mysql> SHOW STATUS LIKE 'ndb_api%session%';
+--------------------------------------------+-----------+
| Variable_name                              | Value     |
+--------------------------------------------+-----------+
| Ndb_api_wait_exec_complete_count_session   | 8         |
| Ndb_api_wait_scan_result_count_session     | 0         |
| Ndb_api_wait_meta_request_count_session    | 17        |
| Ndb_api_wait_nanos_count_session           | 706871709 |
| Ndb_api_bytes_sent_count_session           | 2376      |
| Ndb_api_bytes_received_count_session       | 3844      |
| Ndb_api_trans_start_count_session          | 4         |
| Ndb_api_trans_commit_count_session         | 4         |
| Ndb_api_trans_abort_count_session          | 0         |
| Ndb_api_trans_close_count_session          | 4         |
| Ndb_api_pk_op_count_session                | 6         |
| Ndb_api_uk_op_count_session                | 0         |
| Ndb_api_table_scan_count_session           | 0         |
| Ndb_api_range_scan_count_session           | 0         |
| Ndb_api_pruned_scan_count_session          | 0         |
| Ndb_api_scan_batch_count_session           | 0         |
| Ndb_api_read_row_count_session             | 1         |
| Ndb_api_trans_local_read_row_count_session | 1         |
+--------------------------------------------+-----------+
18 rows in set (0.00 sec)
```

Similarly, you can see the changes in the NDB API statistics counters caused by inserting a row into `t`:

Insert the row, then run the same SHOW STATUS statement used in the previous example, as shown here:

```sql
mysql> INSERT INTO t VALUES (100);
Query OK, 1 row affected (0.00 sec)
mysql> SHOW STATUS LIKE 'ndb_api%session%';
+--------------------------------------------+-----------+
| Variable_name                              | Value     |
+--------------------------------------------+-----------+
| Ndb_api_wait_exec_complete_count_session   | 11        |
| Ndb_api_wait_scan_result_count_session     | 6         |
| Ndb_api_wait_meta_request_count_session    | 20        |
| Ndb_api_wait_nanos_count_session           | 707370418 |
| Ndb_api_bytes_sent_count_session           | 2724      |
| Ndb_api_bytes_received_count_session       | 4316      |
| Ndb_api_trans_start_count_session          | 7         |
+--------------------------------------------+-----------+
18 rows in set (0.00 sec)
```
| Ndb_api_trans_commit_count_session | 6         |
| Ndb_api_transAbort_count_session   | 0         |
| Ndb_api_trans_close_count_session  | 7         |
| Ndb_api_pk_op_count_session        | 8         |
| Ndb_api_uk_op_count_session        | 0         |
| Ndb_api_table_scan_count_session   | 1         |
| Ndb_api_range_scan_count_session   | 0         |
| Ndb_api_pruned_scan_count_session  | 0         |
| Ndb_api_scan_batch_count_session   | 0         |
| Ndb_api_read_row_count_session     | 3         |
| Ndb_apiTrans_local_read_row_count_session | 2         |

18 rows in set (0.00 sec)

We can make a number of observations from these results:

- Although we created t with no explicit primary key, 5 primary key operations were performed in doing so (the difference in the "before" and "after" values of Ndb_api_pk_op_count_session, or 6 minus 1). This reflects the creation of the hidden primary key that is a feature of all tables using the NDB storage engine.

- By comparing successive values for Ndb_api_wait_nanos_count_session, we can see that the NDB API operations implementing the CREATE TABLE statement waited much longer (706871709 - 820705 = 706051004 nanoseconds, or approximately 0.7 second) for responses from the data nodes than those executed by the INSERT (70370418 - 706871709 = 498709 ns or roughly .0005 second). The execution times reported for these statements in the mysql client correlate roughly with these figures.

On platforms without sufficient (nanosecond) time resolution, small changes in the value of the WaitNanosCount NDB API counter due to SQL statements that execute very quickly may not always be visible in the values of Ndb_api_wait_nanos_count_session, Ndb_api_wait_nanos_count_slave, or Ndb_api_wait_nanos_count.

- The INSERT statement incremented both the ReadRowCount and TransLocalReadRowCount NDB API statistics counters, as reflected by the increased values of Ndb_api_read_row_count_session and Ndb_api_trans_local_read_row_count_session.

### 18.6 NDB Cluster Replication

NDB Cluster supports **asynchronous replication**, more usually referred to simply as “replication”. This section explains how to set up and manage a configuration in which one group of computers operating as an NDB Cluster replicates to a second computer or group of computers. We assume some familiarity on the part of the reader with standard MySQL replication as discussed elsewhere in this Manual. (See Chapter 17, Replication).

**Note**

NDB Cluster does not support replication using GTIDs; semisynchronous replication is also not supported by the NDB storage engine.

Normal (non-clustered) replication involves a “master” server and a “slave” server, the master being the source of the operations and data to be replicated and the slave being the recipient of these. In NDB Cluster, replication is conceptually very similar but can be more complex in practice, as it may be extended to cover a number of different configurations including replicating between two complete clusters. Although an NDB Cluster itself depends on the NDB storage engine for clustering functionality, it is not necessary to use NDB as the storage engine for the slave’s copies of the replicated tables (see Replication from NDB to other storage engines). However, for maximum availability, it is possible (and preferable) to replicate from one NDB Cluster to another, and it is this scenario that we discuss, as shown in the following figure:
In this scenario, the replication process is one in which successive states of a master cluster are logged and saved to a slave cluster. This process is accomplished by a special thread known as the NDB binary log injector thread, which runs on each MySQL server and produces a binary log (binlog). This thread ensures that all changes in the cluster producing the binary log—and not just those changes that are effected through the MySQL Server—are inserted into the binary log with the correct serialization order. We refer to the MySQL replication master and replication slave servers as replication servers or replication nodes, and the data flow or line of communication between them as a replication channel.

For information about performing point-in-time recovery with NDB Cluster and NDB Cluster Replication, see Section 18.6.9.2, “Point-In-Time Recovery Using NDB Cluster Replication”.

**NDB API _slave status variables.** NDB API counters can provide enhanced monitoring capabilities on NDB Cluster replication slaves. These are implemented as NDB statistics _slave status variables, as seen in the output of SHOW STATUS, or in the results of queries against the SESSION_STATUS or GLOBAL_STATUS table in a mysql client session connected to a MySQL Server that is acting as a slave in NDB Cluster Replication. By comparing the values of these status variables before and after the execution of statements affecting replicated NDB tables, you can observe the corresponding actions taken on the NDB API level by the slave, which can be useful when monitoring or troubleshooting NDB Cluster Replication. Section 18.5.16, “NDB API Statistics Counters and Variables”, provides additional information.

**Replication from NDB to non-NDB tables.** It is possible to replicate NDB tables from an NDB Cluster acting as the master to tables using other MySQL storage engines such as InnoDB or MyISAM on a slave mysqld. This is subject to a number of conditions; see Replication from NDB to other storage engines, and Replication from NDB to a nontransactional storage engine, for more information.

### 18.6.1 NDB Cluster Replication: Abbreviations and Symbols

Throughout this section, we use the following abbreviations or symbols for referring to the master and slave clusters, and to processes and commands run on the clusters or cluster nodes:

**Table 18.361 Abbreviations used throughout this section referring to master and slave clusters, and to processes and commands run on nodes**

<table>
<thead>
<tr>
<th>Symbol or Abbreviation</th>
<th>Description (Refers to...)</th>
</tr>
</thead>
<tbody>
<tr>
<td>M</td>
<td>The cluster serving as the (primary) replication master</td>
</tr>
</tbody>
</table>
### 18.6.2 General Requirements for NDB Cluster Replication

A replication channel requires two MySQL servers acting as replication servers (one each for the master and slave). For example, this means that in the case of a replication setup with two replication channels (to provide an extra channel for redundancy), there will be a total of four replication nodes, two per cluster.

Replication of an NDB Cluster as described in this section and those following is dependent on row-based replication. This means that the replication master MySQL server must be running with \`--binlog-format=ROW\` or \`--binlog-format=MIXED\`, as described in Section 18.6.6, “Starting NDB Cluster Replication (Single Replication Channel)”. For general information about row-based replication, see Section 17.1.2, “Replication Formats”.

#### Important

If you attempt to use NDB Cluster Replication with \`--binlog-format=STATEMENT\`, replication fails to work properly because the `ndb_binlog_index` table on the master and the `epoch` column of the `ndb_apply_status` table on the slave are not updated (see Section 18.6.4, “NDB Cluster Replication Schema and Tables”). Instead, only updates on the MySQL server acting as the replication master propagate to the slave, and no updates from any other SQL nodes on the master cluster are replicated.

The default value for the \`--binlog-format\` option in NDB Cluster 7.3 and NDB Cluster 7.4 is `MIXED`.

Each MySQL server used for replication in either cluster must be uniquely identified among all the MySQL replication servers participating in either cluster (you cannot have replication servers on both the master and slave clusters sharing the same ID). This can be done by starting each SQL node using the \`--server-id=id\` option, where `id` is a unique integer. Although it is not strictly necessary, we will assume for purposes of this discussion that all NDB Cluster binaries are of the same release version.

It is generally true in MySQL Replication that both MySQL servers (`mysqld` processes) involved must be compatible with one another with respect to both the version of the replication protocol used and the
Known Issues in NDB Cluster Replication

SQL feature sets which they support (see Section 17.4.2, “Replication Compatibility Between MySQL Versions”). It is due to such differences between the binaries in the NDB Cluster and MySQL Server 5.6 distributions that NDB Cluster Replication has the additional requirement that both mysqld binaries come from an NDB Cluster distribution. The simplest and easiest way to assure that the mysqld servers are compatible is to use the same NDB Cluster distribution for all master and slave mysqld binaries.

We assume that the slave server or cluster is dedicated to replication of the master, and that no other data is being stored on it.

All NDB tables being replicated must be created using a MySQL server and client. Tables and other database objects created using the NDB API (with, for example, Dictionary::createTable()) are not visible to a MySQL server and so are not replicated. Updates by NDB API applications to existing tables that were created using a MySQL server can be replicated.

Note

It is possible to replicate an NDB Cluster using statement-based replication. However, in this case, the following restrictions apply:

• All updates to data rows on the cluster acting as the master must be directed to a single MySQL server.

• It is not possible to replicate a cluster using multiple simultaneous MySQL replication processes.

• Only changes made at the SQL level are replicated.

These are in addition to the other limitations of statement-based replication as opposed to row-based replication; see Section 17.1.2.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”, for more specific information concerning the differences between the two replication formats.

18.6.3 Known Issues in NDB Cluster Replication

This section discusses known problems or issues when using replication with NDB Cluster 7.3 and NDB Cluster 7.4.

Loss of master-slave connection. A loss of connection can occur either between the replication master SQL node and the replication slave SQL node, or between the replication master SQL node and the data nodes in the master cluster. In the latter case, this can occur not only as a result of loss of physical connection (for example, a broken network cable), but due to the overflow of data node event buffers; if the SQL node is too slow to respond, it may be dropped by the cluster (this is controllable to some degree by adjusting the MaxBufferedEpochs and TimeBetweenEpochs configuration parameters). If this occurs, it is entirely possible for new data to be inserted into the replication master's binary log. For this reason, to guarantee high availability, it is extremely important to maintain a backup replication channel, to monitor the primary channel, and to fail over to the secondary replication channel when necessary to keep the slave cluster synchronized with the master. NDB Cluster is not designed to perform such monitoring on its own; for this, an external application is required.

The replication master issues a “gap” event when connecting or reconnecting to the master cluster. (A gap event is a type of “incident event,” which indicates an incident that occurs that affects the contents of the database but that cannot easily be represented as a set of changes. Examples of incidents are server crashes, database resynchronization, (some) software updates, and (some) hardware changes.) When the slave encounters a gap in the replication log, it stops with an error message. This message is
Known Issues in NDB Cluster Replication

Available in the output of `SHOW SLAVE STATUS`, and indicates that the SQL thread has stopped due to an incident registered in the replication stream, and that manual intervention is required. See Section 18.6.8, “Implementing Failover with NDB Cluster Replication”, for more information about what to do in such circumstances.

**Important**

Because NDB Cluster is not designed on its own to monitor replication status or provide failover, if high availability is a requirement for the slave server or cluster, then you must set up multiple replication lines, monitor the master `mysqld` on the primary replication line, and be prepared fail over to a secondary line if and as necessary. This must be done manually, or possibly by means of a third-party application. For information about implementing this type of setup, see Section 18.6.7, “Using Two Replication Channels for NDB Cluster Replication”, and Section 18.6.8, “Implementing Failover with NDB Cluster Replication”.

However, if you are replicating from a standalone MySQL server to an NDB Cluster, one channel is usually sufficient.

**Circular replication.** NDB Cluster Replication supports circular replication, as shown in the next example. The replication setup involves three NDB Clusters numbered 1, 2, and 3, in which Cluster 1 acts as the replication master for Cluster 2, Cluster 2 acts as the master for Cluster 3, and Cluster 3 acts as the master for Cluster 1, thus completing the circle. Each NDB Cluster has two SQL nodes, with SQL nodes A and B belonging to Cluster 1, SQL nodes C and D belonging to Cluster 2, and SQL nodes E and F belonging to Cluster 3.

Circular replication using these clusters is supported as long as the following conditions are met:

- The SQL nodes on all masters and slaves are the same.
- All SQL nodes acting as replication masters and slaves are started with the `log_slave_updates` system variable enabled.

This type of circular replication setup is shown in the following diagram:
Known Issues in NDB Cluster Replication

**Figure 18.23 NDB Cluster Circular Replication With All Masters As Slaves**

In this scenario, SQL node A in Cluster 1 replicates to SQL node C in Cluster 2; SQL node C replicates to SQL node E in Cluster 3; SQL node E replicates to SQL node A. In other words, the replication line (indicated by the curved arrows in the diagram) directly connects all SQL nodes used as replication masters and slaves.

It should also be possible to set up circular replication in which not all master SQL nodes are also slaves, as shown here:
Known Issues in NDB Cluster Replication

Figure 18.24 NDB Cluster Circular Replication Where Not All Masters Are Slaves

In this case, different SQL nodes in each cluster are used as replication masters and slaves. However, you must not start any of the SQL nodes with the \texttt{log_slave_updates} system variable enabled. This type of circular replication scheme for NDB Cluster, in which the line of replication (again indicated by the curved arrows in the diagram) is discontinuous, should be possible, but it should be noted that it has not yet been thoroughly tested and must therefore still be considered experimental.

\begin{note}

The NDB storage engine uses \textit{idempotent execution mode}, which suppresses duplicate-key and other errors that otherwise break circular replication of NDB Cluster. This is equivalent to setting the global \texttt{slave_exec_mode} system variable to \texttt{IDEMPOTENT}, although this is not necessary in NDB Cluster replication, since NDB Cluster sets this variable automatically and ignores any attempts to set it explicitly.

\textbf{NDB Cluster replication and primary keys.} In the event of a node failure, errors in replication of NDB tables without primary keys can still occur, due to the possibility of duplicate rows being inserted in such cases. For this reason, it is highly recommended that all NDB tables being replicated have primary keys.

\textbf{NDB Cluster Replication and Unique Keys.} In older versions of NDB Cluster, operations that updated values of unique key columns of NDB tables could result in duplicate-key errors when replicated.
\end{note}
This issue is solved for replication between NDB tables by deferring unique key checks until after all table row updates have been performed.

Deferring constraints in this way is currently supported only by NDB. Thus, updates of unique keys when replicating from NDB to a different storage engine such as MyISAM or InnoDB are still not supported.

The problem encountered when replicating without deferred checking of unique key updates can be illustrated using NDB table such as t, is created and populated on the master (and replicated to a slave that does not support deferred unique key updates) as shown here:

```sql
CREATE TABLE t (
  p INT PRIMARY KEY,
  c INT,
  UNIQUE KEY u (c)
) ENGINE NDB;

INSERT INTO t
VALUES (1,1), (2,2), (3,3), (4,4), (5,5);
```

The following UPDATE statement on t succeeded on the master, since the rows affected are processed in the order determined by the ORDER BY option, performed over the entire table:

```sql
UPDATE t SET c = c - 1 ORDER BY p;
```

However, the same statement failed with a duplicate key error or other constraint violation on the slave, because the ordering of the row updates was done for one partition at a time, rather than for the table as a whole.

**Note**

Every NDB table is implicitly partitioned by key when it is created. See Section 19.2.5, “KEY Partitioning”, for more information.

**GTIDs not supported.** Replication using global transaction IDs is not compatible with the NDB storage engine, and is not supported. Enabling GTIDs is likely to cause NDB Cluster Replication to fail.

**Multithreaded slaves not supported.** NDB Cluster does not support multithreaded slaves, and setting related system variables such as slave_parallel_workers, slave_checkpoint_group, and slave_checkpoint_group (or the equivalent mysqld startup options) has no effect.

This is because the slave may not be able to separate transactions occurring in one database from those in another if they are written within the same epoch. In addition, every transaction handled by the NDB storage engine involves at least two databases—the target database and the mysql system database—due to the requirement for updating the mysql.ndb_apply_status table (see Section 18.6.4, “NDB Cluster Replication Schema and Tables”). This in turn breaks the requirement for multithreading that the transaction is specific to a given database.

**Restarting with --initial.** Restarting the cluster with the --initial option causes the sequence of GCI and epoch numbers to start over from 0. (This is generally true of NDB Cluster and not limited to replication scenarios using NDB.) The MySQL servers involved in replication should in this case be restarted. After this, you should use the RESET MASTER and RESET SLAVE statements to clear the invalid ndb_binlog_index and ndb_apply_status tables, respectively.

**Replication from NDB to other storage engines.** It is possible to replicate an NDB table on the master to a table using a different storage engine on the slave, taking into account the restrictions listed here:
Known Issues in NDB Cluster Replication

- Multi-master and circular replication are not supported (tables on both the master and the slave must use the NDB storage engine for this to work).
- Using a storage engine which does not perform binary logging for slave tables requires special handling.
- Use of a nontransactional storage engine for slave tables also requires special handling.
- The master `mysqld` must be started with `--ndb-log-update-as-write=0` or `--ndb-log-update-as-write=OFF`.

The next few paragraphs provide additional information about each of the issues just described.

**Multiple masters not supported when replicating NDB to other storage engines.** For replication from NDB to a different storage engine, the relationship between the two databases must be a simple master-slave one. This means that circular or master-master replication is not supported between NDB Cluster and other storage engines.

In addition, it is not possible to configure more than one replication channel when replicating between NDB and a different storage engine. (However, an NDB Cluster database can simultaneously replicate to multiple slave NDB Cluster databases.) If the master uses NDB tables, it is still possible to have more than one MySQL Server maintain a binary log of all changes; however, for the slave to change masters (fail over), the new master-slave relationship must be explicitly defined on the slave.

**Replicating NDB to a slave storage engine that does not perform binary logging.** If you attempt to replicate from an NDB Cluster to a slave that uses a storage engine that does not handle its own binary logging, the replication process aborts with the error `Binary logging not possible ... Statement cannot be written atomically since more than one engine involved and at least one engine is self-logging (Error 1595)`. It is possible to work around this issue in one of the following ways:

- **Turn off binary logging on the slave.** This can be accomplished by setting `sql_log_bin = 0`.
- **Change the storage engine used for the `mysql.ndb_apply_status` table.** Causing this table to use an engine that does not handle its own binary logging can also eliminate the conflict. This can be done by issuing a statement such as `ALTER TABLE mysql.ndb_apply_status ENGINE=MyISAM` on the slave. It is safe to do this when using a non-NDB storage engine on the slave, since you do not then need to worry about keeping multiple slave SQL nodes synchronized.
- **Filter out changes to the `mysql.ndb_apply_status` table on the slave.** This can be done by starting the slave SQL node with `--replicate-ignore-table=mysql.ndb_apply_status`. If you need for other tables to be ignored by replication, you might wish to use an appropriate `--replicate-wild-ignore-table` option instead.

**Important**
You should *not* disable replication or binary logging of `mysql.ndb_apply_status` or change the storage engine used for this table when replicating from one NDB Cluster to another. See Replication and binary log filtering rules with replication between NDB Clusters, for details.

**Replication from NDB to a nontransactional storage engine.** When replicating from NDB to a nontransactional storage engine such as MyISAM, you may encounter unnecessary duplicate key errors when replicating `INSERT ... ON DUPLICATE KEY UPDATE` statements. You can suppress these by using `--ndb-log-update-as-write=0`, which forces updates to be logged as writes (rather than as updates).

**Replication and binary log filtering rules with replication between NDB Clusters.** If you are using any of the options `--replicate-do-*`, `--replicate-ignore-*`, `--binlog-do-db`, or `--binlog-
To filter databases or tables being replicated, care must be taken not to block replication or binary logging of the `mysql.ndb_apply_status`, which is required for replication between NDB Clusters to operate properly. In particular, you must keep in mind the following:

1. Using `--replicate-do-db=db_name` (and no other `--replicate-do-*` or `--replicate-ignore-*` options) means that only tables in database `db_name` are replicated. In this case, you should also use `--replicate-do-db=mysql,--binlog-do-db=mysql,or --replicate-do-table=mysql.ndb_apply_status` to ensure that `mysql.ndb_apply_status` is populated on slaves.

Using `--binlog-do-db=db_name` (and no other `--binlog-do-db` options) means that changes only to tables in database `db_name` are written to the binary log. In this case, you should also use `--replicate-do-db=mysql,--binlog-do-db=mysql,or --replicate-do-table=mysql.ndb_apply_status` to ensure that `mysql.ndb_apply_status` is populated on slaves.

2. Using `--replicate-ignore-db=mysql` means that no tables in the `mysql` database are replicated. In this case, you should also use `--replicate-do-table=mysql.ndb_apply_status` to ensure that `mysql.ndb_apply_status` is replicated.

Using `--binlog-ignore-db=mysql` means that no changes to tables in the `mysql` database are written to the binary log. In this case, you should also use `--replicate-do-table=mysql.ndb_apply_status` to ensure that `mysql.ndb_apply_status` is replicated.

You should also remember that each replication rule requires the following:

1. Its own `--replicate-do-*` or `--replicate-ignore-*` option, and that multiple rules cannot be expressed in a single replication filtering option. For information about these rules, see Section 17.1.4, “Replication and Binary Logging Options and Variables”.

2. Its own `--binlog-do-db` or `--binlog-ignore-db` option, and that multiple rules cannot be expressed in a single binary log filtering option. For information about these rules, see Section 5.4.4, “The Binary Log”.

If you are replicating an NDB Cluster to a slave that uses a storage engine other than NDB, the considerations just given previously may not apply, as discussed elsewhere in this section.

**NDB Cluster Replication and IPv6.** Currently, the NDB API and MGM API do not support IPv6. However, MySQL Servers—including those acting as SQL nodes in an NDB Cluster—can use IPv6 to contact other MySQL Servers. This means that you can replicate between NDB Clusters using IPv6 to connect the master and slave SQL nodes as shown by the dotted arrow in the following diagram:
However, all connections originating within the NDB Cluster—represented in the preceding diagram by solid arrows—must use IPv4. In other words, all NDB Cluster data nodes, management servers, and management clients must be accessible from one another using IPv4. In addition, SQL nodes must use IPv4 to communicate with the cluster.

Since there is currently no support in the NDB and MGM APIs for IPv6, any applications written using these APIs must also make all connections using IPv4.

**Attribute promotion and demotion.** NDB Cluster Replication includes support for attribute promotion and demotion. The implementation of the latter distinguishes between lossy and non-lossy type conversions, and their use on the slave can be controlled by setting the `slave_type_conversions` global server system variable.

For more information about attribute promotion and demotion in NDB Cluster, see [Row-based replication: attribute promotion and demotion](#).

### 18.6.4 NDB Cluster Replication Schema and Tables

Replication in NDB Cluster makes use of a number of dedicated tables in the `mysql` database on each MySQL Server instance acting as an SQL node in both the cluster being replicated and the replication slave (whether the slave is a single server or a cluster). These tables are created during the MySQL installation process by the `mysql_install_db` script, and include a table for storing the binary log’s indexing data. Since the `ndb_binlog_index` table is local to each MySQL server and does not participate in clustering, it uses the MyISAM storage engine. This means that it must be created separately on each `mysqld` participating in the master cluster. (However, the binary log itself contains updates from all MySQL servers in the cluster to be replicated.) This table is defined as follows:

```sql
CREATE TABLE `ndb_binlog_index` (  `Position` BIGINT(20) UNSIGNED NOT NULL,  `File` VARCHAR(255) NOT NULL,  `epoch` BIGINT(20) UNSIGNED NOT NULL,
```
The size of this table is dependent on the number of epochs per binary log file and the number of binary log files. The number of epochs per binary log file normally depends on the amount of binary log generated per epoch and the size of the binary log file, with smaller epochs resulting in more epochs per file. You should be aware that empty epochs produce inserts to the `ndb_binlog_index` table, even when the `--ndb-log-empty-epochs` option is OFF, meaning that the number of entries per file depends on the length of time that the file is in use; that is,

\[
\text{[number of epochs per file]} = \frac{\text{[time spent per file]}}{\text{TimeBetweenEpochs}}
\]

A busy NDB Cluster writes to the binary log regularly and presumably rotates binary log files more quickly than a quiet one. This means that a “quiet” NDB Cluster with `--ndb-log-empty-epochs=ON` can actually have a much higher number of `ndb_binlog_index` rows per file than one with a great deal of activity.

When `mysqld` is started with the `--ndb-log-orig` option, the `orig_server_id` and `orig_epoch` columns store, respectively, the ID of the server on which the event originated and the epoch in which the event took place on the originating server, which is useful in NDB Cluster replication setups employing multiple masters. The `SELECT` statement used to find the closest binary log position to the highest applied epoch on the slave in a multi-master setup (see Section 18.6.10, “NDB Cluster Replication: Multi-Master and Circular Replication”) employs these two columns, which are not indexed. This can lead to performance issues when trying to fail over, since the query must perform a table scan, especially when the master has been running with `--ndb-log-empty-epochs=ON`. You can improve multi-master failover times by adding an index to these columns, as shown here:

```
ALTER TABLE mysql.ndb_binlog_index
ADD INDEX orig_lookup USING BTREE (orig_server_id, orig_epoch);
```

Adding this index provides no benefit when replicating from a single master to a single slave, since the query used to get the binary log position in such cases makes no use of `orig_server_id` or `orig_epoch`.

See Section 18.6.8, “Implementing Failover with NDB Cluster Replication”, for more information about using the `next_position` and `next_file` columns.

The following figure shows the relationship of the NDB Cluster replication master server, its binary log injector thread, and the `mysql.ndb_binlog_index` table.
An additional table, named `ndb_apply_status`, is used to keep a record of the operations that have been replicated from the master to the slave. Unlike the case with `ndb_binlog_index`, the data in this table is not specific to any one SQL node in the (slave) cluster, and so `ndb_apply_status` can use the NDBCLUSTER storage engine, as shown here:

```sql
CREATE TABLE `ndb_apply_status` (
    `server_id`   INT(10) UNSIGNED NOT NULL,
    `epoch`       BIGINT(20) UNSIGNED NOT NULL,
    `log_name`    VARCHAR(255) CHARACTER SET latin1 COLLATE latin1_bin NOT NULL,
    `start_pos`   BIGINT(20) UNSIGNED NOT NULL,
    `end_pos`     BIGINT(20) UNSIGNED NOT NULL,
    PRIMARY KEY (`server_id`) USING HASH
) ENGINE=NDBCLUSTER   DEFAULT CHARSET=latin1;
```

The `ndb_apply_status` table is populated only on slaves, which means that, on the master, this table never contains any rows; thus, there is no need to allow for DataMemory or IndexMemory to be allotted to `ndb_apply_status` there.

Because this table is populated from data originating on the master, it should be allowed to replicate; any replication filtering or binary log filtering rules that inadvertently prevent the slave from updating `ndb_apply_status` or the master from writing into the binary log may prevent replication between clusters from operating properly. For more information about potential problems arising from such filtering rules, see Replication and binary log filtering rules with replication between NDB Clusters.

The `ndb_binlog_index` and `ndb_apply_status` tables are created in the mysql database because they should not be explicitly replicated by the user. User intervention is normally not required to create or maintain either of these tables, since both `ndb_binlog_index` and the `ndb_apply_status` are maintained by the NDB binary log (binlog) injector thread. This keeps the master `mysqld` process updated to changes performed by the NDB storage engine. The NDB binlog injector thread receives events...
Preparing the NDB Cluster for Replication

Directly from the NDB storage engine. The NDB injector is responsible for capturing all the data events within the cluster, and ensures that all events which change, insert, or delete data are recorded in the ndb_binlog_index table. The slave I/O thread transfers the events from the master's binary log to the slave's relay log.

However, it is advisable to check for the existence and integrity of these tables as an initial step in preparing an NDB Cluster for replication. It is possible to view event data recorded in the binary log by querying the mysql.ndb_binlog_index table directly on the master. This can be also be accomplished using the SHOW BINLOG EVENTS statement on either the replication master or slave MySQL servers. (See Section 13.7.5.3, “SHOW BINLOG EVENTS Syntax”.)

You can also obtain useful information from the output of SHOW ENGINE NDB STATUS.

**Note**

When performing schema changes on NDB tables, applications should wait until the ALTER TABLE statement has returned in the MySQL client connection that issued the statement before attempting to use the updated definition of the table.

If the ndb_apply_status table does not exist on the slave, ndb_restore re-creates it.

Conflict resolution for NDB Cluster Replication requires the presence of an additional mysql.ndb_replication table. Currently, this table must be created manually. For information about how to do this, see Section 18.6.11, “NDB Cluster Replication Conflict Resolution”.

### 18.6.5 Preparing the NDB Cluster for Replication

Preparing the NDB Cluster for replication consists of the following steps:

1. Check all MySQL servers for version compatibility (see Section 18.6.2, “General Requirements for NDB Cluster Replication”).

2. Create a slave account on the master Cluster with the appropriate privileges:

   ```
   mysql>
   GRANT REPLICATION SLAVE
   -> ON *.* TO 'slave_user'@'slave_host'
   -> IDENTIFIED BY 'slave_password';
   ```

   In the previous statement, *slave_user* is the slave account user name, *slave_host* is the host name or IP address of the replication slave, and *slave_password* is the password to assign to this account.

   For example, to create a slave user account with the name *myslave*, logging in from the host named *rep-slave*, and using the password *53cr37*, use the following GRANT statement:

   ```
   mysql>
   GRANT REPLICATION SLAVE
   -> ON *.* TO 'myslave'@'rep-slave'
   -> IDENTIFIED BY '53cr37';
   ```

   For security reasons, it is preferable to use a unique user account—not employed for any other purpose—for the replication slave account.

3. Configure the slave to use the master. Using the MySQL Monitor, this can be accomplished with the CHANGE MASTER TO statement:

   ```
   mysql>
   CHANGE MASTER TO
   -> MASTER_HOST='master_host',
   ```
Preparing the NDB Cluster for Replication

```sql
-- MASTER_PORT=master_port,
-- MASTER_USER='slave_user',
-- MASTER_PASSWORD='slave_password';
```

In the previous statement, `master_host` is the host name or IP address of the replication master, `master_port` is the port for the slave to use for connecting to the master, `slave_user` is the user name set up for the slave on the master, and `slave_password` is the password set for that user account in the previous step.

For example, to tell the slave to replicate from the MySQL server whose host name is `rep-master`, using the replication slave account created in the previous step, use the following statement:

```sql
mysql>
```

```sql
CHANGE MASTER TO
-- MASTER_HOST='rep-master',
-- MASTER_PORT=3306,
-- MASTER_USER='myslave',
-- MASTER_PASSWORD='53cr37';
```

For a complete list of options that can be used with this statement, see Section 13.4.2.1, “CHANGE MASTER TO Syntax”.

To provide replication backup capability, you also need to add an `--ndb-connectstring` option to the slave’s `my.cnf` file prior to starting the replication process. See Section 18.6.9, “NDB Cluster Backups With NDB Cluster Replication”, for details.

For additional options that can be set in `my.cnf` for replication slaves, see Section 17.1.4, “Replication and Binary Logging Options and Variables”.

4. If the master cluster is already in use, you can create a backup of the master and load this onto the slave to cut down on the amount of time required for the slave to synchronize itself with the master. If the slave is also running NDB Cluster, this can be accomplished using the backup and restore procedure described in Section 18.6.9, “NDB Cluster Backups With NDB Cluster Replication”.

