restart, the redo log files are created. The number of these files is equal to NoOfFragmentLogFiles.

  For a system restart:
  - Read schema or schemas.
  - Read data from the local checkpoint.
  - Apply all redo information until the latest restorable global checkpoint has been reached.

  For a node restart, find the tail of the redo log.

• **Phase 5.** Most of the database-related portion of a data node start is performed during this phase. For an initial start or system restart, a local checkpoint is executed, followed by a global checkpoint. Periodic checks of memory usage begin during this phase, and any required node takeovers are performed.

• **Phase 6.** In this phase, node groups are defined and set up.

• **Phase 7.** The arbitrator node is selected and begins to function. The next backup ID is set, as is the backup disk write speed. Nodes reaching this start phase are marked as Started. It is now possible for API nodes (including SQL nodes) to connect to the cluster.

• **Phase 8.** If this is a system restart, all indexes are rebuilt (by DBDIH).

• **Phase 9.** The node internal startup variables are reset.

• **Phase 100 (OBsolete).** Formerly, it was at this point during a node restart or initial node restart that API nodes could connect to the node and begin to receive events. Currently, this phase is empty.
• **Phase 101.** At this point in a node restart or initial node restart, event delivery is handed over to the node joining the cluster. The newly-joined node takes over responsibility for delivering its primary data to subscribers. This phase is also referred to as *SUMA handover phase.*

After this process is completed for an initial start or system restart, transaction handling is enabled. For a node restart or initial node restart, completion of the startup process means that the node may now act as a transaction coordinator.

### 18.5.2 Commands in the NDB Cluster Management Client

In addition to the central configuration file, a cluster may also be controlled through a command-line interface available through the management client `ndb_mgm`. This is the primary administrative interface to a running cluster.

Commands for the event logs are given in [Section 18.5.6, “Event Reports Generated in NDB Cluster”](#); commands for creating backups and restoring from them are provided in [Section 18.5.3, “Online Backup of NDB Cluster”](#).

**Using ndb_mgm with MySQL Cluster Manager.** MySQL Cluster Manager handles starting and stopping processes and tracks their states internally, so it is not necessary to use `ndb_mgm` for these tasks for an NDB Cluster that is under MySQL Cluster Manager control. It is recommended not to use the `ndb_mgm` command-line client that comes with the NDB Cluster distribution to perform operations that involve starting or stopping nodes. These include but are not limited to the `START`, `STOP`, `RESTART`, and `SHUTDOWN` commands. For more information, see [MySQL Cluster Manager Process Commands](#).

The management client has the following basic commands. In the listing that follows, `node_id` denotes either a data node ID or the keyword `ALL`, which indicates that the command should be applied to all of the cluster’s data nodes.

- **HELP**
  Displays information on all available commands.

- **CONNECT connection-string**
  Connects to the management server indicated by the connection string. If the client is already connected to this server, the client reconnects.

- **SHOW**
  Displays information on the cluster’s status. Possible node status values include `UNKNOWN`, `NO_CONTACT`, `NOT_STARTED`, `STARTING`, `STARTED`, `SHUTTING_DOWN`, and `RESTARTING`. The output from this command also indicates when the cluster is in single user mode (status `SINGLE USER MODE`).

- **node_id** **START**
  Brings online the data node identified by `node_id` (or all data nodes).
  `ALL START` works on all data nodes only, and does not affect management nodes.

  **Important**
  To use this command to bring a data node online, the data node must have been started using `--nostart` or `-n`.

- **node_id** **STOP** **[-a]** **[-f]**
  Stops the data or management node identified by `node_id`. 

---

2938
Commands in the NDB Cluster Management Client

Note

ALL STOP works to stop all data nodes only, and does not affect management nodes.

A node affected by this command disconnects from the cluster, and its associated ndbd or ndb_mgmd process terminates.

The -a option causes the node to be stopped immediately, without waiting for the completion of any pending transactions.

Normally, STOP fails if the result would cause an incomplete cluster. The -f option forces the node to shut down without checking for this. If this option is used and the result is an incomplete cluster, the cluster immediately shuts down.

Warning

Use of the -a option also disables the safety check otherwise performed when STOP is invoked to insure that stopping the node does not cause an incomplete cluster. In other words, you should exercise extreme care when using the -a option with the STOP command, due to the fact that this option makes it possible for the cluster to undergo a forced shutdown because it no longer has a complete copy of all data stored in NDB.

• node_id RESTART [-n] [-i] [-a] [-f]

Restarts the data node identified by node_id (or all data nodes).

Using the -i option with RESTART causes the data node to perform an initial restart; that is, the node's file system is deleted and recreated. The effect is the same as that obtained from stopping the data node process and then starting it again using ndbd --initial from the system shell.

Note

Backup files and Disk Data files are not removed when this option is used.

Using the -n option causes the data node process to be restarted, but the data node is not actually brought online until the appropriate START command is issued. The effect of this option is the same as that obtained from stopping the data node and then starting it again using ndbd --nostart or ndbd -n from the system shell.

Using the -a causes all current transactions relying on this node to be aborted. No GCP check is done when the node rejoins the cluster.

Normally, RESTART fails if taking the node offline would result in an incomplete cluster. The -f option forces the node to restart without checking for this. If this option is used and the result is an incomplete cluster, the entire cluster is restarted.

• node_id STATUS

Displays status information for the data node identified by node_id (or for all data nodes).

The output from this command also indicates when the cluster is in single user mode.

• node_id REPORT report-type
Displays a report of type `report-type` for the data node identified by `node_id`, or for all data nodes using `ALL`.

Currently, there are three accepted values for `report-type`:

- **BackupStatus** provides a status report on a cluster backup in progress
- **MemoryUsage** displays how much data memory and index memory is being used by each data node as shown in this example:

```
ndb_mgm> ALL REPORT MEMORY
Node 1: Data usage is 5%(177 32K pages of total 3200)
Node 1: Index usage is 0%(108 8K pages of total 12832)
Node 2: Data usage is 5%(177 32K pages of total 3200)
Node 2: Index usage is 0%(108 8K pages of total 12832)
```

This information is also available from the `ndbinfo.memoryusage` table.

- **EventLog** reports events from the event log buffers of one or more data nodes.

  `report-type` is case-insensitive and “fuzzy”; for `MemoryUsage`, you can use `MEMORY` (as shown in the prior example), `memory`, or even simply `MEM` (or `mem`). You can abbreviate `BackupStatus` in a similar fashion.

- **ENTER SINGLE USER MODE node_id**

  Enters single user mode, whereby only the MySQL server identified by the node ID `node_id` is permitted to access the database.

- **EXIT SINGLE USER MODE**

  Exits single user mode, enabling all SQL nodes (that is, all running `mysqld` processes) to access the database.

  **Note**

  It is possible to use `EXIT SINGLE USER MODE` even when not in single user mode, although the command has no effect in this case.

- **QUIT, EXIT**

  Terminates the management client.

  This command does not affect any nodes connected to the cluster.

- **SHUTDOWN**

  Shuts down all cluster data nodes and management nodes. To exit the management client after this has been done, use `EXIT` or `QUIT`.

  This command does not shut down any SQL nodes or API nodes that are connected to the cluster.

- **CREATE NODEGROUP nodeid[, nodeid, ...]**

  Creates a new NDB Cluster node group and causes data nodes to join it.
This command is used after adding new data nodes online to an NDB Cluster, and causes them to join a new node group and thus to begin participating fully in the cluster. The command takes as its sole parameter a comma-separated list of node IDs—these are the IDs of the nodes just added and started that are to join the new node group. The number of nodes must be the same as the number of nodes in each node group that is already part of the cluster (each NDB Cluster node group must have the same number of nodes). In other words, if the NDB Cluster has 2 node groups of 2 data nodes each, then the new node group must also have 2 data nodes.

The node group ID of the new node group created by this command is determined automatically, and always the next highest unused node group ID in the cluster; it is not possible to set it manually.

For more information, see Section 18.5.14, “Adding NDB Cluster Data Nodes Online”.

- **DROP NODEGROUP nodegroup_id**

  Drops the NDB Cluster node group with the given `nodegroup_id`.

  This command can be used to drop a node group from an NDB Cluster. **DROP NODEGROUP** takes as its sole argument the node group ID of the node group to be dropped.

  **DROP NODEGROUP** acts only to remove the data nodes in the effected node group from that node group. It does not stop data nodes, assign them to a different node group, or remove them from the cluster’s configuration. A data node that does not belong to a node group is indicated in the output of the management client **SHOW** command with **no nodegroup** in place of the node group ID, like this (indicated using bold text):

  ```
  id=3    @10.100.2.67  (5.6.45-ndb-7.4.25, no nodegroup)
  ```

  Prior to NDB 7.0.4, the **SHOW** output was not updated correctly following **DROP NODEGROUP**. (Bug #43413)

  **DROP NODEGROUP** works only when all data nodes in the node group to be dropped are completely empty of any table data and table definitions. Since there is currently no way using **ndb_mgm** or the **mysql** client to remove all data from a specific data node or node group, this means that the command succeeds only in the two following cases:

  1. After issuing **CREATE NODEGROUP** in the **ndb_mgm** client, but before issuing any **ALTER ONLINE TABLE ... REORGANIZE PARTITION** statements in the **mysql** client.

  2. After dropping all **NDBCLUSTER** tables using **DROP TABLE**.

    **TRUNCATE TABLE** does not work for this purpose because this removes only the table data; the data nodes continue to store an **NDBCLUSTER** table’s definition until a **DROP TABLE** statement is issued that causes the table metadata to be dropped.

    For more information about **DROP NODEGROUP**, see Section 18.5.14, “Adding NDB Cluster Data Nodes Online”.

**Additional commands.** A number of other commands available in the **ndb_mgm** client are described elsewhere, as shown in the following list:

- **START BACKUP** is used to perform an online backup in the **ndb_mgm** client; the **ABORT BACKUP** command is used to cancel a backup already in progress. For more information, see Section 18.5.3, “Online Backup of NDB Cluster”.

2941
Online Backup of NDB Cluster

• The \texttt{CLUSTERLOG} command is used to perform various logging functions. See Section 18.5.6, “Event Reports Generated in NDB Cluster”, for more information and examples.

• For testing and diagnostics work, the client also supports a \texttt{DUMP} command which can be used to execute internal commands on the cluster. It should never be used in a production setting unless directed to do so by MySQL Support. For more information, see MySQL NDB Cluster Internals Manual.

18.5.3 Online Backup of NDB Cluster

The next few sections describe how to prepare for and then to create an NDB Cluster backup using the functionality for this purpose found in the \texttt{ndb_mgm} management client. To distinguish this type of backup from a backup made using \texttt{mysqldump}, we sometimes refer to it as a “native” NDB Cluster backup. (For information about the creation of backups with \texttt{mysqldump}, see Section 4.5.4, ”\texttt{mysqldump} — A Database Backup Program“.) Restoration of NDB Cluster backups is done using the \texttt{ndb_restore} utility provided with the NDB Cluster distribution; for information about \texttt{ndb_restore} and its use in restoring NDB Cluster backups, see Section 18.4.22, ”\texttt{ndb_restore} — Restore an NDB Cluster Backup“.

18.5.3.1 NDB Cluster Backup Concepts

A backup is a snapshot of the database at a given time. The backup consists of three main parts:

• \textbf{Metadata.} The names and definitions of all database tables

• \textbf{Table records.} The data actually stored in the database tables at the time that the backup was made

• \textbf{Transaction log.} A sequential record telling how and when data was stored in the database

Each of these parts is saved on all nodes participating in the backup. During backup, each node saves these three parts into three files on disk:

• \texttt{BACKUP-backup_id.node_id.ctl}

  A control file containing control information and metadata. Each node saves the same table definitions (for all tables in the cluster) to its own version of this file.

• \texttt{BACKUP-backup_id-0.node_id.data}

  A data file containing the table records, which are saved on a per-fragment basis. That is, different nodes save different fragments during the backup. The file saved by each node starts with a header that states the tables to which the records belong. Following the list of records there is a footer containing a checksum for all records.

• \texttt{BACKUP-backup_id.node_id.log}

  A log file containing records of committed transactions. Only transactions on tables stored in the backup are stored in the log. Nodes involved in the backup save different records because different nodes host different database fragments.

  In the listing just shown, \texttt{backup_id} stands for the backup identifier and \texttt{node_id} is the unique identifier for the node creating the file.

  The location of the backup files is determined by the \texttt{BackupDataDir} parameter.

18.5.3.2 Using The NDB Cluster Management Client to Create a Backup

Before starting a backup, make sure that the cluster is properly configured for performing one. (See Section 18.5.3.3, “Configuration for NDB Cluster Backups”.)
The `START BACKUP` command is used to create a backup:

```
START BACKUP [backup_id] [wait_option] [snapshot_option]
```

**wait_option:**
WAIT (STARTED | COMPLETED) | NOWAIT

**snapshot_option:**
SNAPSHOTSTART | SNAPSHOTEND

Successive backups are automatically identified sequentially, so the `backup_id`, an integer greater than or equal to 1, is optional; if it is omitted, the next available value is used. If an existing `backup_id` value is used, the backup fails with the error `Backup failed: file already exists`. If used, the `backup_id` must follow `START BACKUP` immediately, before any other options are used.

The `wait_option` can be used to determine when control is returned to the management client after a `START BACKUP` command is issued, as shown in the following list:

- If `NOWAIT` is specified, the management client displays a prompt immediately, as seen here:

  ```
  ndb_mgm> START BACKUP NOWAIT
  ndb_mgm>
  ```

  In this case, the management client can be used even while it prints progress information from the backup process.

- With `WAIT STARTED` the management client waits until the backup has started before returning control to the user, as shown here:

  ```
  ndb_mgm> START BACKUP WAIT STARTED
  Waiting for started, this may take several minutes
  Node 2: Backup 3 started from node 1
  ndb_mgm>
  ```

- `WAIT COMPLETED` causes the management client to wait until the backup process is complete before returning control to the user.

  `WAIT COMPLETED` is the default.

A `snapshot_option` can be used to determine whether the backup matches the state of the cluster when `START BACKUP` was issued, or when it was completed. `SNAPSHOTSTART` causes the backup to match the state of the cluster when the backup began; `SNAPSHOTEND` causes the backup to reflect the state of the cluster when the backup was finished. `SNAPSHOTEND` is the default, and matches the behavior found in previous NDB Cluster releases.

**Note**

If you use the `SNAPSHOTSTART` option with `START BACKUP`, and the `CompressedBackup` parameter is enabled, only the data and control files are compressed—the log file is not compressed.

If both a `wait_option` and a `snapshot_option` are used, they may be specified in either order. For example, all of the following commands are valid, assuming that there is no existing backup having 4 as its ID:

```
START BACKUP WAIT STARTED SNAPSHOTSTART
```
The procedure for creating a backup consists of the following steps:

1. Start the management client (ndb_mgm), if it not running already.

2. Execute the **START BACKUP** command. This produces several lines of output indicating the progress of the backup, as shown here:

   
   ```
   ndb_mgm> START BACKUP
   Waiting for completed, this may take several minutes
   Node 2: Backup 1 started from node 1
   Node 2: Backup 1 started from node 1 completed
   StartGCP: 177 StopGCP: 180
   #Records: 7362 #LogRecords: 0
   Data: 453648 bytes Log: 0 bytes
   ndb_mgm>
   ```

3. When the backup has started the management client displays this message:

   ```
   Backup backup_id started from node node_id
   ```

   *backup_id* is the unique identifier for this particular backup. This identifier is saved in the cluster log, if it has not been configured otherwise. *node_id* is the identifier of the management server that is coordinating the backup with the data nodes. At this point in the backup process the cluster has received and processed the backup request. It does not mean that the backup has finished. An example of this statement is shown here:

   ```
   Node 2: Backup 1 started from node 1
   ```

4. The management client indicates with a message like this one that the backup has started:

   ```
   Backup backup_id started from node node_id completed
   ```

   As is the case for the notification that the backup has started, *backup_id* is the unique identifier for this particular backup, and *node_id* is the node ID of the management server that is coordinating the backup with the data nodes. This output is accompanied by additional information including relevant global checkpoints, the number of records backed up, and the size of the data, as shown here:

   ```
   Node 2: Backup 1 started from node 1 completed
   StartGCP: 177 StopGCP: 180
   #Records: 7362 #LogRecords: 0
   Data: 453648 bytes Log: 0 bytes
   ```

   It is also possible to perform a backup from the system shell by invoking ndb_mgm with the **-e** or **--execute** option, as shown in this example:

   ```
   shell> ndb_mgm -e "START BACKUP 6 WAIT COMPLETED SNAPSHOTSTART"
   ```

   When using **START BACKUP** in this way, you must specify the backup ID.

   Cluster backups are created by default in the **BACKUP** subdirectory of the **DataDir** on each data node. This can be overridden for one or more data nodes individually, or for all cluster data nodes in the
config.ini file using the BackupDataDir configuration parameter. The backup files created for a backup with a given backup_id are stored in a subdirectory named BACKUP-backup_id in the backup directory.

**Cancelling backups.** To cancel or abort a backup that is already in progress, perform the following steps:

1. Start the management client.

2. Execute this command:

   ```
   ndb_mgm> ABORT BACKUP backup_id
   ```

   The number backup_id is the identifier of the backup that was included in the response of the management client when the backup was started (in the message Backup backup_id started from node management_node_id).

3. The management client will acknowledge the abort request with Abort of backup backup_id ordered.

   **Note**
   At this point, the management client has not yet received a response from the cluster data nodes to this request, and the backup has not yet actually been aborted.

4. After the backup has been aborted, the management client will report this fact in a manner similar to what is shown here:

   ```
   Node 1: Backup 3 started from 5 has been aborted.
   Error: 1321 - Backup aborted by user request: Permanent error: User defined error
   Node 3: Backup 3 started from 5 has been aborted.
   Error: 1323 - 1323: Permanent error: Internal error
   Node 2: Backup 3 started from 5 has been aborted.
   Error: 1323 - 1323: Permanent error: Internal error
   Node 4: Backup 3 started from 5 has been aborted.
   Error: 1323 - 1323: Permanent error: Internal error
   ```

   In this example, we have shown sample output for a cluster with 4 data nodes, where the sequence number of the backup to be aborted is 3, and the management node to which the cluster management client is connected has the node ID 5. The first node to complete its part in aborting the backup reports that the reason for the abort was due to a request by the user. (The remaining nodes report that the backup was aborted due to an unspecified internal error.)

   **Note**
   There is no guarantee that the cluster nodes respond to an ABORT BACKUP command in any particular order.

   The Backup backup_id started from node management_node_id has been aborted messages mean that the backup has been terminated and that all files relating to this backup have been removed from the cluster file system.

   It is also possible to abort a backup in progress from a system shell using this command:

   ```
   shell> ndb_mgm -e "ABORT BACKUP backup_id"
   ```
18.5.3.3 Configuration for NDB Cluster Backups

Five configuration parameters are essential for backup:

- **BackupDataBufferSize**
  The amount of memory used to buffer data before it is written to disk.

- **BackupLogBufferSize**
  The amount of memory used to buffer log records before these are written to disk.

- **BackupMemory**
  The total memory allocated in a data node for backups. This should be the sum of the memory allocated for the backup data buffer and the backup log buffer.

- **BackupWriteSize**
  The default size of blocks written to disk. This applies for both the backup data buffer and the backup log buffer.

- **BackupMaxWriteSize**
  The maximum size of blocks written to disk. This applies for both the backup data buffer and the backup log buffer.

More detailed information about these parameters can be found in Backup Parameters.

You can also set a location for the backup files using the `BackupDataDir` configuration parameter. The default is `FileSystemPath /BACKUP/BACKUP-backup_id`.

18.5.3.4 NDB Cluster Backup Troubleshooting

If an error code is returned when issuing a backup request, the most likely cause is insufficient memory or disk space. You should check that there is enough memory allocated for the backup.

**Important**

If you have set `BackupDataBufferSize` and `BackupLogBufferSize` and their sum is greater than 4MB, then you must also set `BackupMemory` as well.

You should also make sure that there is sufficient space on the hard drive partition of the backup target.

**NDB** does not support repeatable reads, which can cause problems with the restoration process. Although the backup process is “hot”, restoring an NDB Cluster from backup is not a 100% “hot” process. This is due to the fact that, for the duration of the restore process, running transactions get nonrepeatable reads from the restored data. This means that the state of the data is inconsistent while the restore is in progress.

18.5.4 MySQL Server Usage for NDB Cluster
**MySQL Server Usage for NDB Cluster**

`mysqld` is the traditional MySQL server process. To be used with NDB Cluster, `mysqld` needs to be built with support for the NDB storage engine, as it is in the precompiled binaries available from [https://dev.mysql.com/downloads/](https://dev.mysql.com/downloads/). If you build MySQL from source, you must invoke `CMake` with the `-DWITH_NDBCLUSTER=1` option to include support for NDB.

For more information about compiling NDB Cluster from source, see Section 18.2.2.4, “Building NDB Cluster from Source on Linux”, and Section 18.2.3.2, “Compiling and Installing NDB Cluster from Source on Windows”.

(For information about `mysqld` options and variables, in addition to those discussed in this section, which are relevant to NDB Cluster, see Section 18.3.3.8, “MySQL Server Options and Variables for NDB Cluster”.)

If the `mysqld` binary has been built with Cluster support, the NDBCLUSTER storage engine is still disabled by default. You can use either of two possible options to enable this engine:

- Use `--ndbcluster` as a startup option on the command line when starting `mysqld`.
- Insert a line containing `ndbcluster` in the `[mysqld]` section of your `my.cnf` file.

An easy way to verify that your server is running with the NDBCLUSTER storage engine enabled is to issue the `SHOW ENGINES` statement in the MySQL Monitor (`mysql`). You should see the value `YES` as the `Support` value in the row for `NDBCLUSTER`. If you see `NO` in this row or if there is no such row displayed in the output, you are not running an NDB-enabled version of MySQL. If you see `DISABLED` in this row, you need to enable it in either one of the two ways just described.

To read cluster configuration data, the MySQL server requires at a minimum three pieces of information:

- The MySQL server’s own cluster node ID
- The host name or IP address for the management server (MGM node)
- The number of the TCP/IP port on which it can connect to the management server

Node IDs can be allocated dynamically, so it is not strictly necessary to specify them explicitly.

The `mysqld` parameter `ndb-connectstring` is used to specify the connection string either on the command line when starting `mysqld` or in `my.cnf`. The connection string contains the host name or IP address where the management server can be found, as well as the TCP/IP port it uses.

In the following example, `ndb_mgmd.mysql.com` is the host where the management server resides, and the management server listens for cluster messages on port 1186:

```
shell> mysqld --ndbcluster --ndb-connectstring=ndb_mgmd.mysql.com:1186
```

See Section 18.3.3.3, “NDB Cluster Connection Strings”, for more information on connection strings.

Given this information, the MySQL server will be a full participant in the cluster. (We often refer to a `mysqld` process running in this manner as an SQL node.) It will be fully aware of all cluster data nodes as well as their status, and will establish connections to all data nodes. In this case, it is able to use any data node as a transaction coordinator and to read and update node data.

You can see in the `mysql` client whether a MySQL server is connected to the cluster using `SHOW PROCESSLIST`. If the MySQL server is connected to the cluster, and you have the `PROCESS` privilege, then the first row of the output is as shown here:
Important

To participate in an NDB Cluster, the `mysqld` process must be started with both the options `--ndbcluster` and `--ndb-connectstring` (or their equivalents in `my.cnf`). If `mysqld` is started with only the `--ndbcluster` option, or if it is unable to contact the cluster, it is not possible to work with NDB tables, nor is it possible to create any new tables regardless of storage engine. The latter restriction is a safety measure intended to prevent the creation of tables having the same names as NDB tables while the SQL node is not connected to the cluster. If you wish to create tables using a different storage engine while the `mysqld` process is not participating in an NDB Cluster, you must restart the server without the `--ndbcluster` option.

### 18.5.5 Performing a Rolling Restart of an NDB Cluster

This section discusses how to perform a rolling restart of an NDB Cluster installation, so called because it involves stopping and starting (or restarting) each node in turn, so that the cluster itself remains operational. This is often done as part of a rolling upgrade or rolling downgrade, where high availability of the cluster is mandatory and no downtime of the cluster as a whole is permissible. Where we refer to upgrades, the information provided here also generally applies to downgrades as well.

There are a number of reasons why a rolling restart might be desirable. These are described in the next few paragraphs.

**Configuration change.** To make a change in the cluster's configuration, such as adding an SQL node to the cluster, or setting a configuration parameter to a new value.

**NDB Cluster software upgrade or downgrade.** To upgrade the cluster to a newer version of the NDB Cluster software (or to downgrade it to an older version). This is usually referred to as a “rolling upgrade” (or “rolling downgrade”, when reverting to an older version of NDB Cluster).

**Change on node host.** To make changes in the hardware or operating system on which one or more NDB Cluster node processes are running.

**System reset (cluster reset).** To reset the cluster because it has reached an undesirable state. In such cases it is often desirable to reload the data and metadata of one or more data nodes. This can be done in any of three ways:

- Start each data node process (`ndbd` or possibly `ndbmd`) with the `--initial` option, which forces the data node to clear its file system and to reload all NDB Cluster data and metadata from the other data nodes.

- Create a backup using the `ndb_mgm` client `START BACKUP` command prior to performing the restart. Following the upgrade, restore the node or nodes using `ndb_restore`.

See Section 18.5.3, “Online Backup of NDB Cluster”, and Section 18.4.22, “ndb_restore — Restore an NDB Cluster Backup”, for more information.
Performing a Rolling Restart of an NDB Cluster

- Use `mysqldump` to create a backup prior to the upgrade; afterward, restore the dump using `LOAD DATA`.

**Resource Recovery.**

To free memory previously allocated to a table by successive `INSERT` and `DELETE` operations, for re-use by other NDB Cluster tables.

The process for performing a rolling restart may be generalized as follows:

1. Stop all cluster management nodes (`ndb_mgmd` processes), reconfigure them, then restart them. (See [Rolling restarts with multiple management servers](#).)

2. Stop, reconfigure, then restart each cluster data node (`ndbd` process) in turn.

   Some node configuration parameters can be updated by issuing `RESTART` for each of the data nodes in the `ndb_mgm` client following the previous step; others require that the data node be stopped completely using a shell command (such as `kill` on most Unix systems) or the management client `STOP` command, then started again from a system shell by invoking the `ndbd` or `ndbmt` executable as appropriate.

   **Note**

   On Windows, you can also use `SC STOP` and `SC START` commands, `NET STOP` and `NET START` commands, or the Windows Service Manager to stop and start nodes which have been installed as Windows services (see Section 18.2.3.4, “Installing NDB Cluster Processes as Windows Services”).