```sql
ndb-connectstring=management_host[:port]
```

In the event that you are not using NDB Cluster on the replication slave, you can create a backup with this command on the replication master:

```shell
shell>$ mysqldump --master-data=1
```

Then import the resulting data dump onto the slave by copying the dump file over to the slave. After this, you can use the `mysql` client to import the data from the dumpfile into the slave database as shown here, where `dump_file` is the name of the file that was generated using `mysqldump` on the master, and `db_name` is the name of the database to be replicated:

```shell
shell>$ mysql -u root -p db_name < dump_file
```

For a complete list of options to use with `mysqldump`, see Section 4.5.4, “mysqldump — A Database Backup Program”.

**Note**

If you copy the data to the slave in this fashion, you should make sure that the slave is started with the `--skip-slave-start` option on the command line, or else include `skip-slave-start` in the slave’s `my.cnf` file to keep it
from trying to connect to the master to begin replicating before all the data has been loaded. Once the data loading has completed, follow the additional steps outlined in the next two sections.

5. Ensure that each MySQL server acting as a replication master is configured with a unique server ID, and with binary logging enabled, using the row format. (See Section 17.1.2, “Replication Formats.”) These options can be set either in the master server’s my.cnf file, or on the command line when starting the master mysqld process. See Section 18.6.6, “Starting NDB Cluster Replication (Single Replication Channel),” for information regarding the latter option.

18.6.6 Starting NDB Cluster Replication (Single Replication Channel)

This section outlines the procedure for starting NDB Cluster replication using a single replication channel.

1. Start the MySQL replication master server by issuing this command:

```
shellM> mysqld --ndbcluster --server-id=id \
   --log-bin &
```

In the previous statement, \texttt{id} is this server’s unique ID (see Section 18.6.2, “General Requirements for NDB Cluster Replication”). This starts the server’s mysqld process with binary logging enabled using the proper logging format.

\textbf{Note}

You can also start the master with \texttt{--binlog-format=MIXED}, in which case row-based replication is used automatically when replicating between clusters. \textbf{STATEMENT} based binary logging is not supported for NDB Cluster Replication (see Section 18.6.2, “General Requirements for NDB Cluster Replication”).

2. Start the MySQL replication slave server as shown here:

```
shellS> mysqld --ndbcluster --server-id=id &
```

In the command just shown, \texttt{id} is the slave server’s unique ID. It is not necessary to enable logging on the replication slave.

\textbf{Note}

You should use the \texttt{--skip-slave-start} option with this command or else you should include \texttt{skip-slave-start} in the slave server’s my.cnf file, unless you want replication to begin immediately. With the use of this option, the start of replication is delayed until the appropriate \texttt{START SLAVE} statement has been issued, as explained in Step 4 below.

3. It is necessary to synchronize the slave server with the master server’s replication binary log. If binary logging has not previously been running on the master, run the following statement on the slave:

```
mysqlS> CHANGE MASTER TO \
   -> MASTER_LOG_FILE='', \
   -> MASTER_LOG_POS=4;
```

This instructs the slave to begin reading the master’s binary log from the log’s starting point. Otherwise—that is, if you are loading data from the master using a backup—see Section 18.6.8, “Implementing Failover with NDB Cluster Replication,” for information on how to obtain the correct values to use for \texttt{MASTER_LOG_FILE} and \texttt{MASTER_LOG_POS} in such cases.
4. Finally, you must instruct the slave to begin applying replication by issuing this command from the `mysql` client on the replication slave:

```
mysql> START SLAVE;
```

This also initiates the transmission of replication data from the master to the slave.

It is also possible to use two replication channels, in a manner similar to the procedure described in the next section; the differences between this and using a single replication channel are covered in Section 18.6.7, “Using Two Replication Channels for NDB Cluster Replication”.

It is also possible to improve cluster replication performance by enabling batched updates. This can be accomplished by setting the `slave_allow_batching` system variable on the slave `mysqld` processes. Normally, updates are applied as soon as they are received. However, the use of batching causes updates to be applied in 32 KB batches, which can result in higher throughput and less CPU usage, particularly where individual updates are relatively small.

**Note**

Slave batching works on a per-epoch basis; updates belonging to more than one transaction can be sent as part of the same batch.

All outstanding updates are applied when the end of an epoch is reached, even if the updates total less than 32 KB.

Batching can be turned on and off at runtime. To activate it at runtime, you can use either of these two statements:

```
SET GLOBAL slave_allow_batching = 1;
SET GLOBAL slave_allow_batching = ON;
```

If a particular batch causes problems (such as a statement whose effects do not appear to be replicated correctly), slave batching can be deactivated using either of the following statements:

```
SET GLOBAL slave_allow_batching = 0;
SET GLOBAL slave_allow_batching = OFF;
```

You can check whether slave batching is currently being used by means of an appropriate `SHOW VARIABLES` statement, like this one:

```
mysql> SHOW VARIABLES LIKE 'slave%';
+---------------------------+-------+
<table>
<thead>
<tr>
<th>Variable_name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>slave_allow_batching</td>
<td>ON</td>
</tr>
<tr>
<td>slave_compressed_protocol</td>
<td>OFF</td>
</tr>
<tr>
<td>slave_load_tmpdir</td>
<td>/tmp</td>
</tr>
<tr>
<td>slave_net_timeout</td>
<td>3600</td>
</tr>
<tr>
<td>slave_skip_errors</td>
<td>OFF</td>
</tr>
<tr>
<td>slave_transaction_retries</td>
<td>10</td>
</tr>
</tbody>
</table>
+---------------------------+-------+
6 rows in set (0.00 sec)
```

### 18.6.7 Using Two Replication Channels for NDB Cluster Replication

In a more complete example scenario, we envision two replication channels to provide redundancy and thereby guard against possible failure of a single replication channel. This requires a total of four replication
Implementing Failover with NDB Cluster Replication

servers, two masters for the master cluster and two slave servers for the slave cluster. For purposes of the discussion that follows, we assume that unique identifiers are assigned as shown here:

| Table 18.362 NDB Cluster replication servers described in the text |
|------------------------|-----------------------------|
| Server ID | Description |
| 1 | Master - primary replication channel (M) |
| 2 | Master - secondary replication channel (M') |
| 3 | Slave - primary replication channel (S) |
| 4 | Slave - secondary replication channel (S') |

Setting up replication with two channels is not radically different from setting up a single replication channel. First, the `mysqld` processes for the primary and secondary replication masters must be started, followed by those for the primary and secondary slaves. Then the replication processes may be initiated by issuing the `START SLAVE` statement on each of the slaves. The commands and the order in which they need to be issued are shown here:

1. Start the primary replication master:

   ```shell
   M> mysqld --ndbcluster --server-id=1 --log-bin &
   ```

2. Start the secondary replication master:

   ```shell
   M'> mysqld --ndbcluster --server-id=2 --log-bin &
   ```

3. Start the primary replication slave server:

   ```shell
   S> mysqld --ndbcluster --server-id=3 --skip-slave-start &
   ```

4. Start the secondary replication slave:

   ```shell
   S'> mysqld --ndbcluster --server-id=4 --skip-slave-start &
   ```

5. Finally, initiate replication on the primary channel by executing the `START SLAVE` statement on the primary slave as shown here:

   ```mysql
   S> START SLAVE;
   ```

   **Warning**

   Only the primary channel is to be started at this point. The secondary replication channel is to be started only in the event that the primary replication channel fails, as described in Section 18.6.8, "Implementing Failover with NDB Cluster Replication". Running multiple replication channels simultaneously can result in unwanted duplicate records being created on the replication slaves.

As mentioned previously, it is not necessary to enable binary logging on replication slaves.

**18.6.8 Implementing Failover with NDB Cluster Replication**
Implementing Failover with NDB Cluster Replication

In the event that the primary Cluster replication process fails, it is possible to switch over to the secondary replication channel. The following procedure describes the steps required to accomplish this.

1. Obtain the time of the most recent global checkpoint (GCP). That is, you need to determine the most recent epoch from the `ndb_apply_status` table on the slave cluster, which can be found using the following query:

   ```
   mysql
   SELECT @latest:=MAX(epoch)
   -> FROM mysql.ndb_apply_status;
   ```

   In a circular replication topology, with a master and a slave running on each host, when you are using `ndb_log_apply_status=1`, NDB Cluster epochs are written in the slave binary logs. This means that the `ndb_apply_status` table contains information for the slave on this host as well as for any other host which acts as a slave of the master running on this host.

   In this case, you need to determine the latest epoch on this slave to the exclusion of any epochs from any other slaves in this slave's binary log that were not listed in the `IGNORE_SERVER_IDS` options of the `CHANGE MASTER TO` statement used to set up this slave. The reason for excluding such epochs is that rows in the `mysql.ndb_apply_status` table whose server IDs have a match in the `IGNORE_SERVER_IDS` list used with the `CHANGE MASTER TO` statement used to prepare this slave's master are also considered to be from local servers, in addition to those having the slave's own server ID. You can retrieve this list as `Replicate_Ignore_Server_Ids` from the output of `SHOW SLAVE STATUS`. We assume that you have obtained this list and are substituting it for `ignore_server_ids` in the query shown here, which like the previous version of the query, selects the greatest epoch into a variable named `@latest`:

   ```
   mysql
   SELECT @latest:=MAX(epoch)
   -> FROM mysql.ndb_apply_status
   -> WHERE server_id NOT IN (ignore_server_ids);
   ```

   In some cases, it may be simpler or more efficient (or both) to use a list of the server IDs to be included and `server_id IN server_id_list` in the `WHERE` condition of the preceding query.

2. Using the information obtained from the query shown in Step 1, obtain the corresponding records from the `ndb_binlog_index` table on the master cluster.

   In NDB Cluster 7.3 and later, you can use the following query to obtain the needed records from the master's `ndb_binlog_index` table:

   ```
   mysql
   SELECT
   -> @file:=SUBSTRING_INDEX(next_file, '/', -1),
   -> @pos:=next_position
   -> FROM mysql.ndb_binlog_index
   -> WHERE epoch >= @latest
   -> ORDER BY epoch ASC LIMIT 1;
   ```

   These are the records saved on the master since the failure of the primary replication channel. We have employed a user variable `@latest` here to represent the value obtained in Step 1. Of course, it is not possible for one `mysqld` instance to access user variables set on another server instance directly. These values must be “plugged in” to the second query manually or in application code.

   **Important**
   You must ensure that the slave `mysqld` is started with `--slave-skip-errors=ddl_exist_errors` before executing `START SLAVE`. Otherwise, replication may stop with duplicate DDL errors.
3. Now it is possible to synchronize the secondary channel by running the following query on the secondary slave server:

```sql
mysqlS'> SELECT CHANGE MASTER TO
  -> MASTER_LOG_FILE='@file',
  -> MASTER_LOG_POS=@pos;
```

Again we have employed user variables (in this case `@file` and `@pos`) to represent the values obtained in Step 2 and applied in Step 3; in practice these values must be inserted manually or using application code that can access both of the servers involved.

**Note**

@file is a string value such as `'/var/log/mysql/replication-master-bin.00001'`, and so must be quoted when used in SQL or application code. However, the value represented by `@pos` must not be quoted. Although MySQL normally attempts to convert strings to numbers, this case is an exception.

4. You can now initiate replication on the secondary channel by issuing the appropriate command on the secondary slave `mysqlld`:

```sql
mysqlS'> SELECT START SLAVE;
```

Once the secondary replication channel is active, you can investigate the failure of the primary and effect repairs. The precise actions required to do this will depend upon the reasons for which the primary channel failed.

**Warning**

The secondary replication channel is to be started only if and when the primary replication channel has failed. Running multiple replication channels simultaneously can result in unwanted duplicate records being created on the replication slaves.

If the failure is limited to a single server, it should (in theory) be possible to replicate from `M` to `S'`, or from `M'` to `S`; however, this has not yet been tested.

### 18.6.9 NDB Cluster Backups With NDB Cluster Replication

This section discusses making backups and restoring from them using NDB Cluster replication. We assume that the replication servers have already been configured as covered previously (see Section 18.6.5, "Preparing the NDB Cluster for Replication", and the sections immediately following). This having been done, the procedure for making a backup and then restoring from it is as follows:

1. There are two different methods by which the backup may be started.

   - **Method A.** This method requires that the cluster backup process was previously enabled on the master server, prior to starting the replication process. This can be done by including the following line in a `[mysql_cluster]` section in the `my.cnf` file, where `management_host` is the IP address or host name of the NDB management server for the master cluster, and `port` is the management server’s port number:

     ```ini
     ndb-connectstring=management_host[:port]
     ```
Note

The port number needs to be specified only if the default port (1186) is not being used. See Section 18.2.4, “Initial Configuration of NDB Cluster”, for more information about ports and port allocation in NDB Cluster.

In this case, the backup can be started by executing this statement on the replication master:

```
shell> ndb_mgm -e "START BACKUP"
```

- **Method B.** If the `my.cnf` file does not specify where to find the management host, you can start the backup process by passing this information to the NDB management client as part of the START BACKUP command. This can be done as shown here, where `management_host` and `port` are the host name and port number of the management server:

```
shell> ndb_mgm management_host:port -e "START BACKUP"
```

In our scenario as outlined earlier (see Section 18.6.5, “Preparing the NDB Cluster for Replication”), this would be executed as follows:

```
shell> ndb_mgm rep-master:1186 -e "START BACKUP"
```

2. Copy the cluster backup files to the slave that is being brought on line. Each system running an ndbd process for the master cluster will have cluster backup files located on it, and all of these files must be copied to the slave to ensure a successful restore. The backup files can be copied into any directory on the computer where the slave management host resides, so long as the MySQL and NDB binaries have read permissions in that directory. In this case, we will assume that these files have been copied into the directory `/var/BACKUPS/BACKUP-1`.

It is not necessary that the slave cluster have the same number of ndbd processes (data nodes) as the master; however, it is highly recommended this number be the same. It is necessary that the slave be started with the `--skip-slave-start` option, to prevent premature startup of the replication process.

3. Create any databases on the slave cluster that are present on the master cluster that are to be replicated to the slave.

   **Important**

   A CREATE DATABASE (or CREATE SCHEMA) statement corresponding to each database to be replicated must be executed on each SQL node in the slave cluster.

4. Reset the slave cluster using this statement in the MySQL Monitor:

   ```
   mysql> RESET SLAVE;
   ```

5. You can now start the cluster restoration process on the replication slave using the `ndb_restore` command for each backup file in turn. For the first of these, it is necessary to include the `-m` option to restore the cluster metadata:

   ```
   shell> ndb_restore -c slave_host:port -n node-id -b backup-id -m -r dir
   ```
dir is the path to the directory where the backup files have been placed on the replication slave. For the `ndb_restore` commands corresponding to the remaining backup files, the `-m` option should *not* be used.

For restoring from a master cluster with four data nodes (as shown in the figure in Section 18.6, “NDB Cluster Replication”) where the backup files have been copied to the directory `/var/BACKUPS/BACKUP-1`, the proper sequence of commands to be executed on the slave might look like this:

```
shell$ ndb_restore -c rep-slave:1186 -n 2 -b 1 -m \
    -r ./var/BACKUPS/BACKUP-1
shell$ ndb_restore -c rep-slave:1186 -n 3 -b 1 \
    -r ./var/BACKUPS/BACKUP-1
shell$ ndb_restore -c rep-slave:1186 -n 4 -b 1 \
    -r ./var/BACKUPS/BACKUP-1
shell$ ndb_restore -c rep-slave:1186 -n 5 -b 1 -e \
    -r ./var/BACKUPS/BACKUP-1
```

Important

The `-e` (or `--restore-epoch`) option in the final invocation of `ndb_restore` in this example is required in order that the epoch is written to the slave `mysql.ndb_apply_status`. Without this information, the slave will not be able to synchronize properly with the master. (See Section 18.4.22, “ndb_restore — Restore an NDB Cluster Backup”.)

6. Now you need to obtain the most recent epoch from the `ndb_apply_status` table on the slave (as discussed in Section 18.6.8, “Implementing Failover with NDB Cluster Replication”):

```
mysql$ SELECT @latest:=MAX(epoch)
    FROM mysql.ndb_apply_status;
```

7. Using `@latest` as the epoch value obtained in the previous step, you can obtain the correct starting position `@pos` in the correct binary log file `@file` from the master's `mysql.ndb_binlog_index` table using the query shown here:

```
mysql$ SELECT
    -> @file:=SUBSTRING_INDEX(File, '/', -1),
    -> @pos:=Position
    FROM mysql.ndb_binlog_index
    WHERE epoch >= @latest
    ORDER BY epoch ASC LIMIT 1;
```

In the event that there is currently no replication traffic, you can get this information by running `SHOW MASTER STATUS` on the master and using the value in the `Position` column for the file whose name has the suffix with the greatest value for all files shown in the `File` column. However, in this case, you must determine this and supply it in the next step manually or by parsing the output with a script.

8. Using the values obtained in the previous step, you can now issue the appropriate `CHANGE MASTER TO` statement in the slave's `mysql` client:

```
mysql$ CHANGE MASTER TO
    -> MASTER_LOG_FILE='@file',
    -> MASTER_LOG_POS=@pos;
```

9. Now that the slave “knows” from what point in which binary log file to start reading data from the master, you can cause the slave to begin replicating with this standard MySQL statement:
To perform a backup and restore on a second replication channel, it is necessary only to repeat these steps, substituting the host names and IDs of the secondary master and slave for those of the primary master and slave replication servers where appropriate, and running the preceding statements on them.

For additional information on performing Cluster backups and restoring Cluster from backups, see Section 18.5.3, “Online Backup of NDB Cluster”.

### 18.6.9.1 NDB Cluster Replication: Automating Synchronization of the Replication Slave to the Master Binary Log

It is possible to automate much of the process described in the previous section (see Section 18.6.9, “NDB Cluster Backups With NDB Cluster Replication”). The following Perl script `reset-slave.pl` serves as an example of how you can do this.

```
#!/usr/bin/perl -w
#
# file: reset-slave.pl

18.6.9.2 Point-In-Time Recovery Using NDB Cluster Replication

*Point-in-time* recovery—that is, recovery of data changes made since a given point in time—is performed after restoring a full backup that returns the server to its state when the backup was made. Performing point-in-time recovery of NDB Cluster tables with NDB Cluster and NDB Cluster Replication can be accomplished using a native NDB data backup (taken by issuing `CREATE BACKUP` in the `ndb_mgm` client) and restoring the `ndb_binlog_index` table (from a dump made using `mysqldump`).

To perform point-in-time recovery of NDB Cluster, it is necessary to follow the steps shown here:

1. Back up all NDB databases in the cluster, using the `START BACKUP` command in the `ndb_mgm` client (see Section 18.5.3, “Online Backup of NDB Cluster”).

2. At some later point, prior to restoring the cluster, make a backup of the `mysql.ndb_binlog_index` table. It is probably simplest to use `mysqldump` for this task. Also back up the binary log files at this time.

   This backup should be updated regularly—perhaps even hourly—depending on your needs.

3. *(Catastrophic failure or error occurs.)*

4. Locate the last known good backup.

5. Clear the data node file systems (using `ndbd --initial` or `ndbmt --initial`).

   **Note**
   
   NDB Cluster Disk Data tablespace and log files are not removed by `--initial`. You must delete these manually.

6. Use `DROP TABLE` or `TRUNCATE TABLE` with the `mysql.ndb_binlog_index` table.

7. Execute `ndb_restore`, restoring all data. You must include the `--restore-epoch` option when you run `ndb_restore`, so that the `ndb_apply_status` table is populated correctly. (See Section 18.4.22, “`ndb_restore` — Restore an NDB Cluster Backup”, for more information.)

8. Restore the `ndb_binlog_index` table from the output of `mysqldump` and restore the binary log files from backup, if necessary.

9. Find the epoch applied most recently—that is, the maximum `epoch` column value in the `ndb_apply_status` table—as the user variable `@LATEST_EPOCH` (emphasized):

   ```sql
   SELECT @LATEST_EPOCH:=MAX(epoch)
   FROM mysql.ndb_apply_status;
   ```

10. Find the latest binary log file (`@FIRST_FILE`) and position (`Position` column value) within this file that correspond to `@LATEST_EPOCH` in the `ndb_binlog_index` table:

    ```sql
    SELECT Position, @FIRST_FILE:=File
    FROM mysql.ndb_binlog_index
    WHERE epoch > @LATEST_EPOCH ORDER BY epoch ASC LIMIT 1;
    ```

11. Using `mysqlbinlog`, replay the binary log events from the given file and position up to the point of the failure. (See Section 4.6.8, “`mysqlbinlog` — Utility for Processing Binary Log Files”.)

See also Section 7.5, “Point-in-Time (Incremental) Recovery Using the Binary Log”, for more information about the binary log, replication, and incremental recovery.
18.6.10 NDB Cluster Replication: Multi-Master and Circular Replication

It is possible to use NDB Cluster in multi-master replication, including circular replication between a number of NDB Clusters.

Circular replication example. In the next few paragraphs we consider the example of a replication setup involving three NDB Clusters numbered 1, 2, and 3, in which Cluster 1 acts as the replication master for Cluster 2, Cluster 2 acts as the master for Cluster 3, and Cluster 3 acts as the master for Cluster 1. Each cluster has two SQL nodes, with SQL nodes A and B belonging to Cluster 1, SQL nodes C and D belonging to Cluster 2, and SQL nodes E and F belonging to Cluster 3.

Circular replication using these clusters is supported as long as the following conditions are met:

• The SQL nodes on all masters and slaves are the same.

• All SQL nodes acting as replication masters and slaves are started with the `log_slave_updates` system variable enabled.

This type of circular replication setup is shown in the following diagram:

Figure 18.27 NDB Cluster Circular Replication with All Masters As Slaves
In this scenario, SQL node A in Cluster 1 replicates to SQL node C in Cluster 2; SQL node C replicates to SQL node E in Cluster 3; SQL node E replicates to SQL node A. In other words, the replication line (indicated by the curved arrows in the diagram) directly connects all SQL nodes used as replication masters and slaves.

It is also possible to set up circular replication in such a way that not all master SQL nodes are also slaves, as shown here:

**Figure 18.28 NDB Cluster Circular Replication Where Not All Masters Are Slaves**

In this case, different SQL nodes in each cluster are used as replication masters and slaves. However, you must not start any of the SQL nodes with the `log_slave_updates` system variable enabled. This type of circular replication scheme for NDB Cluster, in which the line of replication (again indicated by the curved arrows in the diagram) is discontinuous, should be possible, but it should be noted that it has not yet been thoroughly tested and must therefore still be considered experimental.

**Using NDB-native backup and restore to initialize a slave NDB Cluster.** When setting up circular replication, it is possible to initialize the slave cluster by using the management client `BACKUP` command on one NDB Cluster to create a backup and then applying this backup on another NDB Cluster using `ndb_restore`. However, this does not automatically create binary logs on the second NDB Cluster's SQL node acting as the replication slave. In order to cause the binary logs to be created, you must issue a `SHOW TABLES` statement on that SQL node; this should be done prior to running `START SLAVE`. 
This is a known issue which we intend to address in a future release.

**Multi-master failover example.** In this section, we discuss failover in a multi-master NDB Cluster replication setup with three NDB Clusters having server IDs 1, 2, and 3. In this scenario, Cluster 1 replicates to Clusters 2 and 3; Cluster 2 also replicates to Cluster 3. This relationship is shown here:

**Figure 18.29 NDB Cluster Multi-Master Replication With 3 Masters**

In other words, data replicates from Cluster 1 to Cluster 3 through 2 different routes: directly, and by way of Cluster 2.

Not all MySQL servers taking part in multi-master replication must act as both master and slave, and a given NDB Cluster might use different SQL nodes for different replication channels. Such a case is shown here:

**Figure 18.30 NDB Cluster Multi-Master Replication, With MySQL Servers**

MySQL servers acting as replication slaves must be run with the `log_slave_updates` system variable enabled. Which `mysqld` processes require this option is also shown in the preceding diagram.
NDB Cluster Replication Conflict Resolution

Note
Using the `log_slave_updates` system variable has no effect on servers not being run as replication slaves.

The need for failover arises when one of the replicating clusters goes down. In this example, we consider the case where Cluster 1 is lost to service, and so Cluster 3 loses 2 sources of updates from Cluster 1. Because replication between NDB Clusters is asynchronous, there is no guarantee that Cluster 3’s updates originating directly from Cluster 1 are more recent than those received through Cluster 2. You can handle this by ensuring that Cluster 3 catches up to Cluster 2 with regard to updates from Cluster 1. In terms of MySQL servers, this means that you need to replicate any outstanding updates from MySQL server C to server F.

On server C, perform the following queries:

```sql
mysqlC> SELECT @latest:=MAX(epoch)
       -> FROM mysql.ndb_apply_status
       -> WHERE server_id=1;

mysqlC> SELECT
       -> @file:=SUBSTRING_INDEX(File, '/', -1),
       -> @pos:=Position
       -> FROM mysql.ndb_binlog_index
       -> WHERE orig_epoch >= @latest
       -> AND orig_server_id = 1
       -> ORDER BY epoch ASC LIMIT 1;
```

Note
You can improve the performance of this query, and thus likely speed up failover times significantly, by adding the appropriate index to the `ndb_binlog_index` table. See Section 18.6.4, “NDB Cluster Replication Schema and Tables”, for more information.

Copy over the values for `@file` and `@pos` manually from server C to server F (or have your application perform the equivalent). Then, on server F, execute the following `CHANGE MASTER TO` statement:

```sql
mysqlF> CHANGE MASTER TO
       -> MASTER_HOST = 'serverC'
       -> MASTER_LOG_FILE='@file',
       -> MASTER_LOG_POS=@pos;
```

Once this has been done, you can issue a `START SLAVE` statement on MySQL server F, and any missing updates originating from server B will be replicated to server F.

The `CHANGE MASTER TO` statement also supports an `IGNORE_SERVER_IDS` option which takes a comma-separated list of server IDs and causes events originating from the corresponding servers to be ignored. For more information, see Section 13.4.2.1, “CHANGE MASTER TO Syntax”, and Section 13.7.5.35, “SHOW SLAVE STATUS Syntax”. For information about how this option interacts with the `ndb_log_apply_status` variable, see Section 18.6.8, “Implementing Failover with NDB Cluster Replication”.

18.6.11 NDB Cluster Replication Conflict Resolution

When using a replication setup involving multiple masters (including circular replication), it is possible that different masters may try to update the same row on the slave with different data. Conflict resolution in NDB Cluster Replication provides a means of resolving such conflicts by permitting a user-defined
resolution column to be used to determine whether or not an update on a given master should be applied on the slave.

Some types of conflict resolution supported by NDB Cluster (NDB$OLD(), NDB$MAX(), NDB$MAX_DELETE_WIN()) implement this user-defined column as a “timestamp” column (although its type cannot be TIMESTAMP, as explained later in this section). These types of conflict resolution are always applied a row-by-row basis rather than a transactional basis. The epoch-based conflict resolution functions NDB$EPOCH() and NDB$EPOCH_TRANS() compare the order in which epochs are replicated (and thus these functions are transactional). Different methods can be used to compare resolution column values on the slave when conflicts occur, as explained later in this section; the method used can be set on a per-table basis.

You should also keep in mind that it is the application’s responsibility to ensure that the resolution column is correctly populated with relevant values, so that the resolution function can make the appropriate choice when determining whether to apply an update.

Requirements. Preparations for conflict resolution must be made on both the master and the slave. These tasks are described in the following list:

• On the master writing the binary logs, you must determine which columns are sent (all columns or only those that have been updated). This is done for the MySQL Server as a whole by applying the mysqld startup option --ndb-log-updated-only (described later in this section) or on a per-table basis by entries in the mysql.ndb_replication table (see The ndb_replication system table).

Note

If you are replicating tables with very large columns (such as TEXT or BLOB columns), --ndb-log-updated-only can also be useful for reducing the size of the master and slave binary logs and avoiding possible replication failures due to exceeding max_allowed_packet.

See Section 17.4.1.19, “Replication and max_allowed_packet”, for more information about this issue.

• On the slave, you must determine which type of conflict resolution to apply (“latest timestamp wins”, “same timestamp wins”, “primary wins”, “primary wins, complete transaction”, or none). This is done using the mysql.ndb_replication system table, on a per-table basis (see The ndb_replication system table).

• NDB 7.4.1 and later support read conflict detection, that is, detecting conflicts between reads of a given row in one cluster and updates or deletes of the same row in another cluster. This requires exclusive read locks obtained by setting ndb_log_exclusive_reads equal to 1 on the slave. All rows read by a conflicting read are logged in the exceptions table. For more information, see Read conflict detection and resolution.

When using the functions NDB$OLD(), NDB$MAX(), and NDB$MAX_DELETE_WIN() for timestamp-based conflict resolution, we often refer to the column used for determining updates as a “timestamp” column. However, the data type of this column is never TIMESTAMP; instead, its data type should be INT (INTEGER) or BIGINT. The “timestamp” column should also be UNSIGNED and NOT NULL.

The NDB$EPOCH() and NDB$EPOCH_TRANS() functions discussed later in this section work by comparing the relative order of replication epochs applied on a primary and secondary NDB Cluster, and do not make use of timestamps.

Master column control. We can see update operations in terms of “before” and “after” images—that is, the states of the table before and after the update is applied. Normally, when updating a table with a primary key, the “before” image is not of great interest; however, when we need to determine on a per-
update basis whether or not to use the updated values on a replication slave, we need to make sure that both images are written to the master's binary log. This is done with the `--ndb-log-update-as-write` option for `mysqld`, as described later in this section.

Importantly, whether logging of complete rows or of updated columns only is done is decided when the MySQL server is started, and cannot be changed online; you must either restart `mysqld`, or start a new `mysqld` instance with different logging options.

### Logging Full or Partial Rows (`--ndb-log-updated-only` Option)

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--ndb-log-updated-only[={(OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>ndb_log_updated_only</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

For purposes of conflict resolution, there are two basic methods of logging rows, as determined by the setting of the `--ndb-log-updated-only` option for `mysqld`:

- Log complete rows
- Log only column data that has been updated—that is, column data whose value has been set, regardless of whether or not this value was actually changed. This is the default behavior.

It is usually sufficient—and more efficient—to log updated columns only; however, if you need to log full rows, you can do so by setting `--ndb-log-updated-only` to 0 or `OFF`.

---

### `--ndb-log-update-as-write` Option: Logging Changed Data as Updates

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--ndb-log-update-as-write[={(OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>ndb_log_update_as_write</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
</tbody>
</table>

The setting of the MySQL Server's `--ndb-log-update-as-write` option determines whether logging is performed with or without the “before” image. Because conflict resolution is done in the MySQL Server's update handler, it is necessary to control logging on the master such that updates are updates and not writes; that is, such that updates are treated as changes in existing rows rather than the writing of new rows (even though these replace existing rows). This option is turned on by default; in other words, updates are treated as writes. (That is, updates are by default written as `write_row` events in the binary log, rather than as `update_row` events.)

To turn off the option, start the master `mysqld` with `--ndb-log-update-as-write=0` or `--ndb-log-update-as-write=OFF`. You must do this when replicating from NDB tables to tables using a
different storage engine; see Replication from NDB to other storage engines, and Replication from NDB to a nontransactional storage engine, for more information.

Conflict resolution control. Conflict resolution is usually enabled on the server where conflicts can occur. Like logging method selection, it is enabled by entries in the mysql.ndb_replication table.

The ndb_replication system table. To enable conflict resolution, it is necessary to create an ndb_replication table in the mysql system database on the master, the slave, or both, depending on the conflict resolution type and method to be employed. This table is used to control logging and conflict resolution functions on a per-table basis, and has one row per table involved in replication. ndb_replication is created and filled with control information on the server where the conflict is to be resolved. In a simple master-slave setup where data can also be changed locally on the slave this will typically be the slave. In a more complex master-master (2-way) replication schema this will usually be all of the masters involved. Each row in mysql.ndb_replication corresponds to a table being replicated, and specifies how to log and resolve conflicts (that is, which conflict resolution function, if any, to use) for that table. The definition of the mysql.ndb_replication table is shown here:

```sql
CREATE TABLE mysql.ndb_replication  
  (db VARBINARY(63),
   table_name VARBINARY(63),
   server_id INT UNSIGNED,
   binlog_type INT UNSIGNED,
   conflict_fn VARBINARY(128),
   PRIMARY KEY USING HASH (db, table_name, server_id)
) ENGINE=NDB
PARTITION BY KEY(db,table_name);
```

The columns in this table are described in the next few paragraphs.

**db.** The name of the database containing the table to be replicated. You may employ either or both of the wildcards _ and % as part of the database name. Matching is similar to what is implemented for the LIKE operator.

**table_name.** The name of the table to be replicated. The table name may include either or both of the wildcards _ and %. Matching is similar to what is implemented for the LIKE operator.

**server_id.** The unique server ID of the MySQL instance (SQL node) where the table resides.

**binlog_type.** The type of binary logging to be employed. This is determined as shown in the following table:

<table>
<thead>
<tr>
<th>Value</th>
<th>Internal Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>NBT_DEFAULT</td>
<td>Use server default</td>
</tr>
<tr>
<td>1</td>
<td>NBT_NO_LOGGING</td>
<td>Do not log this table in the binary log</td>
</tr>
<tr>
<td>2</td>
<td>NBT_UPDATED_ONLY</td>
<td>Only updated attributes are logged</td>
</tr>
<tr>
<td>3</td>
<td>NBT_FULL</td>
<td>Log full row, even if not updated (MySQL server default behavior)</td>
</tr>
<tr>
<td>4</td>
<td>NBT_USE_UPDATE</td>
<td>(For generating NBT_UPDATED_ONLY_USE_UPDATE and NBT_FULL_USE_UPDATE values only—not intended for separate use)</td>
</tr>
<tr>
<td>5</td>
<td>[Not used]</td>
<td>---</td>
</tr>
<tr>
<td>6</td>
<td>NBT_UPDATED_ONLY (equal to NBT_UPDATED_ONLY_USE_UPDATE)</td>
<td>Use updated attributes, even if values are unchanged</td>
</tr>
</tbody>
</table>
conflict_fn. The conflict resolution function to be applied. This function must be specified as one of those shown in the following list:

- **NDB$OLD(column_name)**
- **NDB$MAX(column_name)**
- **NDB$MAX_DELETE_WIN()**
- **NDB$EPOCH()** and **NDB$EPOCH_TRANS()**
- **NDB$EPOCH_TRANS()**
- **NDB$EPOCH2()** (NDB 7.4.2 and later)
- **NDB$EPOCH2_TRANS()** (NDB 7.4.2 and later)
- **NULL**: Indicates that conflict resolution is not to be used for the corresponding table.

These functions are described in the next few paragraphs.

**NDB$OLD(column_name).** If the value of `column_name` is the same on both the master and the slave, then the update is applied; otherwise, the update is not applied on the slave and an exception is written to the log. This is illustrated by the following pseudocode:

```plaintext
if (master_old_column_value == slave_current_column_value)
  apply_update();
else
  log_exception();
```

This function can be used for "same value wins" conflict resolution. This type of conflict resolution ensures that updates are not applied on the slave from the wrong master.

**Important**

The column value from the master's "before" image is used by this function.

**NDB$MAX(column_name).** If the "timestamp" column value for a given row coming from the master is higher than that on the slave, it is applied; otherwise it is not applied on the slave. This is illustrated by the following pseudocode:

```plaintext
if (master_new_column_value > slave_current_column_value)
  apply_update();
```

This function can be used for "greatest timestamp wins" conflict resolution. This type of conflict resolution ensures that, in the event of a conflict, the version of the row that was most recently updated is the version that persists.
Important

The column value from the master’s “after” image is used by this function.

**NDB$MAX_DELETE_WIN().** This is a variation on **NDB$MAX()**. Due to the fact that no timestamp is available for a delete operation, a delete using **NDB$MAX()** is in fact processed as **NDB$OLD**. However, for some use cases, this is not optimal. For **NDB$MAX_DELETE_WIN()**, if the “timestamp” column value for a given row adding or updating an existing row coming from the master is higher than that on the slave, it is applied. However, delete operations are treated as always having the higher value. This is illustrated in the following pseudocode:

```c
if ( (master_new_column_value > slave_current_column_value)
    ||
    operation.type == "delete")
apply_update();
```

This function can be used for “greatest timestamp, delete wins” conflict resolution. This type of conflict resolution ensures that, in the event of a conflict, the version of the row that was deleted or (otherwise) most recently updated is the version that persists.

**Note**

As with **NDB$MAX()**, the column value from the master’s “after” image is the value used by this function.

**NDB$EPOCH() and NDB$EPOCH_TRANS().** The **NDB$EPOCH()** function tracks the order in which replicated epochs are applied on a slave NDB Cluster relative to changes originating on the slave. This relative ordering is used to determine whether changes originating on the slave are concurrent with any changes that originate locally, and are therefore potentially in conflict.

Most of what follows in the description of **NDB$EPOCH()** also applies to **NDB$EPOCH_TRANS()**. Any exceptions are noted in the text.

**NDB$EPOCH()** is asymmetric, operating on one NDB Cluster in a two-cluster circular replication configuration (sometimes referred to as “active-active” replication). We refer here to cluster on which it operates as the primary, and the other as the secondary. The slave on the primary is responsible for detecting and handling conflicts, while the slave on the secondary is not involved in any conflict detection or handling.

When the slave on the primary detects conflicts, it injects events into its own binary log to compensate for these; this ensures that the secondary NDB Cluster eventually realigns itself with the primary and so keeps the primary and secondary from diverging. This compensation and realignment mechanism requires that the primary NDB Cluster always wins any conflicts with the secondary—that is, that the primary’s changes are always used rather than those from the secondary in event of a conflict. This “primary always wins” rule has the following implications:

- Operations that change data, once committed on the primary, are fully persistent and will not be undone or rolled back by conflict detection and resolution.
- Data read from the primary is fully consistent. Any changes committed on the Primary (locally or from the slave) will not be reverted later.
- Operations that change data on the secondary may later be reverted if the primary determines that they are in conflict.
- Individual rows read on the secondary are self-consistent at all times, each row always reflecting either a state committed by the secondary, or one committed by the primary.
• Sets of rows read on the secondary may not necessarily be consistent at a given single point in time. For `NDB$EPOCH_TRANS()`, this is a transient state; for `NDB$EPOCH()`, it can be a persistent state.

• Assuming a period of sufficient length without any conflicts, all data on the secondary NDB Cluster (eventually) becomes consistent with the primary's data.

`NDB$EPOCH()` and `NDB$EPOCH_TRANS()` do not require any user schema modifications, or application changes to provide conflict detection. However, careful thought must be given to the schema used, and the access patterns used, to verify that the complete system behaves within specified limits.

Each of the `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` functions can take an optional parameter; this is the number of bits to use to represent the lower 32 bits of the epoch, and should be set to no less than

\[
\text{CEIL}( \log_2( \frac{\text{TimeBetweenGlobalCheckpoints}}{\text{TimeBetweenEpochs}} ), 1)\]

For the default values of these configuration parameters (2000 and 100 milliseconds, respectively), this gives a value of 5 bits, so the default value (6) should be sufficient, unless other values are used for `TimeBetweenGlobalCheckpoints`, `TimeBetweenEpochs`, or both. A value that is too small can result in false positives, while one that is too large could lead to excessive wasted space in the database.

Both `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` insert entries for conflicting rows into the relevant exceptions tables, provided that these tables have been defined according to the same exceptions table schema rules as described elsewhere in this section (see `NDB$OLD(column_name)`). You need to create any exceptions table before creating the table with which it is to be used.

As with the other conflict detection functions discussed in this section, `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` are activated by including relevant entries in the `mysql.ndb_replication` table (see `The ndb_replication system table`). The roles of the primary and secondary NDB Clusters in this scenario are fully determined by `mysql.ndb_replication` table entries.

Because the conflict detection algorithms employed by `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` are asymmetric, you must use different values for the primary slave's and secondary slave's `server_id` entries.

Prior to NDB 7.3.6, conflicts between `DELETE` operations were handled like those for `UPDATE` operations, and within the same epoch were considered in conflict. In NDB 7.3.6 and later, a conflict between `DELETE` operations alone is not sufficient to trigger a conflict using `NDB$EPOCH()` or `NDB$EPOCH_TRANS()`, and the relative placement within epochs does not matter. (Bug #18459944)

Conflicts detected in the same epoch will not necessarily lead to a conflict. (Bug #18459944)

Conflict detection status variables. Several status variables can be used to monitor conflict detection. You can see how many rows have been found in conflict by `NDB$EPOCH()` since this slave was last restarted from the current value of the `Ndb_conflict_fn_epoch` system status variable.

`Ndb_conflict_fn_epoch_trans` provides the number of rows that have been found directly in conflict by `NDB$EPOCH_TRANS()`. `Ndb_conflict_fn_epoch2` and `Ndb_conflict_fn_epoch2_trans`, added in NDB 7.4.2, show the number of rows found in conflict by `NDB$EPOCH2()` and `NDB$EPOCH2_TRANS()`, respectively. The number of rows actually realigned, including those affected due to their membership in or dependency on the same transactions as other conflicting rows, is given by `Ndb_conflict_trans_row_reject_count`.

For more information, see `NDB Cluster Status Variables`.

Limitations on `NDB$EPOCH()`. The following limitations currently apply when using `NDB$EPOCH()` to perform conflict detection:

• Conflicts are detected using NDB Cluster epoch boundaries, with granularity proportional to `TimeBetweenEpochs` (default: 100 milliseconds). The minimum conflict window is the minimum
time during which concurrent updates to the same data on both clusters always report a conflict. This is always a nonzero length of time, and is roughly proportional to $2 \times (\text{latency} + \text{queueing} + \text{TimeBetweenEpochs})$. This implies that—assuming the default for \text{TimeBetweenEpochs} and ignoring any latency between clusters (as well as any queuing delays)—the minimum conflict window size is approximately 200 milliseconds. This minimum window should be considered when looking at expected application “race” patterns.

- Additional storage is required for tables using the \text{NDB$EPOCH()} and \text{NDB$EPOCH\_TRANS()} functions; from 1 to 32 bits extra space per row is required, depending on the value passed to the function.

- Conflicts between delete operations may result in divergence between the primary and secondary. When a row is deleted on both clusters concurrently, the conflict can be detected, but is not recorded, since the row is deleted. This means that further conflicts during the propagation of any subsequent realignment operations will not be detected, which can lead to divergence.

  Deletes should be externally serialized, or routed to one cluster only. Alternatively, a separate row should be updated transactionally with such deletes and any inserts that follow them, so that conflicts can be tracked across row deletes. This may require changes in applications.

- Only two NDB Clusters in a circular “active-active” configuration are currently supported when using \text{NDB$EPOCH()} or \text{NDB$EPOCH\_TRANS()} for conflict detection.

- Tables having \text{BLOB} or \text{TEXT} columns are not currently supported with \text{NDB$EPOCH()} or \text{NDB$EPOCH\_TRANS()}.

\text{NDB$EPOCH\_TRANS()}. \quad \text{NDB$EPOCH\_TRANS()} extends the \text{NDB$EPOCH()} function. Conflicts are detected and handled in the same way using the “primary wins all” rule (see \text{NDB$EPOCH()} and \text{NDB$EPOCH\_TRANS()})) but with the extra condition that any other rows updated in the same transaction in which the conflict occurred are also regarded as being in conflict. In other words, where \text{NDB$EPOCH()} realigns individual conflicting rows on the secondary, \text{NDB$EPOCH\_TRANS()} realigns conflicting transactions.

In addition, any transactions which are detectably dependent on a conflicting transaction are also regarded as being in conflict, these dependencies being determined by the contents of the secondary cluster’s binary log. Since the binary log contains only data modification operations (inserts, updates, and deletes), only overlapping data modifications are used to determine dependencies between transactions.

\text{NDB$EPOCH\_TRANS()} is subject to the same conditions and limitations as \text{NDB$EPOCH()}, and in addition requires that Version 2 binary log row events are used (\text{log\_bin\_use\_v1\_row\_events} equal to 0), which adds a storage overhead of 2 bytes per event in the binary log. In addition, all transaction IDs must be recorded in the secondary's binary log (\text{--ndb-log-transaction-id} option), which adds a further variable overhead (up to 13 bytes per row).

See \text{NDB$EPOCH()} and \text{NDB$EPOCH\_TRANS()}.

\text{Status information.} \quad A server status variable \text{Ndb\_conflict\_fn\_max} provides a count of the number of times that a row was not applied on the current SQL node due to “greatest timestamp wins” conflict resolution since the last time that \text{mysqld} was started.

The number of times that a row was not applied as the result of “same timestamp wins” conflict resolution on a given \text{mysqld} since the last time it was restarted is given by the global status variable \text{Ndb\_conflict\_fn\_old}. In addition to incrementing \text{Ndb\_conflict\_fn\_old}, the primary key of the row that was not used is inserted into an \text{exceptions table}, as explained later in this section.

\text{NDB$EPOCH2()}. \quad The \text{NDB$EPOCH2()} function, added in NDB 7.4.2, is similar to \text{NDB$EPOCH()}, except that \text{NDB$EPOCH2()} provides for delete-delete handling with a circular replication (“master-master”)
In this scenario, primary and secondary roles are assigned to the two masters by setting the `ndb_slave_conflict_role` system variable to the appropriate value on each master (usually one each of PRIMARY, SECONDARY). When this is done, modifications made by the secondary are reflected by the primary back to the secondary which then conditionally applies them.

**NDB$EPOCH2_TRANS().** In NDB 7.4.2 and later, `NDB$EPOCH2_TRANS()` extends the `NDB$EPOCH2()` function. Conflicts are detected and handled in the same way, and assigning primary and secondary roles to the replicating clusters, but with the extra condition that any other rows updated in the same transaction in which the conflict occurred are also regarded as being in conflict. That is, `NDB$EPOCH2()` realigns individual conflicting rows on the secondary, while `NDB$EPOCH_TRANS()` realigns conflicting transactions.

Where `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` use metadata that is specified per row, per last modified epoch, to determine on the primary whether an incoming replicated row change from the secondary is concurrent with a locally committed change; concurrent changes are regarded as conflicting, with subsequent exceptions table updates and realignment of the secondary. A problem arises when a row is deleted on the primary so there is no longer any last-modified epoch available to determine whether any replicated operations conflict, which means that conflicting delete operations are not detected. This can result in divergence, an example being a delete on one cluster which is concurrent with a delete and insert on the other; this why delete operations can be routed to only one cluster when using `NDB$EPOCH()` and `NDB$EPOCH_TRANS()`.

`NDB$EPOCH2()` bypasses the issue just described—storing information about deleted rows on the PRIMARY—by ignoring any delete-delete conflict, and by avoiding any potential resultant divergence as well. This is accomplished by reflecting any operation successfully applied on and replicated from the secondary back to the secondary. On its return to the secondary, it can be used to reapply an operation on the secondary which was deleted by an operation originating from the primary.

When using `NDB$EPOCH2()`, you should keep in mind that the secondary applies the delete from the primary, removing the new row until it is restored by a reflected operation. In theory, the subsequent insert or update on the secondary conflicts with the delete from the primary, but in this case, we choose to ignore this and allow the secondary to “win”, in the interest of preventing divergence between the clusters. In other words, after a delete, the primary does not detect conflicts, and instead adopts the secondary’s following changes immediately. Because of this, the secondary’s state can revisit multiple previous committed states as it progresses to a final (stable) state, and some of these may be visible.

You should also be aware that reflecting all operations from the secondary back to the primary increases the size of the primary’s logbinary log, as well as demands on bandwidth, CPU usage, and disk I/O.

Application of reflected operations on the secondary depends on the state of the target row on the secondary. Whether or not reflected changes are applied on the secondary can be tracked by checking the `Ndb_conflict_reflected_op_prepare_count` and `Ndb_conflict_reflected_op_discard_count` status variables (both added in NDB 7.4.2). The number of changes applied is simply the difference between these two values (note that `Ndb_conflict_reflected_op_prepare_count` is always greater than or equal to `Ndb_conflict_reflected_op_discard_count`).

Events are applied if and only if both of the following conditions are true:

- The existence of the row—that is, whether or not it exists—is in accordance with the type of event. For delete and update operations, the row must already exist. For insert operations, the row must *not* exist.

- The row was last modified by the primary. It is possible that the modification was accomplished through the execution of a reflected operation.

If both of the conditions are not met, the reflected operation is discarded by the secondary.
Conflict resolution exceptions table. To use the `NDB$OLD` conflict resolution function, it is also necessary to create an exceptions table corresponding to each `NDB` table for which this type of conflict resolution is to be employed. This is also true when using `NDB$EPOCH` or `NDB$EPOCH_TRANS`. The name of this table is that of the table for which conflict resolution is to be applied, with the string `$EX` appended. (For example, if the name of the original table is `mytable`, the name of the corresponding exceptions table name should be `mytable$EX`.) Prior to NDB 7.4.1, this table is created as shown:

```sql
CREATE TABLE original_table$EX  (
    server_id INT UNSIGNED,
    master_server_id INT UNSIGNED,
    master_epoch BIGINT UNSIGNED,
    count INT UNSIGNED,
    original_table_pk_columns,
    [additional_columns,]
    PRIMARY KEY(server_id, master_server_id, master_epoch, count)
) ENGINE=NDB;
```

NDB 7.4.1 and later support an extended exceptions table definition that includes optional columns providing information about an exception's type, cause, and originating transaction. In these versions, the syntax for creating the exceptions table is as shown here:

```sql
CREATE TABLE original_table$EX  (
    [NDB$]server_id INT UNSIGNED,
    [NDB$]master_server_id INT UNSIGNED,
    [NDB$]master_epoch BIGINT UNSIGNED,
    [NDB$]count INT UNSIGNED,
    [NDB$OP_TYPE ENUM('WRITE_ROW','UPDATE_ROW', 'DELETE_ROW', 'REFRESH_ROW', 'READ_ROW') NOT NULL,]
    [NDB$CFT_CAUSE ENUM('ROW_DOES_NOT_EXIST', 'ROW_ALREADY_EXISTS', 'DATA_IN_CONFLICT', 'TRANS_IN_CONFLICT') NOT NULL,]
    [NDB$ORIG_TRANSID BIGINT UNSIGNED NOT NULL,]
    original_table_pk_columns,
    [orig_table_column|orig_table_column$OLD|orig_table_column$NEW,]
    [additional_columns,]
) ENGINE=NDB;
```

The first four columns are required. The names of the first four columns and the columns matching the original table's primary key columns are not critical; however, we suggest for reasons of clarity and consistency, that you use the names shown here for the `server_id`, `master_server_id`, `master_epoch`, and `count` columns, and that you use the same names as in the original table for the columns matching those in the original table's primary key.

Starting with NDB 7.4.1, if the exceptions table uses one or more of the optional columns `NDB$OP_TYPE`, `NDB$CFT_CAUSE`, or `NDB$ORIG_TRANSID` discussed later in this section, then each of the required columns must also be named using the prefix `NDB$`. If desired, you can use the `NDB$` prefix to name the required columns even if you do not define any optional columns, but in this case, all four of the required columns must be named using the prefix.

Following these columns, the columns making up the original table's primary key should be copied in the order in which they are used to define the primary key of the original table. The data types for the columns duplicating the primary key columns of the original table should be the same as (or larger than) those of the
original columns. In NDB Cluster 7.3 and earlier, the exceptions table's primary key must be reproduced column for column. Beginning with NDB 7.4.1, a subset of the primary key columns may be used instead.

Regardless of the NDB Cluster version employed, the exceptions table must use the NDB storage engine. (An example that uses NDB\$OLD() with an exceptions table is shown later in this section.)

Additional columns may optionally be defined following the copied primary key columns, but not before any of them; any such extra columns cannot be NOT NULL. In NDB 7.4.1 and later, support is provided for three additional, predefined optional columns NDB\$OP\_TYPE, NDB\$CFT\_CAUSE, and NDB\$ORIG\_TRANSID, which are described in the next few paragraphs.

**NDB\$OP\_TYPE:** This column can be used to obtain the type of operation causing the conflict. If you use this column, define it as shown here:

```sql
NDB\$OP\_TYPE ENUM('WRITE\_ROW', 'UPDATE\_ROW', 'DELETE\_ROW', 'REFRESH\_ROW', 'READ\_ROW') NOT NULL
```

The WRITE\_ROW, UPDATE\_ROW, and DELETE\_ROW operation types represent user-initiated operations. REFRESH\_ROW operations are operations generated by conflict resolution in compensating transactions sent back to the originating cluster from the cluster that detected the conflict. READ\_ROW operations are user-initiated read tracking operations defined with exclusive row locks.

**NDB\$CFT\_CAUSE:** You can define an optional column NDB\$CFT\_CAUSE which provides the cause of the registered conflict. This column, if used, is defined as shown here:

```sql
NDB\$CFT\_CAUSE ENUM('ROW\_DOES\_NOT\_EXIST', 'ROW\_ALREADY\_EXISTS', 'DATA\_IN\_CONFLICT', 'TRANS\_IN\_CONFLICT') NOT NULL
```

ROW\_DOES\_NOT\_EXIST can be reported as the cause for UPDATE\_ROW and WRITE\_ROW operations; ROW\_ALREADY\_EXISTS can be reported for WRITE\_ROW events. DATA\_IN\_CONFLICT is reported when a row-based conflict function detects a conflict; TRANS\_IN\_CONFLICT is reported when a transactional conflict function rejects all of the operations belonging to a complete transaction.

**NDB\$ORIG\_TRANSID:** The NDB\$ORIG\_TRANSID column, if used, contains the ID of the originating transaction. This column should be defined as follows:

```sql
NDB\$ORIG\_TRANSID BIGINT UNSIGNED NOT NULL
```

NDB\$ORIG\_TRANSID is a 64-bit value generated by NDB. This value can be used to correlate multiple exceptions table entries belonging to the same conflicting transaction from the same or different exceptions tables.

In NDB 7.4.1 and later, additional reference columns which are not part of the original table's primary key can be named colname\$OLD or colname\$NEW. colname\$OLD references old values in update and delete operations—that is, operations containing DELETE\_ROW events. colname\$NEW can be used to reference new values in insert and update operations—in other words, operations using WRITE\_ROW events, UPDATE\_ROW events, or both types of events. Where a conflicting operation does not supply a value for a given non-primary-key reference column, the exceptions table row contains either NULL, or a defined default value for that column.

**Important**

The mysql.ndb_replication table is read when a data table is set up for replication, so the row corresponding to a table to be replicated must be inserted into mysql.ndb_replication before the table to be replicated is created.
Examples

The following examples assume that you have already a working NDB Cluster replication setup, as described in Section 18.6.5, "Preparing the NDB Cluster for Replication", and Section 18.6.6, “Starting NDB Cluster Replication (Single Replication Channel)".

**NDB$MAX() example.** Suppose you wish to enable “greatest timestamp wins” conflict resolution on table *test.t1*, using column *mycol* as the “timestamp”. This can be done using the following steps:

1. Make sure that you have started the master *mysqld* with `--ndb-log-update-as-write=OFF`.
2. On the master, perform this INSERT statement:

   ```sql
   INSERT INTO mysql.ndb_replication
   VALUES ('test', 't1', 0, NULL, 'NDB$MAX(mycol)');
   ```

   Inserting a 0 into the *server_id* indicates that all SQL nodes accessing this table should use conflict resolution. If you want to use conflict resolution on a specific *mysqld* only, use the actual server ID.

   Inserting NULL into the *binlog_type* column has the same effect as inserting 0 (*NBT_DEFAULT*); the server default is used.
3. Create the *test.t1* table:

   ```sql
   CREATE TABLE test.t1 (mycol INT UNSIGNED,
   ) ENGINE=NDB;
   ```

   Now, when updates are done on this table, conflict resolution is applied, and the version of the row having the greatest value for *mycol* is written to the slave.

   **Note**

   Other *binlog_type* options—such as *NBT_UPDATED_ONLY_USE_UPDATE* should be used to control logging on the master using the *ndb_replication* table rather than by using command-line options.

**NDB$OLD() example.** Suppose an *NDB* table such as the one defined here is being replicated, and you wish to enable “same timestamp wins” conflict resolution for updates to this table:

```sql
CREATE TABLE test.t2 (a INT UNSIGNED NOT NULL,
   b CHAR(25) NOT NULL,
   mycol INT UNSIGNED NOT NULL,
   ) ENGINE=NDB;
```

The following steps are required, in the order shown:

1. First—and *prior* to creating *test.t2*—you must insert a row into the *mysql.ndb_replication* table, as shown here:

   ```sql
   INSERT INTO mysql.ndb_replication
   ```
Possible values for the `binlog_type` column are shown earlier in this section. The value `NDB$OLD(mycol)` should be inserted into the `conflict_fn` column.

2. Create an appropriate exceptions table for `test.t2`. The table creation statement shown here includes all required columns; any additional columns must be declared following these columns, and before the definition of the table’s primary key.

```sql
CREATE TABLE test.t2$EX  (
    server_id INT UNSIGNED,
    master_server_id INT UNSIGNED,
    master_epoch BIGINT UNSIGNED,
    count INT UNSIGNED,
    a INT UNSIGNED NOT NULL,
    b CHAR(25) NOT NULL,
    [additional_columns],
    PRIMARY KEY(server_id, master_server_id, master_epoch, count)
) ENGINE=NDB;
```

In NDB 7.4.1 and later, we can include additional columns for information about the type, cause, and originating transaction ID for a given conflict. We are also not required to supply matching columns for all primary key columns in the original table. In these versions, you can create the exceptions table like this:

```sql
CREATE TABLE test.t2$EX  (
    NDB$server_id INT UNSIGNED,
    NDB$master_server_id INT UNSIGNED,
    NDB$master_epoch BIGINT UNSIGNED,
    NDB$count INT UNSIGNED,
    a INT UNSIGNED NOT NULL,
    NDB$OP_TYPE ENUM('WRITE_ROW', 'UPDATE_ROW', 'DELETE_ROW', 'REFRESH_ROW', 'READ_ROW') NOT NULL,
    NDB$CFT_CAUSE ENUM('ROW_DOES_NOT_EXIST', 'ROW_ALREADY_EXISTS', 'DATA_IN_CONFLICT', 'TRANS_IN_CONFLICT') NOT NULL,
    NDB$ORIG_TRANSID BIGINT UNSIGNED NOT NULL,
    [additional_columns],
    PRIMARY KEY(NDB$server_id, NDB$master_server_id, NDB$master_epoch, NDB$count)
) ENGINE=NDB;
```

Note
---

The `NDB$` prefix is required for the four required columns since we included at least one of the columns `NDB$OP_TYPE`, `NDB$CFT_CAUSE`, or `NDB$ORIG_TRANSID` in the table definition.

3. Create the table `test.t2` as shown previously.

These steps must be followed for every table for which you wish to perform conflict resolution using `NDB$OLD()`. For each such table, there must be a corresponding row in `mysql.ndb_replication`, and there must be an exceptions table in the same database as the table being replicated.

**Read conflict detection and resolution.** NDB 7.4.1 and later support tracking of read operations, which makes it possible in circular replication setups to manage conflicts between reads of a given row in one cluster and updates or deletes of the same row in another. This example uses `employee` and
department tables to model a scenario in which an employee is moved from one department to another on the master cluster (which we refer to hereafter as cluster A) while the slave cluster (hereafter B) updates the employee count of the employee’s former department in an interleaved transaction.

The data tables have been created using the following SQL statements:

```sql
# Employee table
CREATE TABLE employee (
    id INT PRIMARY KEY,
    name VARCHAR(2000),
    dept INT NOT NULL
) ENGINE=NDB;

# Department table
CREATE TABLE department (
    id INT PRIMARY KEY,
    name VARCHAR(2000),
    members INT
) ENGINE=NDB;
```

The contents of the two tables include the rows shown in the (partial) output of the following SELECT statements:

```sql
mysql> SELECT id, name, dept FROM employee;
+---------------+------+
| id | name | dept |
+------+--------+------+
...  
| 998  | Mike  | 3    |
| 999  | Joe   | 3    |
| 1000 | Mary  | 3    |
...  

mysql> SELECT id, name, members FROM department;
+-----+-------------+---------+
| id  | name        | members |
+-----+-------------+---------+
...  
| 3   | Old project | 24      |
...  
```

We assume that we are already using an exceptions table that includes the four required columns (and these are used for this table’s primary key), the optional columns for operation type and cause, and the original table’s primary key column, created using the SQL statement shown here:

```sql
CREATE TABLE employee$EX (
    NDB$server_id INT UNSIGNED,
    NDB$master_server_id INT UNSIGNED,
    NDB$master_epoch BIGINT UNSIGNED,
    NDB$count INT UNSIGNED,
    NDB$OP_TYPE ENUM( 'WRITE_ROW', 'UPDATE_ROW', 'DELETE_ROW', 'REFRESH_ROW', 'READ_ROW') NOT NULL,
    NDB$CFT_CAUSE ENUM( 'ROW_DOES_NOT_EXIST', 'ROW_ALREADY_EXISTS', 'DATA_IN_CONFLICT', 'TRANS_IN_CONFLICT') NOT NULL,
    id INT NOT NULL,
```
Suppose there occur the two simultaneous transactions on the two clusters. On cluster \textit{A}, we create a new department, then move employee number 999 into that department, using the following SQL statements:

```
BEGIN;
  INSERT INTO department VALUES (4, "New project", 1);
  UPDATE employee SET dept = 4 WHERE id = 999;
COMMIT;
```

At the same time, on cluster \textit{B}, another transaction reads from \texttt{employee}, as shown here:

```
BEGIN;
  SELECT name FROM employee WHERE id = 999;
  UPDATE department SET members = members - 1 WHERE id = 3;
commit;
```

The conflicting transactions are not normally detected by the conflict resolution mechanism, since the conflict is between a read (\texttt{SELECT}) and an update operation. Beginning with NDB 7.4.1, we can circumvent this issue by executing \texttt{SET ndb_log_exclusive_reads = 1} on the slave cluster. Acquiring exclusive read locks in this way causes any rows read on the master to be flagged as needing conflict resolution on the slave cluster. If we enable exclusive reads in this way prior to the logging of these transactions, the read on cluster \textit{B} is tracked and sent to cluster \textit{A} for resolution; the conflict on the employee row will be detected and the transaction on cluster \textit{B} is aborted.

The conflict is registered in the exceptions table (on cluster \textit{A}) as a \texttt{READ_ROW} operation (see Conflict resolution exceptions table, for a description of operation types), as shown here:

```
mysql> SELECT id, NDB$OP_TYPE, NDB$CFT_CAUSE FROM employee$EX;
+-------+-------------+-------------------+
| id    | NDB$OP_TYPE | NDB$CFT_CAUSE     |
|-------+-------------+-------------------|
| 999   | READ_ROW    | TRANS_IN_CONFLICT |
+-------+-------------+-------------------+
```

Any existing rows found in the read operation are flagged. This means that multiple rows resulting from the same conflict may be logged in the exception table, as shown by examining the effects a conflict between an update on cluster \textit{A} and a read of multiple rows on cluster \textit{B} from the same table in simultaneous transactions. The transaction executed on cluster \textit{A} is shown here:

```
BEGIN;
  INSERT INTO department VALUES (4, "New project", 0);
  UPDATE employee SET dept = 4 WHERE dept = 3;
  SELECT COUNT(*) INTO @count FROM employee WHERE dept = 4;
  UPDATE department SET members = @count WHERE id = 4;
COMMIT;
```

Concurrently a transaction containing the statements shown here runs on cluster \textit{B}:

```
SET ndb_log_exclusive_reads = 1;  # Must be set if not already enabled
...
BEGIN;
  SELECT COUNT(*) INTO @count FROM employee WHERE dept = 3 FOR UPDATE;
  UPDATE department SET members = @count WHERE id = 3;
COMMIT;
```
In this case, all three rows matching the **WHERE** condition in the second transaction's **SELECT** are read, and are thus flagged in the exceptions table, as shown here:

```sql
mysql> SELECT id, NDB$OP_TYPE, NDB$CFT_CAUSE FROM employee$EX;
+-------+-------------+-------------------+
<table>
<thead>
<tr>
<th>id</th>
<th>NDB$OP_TYPE</th>
<th>NDB$CFT_CAUSE</th>
</tr>
</thead>
<tbody>
<tr>
<td>998</td>
<td>READ_ROW</td>
<td>TRANS_IN_CONFLICT</td>
</tr>
<tr>
<td>999</td>
<td>READ_ROW</td>
<td>TRANS_IN_CONFLICT</td>
</tr>
<tr>
<td>1000</td>
<td>READ_ROW</td>
<td>TRANS_IN_CONFLICT</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

Read tracking is performed on the basis of existing rows only. A read based on a given condition track conflicts only of any rows that are *found* and not of any rows that are inserted in an interleaved transaction. This is similar to how exclusive row locking is performed in a single instance of NDB Cluster.

### 18.7 NDB Cluster Release Notes

Changes in NDB Cluster releases are documented separately from this reference manual; you can find release notes for the changes in each NDB Cluster 7.4 release at [NDB Cluster 7.4 Release Notes](#), and for NDB Cluster 7.3 releases at [NDB Cluster 7.3 Release Notes](#).

You can obtain release notes for older versions of NDB Cluster from [NDB Cluster Release Notes](#).

This chapter discusses MySQL’s implementation of user-defined partitioning. You can determine whether your MySQL Server supports partitioning by checking the output of the SHOW PLUGINS statement, like this:

```
mysql> SHOW PLUGINS;
+----------+--------+----------------+---------+---------+
| Name     | Status | Type           | Library | License |
+----------+--------+----------------+---------+---------+
| binlog   | ACTIVE | STORAGE ENGINE | NULL    | GPL     |
| partition| ACTIVE | STORAGE ENGINE | NULL    | GPL     |
| ARCHIVE  | ACTIVE | STORAGE ENGINE | NULL    | GPL     |

```

Previous versions of MySQL had the have_partitioning variable, which was deprecated and removed in MySQL 5.6.1.
You can also check the `INFORMATION_SCHEMA.PLUGINS` table with a query similar to this one:

```sql
mysql> SELECT PLUGIN_NAME as Name, PLUGIN_VERSION as Version, PLUGIN_STATUS as Status FROM INFORMATION_SCHEMA.PLUGINS WHERE PLUGIN_TYPE='STORAGE ENGINE';
```

<table>
<thead>
<tr>
<th>Name</th>
<th>Version</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>

<td>ACTIVE</td>
</tr>
</tbody>
</table>
```

In either case, if you do not see the `partition` plugin listed with the value `ACTIVE` for the `Status` column in the output (shown in bold text in each of the examples just given), then your version of MySQL was not built with partitioning support.

MySQL 5.6 Community binaries provided by Oracle include partitioning support. For information about partitioning support offered in MySQL Enterprise Edition binaries, see Chapter 25, *MySQL Enterprise Edition*.

To enable partitioning if you are compiling MySQL 5.6 from source, the build must be configured with the `-DWITH_PARTITION_STORAGE_ENGINE` option. For more information, see Section 2.9, “Installing MySQL from Source”.

If your MySQL binary is built with partitioning support, nothing further needs to be done to enable it (for example, no special entries are required in your `my.cnf` file).

If you want to disable partitioning support, you can start the MySQL Server with the `--skip-partition` option, in which case the value of `have_partitioning` is `DISABLED`. When partitioning support is disabled, you can see any existing partitioned tables and drop them (although doing this is not advised), but you cannot otherwise manipulate them or access their data.

MySQL supports several types of partitioning as well as subpartitioning; see Section 19.2, “Partitioning Types”, and Section 19.2.6, “Subpartitioning”.

Section 19.3.4, “Maintenance of Partitions”, discusses table maintenance commands for use with partitioned tables.

The `PARTITIONS` table in the `INFORMATION_SCHEMA` database provides information about partitions and partitioned tables. See Section 21.14, “The INFORMATION_SCHEMA PARTITIONS Table”, for more information; for some examples of queries against this table, see Section 19.2.7, “How MySQL Partitioning Handles NULL”.
Overview of Partitioning in MySQL

For known issues with partitioning in MySQL 5.6, see Section 19.6, “Restrictions and Limitations on Partitioning”.

You may also find the following resources to be useful when working with partitioned tables.

**Additional Resources.** Other sources of information about user-defined partitioning in MySQL include the following:

- **MySQL Partitioning Forum**
  This is the official discussion forum for those interested in or experimenting with MySQL Partitioning technology. It features announcements and updates from MySQL developers and others. It is monitored by members of the Partitioning Development and Documentation Teams.

- **Mikael Ronström's Blog**
  MySQL Partitioning Architect and Lead Developer Mikael Ronström frequently posts articles here concerning his work with MySQL Partitioning and NDB Cluster.

- **PlanetMySQL**
  A MySQL news site featuring MySQL-related blogs, which should be of interest to anyone using my MySQL. We encourage you to check here for links to blogs kept by those working with MySQL Partitioning, or to have your own blog added to those covered.

MySQL 5.6 binaries are available from [https://dev.mysql.com/downloads/mysql/5.6.html](https://dev.mysql.com/downloads/mysql/5.6.html). However, for the latest partitioning bugfixes and feature additions, you can obtain the source from our GitHub repository. To enable partitioning, the build must be configured with the `-DWITH_PARTITION_STORAGE_ENGINE` option. For more information about building MySQL, see Section 2.9, “Installing MySQL from Source”. If you have problems compiling a partitioning-enabled MySQL 5.6 build, check the MySQL Partitioning Forum and ask for assistance there if you do not find a solution to your problem already posted.

### 19.1 Overview of Partitioning in MySQL

This section provides a conceptual overview of partitioning in MySQL 5.6.

For information on partitioning restrictions and feature limitations, see Section 19.6, “Restrictions and Limitations on Partitioning”.

The SQL standard does not provide much in the way of guidance regarding the physical aspects of data storage. The SQL language itself is intended to work independently of any data structures or media underlying the schemas, tables, rows, or columns with which it works. Nonetheless, most advanced database management systems have evolved some means of determining the physical location to be used for storing specific pieces of data in terms of the file system, hardware or even both. In MySQL, the InnoDB storage engine has long supported the notion of a tablespace, and the MySQL Server, even prior to the introduction of partitioning, could be configured to employ different physical directories for storing different databases (see Section 8.12.3, “Using Symbolic Links”, for an explanation of how this is done).

**Partitioning** takes this notion a step further, by enabling you to distribute portions of individual tables across a file system according to rules which you can set largely as needed. In effect, different portions of a table are stored as separate tables in different locations. The user-selected rule by which the division of data is accomplished is known as a *partitioning function*, which in MySQL can be the modulus, simple matching against a set of ranges or value lists, an internal hashing function, or a linear hashing function. The function is selected according to the partitioning type specified by the user, and takes as its parameter the value of a user-supplied expression. This expression can be a column value, a function acting on one or more column values, or a set of one or more column values, depending on the type of partitioning that is used.
In the case of \texttt{RANGE}, \texttt{LIST}, and \texttt{LINEAR HASH} partitioning, the value of the partitioning column is passed to the partitioning function, which returns an integer value representing the number of the partition in which that particular record should be stored. This function must be nonconstant and nonrandom. It may not contain any queries, but may use an SQL expression that is valid in MySQL, as long as that expression returns either \texttt{NULL} or an integer \texttt{intval} such that

\[ -\text{MAXVALUE} \leq \text{intval} \leq \text{MAXVALUE} \]

(\texttt{MAXVALUE} is used to represent the least upper bound for the type of integer in question. \texttt{MAXVALUE} represents the greatest lower bound.)

For \texttt{LINEAR KEY}, \texttt{RANGE COLUMNS}, and \texttt{LIST COLUMNS} partitioning, the partitioning expression consists of a list of one or more columns.

For \texttt{LINEAR KEY} partitioning, the partitioning function is supplied by MySQL.

For more information about permitted partitioning column types and partitioning functions, see Section 19.2, “Partitioning Types”, as well as Section 13.1.17, “\texttt{CREATE TABLE} Syntax”, which provides partitioning syntax descriptions and additional examples. For information about restrictions on partitioning functions, see Section 19.6.3, “Partitioning Limitations Relating to Functions”.

This is known as \textit{horizontal partitioning}—that is, different rows of a table may be assigned to different physical partitions. MySQL 5.6 does not support \textit{vertical partitioning}, in which different columns of a table are assigned to different physical partitions. There are no plans at this time to introduce vertical partitioning into MySQL.

For information about determining whether your MySQL Server binary supports user-defined partitioning, see Chapter 19, \textit{Partitioning}.

For creating partitioned tables, you can use most storage engines that are supported by your MySQL server; the MySQL partitioning engine runs in a separate layer and can interact with any of these. In MySQL 5.6, all partitions of the same partitioned table must use the same storage engine; for example, you cannot use \texttt{MyISAM} for one partition and \texttt{InnoDB} for another. However, there is nothing preventing you from using different storage engines for different partitioned tables on the same MySQL server or even in the same database.

MySQL partitioning cannot be used with the \texttt{MERGE}, \texttt{CSV}, or \texttt{FEDERATED} storage engines.

Partitioning by \texttt{KEY} or \texttt{LINEAR KEY} is possible with \texttt{NDB}, but other types of user-defined partitioning are not supported for tables using this storage engine. In addition, an \texttt{NDB} table that employs user-defined partitioning must have an explicit primary key, and any columns referenced in the table’s partitioning expression must be part of the primary key. However, if no columns are listed in the \texttt{PARTITION BY KEY} or \texttt{PARTITION BY LINEAR KEY} clause of the \texttt{CREATE TABLE} or \texttt{ALTER TABLE} statement used to create or modify a user-partitioned \texttt{NDB} table, then the table is not required to have an explicit primary key. For more information, see Section 18.1.7.1, “Noncompliance with SQL Syntax in NDB Cluster”.

To employ a particular storage engine for a partitioned table, it is necessary only to use the \texttt{[STORAGE] ENGINE} option just as you would for a nonpartitioned table. However, you should keep in mind that \texttt{[STORAGE] ENGINE} (and other table options) need to be listed \textit{before} any partitioning options are used in a \texttt{CREATE TABLE} statement. This example shows how to create a table that is partitioned by hash into 6 partitions and which uses the \texttt{InnoDB} storage engine:

\begin{verbatim}
CREATE TABLE ti (id INT, amount DECIMAL(7,2), tr_date DATE)
   ENGINE=INNODB
   PARTITION BY HASH( MONTH(tr_date) )
\end{verbatim}
Each `PARTITION` clause can include a `[STORAGE] ENGINE` option, but in MySQL 5.6 this has no effect.

**Important**

Data and indexes for each partition can be assigned to a specific directory using the `DATA DIRECTORY` and `INDEX DIRECTORY` options for the `PARTITION` clause of the `CREATE TABLE` statement used to create the partitioned table.

The `DATA DIRECTORY` and `INDEX DIRECTORY` are not supported for individual partitions or subpartitions of `MyISAM` tables on Windows.

Only the `DATA DIRECTORY` option is supported for individual partitions and subpartitions of `InnoDB` tables.

All columns used in the table’s partitioning expression must be part of every unique key that the table may have, including any primary key. This means that a table such as this one, created by the following SQL statement, cannot be partitioned:

```sql
CREATE TABLE tnp (
    id INT NOT NULL AUTO_INCREMENT,
    ref BIGINT NOT NULL,
    name VARCHAR(255),
    PRIMARY KEY pk (id),
    UNIQUE KEY uk (name)
);
```

Because the keys `pk` and `uk` have no columns in common, there are no columns available for use in a partitioning expression. Possible workarounds in this situation include adding the `name` column to the table’s primary key, adding the `id` column to `uk`, or simply removing the unique key altogether. See Section 19.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”, for more information.

In addition, `MAX_ROWS` and `MIN_ROWS` can be used to determine the maximum and minimum numbers of rows, respectively, that can be stored in each partition. The `MAX_ROWS` option can be useful for causing NDB Cluster tables to be created with extra partitions, thus allowing for greater storage of hash indexes. See the documentation for the `DataMemory` data node configuration parameter, as well as Section 18.1.2, “NDB Cluster Nodes, Node Groups, Replicas, and Partitions”, for more information.

Some advantages of partitioning are listed here:

- Partitioning makes it possible to store more data in one table than can be held on a single disk or file system partition.
- Data that loses its usefulness can often be easily removed from a partitioned table by dropping the partition (or partitions) containing only that data. Conversely, the process of adding new data can in some cases be greatly facilitated by adding one or more new partitions for storing specifically that data.
- Some queries can be greatly optimized in virtue of the fact that data satisfying a given `WHERE` clause can be stored only on one or more partitions, which automatically excludes any remaining partitions from the search. Because partitions can be altered after a partitioned table has been created, you can reorganize your data to enhance frequent queries that may not have been often used when the partitioning scheme was first set up. This ability to exclude non-matching partitions (and thus any rows they contain) is often referred to as *partition pruning*. For more information, see Section 19.4, “Partition Pruning”. 

In addition, MySQL 5.6 supports explicit partition selection for queries. For example, `SELECT * FROM t PARTITION (p0,p1) WHERE c < 5` selects only those rows in partitions `p0` and `p1` that match the `WHERE` condition. In this case, MySQL does not check any other partitions of table `t`; this can greatly speed up queries when you already know which partition or partitions you wish to examine. Partition selection is also supported for the data modification statements `DELETE, INSERT, REPLACE, UPDATE, and LOAD DATA, LOAD XML`. See the descriptions of these statements for more information and examples.

### 19.2 Partitioning Types

This section discusses the types of partitioning which are available in MySQL 5.6. These include the types listed here:

- **RANGE partitioning.** This type of partitioning assigns rows to partitions based on column values falling within a given range. See Section 19.2.1, “RANGE Partitioning”. For information about an extension to this type, `RANGE COLUMNS`, see Section 19.2.3.1, “RANGE COLUMNS partitioning”.

- **LIST partitioning.** Similar to partitioning by `RANGE`, except that the partition is selected based on columns matching one of a set of discrete values. See Section 19.2.2, “LIST Partitioning”. For information about an extension to this type, `LIST COLUMNS`, see Section 19.2.3.2, “LIST COLUMNS partitioning”.

- **HASH partitioning.** With this type of partitioning, a partition is selected based on the value returned by a user-defined expression that operates on column values in rows to be inserted into the table. The function may consist of any expression valid in MySQL that yields a nonnegative integer value. An extension to this type, `LINEAR HASH`, is also available. See Section 19.2.4, “HASH Partitioning”.

- **KEY partitioning.** This type of partitioning is similar to partitioning by `HASH`, except that only one or more columns to be evaluated are supplied, and the MySQL server provides its own hashing function. These columns can contain other than integer values, since the hashing function supplied by MySQL guarantees an integer result regardless of the column data type. An extension to this type, `LINEAR KEY`, is also available. See Section 19.2.5, “KEY Partitioning”.

A very common use of database partitioning is to segregate data by date. Some database systems support explicit date partitioning, which MySQL does not implement in 5.6. However, it is not difficult in MySQL to create partitioning schemes based on `DATE`, `TIME`, or `DATETIME` columns, or based on expressions making use of such columns.

When partitioning by `KEY` or `LINEAR KEY`, you can use a `DATE`, `TIME`, or `DATETIME` column as the partitioning column without performing any modification of the column value. For example, this table creation statement is perfectly valid in MySQL:

```sql
CREATE TABLE members (  
    firstname VARCHAR(25) NOT NULL,  
    lastname VARCHAR(25) NOT NULL,  
    username VARCHAR(16) NOT NULL,  
    email VARCHAR(35),  
    joined DATE NOT NULL  
)  
PARTITION BY KEY(joined)  
PARTITIONS 6;
```

In MySQL 5.6, it is also possible to use a `DATE` or `DATETIME` column as the partitioning column using `RANGE COLUMNS` and `LIST COLUMNS` partitioning.
MySQL's other partitioning types, however, require a partitioning expression that yields an integer value or NULL. If you wish to use date-based partitioning by RANGE, LIST, HASH, or LINEAR HASH, you can simply employ a function that operates on a DATE, TIME, or DATETIME column and returns such a value, as shown here:

```sql
CREATE TABLE members (  
    firstname VARCHAR(25) NOT NULL,  
    lastname VARCHAR(25) NOT NULL,  
    username VARCHAR(16) NOT NULL,  
    email VARCHAR(35),  
    joined DATE NOT NULL  
)  
PARTITION BY RANGE( YEAR(joined) ) (  
    PARTITION p0 VALUES LESS THAN (1960),  
    PARTITION p1 VALUES LESS THAN (1970),  
    PARTITION p2 VALUES LESS THAN (1980),  
    PARTITION p3 VALUES LESS THAN (1990),  
    PARTITION p4 VALUES LESS THAN MAXVALUE  
);  
```

Additional examples of partitioning using dates may be found in the following sections of this chapter:

- Section 19.2.1, “RANGE Partitioning”
- Section 19.2.4, “HASH Partitioning”
- Section 19.2.4.1, “LINEAR HASH Partitioning”

For more complex examples of date-based partitioning, see the following sections:

- Section 19.4, “Partition Pruning”
- Section 19.2.6, “Subpartitioning”

MySQL partitioning is optimized for use with the TO_DAYS(), YEAR(), and TO_SECONDS() functions. However, you can use other date and time functions that return an integer or NULL, such as WEEKDAY(), DAYOFYEAR(), or MONTH(). See Section 12.7, “Date and Time Functions”, for more information about such functions.