   The type of restart required is indicated in the documentation for each node configuration parameter. See Section 18.3.3, “NDB Cluster Configuration Files”.

3. Stop, reconfigure, then restart each cluster SQL node (`mysqld` process) in turn.

   NDB Cluster supports a somewhat flexible order for upgrading nodes. When upgrading an NDB Cluster, you may upgrade API nodes (including SQL nodes) before upgrading the management nodes, data nodes, or both. In other words, you are permitted to upgrade the API and SQL nodes in any order. This is subject to the following provisions:

   - This functionality is intended for use as part of an online upgrade only. A mix of node binaries from different NDB Cluster releases is neither intended nor supported for continuous, long-term use in a production setting.

   - All management nodes must be upgraded before any data nodes are upgraded. This remains true regardless of the order in which you upgrade the cluster's API and SQL nodes.

   - Features specific to the “new” version must not be used until all management nodes and data nodes have been upgraded.

      This also applies to any MySQL Server version change that may apply, in addition to the NDB engine version change, so do not forget to take this into account when planning the upgrade. (This is true for online upgrades of NDB Cluster in general.)

      See also Bug #48528 and Bug #49163.

   **Note**

   It is not possible for any API node to perform schema operations (such as data definition statements) during a node restart.
Rolling restarts with multiple management servers. When performing a rolling restart of an NDB Cluster with multiple management nodes, you should keep in mind that ndb_mgmd checks to see if any other management node is running, and, if so, tries to use that node's configuration data. To keep this from occurring, and to force ndb_mgmd to reread its configuration file, perform the following steps:

1. Stop all NDB Cluster ndb_mgmd processes.
2. Update all config.ini files.
3. Start a single ndb_mgmd with --reload, --initial, or both options as desired.
4. If you started the first ndb_mgmd with the --initial option, you must also start any remaining ndb_mgmd processes using --initial.

Regardless of any other options used when starting the first ndb_mgmd, you should not start any remaining ndb_mgmd processes after the first one using --reload.
5. Complete the rolling restarts of the data nodes and API nodes as normal.

When performing a rolling restart to update the cluster's configuration, you can use the config_generation column of the ndbinfo.nodes table to keep track of which data nodes have been successfully restarted with the new configuration. See Section 18.5.10.18, “The ndbinfo nodes Table”.

18.5.6 Event Reports Generated in NDB Cluster

In this section, we discuss the types of event logs provided by NDB Cluster, and the types of events that are logged.

NDB Cluster provides two types of event log:

• The cluster log, which includes events generated by all cluster nodes. The cluster log is the log recommended for most uses because it provides logging information for an entire cluster in a single location.

By default, the cluster log is saved to a file named ndb_node_id_cluster.log (where node_id is the node ID of the management server) in the management server’s DataDir.

Cluster logging information can also be sent to stdout or a syslog facility in addition to or instead of being saved to a file, as determined by the values set for the DataDir and LogDestination configuration parameters. See Section 18.3.3.5, “Defining an NDB Cluster Management Server”, for more information about these parameters.

• Node logs are local to each node.

Output generated by node event logging is written to the file ndb_node_id_out.log (where node_id is the node’s node ID) in the node’s DataDir. Node event logs are generated for both management nodes and data nodes.

Node logs are intended to be used only during application development, or for debugging application code.

Both types of event logs can be set to log different subsets of events.

Each reportable event can be distinguished according to three different criteria:

• Category: This can be any one of the following values: STARTUP, SHUTDOWN, STATISTICS, CHECKPOINT, NODERESTART, CONNECTION, ERROR, or INFO.
• **Priority**: This is represented by one of the numbers from 0 to 15 inclusive, where 0 indicates “most important” and 15 “least important.”

• **Severity Level**: This can be any one of the following values: **ALERT**, **CRITICAL**, **ERROR**, **WARNING**, **INFO**, or **DEBUG**.

Both the cluster log and the node log can be filtered on these properties.

The format used in the cluster log is as shown here:

```
2007-01-26 19:35:55 [MgmSrvr] INFO     -- Node 1: Data usage is 2%(60 32K pages of total 2560)
```

Each line in the cluster log contains the following information:

• A timestamp in **YYYY-MM-DD HH:MM:SS** format.

• The type of node which is performing the logging. In the cluster log, this is always **[MgmSrvr]**.

• The severity of the event.

• The ID of the node reporting the event.

• A description of the event. The most common types of events to appear in the log are connections and disconnections between different nodes in the cluster, and when checkpoints occur. In some cases, the description may contain status information.

### 18.5.6.1 NDB Cluster Logging Management Commands

`ndb_mgm` supports a number of management commands related to the cluster log. In the listing that follows, **node_id** denotes either a data node ID or the keyword **ALL**, which indicates that the command should be applied to all of the cluster’s data nodes.

• **CLUSTERLOG ON**
  
  Turns the cluster log on.

• **CLUSTERLOG OFF**
  
  Turns the cluster log off.

• **CLUSTERLOG INFO**
Provides information about cluster log settings.

- **node_id CLUSTERLOG category=threshold**
  
  Logs `category` events with priority less than or equal to `threshold` in the cluster log.

- **CLUSTERLOG FILTER severity_level**
  
  Toggles cluster logging of events of the specified `severity_level`.

The following table describes the default setting (for all data nodes) of the cluster log category threshold. If an event has a priority with a value lower than or equal to the priority threshold, it is reported in the cluster log.

![Note]

Events are reported per data node, and that the threshold can be set to different values on different nodes.

**Table 18.327 Cluster log categories, with default threshold setting**

<table>
<thead>
<tr>
<th>Category</th>
<th>Default threshold (All data nodes)</th>
</tr>
</thead>
<tbody>
<tr>
<td>STARTUP</td>
<td>7</td>
</tr>
<tr>
<td>SHUTDOWN</td>
<td>7</td>
</tr>
<tr>
<td>STATISTICS</td>
<td>7</td>
</tr>
<tr>
<td>CHECKPOINT</td>
<td>7</td>
</tr>
<tr>
<td>NODERESTART</td>
<td>7</td>
</tr>
<tr>
<td>CONNECTION</td>
<td>7</td>
</tr>
<tr>
<td>ERROR</td>
<td>15</td>
</tr>
<tr>
<td>INFO</td>
<td>7</td>
</tr>
</tbody>
</table>

The `STATISTICS` category can provide a great deal of useful data. See Section 18.5.6.3, “Using CLUSTERLOG STATISTICS in the NDB Cluster Management Client”, for more information.

Thresholds are used to filter events within each category. For example, a `STARTUP` event with a priority of 3 is not logged unless the threshold for `STARTUP` is set to 3 or higher. Only events with priority 3 or lower are sent if the threshold is 3.

The following table shows the event severity levels.

![Note]

These correspond to Unix `syslog` levels, except for `LOG_EMERG` and `LOG_NOTICE`, which are not used or mapped.

**Table 18.328 Event severity levels**

<table>
<thead>
<tr>
<th>Severity Level Value</th>
<th>Severity</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>ALERT</td>
<td>A condition that should be corrected immediately, such as a corrupted system database</td>
</tr>
<tr>
<td>2</td>
<td>CRITICAL</td>
<td>Critical conditions, such as device errors or insufficient resources</td>
</tr>
</tbody>
</table>
### Event Reports Generated in NDB Cluster

<table>
<thead>
<tr>
<th>Severity Level Value</th>
<th>Severity</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>ERROR</td>
<td>Conditions that should be corrected, such as configuration errors</td>
</tr>
<tr>
<td>4</td>
<td>WARNING</td>
<td>Conditions that are not errors, but that might require special handling</td>
</tr>
<tr>
<td>5</td>
<td>INFO</td>
<td>Informational messages</td>
</tr>
<tr>
<td>6</td>
<td>DEBUG</td>
<td>Debugging messages used for NDBCLUSTER development</td>
</tr>
</tbody>
</table>

Event severity levels can be turned on or off (using `CLUSTERLOG FILTER`—see above). If a severity level is turned on, then all events with a priority less than or equal to the category thresholds are logged. If the severity level is turned off then no events belonging to that severity level are logged.

### Important

Cluster log levels are set on a per `ndb_mgmd`, per subscriber basis. This means that, in an NDB Cluster with multiple management servers, using a `CLUSTERLOG` command in an instance of `ndb_mgm` connected to one management server affects only logs generated by that management server but not by any of the others. This also means that, should one of the management servers be restarted, only logs generated by that management server are affected by the resetting of log levels caused by the restart.

### 18.5.6.2 NDB Cluster Log Events

An event report reported in the event logs has the following format:

```
datetime [string] severity -- message
```

For example:

```
```

This section discusses all reportable events, ordered by category and severity level within each category.

#### CONNECTION Events

These events are associated with connections between Cluster nodes.

<table>
<thead>
<tr>
<th>Event</th>
<th>Priority</th>
<th>Severity Level</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connected</td>
<td>8</td>
<td>INFO</td>
<td>Data nodes connected</td>
</tr>
<tr>
<td>Disconnected</td>
<td>8</td>
<td>ALERT</td>
<td>Data nodes disconnected</td>
</tr>
<tr>
<td>CommunicationClosed</td>
<td>8</td>
<td>INFO</td>
<td>SQL node or data node connection closed</td>
</tr>
<tr>
<td>CommunicationOpened</td>
<td>8</td>
<td>INFO</td>
<td>SQL node or data node connection open</td>
</tr>
<tr>
<td>ConnectedApiVersion</td>
<td>8</td>
<td>INFO</td>
<td>Connection using API version</td>
</tr>
</tbody>
</table>

#### CHECKPOINT Events
The logging messages shown here are associated with checkpoints.

**Table 18.330 Events associated with checkpoints**

<table>
<thead>
<tr>
<th>Event</th>
<th>Priority</th>
<th>Severity Level</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlobalCheckpointStarted</td>
<td>9</td>
<td>INFO</td>
<td>Start of GCP: REDO log is written to disk</td>
</tr>
<tr>
<td>GlobalCheckpointCompleted</td>
<td>10</td>
<td>INFO</td>
<td>GCP finished</td>
</tr>
<tr>
<td>LocalCheckpointStarted</td>
<td>7</td>
<td>INFO</td>
<td>Start of LCP: data written to disk</td>
</tr>
<tr>
<td>LocalCheckpointCompleted</td>
<td>7</td>
<td>INFO</td>
<td>LCP completed normally</td>
</tr>
<tr>
<td>LCPStoppedInCalcKeepGci</td>
<td>0</td>
<td>ALERT</td>
<td>LCP stopped</td>
</tr>
<tr>
<td>LCPFragrimentCompleted</td>
<td>11</td>
<td>INFO</td>
<td>LCP on a fragment has been completed</td>
</tr>
<tr>
<td>UndoLogBlocked</td>
<td>7</td>
<td>INFO</td>
<td>UNDO logging blocked; buffer near overflow</td>
</tr>
<tr>
<td>RedoStatus</td>
<td>7</td>
<td>INFO</td>
<td>Redo status</td>
</tr>
</tbody>
</table>

**STARTUP Events**

The following events are generated in response to the startup of a node or of the cluster and of its success or failure. They also provide information relating to the progress of the startup process, including information concerning logging activities.

**Table 18.331 Events relating to the startup of a node or cluster**

<table>
<thead>
<tr>
<th>Event</th>
<th>Priority</th>
<th>Severity Level</th>

18.5.6.3 Using CLUSTERLOG STATISTICS in the NDB Cluster Management Client

The NDB management client's CLUSTERLOG STATISTICS command can provide a number of useful statistics in its output. Counters providing information about the state of the cluster are updated at 5-second reporting intervals by the transaction coordinator (TC) and the local query handler (LQH), and written to the cluster log.

Transaction coordinator statistics. Each transaction has one transaction coordinator, which is chosen by one of the following methods:

- In a round-robin fashion
- By communication proximity
- By supplying a data placement hint when the transaction is started

**Note**

You can determine which TC selection method is used for transactions started from a given SQL node using the ndb_optimized_node_selection system variable.

All operations within the same transaction use the same transaction coordinator, which reports the following statistics:
• **Trans count.** This is the number transactions started in the last interval using this TC as the transaction coordinator. Any of these transactions may have committed, have been aborted, or remain uncommitted at the end of the reporting interval.

    **Note**
    Transactions do not migrate between TCs.

• **Commit count.** This is the number of transactions using this TC as the transaction coordinator that were committed in the last reporting interval. Because some transactions committed in this reporting interval may have started in a previous reporting interval, it is possible for **Commit count** to be greater than **Trans count**.

• **Read count.** This is the number of primary key read operations using this TC as the transaction coordinator that were started in the last reporting interval, including simple reads. This count also includes reads performed as part of unique index operations. A unique index read operation generates 2 primary key read operations—1 for the hidden unique index table, and 1 for the table on which the read takes place.

• **Simple read count.** This is the number of simple read operations using this TC as the transaction coordinator that were started in the last reporting interval.

• **Write count.** This is the number of primary key write operations using this TC as the transaction coordinator that were started in the last reporting interval. This includes all inserts, updates, writes and deletes, as well as writes performed as part of unique index operations.

    **Note**
    A unique index update operation can generate multiple PK read and write operations on the index table and on the base table.

• **AttrInfoCount.** This is the number of 32-bit data words received in the last reporting interval for primary key operations using this TC as the transaction coordinator. For reads, this is proportional to the number of columns requested. For inserts and updates, this is proportional to the number of columns written, and the size of their data. For delete operations, this is usually zero.

    Unique index operations generate multiple PK operations and so increase this count. However, data words sent to describe the PK operation itself, and the key information sent, are not counted here. Attribute information sent to describe columns to read for scans, or to describe ScanFilters, is also not counted in **AttrInfoCount**.

• **Concurrent Operations.** This is the number of primary key or scan operations using this TC as the transaction coordinator that were started during the last reporting interval but that were not completed. Operations increment this counter when they are started and decrement it when they are completed; this occurs after the transaction commits. Dirty reads and writes—as well as failed operations—decrement this counter.

    The maximum value that **Concurrent Operations** can have is the maximum number of operations that a TC block can support; currently, this is \(2 \times \text{MaxNoOfConcurrentOperations} + 16 + \text{MaxNoOfConcurrentTransactions}\). (For more information about these configuration parameters, see the **Transaction Parameters** section of Section 18.3.3.6, “Defining NDB Cluster Data Nodes”.

• **Abort count.** This is the number of transactions using this TC as the transaction coordinator that were aborted during the last reporting interval. Because some transactions that were aborted in the last reporting interval may have started in a previous reporting interval, **Abort count** can sometimes be greater than **Trans count**.
Event Reports Generated in NDB Cluster

- **Scans.** This is the number of table scans using this TC as the transaction coordinator that were started during the last reporting interval. This does not include range scans (that is, ordered index scans).

- **Range scans.** This is the number of ordered index scans using this TC as the transaction coordinator that were started in the last reporting interval.

- **Local reads.** This is the number of primary-key read operations performed using a transaction coordinator on a node that also holds the primary replica of the record. This count can also be obtained from the `LOCAL_READS` counter in the `ndbinfo.counters` table.

- **Local writes.** This contains the number of primary-key read operations that were performed using a transaction coordinator on a node that also holds the primary replica of the record. This count can also be obtained from the `LOCAL_WRITES` counter in the `ndbinfo.counters` table.

**Local query handler statistics (Operations).** There is 1 cluster event per local query handler block (that is, 1 per data node process). Operations are recorded in the LQH where the data they are operating on resides.

- **Note**

  A single transaction may operate on data stored in multiple LQH blocks.

The `Operations` statistic provides the number of local operations performed by this LQH block in the last reporting interval, and includes all types of read and write operations (insert, update, write, and delete operations). This also includes operations used to replicate writes. For example, in a 2-replica cluster, the write to the primary replica is recorded in the primary LQH, and the write to the backup will be recorded in the backup LQH. Unique key operations may result in multiple local operations; however, this does not include local operations generated as a result of a table scan or ordered index scan, which are not counted.

**Process scheduler statistics.** In addition to the statistics reported by the transaction coordinator and local query handler, each `ndbd` process has a scheduler which also provides useful metrics relating to the performance of an NDB Cluster. This scheduler runs in an infinite loop; during each loop the scheduler performs the following tasks:

1. Read any incoming messages from sockets into a job buffer.
2. Check whether there are any timed messages to be executed; if so, put these into the job buffer as well.
3. Execute (in a loop) any messages in the job buffer.
4. Send any distributed messages that were generated by executing the messages in the job buffer.
5. Wait for any new incoming messages.

Process scheduler statistics include the following:

- **Mean Loop Counter.** This is the number of loops executed in the third step from the preceding list. This statistic increases in size as the utilization of the TCP/IP buffer improves. You can use this to monitor changes in performance as you add new data node processes.

- **Mean send size and Mean receive size.** These statistics enable you to gauge the efficiency of, respectively writes and reads between nodes. The values are given in bytes. Higher values mean a lower cost per byte sent or received; the maximum value is 64K.
To cause all cluster log statistics to be logged, you can use the following command in the NDB management client:

```
ndb_mgm> ALL CLUSTERLOG STATISTICS=15
```

**Note**

Setting the threshold for `STATISTICS` to 15 causes the cluster log to become very verbose, and to grow quite rapidly in size, in direct proportion to the number of cluster nodes and the amount of activity in the NDB Cluster.

For more information about NDB Cluster management client commands relating to logging and reporting, see Section 18.5.6.1, “NDB Cluster Logging Management Commands”.

### 18.5.7 NDB Cluster Log Messages

This section contains information about the messages written to the cluster log in response to different cluster log events. It provides additional, more specific information on NDB transporter errors.

#### 18.5.7.1 NDB Cluster: Messages in the Cluster Log

The following table lists the most common NDB cluster log messages. For information about the cluster log, log events, and event types, see Section 18.5.6, “Event Reports Generated in NDB Cluster”. These log messages also correspond to log event types in the MGM API; see The Ndb_logevent_type Type, for related information of interest to Cluster API developers.

**Table 18.339 Common NDB cluster log messages**

### NDB Cluster Single User Mode

**Single user mode** enables the database administrator to restrict access to the database system to a single API node, such as a MySQL server (SQL node) or an instance of `ndb_restore`. When entering single user mode, connections to all other API nodes are closed gracefully and all running transactions are aborted. No new transactions are permitted to start.

Once the cluster has entered single user mode, only the designated API node is granted access to the database.

You can use the `ALL STATUS` command in the `ndb_mgm` client to see when the cluster has entered single user mode. You can also check the `status` column of the `ndbinfo.nodes` table (see Section 18.5.10.18, “The ndbinfo nodes Table”, for more information).

**Example:**

```
ndb_mgm> ENTER SINGLE USER MODE 5
```

After this command has executed and the cluster has entered single user mode, the API node whose node ID is 5 becomes the cluster's only permitted user.

The node specified in the preceding command must be an API node; attempting to specify any other type of node will be rejected.

**Note**

When the preceding command is invoked, all transactions running on the designated node are aborted, the connection is closed, and the server must be restarted.

The command `EXIT SINGLE USER MODE` changes the state of the cluster's data nodes from single user mode to normal mode. API nodes—such as MySQL Servers—waiting for a connection (that is, waiting for the cluster to become ready and available), are again permitted to connect. The API node denoted as the single-user node continues to run (if still connected) during and after the state change.

**Example:**

```
ndb_mgm> EXIT SINGLE USER MODE
```

There are two recommended ways to handle a node failure when running in single user mode:

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Error Name</th>
<th>Error Text</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x1f</td>
<td><code>TE_SCI_UNABLE_TO_REMOVE_SEGMENT</code></td>
<td>Cannot free the resources used by this segment (step 2)</td>
</tr>
<tr>
<td>0x20</td>
<td><code>TE_SCI_UNABLE_TO_DISCONNECT_SEGMENT</code></td>
<td>Cannot disconnect from a remote segment</td>
</tr>
<tr>
<td>0x21</td>
<td><code>TE_SHM_IPC_PERMANENT</code></td>
<td>Shm ipc Permanent error</td>
</tr>
<tr>
<td>0x22</td>
<td><code>TE_SCI_UNABLE_TO_CLOSE_CHANNEL</code></td>
<td>Unable to close the sci channel and the resources allocated</td>
</tr>
</tbody>
</table>
• Method 1:
  1. Finish all single user mode transactions
  2. Issue the `EXIT SINGLE USER MODE` command
  3. Restart the cluster's data nodes

• Method 2:
  Restart data nodes prior to entering single user mode.

### 18.5.9 Quick Reference: NDB Cluster SQL Statements

This section discusses several SQL statements that can prove useful in managing and monitoring a MySQL server that is connected to an NDB Cluster, and in some cases provide information about the cluster itself.

- **SHOW ENGINE NDB STATUS, SHOW ENGINE NDBCLUSTER STATUS**

  The output of this statement contains information about the server's connection to the cluster, creation and usage of NDB Cluster objects, and binary logging for NDB Cluster replication.

  See Section 13.7.5.16, “SHOW ENGINE Syntax”, for a usage example and more detailed information.

- **SHOW ENGINES**

  This statement can be used to determine whether or not clustering support is enabled in the MySQL server, and if so, whether it is active.

  See Section 13.7.5.17, “SHOW ENGINES Syntax”, for more detailed information.

  **Note**
  
  This statement does not support a `LIKE` clause. However, you can use `LIKE` to filter queries against the `INFORMATION_SCHEMA.ENGINES` table, as discussed in the next item.

- **SELECT * FROM INFORMATION_SCHEMA.ENGINES [WHERE ENGINE LIKE 'NDB%']**

  This is the equivalent of `SHOW ENGINES`, but uses the `ENGINES` table of the `INFORMATION_SCHEMA` database. Unlike the case with the `SHOW ENGINES` statement, it is possible to filter the results using a `LIKE` clause, and to select specific columns to obtain information that may be of use in scripts. For example, the following query shows whether the server was built with NDB support and, if so, whether it is enabled:

  ```
  mysql> SELECT SUPPORT FROM INFORMATION_SCHEMA.ENGINES
     -> WHERE ENGINE LIKE 'NDB%';
  +---------+
  | support |
  | ENABLED |
  +---------+
  ```

  See Section 21.7, “The INFORMATION_SCHEMA ENGINES Table”, for more information.

- **SHOW VARIABLES LIKE 'NDB%'**
This statement provides a list of most server system variables relating to the NDB storage engine, and their values, as shown here:

```sql
mysql> SHOW VARIABLES LIKE 'NDB%';
+-------------------------------------+-------+
| Variable_name                       | Value |
+-------------------------------------+-------+
| ndb_autoincrement_prefetch_sz       | 32    |
| ndb_cache_check_time                | 0     |
| ndb_extra_logging                   | 0     |
| ndb_force_send                      | ON    |
| ndb_index_stat_cache_entries        | 32    |
| ndb_index_stat_enable               | OFF   |
| ndb_index_stat_update_freq          | 20    |
| ndb_report_thresh_binlog_epoch_slip | 3     |
| ndb_report_thresh_binlog_mem_usage  | 10    |
| ndb_use_copying_alter_table         | OFF   |
| ndb_use_exact_count                 | ON    |
| ndb_use_transactions                | ON    |
+-------------------------------------+-------+
```

See Section 5.1.7, “Server System Variables”, for more information.

- ```sql
  SELECT * FROM INFORMATION_SCHEMA.GLOBAL_VARIABLES WHERE VARIABLE_NAME LIKE 'NDB%';
  ```

This statement is the equivalent of the `SHOW` command described in the previous item, and provides almost identical output, as shown here:

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.GLOBAL_VARIABLES
      -> WHERE VARIABLE_NAME LIKE 'NDB%';
+-------------------------------------+----------------+
| VARIABLE_NAME                       | VARIABLE_VALUE |
+-------------------------------------+----------------+
| NDB_AUTOINCREMENT_PREFETCH_SZ       | 32             |
| NDB_CACHE_CHECK_TIME                | 0              |
| NDB_EXTRA_LOGGING                   | 0              |
| NDB_FORCE_SEND                      | ON             |
| NDB_INDEX_STAT_CACHE_ENTRIES        | 32             |
| NDB_INDEX_STAT_ENABLE               | OFF            |
| NDB_INDEX_STAT_UPDATE_FREQ          | 20             |
| NDB_REPORT_THRESH_BINLOG_EPOCH_SLIP | 3              |
| NDB_REPORT_THRESH_BINLOG_MEM_USAGE  | 10             |
| NDB_USE_COPYING_ALTER_TABLE         | OFF            |
| NDB_USE_EXACT_COUNT                 | ON             |
| NDB_USE_TRANSACTIONS                | ON             |
+-------------------------------------+----------------+
```

Unlike the case with the `SHOW` command, it is possible to select individual columns. For example:

```sql
mysql> SELECT VARIABLE_VALUE
      -> FROM INFORMATION_SCHEMA.GLOBAL_VARIABLES
      -> WHERE VARIABLE_NAME = 'ndb_force_send';
+----------------+
| VARIABLE_VALUE |
|----------------+
| ON             |
+----------------+
```

• **SHOW STATUS LIKE 'NDB%'**

This statement shows at a glance whether or not the MySQL server is acting as a cluster SQL node, and if so, it provides the MySQL server's cluster node ID, the host name and port for the cluster management server to which it is connected, and the number of data nodes in the cluster, as shown here:

```
mysql> SHOW STATUS LIKE 'NDB%';
+--------------------------+----------------+
| Variable_name            | Value          |
+--------------------------+----------------+
| Ndb_cluster_node_id      | 10             |
| Ndb_config_from_host     | 198.51.100.103 |
| Ndb_config_from_port     | 1186           |
| Ndb_number_of_data_nodes | 4              |
+--------------------------+----------------+
```

If the MySQL server was built with clustering support, but it is not connected to a cluster, all rows in the output of this statement contain a zero or an empty string:

```
mysql> SHOW STATUS LIKE 'NDB%';
+--------------------------+-------+
| Variable_name            | Value |
+--------------------------+-------+
| Ndb_cluster_node_id      | 0     |
| Ndb_config_from_host     |       |
| Ndb_config_from_port     | 0     |
| Ndb_number_of_data_nodes | 0     |
+--------------------------+-------+
```

See also Section 13.7.5.36, “SHOW STATUS Syntax”.

• **SELECT * FROM INFORMATION_SCHEMA.GLOBAL_STATUS WHERE VARIABLE_NAME LIKE 'NDB %';**

This statement provides similar output to the SHOW command discussed in the previous item. However, unlike the case with SHOW STATUS, it is possible using the SELECT to extract values in SQL for use in scripts for monitoring and automation purposes.

See Section 21.9, “The INFORMATION_SCHEMA GLOBAL_STATUS and SESSION_STATUS Tables”, for more information.

You can also query the tables in the ndbinfo information database for real-time data about many NDB Cluster operations. See Section 18.5.10, “ndbinfo: The NDB Cluster Information Database”.

### 18.5.10 ndbinfo: The NDB Cluster Information Database

**ndbinfo** is a database containing information specific to NDB Cluster.

This database contains a number of tables, each providing a different sort of data about NDB Cluster node status, resource usage, and operations. You can find more detailed information about each of these tables in the next several sections.

**ndbinfo** is included with NDB Cluster support in the MySQL Server; no special compilation or configuration steps are required; the tables are created by the MySQL Server when it connects to the cluster. You can verify that **ndbinfo** support is active in a given MySQL Server instance using **SHOW**
**ndbinfo**: The NDB Cluster Information Database

**PLUGINS**: If `ndbinfo` support is enabled, you should see a row containing `ndbinfo` in the **Name** column and **ACTIVE** in the **Status** column, as shown here (emphasized text):