It is important to remember—regardless of the type of partitioning that you use—that partitions are always numbered automatically and in sequence when created, starting with 0. When a new row is inserted into a partitioned table, it is these partition numbers that are used in identifying the correct partition. For example, if your table uses 4 partitions, these partitions are numbered 0, 1, 2, and 3. For the RANGE and LIST partitioning types, it is necessary to ensure that there is a partition defined for each partition number. For HASH partitioning, the user-supplied expression must evaluate to an integer value greater than 0. For KEY partitioning, this issue is taken care of automatically by the hashing function which the MySQL server employs internally.

Names of partitions generally follow the rules governing other MySQL identifiers, such as those for tables and databases. However, partition names are not case-sensitive. For example, the following CREATE TABLE statement fails as shown:

```sql
mysql> CREATE TABLE t2 (val INT)  
    -> PARTITION BY LIST(val)(  
    ->    PARTITION mypart VALUES IN (1,3,5),  
    ->    PARTITION MyPart VALUES IN (2,4,6)  
    -> );  
ERROR 1488 (HY000): Duplicate partition name mypart
```
Failure occurs because MySQL sees no difference between the partition names `mypart` and `MyPart`.

When you specify the number of partitions for the table, this must be expressed as a positive, nonzero integer literal with no leading zeros, and may not be an expression such as `0.8E+01` or `6-2`, even if it evaluates to an integer value. Decimal fractions are not permitted.

In the sections that follow, we do not necessarily provide all possible forms for the syntax that can be used for creating each partition type; this information may be found in Section 13.1.17, “CREATE TABLE Syntax”.

19.2.1 RANGE Partitioning

A table that is partitioned by range is partitioned in such a way that each partition contains rows for which the partitioning expression value lies within a given range. Ranges should be contiguous but not overlapping, and are defined using the `VALUES LESS THAN` operator. For the next few examples, suppose that you are creating a table such as the following to hold personnel records for a chain of 20 video stores, numbered 1 through 20:

```sql
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT NOT NULL,
    store_id INT NOT NULL
);
```

**Note**

The `employees` table used here has no primary or unique keys. While the examples work as shown for purposes of the present discussion, you should keep in mind that tables are extremely likely in practice to have primary keys, unique keys, or both, and that allowable choices for partitioning columns depend on the columns used for these keys, if any are present. For a discussion of these issues, see Section 19.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”.

This table can be partitioned by range in a number of ways, depending on your needs. One way would be to use the `store_id` column. For instance, you might decide to partition the table 4 ways by adding a `PARTITION BY RANGE` clause as shown here:

```sql
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT NOT NULL,
    store_id INT NOT NULL
) PARTITION BY RANGE (store_id) {
    PARTITION p0 VALUES LESS THAN (6),
    PARTITION p1 VALUES LESS THAN (11),
    PARTITION p2 VALUES LESS THAN (16),
    PARTITION p3 VALUES LESS THAN (21)
};
```

In this partitioning scheme, all rows corresponding to employees working at stores 1 through 5 are stored in partition `p0`, to those employed at stores 6 through 10 are stored in partition `p1`, and so on. Each
RANGE Partitioning

partition is defined in order, from lowest to highest. This is a requirement of the `PARTITION BY RANGE` syntax; you can think of it as being analogous to a series of `if ... elseif ...` statements in C or Java in this regard.

It is easy to determine that a new row containing the data (72, 'Mitchell', 'Wilson', '1998-06-25', NULL, 13) is inserted into partition p2, but what happens when your chain adds a 21st store? Under this scheme, there is no rule that covers a row whose `store_id` is greater than 20, so an error results because the server does not know where to place it. You can keep this from occurring by using a “catchall” `VALUES LESS THAN` clause in the `CREATE TABLE` statement that provides for all values greater than the highest value explicitly named:

```sql
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT NOT NULL,
  store_id INT NOT NULL
)
PARTITION BY RANGE (store_id) (
  PARTITION p0 VALUES LESS THAN (6),
  PARTITION p1 VALUES LESS THAN (11),
  PARTITION p2 VALUES LESS THAN (16),
  PARTITION p3 VALUES LESS THAN MAXVALUE
);
```

Note: Another way to avoid an error when no matching value is found is to use the `IGNORE` keyword as part of the `INSERT` statement. For an example, see Section 19.2.2, “LIST Partitioning”. Also see Section 13.2.5, “INSERT Syntax”, for general information about `IGNORE`.

`MAXVALUE` represents an integer value that is always greater than the largest possible integer value (in mathematical language, it serves as a least upper bound). Now, any rows whose `store_id` column value is greater than or equal to 16 (the highest value defined) are stored in partition p3. At some point in the future—when the number of stores has increased to 25, 30, or more—you can use an `ALTER TABLE` statement to add new partitions for stores 21-25, 26-30, and so on (see Section 19.3, “Partition Management”, for details of how to do this).

In much the same fashion, you could partition the table based on employee job codes—that is, based on ranges of `job_code` column values. For example—assuming that two-digit job codes are used for regular (in-store) workers, three-digit codes are used for office and support personnel, and four-digit codes are used for management positions—you could create the partitioned table using the following statement:

```sql
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT NOT NULL,
  store_id INT NOT NULL
)
PARTITION BY RANGE (job_code) (
  PARTITION p0 VALUES LESS THAN (100),
  PARTITION p1 VALUES LESS THAN (1000),
  PARTITION p2 VALUES LESS THAN (10000)
);
```
In this instance, all rows relating to in-store workers would be stored in partition $p0$, those relating to office and support staff in $p1$, and those relating to managers in partition $p2$.

It is also possible to use an expression in `VALUES LESS THAN` clauses. However, MySQL must be able to evaluate the expression's return value as part of a `LESS THAN` ($<$) comparison.

Rather than splitting up the table data according to store number, you can use an expression based on one of the two `DATE` columns instead. For example, let us suppose that you wish to partition based on the year that each employee left the company; that is, the value of `YEAR(separated)`. An example of a `CREATE TABLE` statement that implements such a partitioning scheme is shown here:

```sql
CREATE TABLE employees (  
id INT NOT NULL,  
fname VARCHAR(30),  
lname VARCHAR(30),  
hired DATE NOT NULL DEFAULT '1970-01-01',  
separated DATE NOT NULL DEFAULT '9999-12-31',  
job_code INT,  
store_id INT  )  
PARTITION BY RANGE ( YEAR(separated) ) (  
PARTITION p0 VALUES LESS THAN (1991),  
PARTITION p1 VALUES LESS THAN (1996),  
PARTITION p2 VALUES LESS THAN (2001),  
PARTITION p3 VALUES LESS THAN MAXVALUE  );
```

In this scheme, for all employees who left before 1991, the rows are stored in partition $p0$; for those who left in the years 1991 through 1995, in $p1$; for those who left in the years 1996 through 2000, in $p2$; and for any workers who left after the year 2000, in $p3$.

It is also possible to partition a table by `RANGE`, based on the value of a `TIMESTAMP` column, using the `UNIX_TIMESTAMP()` function, as shown in this example:

```sql
CREATE TABLE quarterly_report_status (  
report_id INT NOT NULL,  
report_status VARCHAR(20) NOT NULL,  
report_updated TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP  )  
PARTITION BY RANGE ( UNIX_TIMESTAMP(report_updated) ) (  
PARTITION p0 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-01-01 00:00:00') ),  
PARTITION p1 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-04-01 00:00:00') ),  
PARTITION p2 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-07-01 00:00:00') ),  
PARTITION p3 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-10-01 00:00:00') ),  
PARTITION p4 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-01-01 00:00:00') ),  
PARTITION p5 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-04-01 00:00:00') ),  
PARTITION p6 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-07-01 00:00:00') ),  
PARTITION p7 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-10-01 00:00:00') ),  
PARTITION p8 VALUES LESS THAN ( UNIX_TIMESTAMP('2010-01-01 00:00:00') ),  
PARTITION p9 VALUES LESS THAN (MAXVALUE)  );
```

Any other expressions involving `TIMESTAMP` values are not permitted. (See Bug #42849.)

Range partitioning is particularly useful when one or more of the following conditions is true:

- You want or need to delete "old" data. If you are using the partitioning scheme shown previously for the `employees` table, you can simply use `ALTER TABLE employees DROP PARTITION p0`; to delete all rows relating to employees who stopped working for the firm prior to 1991. (See Section 13.1.7,
"ALTER TABLE Syntax", and Section 19.3, “Partition Management”, for more information.) For a table with a great many rows, this can be much more efficient than running a DELETE query such as DELETE FROM employees WHERE YEAR(separated) <= 1990;

- You want to use a column containing date or time values, or containing values arising from some other series.

- You frequently run queries that depend directly on the column used for partitioning the table. For example, when executing a query such as EXPLAIN PARTITIONS SELECT COUNT(*) FROM employees WHERE separated BETWEEN '2000-01-01' AND '2000-12-31' GROUP BY store_id;, MySQL can quickly determine that only partition p2 needs to be scanned because the remaining partitions cannot contain any records satisfying the WHERE clause. See Section 19.4, “Partition Pruning”, for more information about how this is accomplished.

A variant on this type of partitioning is RANGE COLUMNS partitioning. Partitioning by RANGE COLUMNS makes it possible to employ multiple columns for defining partitioning ranges that apply both to placement of rows in partitions and for determining the inclusion or exclusion of specific partitions when performing partition pruning. See Section 19.2.3.1, “RANGE COLUMNS partitioning”, for more information.

Partitioning schemes based on time intervals. If you wish to implement a partitioning scheme based on ranges or intervals of time in MySQL 5.6, you have two options:

1. Partition the table by RANGE, and for the partitioning expression, employ a function operating on a DATE, TIME, or DATETIME column and returning an integer value, as shown here:

```sql
CREATE TABLE members (
    firstname VARCHAR(25) NOT NULL,
    lastname VARCHAR(25) NOT NULL,
    username VARCHAR(16) NOT NULL,
    email VARCHAR(35),
    joined DATE NOT NULL
) PARTITION BY RANGE( YEAR(joined) ) (
    PARTITION p0 VALUES LESS THAN (1960),
    PARTITION p1 VALUES LESS THAN (1970),
    PARTITION p2 VALUES LESS THAN (1980),
    PARTITION p3 VALUES LESS THAN (1990),
    PARTITION p4 VALUES LESS THAN MAXVALUE
);```

In MySQL 5.6, it is also possible to partition a table by RANGE based on the value of a TIMESTAMP column, using the UNIX_TIMESTAMP () function, as shown in this example:

```sql
CREATE TABLE quarterly_report_status (
    report_id INT NOT NULL,
    report_status VARCHAR(20) NOT NULL,
    report_updated TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP
) PARTITION BY RANGE ( UNIX_TIMESTAMP(report_updated) ) (
    PARTITION p0 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-01-01 00:00:00') ),
    PARTITION p1 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-04-01 00:00:00') ),
    PARTITION p2 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-07-01 00:00:00') ),
    PARTITION p3 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-10-01 00:00:00') ),
    PARTITION p4 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-01-01 00:00:00') ),
    PARTITION p5 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-04-01 00:00:00') ),
    PARTITION p6 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-07-01 00:00:00') ),
    PARTITION p7 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-10-01 00:00:00') ),
    PARTITION p8 VALUES LESS THAN ( UNIX_TIMESTAMP('2010-01-01 00:00:00') ),
    PARTITION p9 VALUES LESS THAN (MAXVALUE)
);```
In MySQL 5.6, any other expressions involving `TIMESTAMP` values are not permitted. (See Bug #42849.)

**Note**

It is also possible in MySQL 5.6 to use `UNIX_TIMESTAMP(timestamp_column)` as a partitioning expression for tables that are partitioned by `LIST`. However, it is usually not practical to do so.

2. Partition the table by `RANGE COLUMNS`, using a `DATE` or `DATETIME` column as the partitioning column. For example, the `members` table could be defined using the `joined` column directly, as shown here:

```sql
CREATE TABLE members {
    firstname VARCHAR(25) NOT NULL,
    lastname VARCHAR(25) NOT NULL,
    username VARCHAR(16) NOT NULL,
    email VARCHAR(35),
    joined DATE NOT NULL
}
PARTITION BY RANGE COLUMNS(joined) {
    PARTITION p0 VALUES LESS THAN ('1960-01-01'),
    PARTITION p1 VALUES LESS THAN ('1970-01-01'),
    PARTITION p2 VALUES LESS THAN ('1980-01-01'),
    PARTITION p3 VALUES LESS THAN ('1990-01-01'),
    PARTITION p4 VALUES LESS THAN MAXVALUE
};
```

**Note**

The use of partitioning columns employing date or time types other than `DATE` or `DATETIME` is not supported with `RANGE COLUMNS`.

### 19.2.2 LIST Partitioning

List partitioning in MySQL is similar to range partitioning in many ways. As in partitioning by `RANGE`, each partition must be explicitly defined. The chief difference between the two types of partitioning is that, in list partitioning, each partition is defined and selected based on the membership of a column value in one of a set of value lists, rather than in one of a set of contiguous ranges of values. This is done by using `PARTITION BY LIST(expr)` where `expr` is a column value or an expression based on a column value and returning an integer value, and then defining each partition by means of a `VALUES IN (value_list)`, where `value_list` is a comma-separated list of integers.

**Note**

In MySQL 5.6, it is possible to match against only a list of integers (and possibly `NULL`—see Section 19.2.7, “How MySQL Partitioning Handles NULL”) when partitioning by `LIST`.

However, other column types may be used in value lists when employing `LIST COLUMN` partitioning, which is described later in this section.

Unlike the case with partitions defined by range, list partitions do not need to be declared in any particular order. For more detailed syntactical information, see Section 13.1.17, “CREATE TABLE Syntax”.

For the examples that follow, we assume that the basic definition of the table to be partitioned is provided by the `CREATE TABLE` statement shown here:
CREATE TABLE employees {
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT,
  store_id INT
};

(This is the same table used as a basis for the examples in Section 19.2.1, “RANGE Partitioning”.)

Suppose that there are 20 video stores distributed among 4 franchises as shown in the following table.

<table>
<thead>
<tr>
<th>Region</th>
<th>Store ID Numbers</th>
</tr>
</thead>
<tbody>
<tr>
<td>North</td>
<td>3, 5, 6, 9, 17</td>
</tr>
<tr>
<td>East</td>
<td>1, 2, 10, 11, 19, 20</td>
</tr>
<tr>
<td>West</td>
<td>4, 12, 13, 14, 18</td>
</tr>
<tr>
<td>Central</td>
<td>7, 8, 15, 16</td>
</tr>
</tbody>
</table>

To partition this table in such a way that rows for stores belonging to the same region are stored in the same partition, you could use the `CREATE TABLE` statement shown here:

CREATE TABLE employees {
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT,
  store_id INT
}

PARTITION BY LIST(store_id) {
  PARTITION pNorth VALUES IN (3,5,6,9,17),
  PARTITION pEast VALUES IN (1,2,10,11,19,20),
  PARTITION pWest VALUES IN (4,12,13,14,18),
  PARTITION pCentral VALUES IN (7,8,15,16)
};

This makes it easy to add or drop employee records relating to specific regions to or from the table. For instance, suppose that all stores in the West region are sold to another company. In MySQL 5.6, all rows relating to employees working at stores in that region can be deleted with the query `ALTER TABLE employees TRUNCATE PARTITION pWest`, which can be executed much more efficiently than the equivalent `DELETE` statement `DELETE FROM employees WHERE store_id IN (4,12,13,14,18);`. (Using `ALTER TABLE employees DROP PARTITION pWest` would also delete all of these rows, but would also remove the partition `pWest` from the definition of the table; you would need to use an `ALTER TABLE ... ADD PARTITION` statement to restore the table's original partitioning scheme.)

As with `RANGE` partitioning, it is possible to combine `LIST` partitioning with partitioning by hash or key to produce a composite partitioning (subpartitioning). See Section 19.2.6, “Subpartitioning”.

Unlike the case with `RANGE` partitioning, there is no “catch-all” such as `MAXVALUE`; all expected values for the partitioning expression should be covered in `PARTITION ... VALUES IN (...)` clauses. An `INSERT` statement containing an unmatched partitioning column value fails with an error, as shown in this example:

```
mysql> CREATE TABLE h2 {
               ->  c1 INT,
```
When inserting multiple rows using a single `INSERT` statement the behavior depends on whether the table uses a transactional storage engine. For an InnoDB table, the statement is considered a single transaction, so the presence of any unmatched values causes the statement to fail completely, and no rows are inserted. For a table using a nontransactional storage engine such as MyISAM, any rows coming before the row containing the unmatched value are inserted, but any coming after it are not.

You can cause this type of error to be ignored by using the `IGNORE` keyword. If you do so, rows containing unmatched partitioning column values are not inserted, but any rows with matching values are inserted, and no errors are reported:

MySQL 5.6 provides support for `LIST COLUMNS` partitioning. This is a variant of `LIST` partitioning that enables you to use columns of types other than integer types for partitioning columns, as well as to use multiple columns as partitioning keys. For more information, see Section 19.2.3.2, “LIST COLUMNS partitioning”.

### 19.2.3 COLUMNS Partitioning

The next two sections discuss `COLUMNS partitioning`, which are variants on `RANGE` and `LIST` partitioning. `COLUMNS` partitioning enables the use of multiple columns in partitioning keys. All of these columns are taken into account both for the purpose of placing rows in partitions and for the determination of which partitions are to be checked for matching rows in partition pruning.

In addition, both `RANGE COLUMNS` partitioning and `LIST COLUMNS` partitioning support the use of non-integer columns for defining value ranges or list members. The permitted data types are shown in the following list:

- All integer types: `TINYINT`, `SMALLINT`, `MEDIUMINT`, `INT (INTEGER)`, and `BIGINT`. (This is the same as with partitioning by `RANGE` and `LIST`.)

Other numeric data types (such as `DECIMAL` or `FLOAT`) are not supported as partitioning columns.
• **DATE** and **DATETIME**.

Columns using other data types relating to dates or times are not supported as partitioning columns.

• The following string types: **CHAR**, **VARCHAR**, **BINARY**, and **VARBINARY**.

**TEXT** and **BLOB** columns are not supported as partitioning columns.

The discussions of **RANGE COLUMNS** and **LIST COLUMNS** partitioning in the next two sections assume that you are already familiar with partitioning based on ranges and lists as supported in MySQL 5.1 and later; for more information about these, see Section 19.2.1, “RANGE Partitioning”, and Section 19.2.2, “LIST Partitioning”, respectively.

### 19.2.3.1 RANGE COLUMNS partitioning

Range columns partitioning is similar to range partitioning, but enables you to define partitions using ranges based on multiple column values. In addition, you can define the ranges using columns of types other than integer types.

**RANGE COLUMNS** partitioning differs significantly from **RANGE** partitioning in the following ways:

• **RANGE COLUMNS** does not accept expressions, only names of columns.

• **RANGE COLUMNS** accepts a list of one or more columns.

**RANGE COLUMNS** partitions are based on comparisons between *tuples* (lists of column values) rather than comparisons between scalar values. Placement of rows in **RANGE COLUMNS** partitions is also based on comparisons between tuples; this is discussed further later in this section.

• **RANGE COLUMNS** partitioning columns are not restricted to integer columns; string, **DATE** and **DATETIME** columns can also be used as partitioning columns. (See Section 19.2.3, “COLUMNS Partitioning”, for details.)

The basic syntax for creating a table partitioned by **RANGE COLUMNS** is shown here:

```sql
CREATE TABLE table_name
PARTITIONED BY RANGE COLUMNS(column_list) {
    PARTITION partition_name VALUES LESS THAN (value_list)[,]
    PARTITION partition_name VALUES LESS THAN (value_list)][,
    ...
}

column_list:
    column_name[, column_name][, ...]

value_list:
    value[, value][, ...]
```

**Note**

Not all **CREATE TABLE** options that can be used when creating partitioned tables are shown here. For complete information, see Section 13.1.17, “CREATE TABLE Syntax”.

In the syntax just shown, **column_list** is a list of one or more columns (sometimes called a **partitioning column list**), and **value_list** is a list of values (that is, it is a **partition definition value list**). A **value_list** must be supplied for each partition definition, and each **value_list** must have the same number of values as the **column_list** has columns. Generally speaking, if you use **N** columns in the **COLUMNS** clause, then each **VALUES LESS THAN** clause must also be supplied with a list of **N** values.
The elements in the partitioning column list and in the value list defining each partition must occur in the same order. In addition, each element in the value list must be of the same data type as the corresponding element in the column list. However, the order of the column names in the partitioning column list and the value lists does not have to be the same as the order of the table column definitions in the main part of the CREATE TABLE statement. As with table partitioned by RANGE, you can use MAXVALUE to represent a value such that any legal value inserted into a given column is always less than this value. Here is an example of a CREATE TABLE statement that helps to illustrate all of these points:

```sql
mysql> CREATE TABLE rcx (  
-> a INT,
-> b INT,
-> c CHAR(3),
-> d INT
-> )  
-> PARTITION BY RANGE COLUMNS(a,d,c) (  
-> PARTITION p0 VALUES LESS THAN (5,10,'ggg'),
-> PARTITION p1 VALUES LESS THAN (10,20,'mmm'),
-> PARTITION p2 VALUES LESS THAN (15,30,'sss'),
-> PARTITION p3 VALUES LESS THAN (MAXVALUE,MAXVALUE,MAXVALUE)
-> );
Query OK, 0 rows affected (0.15 sec)
```

Table `rcx` contains the columns `a`, `b`, `c`, `d`. The partitioning column list supplied to the COLUMNS clause uses 3 of these columns, in the order `a`, `d`, `c`. Each value list used to define a partition contains 3 values in the same order; that is, each value list tuple has the form (`INT`, `INT`, `CHAR(3)`), which corresponds to the data types used by columns `a`, `d`, and `c` (in that order).

Placement of rows into partitions is determined by comparing the tuple from a row to be inserted that matches the column list in the COLUMNS clause with the tuples used in the VALUES LESS THAN clauses to define partitions of the table. Because we are comparing tuples (that is, lists or sets of values) rather than scalar values, the semantics of VALUES LESS THAN as used with RANGE COLUMNS partitions differs somewhat from the case with simple RANGE partitions. In RANGE partitioning, a row generating an expression value that is equal to a limiting value in a VALUES LESS THAN is never placed in the corresponding partition; however, when using RANGE COLUMNS partitioning, it is sometimes possible for a row whose partitioning column list's first element is equal in value to the that of the first element in a VALUES LESS THAN value list to be placed in the corresponding partition.

Consider the RANGE partitioned table created by this statement:

```sql
CREATE TABLE r1 (  
  a INT,
  b INT
)  
PARTITION BY RANGE (a) (  
  PARTITION p0 VALUES LESS THAN (5),
  PARTITION p1 VALUES LESS THAN (MAXVALUE)
);
```

If we insert 3 rows into this table such that the column value for `a` is 5 for each row, all 3 rows are stored in partition `p1` because the `a` column value is in each case not less than 5, as we can see by executing the proper query against the INFORMATION_SCHEMA.PARTITIONS table:

```sql
mysql> INSERT INTO r1 VALUES (5,10), (5,11), (5,12);
Query OK, 3 rows affected (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 0
mysql> SELECT PARTITION_NAME, TABLE_ROWS  
  -> FROM INFORMATION_SCHEMA.PARTITIONS
```
Now consider a similar table `rc1` that uses `RANGE COLUMNS` partitioning with both columns `a` and `b` referenced in the `COLUMNS` clause, created as shown here:

```sql
CREATE TABLE rc1 (  
a INT,
b INT
) 
PARTITION BY RANGE COLUMNS(a, b) (  
  PARTITION p0 VALUES LESS THAN (5, 12),
  PARTITION p3 VALUES LESS THAN (MAXVALUE, MAXVALUE)
);
```

If we insert exactly the same rows into `rc1` as we just inserted into `r1`, the distribution of the rows is quite different:

```sql
mysql> INSERT INTO rc1 VALUES (5,10), (5,11), (5,12);
Query OK, 3 rows affected (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 0
```

```sql
mysql> SELECT PARTITION_NAME, TABLE_ROWS
-> FROM INFORMATION_SCHEMA.PARTITIONS
-> WHERE TABLE_NAME = 'rc1';
```

```
+--------------+----------------+------------+
| TABLE_SCHEMA | PARTITION_NAME | TABLE_ROWS |
| p            | p0             |          2 |
| p            | p1             |          1 |
+--------------+----------------+------------+
2 rows in set (0.00 sec)
```

This is because we are comparing rows rather than scalar values. We can compare the row values inserted with the limiting row value from the `VALUES THAN LESS THAN` clause used to define partition `p0` in table `rc1`, like this:

```sql
mysql> SELECT (5,10) < (5,12), (5,11) < (5,12), (5,12) < (5,12);
```

```
+-----------------+-----------------+-----------------+
| (5,10) < (5,12) | (5,11) < (5,12) | (5,12) < (5,12) |
+-----------------+-----------------+-----------------+
|               1 |               1 |               0 |
+-----------------+-----------------+-----------------+
1 row in set (0.00 sec)
```

The 2 tuples `(5,10)` and `(5,11)` evaluate as less than `(5,12)`, so they are stored in partition `p0`. Since 5 is not less than 5 and 12 is not less than 12, `(5,12)` is considered not less than `(5,12)`, and is stored in partition `p1`.

The `SELECT` statement in the preceding example could also have been written using explicit row constructors, like this:

```sql
SELECT ROW(5,10) < ROW(5,12), ROW(5,11) < ROW(5,12), ROW(5,12) < ROW(5,12);
```
For more information about the use of row constructors in MySQL, see Section 13.2.10.5, “Row Subqueries”.

For a table partitioned by `RANGE COLUMNS` using only a single partitioning column, the storing of rows in partitions is the same as that of an equivalent table that is partitioned by `RANGE`. The following `CREATE TABLE` statement creates a table partitioned by `RANGE COLUMNS` using 1 partitioning column:

```sql
CREATE TABLE rx (  
a INT,  
b INT
)  
PARTITION BY RANGE COLUMNS (a)  
       (  
PARTITION p0 VALUES LESS THAN (5),  
PARTITION p1 VALUES LESS THAN (MAXVALUE)
);  
```

If we insert the rows `(5,10)`, `(5,11)`, and `(5,12)` into this table, we can see that their placement is the same as it is for the table `r` we created and populated earlier:

```
mysql> INSERT INTO rx VALUES (5,10), (5,11), (5,12);
Query OK, 3 rows affected (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 0

mysql> SELECT PARTITION_NAME, TABLE_ROWS
-> FROM INFORMATION_SCHEMA.PARTITIONS
-> WHERE TABLE_NAME = 'rx';
+--------------+----------------+------------+
<table>
<thead>
<tr>
<th>TABLE_SCHEMA</th>
<th>PARTITION_NAME</th>
<th>TABLE_ROWS</th>
</tr>
</thead>
<tbody>
<tr>
<td>p</td>
<td>p0</td>
<td>0</td>
</tr>
<tr>
<td>p</td>
<td>p1</td>
<td>3</td>
</tr>
</tbody>
</table>
+--------------+----------------+------------+
2 rows in set (0.00 sec)
```

It is also possible to create tables partitioned by `RANGE COLUMNS` where limiting values for one or more columns are repeated in successive partition definitions. You can do this as long as the tuples of column values used to define the partitions are strictly increasing. For example, each of the following `CREATE TABLE` statements is valid:

```sql
CREATE TABLE rc2 (  
a INT,  
b INT
)  
PARTITION BY RANGE COLUMNS(a,b)  
       (  
PARTITION p0 VALUES LESS THAN (0,10),  
PARTITION p1 VALUES LESS THAN (10,20),  
PARTITION p2 VALUES LESS THAN (10,30),  
PARTITION p3 VALUES LESS THAN (10,35),  
PARTITION p4 VALUES LESS THAN (20,40),  
PARTITION p5 VALUES LESS THAN (MAXVALUE,MAXVALUE)
);  
```

```sql
CREATE TABLE rc3 (  
a INT,  
b INT
)  
PARTITION BY RANGE COLUMNS(a,b)  
       (  
PARTITION p0 VALUES LESS THAN (0,10),  
PARTITION p1 VALUES LESS THAN (10,20),  
PARTITION p2 VALUES LESS THAN (10,30),  
PARTITION p3 VALUES LESS THAN (10,35),  
PARTITION p4 VALUES LESS THAN (20,40),  
PARTITION p5 VALUES LESS THAN (MAXVALUE,MAXVALUE)
);  
```
The following statement also succeeds, even though it might appear at first glance that it would not, since the limiting value of column \( b \) is 25 for partition \( p_0 \) and 20 for partition \( p_1 \), and the limiting value of column \( c \) is 100 for partition \( p_1 \) and 50 for partition \( p_2 \):

```sql
CREATE TABLE rc4 (
a INT,
b INT,
c INT
)
PARTITION BY RANGE COLUMNS(a,b,c) {
    PARTITION p0 VALUES LESS THAN (0,25,50),
    PARTITION p1 VALUES LESS THAN (10,20,100),
    PARTITION p2 VALUES LESS THAN (10,30,50)
PARTITION p3 VALUES LESS THAN (MAXVALUE,MAXVALUE,MAXVALUE)
};
```

When designing tables partitioned by `RANGE COLUMNS`, you can always test successive partition definitions by comparing the desired tuples using the `mysql` client, like this:

```sql
mysql> SELECT (0,25,50) < (10,20,100), (10,20,100) < (10,30,50);
+-------------------------+--------------------------+
| (0,25,50) < (10,20,100) | (10,20,100) < (10,30,50) |
|                        1 |                        1 |
+-------------------------+--------------------------+
1 row in set (0.00 sec)
```

If a `CREATE TABLE` statement contains partition definitions that are not in strictly increasing order, it fails with an error, as shown in this example:

```sql
mysql> CREATE TABLE rcf {
    -> a INT,
    -> b INT,
    -> c INT
    -> }
    -> PARTITION BY RANGE COLUMNS(a,b,c) {
    -> PARTITION p0 VALUES LESS THAN (0,25,50),
    -> PARTITION p1 VALUES LESS THAN (20,20,100),
    -> PARTITION p2 VALUES LESS THAN (10,30,50),
    -> PARTITION p3 VALUES LESS THAN (MAXVALUE,MAXVALUE,MAXVALUE)
    -> ];
ERROR 1493 (HY000): VALUES LESS THAN value must be strictly increasing for each partition
```

When you get such an error, you can deduce which partition definitions are invalid by making “less than” comparisons between their column lists. In this case, the problem is with the definition of partition \( p_2 \) because the tuple used to define it is not less than the tuple used to define partition \( p_3 \), as shown here:

```sql
mysql> SELECT (0,25,50) < (20,20,100), (20,20,100) < (10,30,50);
+-------------------------+--------------------------+
| (0,25,50) < (20,20,100) | (20,20,100) < (10,30,50) |
|                       1 |                        0 |
+-------------------------+--------------------------+
1 row in set (0.00 sec)
```

It is also possible for `MAXVALUE` to appear for the same column in more than one `VALUES LESS THAN` clause when using `RANGE COLUMNS`. However, the limiting values for individual columns in successive partition definitions should otherwise be increasing, there should be no more than one partition defined where `MAXVALUE` is used as the upper limit for all column values, and this partition definition should appear
last in the list of `PARTITION ... VALUES LESS THAN` clauses. In addition, you cannot use `MAXVALUE` as the limiting value for the first column in more than one partition definition.

As stated previously, it is also possible with `RANGE COLUMNS` partitioning to use non-integer columns as partitioning columns. (See Section 19.2.3, “COLUMNS Partitioning”, for a complete listing of these.) Consider a table named `employees` (which is not partitioned), created using the following statement:

```sql
CREATE TABLE employees (  
id INT NOT NULL,  
fname VARCHAR(30),  
lname VARCHAR(30),  
hired DATE NOT NULL DEFAULT '1970-01-01',  
separated DATE NOT NULL DEFAULT '9999-12-31',  
job_code INT NOT NULL,  
store_id INT NOT NULL
);
```

Using `RANGE COLUMNS` partitioning, you can create a version of this table that stores each row in one of four partitions based on the employee's last name, like this:

```sql
CREATE TABLE employees_by_lname (  
id INT NOT NULL,  
fname VARCHAR(30),  
lname VARCHAR(30),  
hired DATE NOT NULL DEFAULT '1970-01-01',  
separated DATE NOT NULL DEFAULT '9999-12-31',  
job_code INT NOT NULL,  
store_id INT NOT NULL
)  
PARTITION BY RANGE COLUMNS (lname)  
    PARTITION p0 VALUES LESS THAN ('g'),  
    PARTITION p1 VALUES LESS THAN ('m'),  
    PARTITION p2 VALUES LESS THAN ('t'),  
    PARTITION p3 VALUES LESS THAN (MAXVALUE);
```

Alternatively, you could cause the `employees` table as created previously to be partitioned using this scheme by executing the following `ALTER TABLE` statement:

```sql
ALTER TABLE employees PARTITION BY RANGE COLUMNS (lname)  
    PARTITION p0 VALUES LESS THAN ('g'),  
    PARTITION p1 VALUES LESS THAN ('m'),  
    PARTITION p2 VALUES LESS THAN ('t'),  
    PARTITION p3 VALUES LESS THAN (MAXVALUE);
```

### Note

Because different character sets and collations have different sort orders, the character sets and collations in use may effect which partition of a table partitioned by `RANGE COLUMNS` a given row is stored in when using string columns as partitioning columns. In addition, changing the character set or collation for a given database, table, or column after such a table is created may cause changes in how rows are distributed. For example, when using a case-sensitive collation, 'and' sorts before 'Andersen', but when using a collation that is case insensitive, the reverse is true.

For information about how MySQL handles character sets and collations, see Chapter 10, *Character Sets, Collations, Unicode*.
Similarly, you can cause the `employees` table to be partitioned in such a way that each row is stored in one of several partitions based on the decade in which the corresponding employee was hired using the `ALTER TABLE` statement shown here:

```sql
ALTER TABLE employees PARTITION BY RANGE COLUMNS (hired)  (
  PARTITION p0 VALUES LESS THAN ('1970-01-01'),
  PARTITION p1 VALUES LESS THAN ('1980-01-01'),
  PARTITION p2 VALUES LESS THAN ('1990-01-01'),
  PARTITION p3 VALUES LESS THAN ('2000-01-01'),
  PARTITION p4 VALUES LESS THAN ('2010-01-01'),
  PARTITION p5 VALUES LESS THAN (MAXVALUE)
);
```

See Section 13.1.17, “CREATE TABLE Syntax”, for additional information about `PARTITION BY RANGE COLUMNS` syntax.

### 19.2.3.2 LIST COLUMNS partitioning

MySQL 5.6 provides support for `LIST COLUMNS` partitioning. This is a variant of `LIST` partitioning that enables the use of multiple columns as partition keys, and for columns of data types other than integer types to be used as partitioning columns; you can use string types, `DATE`, and `DATETIME` columns. (For more information about permitted data types for `COLUMNS` partitioning columns, see Section 19.2.3, “COLUMNS Partitioning”.)

Suppose that you have a business that has customers in 12 cities which, for sales and marketing purposes, you organize into 4 regions of 3 cities each as shown in the following table:

<table>
<thead>
<tr>
<th>Region</th>
<th>Cities</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Oskarshamn, Högsby, Mönsterås</td>
</tr>
<tr>
<td>2</td>
<td>Vimmerby, Hultsfred, Västervik</td>
</tr>
<tr>
<td>3</td>
<td>Nässjö, Eksjö, Vetlanda</td>
</tr>
<tr>
<td>4</td>
<td>Uppvidinge, Alvesta, Växjo</td>
</tr>
</tbody>
</table>

With `LIST COLUMNS` partitioning, you can create a table for customer data that assigns a row to any of 4 partitions corresponding to these regions based on the name of the city where a customer resides, as shown here:

```sql
CREATE TABLE customers_1 (  
  first_name VARCHAR(25),  
  last_name VARCHAR(25),  
  street_1 VARCHAR(30),  
  street_2 VARCHAR(30),  
  city VARCHAR(15),  
  renewal DATE  
)  
PARTITION BY LIST COLUMNS(city) (  
  PARTITION pRegion_1 VALUES IN('Oskarshamn', 'Högsby', 'Mönsterås'),  
  PARTITION pRegion_2 VALUES IN('Vimmerby', 'Hultsfred', 'Västervik'),  
  PARTITION pRegion_3 VALUES IN('Nässjö', 'Eksjö', 'Vetlanda'),  
  PARTITION pRegion_4 VALUES IN('Uppvidinge', 'Alvesta', 'Växjo')  
);
```

As with partitioning by `RANGE COLUMNS`, you do not need to use expressions in the `COLUMNS()` clause to convert column values into integers. (In fact, the use of expressions other than column names is not permitted with `COLUMNS()`.)
It is also possible to use `DATE` and `DATETIME` columns, as shown in the following example that uses the same name and columns as the `customers_1` table shown previously, but employs `LIST COLUMNS` partitioning based on the `renewal` column to store rows in one of 4 partitions depending on the week in February 2010 the customer's account is scheduled to renew:

```sql
CREATE TABLE customers_2 (  
    first_name VARCHAR(25),  
    last_name VARCHAR(25),  
    street_1 VARCHAR(30),  
    street_2 VARCHAR(30),  
    city VARCHAR(15),  
    renewal DATE  
)  
PARTITION BY LIST COLUMNS(renewal) (  
    PARTITION pWeek_1 VALUES IN('2010-02-01', '2010-02-02', '2010-02-03', '2010-02-04', '2010-02-05', '2010-02-06', '2010-02-07'),  
    PARTITION pWeek_2 VALUES IN('2010-02-08', '2010-02-09', '2010-02-10', '2010-02-11', '2010-02-12', '2010-02-13', '2010-02-14'),  
    PARTITION pWeek_3 VALUES IN('2010-02-15', '2010-02-16', '2010-02-17', '2010-02-18', '2010-02-19', '2010-02-20', '2010-02-21'),  
    PARTITION pWeek_4 VALUES IN('2010-02-22', '2010-02-23', '2010-02-24', '2010-02-25', '2010-02-26', '2010-02-27', '2010-02-28')
);  
```

This works, but becomes cumbersome to define and maintain if the number of dates involved grows very large; in such cases, it is usually more practical to employ `RANGE` or `RANGE COLUMNS` partitioning instead. In this case, since the column we wish to use as the partitioning key is a `DATE` column, we use `RANGE COLUMNS` partitioning, as shown here:

```sql
CREATE TABLE customers_3 (  
    first_name VARCHAR(25),  
    last_name VARCHAR(25),  
    street_1 VARCHAR(30),  
    street_2 VARCHAR(30),  
    city VARCHAR(15),  
    renewal DATE  
)  
PARTITION BY RANGE COLUMNS(renewal) (  
    PARTITION pWeek_1 VALUES LESS THAN('2010-02-09'),  
    PARTITION pWeek_2 VALUES LESS THAN('2010-02-15'),  
    PARTITION pWeek_3 VALUES LESS THAN('2010-02-22'),  
    PARTITION pWeek_4 VALUES LESS THAN('2010-03-01')
);  
```

See Section 19.2.3.1, “RANGE COLUMNS partitioning”, for more information.

In addition (as with `RANGE COLUMNS` partitioning), you can use multiple columns in the `COLUMNS()` clause.

See Section 13.1.17, “CREATE TABLE Syntax”, for additional information about `PARTITION BY LIST COLUMNS()` syntax.

### 19.2.4 HASH Partitioning

Partitioning by `HASH` is used primarily to ensure an even distribution of data among a predetermined number of partitions. With range or list partitioning, you must specify explicitly into which partition a given column value or set of column values is to be stored; with hash partitioning, MySQL takes care of this for you, and you need only specify a column value or expression based on a column value to be hashed and the number of partitions into which the partitioned table is to be divided.
To partition a table using **HASH** partitioning, it is necessary to append to the `CREATE TABLE` statement a `PARTITION BY HASH (expr)` clause, where `expr` is an expression that returns an integer. This can simply be the name of a column whose type is one of MySQL's integer types. In addition, you most likely want to follow this with `PARTITIONS num`, where `num` is a positive integer representing the number of partitions into which the table is to be divided.

**Note**

For simplicity, the tables in the examples that follow do not use any keys. You should be aware that, if a table has any unique keys, every column used in the partitioning expression for this table must be part of every unique key, including the primary key. See Section 19.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”, for more information.

The following statement creates a table that uses hashing on the `store_id` column and is divided into 4 partitions:

```sql
CREATE TABLE employees {
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT,
    store_id INT
}
PARTITION BY HASH(store_id)
PARTITIONS 4;
```

If you do not include a `PARTITIONS` clause, the number of partitions defaults to 1.

Using the `PARTITIONS` keyword without a number following it results in a syntax error.

You can also use an SQL expression that returns an integer for `expr`. For instance, you might want to partition based on the year in which an employee was hired. This can be done as shown here:

```sql
CREATE TABLE employees {
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT,
    store_id INT
}
PARTITION BY HASH(YEAR(hired))
PARTITIONS 4;
```

`expr` must return a nonconstant, nonrandom integer value (in other words, it should be varying but deterministic), and must not contain any prohibited constructs as described in Section 19.6. “Restrictions and Limitations on Partitioning”. You should also keep in mind that this expression is evaluated each time a row is inserted or updated (or possibly deleted); this means that very complex expressions may give rise to performance issues, particularly when performing operations (such as batch inserts) that affect a great many rows at one time.

The most efficient hashing function is one which operates upon a single table column and whose value increases or decreases consistently with the column value, as this allows for “pruning” on ranges of partitions. That is, the more closely that the expression varies with the value of the column on which it is based, the more efficiently MySQL can use the expression for hash partitioning.
For example, where `date_col` is a column of type `DATE`, then the expression `TO_DAYS(date_col)` is said to vary directly with the value of `date_col`, because for every change in the value of `date_col`, the value of the expression changes in a consistent manner. The variance of the expression `YEAR(date_col)` with respect to `date_col` is not quite as direct as that of `TO_DAYS(date_col)`, because not every possible change in `date_col` produces an equivalent change in `YEAR(date_col)`. Even so, `YEAR(date_col)` is a good candidate for a hashing function, because it varies directly with a portion of `date_col` and there is no possible change in `date_col` that produces a disproportionate change in `YEAR(date_col)`.

By way of contrast, suppose that you have a column named `int_col` whose type is `INT`. Now consider the expression `POW(5-int_col,3) + 6`. This would be a poor choice for a hashing function because a change in the value of `int_col` is not guaranteed to produce a proportional change in the value of the expression. Changing the value of `int_col` by a given amount can produce widely differing changes in the value of the expression. For example, changing `int_col` from 5 to 6 produces a change of -1 in the value of the expression, but changing the value of `int_col` from 6 to 7 produces a change of -7 in the expression value.

In other words, the more closely the graph of the column value versus the value of the expression follows a straight line as traced by the equation \( y=cx \) where \( c \) is some nonzero constant, the better the expression is suited to hashing. This has to do with the fact that the more nonlinear an expression is, the more uneven the distribution of data among the partitions it tends to produce.

In theory, pruning is also possible for expressions involving more than one column value, but determining which of such expressions are suitable can be quite difficult and time-consuming. For this reason, the use of hashing expressions involving multiple columns is not particularly recommended.

When `PARTITION BY HASH` is used, MySQL determines which partition of `num` partitions to use based on the modulus of the result of the expression. In other words, for a given expression `expr`, the partition in which the record is stored is partition number `N`, where \( N = \text{MOD}(expr, num) \). Suppose that table `t1` is defined as follows, so that it has 4 partitions:

```sql
CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATE)
PARTITION BY HASH( YEAR(col3) )
PARTITIONS 4;
```

If you insert a record into `t1` whose `col3` value is `'2005-09-15'`, then the partition in which it is stored is determined as follows:

```sql
MOD(YEAR('2005-09-01'),4) = MOD(2005,4) = 1
```

MySQL 5.6 also supports a variant of `HASH` partitioning known as `linear hashing` which employs a more complex algorithm for determining the placement of new rows inserted into the partitioned table. See Section 19.2.4.1, “LINEAR HASH Partitioning”, for a description of this algorithm.

The user-supplied expression is evaluated each time a record is inserted or updated. It may also—depending on the circumstances—be evaluated when records are deleted.

**19.2.4.1 LINEAR HASH Partitioning**

MySQL also supports linear hashing, which differs from regular hashing in that linear hashing utilizes a linear powers-of-two algorithm whereas regular hashing employs the modulus of the hashing function's value.
Syntactically, the only difference between linear-hash partitioning and regular hashing is the addition of the `LINEAR` keyword in the `PARTITION BY` clause, as shown here:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT,
    store_id INT
) PARTITION BY LINEAR HASH( YEAR(hired) )
PARTITIONS 4;
```

Given an expression `expr`, the partition in which the record is stored when linear hashing is used is partition number `N` from among `num` partitions, where `N` is derived according to the following algorithm:

1. Find the next power of 2 greater than `num`. We call this value `V`; it can be calculated as:
   \[
   V = \text{POW}(2, \text{CEILING}(\log(2, num)))
   \]
   (Suppose that `num` is 13. Then `\log(2, 13)` is 3.7004397181411. `CEILING(3.7004397181411)` is 4, and `V = \text{POW}(2, 4)`, which is 16.)

2. Set `N = F(column_list) \& (V - 1)`.

3. While `N >= num`:
   - Set `V = V/2`
   - Set `N = N \& (V - 1)`

Suppose that the table `t1`, using linear hash partitioning and having 6 partitions, is created using this statement:

```
CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATE)
PARTITION BY LINEAR HASH( YEAR(col3) )
PARTITIONS 6;
```

Now assume that you want to insert two records into `t1` having the `col3` column values '2003-04-14' and '1998-10-19'. The partition number for the first of these is determined as follows:

```
V = \text{POW}(2, \text{CEILING}( \log(2, 6) )) = 8
N = \text{YEAR('2003-04-14')} \& (8 - 1)
   = 2003 \& 7
   = 3
(3 >= 6 is FALSE: record stored in partition #3)
```

The number of the partition where the second record is stored is calculated as shown here:

```
V = 8
N = \text{YEAR('1998-10-19')} \& (8 - 1)
   = 1998 \& 7
   = 6
(6 >= 6 is TRUE: additional step required)
```
The advantage in partitioning by linear hash is that the adding, dropping, merging, and splitting of partitions is made much faster, which can be beneficial when dealing with tables containing extremely large amounts (terabytes) of data. The disadvantage is that data is less likely to be evenly distributed between partitions as compared with the distribution obtained using regular hash partitioning.

19.2.5 KEY Partitioning

Partitioning by key is similar to partitioning by hash, except that where hash partitioning employs a user-defined expression, the hashing function for key partitioning is supplied by the MySQL server. NDB Cluster uses \texttt{MD5()} for this purpose; for tables using other storage engines, the server employs its own internal hashing function which is based on the same algorithm as \texttt{PASSWORD()}.

The syntax rules for \texttt{CREATE TABLE ... PARTITION BY KEY} are similar to those for creating a table that is partitioned by hash. The major differences are listed here:

- \texttt{KEY} is used rather than \texttt{HASH}.
- \texttt{KEY} takes only a list of zero or more column names. Any columns used as the partitioning key must comprise part or all of the table's primary key, if the table has one. Where no column name is specified as the partitioning key, the table's primary key is used, if there is one. For example, the following \texttt{CREATE TABLE} statement is valid in MySQL 5.6:

```
CREATE TABLE k1 (
    id INT NOT NULL PRIMARY KEY,
    name VARCHAR(20)
) PARTITION BY KEY()
PARTITIONS 2;
```

If there is no primary key but there is a unique key, then the unique key is used for the partitioning key:

```
CREATE TABLE k1 (
    id INT NOT NULL,
    name VARCHAR(20),
    UNIQUE KEY (id)
) PARTITION BY KEY()
PARTITIONS 2;
```

However, if the unique key column were not defined as \texttt{NOT NULL}, then the previous statement would fail.

In both of these cases, the partitioning key is the \texttt{id} column, even though it is not shown in the output of \texttt{SHOW CREATE TABLE} or in the \texttt{PARTITION_EXPRESSION} column of the \texttt{INFORMATION_SCHEMA.PARTITIONS} table.

Unlike the case with other partitioning types, columns used for partitioning by \texttt{KEY} are not restricted to integer or \texttt{NULL} values. For example, the following \texttt{CREATE TABLE} statement is valid:

```
CREATE TABLE tml ( 
    sl CHAR(32) PRIMARY KEY
```
Subpartitioning

The preceding statement would not be valid, were a different partitioning type to be specified. (In this case, simply using PARTITION BY KEY() would also be valid and have the same effect as PARTITION BY KEY(s1), since s1 is the table's primary key.)

For additional information about this issue, see Section 19.6, “Restrictions and Limitations on Partitioning”.

Note

Tables using the NDB storage engine are implicitly partitioned by KEY, again using the table's primary key as the partitioning key. In the event that the NDB Cluster table has no explicit primary key, the "hidden" primary key generated by the NDB storage engine for each NDB Cluster table is used as the partitioning key.

If you define an explicit partitioning scheme for an NDB table, the table must have an explicit primary key, and any columns used in the partitioning expression must be part of this key. However, if the table uses an “empty” partitioning expression—that is, PARTITION BY KEY() with no column references—then no explicit primary key is required.

You can observe this partitioning using the ndb_desc utility (with the \texttt{-p} option).

Important

For a key-partitioned table, you cannot execute an \texttt{ALTER TABLE DROP PRIMARY KEY}, as doing so generates the error \texttt{ERROR 1466 (HY000): Field in list of fields for partition function not found in table}. This is not an issue for NDB Cluster tables which are partitioned by \texttt{KEY}; in such cases, the table is reorganized using the "hidden" primary key as the table's new partitioning key. See Chapter 18, MySQL NDB Cluster 7.3 and NDB Cluster 7.4.

It is also possible to partition a table by linear key. Here is a simple example:

```sql
CREATE TABLE tk (  
  col1 INT NOT NULL,  
  col2 CHAR(5),  
  col3 DATE  
)  
PARTITION BY LINEAR KEY (col1)  
PARTITIONS 3;
```

Using \texttt{LINEAR} has the same effect on \texttt{KEY} partitioning as it does on \texttt{HASH} partitioning, with the partition number being derived using a powers-of-two algorithm rather than modulo arithmetic. See Section 19.2.4.1, “LINEAR HASH Partitioning”, for a description of this algorithm and its implications.

19.2.6 Subpartitioning

Subpartitioning—also known as \textit{composite partitioning}—is the further division of each partition in a partitioned table. Consider the following \texttt{CREATE TABLE} statement:

```sql
CREATE TABLE ts (id INT, purchased DATE)
```
Subpartitioning

```sql
PARTITION BY RANGE( YEAR(purchased) )
    SUBPARTITION BY HASH( TO_DAYS(purchased) )
    SUBPARTITIONS 2 {
        PARTITION p0 VALUES LESS THAN (1990),
        PARTITION p1 VALUES LESS THAN (2000),
        PARTITION p2 VALUES LESS THAN MAXVALUE
    };
```

Table `ts` has 3 `RANGE` partitions. Each of these partitions—`p0`, `p1`, and `p2`—is further divided into 2 subpartitions. In effect, the entire table is divided into `3 * 2 = 6` partitions. However, due to the action of the `PARTITION BY RANGE` clause, the first 2 of these store only those records with a value less than 1990 in the `purchased` column.

In MySQL 5.6, it is possible to subpartition tables that are partitioned by `RANGE` or `LIST`. Subpartitions may use either `HASH` or `KEY` partitioning. This is also known as composite partitioning.

**Note**

`SUBPARTITION BY HASH` and `SUBPARTITION BY KEY` generally follow the same syntax rules as `PARTITION BY HASH` and `PARTITION BY KEY`, respectively. An exception to this is that `SUBPARTITION BY KEY` (unlike `PARTITION BY KEY`) does not currently support a default column, so the column used for this purpose must be specified, even if the table has an explicit primary key. This is a known issue which we are working to address; see Issues with subpartitions, for more information and an example.

It is also possible to define subpartitions explicitly using `SUBPARTITION` clauses to specify options for individual subpartitions. For example, a more verbose fashion of creating the same table `ts` as shown in the previous example would be:

```sql
CREATE TABLE ts (id INT, purchased DATE)
    PARTITION BY RANGE( YEAR(purchased) )
        SUBPARTITION BY HASH( TO_DAYS(purchased) ) (  
            PARTITION p0 VALUES LESS THAN (1990) (  
                SUBPARTITION s0,
                SUBPARTITION s1
            ),  
            PARTITION p1 VALUES LESS THAN (2000) (  
                SUBPARTITION s2,
                SUBPARTITION s3
            ),  
            PARTITION p2 VALUES LESS THAN MAXVALUE (  
                SUBPARTITION s4,
                SUBPARTITION s5
            )
        )
    };
```

Some syntactical items of note are listed here:

- Each partition must have the same number of subpartitions.
- If you explicitly define any subpartitions using `SUBPARTITION` on any partition of a partitioned table, you must define them all. In other words, the following statement will fail:

```sql
CREATE TABLE ts (id INT, purchased DATE)
    PARTITION BY RANGE( YEAR(purchased) )
        SUBPARTITION BY HASH( TO_DAYS(purchased) ) (  
            PARTITION p0 VALUES LESS THAN (1990) (  
                SUBPARTITION s0,
            
```
This statement would still fail even if it included a `SUBPARTITIONS 2` clause.

- Each `SUBPARTITION` clause must include (at a minimum) a name for the subpartition. Otherwise, you may set any desired option for the subpartition or allow it to assume its default setting for that option.

- Subpartition names must be unique across the entire table. For example, the following `CREATE TABLE` statement is valid in MySQL 5.6:

```sql
CREATE TABLE ts (id INT, purchased DATE)
PARTITION BY RANGE( YEAR(purchased) )
SUBPARTITION BY HASH( TO_DAYS(purchased) )
  (PARTITION p0 VALUES LESS THAN (1990) (%
   SUBPARTITION s0,
   SUBPARTITION s1
  ),
  PARTITION p1 VALUES LESS THAN (2000) (
   SUBPARTITION s2,
   SUBPARTITION s3
  ),
  PARTITION p2 VALUES LESS THAN MAXVALUE (%
   SUBPARTITION s4,
   SUBPARTITION s5
  )
);
```

Subpartitions can be used with especially large MyISAM tables to distribute data and indexes across many disks. Suppose that you have 6 disks mounted as `/disk0`, `/disk1`, `/disk2`, and so on. Now consider the following example:

```sql
CREATE TABLE ts (id INT, purchased DATE)
  ENGINE = MYISAM
PARTITION BY RANGE( YEAR(purchased) )
SUBPARTITION BY HASH( TO_DAYS(purchased) )
  (PARTITION p0 VALUES LESS THAN (1990) (%
   SUBPARTITION s0
   DATA DIRECTORY = '/disk0/data'
   INDEX DIRECTORY = '/disk0/idx',
   SUBPARTITION s1
   DATA DIRECTORY = '/disk1/data'
   INDEX DIRECTORY = '/disk1/idx'
  ),
  PARTITION p1 VALUES LESS THAN (2000) (%
   SUBPARTITION s2
   DATA DIRECTORY = '/disk2/data'
   INDEX DIRECTORY = '/disk2/idx',
   SUBPARTITION s3
   DATA DIRECTORY = '/disk3/data'
   INDEX DIRECTORY = '/disk3/idx'
  ),
  PARTITION p2 VALUES LESS THAN MAXVALUE (%
   SUBPARTITION s4
   DATA DIRECTORY = '/disk4/data'
   INDEX DIRECTORY = '/disk4/idx',
   SUBPARTITION s5
  )
);
```
In this case, a separate disk is used for the data and for the indexes of each RANGE. Many other variations are possible; another example might be:

```
CREATE TABLE ts (id INT, purchased DATE)
    ENGINE = MYISAM
    PARTITION BY RANGE(YEAR(purchased))
    SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
        PARTITION p0 VALUES LESS THAN (1990) (  
            SUBPARTITION s0a  
                DATA DIRECTORY = '/disk0'  
                INDEX DIRECTORY = '/disk1',  
            SUBPARTITION s0b  
                DATA DIRECTORY = '/disk2'  
                INDEX DIRECTORY = '/disk3'  
        ),
        PARTITION p1 VALUES LESS THAN (2000) (  
            SUBPARTITION s1a  
                DATA DIRECTORY = '/disk4/data'  
                INDEX DIRECTORY = '/disk4/idx',  
            SUBPARTITION s1b  
                DATA DIRECTORY = '/disk5/data'  
                INDEX DIRECTORY = '/disk5/idx'  
        ),
        PARTITION p2 VALUES LESS THAN MAXVALUE (  
            SUBPARTITION s2a,  
            SUBPARTITION s2b  
        )
    );
```

Here, the storage is as follows:

- **Rows with purchased dates from before 1990** take up a vast amount of space, so are split up 4 ways, with a separate disk dedicated to the data and to the indexes for each of the two subpartitions (s0a and s0b) making up partition p0. In other words:
  - The data for subpartition s0a is stored on /disk0.
  - The indexes for subpartition s0a are stored on /disk1.
  - The data for subpartition s0b is stored on /disk2.
  - The indexes for subpartition s0b are stored on /disk3.

- **Rows containing dates ranging from 1990 to 1999** (partition p1) do not require as much room as those from before 1990. These are split between 2 disks (/disk4 and /disk5) rather than 4 disks as with the legacy records stored in p0:
  - Data and indexes belonging to p1’s first subpartition (s1a) are stored on /disk4—the data in /disk4/data, and the indexes in /disk4/idx.
  - Data and indexes belonging to p1’s second subpartition (s1b) are stored on /disk5—the data in /disk5/data, and the indexes in /disk5/idx.

- **Rows reflecting dates from the year 2000 to the present** (partition p2) do not take up as much space as required by either of the two previous ranges. Currently, it is sufficient to store all of these in the default location.
In future, when the number of purchases for the decade beginning with the year 2000 grows to a point where the default location no longer provides sufficient space, the corresponding rows can be moved using an `ALTER TABLE ... REORGANIZE PARTITION` statement. See Section 19.3, “Partition Management”, for an explanation of how this can be done.

The `DATA DIRECTORY` and `INDEX DIRECTORY` options are not permitted in partition definitions when the `NO_DIR_IN_CREATE` server SQL mode is in effect. In MySQL 5.6, these options are also not permitted when defining subpartitions (Bug #42954).

### 19.2.7 How MySQL Partitioning Handles NULL

Partitioning in MySQL does nothing to disallow `NULL` as the value of a partitioning expression, whether it is a column value or the value of a user-supplied expression. Even though it is permitted to use `NULL` as the value of an expression that must otherwise yield an integer, it is important to keep in mind that `NULL` is not a number. MySQL’s partitioning implementation treats `NULL` as being less than any non-`NULL` value, just as `ORDER BY` does.

This means that treatment of `NULL` varies between partitioning of different types, and may produce behavior which you do not expect if you are not prepared for it. This being the case, we discuss in this section how each MySQL partitioning type handles `NULL` values when determining the partition in which a row should be stored, and provide examples for each.

**Handling of NULL with RANGE partitioning.** If you insert a row into a table partitioned by `RANGE` such that the column value used to determine the partition is `NULL`, the row is inserted into the lowest partition.

Consider these two tables in a database named `p`, created as follows:

```sql
mysql> CREATE TABLE t1 (c1 INT, c2 VARCHAR(20)) PARTITION BY RANGE(c1) (PARTITION p0 VALUES LESS THAN (0), PARTITION p1 VALUES LESS THAN (10), PARTITION p2 VALUES LESS THAN MAXVALUE);
Query OK, 0 rows affected (0.09 sec)

mysql> CREATE TABLE t2 (c1 INT, c2 VARCHAR(20)) PARTITION BY RANGE(c1) (PARTITION p0 VALUES LESS THAN (-5), PARTITION p1 VALUES LESS THAN (0), PARTITION p2 VALUES LESS THAN (10), PARTITION p3 VALUES LESS THAN MAXVALUE);
Query OK, 0 rows affected (0.09 sec)
```

You can see the partitions created by these two `CREATE TABLE` statements using the following query against the `PARTITIONS` table in the `INFORMATION_SCHEMA` database:

```sql
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH FROM INFORMATION_SCHEMA.PARTITIONS WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME LIKE 't_';
+------------+----------------+------------+----------------+-------------+
<table>
<thead>
<tr>
<th>TABLE_NAME</th>
<th>PARTITION_NAME</th>
<th>TABLE_ROWS</th>
<th>AVG_ROW_LENGTH</th>
<th>DATA_LENGTH</th>
</tr>
</thead>
</table>
+------------+----------------+------------+----------------+-------------+
```

3125
How MySQL Partitioning Handles NULL

| t1   | p0                  | 0 | 0 | 0 |
| t1   | p1                  | 0 | 0 | 0 |
| t1   | p2                  | 0 | 0 | 0 |
| t2   | p0                  | 0 | 0 | 0 |
| t2   | p1                  | 0 | 0 | 0 |
| t2   | p2                  | 0 | 0 | 0 |
| t2   | p3                  | 0 | 0 | 0 |

(For more information about this table, see Section 21.14, “The INFORMATION_SCHEMA PARTITIONS Table”. Now let us populate each of these tables with a single row containing a NULL in the column used as the partitioning key, and verify that the rows were inserted using a pair of SELECT statements:

```sql
mysql> INSERT INTO t1 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO t2 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM t1;
+------+--------+
| id   | name   |
+------+--------+
| NULL | mothra |
+------+--------+
1 row in set (0.00 sec)

mysql> SELECT * FROM t2;
+------+--------+
| id   | name   |
+------+--------+
| NULL | mothra |
+------+--------+
1 row in set (0.00 sec)
```

You can see which partitions are used to store the inserted rows by rerunning the previous query against INFORMATION_SCHEMA.PARTITIONS and inspecting the output:

```sql
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH FROM INFORMATION_SCHEMA.PARTITIONS WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME LIKE 't_';
+------------+----------------+------------+----------------+-------------+
| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
+------------+----------------+------------+----------------+-------------+
| t1         | p0             |          1 |             20 |          20 |
| t1         | p1             |          0 |              0 |           0 |
| t1         | p2             |          0 |              0 |           0 |
| t2         | p0             |          1 |             20 |          20 |
| t2         | p1             |          0 |              0 |           0 |
| t2         | p2             |          0 |              0 |           0 |
| t2         | p3             |          0 |              0 |           0 |
+------------+----------------+------------+----------------+-------------+
7 rows in set (0.01 sec)
```

You can also demonstrate that these rows were stored in the lowest partition of each table by dropping these partitions, and then re-running the SELECT statements:

```sql
mysql> ALTER TABLE t1 DROP PARTITION p0;
Query OK, 0 rows affected (0.16 sec)

mysql> ALTER TABLE t2 DROP PARTITION p0;
```
NULL is also treated in this way for partitioning expressions that use SQL functions. Suppose that we define a table using a CREATE TABLE statement such as this one:

```
CREATE TABLE tndate (
    id INT,
    dt DATE
) PARTITION BY RANGE( YEAR(dt) ) (
    PARTITION p0 VALUES LESS THAN (1990),
    PARTITION p1 VALUES LESS THAN (2000),
    PARTITION p2 VALUES LESS THAN MAXVALUE
);
```

As with other MySQL functions, YEAR(NULL) returns NULL. A row with a dt column value of NULL is treated as though the partitioning expression evaluated to a value less than any other value, and so is inserted into partition p0.

Handling of NULL with LIST partitioning. A table that is partitioned by LIST admits NULL values if and only if one of its partitions is defined using that value list that contains NULL. The converse of this is that a table partitioned by LIST which does not explicitly use NULL in a value list rejects rows resulting in a NULL value for the partitioning expression, as shown in this example:

```
mysql> CREATE TABLE ts1 (
    ->     c1 INT,
    ->     c2 VARCHAR(20)
    -> )
    -> PARTITION BY LIST(c1) (
    ->     PARTITION p0 VALUES IN (0, 3, 6),
    ->     PARTITION p1 VALUES IN (1, 4, 7),
    ->     PARTITION p2 VALUES IN (2, 5, 8)
    -> );
Query OK, 0 rows affected (0.01 sec)
```

```
mysql> INSERT INTO ts1 VALUES (9, 'mothra');
ERROR 1504 (HY000): Table has no partition for value 9
```

```
mysql> INSERT INTO ts1 VALUES (NULL, 'mothra');
ERROR 1504 (HY000): Table has no partition for value NULL
```

Only rows having a c1 value between 0 and 8 inclusive can be inserted into ts1. NULL falls outside this range, just like the number 9. We can create tables ts2 and ts3 having value lists containing NULL, as shown here:

```
mysql> CREATE TABLE ts2 (
    ->     c1 INT,
    ->     c2 VARCHAR(20)
    -> )
    -> PARTITION BY LIST(c1) (
    ->     PARTITION p0 VALUES IN (0, 3, 6),
    -> );
```

```
mysql> CREATE TABLE ts3 (
    ->     c1 INT,
    ->     c2 VARCHAR(20)
    -> )
    -> PARTITION BY LIST(c1) (
    ->     PARTITION p0 VALUES IN (0, 3, 6),
    -> );
```
When defining value lists for partitioning, you can (and should) treat NULL just as you would any other value. For example, both VALUES IN (NULL) and VALUES IN (1, 4, 7, NULL) are valid, as are VALUES IN (1, NULL, 4, 7), VALUES IN (NULL, 1, 4, 7), and so on. You can insert a row having NULL for column c1 into each of the tables ts2 and ts3:

```
mysql> INSERT INTO ts2 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)
mysql> INSERT INTO ts3 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)
```

By issuing the appropriate query against INFORMATION_SCHEMA.PARTITIONS, you can determine which partitions were used to store the rows just inserted (we assume, as in the previous examples, that the partitioned tables were created in the p database):

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
    > FROM INFORMATION_SCHEMA.PARTITIONS
    > WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME LIKE 'ts_';
```

```
<table>
<thead>
<tr>
<th>TABLE_NAME</th>
<th>PARTITION_NAME</th>
<th>TABLE_ROWS</th>
<th>AVG_ROW_LENGTH</th>
<th>DATA_LENGTH</th>
</tr>
</thead>
<tbody>
<tr>
<td>ts2</td>
<td>p0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>ts2</td>
<td>p1</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>ts2</td>
<td>p2</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>ts2</td>
<td>p3</td>
<td>1</td>
<td>20</td>
<td>20</td>
</tr>
<tr>
<td>ts3</td>
<td>p0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>ts3</td>
<td>p1</td>
<td>1</td>
<td>20</td>
<td>20</td>
</tr>
<tr>
<td>ts3</td>
<td>p2</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>
```

7 rows in set (0.01 sec)

As shown earlier in this section, you can also verify which partitions were used for storing the rows by deleting these partitions and then performing a SELECT.

**Handling of NULL with HASH and KEY partitioning.** NULL is handled somewhat differently for tables partitioned by HASH or KEY. In these cases, any partition expression that yields a NULL value is treated as though its return value were zero. We can verify this behavior by examining the effects on the file system of creating a table partitioned by HASH and populating it with a record containing appropriate values. Suppose that you have a table th (also in the p database) created using the following statement:

```
mysql> CREATE TABLE th (
    > c1 INT,
    > c2 VARCHAR(20)
);```

Query OK, 0 rows affected (0.01 sec)
The partitions belonging to this table can be viewed using the query shown here:

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
    > FROM INFORMATION_SCHEMA.PARTITIONS
    > WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME = 'th';
```

<table>
<thead>
<tr>
<th>TABLE_NAME</th>
<th>PARTITION_NAME</th>
<th>TABLE_ROWS</th>
<th>AVG_ROW_LENGTH</th>
<th>DATA_LENGTH</th>
</tr>
</thead>
<tbody>
<tr>
<td>th</td>
<td>p0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>th</td>
<td>p1</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

2 rows in set (0.00 sec)

Notice that `TABLE_ROWS` for each partition is 0. Now insert two rows into `th` whose `c1` column values are `NULL` and 0, and verify that these rows were inserted, as shown here:

```
mysql> INSERT INTO th VALUES (NULL, 'mothra'), (0, 'gigan');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM th;
```

<table>
<thead>
<tr>
<th>c1</th>
<th>c2</th>
</tr>
</thead>
<tbody>
<tr>
<td>NULL</td>
<td>mothra</td>
</tr>
<tr>
<td>0</td>
<td>gigan</td>
</tr>
</tbody>
</table>

2 rows in set (0.01 sec)

Recall that for any integer N, the value of `NULL MOD N` is always `NULL`. For tables that are partitioned by `HASH` or `KEY`, this result is treated for determining the correct partition as 0. Checking the `INFORMATION_SCHEMA.PARTITIONS` table once again, we can see that both rows were inserted into partition `p0`:

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
    > FROM INFORMATION_SCHEMA.PARTITIONS
    > WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME = 'th';
```

<table>
<thead>
<tr>
<th>TABLE_NAME</th>
<th>PARTITION_NAME</th>
<th>TABLE_ROWS</th>
<th>AVG_ROW_LENGTH</th>
<th>DATA_LENGTH</th>
</tr>
</thead>
<tbody>
<tr>
<td>th</td>
<td>p0</td>
<td>2</td>
<td>20</td>
<td>20</td>
</tr>
<tr>
<td>th</td>
<td>p1</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

2 rows in set (0.00 sec)

If you repeat this example using `PARTITION BY KEY` in place of `PARTITION BY HASH` in the definition of the table, you can verify easily that `NULL` is also treated like 0 for this type of partitioning.

### 19.3 Partition Management

MySQL 5.6 provides a number of ways to modify partitioned tables. It is possible to add, drop, redefine, merge, or split existing partitions. All of these actions can be carried out using the partitioning extensions to the `ALTER TABLE` statement. There are also ways to obtain information about partitioned tables and partitions. We discuss these topics in the sections that follow.
For information about partition management in tables partitioned by RANGE or LIST, see Section 19.3.1, “Management of RANGE and LIST Partitions”.

For a discussion of managing HASH and KEY partitions, see Section 19.3.2, “Management of HASH and KEY Partitions”.

See Section 19.3.5, “Obtaining Information About Partitions”, for a discussion of mechanisms provided in MySQL 5.6 for obtaining information about partitioned tables and partitions.

For a discussion of performing maintenance operations on partitions, see Section 19.3.4, “Maintenance of Partitions”.

**Note**

In MySQL 5.6, all partitions of a partitioned table must have the same number of subpartitions, and it is not possible to change the subpartitioning once the table has been created.

To change a table’s partitioning scheme, it is necessary only to use the `ALTER TABLE` statement with a `partition_options` clause. This clause has the same syntax as that as used with `CREATE TABLE` for creating a partitioned table, and always begins with the keywords `PARTITION BY`. Suppose that you have a table partitioned by range using the following `CREATE TABLE` statement:

```
CREATE TABLE trb3 (id INT, name VARCHAR(50), purchased DATE)
    PARTITION BY RANGE (YEAR(purchased)) (
        PARTITION p0 VALUES LESS THAN (1990),
        PARTITION p1 VALUES LESS THAN (1995),
        PARTITION p2 VALUES LESS THAN (2000),
        PARTITION p3 VALUES LESS THAN (2005)
    );
```

To repartition this table so that it is partitioned by key into two partitions using the `id` column value as the basis for the key, you can use this statement:

```
ALTER TABLE trb3 PARTITION BY KEY(id) PARTITIONS 2;
```

This has the same effect on the structure of the table as dropping the table and re-creating it using `CREATE TABLE trb3 PARTITION BY KEY(id) PARTITIONS 2;`.

`ALTER TABLE ... ENGINE = ...` changes only the storage engine used by the table, and leaves the table’s partitioning scheme intact. Use `ALTER TABLE ... REMOVE PARTITIONING` to remove a table’s partitioning. See Section 13.1.7, “ALTER TABLE Syntax”.

**Important**

Only a single `PARTITION BY`, `ADD PARTITION`, `DROP PARTITION`, `REORGANIZE PARTITION`, or `COALESCE PARTITION` clause can be used in a given `ALTER TABLE` statement. If you (for example) wish to drop a partition and reorganize a table’s remaining partitions, you must do so in two separate `ALTER TABLE` statements (one using `DROP PARTITION` and then a second one using `REORGANIZE PARTITION`).

In MySQL 5.6, it is possible to delete all rows from one or more selected partitions using `ALTER TABLE ... TRUNCATE PARTITION`.

### 19.3.1 Management of RANGE and LIST Partitions
Management of RANGE and LIST Partitions

Adding and dropping of range and list partitions are handled in a similar fashion, so we discuss the management of both sorts of partitioning in this section. For information about working with tables that are partitioned by hash or key, see Section 19.3.2, "Management of HASH and KEY Partitions".

Dropping a partition from a table that is partitioned by either RANGE or by LIST can be accomplished using the ALTER TABLE statement with the DROP PARTITION option. Suppose that you have created a table that is partitioned by range and then populated with 10 records using the following CREATE TABLE and INSERT statements:

```
Query OK, 0 rows affected (0.28 sec)
```

```
Query OK, 10 rows affected (0.05 sec)
```

You can see which items should have been inserted into partition p2 as shown here:

```
mysql> SELECT * FROM tr WHERE purchased BETWEEN '1995-01-01' AND '1999-12-31';
+------+-------------+------------+
| id   | name        | purchased  |
+------+-------------+------------+
| 2    | alarm clock | 1997-11-05 |
| 10   | lava lamp   | 1998-12-25 |
+------+-------------+------------+
2 rows in set (0.00 sec)
```

You can also get this information using partition selection, as shown here:

```
mysql> SELECT * FROM tr PARTITION (p2);
+------+-------------+------------+
| id   | name        | purchased  |
+------+-------------+------------+
| 2    | alarm clock | 1997-11-05 |
| 10   | lava lamp   | 1998-12-25 |
+------+-------------+------------+
2 rows in set (0.00 sec)
```

See Section 19.5, "Partition Selection", for more information.

To drop the partition named p2, execute the following command:

```
mysql> DROP PARTITION (p2) FROM tr;
Query OK, 0 rows affected (0.00 sec)
```
MySQL> \texttt{ALTER TABLE tr DROP PARTITION p2};
Query OK, 0 rows affected (0.03 sec)

\begin{quote}
\textbf{Note}

The \texttt{NDBCLUSTER} storage engine does not support \texttt{ALTER TABLE ... DROP PARTITION}. It does, however, support the other partitioning-related extensions to \texttt{ALTER TABLE} that are described in this chapter.
\end{quote}

It is very important to remember that, \textit{when you drop a partition, you also delete all the data that was stored in that partition}. You can see that this is the case by re-running the previous \texttt{SELECT} query:

MySQL> \texttt{SELECT * FROM tr WHERE purchased -> BETWEEN '1995-01-01' AND '1999-12-31';}
Empty set (0.00 sec)

Because of this, you must have the \texttt{DROP} privilege for a table before you can execute \texttt{ALTER TABLE ... DROP PARTITION} on that table.

If you wish to drop all data from all partitions while preserving the table definition and its partitioning scheme, use the \texttt{TRUNCATE TABLE} statement. (See Section 13.1.33, “TRUNCATE TABLE Syntax”.)

If you intend to change the partitioning of a table \textit{without} losing data, use \texttt{ALTER TABLE ... REORGANIZE PARTITION} instead. See below or in Section 13.1.7, “ALTER TABLE Syntax”, for information about \texttt{REORGANIZE PARTITION}.

If you now execute a \texttt{SHOW CREATE TABLE} statement, you can see how the partitioning makeup of the table has been changed:

MySQL> \texttt{SHOW CREATE TABLE tr\G}

\begin{verbatim}
*************************** 1. row ***************************
Table: tr
Create Table: CREATE TABLE `tr` (
  `id` int(11) DEFAULT NULL,
  `name` varchar(50) DEFAULT NULL,
  `purchased` date DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
/*!50100 PARTITION BY RANGE ( YEAR(purchased))
(PARTITION p0 VALUES LESS THAN (1990) ENGINE = InnoDB,
 PARTITION p1 VALUES LESS THAN (1995) ENGINE = InnoDB,
 PARTITION p3 VALUES LESS THAN (2005) ENGINE = InnoDB,
 PARTITION p4 VALUES LESS THAN (2010) ENGINE = InnoDB,
 PARTITION p5 VALUES LESS THAN (2015) ENGINE = InnoDB) */
1 row in set (0.00 sec)
\end{verbatim}

When you insert new rows into the changed table with \texttt{purchased} column values between \texttt{'1995-01-01'} and \texttt{'2004-12-31'} inclusive, those rows will be stored in partition \texttt{p3}. You can verify this as follows:

MySQL> \texttt{INSERT INTO tr VALUES (11, 'pencil holder', '1995-07-12');}
Query OK, 1 row affected (0.00 sec)

MySQL> \texttt{SELECT * FROM tr WHERE purchased -> BETWEEN '1995-01-01' AND '2004-12-31';}

\begin{verbatim}
+------+----------------+------------+
<table>
<thead>
<tr>
<th>id</th>
<th>name</th>
<th>purchased</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>desk organiser</td>
<td>2003-10-15</td>
</tr>
<tr>
<td>11</td>
<td>pencil holder</td>
<td>1995-07-12</td>
</tr>
</tbody>
</table>
+------+----------------+------------+
\end{verbatim}
The number of rows dropped from the table as a result of `ALTER TABLE ... DROP PARTITION` is not reported by the server as it would be by the equivalent `DELETE` query.

Dropping `LIST` partitions uses exactly the same `ALTER TABLE ... DROP PARTITION` syntax as used for dropping `RANGE` partitions. However, there is one important difference in the effect this has on your use of the table afterward: You can no longer insert into the table any rows having any of the values that were included in the value list defining the deleted partition. (See Section 19.2.2, “LIST Partitioning”, for an example.)

To add a new range or list partition to a previously partitioned table, use the `ALTER TABLE ... ADD PARTITION` statement. For tables which are partitioned by `RANGE`, this can be used to add a new range to the end of the list of existing partitions. Suppose that you have a partitioned table containing membership data for your organization, which is defined as follows:

```sql
CREATE TABLE members (  
id INT,  
fname VARCHAR(25),  
lname VARCHAR(25),  
dob DATE  )  
PARTITION BY RANGE( YEAR(dob) ) (  
    PARTITION p0 VALUES LESS THAN (1980),  
    PARTITION p1 VALUES LESS THAN (1990),  
    PARTITION p2 VALUES LESS THAN (2000)  );
```

Suppose further that the minimum age for members is 16. As the calendar approaches the end of 2015, you realize that you will soon be admitting members who were born in 2000 (and later). You can modify the `members` table to accommodate new members born in the years 2000 to 2010 as shown here:

```sql
ALTER TABLE members ADD PARTITION (PARTITION p3 VALUES LESS THAN (2010));
```

With tables that are partitioned by range, you can use `ADD PARTITION` to add new partitions to the high end of the partitions list only. Trying to add a new partition in this manner between or before existing partitions results in an error as shown here:

```sql
mysql> ALTER TABLE members  
>   ADD PARTITION (PARTITION n VALUES LESS THAN (1970));  
ERROR 1463 (HY000): VALUES LESS THAN value must be strictly increasing for each partition
```

You can work around this problem by reorganizing the first partition into two new ones that split the range between them, like this:

```sql
ALTER TABLE members  
REORGANIZE PARTITION p0 INTO (  
    PARTITION n0 VALUES LESS THAN (1970),  
    PARTITION n1 VALUES LESS THAN (1980)  );
```
Using `SHOW CREATE TABLE` you can see that the `ALTER TABLE` statement has had the desired effect:

```sql
mysql> SHOW CREATE TABLE members
+--------------------+
| Table: members      |
| Create Table: CREATE TABLE `members` (  |
|   `id` int(11) DEFAULT NULL,  |
|   `fname` varchar(25) DEFAULT NULL,  |
|   `lname` varchar(25) DEFAULT NULL,  |
|   `dob` date DEFAULT NULL  |
| ) ENGINE=InnoDB DEFAULT CHARSET=latin1  |
| PARTITION BY RANGE ( YEAR(dob))  |
| (PARTITION n0 VALUES LESS THAN (1970) ENGINE = InnoDB,  |
| PARTITION n1 VALUES LESS THAN (1980) ENGINE = InnoDB,  |
| PARTITION p1 VALUES LESS THAN (1990) ENGINE = InnoDB,  |
| PARTITION p2 VALUES LESS THAN (2000) ENGINE = InnoDB,  |
| PARTITION p3 VALUES LESS THAN (2010) ENGINE = InnoDB) */ |
| 1 row in set (0.00 sec) |
```

See also Section 13.1.7.1, “ALTER TABLE Partition Operations”.

You can also use `ALTER TABLE ... ADD PARTITION` to add new partitions to a table that is partitioned by `LIST`. Suppose a table `tt` is defined using the following `CREATE TABLE` statement:

```sql
CREATE TABLE tt (  |
   id INT,  |
   data INT  |
) PARTITION BY LIST(data) (  |
   PARTITION p0 VALUES IN (5, 10, 15),  |
   PARTITION p1 VALUES IN (6, 12, 18)  |
);
```

You can add a new partition in which to store rows having the `data` column values 7, 14, and 21 as shown:

```sql
ALTER TABLE tt ADD PARTITION (PARTITION p2 VALUES IN (7, 14, 21));
```

Keep in mind that you cannot add a new `LIST` partition encompassing any values that are already included in the value list of an existing partition. If you attempt to do so, an error will result:

```sql
mysql> ALTER TABLE tt ADD PARTITION (PARTITION np VALUES IN (4, 8, 12));
ERROR 1465 (HY000): Multiple definition of same constant » in list partitioning
```

Because any rows with the `data` column value 12 have already been assigned to partition `p1`, you cannot create a new partition on table `tt` that includes 12 in its value list. To accomplish this, you could drop `p1`, and add `np` and then a new `p1` with a modified definition. However, as discussed earlier, this would result in the loss of all data stored in `p1`—and it is often the case that this is not what you really want to do. Another solution might appear to be to make a copy of the table with the new partitioning and to copy the data into it using `CREATE TABLE ... SELECT ...`, then drop the old table and rename the new one, but this could be very time-consuming when dealing with a large amounts of data. This also might not be feasible in situations where high availability is a requirement.

You can add multiple partitions in a single `ALTER TABLE ... ADD PARTITION` statement as shown here:

```sql
CREATE TABLE employees (  |
```

3134
id INT NOT NULL,
fname VARCHAR(50) NOT NULL,
lname VARCHAR(50) NOT NULL,
hired DATE NOT NULL
)
PARTITION BY RANGE( YEAR(hired) ) (  
  PARTITION p1 VALUES LESS THAN (1991),
  PARTITION p2 VALUES LESS THAN (1996),
  PARTITION p3 VALUES LESS THAN (2001),
  PARTITION p4 VALUES LESS THAN (2005)
);

ALTER TABLE employees ADD PARTITION (  
  PARTITION p5 VALUES LESS THAN (2010),
  PARTITION p6 VALUES LESS THAN MAXVALUE
);

Fortunately, MySQL’s partitioning implementation provides ways to redefine partitions without losing data. Let us look first at a couple of simple examples involving RANGE partitioning. Recall the members table which is now defined as shown here:

```
mysql> SHOW CREATE TABLE members;
*************************** 1. row ***************************
Table: members
Create Table: CREATE TABLE `members` (  
  `id` int(11) DEFAULT NULL,
  `fname` varchar(25) DEFAULT NULL,
  `lname` varchar(25) DEFAULT NULL,
  `dob` date DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1  
/*!50100 PARTITION BY RANGE ( YEAR(dob))  
(PARTITION n0 VALUES LESS THAN (1970) ENGINE = InnoDB,
  PARTITION n1 VALUES LESS THAN (1980) ENGINE = InnoDB,
  PARTITION p1 VALUES LESS THAN (1990) ENGINE = InnoDB,
  PARTITION p2 VALUES LESS THAN (2000) ENGINE = InnoDB,
  PARTITION p3 VALUES LESS THAN (2010) ENGINE = InnoDB) */
1 row in set (0.00 sec)
```

Suppose that you would like to move all rows representing members born before 1960 into a separate partition. As we have already seen, this cannot be done using `ALTER TABLE ... ADD PARTITION`. However, you can use another partition-related extension to `ALTER TABLE` to accomplish this:

```
ALTER TABLE members REORGANIZE PARTITION n0 INTO (  
  PARTITION s0 VALUES LESS THAN (1960),
  PARTITION s1 VALUES LESS THAN (1970)
);
```

In effect, this command splits partition `p0` into two new partitions `s0` and `s1`. It also moves the data that was stored in `p0` into the new partitions according to the rules embodied in the two `PARTITION ... VALUES ...` clauses, so that `s0` contains only those records for which `YEAR(dob)` is less than 1960 and `s1` contains those rows in which `YEAR(dob)` is greater than or equal to 1960 but less than 1970.

A `REORGANIZE PARTITION` clause may also be used for merging adjacent partitions. You can reverse the effect of the previous statement on the `members` table as shown here:

```
ALTER TABLE members REORGANIZE PARTITION s0,s1 INTO (  
  PARTITION p0 VALUES LESS THAN (1970)
);
```

No data is lost in splitting or merging partitions using `REORGANIZE PARTITION`. In executing the above statement, MySQL moves all of the records that were stored in partitions `s0` and `s1` into partition `p0`.
The general syntax for `REORGANIZE PARTITION` is shown here:

```
ALTER TABLE tbl_name
    REORGANIZE PARTITION partition_list
    INTO (partition_definitions);
```

Here, `tbl_name` is the name of the partitioned table, and `partition_list` is a comma-separated list of names of one or more existing partitions to be changed. `partition_definitions` is a comma-separated list of new partition definitions, which follow the same rules as for the `partition_definitions` list used in `CREATE TABLE`. You are not limited to merging several partitions into one, or to splitting one partition into many, when using `REORGANIZE PARTITION`. For example, you can reorganize all four partitions of the `members` table into two, like this:

```
ALTER TABLE members REORGANIZE PARTITION p0,p1,p2,p3 INTO {
    PARTITION m0 VALUES LESS THAN (1980),
    PARTITION m1 VALUES LESS THAN (2000)
};
```

You can also use `REORGANIZE PARTITION` with tables that are partitioned by `LIST`. Let us return to the problem of adding a new partition to the list-partitioned `tt` table and failing because the new partition had a value that was already present in the value-list of one of the existing partitions. We can handle this by adding a partition that contains only nonconflicting values, and then reorganizing the new partition and the existing one so that the value which was stored in the existing one is now moved to the new one:

```
ALTER TABLE tt ADD PARTITION (PARTITION np VALUES IN (4, 8));
ALTER TABLE tt REORGANIZE PARTITION p1,np INTO {
    PARTITION p1 VALUES IN (6, 18),
    PARTITION np VALUES in (4, 8, 12)
};
```

Here are some key points to keep in mind when using `ALTER TABLE ... REORGANIZE PARTITION` to repartition tables that are partitioned by `RANGE` or `LIST`:

- The `PARTITION` options used to determine the new partitioning scheme are subject to the same rules as those used with a `CREATE TABLE` statement.

  A new `RANGE` partitioning scheme cannot have any overlapping ranges; a new `LIST` partitioning scheme cannot have any overlapping sets of values.

- The combination of partitions in the `partition_definitions` list should account for the same range or set of values overall as the combined partitions named in the `partition_list`.

  For example, partitions `p1` and `p2` together cover the years 1980 through 1999 in the `members` table used as an example in this section. Any reorganization of these two partitions should cover the same range of years overall.

- For tables partitioned by `RANGE`, you can reorganize only adjacent partitions; you cannot skip range partitions.

  For instance, you could not reorganize the example `members` table using a statement beginning with `ALTER TABLE members REORGANIZE PARTITION p0,p2 INTO ...` because `p0` covers the years prior to 1970 and `p2` the years from 1990 through 1999 inclusive, so these are not adjacent partitions. (You cannot skip partition `p1` in this case.)

- You cannot use `REORGANIZE PARTITION` to change the type of partitioning used by the table (for example, you cannot change `RANGE` partitions to `HASH` partitions or the reverse). You also cannot use
this statement to change the partitioning expression or column. To accomplish either of these tasks without dropping and re-creating the table, you can use `ALTER TABLE ... PARTITION BY ...`, as shown here:

```sql
ALTER TABLE members
  PARTITION BY HASH( YEAR(dob) )
PARTITIONS 8;
```

### 19.3.2 Management of HASH and KEY Partitions

Tables which are partitioned by hash or by key are very similar to one another with regard to making changes in a partitioning setup, and both differ in a number of ways from tables which have been partitioned by range or list. For that reason, this section addresses the modification of tables partitioned by hash or by key only. For a discussion of adding and dropping of partitions of tables that are partitioned by range or list, see Section 19.3.1, “Management of RANGE and LIST Partitions”.

You cannot drop partitions from tables that are partitioned by `HASH` or `KEY` in the same way that you can from tables that are partitioned by `RANGE` or `LIST`. However, you can merge `HASH` or `KEY` partitions using the `ALTER TABLE ... COALESCE PARTITION` statement. Suppose that you have a table containing data about clients, which is divided into twelve partitions. The `clients` table is defined as shown here:

```sql
CREATE TABLE clients (  
id INT,  
fname VARCHAR(30),  
lname VARCHAR(30),  
signed DATE  )  
PARTITION BY HASH( MONTH(signed) )  
PARTITIONS 12;
```

To reduce the number of partitions from twelve to eight, execute the following `ALTER TABLE` command:

```sql
mysql> ALTER TABLE clients COALESCE PARTITION 4;  
Query OK, 0 rows affected (0.02 sec)
```

`COALESCE` works equally well with tables that are partitioned by `HASH`, `KEY`, `LINEAR HASH`, or `LINEAR KEY`. Here is an example similar to the previous one, differing only in that the table is partitioned by `LINEAR KEY`:

```sql
mysql> CREATE TABLE clients_lk (  
  -> id INT,  
  -> fname VARCHAR(30),  
  -> lname VARCHAR(30),  
  -> signed DATE  
  -> )  
  -> PARTITION BY LINEAR KEY(signed)  
  -> PARTITIONS 12;  
Query OK, 0 rows affected (0.03 sec)
```

```sql
mysql> ALTER TABLE clients_lk COALESCE PARTITION 4;  
Query OK, 0 rows affected (0.06 sec)  
Records: 0  Duplicates: 0  Warnings: 0
```

The number following `COALESCE PARTITION` is the number of partitions to merge into the remainder—in other words, it is the number of partitions to remove from the table.

If you attempt to remove more partitions than the table has, the result is an error like the one shown:
To increase the number of partitions for the clients table from 12 to 18, use `ALTER TABLE ... ADD PARTITION` as shown here:

`ALTER TABLE clients ADD PARTITION PARTITIONS 6;`

### 19.3.3 Exchanging Partitions and Subpartitions with Tables

In MySQL 5.6, it is possible to exchange a table partition or subpartition with a table using `ALTER TABLE pt EXCHANGE PARTITION p WITH TABLE nt`, where `pt` is the partitioned table and `p` is the partition or subpartition of `pt` to be exchanged with unpartitioned table `nt`, provided that the following statements are true:

1. Table `nt` is not itself partitioned.
2. Table `nt` is not a temporary table.
3. The structures of tables `pt` and `nt` are otherwise identical.
4. Table `nt` contains no foreign key references, and no other table has any foreign keys that refer to `nt`.
5. There are no rows in `nt` that lie outside the boundaries of the partition definition for `p`.
6. For InnoDB tables, both tables use the same row format. To determine the row format of an InnoDB table, query `INFORMATION_SCHEMA.INNODB_SYS_TABLES`.

In addition to the `ALTER`, `INSERT`, and `CREATE` privileges usually required for `ALTER TABLE` statements, you must have the `DROP` privilege to perform `ALTER TABLE ... EXCHANGE PARTITION`.

You should also be aware of the following effects of `ALTER TABLE ... EXCHANGE PARTITION`:

- Executing `ALTER TABLE ... EXCHANGE PARTITION` does not invoke any triggers on either the partitioned table or the table to be exchanged.
- Any `AUTO_INCREMENT` columns in the exchanged table are reset.
- The `IGNORE` keyword has no effect when used with `ALTER TABLE ... EXCHANGE PARTITION`.

The complete syntax of the `ALTER TABLE ... EXCHANGE PARTITION` statement is shown here, where `pt` is the partitioned table, `p` is the partition or subpartition to be exchanged, and `nt` is the nonpartitioned table to be exchanged with `p`:

```
ALTER TABLE pt
  EXCHANGE PARTITION p
WITH TABLE nt;
```

One and only one partition or subpartition may be exchanged with one and only one nonpartitioned table in a single `ALTER TABLE EXCHANGE PARTITION` statement. To exchange multiple partitions or subpartitions, use multiple `ALTER TABLE EXCHANGE PARTITION` statements. `EXCHANGE PARTITION` may not be combined with other `ALTER TABLE` options. The partitioning and (if applicable) subpartitioning used by the partitioned table may be of any type or types supported in MySQL 5.6.

### Exchanging a Partition with a Nonpartitioned Table

Suppose that a partitioned table `e` has been created and populated using the following SQL statements:
CREATE TABLE e ( 
  id INT NOT NULL, 
  ffname VARCHAR(30), 
  lname VARCHAR(30) 
) 
PARTITION BY RANGE (id) { 
  PARTITION p0 VALUES LESS THAN (50), 
  PARTITION p1 VALUES LESS THAN (100), 
  PARTITION p2 VALUES LESS THAN (150), 
  PARTITION p3 VALUES LESS THAN (MAXVALUE) 
};

INSERT INTO e VALUES 
(1669, "Jim", "Smith"), 
(337, "Mary", "Jones"), 
(16, "Frank", "White"), 
(2005, "Linda", "Black");

Now we create a nonpartitioned copy of e named e2. This can be done using the mysql client as shown here:

mysql> CREATE TABLE e2 LIKE e; 
Query OK, 0 rows affected (1.34 sec)

mysql> ALTER TABLE e2 REMOVE PARTITIONING; 
Query OK, 0 rows affected (0.90 sec)

You can see which partitions in table e contain rows by querying the INFORMATION_SCHEMA.PARTITIONS table, like this:

mysql> SELECT PARTITION_NAME, TABLE_ROWS 
FROM INFORMATION_SCHEMA.PARTITIONS 
WHERE TABLE_NAME = 'e';

+----------------+------------+ 
| PARTITION_NAME | TABLE_ROWS |
+----------------+------------+ 
| p0             |          1 |
| p1             |          0 |
| p2             |          0 |
| p3             |          3 |
+----------------+------------+ 
4 rows in set (0.00 sec)

Note
For partitioned InnoDB tables, the row count given in the TABLE_ROWS column of the INFORMATION_SCHEMA.PARTITIONS table is only an estimated value used in SQL optimization, and is not always exact.

To exchange partition p0 in table e with table e2, you can use the ALTER TABLE statement shown here:

mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e2; 
Query OK, 0 rows affected (0.28 sec)

More precisely, the statement just issued causes any rows found in the partition to be swapped with those found in the table. You can observe how this has happened by querying the INFORMATION_SCHEMA.PARTITIONS table, as before. The table row that was previously found in partition p0 is no longer present:
Exchanging Partitions and Subpartitions with Tables

mysql> SELECT PARTITION_NAME, TABLE_ROWS
    -> FROM INFORMATION_SCHEMA.PARTITIONS
    -> WHERE TABLE_NAME = 'e';
+----------------+------------+
| PARTITION_NAME | TABLE_ROWS |
|----------------+------------|
| p0             |          0 |
| p1             |          0 |
| p2             |          0 |
| p3             |          3 |
+----------------+------------+
4 rows in set (0.00 sec)

If you query table e2, you can see that the “missing” row can now be found there:

mysql> SELECT * FROM e2;
+----+-------+-------+
| id | fname | lname |
|----|-------+-------|
| 16 | Frank | White |
+----+-------+-------+
1 row in set (0.00 sec)

The table to be exchanged with the partition does not necessarily have to be empty. To demonstrate this, we first insert a new row into table e, making sure that this row is stored in partition p0 by choosing an id column value that is less than 50, and verifying this afterward by querying the PARTITIONS table:

mysql> INSERT INTO e VALUES (41, "Michael", "Green");
Query OK, 1 row affected (0.05 sec)

mysql> SELECT PARTITION_NAME, TABLE_ROWS
    -> FROM INFORMATION_SCHEMA.PARTITIONS
    -> WHERE TABLE_NAME = 'e';
+----------------+------------+
| PARTITION_NAME | TABLE_ROWS |
|----------------+------------|
| p0             |          1 |
| p1             |          0 |
| p2             |          0 |
| p3             |          3 |
+----------------+------------+
4 rows in set (0.00 sec)

Now we once again exchange partition p0 with table e2 using the same ALTER TABLE statement as previously:

mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e2;
Query OK, 0 rows affected (0.28 sec)

The output of the following queries shows that the table row that was stored in partition p0 and the table row that was stored in table e2, prior to issuing the ALTER TABLE statement, have now switched places:

mysql> SELECT * FROM e;
+----+-------+-------+
| id | fname | lname |
|----|-------+-------|
| 16 | Frank | White |
| 1669 | Jim | Smith |
| 337 | Mary | Jones |
| 2005 | Linda | Black |
+----+-------+-------+
Exchanging Partitions and Subpartitions with Tables

Non-Matching Rows

You should keep in mind that any rows found in the nonpartitioned table prior to issuing the `ALTER TABLE ... EXCHANGE PARTITION` statement must meet the conditions required for them to be stored in the target partition; otherwise, the statement fails. To see how this occurs, first insert a row into `e2` that is outside the boundaries of the partition definition for partition `p0` of table `e`. For example, insert a row with an `id` column value that is too large; then, try to exchange the table with the partition again:

```sql
mysql> INSERT INTO e2 VALUES (51, "Ellen", "McDonald");
Query OK, 1 row affected (0.08 sec)

mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e2;
ERROR 1707 (HY000): Found row that does not match the partition
```

The `IGNORE` keyword is accepted, but has no effect when used with `EXCHANGE PARTITION`, as shown here:

```sql
mysql> ALTER IGNORE TABLE e EXCHANGE PARTITION p0 WITH TABLE e2;
ERROR 1707 (HY000): Found row that does not match the partition
```

Exchanging a Subpartition with a Nonpartitioned Table

You can also exchange a subpartition of a subpartitioned table (see Section 19.2.6, “Subpartitioning”) with a nonpartitioned table using an `ALTER TABLE ... EXCHANGE PARTITION` statement. In the following example, we first create a table `es` that is partitioned by `RANGE` and subpartitioned by `KEY`, populate this table as we did table `e`, and then create an empty, nonpartitioned copy `es2` of the table, as shown here:

```sql
mysql> CREATE TABLE es (        ->  id INT NOT NULL,
    ->  fname VARCHAR(30),
    ->  lname VARCHAR(30)
    ->  )        ->  PARTITION BY RANGE (id)
    ->  SUBPARTITION BY KEY (lname)
    ->  SUBPARTITIONS 2 (        ->  PARTITION p0 VALUES LESS THAN (50),
```
Exchanging Partitions and Subpartitions with Tables

```
-> PARTITION p1 VALUES LESS THAN (100),
-> PARTITION p2 VALUES LESS THAN (150),
-> PARTITION p3 VALUES LESS THAN (MAXVALUE)
->
Query OK, 0 rows affected (2.76 sec)
```

```
mysql> INSERT INTO es VALUES
-> (1669, "Jim", "Smith"),
-> (337, "Mary", "Jones"),
-> (16, "Frank", "White"),
-> (2005, "Linda", "Black");
Query OK, 4 rows affected (0.04 sec)
Records: 4  Duplicates: 0  Warnings: 0
```

```
mysql> CREATE TABLE es2 LIKE es;
Query OK, 0 rows affected (1.27 sec)
```

```
mysql> ALTER TABLE es2 REMOVE PARTITIONING;
Query OK, 0 rows affected (0.70 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

Although we did not explicitly name any of the subpartitions when creating table `es`, we can obtain generated names for these by including the `SUBPARTITION_NAME` of the `PARTITIONS` table from `INFORMATION_SCHEMA` when selecting from that table, as shown here:

```
mysql> SELECT PARTITION_NAME, SUBPARTITION_NAME, TABLE_ROWS
-> FROM INFORMATION_SCHEMA.PARTITIONS
-> WHERE TABLE_NAME = 'es';
+----------------+-------------------+------------+
| PARTITION_NAME | SUBPARTITION_NAME | TABLE_ROWS |
+----------------+-------------------+------------+
| p0             | p0sp0             |          1 |
| p0             | p0sp1             |          0 |
| p1             | p1sp0             |          0 |
| p1             | p1sp1             |          0 |
| p2             | p2sp0             |          0 |
| p2             | p2sp1             |          0 |
| p3             | p3sp0             |          3 |
| p3             | p3sp1             |          0 |
+----------------+-------------------+------------+
8 rows in set (0.00 sec)
```

The following `ALTER TABLE` statement exchanges subpartition `p3sp0` table `es` with the nonpartitioned table `es2`:

```
mysql> ALTER TABLE es EXCHANGE PARTITION p3sp0 WITH TABLE es2;
Query OK, 0 rows affected (0.29 sec)
```

You can verify that the rows were exchanged by issuing the following queries:

```
mysql> SELECT PARTITION_NAME, SUBPARTITION_NAME, TABLE_ROWS
-> FROM INFORMATION_SCHEMA.PARTITIONS
-> WHERE TABLE_NAME = 'es';
+----------------+-------------------+------------+
| PARTITION_NAME | SUBPARTITION_NAME | TABLE_ROWS |
+----------------+-------------------+------------+
| p0             | p0sp0             |          1 |
| p0             | p0sp1             |          0 |
| p1             | p1sp0             |          0 |
| p1             | p1sp1             |          0 |
| p2             | p2sp0             |          0 |
| p2             | p2sp1             |          0 |
| p3             | p3sp0             |          0 |
| p3             | p3sp1             |          0 |
+----------------+-------------------+------------+
```

3142
If a table is subpartitioned, you can exchange only a subpartition of the table—not an entire partition—with an unpartitioned table, as shown here:

```sql
mysql> SELECT * FROM es2;
+----+-----+-----+
| id | fname | lname |
+----+-----+-----+
| 1669 | Jim | Smith |
| 337 | Mary | Jones |
| 2005 | Linda | Black |
+----+-----+-----+
3 rows in set (0.00 sec)
```

The comparison of table structures used by MySQL is very strict. The number, order, names, and types of columns and indexes of the partitioned table and the nonpartitioned table must match exactly. In addition, both tables must use the same storage engine:

```sql
mysql> CREATE TABLE es3 LIKE e;
Query OK, 0 rows affected (1.31 sec)

mysql> ALTER TABLE es3 REMOVE PARTITIONING;
Query OK, 0 rows affected (0.53 sec)
Records: 0  Duplicates: 0  Warnings: 0

mysql> SHOW CREATE TABLE es3\G
*************************** 1. row ***************************
Table: es3
Create Table: CREATE TABLE `es3` (
  `id` int(11) NOT NULL,
  `fname` varchar(30) DEFAULT NULL,
  `lname` varchar(30) DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
1 row in set (0.00 sec)

mysql> ALTER TABLE es3 ENGINE = MyISAM;
Query OK, 0 rows affected (0.15 sec)
Records: 0  Duplicates: 0  Warnings: 0

mysql> ALTER TABLE es EXCHANGE PARTITION p3sp0 WITH TABLE es3;
ERROR 1497 (HY000): The mix of handlers in the partitions is not allowed in this version of MySQL
```

### 19.3.4 Maintenance of Partitions

A number of table and partition maintenance tasks can be carried out using SQL statements intended for such purposes on partitioned tables in MySQL 5.6.

Table maintenance of partitioned tables can be accomplished using the statements `CHECK TABLE`, `OPTIMIZE TABLE`, `ANALYZE TABLE`, and `REPAIR TABLE`, which are supported for partitioned tables.

You can use a number of extensions to `ALTER TABLE` for performing operations of this type on one or more partitions directly, as described in the following list:

- **Rebuilding partitions.** Rebuilds the partition; this has the same effect as dropping all records stored in the partition, then reinserting them. This can be useful for purposes of defragmentation.
Maintenance of Partitions

Example:

```
ALTER TABLE t1 REBUILD PARTITION p0, p1;
```

- **Optimizing partitions.** If you have deleted a large number of rows from a partition or if you have made many changes to a partitioned table with variable-length rows (that is, having `VARCHAR`, `BLOB`, or `TEXT` columns), you can use `ALTER TABLE ... OPTIMIZE PARTITION` to reclaim any unused space and to defragment the partition data file.

Example:

```
ALTER TABLE t1 OPTIMIZE PARTITION p0, p1;
```

Using `OPTIMIZE PARTITION` on a given partition is equivalent to running `CHECK PARTITION`, `ANALYZE PARTITION`, and `REPAIR PARTITION` on that partition.

Some MySQL storage engines, including InnoDB, do not support per-partition optimization; in these cases, `ALTER TABLE ... OPTIMIZE PARTITION` rebuilds the entire table. In MySQL 5.6.9 and later, running this statement on such a table causes the entire table to be rebuilt and analyzed, and an appropriate warning to be issued. (Bug #11751825, Bug #42822) Use `ALTER TABLE ... REBUILD PARTITION` and `ALTER TABLE ... ANALYZE PARTITION` instead, to avoid this issue.

- **Analyzing partitions.** This reads and stores the key distributions for partitions.

Example:

```
ALTER TABLE t1 ANALYZE PARTITION p3;
```

- **Repairing partitions.** This repairs corrupted partitions.

Example:

```
ALTER TABLE t1 REPAIR PARTITION p0,p1;
```

- **Checking partitions.** You can check partitions for errors in much the same way that you can use `CHECK TABLE` with nonpartitioned tables.

Example:

```
ALTER TABLE t1b3 CHECK PARTITION p1;
```

This command will tell you if the data or indexes in partition `p1` of table `t1` are corrupted. If this is the case, use `ALTER TABLE ... REPAIR PARTITION` to repair the partition.

Each of the statements in the list just shown also supports the keyword `ALL` in place of the list of partition names. Using `ALL` causes the statement to act on all partitions in the table.

The use of `mysqlcheck` and `myisamchk` is not supported with partitioned tables.

In MySQL 5.6, you can also truncate partitions using `ALTER TABLE ... TRUNCATE PARTITION`. This statement can be used to delete all rows from one or more partitions in much the same way that `TRUNCATE TABLE` deletes all rows from a table.

```
ALTER TABLE ... TRUNCATE PARTITION ALL
```

truncates all partitions in the table.
ANALYZE, CHECK, OPTIMIZE, REBUILD, REPAIR, and TRUNCATE operations are not supported for subpartitions.

19.3.5 Obtaining Information About Partitions

This section discusses obtaining information about existing partitions, which can be done in a number of ways. Methods of obtaining such information include the following:

- Using the SHOW CREATE TABLE statement to view the partitioning clauses used in creating a partitioned table.
- Using the SHOW TABLE STATUS statement to determine whether a table is partitioned.
- Querying the INFORMATION_SCHEMA.PARTITIONS table.
- Using the statement EXPLAIN PARTITIONS SELECT to see which partitions are used by a given SELECT.

As discussed elsewhere in this chapter, SHOW CREATE TABLE includes in its output the PARTITION BY clause used to create a partitioned table. For example:

```sql
mysql> SHOW CREATE TABLE trb3\G
*************************** 1. row ***************************
Table: trb3
Create Table: CREATE TABLE `trb3` (`id` int(11) default NULL, `name` varchar(50) default NULL, `purchased` date default NULL) ENGINE=MyISAM DEFAULT CHARSET=latin1
PARTITION BY RANGE (YEAR(purchased)) {
  PARTITION p0 VALUES LESS THAN (1990) ENGINE = MyISAM,
  PARTITION p1 VALUES LESS THAN (1995) ENGINE = MyISAM,
  PARTITION p2 VALUES LESS THAN (2000) ENGINE = MyISAM,
  PARTITION p3 VALUES LESS THAN (2005) ENGINE = MyISAM
}
1 row in set (0.00 sec)
```

The output from SHOW TABLE STATUS for partitioned tables is the same as that for nonpartitioned tables, except that the Create_options column contains the string partitioned. The Engine column contains the name of the storage engine used by all partitions of the table. (See Section 13.7.5.37, “SHOW TABLE STATUS Syntax”, for more information about this statement.)

You can also obtain information about partitions from INFORMATION_SCHEMA, which contains a PARTITIONS table. See Section 21.14, “The INFORMATION_SCHEMA PARTITIONS Table”.

It is possible to determine which partitions of a partitioned table are involved in a given SELECT query using EXPLAIN PARTITIONS. The PARTITIONS keyword adds a partitions column to the output of EXPLAIN listing the partitions from which records would be matched by the query.

Suppose that you have a table `trb1` created and populated as follows:

```sql
CREATE TABLE trb1 (id INT, name VARCHAR(50), purchased DATE)
PARTITION BY RANGE(id)
{
  PARTITION p0 VALUES LESS THAN (3),
  PARTITION p1 VALUES LESS THAN (7),
  PARTITION p2 VALUES LESS THAN (9),
  PARTITION p3 VALUES LESS THAN (11)
};
```
Obtaining Information About Partitions

```
INSERT INTO trb1 VALUES
(1, 'desk organiser', '2003-10-15'),
(2, 'CD player', '1993-11-05'),
(3, 'TV set', '1996-03-10'),
(4, 'bookcase', '1982-01-10'),
(5, 'exercise bike', '2004-05-09'),
(6, 'sofa', '1987-06-05'),
(7, 'popcorn maker', '2001-11-22'),
(8, 'aquarium', '1992-08-04'),
(9, 'study desk', '1984-09-16'),
(10, 'lava lamp', '1998-12-25');
```

You can see which partitions are used in a query such as `SELECT * FROM trb1;`, as shown here:

```sql
mysql> EXPLAIN PARTITIONS SELECT * FROM trb1;
*************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: trb1
partitions: p0,p1,p2,p3
type: ALL
possible_keys: NULL
key: NULL
key_len: NULL
ref: NULL
rows: 10
Extra: Using filesort
```

In this case, all four partitions are searched. However, when a limiting condition making use of the partitioning key is added to the query, you can see that only those partitions containing matching values are scanned, as shown here:

```sql
mysql> EXPLAIN PARTITIONS SELECT * FROM trb1 WHERE id < 5;
*************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: trb1
partitions: p0,p1
type: range
possible_keys: PRIMARY
key: PRIMARY
rows: 10
Extra: Using where
```

`EXPLAIN PARTITIONS` provides information about keys used and possible keys, just as with the standard `EXPLAIN SELECT` statement:

```sql
mysql> ALTER TABLE trb1 ADD PRIMARY KEY (id);
Query OK, 10 rows affected (0.03 sec)
Records: 10  Duplicates: 0  Warnings: 0
mysql> EXPLAIN PARTITIONS SELECT * FROM trb1 WHERE id < 5;
*************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: trb1
partitions: p0,p1
type: range
possible_keys: PRIMARY
key: PRIMARY
```
You should take note of the following restrictions and limitations on `EXPLAIN PARTITIONS`:

- You cannot use the `PARTITIONS` and `EXTENDED` keywords together in the same `EXPLAIN ... SELECT` statement. Attempting to do so produces a syntax error.

- If `EXPLAIN PARTITIONS` is used to examine a query against a nonpartitioned table, no error is produced, but the value of the `partitions` column is always `NULL`.

The `rows` column of `EXPLAIN PARTITIONS` output displays the total number of rows in the table.

See also Section 13.8.2, “EXPLAIN Syntax”.