```
mysql> SHOW PLUGINS;
+----------------------------------+--------+--------------------+---------+---------+
| Name                             | Status | Type               | Library | License |
+----------------------------------+--------+--------------------+---------+---------+
| binlog                           | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| mysql_native_password            | ACTIVE | AUTHENTICATION     | NULL    | GPL     |
| mysql_old_password               | ACTIVE | AUTHENTICATION     | NULL    | GPL     |
| CSV                              | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| MEMORY                           | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| MRG_MYISAM                       | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| MyISAM                           | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| PERFORMANCE_SCHEMA               | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| BLACKHOLE                        | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| ARCHIVE                          | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| ndbcluster                       | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| ndbinfo                          | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| ndb_transid_mysql_connection_map | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| InnoDB                           | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| XA: NO                           |        |                    |         |         |
| Savepoints: NO                   |        |                    |         |         |
| 22 rows in set (0.00 sec)        |        |                    |         |         |
```

You can also do this by checking the output of **SHOW ENGINES** for a line including `ndbinfo` in the **Engine** column and **YES** in the **Support** column, as shown here (emphasized text):

```
mysql> SHOW ENGINES\G
*************************** 1. row ***************************
 Engine: ndbcluster
 Support: YES
 Comment: Clustered, fault-tolerant tables
Transactions: YES
XA: NO
Savepoints: NO
*************************** 2. row ***************************
 Engine: MRG_MYISAM
 Support: YES
 Comment: Collection of identical MyISAM tables
Transactions: NO
XA: NO
Savepoints: NO
*************************** 3. row ***************************
 Engine: ndbinfo
 Support: YES
 Comment: NDB Cluster system information storage engine
Transactions: NO
XA: NO
Savepoints: NO
*************************** 4. row ***************************
 Engine: CSV
 Support: YES
 Comment: CSV storage engine
Transactions: NO
XA: NO
Savepoints: NO
```

2980
If `ndbinfo` support is enabled, then you can access `ndbinfo` using SQL statements in `mysql` or another MySQL client. For example, you can see `ndbinfo` listed in the output of `SHOW DATABASES`, as shown here (emphasized text):

```sql
mysql> SHOW DATABASES;
+--------------------+
| Database           |
+--------------------+
| information_schema |
| mysql              |
| ndbinfo            |
| test               |
+--------------------+
4 rows in set (0.00 sec)
```

If the `mysqld` process was not started with the `--ndbcluster` option, `ndbinfo` is not available and is not displayed by `SHOW DATABASES`. If `mysqld` was formerly connected to an NDB Cluster but the cluster becomes unavailable (due to events such as cluster shutdown, loss of network connectivity, and so forth), `ndbinfo` and its tables remain visible, but an attempt to access any tables (other than `blocks` or `config_params`) fails with `Got error 157 'Connection to NDB failed' from NDBINFO`.

10 rows in set (0.00 sec)
With the exception of the `blocks` and `config_params` tables, what we refer to as `ndbinfo` “tables” are actually views generated from internal `NDB` tables not normally visible to the MySQL Server.

All `ndbinfo` tables are read-only, and are generated on demand when queried. Because many of them are generated in parallel by the data nodes while other are specific to a given SQL node, they are not guaranteed to provide a consistent snapshot.

In addition, pushing down of joins is not supported on `ndbinfo` tables; so joining large `ndbinfo` tables can require transfer of a large amount of data to the requesting API node, even when the query makes use of a `WHERE` clause.

`ndbinfo` tables are not included in the query cache. (Bug #59831)

You can select the `ndbinfo` database with a `USE` statement, and then issue a `SHOW TABLES` statement to obtain a list of tables, just as for any other database, like this:

```sql
mysql> USE ndbinfo;
Database changed

mysql> SHOW TABLES;
+---------------------------------+
| Tables_in_ndbinfo               |
+---------------------------------+
| arbitrator_validity_detail      |
| arbitrator_validity_summary     |
| blocks                          |
| cluster_operations              |
| cluster_transactions           |
| config_params                   |
| counters                        |
| dict_obj_types                  |
| disk_write_speed_aggregate      |
| disk_write_speed_aggregate_node |
| disk_write_speed_base           |
| diskpagebuffer                  |
| logbuffers                      |
| logspaces                       |
| membership                      |
| memory_per_fragment             |
| memoryusage                     |
| nodes                           |
| operations_per_fragment         |
| resources                       |
| restart_info                    |
| server_operations               |
| server_transactions             |
| threadblocks                    |
| threadstat                      |
| transporters                    |
+---------------------------------+
26 rows in set (0.00 sec)
```

The `dict_obj_types`, `disk_write_speed_aggregate`, `disk_write_speed_aggregate_node`, `disk_write_speed_base`, and `memory_per_fragment` tables were added in NDB 7.4.1. The `restart_info` table was added in NDB 7.4.2. The `operations_per_fragment` table was added in NDB 7.4.3.

You can execute `SELECT` statements against these tables, just as you would normally expect:

```sql
mysql> SELECT * FROM memoryusage;
+---------+---------------------+--------+------------+------------+-------------+
| node_id | memory_type         | used   | used_pages | total      | total_pages |
+---------+---------------------+--------+------------+------------+-------------+
```

2982
The NDB Cluster Information Database

### Table: ndbinfo

<table>
<thead>
<tr>
<th>node_id</th>
<th>Data memory</th>
<th>Index memory</th>
<th>Long message buffer</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>753664</td>
<td>163840</td>
<td>2304</td>
</tr>
<tr>
<td>6</td>
<td>753664</td>
<td>163840</td>
<td>2304</td>
</tr>
</tbody>
</table>

More complex queries, such as the two following SELECT statements using the memoryusage table, are possible:

```sql
mysql> SELECT SUM(used) as 'Data Memory Used, All Nodes'
> FROM memoryusage
> WHERE memory_type = 'Data memory';

+-----------------------------+
| Data Memory Used, All Nodes |
| 6460                       |
+-----------------------------+
```

```sql
mysql> SELECT SUM(max) as 'Total IndexMemory Available'
> FROM memoryusage
> WHERE memory_type = 'Index memory';

+-----------------------------+
| Total IndexMemory Available |
| 25664                      |
+-----------------------------+
```

### ndbinfo Table and Column Names

The `ndbinfo` table and column names are case sensitive (as is the name of the `ndbinfo` database itself). These identifiers are in lowercase. Trying to use the wrong lettercase results in an error, as shown in this example:

```sql
mysql> SELECT * FROM nodes;

+---------+--------+---------+-------------+
| node_id | uptime | status  | start_phase |
|---------|--------|---------|-------------+
|       1 | 13602  | STARTED |           0 |
|       2 |     16 | STARTED |           0 |
+---------+--------+---------+-------------+
```

```sql
mysql> SELECT * FROM Nodes;

ERROR 1146 (42S02): Table 'ndbinfo.Nodes' doesn't exist
```

### mysqldump

mysqldump ignores the `ndbinfo` database entirely, and excludes it from any output. This is true even when using the `--databases` or `--all-databases` option.

NDB Cluster also maintains tables in the INFORMATION_SCHEMA information database, including the FILES table which contains information about files used for NDB Cluster Disk Data storage, and the ndb_transid_mysql_connection_map table, which shows the relationships between transactions, transaction coordinators, and NDB Cluster API nodes. For more information, see the descriptions of the tables or Section 21.31, “INFORMATION_SCHEMA NDB Cluster Tables”.

### 18.5.10.1 The ndbinfo arbitrator_validity_detail Table

The arbitrator_validity_detail table shows the view that each data node in the cluster has of the arbitrator. It is a subset of the membership table.
The following table provides information about the columns in the `arbitrator_validity_detail` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

**Table 18.341 Columns of the arbitrator_validity_detail table**

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>This node's node ID</td>
</tr>
<tr>
<td>arbitrator</td>
<td>integer</td>
<td>Node ID of arbitrator</td>
</tr>
<tr>
<td>arb_ticket</td>
<td>string</td>
<td>Internal identifier used to track arbitration</td>
</tr>
<tr>
<td>arb_connected</td>
<td>Yes or No</td>
<td>Whether this node is connected to the arbitrator</td>
</tr>
<tr>
<td>arb_state</td>
<td>Enumeration (see text)</td>
<td>Arbitration state</td>
</tr>
</tbody>
</table>

The node ID is the same as that reported by `ndb_mgm -e "SHOW"`.

All nodes should show the same `arbitrator` and `arb_ticket` values as well as the same `arb_state` value. Possible `arb_state` values are `ARBIT_NULL`, `ARBIT_INIT`, `ARBIT_FIND`, `ARBIT_PREP1`, `ARBIT_PREP2`, `ARBIT_START`, `ARBIT_RUN`, `ARBIT_CHOOSE`, `ARBIT_CRASH`, and `UNKNOWN`.

`arb_connected` shows whether the current node is connected to the arbitrator.

**18.5.10.2 The ndbinfo arbitrator_validity_summary Table**

The `arbitrator_validity_summary` table provides a composite view of the arbitrator with regard to the cluster's data nodes.

The following table provides information about the columns in the `arbitrator_validity_summary` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

**Table 18.342 Columns of the arbitrator_validity_summary table**

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>arbitrator</td>
<td>integer</td>
<td>Node ID of arbitrator</td>
</tr>
<tr>
<td>arb_ticket</td>
<td>string</td>
<td>Internal identifier used to track arbitration</td>
</tr>
<tr>
<td>arb_connected</td>
<td>Yes or No</td>
<td>Whether this arbitrator is connected to the cluster</td>
</tr>
<tr>
<td>consensus_count</td>
<td>integer</td>
<td>Number of data nodes that see this node as arbitrator</td>
</tr>
</tbody>
</table>

In normal operations, this table should have only 1 row for any appreciable length of time. If it has more than 1 row for longer than a few moments, then either not all nodes are connected to the arbitrator, or all nodes are connected, but do not agree on the same arbitrator.

The `arbitrator` column shows the arbitrator's node ID.

`arb_ticket` is the internal identifier used by this arbitrator.

`arb_connected` shows whether this node is connected to the cluster as an arbitrator.

**18.5.10.3 The ndbinfo blocks Table**
The `blocks` table is a static table which simply contains the names and internal IDs of all NDB kernel blocks (see NDB Kernel Blocks). It is for use by the other `ndbinfo` tables (most of which are actually views) in mapping block numbers to block names for producing human-readable output.

The following table provides information about the columns in the `blocks` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

**Table 18.343 Columns of the `blocks` table**

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>block_number</td>
<td>integer</td>
<td>Block number</td>
</tr>
<tr>
<td>block_name</td>
<td>string</td>
<td>Block name</td>
</tr>
</tbody>
</table>

To obtain a list of all block names, simply execute `SELECT block_name FROM ndbinfo.blocks`. Although this is a static table, its content can vary between different NDB Cluster releases.

### 18.5.10.4 The `ndbinfo cluster_operations` Table

The `cluster_operations` table provides a per-operation (stateful primary key op) view of all activity in the NDB Cluster from the point of view of the local data management (LQH) blocks (see The DBLQH Block).

The following table provides information about the columns in the `cluster_operations` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

**Table 18.344 Columns of the `cluster_operations` table**

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>Node ID of reporting LQH block</td>
</tr>
<tr>
<td>block_instance</td>
<td>integer</td>
<td>LQH block instance</td>
</tr>
<tr>
<td>transid</td>
<td>integer</td>
<td>Transaction ID</td>
</tr>
<tr>
<td>operation_type</td>
<td>string</td>
<td>Operation type (see text for possible values)</td>
</tr>
<tr>
<td>state</td>
<td>string</td>
<td>Operation state (see text for possible values)</td>
</tr>
<tr>
<td>tableid</td>
<td>integer</td>
<td>Table ID</td>
</tr>
<tr>
<td>fragmentid</td>
<td>integer</td>
<td>Fragment ID</td>
</tr>
<tr>
<td>client_node_id</td>
<td>integer</td>
<td>Client node ID</td>
</tr>
<tr>
<td>client_block_ref</td>
<td>integer</td>
<td>Client block reference</td>
</tr>
<tr>
<td>tc_node_id</td>
<td>integer</td>
<td>Transaction coordinator node ID</td>
</tr>
<tr>
<td>tc_block_no</td>
<td>integer</td>
<td>Transaction coordinator block number</td>
</tr>
<tr>
<td>tc_block_instance</td>
<td>integer</td>
<td>Transaction coordinator block instance</td>
</tr>
</tbody>
</table>

The transaction ID is a unique 64-bit number which can be obtained using the NDB API’s `getTransactionId()` method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

The `operation_type` column can take any one of the values `READ`, `READ-SH`, `READ-EX`, `INSERT`, `UPDATE`, `DELETE`, `WRITE`, `UNLOCK`, `REFRESH`, `SCAN`, `SCAN-SH`, `SCAN-EX`, or `<unknown>`.

The `state` column can have any one of the values `ABORT_QUEUED`, `ABORT_STOPPED`, `COMMITTED`, `COMMIT_QUEUED`, `COMMIT_STOPPED`, `COPY_CLOSE_STOPPED`, `<unknown>`.
COPY_FIRST_STOPPED, COPY_STOPPED, COPY_TUPKEY, IDLE, LOG_ABORT_QUEUED, LOG_COMMIT_QUEUED, LOG_COMMIT_QUEUED_WAIT_SIGNAL, LOG_COMMIT_WRITTEN, LOG_COMMIT_WRITTEN_WAIT_SIGNAL, LOG_QUEUED, PREPARED, PREPARED_RECEIVED_COMMIT, SCAN_CHECK_STOPPED, SCAN_CLOSE_STOPPED, SCAN_FIRST_STOPPED, SCAN_RELEASE_STOPPED, SCAN_STATE_USED, SCAN_STOPPED, SCAN_TUPKEY, STOPPED, TC_NOT_CONNECTED, WAIT_ACC, WAIT_ACC_ABORT, WAIT_AI_AFTER_ABORT, WAIT_ATTR, WAIT_SCAN_AI, WAIT_TUP, WAIT_TUPKEYINFO, WAIT_TUP_COMMIT, or WAIT_TUP_TO_ABORT. (If the MySQL Server is running with ndbinfo_show_hidden enabled, you can view this list of states by selecting from the ndb $dblqh_tcconnect_state table, which is normally hidden.)

You can obtain the name of an NDB table from its table ID by checking the output of ndb_show_tables.

The fragid is the same as the partition number seen in the output of ndb_desc --extra-partition-info (short form -p).

In client_node_id and client_block_ref, client refers to an NDB Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

The block_instance and tc_block_instance column provide, respectively, the DBLQH and DBTC block instance numbers. You can use these along with the block names to obtain information about specific threads from the threadblocks table.

### 18.5.10.5 The ndbinfo cluster_transactions Table

The cluster_transactions table shows information about all ongoing transactions in an NDB Cluster.

The following table provides information about the columns in the cluster_transactions table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

#### Table 18.345 Columns of the cluster_transactions table

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>Node ID of transaction coordinator</td>
</tr>
<tr>
<td>block_instance</td>
<td>integer</td>
<td>TC block instance</td>
</tr>
<tr>
<td>transid</td>
<td>integer</td>
<td>Transaction ID</td>
</tr>
<tr>
<td>state</td>
<td>string</td>
<td>Operation state (see text for possible values)</td>
</tr>
<tr>
<td>count_operations</td>
<td>integer</td>
<td>Number of stateful primary key operations in transaction (includes reads with locks, as well as DML operations)</td>
</tr>
<tr>
<td>outstanding_operations</td>
<td>integer</td>
<td>Operations still being executed in local data management blocks</td>
</tr>
<tr>
<td>inactive_seconds</td>
<td>integer</td>
<td>Time spent waiting for API</td>
</tr>
<tr>
<td>client_node_id</td>
<td>integer</td>
<td>Client node ID</td>
</tr>
<tr>
<td>client_block_ref</td>
<td>integer</td>
<td>Client block reference</td>
</tr>
</tbody>
</table>

The transaction ID is a unique 64-bit number which can be obtained using the NDB API's getTransactionId() method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

block_instance refers to an instance of a kernel block. Together with the block name, this number can be used to look up a given instance in the threadblocks table.
The state column can have any one of the values `CS_ABORTING, CS_COMMITTING, CS_COMMIT_SENT, CS_COMPLETE_SENT, CS_COMPLETING, CS_CONNECTED, CS_DISCONNECTED, CS_FAIL_ABORTED, CS_FAIL_ABORTING, CS_FAIL_COMMITTED, CS_FAIL_COMMITTING, CS_FAIL_COMPLETED, CS_FAIL_PREPARED, CS_PREPARE_TO_COMMIT, CS_RECEIVING, CS_REC_COMMITTING, CS_RESTART, CS_SEND_FIRE_TRIG_REQ, CS_STARTED, CS_START_COMMITTING, CS_START_SCAN, CS_WAIT_ABORT_CONF, CS_WAIT_COMMIT_CONF, CS_WAIT_COMPLETE_CONF, CS_WAIT_FIRE_TRIG_REQ`. (If the MySQL Server is running with `ndbinfo_show_hidden` enabled, you can view this list of states by selecting from the `ndb$dbtc_apiconnect_state` table, which is normally hidden.)

In `client_node_id` and `client_block_ref`, client refers to an NDB Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

The `tc_block_instance` column provides the DBTC block instance number. You can use this along with the block name to obtain information about specific threads from the `threadblocks` table.

### 18.5.10.6 The ndbinfo config_params Table

The `config_params` table is a static table which provides the names and internal ID numbers of and other information about NDB Cluster configuration parameters.

The following table provides information about the columns in the `config_params` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>param_number</td>
<td>integer</td>
<td>The parameter's internal ID number</td>
</tr>
<tr>
<td>param_name</td>
<td>string</td>
<td>The name of the parameter</td>
</tr>
</tbody>
</table>

Although this is a static table, its content can vary between NDB Cluster installations, since supported parameters can vary due to differences between software releases, cluster hardware configurations, and other factors.

### 18.5.10.7 The ndbinfo counters Table

The `counters` table provides running totals of events such as reads and writes for specific kernel blocks and data nodes. Counts are kept from the most recent node start or restart; a node start or restart resets all counters on that node. Not all kernel blocks have all types of counters.

The following table provides information about the columns in the `counters` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>The data node ID</td>
</tr>
<tr>
<td>block_name</td>
<td>string</td>
<td>Name of the associated NDB kernel block (see NDB Kernel Blocks)</td>
</tr>
<tr>
<td>block_instance</td>
<td>integer</td>
<td>Block instance</td>
</tr>
<tr>
<td>counter_id</td>
<td>integer</td>
<td>The counter's internal ID number; normally an integer between 1 and 10, inclusive.</td>
</tr>
</tbody>
</table>
Each counter is associated with a particular NDB kernel block.

The **OPERATIONS** counter is associated with the **DBLQH** (local query handler) kernel block (see The DBLQH Block). A primary-key read counts as one operation, as does a primary-key update. For reads, there is one operation in **DBLQH** per operation in **DBTC**. For writes, there is one operation counted per replica.

The **ATTRINFO**, **TRANSACTIONS**, **COMMITS**, **READS**, **LOCAL_READS**, **SIMPLE_READS**, **WRITES**, **LOCAL_WRITES**, **ABORTS**, **TABLE_SCANS**, and **RANGE_SCANS** counters are associated with the **DBTC** (transaction co-ordinator) kernel block (see The DBTC Block).

**LOCAL_WRITES** and **LOCAL_READS** are primary-key operations using a transaction coordinator in a node that also holds the primary replica of the record.

The **READS** counter includes all reads. **LOCAL_READS** includes only those reads of the primary replica on the same node as this transaction coordinator. **SIMPLE_READS** includes only those reads in which the read operation is the beginning and ending operation for a given transaction. Simple reads do not hold locks but are part of a transaction, in that they observe uncommitted changes made by the transaction containing them but not of any other uncommitted transactions. Such reads are “simple” from the point of view of the TC block; since they hold no locks they are not durable, and once **DBTC** has routed them to the relevant LQH block, it holds no state for them.

**ATTRINFO** keeps a count of the number of times an interpreted program is sent to the data node. See NDB Protocol Messages, for more information about **ATTRINFO** messages in the NDB kernel.

The **block_name** and **block_instance** columns provide, respectively, the applicable NDB kernel block name and instance number. You can use these to obtain information about specific threads from the threadblocks table.

A number of counters provide information about transporter overload and send buffer sizing when troubleshooting such issues. For each LQH instance, there is one instance of each counter in the following list:

- **LQHKEY_OVERLOAD**: Number of primary key requests rejected at the LQH block instance due to transporter overload
- **LQHKEY_OVERLOAD_TC**: Count of instances of **LQHKEY_OVERLOAD** where the TC node transporter was overloaded
- **LQHKEY_OVERLOAD_READER**: Count of instances of **LQHKEY_OVERLOAD** where the API reader (reads only) node was overloaded.
• **LQHKEY_OVERLOAD_NODE_PEER**: Count of instances of `LQHKEY_OVERLOAD` where the next backup data node (writes only) was overloaded.

• **LQHKEY_OVERLOAD_SUBSCRIBER**: Count of instances of `LQHKEY_OVERLOAD` where an event subscriber (writes only) was overloaded.

• **LQHSCAN_SLOWDOWNS**: Count of instances where a fragment scan batch size was reduced due to scanning API transporter overload.

### 18.5.10.8 The ndbinfo `dict_obj_types` Table

The `dict_obj_types` table is a static table listing possible dictionary object types used in the NDB kernel. These are the same types defined by `Object::Type` in the NDB API.

The following table provides information about the columns in the `dict_obj_types` table. For each column, the table shows the name, data type, and a brief description.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>type_id</code></td>
<td>integer</td>
<td>The type ID for this type</td>
</tr>
<tr>
<td><code>type_name</code></td>
<td>string</td>
<td>The name of this type</td>
</tr>
</tbody>
</table>

This table was added in NDB 7.4.1.

### 18.5.10.9 The ndbinfo `disk_write_speed_base` Table

The `disk_write_speed_base` table provides base information about the speed of disk writes during LCP, backup, and restore operations.

The following table provides information about the columns in the `disk_write_speed_base` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>node_id</code></td>
<td>integer</td>
<td>Node ID of this node</td>
</tr>
<tr>
<td><code>thr_no</code></td>
<td>integer</td>
<td>Thread ID of this LDM thread</td>
</tr>
<tr>
<td><code>millis_ago</code></td>
<td>integer</td>
<td>Milliseconds since this reporting period ended</td>
</tr>
<tr>
<td><code>millis_passed</code></td>
<td>integer</td>
<td>Milliseconds elapsed in this reporting period</td>
</tr>
<tr>
<td><code>backup_lcp_bytes_written</code></td>
<td>integer</td>
<td>Number of bytes written to disk by local checkpoints and backup processes during this period</td>
</tr>
<tr>
<td><code>redo_bytes_written</code></td>
<td>integer</td>
<td>Number of bytes written to REDO log during this period</td>
</tr>
<tr>
<td><code>target_disk_write_speed</code></td>
<td>integer</td>
<td>Actual speed of disk writes per LDM thread (base data)</td>
</tr>
</tbody>
</table>

This table was added in NDB 7.4.1.

### 18.5.10.10 The ndbinfo `disk_write_speed_aggregate` Table

The `disk_write_speed_aggregate` table provides aggregated information about the speed of disk writes during LCP, backup, and restore operations.
The following table provides information about the columns in the `disk_write_speed_aggregate` table in NDB 7.4.3 and later; information about `disk_write_speed_aggregate` in NDB 7.4.2 and earlier can be found later in this section. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

**Table 18.350 Columns in the disk_write_speed_aggregate table**

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>Node ID of this node</td>
</tr>
<tr>
<td>thr_no</td>
<td>integer</td>
<td>Thread ID of this LDM thread</td>
</tr>
<tr>
<td>backup_lcp_speed_last_sec</td>
<td>integer</td>
<td>Number of bytes written to disk by backup and LCP processes in the last second</td>
</tr>
<tr>
<td>redo_speed_last_sec</td>
<td>integer</td>
<td>Number of bytes written to REDO log in the last second</td>
</tr>
<tr>
<td>backup_lcp_speed_last_10sec</td>
<td>integer</td>
<td>Number of bytes written to disk by backup and LCP processes per second, averaged over the last 10 seconds</td>
</tr>
<tr>
<td>redo_speed_last_10sec</td>
<td>integer</td>
<td>Number of bytes written to REDO log per second, averaged over the last 10 seconds</td>
</tr>
<tr>
<td>std_dev_backup_lcp_speed_last_10sec</td>
<td>integer</td>
<td>Standard deviation in number of bytes written to disk by backup and LCP processes per second, averaged over the last 10 seconds</td>
</tr>
<tr>
<td>std_dev_redo_speed_last_10sec</td>
<td>integer</td>
<td>Standard deviation in number of bytes written to REDO log per second, averaged over the last 10 seconds</td>
</tr>
<tr>
<td>backup_lcp_speed_last_60sec</td>
<td>integer</td>
<td>Number of bytes written to disk by backup and LCP processes per second, averaged over the last 60 seconds</td>
</tr>
<tr>
<td>redo_speed_last_60sec</td>
<td>integer</td>
<td>Number of bytes written to REDO log per second, averaged over the last 60 seconds</td>
</tr>
<tr>
<td>std_dev_backup_lcp_speed_last_60sec</td>
<td>integer</td>
<td>Standard deviation in number of bytes written to disk by backup and LCP processes per second, averaged over the last 60 seconds</td>
</tr>
<tr>
<td>std_dev_redo_speed_last_60sec</td>
<td>integer</td>
<td>Standard deviation in number of bytes written to REDO log per second, averaged over the last 60 seconds</td>
</tr>
<tr>
<td>slowdowns_due_to_io_lag</td>
<td>integer</td>
<td>Number of seconds since last node start that disk writes were slowed due to REDO log I/O lag</td>
</tr>
<tr>
<td>slowdowns_due_to_high_cpu</td>
<td>integer</td>
<td>Number of seconds since last node start that disk writes were slowed due to high CPU usage</td>
</tr>
<tr>
<td>disk_write_speed_set_to_min</td>
<td>integer</td>
<td>Number of seconds since last node start that disk write speed was set to minimum</td>
</tr>
<tr>
<td>current_target_disk_write_speed</td>
<td>integer</td>
<td>Actual speed of disk writes per LDM thread (aggregated)</td>
</tr>
</tbody>
</table>

Prior to NDB 7.4.3, the standard deviation used in obtaining the values shown in the `std_dev_backup_lcp_speed_last_10sec`, `std_dev_redo_speed_last_10sec`, ...
std_dev_backup_lcp_speed_last_60sec, and std_dev redo_speed_last_60sec columns of this table were not calculated correctly. (Bug #74317, Bug #19795072)

Prior to NDB 7.4.3, some columns of this table showed values in kilobytes or other multiples of bytes. In NDB 7.4.3 and later, all such columns display values in bytes. (Bug #74317, Bug #19795072) The following table provides information about disk_write_speed_aggregate as implemented previously.

**Table 18.351 Columns of the disk_write_speed_aggregate table in NDB 7.4.2 and earlier**

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>

</tr>
<tr>
<td>current_target_disk_write_speed</td>
<td>integer</td>
<td>Actual speed of disk writes per LDM thread (aggregated)</td>
</tr>
</tbody>
</table>
The `disk_write_speed_aggregate` table was added in NDB 7.4.1.

### 18.5.10.11 The ndbinfo `disk_write_speed_aggregate_node` Table

The `disk_write_speed_aggregate_node` table provides aggregated information per node about the speed of disk writes during LCP, backup, and restore operations.

The following table provides information about the columns in the `disk_write_speed_aggregate_node` table as implemented in NDB 7.4.3 and later; information about `disk_write_speed_aggregate_node` in NDB 7.4.2 and earlier can be found later in this section. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

**Table 18.352 Columns of the `disk_write_speed_aggregate_node` table**

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

</tbody>
</table>
### ndbinfo: The NDB Cluster Information Database

The disk_write_speed_aggregate_node table was added in NDB 7.4.1.

#### 18.5.10.12 The ndbinfo diskpagebuffer Table

The diskpagebuffer table provides statistics about disk page buffer usage by NDB Cluster Disk Data tables.

The following table provides information about the columns in the diskpagebuffer table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

<table>
<thead>
<tr>
<th>Column Name</th>

<td>pages_read</td>
<td>integer</td>
<td>Number of pages read from disk.</td>
</tr>
<tr>
<td>log_waits</td>
<td>integer</td>
<td>Number of page writes waiting for log to be written to disk.</td>
</tr>
<tr>
<td>page_requests_direct_return</td>
<td>integer</td>
<td>Number of requests for pages that were available in buffer.</td>
</tr>
<tr>
<td>page_requests_wait_queue</td>
<td>integer</td>
<td>Number of requests that had to wait for pages to become available in buffer</td>
</tr>
<tr>
<td>page_requests_wait_io</td>
<td>integer</td>
<td>Number of requests that had to be read from pages on disk (pages were unavailable in buffer)</td>
</tr>
</tbody>
</table>

You can use this table with NDB Cluster Disk Data tables to determine whether DiskPageBufferMemory is sufficiently large to allow data to be read from the buffer rather than from disk; minimizing disk seeks can help improve performance of such tables.

You can determine the proportion of reads from DiskPageBufferMemory to the total number of reads using a query such as this one, which obtains this ratio as a percentage:

```sql
SELECT
    node_id,
    100 * page_requests_direct_return /
      (page_requests_direct_return + page_requests_wait_io) AS hit_ratio
FROM ndbinfo.diskpagebuffer;
```
The result from this query should be similar to what is shown here, with one row for each data node in the cluster (in this example, the cluster has 4 data nodes):

<table>
<thead>
<tr>
<th>node_id</th>
<th>hit_ratio</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>97.6744</td>
</tr>
<tr>
<td>6</td>
<td>97.6879</td>
</tr>
<tr>
<td>7</td>
<td>98.1776</td>
</tr>
<tr>
<td>8</td>
<td>98.1343</td>
</tr>
</tbody>
</table>

4 rows in set (0.00 sec)

hit_ratio values approaching 100% indicate that only a very small number of reads are being made from disk rather than from the buffer, which means that Disk Data read performance is approaching an optimum level. If any of these values are less than 95%, this is a strong indicator that the setting for DiskPageBufferMemory needs to be increased in the config.ini file.

A change in DiskPageBufferMemory requires a rolling restart of all of the cluster’s data nodes before it takes effect.

The block_instance column provides the NDB kernel block instance number. You can use this to obtain information about specific threads from the threadblocks table.

18.5.10.13 The ndbinfo logbuffers Table

The logbuffer table provides information on NDB Cluster log buffer usage.

The following table provides information about the columns in the logbuffers table. For each column, the table shows the name, data type, and a brief description.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>The ID of this data node.</td>
</tr>
<tr>
<td>log_type</td>
<td>string</td>
<td>Type of log, one of: REDO or DD-UNDO.</td>
</tr>
<tr>
<td>log_id</td>
<td>integer</td>
<td>The log ID.</td>
</tr>
<tr>
<td>log_part</td>
<td>integer</td>
<td>The log part number.</td>
</tr>
<tr>
<td>total</td>
<td>integer</td>
<td>Total space available for this log.</td>
</tr>
<tr>
<td>used</td>
<td>integer</td>
<td>Space used by this log.</td>
</tr>
</tbody>
</table>

Beginning with NDB 7.6.5, logbuffers table rows reflecting two additional log types are available when performing an NDB backup. One of these rows has the log type BACKUP-DATA, which shows the amount of data buffer used during backup to copy fragments to backup files. The other row has the log type BACKUP-LOG, which displays the amount of log buffer used during the backup to record changes made after the backup has started. One each of these log_type rows is shown in the logbuffers table for each data node in the cluster. These rows are not present unless an NDB backup is currently being performed. (Bug #25822988)

18.5.10.14 The ndbinfo logspaces Table

This table provides information about NDB Cluster log space usage.
The following table provides information about the columns in the \texttt{logspaces} table. For each column, the table shows the name, data type, and a brief description.

### Table 18.356 Columns in the \texttt{logspaces} table

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>The ID of this data node.</td>
</tr>
<tr>
<td>log_type</td>
<td>string</td>
<td>Type of log; one of: \texttt{REDO} or \texttt{DD-UNDO}.</td>
</tr>
<tr>
<td>log_id</td>
<td>integer</td>
<td>The log ID.</td>
</tr>
<tr>
<td>log_part</td>
<td>integer</td>
<td>The log part number.</td>
</tr>
<tr>
<td>total</td>
<td>integer</td>
<td>Total space available for this log.</td>
</tr>
<tr>
<td>used</td>
<td>integer</td>
<td>Space used by this log.</td>
</tr>
</tbody>
</table>

### 18.5.10.15 The ndbinfo membership Table

The \texttt{membership} table describes the view that each data node has of all the others in the cluster, including node group membership, president node, arbitrator, arbitrator successor, arbitrator connection states, and other information.

The following table provides information about the columns in the \texttt{membership} table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

### Table 18.357 Columns of the \texttt{membership} table

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>This node's node ID</td>
</tr>
<tr>
<td>group_id</td>
<td>integer</td>
<td>Node group to which this node belongs</td>
</tr>
<tr>
<td>left_node</td>
<td>integer</td>
<td>Node ID of the previous node</td>
</tr>
<tr>
<td>right_node</td>
<td>integer</td>
<td>Node ID of the next node</td>
</tr>
<tr>
<td>president</td>
<td>integer</td>
<td>President's node ID</td>
</tr>
<tr>
<td>successor</td>
<td>integer</td>
<td>Node ID of successor to president</td>
</tr>
<tr>
<td>succession_order</td>
<td>integer</td>
<td>Order in which this node succeeds to presidency</td>
</tr>
<tr>
<td>Conf_HB_order</td>
<td>integer</td>
<td>-</td>
</tr>
<tr>
<td>arbitrator</td>
<td>integer</td>
<td>Node ID of arbitrator</td>
</tr>
<tr>
<td>arb_ticket</td>
<td>string</td>
<td>Internal identifier used to track arbitration</td>
</tr>
<tr>
<td>arb_state</td>
<td>Enumeration</td>
<td>Arbitration state</td>
</tr>
<tr>
<td>arb_connected</td>
<td>Yes or No</td>
<td>Whether this node is connected to the arbitrator</td>
</tr>
<tr>
<td>connected_rank1_arbs</td>
<td>List of node IDs</td>
<td>Connected arbitrators of rank 1</td>
</tr>
<tr>
<td>connected_rank2_arbs</td>
<td>List of node IDs</td>
<td>Connected arbitrators of rank 1</td>
</tr>
</tbody>
</table>

The node ID and node group ID are the same as reported by \texttt{ndb_mgm -e "SHOW"}.

\texttt{left_node} and \texttt{right_node} are defined in terms of a model that connects all data nodes in a circle, in order of their node IDs, similar to the ordering of the numbers on a clock dial, as shown here:
In this example, we have 8 data nodes, numbered 5, 6, 7, 8, 12, 13, 14, and 15, ordered clockwise in a circle. We determine “left” and “right” from the interior of the circle. The node to the left of node 5 is node 15, and the node to the right of node 5 is node 6. You can see all these relationships by running the following query and observing the output:

```sql
mysql> SELECT node_id, left_node, right_node
    -> FROM ndbinfo.membership;
```

+---------+-----------+------------+
<table>
<thead>
<tr>
<th>node_id</th>
<th>left_node</th>
<th>right_node</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>15</td>
<td>6</td>
</tr>
<tr>
<td>6</td>
<td>5</td>
<td>7</td>
</tr>
<tr>
<td>7</td>
<td>6</td>
<td>8</td>
</tr>
<tr>
<td>8</td>
<td>7</td>
<td>12</td>
</tr>
<tr>
<td>12</td>
<td>8</td>
<td>13</td>
</tr>
<tr>
<td>13</td>
<td>12</td>
<td>14</td>
</tr>
<tr>
<td>14</td>
<td>13</td>
<td>15</td>
</tr>
<tr>
<td>15</td>
<td>14</td>
<td>5</td>
</tr>
</tbody>
</table>
+---------+-----------+------------+
8 rows in set (0.00 sec)

The designations “left” and “right” are used in the event log in the same way.

The `president` node is the node viewed by the current node as responsible for setting an arbitrator (see NDB Cluster Start Phases). If the president fails or becomes disconnected, the current node expects the node whose ID is shown in the `successor` column to become the new president. The `succession_order` column shows the place in the succession queue that the current node views itself as having.

In a normal NDB Cluster, all data nodes should see the same node as `president`, and the same node (other than the president) as its `successor`. In addition, the current president should see itself as 1 in the order of succession, the `successor` node should see itself as 2, and so on.

All nodes should show the same `arb_ticket` values as well as the same `arb_state` values. Possible `arb_state` values are `ARBIT_NULL`, `ARBIT_INIT`, `ARBIT_FIND`, `ARBIT_PREP1`, `ARBIT_PREP2`, `ARBIT_START`, `ARBIT_RUN`, `ARBIT_CHOOSE`, `ARBIT_CRASH`, and `UNKNOWN`.

`arb_connected` shows whether this node is connected to the node shown as this node’s `arbiter`.

The `connected_rank1_arbs` and `connected_rank2_arbs` columns each display a list of 0 or more arbitrators having an ArbitrationRank equal to 1, or to 2, respectively.
18.5.10.16 The ndbinfo memoryusage Table

Querying this table provides information similar to that provided by the ALL REPORT MemoryUsage command in the ndb_mgm client, or logged by ALL DUMP 1000.

The following table provides information about the columns in the memoryusage table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Table 18.358 Columns of the memoryusage table

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>The node ID of this data node.</td>
</tr>
<tr>
<td>memory_type</td>
<td>string</td>
<td>One of Data memory, Index memory, or Long message buffer.</td>
</tr>
<tr>
<td>used</td>
<td>integer</td>
<td>Number of bytes currently used for data memory or index memory by this node.</td>
</tr>
<tr>
<td>used_pages</td>
<td>integer</td>
<td>Number of pages currently used for data memory or index memory by this node;</td>
</tr>
<tr>
<td>total</td>
<td>integer</td>
<td>Total number of bytes of data memory or index memory available for this data node; see text.</td>
</tr>
<tr>
<td>total_pages</td>
<td>integer</td>
<td>Total number of memory pages available for data memory or index memory on this data node; see text.</td>
</tr>
</tbody>
</table>

The total column represents the total amount of memory in bytes available for the given resource (data memory or index memory) on a particular data node. This number should be approximately equal to the setting of the corresponding configuration parameter in the config.ini file.

Suppose that the cluster has 2 data nodes having node IDs 5 and 6, and the config.ini file contains the following:

```
[ndbd default]
DataMemory = 1G
IndexMemory = 1G
```

Suppose also that the value of the LongMessageBuffer configuration parameter is allowed to assume its default (64 MB in NDB 7.3.5 and later).

The following query shows approximately the same values:

```
mysql> SELECT node_id, memory_type, total
    > FROM ndbinfo.memoryusage;
```

<table>
<thead>
<tr>
<th>node_id</th>
<th>memory_type</th>
<th>total</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>Data memory</td>
<td>1073741824</td>
</tr>
<tr>
<td>5</td>
<td>Index memory</td>
<td>1074003968</td>
</tr>
<tr>
<td>5</td>
<td>Long message buffer</td>
<td>67108864</td>
</tr>
</tbody>
</table>
In this case, the total column values for index memory are slightly higher than the value set of IndexMemory due to internal rounding.

For the used_pages and total_pages columns, resources are measured in pages, which are 32K in size for DataMemory and 8K for IndexMemory. For long message buffer memory, the page size is 256 bytes.

Long message buffer information can be found in this table beginning with NDB 7.3.5; in earlier versions of NDB Cluster, only data memory and index memory were included.

### 18.5.10.17 The ndbinfo memory_per_fragment Table

The memory_per_fragment table provides information about the usage of memory by individual fragments.

The following table provides information about the columns in the memory_per_fragment table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

#### Table 18.359 Columns of the memory_per_fragment table

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fq_name</td>
<td>string</td>
<td>Name of this fragment</td>
</tr>
<tr>
<td>parent fq_name</td>
<td>string</td>
<td>Name of this fragment's parent</td>
</tr>
<tr>
<td>type</td>
<td>string</td>
<td>Type of object; see text for possible values</td>
</tr>
<tr>
<td>table_id</td>
<td>integer</td>
<td>Table ID for this table</td>
</tr>
<tr>
<td>node_id</td>
<td>integer</td>
<td>Node ID for this node</td>
</tr>
<tr>
<td>block_instance</td>
<td>integer</td>
<td>Kernel block instance ID</td>
</tr>
<tr>
<td>fragment_num</td>
<td>integer</td>
<td>Fragment ID (number)</td>
</tr>
<tr>
<td>fixed_elem_alloc_bytes</td>
<td>integer</td>
<td>Number of bytes allocated for fixed-sized elements</td>
</tr>
<tr>
<td>fixed.elem_free_bytes</td>
<td>integer</td>
<td>Free bytes remaining in pages allocated to fixed-size elements</td>
</tr>
<tr>
<td>fixed_elem_size_bytes</td>
<td>integer</td>
<td>Length of each fixed-size element in bytes</td>
</tr>
<tr>
<td>fixed_elem_count</td>
<td>integer</td>
<td>Number of fixed-size elements</td>
</tr>
<tr>
<td>fixed_elem_free_count</td>
<td>decimal</td>
<td>Number of free rows for fixed-size elements</td>
</tr>
<tr>
<td>var_elem_alloc_bytes</td>
<td>integer</td>
<td>Number of bytes allocated for variable-size elements</td>
</tr>
<tr>
<td>var_elem_free_bytes</td>
<td>integer</td>
<td>Free bytes remaining in pages allocated to variable-size elements</td>
</tr>
<tr>
<td>var_elem_count</td>
<td>integer</td>
<td>Number of variable-size elements</td>
</tr>
<tr>
<td>hash_index_alloc_bytes</td>
<td>integer</td>
<td>Number of bytes allocated to hash indexes</td>
</tr>
</tbody>
</table>

The type column from this table shows the dictionary object type used for this fragment (Object::Type, in the NDB API), and can take any one of the values shown in the following list:
• System table
• User table
• Unique hash index
• Hash index
• Unique ordered index
• Ordered index
• Hash index trigger
• Subscription trigger
• Read only constraint
• Index trigger
• Reorganize trigger
• Tablespace
• Log file group
• Data file
• Undo file
• Hash map
• Foreign key definition
• Foreign key parent trigger
• Foreign key child trigger
• Schema transaction

You can also obtain this list by executing `SELECT * FROM ndbinfo.dict_obj_types` in the `mysql` client.

The `block_instance` column provides the NDB kernel block instance number. You can use this to obtain information about specific threads from the `threadblocks` table.

This table was added in NDB 7.4.1.

### 18.5.10.18 The ndbinfo nodes Table

This table contains information on the status of data nodes. For each data node that is running in the cluster, a corresponding row in this table provides the node's node ID, status, and uptime. For nodes that are starting, it also shows the current start phase.

The following table provides information about the columns in the `nodes` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>The data node's unique node ID in the cluster.</td>
</tr>
</tbody>
</table>
The `uptime` column shows the time in seconds that this node has been running since it was last started or restarted. This is a `BIGINT` value. This figure includes the time actually needed to start the node; in other words, this counter starts running the moment that `ndbd` or `ndbmd` is first invoked; thus, even for a node that has not yet finished starting, `uptime` may show a nonzero value.

The `status` column shows the node's current status. This is one of: `NOTHING`, `CMVMI`, `STARTING`, `STARTED`, `SINGLEUSER`, `STOPPING_1`, `STOPPING_2`, `STOPPING_3`, or `STOPPING_4`. When the status is `STARTING`, you can see the current start phase in the `start_phase` column (see later in this section). `SINGLEUSER` is displayed in the `status` column for all data nodes when the cluster is in single user mode (see Section 18.5.8, “NDB Cluster Single User Mode”). Seeing one of the `STOPPING` states does not necessarily mean that the node is shutting down but can mean rather that it is entering a new state. For example, if you put the cluster in single user mode, you can sometimes see data nodes report their state briefly as `STOPPING_2` before the status changes to `SINGLEUSER`.

The `start_phase` column uses the same range of values as those used in the output of the `ndb_mgm` client `node_id STATUS` command (see Section 18.5.2, “Commands in the NDB Cluster Management Client”). If the node is not currently starting, then this column shows 0. For a listing of NDB Cluster start phases with descriptions, see Section 18.5.1, “Summary of NDB Cluster Start Phases”.

The `config_generation` column shows which version of the cluster configuration is in effect on each data node. This can be useful when performing a rolling restart of the cluster in order to make changes in configuration parameters. For example, from the output of the following `SELECT` statement, you can see that node 3 is not yet using the latest version of the cluster configuration (6) although nodes 1, 2, and 4 are doing so:

```sql
mysql> USE ndbinfo;
Database changed
mysql> SELECT * FROM nodes;
+---------+--------+---------+-------------+-------------------+
<table>
<thead>
<tr>
<th>node_id</th>
<th>uptime</th>
<th>status</th>
<th>start_phase</th>
<th>config_generation</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>10462</td>
<td>STARTED</td>
<td>0</td>
<td>6</td>
</tr>
<tr>
<td>2</td>
<td>10460</td>
<td>STARTED</td>
<td>0</td>
<td>6</td>
</tr>
<tr>
<td>3</td>
<td>10457</td>
<td>STARTED</td>
<td>0</td>
<td>5</td>
</tr>
<tr>
<td>4</td>
<td>10455</td>
<td>STARTED</td>
<td>0</td>
<td>6</td>
</tr>
</tbody>
</table>
+---------+--------+---------+-------------+-------------------+
2 rows in set (0.04 sec)
```

Therefore, for the case just shown, you should restart node 3 to complete the rolling restart of the cluster.

Nodes that are stopped are not accounted for in this table. Suppose that you have an NDB Cluster with 4 data nodes (node IDs 1, 2, 3 and 4), and all nodes are running normally, then this table contains 4 rows, 1 for each data node:

```sql
mysql> USE ndbinfo;
```
If you shut down one of the nodes, only the nodes that are still running are represented in the output of this `SELECT` statement, as shown here:

```sql
ndb_mgm> 2 STOP
Node 2: Node shutdown initiated
Node 2: Node shutdown completed.
Node 2 has shutdown.

mysql> SELECT * FROM nodes;

+---------+--------+---------+-------------+-------------------+
<table>
<thead>
<tr>
<th>node_id</th>
<th>uptime</th>
<th>status</th>
<th>start_phase</th>
<th>config_generation</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>11807</td>
<td>STARTED</td>
<td>0</td>
<td>6</td>
</tr>
<tr>
<td>3</td>
<td>11802</td>
<td>STARTED</td>
<td>0</td>
<td>6</td>
</tr>
<tr>
<td>4</td>
<td>11800</td>
<td>STARTED</td>
<td>0</td>
<td>6</td>
</tr>
</tbody>
</table>
+---------+--------+---------+-------------+-------------------+
3 rows in set (0.02 sec)
```

### 18.5.10.19 The `ndbinfo operations_per_fragment` Table

The `operations_per_fragment` table provides information about the operations performed on individual fragments and fragment replicas, as well as about some of the results from these operations.

The following table provides information about the columns in the `operations_per_fragment` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fq_name</td>
<td>string</td>
<td>Name of this fragment</td>
</tr>
<tr>
<td>parent fq_name</td>
<td>string</td>
<td>Name of this fragment's parent</td>
</tr>
<tr>
<td>type</td>
<td>string</td>
<td>Type of object; see text for possible values</td>
</tr>
<tr>
<td>table_id</td>
<td>integer</td>
<td>Table ID for this table</td>
</tr>
<tr>
<td>node_id</td>
<td>integer</td>
<td>Node ID for this node</td>
</tr>
<tr>
<td>block_instance</td>
<td>integer</td>
<td>Kernel block instance ID</td>
</tr>
<tr>
<td>fragment_num</td>
<td>integer</td>
<td>Fragment ID (number)</td>
</tr>
<tr>
<td>tot_key_reads</td>
<td>integer</td>
<td>Total number of key reads for this fragment replica</td>
</tr>
<tr>
<td>tot_key_inserts</td>
<td>integer</td>
<td>Total number of key inserts for this fragment replica</td>
</tr>
<tr>
<td>tot_key_updates</td>
<td>integer</td>
<td>Total number of key updates for this fragment replica</td>
</tr>
</tbody>
</table>
## ndbinfo: The NDB Cluster Information Database

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tot_key_writes</td>
<td>integer</td>
<td>Total number of key writes for this fragment replica</td>

<tr>
<td>tot_scan_bytes_returned</td>
<td>integer</td>
<td>Total size of data and metadata returned to the client</td>
</tr>
<tr>
<td>tot_scan_prog_bytes</td>
<td>integer</td>
<td>Total size of interpreted programs for scan operations</td>
</tr>
<tr>
<td>tot_scan_bound_bytes</td>
<td>integer</td>
<td>Total size of all bounds used in ordered index scans</td>
</tr>
<tr>
<td>tot_scan_inst_exec</td>
<td>integer</td>
<td>Total number of instructions executed for scans</td>
</tr>
<tr>
<td>tot_qd_frag_scans</td>
<td>integer</td>
<td>Number of times that scans of this fragment replica have been queued</td>
</tr>
<tr>
<td>conc_frag_scans</td>
<td>integer</td>
<td>Number of scans currently active on this fragment replica (excluding queued scans)</td>
</tr>
<tr>
<td>conc_qd_frag_scans</td>
<td>integer</td>
<td>Number of scans currently queued for this fragment replica</td>
</tr>
<tr>
<td>tot_commits</td>
<td>integer</td>
<td>Total number of row changes committed to this fragment replica</td>
</tr>
</tbody>
</table>

The **fq_name** contains the fully qualified name of the schema object to which this fragment replica belongs. This currently has the following formats:

- **Base table:** - `DbName/def/TblName`
- **BLOB table:** - `DbName/def/NDB$BLOB_BaseTblId_ColNo`
- **Ordered index:** - `sys/def/BaseTblId/IndexName`
- **Unique index:** - `sys/def/BaseTblId/IndexName$unique`

The **$unique** suffix shown for unique indexes is added by mysqld; for an index created by a different NDB API client application, this may differ, or not be present.
The syntax just shown for fully qualified object names is an internal interface which is subject to change in future releases.

Consider a table `t1` created and modified by the following SQL statements:

```sql
CREATE DATABASE mydb;
USE mydb;
CREATE TABLE t1 (  
a INT NOT NULL,
b INT NOT NULL,
t TEXT NOT NULL,
PRIMARY KEY (b)
) ENGINE=ndbcluster;
CREATE UNIQUE INDEX ix1 ON t1(b) USING HASH;
```

If `t1` is assigned table ID 11, this yields the `fq_name` values shown here:

- **Base table**: `mydb/def/t1`
- **BLOB table**: `mydb/def/NDB$BLOB_11_2`
- **Ordered index (primary key)**: `sys/def/11(PRIMARY)`
- **Unique index**: `sys/def/11/ix1$unique`

For indexes or BLOB tables, the `parent_fq_name` column contains the `fq_name` of the corresponding base table. For base tables, this column is always `NULL`.

The `type` column shows the schema object type used for this fragment, which can take any one of the values `System table`, `User table`, `Unique hash index`, or `Ordered index`. BLOB tables are shown as `User table`.

The `table_id` column value is unique at any given time, but can be reused if the corresponding object has been deleted. The same ID can be seen using the `ndb_show_tables` utility.

The `block_instance` column shows which LDM instance this fragment replica belongs to. You can use this to obtain information about specific threads from the `threadblocks` table. The first such instance is always numbered 0.

Since there are typically two replicas, and assuming that this is so, each `fragment_num` value should appear twice in the table, on two different data nodes from the same node group.

Since NDB does not use single-key access for ordered indexes, the counts for `tot_key_reads`, `tot_key_inserts`, `tot_key_updates`, `tot_key_writes`, and `tot_key_deletes` are not incremented by ordered index operations.

**Note**

When using `tot_key_writes`, you should keep in mind that a write operation in this context updates the row if the key exists, and inserts a new row otherwise. (One use of this is in the NDB implementation of the REPLACE SQL statement.)

The `tot_key_refs` column shows the number of key operations refused by the LDM. Generally, such a refusal is due to duplicate keys (inserts), key not found errors (updates, deletes, and reads), or the operation was rejected by an interpreted program used as a predicate on the row matching the key.

The `attrinfo` and `keyinfo` attributes counted by the `tot_key_attrinfo_bytes` and `tot_key_keyinfo_bytes` columns are attributes of an LQHKEYREQ signal (see The NDB...
**Communication Protocol** used to initiate a key operation by the LDM. An **attrinfo** typically contains tuple field values (inserts and updates) or projection specifications (for reads); **keyinfo** contains the primary or unique key needed to locate a given tuple in this schema object.

The value shown by **tot_frag_scans** includes both full scans (that examine every row) and scans of subsets. Unique indexes and **BLOB** tables are never scanned, so this value, like other scan-related counts, is 0 for fragment replicas of these.

**tot_scan_rows_examined** may display less than the total number of rows in a given fragment replica, since ordered index scans can limited by bounds. In addition, a client may choose to end a scan before all potentially matching rows have been examined; this occurs when using an SQL statement containing a **LIMIT** or **EXISTS** clause, for example. **tot_scan_rows_returned** is always less than or equal to **tot_scan_rows_examined**.

**tot_scan_bytes_returned** includes, in the case of pushed joins, projections returned to the **DBSPJ** block in the NDB kernel.

**tot_qd_frag_scans** can be effected by the setting for the **MaxParallelScansPerFragment** data node configuration parameter, which limits the number of scans that may execute concurrently on a single fragment replica.

This table was added in NDB 7.4.3.

### 18.5.10.20 The ndbinfo resources Table

This table provides information about data node resource availability and usage.

These resources are sometimes known as **super-pools**.

The following table provides information about the columns in the **resources** table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>The unique node ID of this data node.</td>
</tr>
<tr>
<td>resource_name</td>
<td>string</td>
<td>Name of the resource; see text.</td>
</tr>
<tr>
<td>reserved</td>
<td>integer</td>
<td>The amount reserved for this resource.</td>
</tr>
<tr>
<td>used</td>
<td>integer</td>
<td>The amount actually used by this resource.</td>
</tr>
<tr>
<td>max</td>
<td>integer</td>
<td>The maximum amount of this resource used, since the node was last started.</td>
</tr>
</tbody>
</table>

The **resource_name** can be one of the names shown in the following table:

<table>
<thead>
<tr>
<th>Resource name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RESERVED</td>
<td>Reserved by the system; cannot be overridden.</td>
</tr>
<tr>
<td>DISK_OPERATIONS</td>
<td>If a log file group is allocated, the size of the undo log buffer is used to set the size of this resource. This resource is used only to allocate the undo log buffer for an undo log file group; there can only be one such group. Overallocation occurs as needed by <strong>CREATE LOGFILE GROUP</strong>.</td>
</tr>
<tr>
<td>DISK_RECORDS</td>
<td>Records allocated for Disk Data operations.</td>
</tr>
</tbody>
</table>
### ndbinfo: The NDB Cluster Information Database

<table>
<thead>
<tr>
<th>Resource name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATA_MEMORY</td>
<td>Used for main memory tuples, indexes, and hash indexes. Sum of DataMemory and IndexMemory, plus 8 pages of 32 KB each if IndexMemory has been set. Cannot be overallocated.</td>
</tr>
<tr>
<td>JOBBUFFER</td>
<td>Used for allocating job buffers by the NDB scheduler; cannot be overallocated. This is approximately 2 MB per thread plus a 1 MB buffer in both directions for all threads that can communicate. For large configurations this consume several GB.</td>
</tr>
<tr>
<td>FILE_BUFFERS</td>
<td>Used by the redo log handler in the DBLQH kernel block; cannot be overallocated. Size is NoOfFragmentLogParts * RedoBuffer, plus 1 MB per log file part.</td>
</tr>
<tr>
<td>TRANSPORTER_BUFFERS</td>
<td>Used for send buffers by ndbmttd; the sum of TotalSendBufferMemory and ExtraSendBufferMemory. This resource that can be overallocated by up to 25 percent. TotalSendBufferMemory is calculated by summing the send buffer memory per node, the default value of which is 2 MB. Thus, in a system having four data nodes and eight API nodes, the data nodes have 12 * 2 MB send buffer memory. ExtraSendBufferMemory is used by ndbmttd and amounts to 2 MB extra memory per thread. Thus, with 4 LDM threads, 2 TC threads, 1 main thread, 1 replication thread, and 2 receive threads, ExtraSendBufferMemory is 10 * 2 MB. Overallocation of this resource can be performed by setting the SharedGlobalMemory data node configuration parameter.</td>
</tr>
<tr>
<td>DISK_PAGE_BUFFER</td>
<td>Used for the disk page buffer; determined by the DiskPageBufferMemory configuration parameter. Cannot be overallocated.</td>
</tr>
<tr>
<td>QUERY_MEMORY</td>
<td>Used by the DBSPJ kernel block.</td>
</tr>
<tr>
<td>SCHEMA_TRANS_MEMORY</td>
<td>Minimum is 2 MB; can be overallocated to use any remaining available memory.</td>
</tr>
</tbody>
</table>

### 18.5.10.21 The ndbinfo restart_info Table

The restart_info table contains information about node restart operations. Each entry in the table corresponds to a node restart status report in real time from a data node with the given node ID. Only the most recent report for any given node is shown.

The following table provides information about the columns in the restart_info table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>Node ID in the cluster</td>
</tr>
<tr>
<td>node_restart_status</td>
<td>VARCHAR(256)</td>
<td>Node status; see text for values. Each of these corresponds to a possible value of node_restart_status_int.</td>
</tr>
<tr>
<td>node_restart_status_int</td>
<td>integer</td>
<td>Node status code; see text for values.</td>
</tr>
<tr>
<td>secs_to_complete_node_fail</td>
<td>integer</td>
<td>Time in seconds to complete node failure handling</td>
</tr>
<tr>
<td>secs_to_allocate_node_id</td>
<td>integer</td>
<td>Time in seconds from node failure completion to allocation of node ID</td>
</tr>
<tr>
<td>Column Name</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------------</td>
<td>-----------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>secs_to_include_in_heartbeat_protocol</td>
<td>integer</td>
<td>Time in seconds from allocation of node ID to inclusion in heartbeat protocol</td>
</tr>
<tr>
<td>secs_until_wait_for_ndbcntnt_master</td>
<td>integer</td>
<td>Time in seconds from being included in heartbeat protocol until waiting for NDBCNTNT master began</td>
</tr>
<tr>
<td>secs_wait_for_ndbcntnt_master</td>
<td>integer</td>
<td>Time in seconds spent waiting to be accepted by NDBCNTNT master for starting</td>
</tr>
<tr>
<td>secs_to_get_start_permission</td>
<td>integer</td>
<td>Time in seconds elapsed from receiving of permission for start from master until all nodes have accepted start of this node</td>
</tr>
<tr>
<td>secs_to_wait_for_lcp_for_copy_meta_data</td>
<td>integer</td>
<td>Time in seconds spent waiting for LCP completion before copying meta data</td>
</tr>
<tr>
<td>secs_to_copy_meta_data</td>
<td>integer</td>
<td>Time in seconds required to copy metadata from master to newly starting node</td>
</tr>
<tr>
<td>secs_to_include_node</td>
<td>integer</td>
<td>Time in seconds waited for GCP and inclusion of all nodes into protocols</td>
</tr>
<tr>
<td>secs_starting_node_to_request_local_recovery</td>
<td>integer</td>
<td>Time in seconds that the node just starting spent waiting to request local recovery</td>
</tr>
<tr>
<td>secs_for_local_recovery</td>
<td>integer</td>
<td>Time in seconds required for local recovery by node just starting</td>
</tr>
<tr>
<td>secs_restore.fragments</td>
<td>integer</td>
<td>Time in seconds required to restore fragments from LCP files</td>
</tr>
<tr>
<td>secs_undo_disk_data</td>
<td>integer</td>
<td>Time in seconds required to execute undo log on disk data part of records</td>
</tr>
<tr>
<td>secs_exec_redo_log</td>
<td>integer</td>
<td>Time in seconds required to execute redo log on all restored fragments</td>
</tr>
<tr>
<td>secs_index_rebuild</td>
<td>integer</td>
<td>Time in seconds required to rebuild indexes on restored fragments</td>
</tr>
<tr>
<td>secs_to_synchronize_starting_node</td>
<td>integer</td>
<td>Time in seconds required to synchronize starting node from live nodes</td>
</tr>
<tr>
<td>secs_wait_lcp_for_restart</td>
<td>integer</td>
<td>Time in seconds required for LCP start and completion before restart was completed</td>
</tr>
<tr>
<td>secs_wait_subscription</td>
<td>integer</td>
<td>Time in seconds spent waiting for handover of replication subscriptions</td>
</tr>
<tr>
<td>total_restart_secs</td>
<td>integer</td>
<td>Total number of seconds from node failure until node is started again</td>
</tr>
</tbody>
</table>

Defined values for `node_restart_status_int` and corresponding status names and messages (`node_restart_status`) are shown in the following table:

Table 18.365 Status codes and messages used in the restart_info table

<table>
<thead>
<tr>
<th>Column Name</th>

<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>ALLOCATED_NODE_ID</td>
<td>Allocated node id</td>
</tr>
<tr>
<td>1</td>
<td>INCLUDED_IN_HB_PROTOCOL</td>
<td>Included in heartbeat protocol</td>
</tr>
</tbody>
</table>
The `ndbinfo` server_operations Table

The `server_operations` table contains entries for all ongoing NDB operations that the current SQL node (MySQL Server) is currently involved in. It effectively is a subset of the `cluster_operations` table, in which operations for other SQL and API nodes are not shown.

The following table provides information about the columns in the `server_operations` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.
Table 18.366 Columns of the server_operations table

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mysql_connection_id</td>
<td>integer</td>
<td>MySQL Server connection ID</td>
</tr>
<tr>
<td>node_id</td>
<td>integer</td>
<td>Node ID</td>
</tr>
<tr>
<td>block_instance</td>
<td>integer</td>
<td>Block instance</td>
</tr>
<tr>
<td>transid</td>
<td>integer</td>
<td>Transaction ID</td>
</tr>
<tr>
<td>operation_type</td>
<td>string</td>
<td>Operation type (see text for possible values)</td>
</tr>
<tr>
<td>state</td>
<td>string</td>
<td>Operation state (see text for possible values)</td>
</tr>
<tr>
<td>tableid</td>
<td>integer</td>
<td>Table ID</td>
</tr>
<tr>
<td>fragmentid</td>
<td>integer</td>
<td>Fragment ID</td>
</tr>
<tr>
<td>client_node_id</td>
<td>integer</td>
<td>Client node ID</td>
</tr>
<tr>
<td>client_block_ref</td>
<td>integer</td>
<td>Client block reference</td>
</tr>
<tr>
<td>tc_node_id</td>
<td>integer</td>
<td>Transaction coordinator node ID</td>
</tr>
<tr>
<td>tc_block_no</td>
<td>integer</td>
<td>Transaction coordinator block number</td>
</tr>
<tr>
<td>tc_block_instance</td>
<td>integer</td>
<td>Transaction coordinator block instance</td>
</tr>
</tbody>
</table>

The mysql_connection_id is the same as the connection or session ID shown in the output of `SHOW PROCESSLIST`. It is obtained from the INFORMATION_SCHEMA table `NDB_TRANSID_MYSQL_CONNECTION_MAP`.

block_instance refers to an instance of a kernel block. Together with the block name, this number can be used to look up a given instance in the threadblocks table.

The transaction ID (transid) is a unique 64-bit number which can be obtained using the NDB API's `getTransactionId()` method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

The operation_type column can take any one of the values `READ`, `READ-SH`, `READ-EX`, `INSERT`, `UPDATE`, `DELETE`, `WRITE`, `UNLOCK`, `REFRESH`, `SCAN`, `SCAN-SH`, `SCAN-EX`, or `<unknown>`.

The state column can have any one of the values `ABORT_QUEUED`, `ABORT_STOPPED`, `COMMITTED`, `COMMIT_QUEUED`, `COMMIT_STOPPED`, `COPY_CLOSE_STOPPED`, `COPY_FIRST_STOPPED`, `COPY_STOPPED`, `COPY_TUPKEY`, `IDLE`, `LOG_ABORT_QUEUED`, `LOG_ABORT_WRITTEN`, `LOG_COMMIT_QUEUED_WAIT_SIGNAL`, `LOG_COMMIT_WRITTEN`, `LOG_COMMIT_WRITTEN_WAIT_SIGNAL`, `LOG_ABORT_QUEUED`, `LOG_ABORT_WRITTEN`, `LOG_COMMIT_QUEUED_WAIT_SIGNAL`, `LOG_COMMIT_WRITTEN`, `LOG_COMMIT_WRITTEN_WAIT_SIGNAL`, `LOG_QUEUED`, `PREPARED`, `PREPARED_RECEIVED_COMMIT`, `SCAN_CHECK_STOPPED`, `SCAN_CLOSE_STOPPED`, `SCAN_FIRST_STOPPED`, `SCAN_RELEASE_STOPPED`, `SCAN_STATE_USED`, `SCAN_STOPPED`, `SCAN_TUPKEY`, `STOPPED`, `TC_NOT_CONNECTED`, `WAIT_ACC`, `WAIT_ACC_ABORT`, `WAIT_AI_AFTER_ABORT`, `WAIT_ATTR`, `WAIT_SCAN_AI`, `WAIT_TUP`, `WAIT_TUPKEYINFO`, `WAIT_TUP_COMMIT`, or `WAIT_TUP_TO_ABORT`. (If the MySQL Server is running with ndbinfo_show_hidden enabled, you can view this list of states by selecting from the ndb $dblqh_tcconnect_state table, which is normally hidden.)

You can obtain the name of an NDB table from its table ID by checking the output of `ndb_show_tables`.

The fragid is the same as the partition number seen in the output of `ndb_desc --extra-partition-info` (short form `-p`).

In client_node_id and client_block_ref, client refers to an NDB Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).
The block_instance and tc_block_instance column provide NDB kernel block instance numbers. You can use these to obtain information about specific threads from the threadblocks table.

18.5.10.23 The ndbinfo server_transactions Table

The server_transactions table is subset of the cluster_transactions table, but includes only those transactions in which the current SQL node (MySQL Server) is a participant, while including the relevant connection IDs.

The following table provides information about the columns in the server_transactions table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Table 18.367 Columns of the server_transactions table

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mysql_connection_id</td>
<td>integer</td>
<td>MySQL Server connection ID</td>
</tr>
<tr>
<td>node_id</td>
<td>integer</td>
<td>Transaction coordinator node ID</td>
</tr>
<tr>
<td>block_instance</td>
<td>integer</td>
<td>Transaction coordinator block instance</td>
</tr>
<tr>
<td>transid</td>
<td>integer</td>
<td>Transaction ID</td>
</tr>
<tr>
<td>state</td>
<td>string</td>
<td>Operation state (see text for possible values)</td>
</tr>
<tr>
<td>count_operations</td>
<td>integer</td>
<td>Number of stateful operations in the transaction</td>
</tr>
<tr>
<td>outstanding_operations</td>
<td>integer</td>
<td>Operations still being executed by local data management layer (LQH blocks)</td>
</tr>
<tr>
<td>inactive_seconds</td>
<td>integer</td>
<td>Time spent waiting for API</td>
</tr>
<tr>
<td>client_node_id</td>
<td>integer</td>
<td>Client node ID</td>
</tr>
<tr>
<td>client_block_ref</td>
<td>integer</td>
<td>Client block reference</td>
</tr>
</tbody>
</table>

The mysql_connection_id is the same as the connection or session ID shown in the output of SHOW PROCESSLIST. It is obtained from the INFORMATION_SCHEMA table NDB_TRANSID_MYSQL_CONNECTION_MAP.

block_instance refers to an instance of a kernel block. Together with the block name, this number can be used to look up a given instance in the threadblocks table.

The transaction ID (transid) is a unique 64-bit number which can be obtained using the NDB API's getTransactionId() method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

The state column can have any one of the values CS_ABORTING, CS_COMMITTING, CS_COMMIT_SENT, CS_COMPLETE_SENT, CS_COMPLETING, CS_CONNECTED, CS_DISCONNECTED, CS_FAIL_ABORTED, CS_FAIL_ABORTING, CS_FAIL_COMMITTED, CS_FAIL_COMMITTING, CS_FAIL_COMPLETED, CS_FAIL_PREPARED, CS_PREPARE_TO_COMMIT, CS_RECEIVING, CS_REC_COMMITTING, CS_RESTART, CS_SEND_FIRE_TRIG_REQ, CS_STARTED, CS_START_COMMITTING, CS_START_SCAN, CS_WAIT_ABORT_CONF, CS_WAIT_COMMIT_CONF, CS_WAIT_COMPLETE_CONF, CS_WAIT_FIRE_TRIG_REQ. (If the MySQL Server is running with ndbinfo_show_hidden enabled, you can view this list of states by selecting from the ndb$dbtc_apiconnect_state table, which is normally hidden.)

In client_node_id and client_block_ref, client refers to an NDB Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).
The `block_instance` column provides the DBTC kernel block instance number. You can use this to obtain information about specific threads from the `threadblocks` table.

### 18.5.10.24 The `ndbinfo tc_time_track_stats` Table

The `tc_time_track_stats` table provides time-tracking information obtained from the DBTC block (TC) instances in the data nodes, through API nodes access NDB. Each TC instance tracks latencies for a set of activities it undertakes on behalf of API nodes or other data nodes; these activities include transactions, transaction errors, key reads, key writes, unique index operations, failed key operations of any type, scans, failed scans, fragment scans, and failed fragment scans.

A set of counters is maintained for each activity, each counter covering a range of latencies less than or equal to an upper bound. At the conclusion of each activity, its latency is determined and the appropriate counter incremented. `tc_time_track_stats` presents this information as rows, with a row for each instance of the following:

- Data node, using its ID
- TC block instance
- Other communicating data node or API node, using its ID
- Upper bound value

Each row contains a value for each activity type. This is the number of times that this activity occurred with a latency within the range specified by the row (that is, where the latency does not exceed the upper bound).

The following table provides information about the columns in `tc_time_track_stats`. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>Requesting node ID</td>
</tr>
<tr>
<td>block_number</td>
<td>integer</td>
<td>TC block number</td>
</tr>
<tr>
<td>block_instance</td>
<td>integer</td>
<td>TC block instance number</td>
</tr>
<tr>
<td>comm_node_id</td>
<td>integer</td>
<td>Node ID of communicating API or data node</td>
</tr>
<tr>
<td>upper_bound</td>
<td>integer</td>
<td>Upper bound of interval (in microseconds)</td>
</tr>
<tr>
<td>scans</td>
<td>integer</td>
<td>Based on duration of successful scans from opening to closing, tracked against the API or data nodes requesting them.</td>
</tr>
<tr>
<td>scan_errors</td>
<td>integer</td>
<td>Based on duration of failed scans from opening to closing, tracked against the API or data nodes requesting them.</td>
</tr>
<tr>
<td>scan.fragments</td>
<td>integer</td>
<td>Based on duration of successful fragment scans from opening to closing, tracked against the data nodes executing them</td>
</tr>
<tr>
<td>scan_fragment_errors</td>
<td>integer</td>
<td>Based on duration of failed fragment scans from opening to closing, tracked against the data nodes executing them</td>
</tr>
</tbody>
</table>

Table 18.368 Columns of the `tc_time_track_stats` table
### ndbinfo: The NDB Cluster Information Database

The `ndbinfo` command provides information about the NDB Cluster configuration and status. This includes details about NDB kernel blocks, transactions, and system statistics.

#### 18.10.25 The ndbinfo threadblocks Table

The `threadblocks` table is used to associate data nodes, threads, and instances of NDB kernel blocks.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>Node ID</td>
</tr>
<tr>
<td>thr_no</td>
<td>integer</td>
<td>Thread ID</td>
</tr>
<tr>
<td>block_name</td>
<td>string</td>
<td>Block name</td>
</tr>
<tr>
<td>block_instance</td>
<td>integer</td>
<td>Block instance number</td>
</tr>
</tbody>
</table>

The value of the `block_name` column is one of the values found in the `block_name` column when selecting from the `ndbinfo.blocks` table. Although the list of possible values is static for a given NDB Cluster release, the list may vary between releases.

The `block_instance` column provides the kernel block instance number.
18.5.10.26 The ndbinfo threadstat Table

The threadstat table provides a rough snapshot of statistics for threads running in the NDB kernel.

The following table provides information about the columns in the threadstat table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

Table 18.370 Columns of the threadstat table

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>Node ID</td>
</tr>
<tr>
<td>thr_no</td>
<td>integer</td>
<td>Thread ID</td>
</tr>
<tr>
<td>thr_nm</td>
<td>string</td>
<td>Thread name</td>
</tr>
<tr>
<td>c_loop</td>
<td>string</td>
<td>Number of loops in main loop</td>
</tr>
<tr>
<td>c_exec</td>
<td>string</td>
<td>Number of signals executed</td>
</tr>
<tr>
<td>c_wait</td>
<td>string</td>
<td>Number of times waiting for additional input</td>
</tr>
<tr>
<td>c_l_sent_prioa</td>
<td>integer</td>
<td>Number of priority A signals sent to own node</td>
</tr>
<tr>
<td>c_l_sent_priob</td>
<td>integer</td>
<td>Number of priority B signals sent to own node</td>
</tr>
<tr>
<td>c_r_sent_prioa</td>
<td>integer</td>
<td>Number of priority A signals sent to remote node</td>
</tr>
<tr>
<td>c_r_sent_priob</td>
<td>integer</td>
<td>Number of priority B signals sent to remote node</td>
</tr>
<tr>
<td>os_tid</td>
<td>integer</td>
<td>OS thread ID</td>
</tr>
<tr>
<td>os_now</td>
<td>integer</td>
<td>OS time (ms)</td>
</tr>
<tr>
<td>os_ru_utime</td>
<td>integer</td>
<td>OS user CPU time (µs)</td>
</tr>
<tr>
<td>os_ru_stime</td>
<td>integer</td>
<td>OS system CPU time (µs)</td>
</tr>
<tr>
<td>os_ru_minflt</td>
<td>integer</td>
<td>OS page reclaims (soft page faults)</td>
</tr>
<tr>
<td>os_ru_majflt</td>
<td>integer</td>
<td>OS page faults (hard page faults)</td>
</tr>
<tr>
<td>os_ru_nvcsw</td>
<td>integer</td>
<td>OS voluntary context switches</td>
</tr>
<tr>
<td>os_ru_nivcsw</td>
<td>integer</td>
<td>OS involuntary context switches</td>
</tr>
</tbody>
</table>

os_time uses the system gettimeofday() call.

The values of the os_ru_utime, os_ru_stime, os_ru_minflt, os_ru_majflt, os_ru_nvcsw, and os_ru_nivcsw columns are obtained using the system getrusage() call, or the equivalent.

Since this table contains counts taken at a given point in time, for best results it is necessary to query this table periodically and store the results in an intermediate table or tables. The MySQL Server's Event Scheduler can be employed to automate such monitoring. For more information, see Section 20.4, “Using the Event Scheduler”.

18.5.10.27 The ndbinfo transporters Table

This table contains information about NDB transporters.

The following table provides information about the columns in the transporters table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.
### Table 18.371 Columns of the transporters table

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>This data node's unique node ID in the cluster</td>
</tr>
<tr>
<td>remote_node_id</td>
<td>integer</td>
<td>The remote data node's node ID</td>
</tr>
<tr>
<td>status</td>
<td>string</td>
<td>Status of the connection</td>
</tr>
<tr>
<td>remote_address</td>
<td>string</td>
<td>Name or IP address of the remote host</td>
</tr>
<tr>
<td>bytes_sent</td>
<td>integer</td>
<td>Number of bytes sent using this connection</td>
</tr>
<tr>
<td>bytes_received</td>
<td>integer</td>
<td>Number of bytes received using this connection</td>
</tr>
<tr>
<td>connect_count</td>
<td>integer</td>
<td>Number of times connection established on this transporter</td>
</tr>
<tr>
<td>overloaded</td>
<td>boolean (0 or 1)</td>
<td>1 if this transporter is currently overloaded, otherwise 0</td>
</tr>
<tr>
<td>overload_count</td>
<td>integer</td>
<td>Number of times this transporter has entered overload state since connecting</td>
</tr>
<tr>
<td>slowdown</td>
<td>boolean (0 or 1)</td>
<td>1 if this transporter is in slowdown state, otherwise 0</td>
</tr>
<tr>
<td>slowdown_count</td>
<td>integer</td>
<td>Number of times this transporter has entered slowdown state since connecting</td>
</tr>
</tbody>
</table>

For each running data node in the cluster, the transporters table displays a row showing the status of each of that node's connections with all nodes in the cluster, including itself. This information is shown in the table’s status column, which can have any one of the following values: CONNECTING, CONNECTED, DISCONNECTING, or DISCONNECTED.

Connections to API and management nodes which are configured but not currently connected to the cluster are shown with status DISCONNECTED. Rows where the node_id is that of a data node which is not currently connected are not shown in this table. (This is similar omission of disconnected nodes in the ndbinfo.nodes table.

The remote_address is the host name or address for the node whose ID is shown in the remote_node_id column. The bytes_sent from this node and bytes_received by this node are the numbers, respectively, of bytes sent and received by the node using this connection since it was established. For nodes whose status is CONNECTING or DISCONNECTED, these columns always display 0.

Assume you have a 5-node cluster consisting of 2 data nodes, 2 SQL nodes, and 1 management node, as shown in the output of the SHOW command in the ndb_mgm client:

```sql
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
---------------------
[ndbd(NDB)]    2 node(s)
id=1 @10.100.10.1 (5.6.45-ndb-7.4.25, Nodegroup: 0, *)
id=2 @10.100.10.2 (5.6.45-ndb-7.4.25, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=10 @10.100.10.10 (5.6.45-ndb-7.4.25)

[mysqld(API)] 2 node(s)
id=20 @10.100.10.20 (5.6.45-ndb-7.4.25)
id=21 @10.100.10.21 (5.6.45-ndb-7.4.25)
```
There are 10 rows in the `transporters` table—5 for the first data node, and 5 for the second—assuming that all data nodes are running, as shown here:

```sql
mysql> SELECT node_id, remote_node_id, status
>` FROM ndbinfo.transporters;
+---------+----------------+---------------+
<table>
<thead>
<tr>
<th>node_id</th>
<th>remote_node_id</th>
<th>status</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>DISCONNECTED</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>CONNECTED</td>
</tr>
<tr>
<td>1</td>
<td>10</td>
<td>CONNECTED</td>
</tr>
<tr>
<td>1</td>
<td>20</td>
<td>CONNECTED</td>
</tr>
<tr>
<td>1</td>
<td>21</td>
<td>CONNECTED</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>CONNECTED</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
<td>DISCONNECTED</td>
</tr>
<tr>
<td>2</td>
<td>10</td>
<td>CONNECTED</td>
</tr>
<tr>
<td>2</td>
<td>20</td>
<td>CONNECTED</td>
</tr>
<tr>
<td>2</td>
<td>21</td>
<td>CONNECTED</td>
</tr>
</tbody>
</table>
+---------+----------------+---------------+
10 rows in set (0.04 sec)
```

If you shut down one of the data nodes in this cluster using the command `STOP` in the `ndb_mgm` client, then repeat the previous query (again using the `mysql` client), this table now shows only 5 rows—1 row for each connection from the remaining management node to another node, including both itself and the data node that is currently offline—and displays `CONNECTING` for the status of each remaining connection to the data node that is currently offline, as shown here:

```sql
mysql> SELECT node_id, remote_node_id, status
>` FROM ndbinfo.transporters;
+---------+----------------+---------------+
<table>
<thead>
<tr>
<th>node_id</th>
<th>remote_node_id</th>
<th>status</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>DISCONNECTED</td>
</tr>
<tr>
<td>1</td>
<td>2</td>

The `connect_count`, `overloaded`, `overload_count`, `slowdown`, and `slowdown_count` counters are reset on connection, and retain their values after the remote node disconnects. The `bytes_sent` and `bytes_received` counters are also reset on connection, and so retain their values following disconnection (until the next connection resets them).