### 19.4 Partition Pruning

This section discusses an optimization known as `partition pruning`. The core concept behind partition pruning is relatively simple, and can be described as “Do not scan partitions where there can be no matching values”. Suppose that you have a partitioned table `t1` defined by this statement:

```sql
CREATE TABLE t1 (
    fname VARCHAR(50) NOT NULL,
    lname VARCHAR(50) NOT NULL,
    region_code TINYINT UNSIGNED NOT NULL,
    dob DATE NOT NULL
) PARTITION BY RANGE( region_code )(
    PARTITION p0 VALUES LESS THAN (64),
    PARTITION p1 VALUES LESS THAN (128),
    PARTITION p2 VALUES LESS THAN (192),
    PARTITION p3 VALUES LESS THAN MAXVALUE
);
```

Consider the case where you wish to obtain results from a `SELECT` statement such as this one:

```sql
SELECT fname, lname, region_code, dob
FROM t1
WHERE region_code > 125 AND region_code < 130;
```

It is easy to see that none of the rows which ought to be returned will be in either of the partitions `p0` or `p3`; that is, we need to search only in partitions `p1` and `p2` to find matching rows. By doing so, it is possible to expend much less time and effort in finding matching rows than would be required to scan all partitions in the table. This “cutting away” of unneeded partitions is known as `pruning`. When the optimizer can make use of partition pruning in performing this query, execution of the query can be an order of magnitude faster than the same query against a nonpartitioned table containing the same column definitions and data.

**Note**

When pruning is performed on a partitioned `MyISAM` table, all partitions are opened, whether or not they are examined, due to the design of the `MyISAM` storage engine. This means that you must have a sufficient number of file descriptors available to cover all partitions of the table. See `MyISAM and partition file descriptor usage`.

This limitation does not apply to partitioned tables using other MySQL storage engines such as `InnoDB`.

---

---
The optimizer can perform pruning whenever a \textbf{WHERE} condition can be reduced to either one of the following two cases:

\begin{itemize}
\item \textit{partition\_column} = \textit{constant}
\item \textit{partition\_column} IN (\textit{constant1}, \textit{constant2}, \ldots, \textit{constantN})
\end{itemize}

In the first case, the optimizer simply evaluates the partitioning expression for the value given, determines which partition contains that value, and scans only this partition. In many cases, the equal sign can be replaced with another arithmetic comparison, including \textless, \textgreater, =, and \textless\textgreater. Some queries using BETWEEN in the \textbf{WHERE} clause can also take advantage of partition pruning. See the examples later in this section.

In the second case, the optimizer evaluates the partitioning expression for each value in the list, creates a list of matching partitions, and then scans only the partitions in this partition list.

MySQL can apply partition pruning to \textbf{SELECT}, \textbf{DELETE}, and \textbf{UPDATE} statements. An \textbf{INSERT} statement also accesses only one partition per inserted row; this is true even for a table that is partitioned by \textbf{HASH} or \textbf{KEY} although this is not currently shown in the output of \textbf{EXPLAIN}.

Pruning can also be applied to short ranges, which the optimizer can convert into equivalent lists of values. For instance, in the previous example, the \textbf{WHERE} clause can be converted to \textbf{WHERE region\_code IN (126, 127, 128, 129)}. Then the optimizer can determine that the first two values in the list are found in partition \textit{p1}, the remaining two values in partition \textit{p2}, and that the other partitions contain no relevant values and so do not need to be searched for matching rows.

In MySQL 5.6, the optimizer can also perform pruning for \textbf{WHERE} conditions that involve comparisons of the preceding types on multiple columns for tables that use \textbf{RANGE COLUMNS} or \textbf{LIST COLUMNS} partitioning.

This type of optimization can be applied whenever the partitioning expression consists of an equality or a range which can be reduced to a set of equalities, or when the partitioning expression represents an increasing or decreasing relationship. Pruning can also be applied for tables partitioned on a \textbf{DATE} or \textbf{DATETIME} column when the partitioning expression uses the \textbf{YEAR()} or \textbf{TO\_DAYS()} function. In addition, in MySQL 5.6, pruning can be applied for such tables when the partitioning expression uses the \textbf{TO\_SECONDS()} function.

Suppose that table \textit{t2}, defined as shown here, is partitioned on a \textbf{DATE} column:

\begin{verbatim}
CREATE TABLE t2 (   
   fname VARCHAR(50) NOT NULL,   
   lname VARCHAR(50) NOT NULL,   
   region_code TINYINT UNSIGNED NOT NULL,   
   dob DATE NOT NULL   
) PARTITION BY RANGE( YEAR(dob) ) (   
   PARTITION d0 VALUES LESS THAN (1970),   
   PARTITION d1 VALUES LESS THAN (1975),   
   PARTITION d2 VALUES LESS THAN (1980),   
   PARTITION d3 VALUES LESS THAN (1985),   
   PARTITION d4 VALUES LESS THAN (1990),   
   PARTITION d5 VALUES LESS THAN (2000),   
   PARTITION d6 VALUES LESS THAN (2005),   
   PARTITION d7 VALUES LESS THAN MAXVALUE   
);
\end{verbatim}

The following statements using \textit{t2} can make use of partition pruning:

\begin{verbatim}
SELECT * FROM t2 WHERE dob = '1982-06-23';

UPDATE t2 SET region\_code = 8 WHERE dob BETWEEN '1991-02-15' AND '1997-04-25';
\end{verbatim}
DELETE FROM t2 WHERE dob >= '1984-06-21' AND dob <= '1999-06-21'

In the case of the last statement, the optimizer can also act as follows:

1. **Find the partition containing the low end of the range.**

   \[ \text{YEAR('1984-06-21')} \] yields the value 1984, which is found in partition d3.

2. **Find the partition containing the high end of the range.**

   \[ \text{YEAR('1999-06-21')} \] evaluates to 1999, which is found in partition d5.

3. **Scan only these two partitions and any partitions that may lie between them.**

   In this case, this means that only partitions d3, d4, and d5 are scanned. The remaining partitions may be safely ignored (and are ignored).

**Important**

Invalid DATE and DATETIME values referenced in the WHERE condition of a statement against a partitioned table are treated as NULL. This means that a query such as SELECT * FROM partitioned_table WHERE date_column < '2008-12-00' does not return any values (see Bug #40972).

So far, we have looked only at examples using RANGE partitioning, but pruning can be applied with other partitioning types as well.

Consider a table that is partitioned by LIST, where the partitioning expression is increasing or decreasing, such as the table t3 shown here. (In this example, we assume for the sake of brevity that the region_code column is limited to values between 1 and 10 inclusive.)

```sql
CREATE TABLE t3 (  
    fname VARCHAR(50) NOT NULL,  
    lname VARCHAR(50) NOT NULL,  
    region_code TINYINT UNSIGNED NOT NULL,  
    dob DATE NOT NULL  
)  
PARTITION BY LIST(region_code) (  
    PARTITION r0 VALUES IN (1, 3),  
    PARTITION r1 VALUES IN (2, 5, 8),  
    PARTITION r2 VALUES IN (4, 9),  
    PARTITION r3 VALUES IN (6, 7, 10)  
);```

For a statement such as SELECT * FROM t3 WHERE region_code BETWEEN 1 AND 3, the optimizer determines in which partitions the values 1, 2, and 3 are found (r0 and r1) and skips the remaining ones (r2 and r3).

For tables that are partitioned by HASH or [LINEAR] KEY, partition pruning is also possible in cases in which the WHERE clause uses a simple = relation against a column used in the partitioning expression. Consider a table created like this:

```sql
CREATE TABLE t4 (  
    fname VARCHAR(50) NOT NULL,  
    lname VARCHAR(50) NOT NULL,  
    region_code TINYINT UNSIGNED NOT NULL,  
    dob DATE NOT NULL  
)  
PARTITION BY KEY(region_code)
```
Partition Selection

PARTITIONS 8;

A statement that compares a column value with a constant can be pruned:

```
UPDATE t4 WHERE region_code = 7;
```

Pruning can also be employed for short ranges, because the optimizer can turn such conditions into `IN` relations. For example, using the same table `t4` as defined previously, queries such as these can be pruned:

```
SELECT * FROM t4 WHERE region_code > 2 AND region_code < 6;
SELECT * FROM t4 WHERE region_code BETWEEN 3 AND 5;
```

In both these cases, the `WHERE` clause is transformed by the optimizer into `WHERE region_code IN (3, 4, 5)`.

**Important**

This optimization is used only if the range size is smaller than the number of partitions. Consider this statement:

```
DELETE FROM t4 WHERE region_code BETWEEN 4 AND 12;
```

The range in the `WHERE` clause covers 9 values (4, 5, 6, 7, 8, 9, 10, 11, 12), but `t4` has only 8 partitions. This means that the `DELETE` cannot be pruned.

When a table is partitioned by `HASH` or `[LINEAR] KEY`, pruning can be used only on integer columns. For example, this statement cannot use pruning because `dob` is a `DATE` column:

```
SELECT * FROM t4 WHERE dob >= '2001-04-14' AND dob <= '2005-10-15';
```

However, if the table stores year values in an `INT` column, then a query having `WHERE year_col >= 2001 AND year_col <= 2005` can be pruned.

In MySQL 5.6.8 and later, partition pruning is disabled for all tables using a storage engine that provides automatic partitioning, such as the `NDB` storage engine used by NDB Cluster. (Bug #14672885) Beginning with MySQL 5.6.10, such tables can be pruned if they are explicitly partitioned. (Bug #14827952)

### 19.5 Partition Selection

MySQL 5.6 supports explicit selection of partitions and subpartitions that, when executing a statement, should be checked for rows matching a given `WHERE` condition. Partition selection is similar to partition pruning, in that only specific partitions are checked for matches, but differs in two key respects:

1. The partitions to be checked are specified by the issuer of the statement, unlike partition pruning, which is automatic.
2. Whereas partition pruning applies only to queries, explicit selection of partitions is supported for both queries and a number of DML statements.

SQL statements supporting explicit partition selection are listed here:

- `SELECT`
- `DELETE`
Partition Selection

• INSERT
• REPLACE
• UPDATE
• LOAD DATA.
• LOAD XML.

The remainder of this section discusses explicit partition selection as it applies generally to the statements just listed, and provides some examples.

Explicit partition selection is implemented using a **PARTITION** option. For all supported statements, this option uses the syntax shown here:

```
PARTITION (partition_names)
```

**partition_names**: partition_name, ...

This option always follows the name of the table to which the partition or partitions belong. **partition_names** is a comma-separated list of partitions or subpartitions to be used. Each name in this list must be the name of an existing partition or subpartition of the specified table; if any of the partitions or subpartitions are not found, the statement fails with an error (**partition 'partition_name' doesn't exist**). Partitions and subpartitions named in **partition_names** may be listed in any order, and may overlap.

When the **PARTITION** option is used, only the partitions and subpartitions listed are checked for matching rows. This option can be used in a **SELECT** statement to determine which rows belong to a given partition. Consider a partitioned table named **employees**, created and populated using the statements shown here:

```sql
SET @@SQL_MODE = '';
CREATE TABLE employees  
    (id INT NOT NULL AUTO_INCREMENT PRIMARY KEY, 
    fname VARCHAR(25) NOT NULL, 
    lname VARCHAR(25) NOT NULL, 
    store_id INT NOT NULL, 
    department_id INT NOT NULL )  
PARTITION BY RANGE(id)  
    (PARTITION p0 VALUES LESS THAN (5), 
    PARTITION p1 VALUES LESS THAN (10), 
    PARTITION p2 VALUES LESS THAN (15), 
    PARTITION p3 VALUES LESS THAN MAXVALUE);

INSERT INTO employees VALUES  
    ('', 'Bob', 'Taylor', 3, 2), ('', 'Frank', 'Williams', 1, 2), 
    ('', 'Ellen', 'Johnson', 3, 4), ('', 'Jim', 'Smith', 2, 4), 
    ('', 'Mary', 'Jones', 1, 1), ('', 'Linda', 'Black', 2, 3), 
    ('', 'Ed', 'Jones', 2, 1), ('', 'June', 'Wilson', 3, 1), 
    ('', 'Andy', 'Smith', 1, 3), ('', 'Lou', 'Waters', 2, 4), 
    ('', 'Jill', 'Stone', 1, 4), ('', 'Roger', 'White', 3, 2), 
    ('', 'Howard', 'Andrews', 1, 2), ('', 'Fred', 'Goldberg', 3, 3), 
    ('', 'Barbara', 'Brown', 2, 3), ('', 'Alice', 'Rogers', 2, 2), 
    ('', 'Mark', 'Morgan', 3, 3), ('', 'Karen', 'Cole', 3, 2);```

You can see which rows are stored in partition **p1** like this:
Partition Selection

mysql> SELECT * FROM employees PARTITION (p1);
+----+-------+--------+----------+---------------+
<table>
<thead>
<tr>
<th>id</th>
<th>fname</th>
<th>lname</th>
<th>store_id</th>
<th>department_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>Mary</td>
<td>Jones</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>6</td>
<td>Linda</td>
<td>Black</td>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>7</td>
<td>Ed</td>
<td>Jones</td>
<td>2</td>
<td>1</td>
</tr>
<tr>
<td>8</td>
<td>June</td>
<td>Wilson</td>
<td>3</td>
<td>1</td>
</tr>
<tr>
<td>9</td>
<td>Andy</td>
<td>Smith</td>
<td>1</td>
<td>3</td>
</tr>
</tbody>
</table>
+----+-------+--------+----------+---------------+
5 rows in set (0.00 sec)

The result is the same as obtained by the query SELECT * FROM employees WHERE id BETWEEN 5 AND 9.

To obtain rows from multiple partitions, supply their names as a comma-delimited list. For example, SELECT * FROM employees PARTITION (p1, p2) returns all rows from partitions p1 and p2 while excluding rows from the remaining partitions.

Any valid query against a partitioned table can be rewritten with a PARTITION option to restrict the result to one or more desired partitions. You can use WHERE conditions, ORDER BY and LIMIT options, and so on. You can also use aggregate functions with HAVING and GROUP BY options. Each of the following queries produces a valid result when run on the employees table as previously defined:

```sql
mysql> SELECT * FROM employees PARTITION (p0, p2)
   -> WHERE lname LIKE 'S%';
+----+-------+-------+----------+---------------+
<table>
<thead>
<tr>
<th>id</th>
<th>fname</th>
<th>lname</th>
<th>store_id</th>
<th>department_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>Jim</td>
<td>Smith</td>
<td>2</td>
<td>4</td>
</tr>
<tr>
<td>11</td>
<td>Jill</td>
<td>Stone</td>
<td>1</td>
<td>4</td>
</tr>
</tbody>
</table>
+----+-------+-------+----------+---------------+
2 rows in set (0.00 sec)
```

```sql
mysql> SELECT id, CONCAT(fname, ' ', lname) AS name
   -> FROM employees PARTITION (p0) ORDER BY lname;
+----+----------------+
| id | name           |
|----|----------------+
|  3 | Ellen Johnson  |
|  4 | Jim Smith      |
|  1 | Bob Taylor     |
|  2 | Frank Williams |
+----+----------------+
4 rows in set (0.06 sec)
```

```sql
mysql> SELECT store_id, COUNT(department_id) AS c
   -> FROM employees PARTITION (p1,p2,p3)
   -> GROUP BY store_id HAVING c > 4;
+---+----------+
<table>
<thead>
<tr>
<th>c</th>
<th>store_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>2</td>
</tr>
<tr>
<td>5</td>
<td>3</td>
</tr>
</tbody>
</table>
+---+----------+
2 rows in set (0.00 sec)
```

Statements using partition selection can be employed with tables using any of the partitioning types supported in MySQL 5.6. When a table is created using [LINEAR] HASH or [LINEAR] KEY partitioning and the names of the partitions are not specified, MySQL automatically names the partitions p0, p1, p2, ..., pN-1, where N is the number of partitions. For subpartitions not explicitly named, MySQL assigns automatically to the subpartitions in each partition PX the names pXsp0, pXsp1, pXsp2, ..., pXspM-1,
Partition Selection

where $M$ is the number of subpartitions. When executing against this table a `SELECT` (or other SQL statement for which explicit partition selection is allowed), you can use these generated names in a `PARTITION` option, as shown here:

```sql
cREATE TABLE employees_sub  
  (id INT NOT NULL AUTO_INCREMENT, 
   fname VARCHAR(25) NOT NULL, 
   lname VARCHAR(25) NOT NULL, 
   store_id INT NOT NULL, 
   department_id INT NOT NULL, 
   PRIMARY KEY pk (id, lname) 
) 
PARTITION BY RANGE(id) 
SUBPARTITION BY KEY (lname) 
SUBPARTITIONS 2 ( 
  PARTITION p0 VALUES LESS THAN (5), 
  PARTITION p1 VALUES LESS THAN (10), 
  PARTITION p2 VALUES LESS THAN (15), 
  PARTITION p3 VALUES LESS THAN MAXVALUE 
); 
```

You may also use a `PARTITION` option in the `SELECT` portion of an `INSERT ... SELECT` statement, as shown here:

```sql
CREATE TABLE employees_copy LIKE employees; 
```

Partition selection can also be used with joins. Suppose we create and populate two tables using the statements shown here:
CREATE TABLE stores {
   id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
   city VARCHAR(30) NOT NULL
}
PARTITION BY HASH(id)
PARTITIONS 2;

INSERT INTO stores VALUES
('', 'Nambucca'), ('', 'Uranga'),
('', 'Bellingen'), ('', 'Grafton');

CREATE TABLE departments {
   id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
   name VARCHAR(30) NOT NULL
}
PARTITION BY KEY(id)
PARTITIONS 2;

INSERT INTO departments VALUES
('', 'Sales'), ('', 'Customer Service'),
('', 'Delivery'), ('', 'Accounting');

You can explicitly select partitions (or subpartitions, or both) from any or all of the tables in a join. (The PARTITION option used to select partitions from a given table immediately follows the name of the table, before all other options, including any table alias.) For example, the following query gets the name, employee ID, department, and city of all employees who work in the Sales or Delivery department (partition p1 of the departments table) at the stores in either of the cities of Nambucca and Bellingen (partition p0 of the stores table):

```sql
SELECT e.id AS 'Employee ID', CONCAT(e.fname, ' ', e.lname) AS Name,
s.city AS City, d.name AS department
FROM employees AS e
JOIN stores PARTITION (p1) AS s ON e.store_id=s.id
JOIN departments PARTITION (p0) AS d ON e.department_id=d.id
ORDER BY e.lname;
```

<table>
<thead>
<tr>
<th>Employee ID</th>
<th>Name</th>
<th>City</th>
<th>department</th>
</tr>
</thead>
<tbody>
<tr>
<td>14</td>
<td>Fred Goldberg</td>
<td>Bellingen</td>
<td>Delivery</td>
</tr>
<tr>
<td>5</td>
<td>Mary Jones</td>
<td>Nambucca</td>
<td>Sales</td>
</tr>
<tr>
<td>17</td>
<td>Mark Morgan</td>
<td>Bellingen</td>
<td>Delivery</td>
</tr>
<tr>
<td>9</td>
<td>Andy Smith</td>
<td>Nambucca</td>
<td>Delivery</td>
</tr>
<tr>
<td>8</td>
<td>June Wilson</td>
<td>Bellingen</td>
<td>Sales</td>
</tr>
</tbody>
</table>

5 rows in set (0.00 sec)

For general information about joins in MySQL, see Section 13.2.9.2, “JOIN Syntax”.

When the PARTITION option is used with DELETE statements, only those partitions (and subpartitions, if any) listed with the option are checked for rows to be deleted. Any other partitions are ignored, as shown here:

```sql
mysql> SELECT * FROM employees WHERE fname LIKE 'j%';
```

<table>
<thead>
<tr>
<th>id</th>
<th>fname</th>
<th>lname</th>
<th>store_id</th>
<th>department_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>Jim</td>
<td>Smith</td>
<td>2</td>
<td>4</td>
</tr>
<tr>
<td>8</td>
<td>June</td>
<td>Wilson</td>
<td>3</td>
<td>1</td>
</tr>
<tr>
<td>11</td>
<td>Jill</td>
<td>Stone</td>
<td>1</td>
<td>4</td>
</tr>
</tbody>
</table>

3 rows in set (0.00 sec)
Partition Selection

mysql> DELETE FROM employees PARTITION (p0, p1)
    -> WHERE fname LIKE 'j%';
Query OK, 2 rows affected (0.09 sec)

mysql> SELECT * FROM employees WHERE fname LIKE 'j%';
+----+-------+-------+----------+---------------+
<table>
<thead>
<tr>
<th>id</th>
<th>fname</th>
<th>lname</th>
<th>store_id</th>
<th>department_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>Jill</td>
<td>Stone</td>
<td>1</td>
<td>4</td>
</tr>
</tbody>
</table>
+----+-------+-------+----------+---------------+
1 row in set (0.00 sec)

Only the two rows in partitions p0 and p1 matching the WHERE condition were deleted. As you can see from the result when the SELECT is run a second time, there remains a row in the table matching the WHERE condition, but residing in a different partition (p2).

UPDATE statements using explicit partition selection behave in the same way; only rows in the partitions referenced by the PARTITION option are considered when determining the rows to be updated, as can be seen by executing the following statements:

mysql> UPDATE employees PARTITION (p0)
    -> SET store_id = 2 WHERE fname = 'Jill';
Query OK, 0 rows affected (0.00 sec)
Rows matched: 0  Changed: 0  Warnings: 0

mysql> SELECT * FROM employees WHERE fname = 'Jill';
+----+-------+-------+----------+---------------+
<table>
<thead>
<tr>
<th>id</th>
<th>fname</th>
<th>lname</th>
<th>store_id</th>
<th>department_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>Jill</td>
<td>Stone</td>
<td>1</td>
<td>4</td>
</tr>
</tbody>
</table>
+----+-------+-------+----------+---------------+
1 row in set (0.00 sec)

mysql> UPDATE employees PARTITION (p2)
    -> SET store_id = 2 WHERE fname = 'Jill';
Query OK, 1 row affected (0.09 sec)
Rows matched: 1  Changed: 1  Warnings: 0

mysql> SELECT * FROM employees WHERE fname = 'Jill';
+----+-------+-------+----------+---------------+
<table>
<thead>
<tr>
<th>id</th>
<th>fname</th>
<th>lname</th>
<th>store_id</th>
<th>department_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>Jill</td>
<td>Stone</td>
<td>2</td>
<td>4</td>
</tr>
</tbody>
</table>
+----+-------+-------+----------+---------------+
1 row in set (0.00 sec)

In the same way, when PARTITION is used with DELETE, only rows in the partition or partitions named in the partition list are checked for deletion.

For statements that insert rows, the behavior differs in that failure to find a suitable partition causes the statement to fail. This is true for both INSERT and REPLACE statements, as shown here:

mysql> INSERT INTO employees PARTITION (p2) VALUES (20, 'Jan', 'Jones', 1, 3);
ERROR 1729 (HY000): Found a row not matching the given partition set

mysql> INSERT INTO employees PARTITION (p3) VALUES (20, 'Jan', 'Jones', 1, 3);
Query OK, 1 row affected (0.07 sec)

mysql> REPLACE INTO employees PARTITION (p0) VALUES (20, 'Jan', 'Jones', 3, 2);
ERROR 1729 (HY000): Found a row not matching the given partition set

mysql> REPLACE INTO employees PARTITION (p3) VALUES (20, 'Jan', 'Jones', 3, 2);
Query OK, 2 rows affected (0.09 sec)
For statements that write multiple rows to a partitioned table that uses the InnoDB storage engine:
If any row in the list following VALUES cannot be written to one of the partitions specified in the partition_names list, the entire statement fails and no rows are written. This is shown for INSERT statements in the following example, reusing the employees table created previously:

```sql
mysql> ALTER TABLE employees
    -> REORGANIZE PARTITION p3 INTO (
    -> PARTITION p3 VALUES LESS THAN (20),
    -> PARTITION p4 VALUES LESS THAN (25),
    -> PARTITION p5 VALUES LESS THAN MAXVALUE
    -> );
Query OK, 6 rows affected (2.09 sec)
Records: 6  Duplicates: 0  Warnings: 0

mysql> SHOW CREATE TABLE employees\G
*************************** 1. row ***************************
Table: employees
Create Table: CREATE TABLE `employees` (  
`id` int(11) NOT NULL AUTO_INCREMENT,
`fname` varchar(25) NOT NULL,
`lname` varchar(25) NOT NULL,
`store_id` int(11) NOT NULL,
`department_id` int(11) NOT NULL,
PRIMARY KEY (`id`)  
) ENGINE=InnoDB AUTO_INCREMENT=27 DEFAULT CHARSET=latin1
/*!50100 PARTITION BY RANGE (id) */
PARTITION `p0` VALUES LESS THAN (5) ENGINE = InnoDB,
PARTITION `p1` VALUES LESS THAN (10) ENGINE = InnoDB,
PARTITION `p2` VALUES LESS THAN (15) ENGINE = InnoDB,
PARTITION `p3` VALUES LESS THAN (20) ENGINE = InnoDB,
PARTITION `p4` VALUES LESS THAN (25) ENGINE = InnoDB,
PARTITION `p5` VALUES LESS THAN MAXVALUE ENGINE = InnoDB) */
1 row in set (0.00 sec)

mysql> INSERT INTO employees PARTITION (p3, p4) VALUES
    -> (24, 'Tim', 'Greene', 3, 1),  (26, 'Linda', 'Mills', 2, 1);
ERROR 1729 (HY000): Found a row not matching the given partition set

mysql> INSERT INTO employees PARTITION (p3, p4, p5) VALUES
    -> (24, 'Tim', 'Greene', 3, 1),  (26, 'Linda', 'Mills', 2, 1);
Query OK, 2 rows affected (0.06 sec)
Records: 2  Duplicates: 0  Warnings: 0
```

The preceding is true for both INSERT statements and REPLACE statements that write multiple rows.

In MySQL 5.6.10 and later, partition selection is disabled for tables employing a storage engine that supplies automatic partitioning, such as NDB. (Bug #14827952)

### 19.6 Restrictions and Limitations on Partitioning

This section discusses current restrictions and limitations on MySQL partitioning support.

**Prohibited constructs.** The following constructs are not permitted in partitioning expressions:

- Stored procedures, stored functions, UDFs, or plugins.
- Declared variables or user variables.

For a list of SQL functions which are permitted in partitioning expressions, see Section 19.6.3, "Partitioning Limitations Relating to Functions".

**Arithmetic and logical operators.** Use of the arithmetic operators +, -, and * is permitted in partitioning expressions. However, the result must be an integer value or NULL (except in the case of..."
Restricted and Limitations on Partitioning

[LINEAR] **KEY** partitioning, as discussed elsewhere in this chapter; see Section 19.2, “Partitioning Types”, for more information).

The **DIV** operator is also supported, and the **/** operator is not permitted. (Bug #30188, Bug #33182)

The bit operators **|, &,** ^ **,** << **,** >> and ~** are not permitted in partitioning expressions.

**HANDLER** statements. In MySQL 5.6, the **HANDLER** statement is not supported with partitioned tables.

**Server SQL mode.** Tables employing user-defined partitioning do not preserve the SQL mode in effect at the time that they were created. As discussed in Section 5.1.10, “Server SQL Modes”, the results of many MySQL functions and operators may change according to the server SQL mode. Therefore, a change in the SQL mode at any time after the creation of partitioned tables may lead to major changes in the behavior of such tables, and could easily lead to corruption or loss of data. For these reasons, **it is strongly recommended that you never change the server SQL mode after creating partitioned tables.**

**Examples.** The following examples illustrate some changes in behavior of partitioned tables due to a change in the server SQL mode:

1. **Error handling.** Suppose that you create a partitioned table whose partitioning expression is one such as **column DIV 0** or **column MOD 0**, as shown here:

   ```sql
   mysql> CREATE TABLE tn (c1 INT)
       -> PARTITION BY LIST(1 DIV c1) {
       ->     PARTITION p0 VALUES IN (NULL),
       ->     PARTITION p1 VALUES IN (1)
       -> };
   Query OK, 0 rows affected (0.05 sec)
   
   The default behavior for MySQL is to return **NULL** for the result of a division by zero, without producing any errors:
   
   ```sql
   mysql> SELECT @@sql_mode;
   +------------+
   | @@sql_mode |
   +------------+
   |            |
   +------------+
   1 row in set (0.00 sec)
   ```

  mysql> INSERT INTO tn VALUES (NULL), (0), (1);
   Query OK, 3 rows affected (0.00 sec)
   Records: 3  Duplicates: 0  Warnings: 0
   
   However, changing the server SQL mode to treat division by zero as an error and to enforce strict error handling causes the same **INSERT** statement to fail, as shown here:
   
   ```sql
   mysql> SET sql_mode='STRICT_ALL_TABLES,ERROR_FOR_DIVISION BY_ZERO';
   Query OK, 0 rows affected (0.00 sec)
   ```

   ```sql
   mysql> INSERT INTO tn VALUES (NULL), (0), (1);
   ERROR 1365 (22012): Division by 0
   ```

2. **Table accessibility.** Sometimes a change in the server SQL mode can make partitioned tables unusable. The following **CREATE TABLE** statement can be executed successfully only if the **NO_UNSIGNED_SUBTRACTION** mode is in effect:

   ```sql
   mysql> CREATE TABLE tn (c1 INT)
       -> PARTITION BY LIST(1 DIV c1) {
       ->     PARTITION p0 VALUES IN (NULL),
       ->     PARTITION p1 VALUES IN (1)
       -> };
   Query OK, 0 rows affected (0.05 sec)
   ```
Restrictions and Limitations on Partitioning

mysql> SELECT @@sql_mode;
+------------+
| @@sql_mode |
+------------+
1 row in set (0.00 sec)

mysql> CREATE TABLE tu (c1 BIGINT UNSIGNED)
  ->  PARTITION BY RANGE(c1 - 10) (
  ->  PARTITION p0 VALUES LESS THAN (-5),
  ->  PARTITION p1 VALUES LESS THAN (0),
  ->  PARTITION p2 VALUES LESS THAN (5),
  ->  PARTITION p3 VALUES LESS THAN (10),
  ->  PARTITION p4 VALUES LESS THAN (MAXVALUE)
  -> );
ERROR 1563 (HY000): Partition constant is out of partition function domain

mysql> SET sql_mode='NO_UNSIGNED_SUBTRACTION';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @@sql_mode;
+-------------------------+
| @@sql_mode              |
+-------------------------+
| NO_UNSIGNED_SUBTRACTION |
+-------------------------+
1 row in set (0.00 sec)

mysql> CREATE TABLE tu (c1 BIGINT UNSIGNED)
  ->  PARTITION BY RANGE(c1 - 10) (
  ->  PARTITION p0 VALUES LESS THAN (-5),
  ->  PARTITION p1 VALUES LESS THAN (0),
  ->  PARTITION p2 VALUES LESS THAN (5),
  ->  PARTITION p3 VALUES LESS THAN (10),
  ->  PARTITION p4 VALUES LESS THAN (MAXVALUE)
  -> );
Query OK, 0 rows affected (0.05 sec)

If you remove the NO_UNSIGNED_SUBTRACTION server SQL mode after creating tu, you may no longer be able to access this table:

mysql> SET sql_mode='';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM tu;
ERROR 1563 (HY000): Partition constant is out of partition function domain

mysql> INSERT INTO tu VALUES (20);
ERROR 1563 (HY000): Partition constant is out of partition function domain

Server SQL modes also impact replication of partitioned tables. Differing SQL modes on master and slave can lead to partitioning expressions being evaluated differently; this can cause the distribution of data among partitions to be different in the master’s and slave’s copies of a given table, and may even cause inserts into partitioned tables that succeed on the master to fail on the slave. For best results, you should always use the same server SQL mode on the master and on the slave.

Performance considerations. Some effects of partitioning operations on performance are given in the following list:

- **File system operations.** Partitioning and repartitioning operations (such as ALTER TABLE with PARTITION BY ..., REORGANIZE PARTITION, or REMOVE PARTITIONING) depend on file system operations for their implementation. This means that the speed of these operations is affected by such factors as file system type and characteristics, disk speed, swap space, file
Restrictions and Limitations on Partitioning

Handling efficiency of the operating system, and MySQL server options and variables that relate to file handling. In particular, you should make sure that large_files_support is enabled and that open_files_limit is set properly. For partitioned tables using the MyISAM storage engine, increasing myisam_max_sort_file_size may improve performance; partitioning and repartitioning operations involving InnoDB tables may be made more efficient by enabling innodb_file_per_table.

See also Maximum number of partitions.

- **MyISAM and partition file descriptor usage.** For a partitioned MyISAM table, MySQL uses 2 file descriptors for each partition, for each such table that is open. This means that you need many more file descriptors to perform operations on a partitioned MyISAM table than on a table which is identical to it except that the latter table is not partitioned, particularly when performing ALTER TABLE operations.

Assume a MyISAM table t with 100 partitions, such as the table created by this SQL statement:

```sql
CREATE TABLE t (c1 VARCHAR(50))
PARTITION BY KEY (c1) PARTITIONS 100
ENGINE=MYISAM;
```

**Note**

For brevity, we use KEY partitioning for the table shown in this example, but file descriptor usage as described here applies to all partitioned MyISAM tables, regardless of the type of partitioning that is employed. Partitioned tables using other storage engines such as InnoDB are not affected by this issue.

Now assume that you wish to repartition t so that it has 101 partitions, using the statement shown here:

```sql
ALTER TABLE t PARTITION BY KEY (c1) PARTITIONS 101;
```

To process this ALTER TABLE statement, MySQL uses 402 file descriptors—that is, two for each of the 100 original partitions, plus two for each of the 101 new partitions. This is because all partitions (old and new) must be opened concurrently during the reorganization of the table data. It is recommended that, if you expect to perform such operations, you should make sure that the open_files_limit system variable is not set too low to accommodate them.

- **Table locks.** Generally, the process executing a partitioning operation on a table takes a write lock on the table. Reads from such tables are relatively unaffected; pending INSERT and UPDATE operations are performed as soon as the partitioning operation has completed. For InnoDB-specific information related to this limitation, see Partitioning Operations.

- **Storage engine.** Partitioning operations, queries, and update operations generally tend to be faster with MyISAM tables than with InnoDB or NDB tables.

- **Indexes; partition pruning.** As with nonpartitioned tables, proper use of indexes can speed up queries on partitioned tables significantly. In addition, designing partitioned tables and queries on these tables to take advantage of partition pruning can improve performance dramatically. See Section 19.4, “Partition Pruning”, for more information.

  Index condition pushdown is not supported for partitioned tables. See Section 8.2.1.5, “Index Condition Pushdown Optimization”.

- **Performance with LOAD DATA.** In MySQL 5.6, LOAD DATA uses buffering to improve performance. You should be aware that the buffer uses 130 KB memory per partition to achieve this.

Maximum number of partitions.
Restrictions and Limitations on Partitioning

Prior to MySQL 5.6.7, the maximum possible number of partitions for a given table not using the NDB storage engine was 1024. Beginning with MySQL 5.6.7, this limit is increased to 8192 partitions. Regardless of the MySQL Server version, this maximum includes subpartitions.

The maximum possible number of user-defined partitions for a table using the NDB storage engine is determined according to the version of the NDB Cluster software being used, the number of data nodes, and other factors. See NDB and user-defined partitioning, for more information.

If, when creating tables with a large number of partitions (but less than the maximum), you encounter an error message such as Got error ... from storage engine: Out of resources when opening file, you may be able to address the issue by increasing the value of the open_files_limit system variable. However, this is dependent on the operating system, and may not be possible or advisable on all platforms; see Section B.4.2.18, “File Not Found and Similar Errors”, for more information. In some cases, using large numbers (hundreds) of partitions may also not be advisable due to other concerns, so using more partitions does not automatically lead to better results.

See also File system operations.

Query cache not supported.
The query cache is not supported for partitioned tables. Beginning with MySQL 5.6.5, the query cache is automatically disabled for queries involving partitioned tables, and cannot be enabled for such queries. (Bug #53775)

Per-partition key caches.
In MySQL 5.6, key caches are supported for partitioned MyISAM tables, using the CACHE INDEX and LOAD INDEX INTO CACHE statements. Key caches may be defined for one, several, or all partitions, and indexes for one, several, or all partitions may be preloaded into key caches.

Foreign keys not supported for partitioned InnoDB tables.
Partitioned tables using the InnoDB storage engine do not support foreign keys. More specifically, this means that the following two statements are true:

1. No definition of an InnoDB table employing user-defined partitioning may contain foreign key references; no InnoDB table whose definition contains foreign key references may be partitioned.
2. No InnoDB table definition may contain a foreign key reference to a user-partitioned table; no InnoDB table with user-defined partitioning may contain columns referenced by foreign keys.

The scope of the restrictions just listed includes all tables that use the InnoDB storage engine. CREATE TABLE and ALTER TABLE statements that would result in tables violating these restrictions are not allowed.

ALTER TABLE ... ORDER BY. An ALTER TABLE ... ORDER BY column statement run against a partitioned table causes ordering of rows only within each partition.

Effects on REPLACE statements by modification of primary keys. It can be desirable in some cases (see Section 19.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”) to modify a table's primary key. Be aware that, if your application uses REPLACE statements and you do this, the results of these statements can be drastically altered. See Section 13.2.8, “REPLACE Syntax”, for more information and an example.

FULLTEXT indexes.
Partitioned tables do not support FULLTEXT indexes or searches, even for partitioned tables employing the InnoDB or MyISAM storage engine.

Spatial columns. Columns with spatial data types such as POINT or GEOMETRY cannot be used in partitioned tables.
Restrictions and Limitations on Partitioning

**Temporary tables.**
Temporary tables cannot be partitioned. (Bug #17497)

**Log tables.** It is not possible to partition the log tables; an `ALTER TABLE ... PARTITION BY ...` statement on such a table fails with an error.

**Data type of partitioning key.**
A partitioning key must be either an integer column or an expression that resolves to an integer. Expressions employing `ENUM` columns cannot be used. The column or expression value may also be `NULL`. (See Section 19.2.7, “How MySQL Partitioning Handles NULL”.)

There are two exceptions to this restriction:

1. When partitioning by `[LINEAR] KEY`, it is possible to use columns of any valid MySQL data type other than `TEXT` or `BLOB` as partitioning keys, because MySQL’s internal key-hashing functions produce the correct data type from these types. For example, the following two `CREATE TABLE` statements are valid:

   ```sql
   CREATE TABLE tkc (c1 CHAR)
   PARTITION BY KEY(c1)
   PARTITIONS 4;
   