The `overload` state referred to by the `overloaded` and `overload_count` columns occurs when this transporter's send buffer contains more than `OverloadLimit` bytes (default is 80% of `SendBufferMemory`, that is, 0.8 * 2097152 = 1677721 bytes). When a given transporter is in a state of overload, any new transaction that tries to use this transporter fails with Error 1218 (`Send Buffers overloaded in NDB kernel`). This affects both scans and primary key operations.

The `slowdown` state referenced by the `slowdown` and `slowdown_count` columns of this table occurs when the transporter's send buffer contains more than 60% of the overload limit (equal to 0.6 * 2097152 = 1258291 bytes by default). In this state, any new scan using this transporter has its batch size reduced to minimize the load on the transporter.

Common causes of send buffer slowdown or overloading include the following:

- Data size, in particular the quantity of data stored in `TEXT` columns or `BLOB` columns (or both types of columns)
• Having a data node (ndbd or ndbmttd) on the same host as an SQL node that is engaged in binary logging
• Large number of rows per transaction or transaction batch
• Configuration issues such as insufficient SendBufferMemory
• Hardware issues such as insufficient RAM or poor network connectivity

See also Section 18.3.3.13, “Configuring NDB Cluster Send Buffer Parameters”.

18.5.11 NDB Cluster Security Issues

This section discusses security considerations to take into account when setting up and running NDB Cluster.

Topics covered in this section include the following:
• NDB Cluster and network security issues
• Configuration issues relating to running NDB Cluster securely
• NDB Cluster and the MySQL privilege system
• MySQL standard security procedures as applicable to NDB Cluster

18.5.11.1 NDB Cluster Security and Networking Issues

In this section, we discuss basic network security issues as they relate to NDB Cluster. It is extremely important to remember that NDB Cluster “out of the box” is not secure; you or your network administrator must take the proper steps to ensure that your cluster cannot be compromised over the network.

Cluster communication protocols are inherently insecure, and no encryption or similar security measures are used in communications between nodes in the cluster. Because network speed and latency have a direct impact on the cluster's efficiency, it is also not advisable to employ SSL or other encryption to network connections between nodes, as such schemes will effectively slow communications.

It is also true that no authentication is used for controlling API node access to an NDB Cluster. As with encryption, the overhead of imposing authentication requirements would have an adverse impact on Cluster performance.

In addition, there is no checking of the source IP address for either of the following when accessing the cluster:
• SQL or API nodes using “free slots” created by empty [mysqld] or [api] sections in the config.ini file

This means that, if there are any empty [mysqld] or [api] sections in the config.ini file, then any API nodes (including SQL nodes) that know the management server’s host name (or IP address) and port can connect to the cluster and access its data without restriction. (See Section 18.5.11.2, “NDB Cluster and MySQL Privileges”, for more information about this and related issues.)

Note

You can exercise some control over SQL and API node access to the cluster by specifying a HostName parameter for all [mysqld] and [api] sections in the config.ini file. However, this also means that, should you wish to connect an
API node to the cluster from a previously unused host, you need to add an [api] section containing its host name to the config.ini file.

More information is available elsewhere in this chapter about the HostName parameter. Also see Section 18.3.1, “Quick Test Setup of NDB Cluster”, for configuration examples using HostName with API nodes.

- Any ndb_mgm client

This means that any cluster management client that is given the management server’s host name (or IP address) and port (if not the standard port) can connect to the cluster and execute any management client command. This includes commands such as ALL STOP and SHUTDOWN.

For these reasons, it is necessary to protect the cluster on the network level. The safest network configuration for Cluster is one which isolates connections between Cluster nodes from any other network communications. This can be accomplished by any of the following methods:

1. Keeping Cluster nodes on a network that is physically separate from any public networks. This option is the most dependable; however, it is the most expensive to implement.

We show an example of an NDB Cluster setup using such a physically segregated network here:

**Figure 18.19 NDB Cluster with Hardware Firewall**

![Diagram of NDB Cluster with Hardware Firewall]

This setup has two networks, one private (solid box) for the Cluster management servers and data nodes, and one public (dotted box) where the SQL nodes reside. (We show the management and data nodes connected using a gigabit switch since this provides the best performance.) Both networks are protected from the outside by a hardware firewall, sometimes also known as a network-based firewall.

This network setup is safest because no packets can reach the cluster’s management or data nodes from outside the network—and none of the cluster’s internal communications can reach the outside —without going through the SQL nodes, as long as the SQL nodes do not permit any packets to be forwarded. This means, of course, that all SQL nodes must be secured against hacking attempts.

**Important**

With regard to potential security vulnerabilities, an SQL node is no different from any other MySQL server. See Section 6.1.3, “Making MySQL Secure Against...”
2. Using one or more software firewalls (also known as *host-based firewalls*) to control which packets pass through to the cluster from portions of the network that do not require access to it. In this type of setup, a software firewall must be installed on every host in the cluster which might otherwise be accessible from outside the local network.

The host-based option is the least expensive to implement, but relies purely on software to provide protection and so is the most difficult to keep secure.

This type of network setup for NDB Cluster is illustrated here:

**Figure 18.20 NDB Cluster with Software Firewalls**

Using this type of network setup means that there are two zones of NDB Cluster hosts. Each cluster host must be able to communicate with all of the other machines in the cluster, but only those hosting SQL nodes (dotted box) can be permitted to have any contact with the outside, while those in the zone containing the data nodes and management nodes (solid box) must be isolated from any machines that are not part of the cluster. Applications using the cluster and user of those applications must *not* be permitted to have direct access to the management and data node hosts.

To accomplish this, you must set up software firewalls that limit the traffic to the type or types shown in the following table, according to the type of node that is running on each cluster host computer:

**Table 18.372 Node types in a host-based firewall cluster configuration**

<table>
<thead>
<tr>
<th>Node Type</th>
<th>Permitted Traffic</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQL or API node</td>
<td>- It originates from the IP address of a management or data node (using any TCP or UDP port).</td>
</tr>
</tbody>
</table>
### Node Type | Permitted Traffic
---|---
| | It originates from within the network in which the cluster resides and is on the port that your application is using. |
Data node or Management node | It originates from the IP address of a management or data node (using any TCP or UDP port). |
| | It originates from the IP address of an SQL or API node. |

Any traffic other than that shown in the table for a given node type should be denied.

The specifics of configuring a firewall vary from firewall application to firewall application, and are beyond the scope of this Manual. `iptables` is a very common and reliable firewall application, which is often used with `APF` as a front end to make configuration easier. You can (and should) consult the documentation for the software firewall that you employ, should you choose to implement an NDB Cluster network setup of this type, or of a “mixed” type as discussed under the next item.

3. It is also possible to employ a combination of the first two methods, using both hardware and software to secure the cluster—that is, using both network-based and host-based firewalls. This is between the first two schemes in terms of both security level and cost. This type of network setup keeps the cluster behind the hardware firewall, but permits incoming packets to travel beyond the router connecting all cluster hosts to reach the SQL nodes.

One possible network deployment of an NDB Cluster using hardware and software firewalls in combination is shown here:

**Figure 18.21 NDB Cluster with a Combination of Hardware and Software Firewalls**

In this case, you can set the rules in the hardware firewall to deny any external traffic except to SQL nodes and API nodes, and then permit traffic to them only on the ports required by your application.

Whatever network configuration you use, remember that your objective from the viewpoint of keeping the cluster secure remains the same—to prevent any unessential traffic from reaching the cluster while ensuring the most efficient communication between the nodes in the cluster.
Because NDB Cluster requires large numbers of ports to be open for communications between nodes, the recommended option is to use a segregated network. This represents the simplest way to prevent unwanted traffic from reaching the cluster.

**Note**

If you wish to administer an NDB Cluster remotely (that is, from outside the local network), the recommended way to do this is to use `ssh` or another secure login shell to access an SQL node host. From this host, you can then run the management client to access the management server safely, from within the Cluster’s own local network.

Even though it is possible to do so in theory, it is not recommended to use `ndb_mgm` to manage a Cluster directly from outside the local network on which the Cluster is running. Since neither authentication nor encryption takes place between the management client and the management server, this represents an extremely insecure means of managing the cluster, and is almost certain to be compromised sooner or later.

### 18.5.11.2 NDB Cluster and MySQL Privileges

In this section, we discuss how the MySQL privilege system works in relation to NDB Cluster and the implications of this for keeping an NDB Cluster secure.

Standard MySQL privileges apply to NDB Cluster tables. This includes all MySQL privilege types (SELECT privilege, UPDATE privilege, DELETE privilege, and so on) granted on the database, table, and column level. As with any other MySQL Server, user and privilege information is stored in the `mysql` system database. The SQL statements used to grant and revoke privileges on `NDB` tables, databases containing such tables, and columns within such tables are identical in all respects with the `GRANT` and `REVOKE` statements used in connection with database objects involving any (other) MySQL storage engine. The same thing is true with respect to the `CREATE USER` and `DROP USER` statements.

It is important to keep in mind that, by default, the MySQL grant tables use the `MyISAM` storage engine. Because of this, those tables are not normally duplicated or shared among MySQL servers acting as SQL nodes in an NDB Cluster. In other words, changes in users and their privileges do not automatically propagate between SQL nodes by default. If you wish, you can enable automatic distribution of MySQL users and privileges across NDB Cluster SQL nodes; see Section 18.5.15, “Distributed MySQL Privileges for NDB Cluster”, for details.

Conversely, because there is no way in MySQL to deny privileges (privileges can either be revoked or not granted in the first place, but not denied as such), there is no special protection for `NDB` tables on one SQL node from users that have privileges on another SQL node; (This is true even if you are not using automatic distribution of user privileges. The definitive example of this is the MySQL root account, which can perform any action on any database object. In combination with empty `[mysqld]` or `[api]` sections of the `config.ini` file, this account can be especially dangerous. To understand why, consider the following scenario:

- The `config.ini` file contains at least one empty `[mysqld]` or `[api]` section. This means that the NDB Cluster management server performs no checking of the host from which a MySQL Server (or other API node) accesses the NDB Cluster.
- There is no firewall, or the firewall fails to protect against access to the NDB Cluster from hosts external to the network.
- The host name or IP address of the NDB Cluster management server is known or can be determined from outside the network.
If these conditions are true, then anyone, anywhere can start a MySQL Server with `--ndbcluster` `--ndb-connectstring=management_host` and access this NDB Cluster. Using the MySQL root account, this person can then perform the following actions:

- Execute metadata statements such as `SHOW DATABASES` statement (to obtain a list of all NDB databases on the server) or `SHOW TABLES FROM some_ndb_database` statement to obtain a list of all NDB tables in a given database.

- Run any legal MySQL statements on any of the discovered tables, such as:
  - `SELECT * FROM some_table` to read all the data from any table.
  - `DELETE FROM some_table` to delete all the data from a table.
  - `DESCRIBE some_table` or `SHOW CREATE TABLE some_table` to determine the table schema.
  - `UPDATE some_table SET column1 = some_value` to fill a table column with “garbage” data; this could actually cause much greater damage than simply deleting all the data.

More insidious variations might include statements like these:

```
UPDATE some_table SET an_int_column = an_int_column + 1
```

or

```
UPDATE some_table SET a_varchar_column = REVERSE(a_varchar_column)
```

Such malicious statements are limited only by the imagination of the attacker.

The only tables that would be safe from this sort of mayhem would be those tables that were created using storage engines other than NDB, and so not visible to a “rogue” SQL node.

A user who can log in as `root` can also access the INFORMATION_SCHEMA database and its tables, and so obtain information about databases, tables, stored routines, scheduled events, and any other database objects for which metadata is stored in INFORMATION_SCHEMA.

It is also a very good idea to use different passwords for the `root` accounts on different NDB Cluster SQL nodes unless you are using distributed privileges.

In sum, you cannot have a safe NDB Cluster if it is directly accessible from outside your local network.

---

**Important**

*Never leave the MySQL root account password empty.* This is just as true when running MySQL as an NDB Cluster SQL node as it is when running it as a standalone (non-Cluster) MySQL Server, and should be done as part of the MySQL installation process before configuring the MySQL Server as an SQL node in an NDB Cluster.

If you wish to employ NDB Cluster’s distributed privilege capabilities, you should not simply convert the system tables in the `mysql` database to use the NDB storage engine manually. Use the stored procedure provided for this purpose instead; see Section 18.5.15, “Distributed MySQL Privileges for NDB Cluster”.

Otherwise, if you need to synchronize `mysql` system tables between SQL nodes, you can use standard MySQL replication to do so, or employ a script to copy table entries between the MySQL servers.
Summary. The most important points to remember regarding the MySQL privilege system with regard to NDB Cluster are listed here:

1. Users and privileges established on one SQL node do not automatically exist or take effect on other SQL nodes in the cluster. Conversely, removing a user or privilege on one SQL node in the cluster does not remove the user or privilege from any other SQL nodes.

2. You can distribute MySQL users and privileges among SQL nodes using the SQL script, and the stored procedures it contains, that are supplied for this purpose in the NDB Cluster distribution.

3. Once a MySQL user is granted privileges on an NDB table from one SQL node in an NDB Cluster, that user can “see” any data in that table regardless of the SQL node from which the data originated, even if you are not using privilege distribution.

18.5.11.3 NDB Cluster and MySQL Security Procedures

In this section, we discuss MySQL standard security procedures as they apply to running NDB Cluster.

In general, any standard procedure for running MySQL securely also applies to running a MySQL Server as part of an NDB Cluster. First and foremost, you should always run a MySQL Server as the mysql operating system user; this is no different from running MySQL in a standard (non-Cluster) environment. The mysql system account should be uniquely and clearly defined. Fortunately, this is the default behavior for a new MySQL installation. You can verify that the mysqld process is running as the mysql operating system user by using the system command such as the one shown here:

```
shell> ps aux | grep mysql
root     10467  0.0  0.1   3616  1380 pts/3    S    11:53   0:00 /bin/sh ./mysqld_safe --ndbcluster --ndb-connectstring=localhost:1186
mysql    10512  2.5  2.5  58528 26636 pts/3    Sl   11:53   0:00 /usr/local/mysql/libexec/mysqld --basedir=/usr/local/mysql --datadir=/usr/local/mysql/var --user=mysql --ndbcluster --ndb-connectstring=localhost:1186 --pid-file=/usr/local/mysql/var/mothra.pid --log-error=/usr/local/mysql/var/mothra.err
jon      10579  0.0  0.0   2736   688 pts/0    S+   11:54   0:00 grep mysql
```

If the mysqld process is running as any other user than mysql, you should immediately shut it down and restart it as the mysql user. If this user does not exist on the system, the mysql user account should be created, and this user should be part of the mysql user group; in this case, you should also make sure that the MySQL data directory on this system (as set using the --datadir option for mysqld) is owned by the mysql user, and that the SQL node's my.cnf file includes user=mysql in the [mysqld] section. Alternatively, you can start the MySQL server process with --user=mysql on the command line, but it is preferable to use the my.cnf option, since you might forget to use the command-line option and so have mysqld running as another user unintentionally. The mysqld_safe startup script forces MySQL to run as the mysql user.

Important
Never run mysqld as the system root user. Doing so means that potentially any file on the system can be read by MySQL, and thus—should MySQL be compromised—by an attacker.

As mentioned in the previous section (see Section 18.5.11.2, “NDB Cluster and MySQL Privileges”), you should always set a root password for the MySQL Server as soon as you have it running. You should also delete the anonymous user account that is installed by default. You can accomplish these tasks using the following statements:

```
shell> mysql -u root
```
**UPDATE mysql.user**

- SET Password=PASSWORD('secure_password')
- WHERE User='root';

**DELETE FROM mysql.user**

- WHERE User='';

**FLUSH PRIVILEGES;**

Be very careful when executing the **DELETE** statement not to omit the **WHERE** clause, or you risk deleting all MySQL users. Be sure to run the **FLUSH PRIVILEGES** statement as soon as you have modified the **mysql.user** table, so that the changes take immediate effect. Without **FLUSH PRIVILEGES**, the changes do not take effect until the next time that the server is restarted.

**Note**

Many of the NDB Cluster utilities such as **ndb_show_tables**, **ndb_desc**, and **ndb_select_all** also work without authentication and can reveal table names, schemas, and data. By default these are installed on Unix-style systems with the permissions `wxr-xr-x` (755), which means they can be executed by any user that can access the `mysql/bin` directory.

See Section 18.4, “NDB Cluster Programs”, for more information about these utilities.

### 18.5.12 NDB Cluster Disk Data Tables

It is possible to store the nonindexed columns of NDB tables on disk, rather than in RAM.

As part of implementing NDB Cluster Disk Data work, a number of improvements were made in NDB Cluster for the efficient handling of very large amounts (terabytes) of data during node recovery and restart. These include a “no-steal” algorithm for synchronizing a starting node with very large data sets. For more information, see the paper *Recovery Principles of NDB Cluster 5.1*, by NDB Cluster developers Mikael Ronström and Jonas Oreland.

NDB Cluster Disk Data performance can be influenced by a number of configuration parameters. For information about these parameters and their effects, see NDB Cluster Disk Data configuration parameters and NDB Cluster Disk Data storage and GCP Stop errors.

The performance of an NDB Cluster that uses Disk Data storage can also be greatly improved by separating data node file systems from undo log files and tablespace data files, which can be done using symbolic links. For more information, see Section 18.5.12.2, “Using Symbolic Links with Disk Data Objects”.

### 18.5.12.1 NDB Cluster Disk Data Objects

NDB Cluster Disk Data storage is implemented using a number of Disk Data objects. These include the following:

- **Tablespaces** act as containers for other Disk Data objects.
- **Undo log files** undo information required for rolling back transactions.
- One or more undo log files are assigned to a **log file group**, which is then assigned to a tablespace.
- **Data files** store Disk Data table data. A data file is assigned directly to a tablespace.

Undo log files and data files are actual files in the file system of each data node; by default they are placed in `ndb_node_id_fs` in the `DataDir` specified in the NDB Cluster `config.ini` file, and where `node_id`
is the data node’s node ID. It is possible to place these elsewhere by specifying either an absolute or relative path as part of the filename when creating the undo log or data file. Statements that create these files are shown later in this section.

NDB Cluster tables and log file groups are not implemented as files.

Important

Although not all Disk Data objects are implemented as files, they all share the same namespace. This means that each Disk Data object must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and a log file group both named dd1.

Assuming that you have already set up an NDB Cluster with all nodes (including management and SQL nodes), the basic steps for creating an NDB Cluster table on disk are as follows:

1. Create a log file group, and assign one or more undo log files to it (an undo log file is also sometimes referred to as an *undofile*).

Note

Undo log files are necessary only for Disk Data tables; they are not used for NDBCLUSTER tables that are stored only in memory.

2. Create a tablespace; assign the log file group, as well as one or more data files, to the tablespace.

3. Create a Disk Data table that uses this tablespace for data storage.

Each of these tasks can be accomplished using SQL statements in the *mysql* client or other MySQL client application, as shown in the example that follows.

1. We create a log file group named *lg_1* using [CREATE LOGFILE GROUP](https://dev.mysql.com/doc/refman/8.0/en/logfile-group.html). This log file group is to be made up of two undo log files, which we name *undo_1.log* and *undo_2.log*, whose initial sizes are 16 MB and 12 MB, respectively. (The default initial size for an undo log file is 128 MB.) Optionally, you can also specify a size for the log file group’s undo buffer, or permit it to assume the default value of 8 MB. In this example, we set the UNDO buffer’s size at 2 MB. A log file group must be created with an undo log file; so we add *undo_1.log* to *lg_1* in this [CREATE LOGFILE GROUP](https://dev.mysql.com/doc/refman/8.0/en/logfile-group.html) statement:

```sql
CREATE LOGFILE GROUP lg_1
  ADD UNDOFILE 'undo_1.log'
  INITIAL_SIZE 16M
  UNDO_BUFFER_SIZE 2M
  ENGINE NDBCLUSTER;
```

To add *undo_2.log* to the log file group, use the following [ALTER LOGFILE GROUP](https://dev.mysql.com/doc/refman/8.0/en/logfile-group.html) statement:

```sql
ALTER LOGFILE GROUP lg_1
  ADD UNDOFILE 'undo_2.log'
  INITIAL_SIZE 12M
  ENGINE NDBCLUSTER;
```

Some items of note:

- The `.log` file extension used here is not required. We use it merely to make the log files easily recognisable.

- Every [CREATE LOGFILE GROUP](https://dev.mysql.com/doc/refman/8.0/en/logfile-group.html) and [ALTER LOGFILE GROUP](https://dev.mysql.com/doc/refman/8.0/en/logfile-group.html) statement must include an ENGINE option. The only permitted values for this option are NDBCLUSTER and NDB.
Important

There can exist at most one log file group in the same NDB Cluster at any given time.

• When you add an undo log file to a log file group using ADD UNDOFILE 'filename', a file with the name filename is created in the ndb_node_id_fs directory within the DataDir of each data node in the cluster, where node_id is the node ID of the data node. Each undo log file is of the size specified in the SQL statement. For example, if an NDB Cluster has 4 data nodes, then the ALTER LOGFILE GROUP statement just shown creates 4 undo log files, 1 each on in the data directory of each of the 4 data nodes; each of these files is named undo_2.log and each file is 12 MB in size.

• UNDO_BUFFER_SIZE is limited by the amount of system memory available.

• For more information about the CREATE LOGFILE GROUP statement, see Section 13.1.14, “CREATE LOGFILE GROUP Syntax”. For more information about ALTER LOGFILE GROUP, see Section 13.1.4, “ALTER LOGFILE GROUP Syntax”.

2. Now we can create a tablespace, which contains files to be used by NDB Cluster Disk Data tables for storing their data. A tablespace is also associated with a particular log file group. When creating a new tablespace, you must specify the log file group which it is to use for undo logging; you must also specify a data file. You can add more data files to the tablespace after the tablespace is created; it is also possible to drop data files from a tablespace (an example of dropping data files is provided later in this section).

Assume that we wish to create a tablespace named ts_1 which uses lg_1 as its log file group. This tablespace is to contain two data files named data_1.dat and data_2.dat, whose initial sizes are 32 MB and 48 MB, respectively. (The default value for INITIAL_SIZE is 128 MB.) We can do this using two SQL statements, as shown here:

```
CREATE TABLESPACE ts_1
  ADD DATAFILE 'data_1.dat'
  USE LOGFILE GROUP lg_1
  INITIAL_SIZE 32M
  ENGINE NDDBCLUSTER;

ALTER TABLESPACE ts_1
  ADD DATAFILE 'data_2.dat'
  INITIAL_SIZE 48M
  ENGINE NDDBCLUSTER;
```

The CREATE TABLESPACE statement creates a tablespace ts_1 with the data file data_1.dat, and associates ts_1 with log file group lg_1. The ALTER TABLESPACE adds the second data file (data_2.dat).

Some items of note:

• As is the case with the .log file extension used in this example for undo log files, there is no special significance for the .dat file extension; it is used merely for easy recognition of data files.

• When you add a data file to a tablespace using ADD DATAFILE 'filename', a file with the name filename is created in the ndb_node_id_fs directory within the DataDir of each data node in the cluster, where node_id is the node ID of the data node. Each data file is of the size specified in the SQL statement. For example, if an NDB Cluster has 4 data nodes, then the ALTER TABLESPACE statement just shown creates 4 data files, 1 each in the data directory of each of the 4 data nodes; each of these files is named data_2.dat and each file is 48 MB in size.
• All CREATE TABLESPACE and ALTER TABLESPACE statements must contain an ENGINE clause; only tables using the same storage engine as the tablespace can be created in the tablespace. For NDB Cluster tablespaces, the only permitted values for this option are NDBCLUSTER and NDB.

• For more information about the CREATE TABLESPACE and ALTER TABLESPACE statements, see Section 13.1.18, “CREATE TABLESPACE Syntax”, and Section 13.1.8, “ALTER TABLESPACE Syntax”.

3. Now it is possible to create a table whose nonindexed columns are stored on disk in the tablespace ts_1:

   ```sql
   CREATE TABLE dt_1 ( 
       member_id INT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY, 
       last_name VARCHAR(50) NOT NULL, 
       first_name VARCHAR(50) NOT NULL, 
       dob DATE NOT NULL, 
       joined DATE NOT NULL, 
       INDEX(last_name, first_name) 
   ) TABLESPACE ts_1 STORAGE DISK 
   ENGINE NDBCLUSTER;
   ```

   The TABLESPACE ... STORAGE DISK option tells the NDBCLUSTER storage engine to use tablespace ts_1 for disk data storage.

   Once table ts_1 has been created as shown, you can perform INSERT, SELECT, UPDATE, and DELETE statements on it just as you would with any other MySQL table.

   It is also possible to specify whether an individual column is stored on disk or in memory by using a STORAGE clause as part of the column's definition in a CREATE TABLE or ALTER TABLE statement. STORAGE DISK causes the column to be stored on disk, and STORAGE MEMORY causes in-memory storage to be used. See Section 13.1.17, “CREATE TABLE Syntax”, for more information.

   **Indexing of columns implicitly stored on disk.** For table dt_1 as defined in the example just shown, only the dob and joined columns are stored on disk. This is because there are indexes on the id, last_name, and first_name columns, and so data belonging to these columns is stored in RAM. Only nonindexed columns can be held on disk; indexes and indexed column data continue to be stored in memory. This tradeoff between the use of indexes and conservation of RAM is something you must keep in mind as you design Disk Data tables.

   You cannot add an index to a column that has been explicitly declared STORAGE DISK, without first changing its storage type to MEMORY; any attempt to do so fails with an error. A column which implicitly uses disk storage can be indexed; when this is done, the column's storage type is changed to MEMORY automatically. By “implicitly”, we mean a column whose storage type is not declared, but which is which inherited from the parent table. In the following CREATE TABLE statement (using the tablespace ts_1 defined previously), columns c2 and c3 use disk storage implicitly:

   ```sql
   mysql> CREATE TABLE ti ( 
   -> c1 INT PRIMARY KEY, 
   -> c2 INT, 
   -> c3 INT, 
   -> c4 INT 
   -> ) 
   -> STORAGE DISK 
   -> TABLESPACE ts_1 
   -> ENGINE NDBCLUSTER;
   Query OK, 0 rows affected (1.31 sec)
   ```
Because \( c_2, c_3, \) and \( c_4 \) are themselves not declared with `STORAGE DISK`, it is possible to index them. Here, we add indexes to \( c_2 \) and \( c_3 \), using, respectively, `CREATE INDEX` and `ALTER TABLE`:

```sql
mysql> CREATE INDEX i1 ON ti(c2);
Query OK, 0 rows affected (2.72 sec)
Records: 0  Duplicates: 0  Warnings: 0

mysql> ALTER TABLE ti ADD INDEX i2(c3);
Query OK, 0 rows affected (0.92 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

`SHOW CREATE TABLE` confirms that the indexes were added.

```sql
mysql> SHOW CREATE TABLE ti\G
*************************** 1. row ***************************
Table: ti
Create Table: CREATE TABLE `ti` (  `c1` int(11) NOT NULL,  `c2` int(11) DEFAULT NULL,  `c3` int(11) DEFAULT NULL,  `c4` int(11) DEFAULT NULL,  PRIMARY KEY (`c1`),  KEY `i1` (`c2`),  KEY `i2` (`c3`) ) /*!50100 TABLESPACE `ts_1` STORAGE DISK */ ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```

You can see using `ndb_desc` that the indexed columns (emphasized text) now use in-memory rather than on-disk storage:

```bash
shell> ./ndb_desc -d test t1
-- t1 --

```
**Performance note.** The performance of a cluster using Disk Data storage is greatly improved if Disk Data files are kept on a separate physical disk from the data node file system. This must be done for each data node in the cluster to derive any noticeable benefit.

You may use absolute and relative file system paths with `ADD UNDOFILE` and `ADD DATAFILE`. Relative paths are calculated relative to the data node's data directory. You may also use symbolic links; see Section 18.5.12.2, “Using Symbolic Links with Disk Data Objects”, for more information and examples.

A log file group, a tablespace, and any Disk Data tables using these must be created in a particular order. The same is true for dropping any of these objects:

- A log file group cannot be dropped as long as any tablespaces are using it.
- A tablespace cannot be dropped as long as it contains any data files.
- You cannot drop any data files from a tablespace as long as there remain any tables which are using the tablespace.
- It is not possible to drop files created in association with a different tablespace than the one with which the files were created. (Bug #20053)

For example, to drop all the objects created so far in this section, you would use the following statements:

```sql
mysql> DROP TABLE dt_1;

mysql> ALTER TABLESPACE ts_1
   -> DROP DATAFILE 'data_2.dat'
   -> ENGINE NDBCLUSTER;

mysql> ALTER TABLESPACE ts_1
   -> DROP DATAFILE 'data_1.dat'
   -> ENGINE NDBCLUSTER;

mysql> DROP TABLESPACE ts_1
   -> ENGINE NDBCLUSTER;

mysql> DROP LOGFILE GROUP lg_1
   -> ENGINE NDBCLUSTER;
```

These statements must be performed in the order shown, except that the two `ALTER TABLESPACE ... DROP DATAFILE` statements may be executed in either order.

You can obtain information about data files used by Disk Data tables by querying the `FILES` table in the `INFORMATION_SCHEMA` database. An extra “NULL row” provides additional information about undo log files. For more information and examples, see Section 21.31.1, “The INFORMATION_SCHEMA FILES Table”.

### 18.5.12.2 Using Symbolic Links with Disk Data Objects

The performance of an NDB Cluster that uses Disk Data storage can be greatly improved by separating data node file systems from undo log files and tablespace data files and placing these on different disks. In early versions of NDB Cluster, there was no direct support for this in NDB Cluster, but it was possible to achieve this separation using symbolic links as described in this section. NDB Cluster supports the data node configuration parameters `FileSystemPathDD`, `FileSystemPathDataFiles`, and `FileSystemPathUndoFiles`, which make the use of symbolic links for this purpose unnecessary. For more information about these parameters, see Disk Data file system parameters.
Each data node in the cluster creates a file system in the directory named `ndb_node_id_fs` under the data node’s `DataDir` as defined in the `config.ini` file. In this example, we assume that each data node host has 3 disks, aliased as `/data0`, `/data1`, and `/data2`, and that the cluster’s `config.ini` includes the following:

```
[ndbd default]
DataDir= /data0
```

Our objective is to place all Disk Data log files in `/data1`, and all Disk Data data files in `/data2`, on each data node host.

**Note**

In this example, we assume that the cluster’s data node hosts are all using Linux operating systems. For other platforms, you may need to substitute your operating system’s commands for those shown here.

To accomplish this, perform the following steps:

- Under the data node file system create symbolic links pointing to the other drives:

  ```shell
  cd /data0/ndb_2_fs
  ls
  D1  D10  D11  D2  D8  D9  LCP
  ln -s /data0 dnlogs
  ln -s /data1 dndata
  ```

  You should now have two symbolic links:

  ```shell
  ls -l --hide=D*
  lrwxrwxrwx 1 user group   30 2007-03-19 13:58 dndata -> /data1
  lrwxrwxrwx 1 user group   30 2007-03-19 13:59 dnlogs -> /data2
  ```

  We show this only for the data node with node ID 2; however, you must do this for each data node.

- Now, in the `mysql` client, create a log file group and tablespace using the symbolic links, as shown here:

  ```mysql
  CREATE LOGFILE GROUP lg1
  -> ADD UNDOFILE 'dnlogs/undo1.log'
  -> INITIAL_SIZE 150M
  -> UNDO_BUFFER_SIZE = 1M
  -> ENGINE=NDBCLUSTER;
  ```

  ```mysql
  CREATE TABLESPACE ts1
  -> ADD DATAFILE 'dndata/data1.log'
  -> USE LOGFILE GROUP lg1
  -> INITIAL_SIZE 1G
  -> ENGINE=NDBCLUSTER;
  ```

  Verify that the files were created and placed correctly as shown here:

  ```shell
  cd /data1
  ls -l
  total 2099304
  -rw-rw-r-- 1 user group 157286400 2007-03-19 14:02 undo1.dat
  ```

  ```shell
  cd /data2
  ls -l
  ```
• If you are running multiple data nodes on one host, you must take care to avoid having them try to use the same space for Disk Data files. You can make this easier by creating a symbolic link in each data node file system. Suppose you are using /data0 for both data node file systems, but you wish to have the Disk Data files for both nodes on /data1. In this case, you can do something similar to what is shown here:

shell> cd /data0
shell> ln -s /data1/dn2 ndb_2_fs/dd
shell> ls -l --hide=D* ndb_2_fs/dd
lrwxrwxrwx 1 user group 30 2007-03-19 14:22 dd -> /data1/dn2
shell> ls -l --hide=D* ndb_3_fs/dd
lrwxrwxrwx 1 user group 30 2007-03-19 14:22 dd -> /data1/dn3

• Now you can create a logfile group and tablespace using the symbolic link, like this:

mysql> CREATE LOGFILE GROUP lg1
   -> ADD UNDOFILE 'dd/undo1.log'
   -> INITIAL_SIZE 150M
   -> UNDO_BUFFER_SIZE = 1M
   -> ENGINE=NDDBCOLUMN;
mysql> CREATE TABLESPACE ts1
   -> ADD DATAFILE 'dd/data1.log'
   -> USE LOGFILE GROUP lg1
   -> INITIAL_SIZE 1G
   -> ENGINE=NDDBCOLUMN;

Verify that the files were created and placed correctly as shown here:

shell> cd /data1
shell> ls
dn2        dn3
shell> ls dn2
undo1.log        data1.log
shell> ls dn3
undo1.log        data1.log

18.5.12.3 NDB Cluster Disk Data Storage Requirements

The following items apply to Disk Data storage requirements:

• Variable-length columns of Disk Data tables take up a fixed amount of space. For each row, this is equal to the space required to store the largest possible value for that column.

For general information about calculating these values, see Section 11.7, “Data Type Storage Requirements”.

You can obtain an estimate the amount of space available in data files and undo log files by querying the INFORMATION_SCHEMA.FILES table. For more information and examples, see Section 21.31.1, “The INFORMATION_SCHEMA FILES Table”.

Note

The OPTIMIZE TABLE statement does not have any effect on Disk Data tables.
In a Disk Data table, the first 256 bytes of a TEXT or BLOB column are stored in memory; only the remainder is stored on disk.

Each row in a Disk Data table uses 8 bytes in memory to point to the data stored on disk. This means that, in some cases, converting an in-memory column to the disk-based format can actually result in greater memory usage. For example, converting a CHAR(4) column from memory-based to disk-based format increases the amount of DataMemory used per row from 4 to 8 bytes.

Important
Starting the cluster with the --initial option does not remove Disk Data files. You must remove these manually prior to performing an initial restart of the cluster.

Performance of Disk Data tables can be improved by minimizing the number of disk seeks by making sure that DiskPageBufferMemory is of sufficient size. You can query the diskpagebuffer table to help determine whether the value for this parameter needs to be increased.

18.5.13 Online Operations with ALTER TABLE in NDB Cluster

MySQL NDB Cluster 7.5 supports online table schema changes using the standard ALTER TABLE syntax employed by the MySQL Server (ALGORITHM=DEFAULT|INPLACE|COPY), and described elsewhere.

Important
Online table schema changes as implemented in NDB Cluster 5.1 used a syntax specific to NDB that is deprecated in NDB 7.3 and 7.4, and no longer supported in NDB 7.5 or later. (This syntax is not supported by any other MySQL storage engine, including InnoDB.) MySQL NDB Cluster 7.3 and later support the standard ALTER TABLE syntax employed by the MySQL Server (ALGORITHM=DEFAULT|INPLACE|COPY), and described elsewhere in this section. For these reasons, you are strongly encouraged to convert any applications using the old ONLINE and OFFLINE syntax as soon as possible. If you need to refer to documentation of the older syntax for purposes of migration, see Online Operations with ALTER TABLE in NDB Cluster.

Operations that add and drop indexes on variable-width columns of NDB tables occur online. Online operations are noncopying; that is, they do not require that indexes be re-created. They do not lock the table being altered from access by other API nodes in an NDB Cluster (but see Limitations of NDB online operations, later in this section). Such operations do not require single user mode for NDB table alterations made in an NDB cluster with multiple API nodes; transactions can continue uninterrupted during online DDL operations.

ALGORITHM=INPLACE can be used to perform online ADD COLUMN, ADD INDEX (including CREATE INDEX statements), and DROP INDEX operations on NDB tables. Online renaming of NDB tables is also supported.

Currently you cannot add disk-based columns to NDB tables online. This means that, if you wish to add an in-memory column to an NDB table that uses a table-level STORAGE DISK option, you must declare the new column as using memory-based storage explicitly. For example—assuming that you have already created tablespace ts1—suppose that you create table t1 as follows:

```sql
mysql> CREATE TABLE t1 (  
  >   c1 INT NOT NULL PRIMARY KEY,  
  >   c2 VARCHAR(30)  
  > )  
  >   TABLESPACE ts1 STORAGE DISK  
  >   ENGINE NDB;
```

Query OK, 0 rows affected (1.73 sec)
Records: 0  Duplicates: 0  Warnings: 0
You can add a new in-memory column to this table online as shown here:

```sql
mysql> ALTER TABLE t1
    > ADD COLUMN c3 INT COLUMN_FORMAT DYNAMIC STORAGE MEMORY,
    > ALGORITHM=INPLACE;
Query OK, 0 rows affected (1.25 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

This statement fails if the `STORAGE MEMORY` option is omitted:

```sql
mysql> ALTER TABLE t1
    > ADD COLUMN c4 INT COLUMN_FORMAT DYNAMIC,
    > ALGORITHM=INPLACE;
ERROR 1846 (0A000): ALGORITHM=INPLACE is not supported. Reason:
Adding column(s) or add/reorganize partition not supported online. Try
ALGORITHM=COPY.
```

If you omit the `COLUMN_FORMAT DYNAMIC` option, the dynamic column format is employed automatically, but a warning is issued, as shown here:

```sql
mysql> ALTER ONLINE TABLE t1 ADD COLUMN c4 INT STORAGE MEMORY;
Query OK, 0 rows affected, 1 warning (1.17 sec)
Records: 0  Duplicates: 0  Warnings: 0
mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
    Level: Warning
    Code: 1478
    Message: DYNAMIC column c4 with STORAGE DISK is not supported, column will
    become FIXED
```

```sql
mysql> SHOW CREATE TABLE t1\G
*************************** 1. row ***************************
Table: t1
Create Table: CREATE TABLE `t1` (
  `c1` int(11) NOT NULL,
  `c2` varchar(30) DEFAULT NULL,
  `c3` int(11) /*!50606 STORAGE MEMORY */ /*!50606 COLUMN_FORMAT DYNAMIC */ DEFAULT NULL,
  `c4` int(11) /*!50606 STORAGE MEMORY */ DEFAULT NULL,
  PRIMARY KEY (`c1`)
) /*!50606 TABLESPACE ts_1 STORAGE DISK */ ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.03 sec)
```

---

**Note**

The `STORAGE` and `COLUMN_FORMAT` keywords are supported only in NDB Cluster; in any other version of MySQL, attempting to use either of these keywords in a `CREATE TABLE` or `ALTER TABLE` statement results in an error.

It is also possible to use the statement `ALTER TABLE ... REORGANIZE PARTITION, ALGORITHM=INPLACE` with no `partition_names INTO (partition_definitions)` option on NDB tables. This can be used to redistribute NDB Cluster data among new data nodes that have been added to the cluster online. This does not perform any defragmentation, which requires an `OPTIMIZE TABLE` or null `ALTER TABLE` statement. For more information, see Section 18.5.14, “Adding NDB Cluster Data Nodes Online”.

**Limitations of NDB online operations**

Online `DROP COLUMN` operations are not supported.
Online ALTER TABLE, CREATE INDEX, or DROP INDEX statements that add columns or add or drop indexes are subject to the following limitations:

- A given online ALTER TABLE can use only one of ADD COLUMN, ADD INDEX, or DROP INDEX. One or more columns can be added online in a single statement; only one index may be created or dropped online in a single statement.

- The table being altered is not locked with respect to API nodes other than the one on which an online ALTER TABLE ADD COLUMN, ADD INDEX, or DROP INDEX operation (or CREATE INDEX or DROP INDEX statement) is run. However, the table is locked against any other operations originating on the same API node while the online operation is being executed.

- The table to be altered must have an explicit primary key; the hidden primary key created by the NDB storage engine is not sufficient for this purpose.

- The storage engine used by the table cannot be changed online.

- When used with NDB Cluster Disk Data tables, it is not possible to change the storage type (DISK or MEMORY) of a column online. This means, that when you add or drop an index in such a way that the operation would be performed online, and you want the storage type of the column or columns to be changed, you must use ALGORITHM=COPY in the statement that adds or drops the index.

Columns to be added online cannot use the BLOB or TEXT type, and must meet the following criteria:

- The columns must be dynamic; that is, it must be possible to create them using COLUMN_FORMAT DYNAMIC. If you omit the COLUMN_FORMAT DYNAMIC option, the dynamic column format is employed automatically.

- The columns must permit NULL values and not have any explicit default value other than NULL. Columns added online are automatically created as DEFAULT NULL, as can be seen here:

```sql
mysql> CREATE TABLE t2 (  
    >     c1 INT NOT NULL AUTO_INCREMENT PRIMARY KEY  
    > ) ENGINE=NDB;
Query OK, 0 rows affected (1.44 sec)

mysql> ALTER TABLE t2  
    >     ADD COLUMN c2 INT,  
    >     ADD COLUMN c3 INT,  
    >     ALGORITHM=INPLACE;
Query OK, 0 rows affected, 2 warnings (0.93 sec)

mysql> SHOW CREATE TABLE t1\G
*************************** 1. row ***************************
Table: t1
Create Table: CREATE TABLE `t2` (  
`c1` int(11) NOT NULL AUTO_INCREMENT,  
`c2` int(11) DEFAULT NULL,  
`c3` int(11) DEFAULT NULL,  
PRIMARY KEY (`c1`)  
) ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```

- The columns must be added following any existing columns. If you attempt to add a column online before any existing columns or using the FIRST keyword, the statement fails with an error.

- Existing table columns cannot be reordered online.

For online ALTER TABLE operations on NDB tables, fixed-format columns are converted to dynamic when they are added online, or when indexes are created or dropped online, as shown here (repeating the CREATE TABLE and ALTER TABLE statements just shown for the sake of clarity):
Adding NDB Cluster Data Nodes Online

```sql
mysql> CREATE TABLE t2 (  
    > c1 INT NOT NULL AUTO_INCREMENT PRIMARY KEY  
    > ) ENGINE=NDB;
Query OK, 0 rows affected (1.44 sec)

mysql> ALTER TABLE t2  
    > ADD COLUMN c2 INT,  
    > ADD COLUMN c3 INT,  
    > ALGORITHM=INPLACE;
Query OK, 0 rows affected, 2 warnings (0.93 sec)

mysql> SHOW WARNINGS;
*************************** 1. row ***************************
    Level: Warning
    Code: 1478
    Message: Converted FIXED field 'c2' to DYNAMIC to enable online ADD COLUMN

*************************** 2. row ***************************
    Level: Warning
    Code: 1478
    Message: Converted FIXED field 'c3' to DYNAMIC to enable online ADD COLUMN
2 rows in set (0.00 sec)
```

Only the column or columns to be added online must be dynamic. Existing columns need not be; this includes the table's primary key, which may also be `FIXED`, as shown here:

```sql
mysql> CREATE TABLE t3 (  
    > c1 INT NOT NULL AUTO_INCREMENT PRIMARY KEY COLUMN_FORMAT FIXED  
    > ) ENGINE=NDB;
Query OK, 0 rows affected (2.10 sec)

mysql> ALTER TABLE t3 ADD COLUMN c2 INT, ALGORITHM=INPLACE;
Query OK, 0 rows affected, 1 warning (0.78 sec)
Records: 0  Duplicates: 0  Warnings: 0

mysql> SHOW WARNINGS;
*************************** 1. row ***************************
    Level: Warning
    Code: 1478
    Message: Converted FIXED field 'c2' to DYNAMIC to enable online ADD COLUMN
1 row in set (0.00 sec)
```

Columns are not converted from `FIXED` to `DYNAMIC` column format by renaming operations. For more information about `COLUMN_FORMAT`, see Section 13.1.17, “CREATE TABLE Syntax”.

The `KEY`, `CONSTRAINT`, and `IGNORE` keywords are supported in `ALTER TABLE` statements using `ALGORITHM=INPLACE`.

Beginning with NDB Cluster 7.3.18 and 7.4.16, setting `MAX_ROWS` to 0 using an online `ALTER TABLE` statement is disallowed. You must use a copying `ALTER TABLE` to perform this operation. (Bug #21960004)

### 18.5.14 Adding NDB Cluster Data Nodes Online

This section describes how to add NDB Cluster data nodes “online”—that is, without needing to shut down the cluster completely and restart it as part of the process.

**Important**

Currently, you must add new data nodes to an NDB Cluster as part of a new node group. In addition, it is not possible to change the number of replicas (or the number of nodes per node group) online.
18.5.14.1 Adding NDB Cluster Data Nodes Online: General Issues

This section provides general information about the behavior of and current limitations in adding NDB Cluster nodes online.

**Redistribution of Data.** The ability to add new nodes online includes a means to reorganize NDBCLUSTER table data and indexes so that they are distributed across all data nodes, including the new ones, by means of the `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statement. Table reorganization of both in-memory and Disk Data tables is supported. This redistribution does not currently include unique indexes (only ordered indexes are redistributed). Prior to NDB 7.3.3, BLOB table data is also not redistributed using this method (Bug #13714148).

The redistribution for NDBCLUSTER tables already existing before the new data nodes were added is not automatic, but can be accomplished using simple SQL statements in `mysql` or another MySQL client application. However, all data and indexes added to tables created after a new node group has been added are distributed automatically among all cluster data nodes, including those added as part of the new node group.

**Partial starts.** It is possible to add a new node group without all of the new data nodes being started. It is also possible to add a new node group to a degraded cluster—that is, a cluster that is only partially started, or where one or more data nodes are not running. In the latter case, the cluster must have enough nodes running to be viable before the new node group can be added.

**Effects on ongoing operations.** Normal DML operations using NDB Cluster data are not prevented by the creation or addition of a new node group, or by table reorganization. However, it is not possible to perform DDL concurrently with table reorganization—that is, no other DDL statements can be issued while an `ALTER TABLE ... REORGANIZE PARTITION` statement is executing. In addition, during the execution of `ALTER TABLE ... REORGANIZE PARTITION` (or the execution of any other DDL statement), it is not possible to restart cluster data nodes.

**Failure handling.** Failures of data nodes during node group creation and table reorganization are handled as shown in the following table:

<table>
<thead>
<tr>
<th>Failure during</th>
<th>Failure in “Old” data node</th>
<th>Failure in “New” data node</th>
<th>System Failure</th>
</tr>
</thead>
<tbody>
<tr>
<td>Node group creation</td>
<td>• If a node other than the master fails: The creation of the node group is always rolled forward.</td>
<td>• If a node other than the master fails: The creation of the node group is always rolled forward.</td>
<td>• If the execution of CREATE NODEGROUP has reached the internal commit point: When restarted, the cluster includes the new node group. Otherwise it without.</td>
</tr>
<tr>
<td></td>
<td>• If the master fails:</td>
<td>• If the master fails:</td>
<td>• If the execution of CREATE NODEGROUP has not yet reached the internal commit point: When restarted, the cluster</td>
</tr>
<tr>
<td></td>
<td>• If the internal commit point has been reached: The creation of the node group is rolled forward.</td>
<td>• If the internal commit point has been reached: The creation of the node group is rolled forward.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• If the internal commit point has not yet been reached. The</td>
<td>• If the internal commit point has not yet been reached. The</td>
<td></td>
</tr>
</tbody>
</table>
Adding NDB Cluster Data Nodes Online

<table>
<thead>
<tr>
<th>Failure during</th>
<th>Failure in “Old” data node</th>
<th>Failure in “New” data node</th>
<th>System Failure</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>creation of the node group is rolled back</td>
<td>creation of the node group is rolled back</td>
<td>does not include the new node group.</td>
</tr>
</tbody>
</table>

Table reorganization

- If a node other than the master fails: The table reorganization is always rolled forward.
- If the master fails:
  - If the internal commit point has been reached: The table reorganization is rolled forward.
  - If the internal commit point has not yet been reached: The table reorganization is rolled back.
- If the execution of an ALTER TABLE ... REORGANIZE PARTITION statement has reached the internal commit point: When the cluster is restarted, the data and indexes belonging to table are distributed using the “new” data nodes.
- If the execution of an ALTER TABLE ... REORGANIZE PARTITION statement has not yet reached the internal commit point: When the cluster is restarted, the data and indexes belonging to table are distributed using only the “old” data nodes.

Dropping node groups. The ndb_mgm client supports a DROP NODEGROUP command, but it is possible to drop a node group only when no data nodes in the node group contain any data. Since there is currently no way to “empty” a specific data node or node group, this command works only the following two cases:

1. After issuing CREATE NODEGROUP in the ndb_mgm client, but before issuing any ALTER ONLINE TABLE ... REORGANIZE PARTITION statements in the mysql client.
2. After dropping all NDBCLUSTER tables using DROP TABLE.

TRUNCATE TABLE does not work for this purpose because the data nodes continue to store the table definitions.

18.5.14.2 Adding NDB Cluster Data Nodes Online: Basic procedure

In this section, we list the basic steps required to add new data nodes to an NDB Cluster. This procedure applies whether you are using ndbd or ndbmtd binaries for the data node processes. For a more detailed example, see Section 18.5.14.3, “Adding NDB Cluster Data Nodes Online: Detailed Example”.

Assuming that you already have a running NDB Cluster, adding data nodes online requires the following steps:

1. Edit the cluster configuration config.ini file, adding new [ndbd] sections corresponding to the nodes to be added. In the case where the cluster uses multiple management servers, these changes need to be made to all config.ini files used by the management servers.
You must be careful that node IDs for any new data nodes added in the `config.ini` file do not overlap node IDs used by existing nodes. In the event that you have API nodes using dynamically allocated node IDs and these IDs match node IDs that you want to use for new data nodes, it is possible to force any such API nodes to “migrate”, as described later in this procedure.

2. Perform a rolling restart of all NDB Cluster management servers.

**Important**

All management servers must be restarted with the `--reload` or `--initial` option to force the reading of the new configuration.

3. Perform a rolling restart of all existing NDB Cluster data nodes. It is not necessary (or usually even desirable) to use `--initial` when restarting the existing data nodes.

If you are using API nodes with dynamically allocated IDs matching any node IDs that you wish to assign to new data nodes, you must restart all API nodes (including SQL nodes) before restarting any of the data nodes processes in this step. This causes any API nodes with node IDs that were previously not explicitly assigned to relinquish those node IDs and acquire new ones.

4. Perform a rolling restart of any SQL or API nodes connected to the NDB Cluster.

5. Start the new data nodes.

The new data nodes may be started in any order. They can also be started concurrently, as long as they are started after the rolling restarts of all existing data nodes have been completed, and before proceeding to the next step.

6. Execute one or more `CREATE NODEGROUP` commands in the NDB Cluster management client to create the new node group or node groups to which the new data nodes will belong.

7. Redistribute the cluster’s data among all data nodes, including the new ones. Normally this is done by issuing an `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statement in the `mysql` client for each `NDBCLUSTER` table.

*Exception:* For tables created using the `MAX_ROWS` option, this statement does not work; instead, use `ALTER ONLINE TABLE ... MAX_ROWS=...` to reorganize such tables.

**Note**

This needs to be done only for tables already existing at the time the new node group is added. Data in tables created after the new node group is added is distributed automatically; however, data added to any given table `tbl` that existed before the new nodes were added is not distributed using the new nodes until that table has been reorganized.

8. `ALTER ONLINE TABLE ... REORGANIZE PARTITION` reorganizes partitions but does not reclaim the space freed on the “old” nodes. You can do this by issuing, for each `NDBCLUSTER` table, an `OPTIMIZE TABLE` statement in the `mysql` client.

This works for space used by variable-width columns of in-memory NDB tables. `OPTIMIZE TABLE` is not supported for fixed-width columns of in-memory tables; it is also not supported for Disk Data tables.

You can add all the nodes desired, then issue several `CREATE NODEGROUP` commands in succession to add the new node groups to the cluster.
18.5.14.3 Adding NDB Cluster Data Nodes Online: Detailed Example

In this section we provide a detailed example illustrating how to add new NDB Cluster data nodes online, starting with an NDB Cluster having 2 data nodes in a single node group and concluding with a cluster having 4 data nodes in 2 node groups.

**Starting configuration.** For purposes of illustration, we assume a minimal configuration, and that the cluster uses a `config.ini` file containing only the following information:

```
[nbddefault]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster

[nbd]
Id = 1
HostName = 198.51.100.1

[nbd]
Id = 2
HostName = 198.51.100.2

[mgm]
HostName = 198.51.100.10
Id = 10

[api]
Id=20
HostName = 198.51.100.20

[api]
Id=21
HostName = 198.51.100.21
```

**Note**

We have left a gap in the sequence between data node IDs and other nodes. This make it easier later to assign node IDs that are not already in use to data nodes which are newly added.

We also assume that you have already started the cluster using the appropriate command line or `my.cnf` options, and that running `SHOW` in the management client produces output similar to what is shown here:

```
-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
Connected to Management Server at: 198.51.100.10:1186
Cluster Configuration
---------------------
[nxdbd(NDB)] 2 node(s)
id=1  198.51.100.1 (5.6.45-ndb-7.4.25, Nodegroup: 0, *),
id=2  198.51.100.2 (5.6.45-ndb-7.4.25, Nodegroup: 0)

[nxdbd_mgmd(MGM)] 1 node(s)
id=10  198.51.100.10 (5.6.45-ndb-7.4.25)

[mysqld(API)] 2 node(s)
id=20  198.51.100.20 (5.6.45-ndb-7.4.25)
id=21  198.51.100.21 (5.6.45-ndb-7.4.25)
```

Finally, we assume that the cluster contains a single `NDBCLUSTER` table created as shown here:
USE n;

CREATE TABLE ips (  
id BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,  
country_code CHAR(2) NOT NULL,  
type CHAR(4) NOT NULL,  
ip_address VARCHAR(15) NOT NULL,  
adresses BIGINT UNSIGNED DEFAULT NULL,  
date BIGINT UNSIGNED DEFAULT NULL  
) ENGINE NDBCLUSTER;

The memory usage and related information shown later in this section was generated after inserting approximately 50000 rows into this table.

Note

In this example, we show the single-threaded ndbd being used for the data node processes. However—beginning with NDB 7.0.4—you can also apply this example, if you are using the multithreaded ndbmd by substituting ndbmd for ndbd wherever it appears in the steps that follow. (Bug #43108)

Step 1: Update configuration file. Open the cluster global configuration file in a text editor and add [ndbd] sections corresponding to the 2 new data nodes. (We give these data nodes IDs 3 and 4, and assume that they are to be run on host machines at addresses 198.51.100.3 and 198.51.100.4, respectively.) After you have added the new sections, the contents of the config.ini file should look like what is shown here, where the additions to the file are shown in bold type:

```
[ndbd default]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster

[ndbd]
Id = 1
HostName = 198.51.100.1

[ndbd]
Id = 2
HostName = 198.51.100.2

[ndbd]
Id = 3
HostName = 198.51.100.3

[ndbd]
Id = 4
HostName = 198.51.100.4

[mgm]
HostName = 198.51.100.10
Id = 10

[api]
Id=20
HostName = 198.51.100.20

[api]
Id=21
HostName = 198.51.100.21
```

Once you have made the necessary changes, save the file.
Adding NDB Cluster Data Nodes Online

**Step 2: Restart the management server.** Restarting the cluster management server requires that you issue separate commands to stop the management server and then to start it again, as follows:

1. Stop the management server using the management client `STOP` command, as shown here:

   ```
   ndb_mgm> 10 STOP
   Node 10 has shut down.
   Disconnecting to allow Management Server to shutdown
   shell>
   ```

2. Because shutting down the management server causes the management client to terminate, you must start the management server from the system shell. For simplicity, we assume that `config.ini` is in the same directory as the management server binary, but in practice, you must supply the correct path to the configuration file. You must also supply the `--reload` or `--initial` option so that the management server reads the new configuration from the file rather than its configuration cache. If your shell's current directory is also the same as the directory where the management server binary is located, then you can invoke the management server as shown here:

   ```
   shell> ndb_mgmd -f config.ini --reload
   2008-12-08 17:29:23 [MgmSrvr] INFO     -- NDB Cluster Management Server. 5.6.45-ndb-7.4.25
   2008-12-08 17:29:23 [MgmSrvr] INFO     -- Reading cluster configuration from 'config.ini'
   ```

   If you check the output of `SHOW` in the management client after restarting the `ndb_mgm` process, you should now see something like this:

   ```
   -- NDB Cluster -- Management Client --
   ndb_mgm> SHOW
   Connected to Management Server at: 198.51.100.10:1186
   Cluster Configuration
   --------------------
   [ndbd(NDB)] 2 node(s)
   id=1 @198.51.100.1  (5.6.45-ndb-7.4.25, Nodegroup: 0, *)
   id=2 @198.51.100.2  (5.6.45-ndb-7.4.25, Nodegroup: 0)
   id=3 (not connected, accepting connect from 198.51.100.3)
   id=4 (not connected, accepting connect from 198.51.100.4)
   [ndb_mgmd(MGM)] 1 node(s)
   id=10 @198.51.100.10  (5.6.45-ndb-7.4.25)
   [mysqld(API)] 2 node(s)
   id=20 @198.51.100.20  (5.6.45-ndb-7.4.25)
   id=21 @198.51.100.21  (5.6.45-ndb-7.4.25)
   ```

**Step 3: Perform a rolling restart of the existing data nodes.** This step can be accomplished entirely within the cluster management client using the `RESTART` command, as shown here:

```
ndb_mgm> 1 RESTART
Node 1: Node shutdown initiated
Node 1: Node shutdown completed, restarting, no start.
Node 1 is being restarted

ndb_mgm> Node 1: Start initiated (version 7.4.25)
Node 1: Started (version 7.4.25)

ndb_mgm> 2 RESTART
Node 2: Node shutdown initiated
Node 2: Node shutdown completed, restarting, no start.
Node 2 is being restarted
```
Adding NDB Cluster Data Nodes Online

Important
After issuing each `X RESTART` command, wait until the management client reports `Node X: Started (version ...) before proceeding any further.

You can verify that all existing data nodes were restarted using the updated configuration by checking the `ndbinfo.nodes` table in the `mysql` client.

Step 4: Perform a rolling restart of all cluster API nodes. Shut down and restart each MySQL server acting as an SQL node in the cluster using `mysqladmin shutdown` followed by `mysqld_safe` (or another startup script). This should be similar to what is shown here, where `password` is the MySQL root password for a given MySQL server instance:

```
shell> mysqladmin -uroot -p password shutdown
081208 20:19:56 mysqld_safe mysqld from pid file
/usr/local/mysql/var/tonfisk.pid ended
shell> mysqld_safe --ndbcluster --ndb-connectstring=198.51.100.10 &
081208 20:20:06 mysqld_safe Logging to '/usr/local/mysql/var/tonfisk.err'.
081208 20:20:06 mysqld_safe Starting mysqld daemon with databases
from /usr/local/mysql/var
```

Of course, the exact input and output depend on how and where MySQL is installed on the system, as well as which options you choose to start it (and whether or not some or all of these options are specified in a `my.cnf` file).

Step 5: Perform an initial start of the new data nodes. From a system shell on each of the hosts for the new data nodes, start the data nodes as shown here, using the `--initial` option:

```
shell> ndbd -c 198.51.100.10 --initial
```

Note
Unlike the case with restarting the existing data nodes, you can start the new data nodes concurrently; you do not need to wait for one to finish starting before starting the other.

Wait until both of the new data nodes have started before proceeding with the next step. Once the new data nodes have started, you can see in the output of the management client `SHOW` command that they do not yet belong to any node group (as indicated with bold type here):

```
ndb_mgm> SHOW
Connected to Management Server at: 198.51.100.10:1186
 Cluster Configuration
------------------------------------------
 | ndbd(NDB) | 2 node(s)   |
 | id=1     | 198.51.100.1 | (5.6.45-ndb-7.4.25, Nodegroup: 0, *) |
 | id=2     | 198.51.100.2 | (5.6.45-ndb-7.4.25, Nodegroup: 0)  |
 | id=3     | 198.51.100.3 | (5.6.45-ndb-7.4.25, no nodegroup)  |
 | id=4     | 198.51.100.4 | (5.6.45-ndb-7.4.25, no nodegroup)  |

 | ndb_mgm(MGM) | 1 node(s) |
 | id=10    | 198.51.100.10 | (5.6.45-ndb-7.4.25) |

 | mysqld(API) | 2 node(s) |
 | id=20    | 198.51.100.20 | (5.6.45-ndb-7.4.25) |
 | id=21    | 198.51.100.21 | (5.6.45-ndb-7.4.25) |
```
Step 6: Create a new node group. You can do this by issuing a `CREATE NODEGROUP` command in the cluster management client. This command takes as its argument a comma-separated list of the node IDs of the data nodes to be included in the new node group, as shown here:

```
ndb_mgm> CREATE NODEGROUP 3,4
Nodegroup 1 created
```

By issuing `SHOW` again, you can verify that data nodes 3 and 4 have joined the new node group (again indicated in bold type):

```
ndb_mgm> SHOW
Connected to Management Server at: 198.51.100.10:1186
Cluster Configuration
---------------------
[ndbd(NDB)]     2 node(s)
id=1    @198.51.100.1  (5.6.45-ndb-7.4.25, Nodegroup: 0, *)
id=2    @198.51.100.2  (5.6.45-ndb-7.4.25, Nodegroup: 0)
id=3    @198.51.100.3  (5.6.45-ndb-7.4.25, Nodegroup: 1)
id=4    @198.51.100.4  (5.6.45-ndb-7.4.25, Nodegroup: 1)

[ndb_mgmd(MGM)] 1 node(s)
id=10   @198.51.100.10  (5.6.45-ndb-7.4.25)

[mysqld(API)]   2 node(s)
id=20   @198.51.100.20  (5.6.45-ndb-7.4.25)
id=21   @198.51.100.21  (5.6.45-ndb-7.4.25)
```

Step 7: Redistribute cluster data. When a node group is created, existing data and indexes are not automatically distributed to the new node group’s data nodes, as you can see by issuing the appropriate `REPORT` command in the management client:

```
ndb_mgm> ALL REPORT MEMORY
Node 1: Data usage is 5%(177 32K pages of total 3200)
Node 1: Index usage is 0%(108 8K pages of total 12832)
Node 2: Data usage is 5%(177 32K pages of total 3200)
Node 2: Index usage is 0%(108 8K pages of total 12832)
Node 3: Data usage is 0%(0 32K pages of total 3200)
Node 3: Index usage is 0%(0 8K pages of total 12832)
Node 4: Data usage is 0%(0 32K pages of total 3200)
Node 4: Index usage is 0%(0 8K pages of total 12832)
```

By using `ndb_desc` with the `-p` option, which causes the output to include partitioning information, you can see that the table still uses only 2 partitions (in the `Per partition info` section of the output, shown here in bold text):

```
shell> ndb_desc -c 198.51.100.10 -d n ips -p
-- ips --
Version: 1
Fragment type: 9
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 6
Number of primary keys: 1
Length of frm data: 340
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
```

</table>

NDBT_ProgramExit: 0 - OK

You can cause the data to be redistributed among all of the data nodes by performing, for each NDB table, an `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statement in the `mysql` client.

**Important**

`ALTER ONLINE TABLE ... REORGANIZE PARTITION` does not work on tables that were created with the `MAX_ROWS` option. Instead, use `ALTER ONLINE TABLE ... MAX_ROWS=...` to reorganize such tables.

After issuing the statement `ALTER ONLINE TABLE ips REORGANIZE PARTITION`, you can see using `ndb_desc` that the data for this table is now stored using 4 partitions, as shown here (with the relevant portions of the output in bold type):

```shell
shell> ndb_desc -c 198.51.100.10 -d n ips -p
-- ips --
Version: 16777217

NDBT_ProgramExit: 0 - OK

Note

Normally, `ALTER [ONLINE] TABLE table_name REORGANIZE PARTITION` is used with a list of partition identifiers and a set of partition definitions to create a new partitioning scheme for a table that has already been explicitly partitioned. Its use here to redistribute data onto a new NDB Cluster node group is an exception in this regard; when used in this way, only the name of the table is used following the `TABLE` keyword, and no other keywords or identifiers follow `REORGANIZE PARTITION`.

For more information, see Section 13.1.7, “ALTER TABLE Syntax”.

In addition, for each table, the `ALTER ONLINE TABLE` statement should be followed by an `OPTIMIZE TABLE` to reclaim wasted space. You can obtain a list of all NDBCLUSTER tables using the following query against the INFORMATION_SCHEMA.TABLES table:

```
SELECT TABLE_SCHEMA, TABLE_NAME
FROM INFORMATION_SCHEMA.TABLES
WHERE ENGINE = 'NDBCLUSTER';
```

Note

The INFORMATION_SCHEMA.TABLES.ENGINE value for an NDB Cluster table is always NDBCLUSTER, regardless of whether the CREATE TABLE statement used to create the table (or ALTER TABLE statement used to convert an existing table from a different storage engine) used NDB or NDBCLUSTER in its ENGINE option.

You can see after performing these statements in the output of `ALL REPORT MEMORY` that the data and indexes are now redistributed between all cluster data nodes, as shown here:

```
ndb_mgm> ALL REPORT MEMORY

Node 1: Data usage is 5% (176 32K pages of total 3200)  
Node 1: Index usage is 0% (76 8K pages of total 12832)  
Node 2: Data usage is 5% (176 32K pages of total 3200)  
Node 2: Index usage is 0% (76 8K pages of total 12832)  
Node 3: Data usage is 2% (80 32K pages of total 3200)  
Node 3: Index usage is 0% (51 8K pages of total 12832)  
Node 4: Data usage is 2% (80 32K pages of total 3200)  
Node 4: Index usage is 0% (50 8K pages of total 12832)
```

Note

Since only one DDL operation on NDBCLUSTER tables can be executed at a time, you must wait for each `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statement to finish before issuing the next one.

It is not necessary to issue `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statements for NDBCLUSTER tables created after the new data nodes have been added; data added to such tables is distributed among all data nodes automatically. However, in NDBCLUSTER tables that existed prior to the
Adding NDB Cluster Data Nodes Online

addition of the new nodes, neither existing nor new data is distributed using the new nodes until these tables have been reorganized using ALTER ONLINE TABLE ... REORGANIZE PARTITION.

Alternative procedure, without rolling restart. It is possible to avoid the need for a rolling restart by configuring the extra data nodes, but not starting them, when first starting the cluster. We assume, as before, that you wish to start with two data nodes—nodes 1 and 2—in one node group and later to expand the cluster to four data nodes, by adding a second node group consisting of nodes 3 and 4:

```
[nbdb default]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster

[nbdb]
Id = 1
HostName = 198.51.100.1

[nbdb]
Id = 2
HostName = 198.51.100.2

[nbdb]
Id = 3
HostName = 198.51.100.3
Nodegroup = 65536

[nbdb]
Id = 4
HostName = 198.51.100.4
Nodegroup = 65536

[mgm]
HostName = 198.51.100.10
Id = 10

[api]
Id=20
HostName = 198.51.100.20

[api]
Id=21
HostName = 198.51.100.21
```

The data nodes to be brought online at a later time (nodes 3 and 4) can be configured with NodeGroup = 65536, in which case nodes 1 and 2 can each be started as shown here:

```
shell> ndbd -c 198.51.100.10 --initial
```

The data nodes configured with NodeGroup = 65536 are treated by the management server as though you had started nodes 1 and 2 using --nowait-nodes=3,4 after waiting for a period of time determined by the setting for the StartNoNodeGroupTimeout data node configuration parameter. By default, this is 15 seconds (15000 milliseconds).

Note

StartNoNodeGroupTimeout must be the same for all data nodes in the cluster; for this reason, you should always set it in the [ndbd default] section of the config.ini file, rather than for individual data nodes.

When you are ready to add the second node group, you need only perform the following additional steps:
Distributed MySQL Privileges for NDB Cluster

1. Start data nodes 3 and 4, invoking the data node process once for each new node:

```
shell> ndbd -c 198.51.100.10 --initial
```

2. Issue the appropriate `CREATE NODEGROUP` command in the management client:

```
ndb_mgm> CREATE NODEGROUP 3,4
```

3. In the `mysql` client, issue `ALTER ONLINE TABLE ... REORGANIZE PARTITION` and `OPTIMIZE TABLE` statements for each existing `NDBCLUSTER` table. (As noted elsewhere in this section, existing NDB Cluster tables cannot use the new nodes for data distribution until this has been done.)

### 18.5.15 Distributed MySQL Privileges for NDB Cluster

NDB Cluster supports distribution of MySQL users and privileges across all SQL nodes in an NDB Cluster. This support is not enabled by default; you should follow the procedure outlined in this section in order to do so.

Normally, each MySQL server's user privilege tables in the `mysql` database must use the `MyISAM` storage engine, which means that a user account and its associated privileges created on one SQL node are not available on the cluster's other SQL nodes. An SQL file `ndb_dist_priv.sql` is provided with NDB Cluster 7.3 and later distributions. This file can be found in the `share` directory in the MySQL installation directory.

The first step in enabling distributed privileges is to load this script into a MySQL Server that functions as an SQL node (which we refer to after this as the target SQL node or MySQL Server). You can do this by executing the following command from the system shell on the target SQL node after changing to its MySQL installation directory (where `options` stands for any additional options needed to connect to this SQL node):

```
shell> mysql options -uroot < share/ndb_dist_priv.sql
```

Importing `ndb_dist_priv.sql` creates a number of stored routines (six stored procedures and one stored function) in the `mysql` database on the target SQL node. After connecting to the SQL node in the `mysql` client (as the MySQL root user), you can verify that these were created as shown here:

```
mysql> SELECT ROUTINE_NAME, ROUTINE_SCHEMA, ROUTINE_TYPE
-> FROM INFORMATION_SCHEMA.ROUTINES
-> WHERE ROUTINE_NAME LIKE 'mysql_cluster%'
-> ORDER BY ROUTINE_TYPE;
```

```
+---------------------------------------------+----------------+--------------+
| ROUTINE_NAME                                | ROUTINE_SCHEMA | ROUTINE_TYPE  |
|---------------------------------------------+----------------+--------------+
| mysql_cluster_privileges_are_distributed    | mysql          | FUNCTION     |
| mysql_cluster_backup_privileges             | mysql          | PROCEDURE    |
| mysql_cluster_move_grant_tables             | mysql          | PROCEDURE    |
| mysql_cluster_move_privileges               | mysql          | PROCEDURE    |
| mysql_cluster_restore_local_privileges      | mysql          | PROCEDURE    |
| mysql_cluster_restore_privileges            | mysql          | PROCEDURE    |
| mysql_cluster_restore_privileges_from_local | mysql          | PROCEDURE    |
+---------------------------------------------+----------------+--------------+
7 rows in set (0.01 sec)
```

The stored procedure named `mysql_cluster_move_privileges` creates backup copies of the existing privilege tables, then converts them to NDB.
Distributed MySQL Privileges for NDB Cluster

`mysql_cluster_move_privileges` performs the backup and conversion in two steps. The first step is to call `mysql_cluster_backup_privileges`, which creates two sets of copies in the `mysql` database:

- A set of local copies that use the MyISAM storage engine. Their names are generated by adding the suffix `_backup` to the original privilege table names.
- A set of distributed copies that use the NDBCLUSTER storage engine. These tables are named by prefixing `ndb_` and appending `_backup` to the names of the original tables.

After the copies are created, `mysql_cluster_move_privileges` invokes `mysql_cluster_move_grant_tables`, which contains the `ALTER TABLE ... ENGINE = NDB` statements that convert the mysql system tables to NDB.

Normally, you should not invoke either `mysql_cluster_backup_privileges` or `mysql_cluster_move_grant_tables` manually; these stored procedures are intended only for use by `mysql_cluster_move_privileges`.

Although the original privilege tables are backed up automatically, it is always a good idea to create backups manually of the existing privilege tables on all affected SQL nodes before proceeding. You can do this using `mysqldump` in a manner similar to what is shown here:

```
shell> mysqldump options -uroot \
    mysql user db tables_priv columns_priv procs_priv proxies_priv > backup_file
```

To perform the conversion, you must be connected to the target SQL node using the `mysql` client (again, as the MySQL root user). Invoke the stored procedure like this:

```
mysql> CALL mysql.mysql_cluster_move_privileges();
Query OK, 0 rows affected (22.32 sec)
```

Depending on the number of rows in the privilege tables, this procedure may take some time to execute. If some of the privilege tables are empty, you may see one or more `No data - zero rows fetched, selected, or processed` warnings when `mysql_cluster_move_privileges` returns. In such cases, the warnings may be safely ignored. To verify that the conversion was successful, you can use the stored function `mysql_cluster_privileges_are_distributed` as shown here:

```
mysql> SELECT CONCAT('Conversion ', IF(mysql.mysql_cluster_privileges_are_distributed(), 'succeeded', 'failed'), '.') AS Result;
+-----------------------+
<table>

+-----------------------+
```

`mysql_cluster_privileges_are_distributed` checks for the existence of the distributed privilege tables and returns 1 if all of the privilege tables are distributed; otherwise, it returns 0.

You can verify that the backups have been created using a query such as this one:

```
mysql> SELECT TABLE_NAME, ENGINE FROM INFORMATION_SCHEMA.TABLES 
    WHERE TABLE_SCHEMA = 'mysql' AND TABLE_NAME LIKE '%backup'
```
## Distributed MySQL Privileges for NDB Cluster

Once the conversion to distributed privileges has been made, any time a MySQL user account is created, dropped, or has its privileges updated on any SQL node, the changes take effect immediately on all other MySQL servers attached to the cluster. Once privileges are distributed, any new MySQL Servers that connect to the cluster automatically participate in the distribution.

### Note

For clients connected to SQL nodes at the time that `mysql_cluster_move_privileges` is executed, you may need to execute `FLUSH PRIVILEGES` on those SQL nodes, or to disconnect and then reconnect the clients, in order for those clients to be able to see the changes in privileges.

All MySQL user privileges are distributed across all connected MySQL Servers. This includes any privileges associated with views and stored routines, even though distribution of views and stored routines themselves is not currently supported.

In the event that an SQL node becomes disconnected from the cluster while `mysql_cluster_move_privileges` is running, you must drop its privilege tables after reconnecting to the cluster, using a statement such as `DROP TABLE IF EXISTS mysql.user mysql.db mysql.tables_priv mysql.columns_priv mysql.procs_priv`. This causes the SQL node to use the shared privilege tables rather than its own local versions of them. This is not needed when connecting a new SQL node to the cluster for the first time.

In the event of an initial restart of the entire cluster (all data nodes shut down, then started again with `--initial`), the shared privilege tables are lost. If this happens, you can restore them using the original target SQL node either from the backups made by `mysql_cluster_move_privileges` or from a dump file created with `mysqldump`. If you need to use a new MySQL Server to perform the restoration, you should start it with `--skip-grant-tables` when connecting to the cluster for the first time; after this, you can restore the privilege tables locally, then distribute them again using `mysql_cluster_move_privileges`. After restoring and distributing the tables, you should restart this MySQL Server without the `--skip-grant-tables` option.

You can also restore the distributed tables using `ndb_restore --restore-privilege-tables` from a backup made using `START BACKUP` in the `ndb_mgm` client. (The MyISAM tables created by `mysql_cluster_move_privileges` are not backed up by the `START BACKUP` command.) `ndb_restore` does not restore the privilege tables by default; the `--restore-privilege-tables` option causes it to do so.

You can restore the SQL node's local privileges using either of two procedures. `mysql_cluster_restore_privileges` works as follows:
1. If copies of the `mysql.ndb_*_backup` tables are available, attempt to restore the system tables from these.

2. Otherwise, attempt to restore the system tables from the local backups named `*_backup` (without the `ndb_` prefix).

The other procedure, named `mysql_cluster_restore_local_privileges`, restores the system tables from the local backups only, without checking the `ndb_*` backups.

The system tables re-created by `mysql_cluster_restore_privileges` or `mysql_cluster_restore_local_privileges` use the MySQL server default storage engine; they are not shared or distributed in any way, and do not use NDB Cluster’s NDB storage engine.

The additional stored procedure `mysql_cluster_restore_privileges_from_local` is intended for the use of `mysql_cluster_restore_privileges` and `mysql_cluster_restore_local_privileges`. It should not be invoked directly.

**Important**

Applications that access NDB Cluster data directly, including NDB API and ClusterJ applications, are not subject to the MySQL privilege system. This means that, once you have distributed the grant tables, they can be freely accessed by such applications, just as they can any other NDB tables. In particular, you should keep in mind that NDB API and ClusterJ applications can read and write user names, host names, password hashes, and any other contents of the distributed grant tables without any restrictions.

### 18.5.16 NDB API Statistics Counters and Variables

A number of types of statistical counters relating to actions performed by or affecting Ndb objects are available. Such actions include starting and closing (or aborting) transactions; primary key and unique key operations; table, range, and pruned scans; threads blocked while waiting for the completion of various operations; and data and events sent to or received by **NDBCLUSTER**. The counters are incremented inside the NDB kernel whenever NDB API calls are made or data is sent to or received by the data nodes. `mysqld` exposes these counters as system status variables; their values can be read in the output of `SHOW STATUS`, or by querying the `INFORMATION_SCHEMA.SESSION_STATUS` or `INFORMATION_SCHEMA.GLOBAL_STATUS` table. By comparing the values before and after statements operating on NDB tables, you can observe the corresponding actions taken on the API level, and thus the cost of performing the statement.

You can list all of these status variables using the following `SHOW STATUS` statement:

```
mysql> SHOW STATUS LIKE 'ndb_api%';
+----------------+----------+
| Variable_name   | Value    |
+----------------+----------+
| Ndb_api_wait_exec_complete_count_session | 0        |
| Ndb_api_wait_scan_result_count_session     | 0        |
| Ndb_api_wait_meta_request_count_session    | 0        |
| Ndb_api_wait_nanos_count_session           | 0        |
| Ndb_api_bytes_sent_count_session           | 0        |
| Ndb_api_bytes_received_count_session       | 0        |
| Ndb_api_trans_start_count_session          | 0        |
| Ndb_api_trans_commit_count_session         | 0        |
| Ndb_api_trans_abort_count_session          | 0        |
| Ndb_api_trans_close_count_session          | 0        |
| Ndb_api_pk_op_count_session                | 0        |
| Ndb_api_uk_op_count_session                | 0        |
```