   CREATE TABLE tke
   ( c1 ENUM('red', 'orange', 'yellow', 'green', 'blue', 'indigo', 'violet') )
   PARTITION BY LINEAR KEY(c1)
   PARTITIONS 6;
   ```

2. When partitioning by `RANGE COLUMNS` or `LIST COLUMNS`, it is possible to use string, `DATE`, and `DATETIME` columns. For example, each of the following `CREATE TABLE` statements is valid:

   ```sql
   CREATE TABLE rc (c1 INT, c2 DATE)
   PARTITION BY RANGE COLUMNS(c2) (  
     PARTITION p0 VALUES LESS THAN('1990-01-01'),
     PARTITION p1 VALUES LESS THAN('1995-01-01'),
     PARTITION p2 VALUES LESS THAN('2000-01-01'),
     PARTITION p3 VALUES LESS THAN('2005-01-01'),
     PARTITION p4 VALUES LESS THAN(MAXVALUE)
   );

   CREATE TABLE lc (c1 INT, c2 CHAR(1))
   PARTITION BY LIST COLUMNS(c2) {  
     PARTITION p0 VALUES IN('a', 'd', 'g', 'j', 'm', 'p', 's', 'v', 'y'),
     PARTITION p1 VALUES IN('b', 'e', 'h', 'k', 'n', 'q', 't', 'w', 'z'),
     PARTITION p2 VALUES IN('c', 'f', 'i', 'l', 'o', 'r', 'u', 'x', 'Y', NULL)
   );
   ```

Neither of the preceding exceptions applies to `BLOB` or `TEXT` column types.

**Subqueries.**
A partitioning key may not be a subquery, even if that subquery resolves to an integer value or `NULL`.

**Issues with subpartitions.**
Subpartitions must use `HASH` or `KEY` partitioning. Only `RANGE` and `LIST` partitions may be subpartitioned; `HASH` and `KEY` partitions cannot be subpartitioned.

`SUBPARTITION BY KEY` requires that the subpartitioning column or columns be specified explicitly, unlike the case with `PARTITION BY KEY`, where it can be omitted (in which case the table’s primary key column is used by default). Consider the table created by this statement:
CREATE TABLE ts {
  id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  name VARCHAR(30)
};

You can create a table having the same columns, partitioned by `KEY`, using a statement such as this one:

CREATE TABLE ts {
  id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  name VARCHAR(30)
} PARTITION BY KEY()
PARTITIONS 4;

The previous statement is treated as though it had been written like this, with the table’s primary key column used as the partitioning column:

CREATE TABLE ts {
  id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  name VARCHAR(30)
} PARTITION BY KEY(id)
PARTITIONS 4;

However, the following statement that attempts to create a subpartitioned table using the default column as the subpartitioning column fails, and the column must be specified for the statement to succeed, as shown here:

```sql
mysql> CREATE TABLE ts {
  ->   id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  ->   name VARCHAR(30)
  -> } PARTITION BY RANGE(id)
  -> SUBPARTITION BY KEY()
  -> SUBPARTITIONS 4
  -> {
  ->   PARTITION p0 VALUES LESS THAN (100),
  ->   PARTITION p1 VALUES LESS THAN (MAXVALUE)
  -> };
ERROR 1064 (42000): You have an error in your SQL syntax; check the manual that corresponds to your MySQL server version for the right syntax to use near ')
```

```sql
mysql> CREATE TABLE ts {
  ->   id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  ->   name VARCHAR(30)
  -> } PARTITION BY RANGE(id)
  -> SUBPARTITION BY KEY(id)
  -> SUBPARTITIONS 4
  -> {
  ->   PARTITION p0 VALUES LESS THAN (100),
  ->   PARTITION p1 VALUES LESS THAN (MAXVALUE)
  -> };
Query OK, 0 rows affected (0.07 sec)
```

This is a known issue (see Bug #51470).

**DELAYED option not supported.** Use of `INSERT DELAYED` to insert rows into a partitioned table is not supported. Attempting to do so fails with an error.
 **DATA DIRECTORY and INDEX DIRECTORY options.**  
**DATA DIRECTORY** and **INDEX DIRECTORY** are subject to the following restrictions when used with partitioned tables:

- Table-level **DATA DIRECTORY** and **INDEX DIRECTORY** options are ignored (see Bug #32091).
- On Windows, the **DATA DIRECTORY** and **INDEX DIRECTORY** options are not supported for individual partitions or subpartitions of **MyISAM** tables (Bug #30459). However, you can use **DATA DIRECTORY** for individual partitions or subpartitions of **InnoDB** tables.

**Repairing and rebuilding partitioned tables.** The statements **CHECK TABLE**, **OPTIMIZE TABLE**, **ANALYZE TABLE**, and **REPAIR TABLE** are supported for partitioned tables.

In addition, you can use **ALTER TABLE ... REBUILD PARTITION** to rebuild one or more partitions of a partitioned table; **ALTER TABLE ... REORGANIZE PARTITION** also causes partitions to be rebuilt. See Section 13.1.7, “ALTER TABLE Syntax”, for more information about these two statements.

**mysqlcheck**, **myisamchk**, and **myisampack** are not supported with partitioned tables.

**FOR EXPORT option (FLUSH TABLES).** The **FLUSH TABLES** statement's **FOR EXPORT** option is not supported for partitioned **InnoDB** tables in MySQL 5.6.16 and earlier. (Bug #16943907)

### 19.6.1 Partitioning Keys, Primary Keys, and Unique Keys

This section discusses the relationship of partitioning keys with primary keys and unique keys. The rule governing this relationship can be expressed as follows: All columns used in the partitioning expression for a partitioned table must be part of every unique key that the table may have.

In other words, *every unique key on the table must use every column in the table's partitioning expression*. (This also includes the table's primary key, since it is by definition a unique key. This particular case is discussed later in this section.) For example, each of the following table creation statements is invalid:

```sql
CREATE TABLE t1 (  
  col1 INT NOT NULL,  
  col2 DATE NOT NULL,  
  col3 INT NOT NULL,  
  col4 INT NOT NULL,  
  UNIQUE KEY (col1, col2)  
)  
PARTITION BY HASH(col3)  
PARTITIONS 4;  
CREATE TABLE t2 (  
  col1 INT NOT NULL,  
  col2 DATE NOT NULL,  
  col3 INT NOT NULL,  
  col4 INT NOT NULL,  
  UNIQUE KEY (col1),  
  UNIQUE KEY (col3)  
)  
PARTITION BY HASH(col1 + col3)  
PARTITIONS 4;  
```

In each case, the proposed table would have at least one unique key that does not include all columns used in the partitioning expression.

Each of the following statements is valid, and represents one way in which the corresponding invalid table creation statement could be made to work:
CREATE TABLE t1 {
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    UNIQUE KEY (col1, col2, col3)
}
PARTITION BY HASH(col3)
PARTITIONS 4;

CREATE TABLE t2 {
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    UNIQUE KEY (col1, col3)
}
PARTITION BY HASH(col1 + col3)
PARTITIONS 4;

This example shows the error produced in such cases:

mysql> CREATE TABLE t3 {
       -> col1 INT NOT NULL,
       -> col2 DATE NOT NULL,
       -> col3 INT NOT NULL,
       -> col4 INT NOT NULL,
       -> UNIQUE KEY (col1, col2),
       -> UNIQUE KEY (col3)
       -> }
       -> PARTITION BY HASH(col1 + col3)
       -> PARTITIONS 4;
ERROR 1491 (HY000): A PRIMARY KEY must include all columns in the table's partitioning function

The `CREATE TABLE` statement fails because both `col1` and `col3` are included in the proposed partitioning key, but neither of these columns is part of both of unique keys on the table. This shows one possible fix for the invalid table definition:

mysql> CREATE TABLE t3 {
       -> col1 INT NOT NULL,
       -> col2 DATE NOT NULL,
       -> col3 INT NOT NULL,
       -> col4 INT NOT NULL,
       -> UNIQUE KEY (col1, col2, col3),
       -> UNIQUE KEY (col3)
       -> }
       -> PARTITION BY HASH(col3)
       -> PARTITIONS 4;
Query OK, 0 rows affected (0.05 sec)

In this case, the proposed partitioning key `col3` is part of both unique keys, and the table creation statement succeeds.

The following table cannot be partitioned at all, because there is no way to include in a partitioning key any columns that belong to both unique keys:

CREATE TABLE t4 {
    col1 INT NOT NULL,
    col2 INT NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    UNIQUE KEY (col1, col3),
Since every primary key is by definition a unique key, this restriction also includes the table’s primary key, if it has one. For example, the next two statements are invalid:

```sql
CREATE TABLE t5 (  
  col1 INT NOT NULL,  
  col2 DATE NOT NULL,  
  col3 INT NOT NULL,  
  col4 INT NOT NULL,  
  PRIMARY KEY(col1, col2)  
)  
PARTITION BY HASH(col3)  
PARTITIONS 4;
CREATE TABLE t6 (  
  col1 INT NOT NULL,  
  col2 DATE NOT NULL,  
  col3 INT NOT NULL,  
  col4 INT NOT NULL,  
  PRIMARY KEY(col1, col3),  
  UNIQUE KEY(col2)  
)  
PARTITION BY HASH( YEAR(col2) )  
PARTITIONS 4;
```

In both cases, the primary key does not include all columns referenced in the partitioning expression. However, both of the next two statements are valid:

```sql
CREATE TABLE t7 (  
  col1 INT NOT NULL,  
  col2 DATE NOT NULL,  
  col3 INT NOT NULL,  
  col4 INT NOT NULL,  
  PRIMARY KEY(col1, col2)  
)  
PARTITION BY HASH(col1 + YEAR(col2))  
PARTITIONS 4;
CREATE TABLE t8 (  
  col1 INT NOT NULL,  
  col2 DATE NOT NULL,  
  col3 INT NOT NULL,  
  col4 INT NOT NULL,  
  PRIMARY KEY(col1, col2, col4),  
  UNIQUE KEY(col2, col1)  
)  
PARTITION BY HASH(col1 + YEAR(col2))  
PARTITIONS 4;
```

If a table has no unique keys—this includes having no primary key—then this restriction does not apply, and you may use any column or columns in the partitioning expression as long as the column type is compatible with the partitioning type.

For the same reason, you cannot later add a unique key to a partitioned table unless the key includes all columns used by the table’s partitioning expression. Consider the partitioned table created as shown here:

```sql
mysql> CREATE TABLE t_no_pk (c1 INT, c2 INT)  
  -> PARTITION BY RANGE(c1) (  
  ->    PARTITION p0 VALUES LESS THAN (10),  
  ->    PARTITION p1 VALUES LESS THAN (20),
```
Partitioning Keys, Primary Keys, and Unique Keys

It is possible to add a primary key to `t_no_pk` using either of these `ALTER TABLE` statements:

```
# possible PK
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c1);
Query OK, 0 rows affected (0.13 sec)
Records: 0  Duplicates: 0  Warnings: 0

# drop this PK
mysql> ALTER TABLE t_no_pk DROP PRIMARY KEY;
Query OK, 0 rows affected (0.10 sec)
Records: 0  Duplicates: 0  Warnings: 0

# use another possible PK
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c1, c2);
Query OK, 0 rows affected (0.12 sec)
Records: 0  Duplicates: 0  Warnings: 0

# drop this PK
mysql> ALTER TABLE t_no_pk DROP PRIMARY KEY;
Query OK, 0 rows affected (0.09 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

However, the next statement fails, because `c1` is part of the partitioning key, but is not part of the proposed primary key:

```
# fails with error 1503
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c2);
ERROR 1503 (HY000): A PRIMARY KEY must include all columns in the table's partitioning function
```

Since `t_no_pk` has only `c1` in its partitioning expression, attempting to add a unique key on `c2` alone fails. However, you can add a unique key that uses both `c1` and `c2`.

These rules also apply to existing nonpartitioned tables that you wish to partition using `ALTER TABLE ... PARTITION BY`. Consider a table `np_pk` created as shown here:

```
mysql> CREATE TABLE np_pk (  
    -> id INT NOT NULL AUTO_INCREMENT,  
    -> name VARCHAR(50),  
    -> added DATE,  
    -> PRIMARY KEY (id)  
    -> );
Query OK, 0 rows affected (0.08 sec)
```

The following `ALTER TABLE` statement fails with an error, because the `added` column is not part of any unique key in the table:

```
mysql> ALTER TABLE np_pk  
    -> PARTITION BY HASH( TO_DAYS(added) )  
    -> PARTITIONS 4;
ERROR 1503 (HY000): A PRIMARY KEY must include all columns in the table’s partitioning function
```

However, this statement using the `id` column for the partitioning column is valid, as shown here:

```
mysql> ALTER TABLE np_pk  
    -> PARTITION BY HASH(id)
```
In the case of \texttt{np\_pk}, the only column that may be used as part of a partitioning expression is \texttt{id}; if you wish to partition this table using any other column or columns in the partitioning expression, you must first modify the table, either by adding the desired column or columns to the primary key, or by dropping the primary key altogether.

19.6.2 Partitioning Limitations Relating to Storage Engines

The following limitations apply to the use of storage engines with user-defined partitioning of tables.

**MERGE storage engine.**  User-defined partitioning and the \texttt{MERGE} storage engine are not compatible. Tables using the \texttt{MERGE} storage engine cannot be partitioned. Partitioned tables cannot be merged.

**FEDERATED storage engine.**  Partitioning of \texttt{FEDERATED} tables is not supported; it is not possible to create partitioned \texttt{FEDERATED} tables.

**CSV storage engine.**  Partitioned tables using the \texttt{CSV} storage engine are not supported; it is not possible to create partitioned \texttt{CSV} tables.

**InnoDB storage engine.**  InnoDB foreign keys and MySQL partitioning are not compatible. Partitioned InnoDB tables cannot have foreign key references, nor can they have columns referenced by foreign keys. InnoDB tables which have or which are referenced by foreign keys cannot be partitioned.

InnoDB does not support the use of multiple disks for subpartitions. (This is currently supported only by MyISAM.)

In addition, \texttt{ALTER TABLE \ldots OPTIMIZE PARTITION} does not work correctly with partitioned tables that use the InnoDB storage engine. Use \texttt{ALTER TABLE \ldots REBUILD PARTITION} and \texttt{ALTER TABLE \ldots ANALYZE PARTITION}, instead, for such tables. For more information, see Section 13.1.7.1, “ALTER TABLE Partition Operations”.

**User-defined partitioning and the NDB storage engine (NDB Cluster).**  Partitioning by \texttt{KEY} (including \texttt{LINEAR KEY}) is the only type of partitioning supported for the NDB storage engine. It is not possible under normal circumstances in MySQL NDB Cluster 7.4 to create an NDB Cluster table using any partitioning type other than \texttt{[LINEAR] KEY}, and attempting to do so fails with an error.

\textit{Exception (not for production):} It is possible to override this restriction by setting the \texttt{new} system variable on NDB Cluster SQL nodes to \texttt{ON}. If you choose to do this, you should be aware that tables using partitioning types other than \texttt{[LINEAR] KEY} are not supported in production. \textit{In such cases, you can create and use tables with partitioning types other than \texttt{KEY} or \texttt{LINEAR KEY}, but you do this entirely at your own risk.}

The maximum number of partitions that can be defined for an NDB table depends on the number of data nodes and node groups in the cluster, the version of the NDB Cluster software in use, and other factors. See \textit{NDB and user-defined partitioning}, for more information.

The maximum amount of fixed-size data that can be stored per partition in an NDB table is 16 GB.

\texttt{CREATE TABLE} and \texttt{ALTER TABLE} statements that would cause a user-partitioned NDB table not to meet either or both of the following two requirements are not permitted, and fail with an error:

1. The table must have an explicit primary key.
2. All columns listed in the table’s partitioning expression must be part of the primary key.
Exception. If a user-partitioned NDB table is created using an empty column-list (that is, using `PARTITION BY KEY()` or `PARTITION BY LINEAR KEY()`), then no explicit primary key is required.

Upgrading partitioned tables. When performing an upgrade, tables which are partitioned by `KEY` and which use any storage engine other than NDB must be dumped and reloaded.

Same storage engine for all partitions. All partitions of a partitioned table must use the same storage engine and it must be the same storage engine used by the table as a whole. In addition, if one does not specify an engine on the table level, then one must do either of the following when creating or altering a partitioned table:

- Do not specify any engine for any partition or subpartition
- Specify the engine for all partitions or subpartitions

19.6.3 Partitioning Limitations Relating to Functions

This section discusses limitations in MySQL Partitioning relating specifically to functions used in partitioning expressions.

Only the MySQL functions shown in the following list are allowed in partitioning expressions:

- `ABS()`
- `CEILING()` (see `CEILING()` and `FLOOR()`)
- `DATEDIFF()`
- `DAY()`
- `DAYOFMONTH()`
- `DAYOFWEEK()`
- `DAYOFYEAR()`
- `EXTRACT()` (see `EXTRACT()` function with WEEK specifier)
- `FLOOR()` (see `CEILING()` and `FLOOR()`)
- `HOUR()`
- `MICROSECOND()`
- `MINUTE()`
- `MOD()`
- `MONTH()`
- `QUARTER()`
- `SECOND()`
- `TIME_TO_SEC()`
- `TO_DAYS()`
- `TO_SECONDS()`
Partitioning and Locking

- `UNIX_TIMESTAMP()` (with `TIMESTAMP` columns)
- `WEEKDAY()`
- `YEAR()`
- `YEARWEEK()`

In MySQL 5.6, range optimization can be used for the `TO_DAYS()`, `TO_SECONDS()`, and `YEAR()` functions. In addition, beginning with MySQL 5.6.3, `UNIX_TIMESTAMP()` is treated as monotonic in partitioning expressions. See Section 19.4, "Partition Pruning", for more information.

`CEILING()` and `FLOOR()`. Each of these functions returns an integer only if it is passed an argument of an exact numeric type, such as one of the `INT` types or `DECIMAL`. This means, for example, that the following `CREATE TABLE` statement fails with an error, as shown here:

```sql
mysql> CREATE TABLE t (c FLOAT) PARTITION BY LIST( FLOOR(c) ) (  
    -> PARTITION p0 VALUES IN (1,3,5),  
    -> PARTITION p1 VALUES IN (2,4,6)  
    -> );
ERROR 1490 (HY000): The PARTITION function returns the wrong type
```

`EXTRACT()` function with WEEK specifier. The value returned by the `EXTRACT()` function, when used as `EXTRACT(WEEK FROM col)`, depends on the value of the `default_week_format` system variable. For this reason, beginning with MySQL 5.6.2, `EXTRACT()` is no longer permitted as a partitioning function when it specifies the unit as `WEEK`. (Bug #54483)

See Section 12.6.2, "Mathematical Functions", for more information about the return types of these functions, as well as Section 11.2, "Numeric Types".

19.6.4 Partitioning and Locking

In MySQL 5.6.5 and earlier, for storage engines such as `MyISAM` that actually execute table-level locks when executing DML or DDL statements, such a statement affecting a partitioned table imposed a lock on the table as a whole; that is, all partitions were locked until the statement was finished. MySQL 5.6.6 implements partition lock pruning, which eliminates unneeded locks in many cases. In MySQL 5.6.6 and later, most statements reading from or updating a partitioned `MyISAM` table cause only the effected partitions to be locked. For example, prior to MySQL 5.6.6, a `SELECT` from a partitioned `MyISAM` table caused a lock on the entire table; in MySQL 5.6.6 and later, only those partitions actually containing rows that satisfy the `SELECT` statement's `WHERE` condition are locked. This has the effect of increasing the speed and efficiency of concurrent operations on partitioned `MyISAM` tables. This improvement becomes particularly noticeable when working with `MyISAM` tables that have many (32 or more) partitions.

This change in behavior does not have any impact on statements affecting partitioned tables using storage engines such as `InnoDB`, that employ row-level locking and do not actually perform (or need to perform) the locks prior to partition pruning.

The next few paragraphs discuss the effects of partition lock pruning for various MySQL statements on tables using storage engines that employ table-level locks.

**Effects on DML statements**

`SELECT` statements (including those containing unions or joins) now lock only those partitions that actually need to be read. This also applies to `SELECT ... PARTITION`.

An `UPDATE` prunes locks only for tables on which no partitioning columns are updated.
REPLACE and INSERT now lock only those partitions having rows to be inserted or replaced. However, if an AUTO_INCREMENT value is generated for any partitioning column then all partitions are locked.

INSERT ... ON DUPLICATE KEY UPDATE is pruned as long as no partitioning column is updated.

INSERT ... SELECT now locks only those partitions in the source table that need to be read, although all partitions in the target table are locked.

Note

INSERT DELAYED is not supported for partitioned tables.

Locks imposed by LOAD DATA statements on partitioned tables cannot be pruned.

The presence of BEFORE INSERT or BEFORE UPDATE triggers using any partitioning column of a partitioned table means that locks on INSERT and UPDATE statements updating this table cannot be pruned, since the trigger can alter its values: A BEFORE INSERT trigger on any of the table’s partitioning columns means that locks set by INSERT or REPLACE cannot be pruned, since the BEFORE INSERT trigger may change a row's partitioning columns before the row is inserted, forcing the row into a different partition than it would be otherwise. A BEFORE UPDATE trigger on a partitioning column means that locks imposed by UPDATE or INSERT ... ON DUPLICATE KEY UPDATE cannot be pruned.

Affected DDL statements

CREATE VIEW no longer causes any locks.

ALTER TABLE ... EXCHANGE PARTITION now prunes locks; only the exchanged table and the exchanged partition are locked.

ALTER TABLE ... TRUNCATE PARTITION now prunes locks; only the partitions to be emptied are locked.

ALTER TABLE statements still take metadata locks on the table level.

Other statements

LOCK TABLES cannot prune partition locks.

CALL stored_procedure(expr) supports lock pruning, but evaluating expr does not.

DO and SET statements do not support partitioning lock pruning.

This chapter discusses stored database objects that are defined in terms of SQL code that is stored on the server for later execution.

Stored objects include these object types:

- Stored procedure: An object created with CREATE PROCEDURE and invoked using the CALL statement. A procedure does not have a return value but can modify its parameters for later inspection by the caller. It can also generate result sets to be returned to the client program.

- Stored function: An object created with CREATE FUNCTION and used much like a built-in function. You invoke it in an expression and it returns a value during expression evaluation.

- Trigger: An object created with CREATE TRIGGER that is associated with a table. A trigger is activated when a particular event occurs for the table, such as an insert or update.

- Event: An object created with CREATE EVENT and invoked by the server according to schedule.

- View: An object created with CREATE VIEW that when referenced produces a result set. A view acts as a virtual table.

Terminology used in this document reflects the stored object hierarchy:
• Stored routines include stored procedures and functions.
• Stored programs include stored routines, triggers, and events.
• Stored objects include stored programs and views.

This chapter describes how to use stored objects. The following sections provide additional information about SQL syntax for statements related to these objects, and about object processing:

• For each object type, there are CREATE, ALTER, and DROP statements that control which objects exist and how they are defined. See Section 13.1, “Data Definition Statements”.

• The CALL statement is used to invoke stored procedures. See Section 13.2.1, “CALL Syntax”.

• Stored program definitions include a body that may use compound statements, loops, conditionals, and declared variables. See Section 13.6, “Compound-Statement Syntax”.

• Metadata changes to objects referred to by stored programs are detected and cause automatic reparsing of the affected statements when the program is next executed. For more information, see Section 8.10.4, “Caching of Prepared Statements and Stored Programs”.

20.1 Defining Stored Programs

Each stored program contains a body that consists of an SQL statement. This statement may be a compound statement made up of several statements separated by semicolon (; ) characters. For example, the following stored procedure has a body made up of a BEGIN . . . END block that contains a SET statement and a REPEAT loop that itself contains another SET statement:

```
CREATE PROCEDURE dorepeat(p1 INT)
BEGIN
  SET @x = 0;
  REPEAT SET @x = @x + 1; UNTIL @x > p1 END REPEAT;
END;
```

If you use the mysql client program to define a stored program containing semicolon characters, a problem arises. By default, mysql itself recognizes the semicolon as a statement delimiter, so you must redefine the delimiter temporarily to cause mysql to pass the entire stored program definition to the server.

To redefine the mysql delimiter, use the delimiter command. The following example shows how to do this for the dorepeat() procedure just shown. The delimiter is changed to // to enable the entire definition to be passed to the server as a single statement, and then restored to ; before invoking the procedure. This enables the ; delimiter used in the procedure body to be passed through to the server rather than being interpreted by mysql itself.

```
mysql> delimiter //
mysql> CREATE PROCEDURE dorepeat(p1 INT)
    -> BEGIN
    -> SET @x = 0;
    -> REPEAT SET @x = @x + 1; UNTIL @x > p1 END REPEAT;
    -> END
    -> //
Query OK, 0 rows affected (0.00 sec)
mysql> delimiter ;
mysql> CALL dorepeat(1000);
Query OK, 0 rows affected (0.00 sec)
```
You can redefine the delimiter to a string other than //, and the delimiter can consist of a single character or multiple characters. You should avoid the use of the backslash (\) character because that is the escape character for MySQL.

The following is an example of a function that takes a parameter, performs an operation using an SQL function, and returns the result. In this case, it is unnecessary to use delimiter because the function definition contains no internal ; statement delimiters:

```
mysql> CREATE FUNCTION hello (s CHAR(20))
mysql> RETURNS CHAR(50) DETERMINISTIC
mysql> -> RETURN CONCAT('Hello, ',s,'!');
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT hello('world');
+----------------+
| hello('world') |
+----------------+
| Hello, world!  |
+----------------+
1 row in set (0.00 sec)
```

20.2 Using Stored Routines

MySQL supports stored routines (procedures and functions). A stored routine is a set of SQL statements that can be stored in the server. Once this has been done, clients don’t need to keep reissuing the individual statements but can refer to the stored routine instead.

Stored routines require the proc table in the mysql database. This table is created during the MySQL installation procedure. If you are upgrading to MySQL 5.6 from an earlier version, be sure to update your grant tables to make sure that the proc table exists. See Section 4.4.7, “mysql_upgrade — Check and Upgrade MySQL Tables”.

Stored routines can be particularly useful in certain situations:

- When multiple client applications are written in different languages or work on different platforms, but need to perform the same database operations.

- When security is paramount. Banks, for example, use stored procedures and functions for all common operations. This provides a consistent and secure environment, and routines can ensure that each operation is properly logged. In such a setup, applications and users would have no access to the database tables directly, but can only execute specific stored routines.

Stored routines can provide improved performance because less information needs to be sent between the server and the client. The tradeoff is that this does increase the load on the database server because more of the work is done on the server side and less is done on the client (application) side. Consider this if many client machines (such as Web servers) are serviced by only one or a few database servers.

Stored routines also enable you to have libraries of functions in the database server. This is a feature shared by modern application languages that enable such design internally (for example, by using classes). Using these client application language features is beneficial for the programmer even outside the scope of database use.
MySQL follows the SQL:2003 syntax for stored routines, which is also used by IBM's DB2. All syntax described here is supported and any limitations and extensions are documented where appropriate.

**Additional Resources**

- You may find the Stored Procedures User Forum of use when working with stored procedures and functions.
- For answers to some commonly asked questions regarding stored routines in MySQL, see Section A.4, “MySQL 5.6 FAQ: Stored Procedures and Functions”.
- There are some restrictions on the use of stored routines. See Section 20.8, “Restrictions on Stored Programs”.
- Binary logging for stored routines takes place as described in Section 20.7, “Stored Program Binary Logging”.

### 20.2.1 Stored Routine Syntax

A stored routine is either a procedure or a function. Stored routines are created with the `CREATE PROCEDURE` and `CREATE FUNCTION` statements (see Section 13.1.15, “CREATE PROCEDURE and CREATE FUNCTION Syntax”). A procedure is invoked using a `CALL` statement (see Section 13.2.1, “CALL Syntax”), and can only pass back values using output variables. A function can be called from inside a statement just like any other function (that is, by invoking the function’s name), and can return a scalar value. The body of a stored routine can use compound statements (see Section 13.6, “Compound-Statement Syntax”).

Stored routines can be dropped with the `DROP PROCEDURE` and `DROP FUNCTION` statements (see Section 13.1.26, “DROP PROCEDURE and DROP FUNCTION Syntax”), and altered with the `ALTER PROCEDURE` and `ALTER FUNCTION` statements (see Section 13.1.5, “ALTER PROCEDURE Syntax”).

A stored procedure or function is associated with a particular database. This has several implications:

- When the routine is invoked, an implicit `USE db_name` is performed (and undone when the routine terminates). `USE` statements within stored routines are not permitted.
- You can qualify routine names with the database name. This can be used to refer to a routine that is not in the current database. For example, to invoke a stored procedure `p` or function `f` that is associated with the `test` database, you can say `CALL test.p()` or `test.f()`.
- When a database is dropped, all stored routines associated with it are dropped as well.

Stored functions cannot be recursive.

Recursion in stored procedures is permitted but disabled by default. To enable recursion, set the `max_sp_recursion_depth` server system variable to a value greater than zero. Stored procedure recursion increases the demand on thread stack space. If you increase the value of `max_sp_recursion_depth`, it may be necessary to increase thread stack size by increasing the value of `thread_stack` at server startup. See Section 5.1.7, “Server System Variables”, for more information.

MySQL supports a very useful extension that enables the use of regular `SELECT` statements (that is, without using cursors or local variables) inside a stored procedure. The result set of such a query is simply sent directly to the client. Multiple `SELECT` statements generate multiple result sets, so the client must use a MySQL client library that supports multiple result sets. This means the client must use a client library from a version of MySQL at least as recent as 4.1. The client should also specify the `CLIENT_MULTI_RESULTS` option when it connects. For C programs, this can be done with the
mysql_real_connect() C API function. See Section 23.8.73, “mysql_real_connect()”, and Section 23.8.16, “C API Multiple Statement Execution Support”.

20.2.2 Stored Routines and MySQL Privileges

The MySQL grant system takes stored routines into account as follows:

• The CREATE ROUTINE privilege is needed to create stored routines.

• The ALTER ROUTINE privilege is needed to alter or drop stored routines. This privilege is granted automatically to the creator of a routine if necessary, and dropped from the creator when the routine is dropped.

• The EXECUTE privilege is required to execute stored routines. However, this privilege is granted automatically to the creator of a routine if necessary (and dropped from the creator when the routine is dropped). Also, the default SQL SECURITY characteristic for a routine is DEFINER, which enables users who have access to the database with which the routine is associated to execute the routine.

• If the automatic_sp_privileges system variable is 0, the EXECUTE and ALTER ROUTINE privileges are not automatically granted to and dropped from the routine creator.

• The creator of a routine is the account used to execute the CREATE statement for it. This might not be the same as the account named as the DEFINER in the routine definition.

The server manipulates the mysql.proc table in response to statements that create, alter, or drop stored routines. It is not supported that the server will notice manual manipulation of this table.

20.2.3 Stored Routine Metadata

Metadata about stored routines can be obtained as follows:

• Query the ROUTINES table of the INFORMATION_SCHEMA database. See Section 21.19, “The INFORMATION_SCHEMA ROUTINES Table”.

• Use the SHOW CREATE PROCEDURE and SHOW CREATE FUNCTION statements to see routine definitions. See Section 13.7.5.11, “SHOW CREATE PROCEDURE Syntax”.

• Use the SHOW PROCEDURE STATUS and SHOW FUNCTION STATUS statements to see routine characteristics. See Section 13.7.5.29, “SHOW PROCEDURE STATUS Syntax”.

20.2.4 Stored Procedures, Functions, Triggers, and LAST_INSERT_ID()

Within the body of a stored routine (procedure or function) or a trigger, the value of LAST_INSERT_ID() changes the same way as for statements executed outside the body of these kinds of objects (see Section 12.15, “Information Functions”). The effect of a stored routine or trigger upon the value of LAST_INSERT_ID() that is seen by following statements depends on the kind of routine:

• If a stored procedure executes statements that change the value of LAST_INSERT_ID(), the changed value is seen by statements that follow the procedure call.

• For stored functions and triggers that change the value, the value is restored when the function or trigger ends, so following statements do not see a changed value.

20.3 Using Triggers

A trigger is a named database object that is associated with a table, and that activates when a particular event occurs for the table. Some uses for triggers are to perform checks of values to be inserted into a table or to perform calculations on values involved in an update.
A trigger is defined to activate when a statement inserts, updates, or deletes rows in the associated table. These row operations are trigger events. For example, rows can be inserted by INSERT or LOAD DATA statements, and an insert trigger activates for each inserted row. A trigger can be set to activate either before or after the trigger event. For example, you can have a trigger activate before each row that is inserted into a table or after each row that is updated.

**Important**

MySQL triggers activate only for changes made to tables by SQL statements. This includes changes to base tables that underlie updatable views. Triggers do not activate for changes to tables made by APIs that do not transmit SQL statements to the MySQL Server. This means that triggers are not activated by updates made using the NDB API.

Triggers are not activated by changes in INFORMATION_SCHEMA or performance_schema tables. Those tables are actually views and triggers are not permitted on views.

The following sections describe the syntax for creating and dropping triggers, show some examples of how to use them, and indicate how to obtain trigger metadata.

### Additional Resources

- You may find the Triggers User Forum of use when working with triggers.
- For answers to commonly asked questions regarding triggers in MySQL, see Section A.5, “MySQL 5.6 FAQ: Triggers”.
- There are some restrictions on the use of triggers; see Section 20.8, “Restrictions on Stored Programs”.
- Binary logging for triggers takes place as described in Section 20.7, “Stored Program Binary Logging”.

#### 20.3.1 Trigger Syntax and Examples

To create a trigger or drop a trigger, use the CREATE TRIGGER or DROP TRIGGER statement, described in Section 13.1.19, “CREATE TRIGGER Syntax”, and Section 13.1.30, “DROP TRIGGER Syntax”.

Here is a simple example that associates a trigger with a table, to activate for INSERT operations. The trigger acts as an accumulator, summing the values inserted into one of the columns of the table.

```sql
mysql> CREATE TABLE account (acct_num INT, amount DECIMAL(10,2));
Query OK, 0 rows affected (0.03 sec)

mysql> CREATE TRIGGER ins_sum BEFORE INSERT ON account
   FOR EACH ROW SET @sum = @sum + NEW.amount;
Query OK, 0 rows affected (0.01 sec)
```

The CREATE TRIGGER statement creates a trigger named ins_sum that is associated with the account table. It also includes clauses that specify the trigger action time, the triggering event, and what to do when the trigger activates:

- The keyword BEFORE indicates the trigger action time. In this case, the trigger activates before each row inserted into the table. The other permitted keyword here is AFTER.
- The keyword INSERT indicates the trigger event; that is, the type of operation that activates the trigger. In the example, INSERT operations cause trigger activation. You can also create triggers for DELETE and UPDATE operations.
Trigger Syntax and Examples

The statement following `FOR EACH ROW` defines the trigger body; that is, the statement to execute each time the trigger activates, which occurs once for each row affected by the triggering event. In the example, the trigger body is a simple `SET` that accumulates into a user variable the values inserted into the `amount` column. The statement refers to the column as `NEW.amount` which means “the value of the `amount` column to be inserted into the new row.”

To use the trigger, set the accumulator variable to zero, execute an `INSERT` statement, and then see what value the variable has afterward:

```
mysql> SET @sum = 0;
mysql> INSERT INTO account VALUES(137,14.98),(141,1937.50),(97,-100.00);
mysql> SELECT @sum AS 'Total amount inserted';
+-----------------------+
<table>
<thead>
<tr>
<th>Total amount inserted</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
</tr>
<tr>
<td>1852.48</td>
</tr>
</tbody>
</table>
+-----------------------+
```

In this case, the value of `@sum` after the `INSERT` statement has executed is $14.98 + 1937.50 - 100$, or $1852.48$.

To destroy the trigger, use a `DROP TRIGGER` statement. You must specify the schema name if the trigger is not in the default schema:

```
mysql> DROP TRIGGER test.ins_sum;
```

If you drop a table, any triggers for the table are also dropped.

Trigger names exist in the schema namespace, meaning that all triggers must have unique names within a schema. Triggers in different schemas can have the same name.

In addition to the requirement that trigger names be unique for a schema, there are other limitations on the types of triggers you can create. In particular, there cannot be multiple triggers for a given table that have the same trigger event and action time. For example, you cannot have two `BEFORE UPDATE` triggers for a table. To work around this, you can define a trigger that executes multiple statements by using the `BEGIN ... END` compound statement construct after `FOR EACH ROW`. (An example appears later in this section.)

Within the trigger body, the `OLD` and `NEW` keywords enable you to access columns in the rows affected by a trigger. `OLD` and `NEW` are MySQL extensions to triggers; they are not case-sensitive.

In an `INSERT` trigger, only `NEW.col_name` can be used; there is no old row. In a `DELETE` trigger, only `OLD.col_name` can be used; there is no new row. In an `UPDATE` trigger, you can use `OLD.col_name` to refer to the columns of a row before it is updated and `NEW.col_name` to refer to the columns of the row after it is updated.

A column named with `OLD` is read only. You can refer to it (if you have the `SELECT` privilege), but not modify it. You can refer to a column named with `NEW` if you have the `SELECT` privilege for it. In a `BEFORE` trigger, you can also change its value with `SET NEW.col_name = value` if you have the `UPDATE` privilege for it. This means you can use a trigger to modify the values to be inserted into a new row or used to update a row. (Such a `SET` statement has no effect in an `AFTER` trigger because the row change will have already occurred.)

In a `BEFORE` trigger, the `NEW` value for an `AUTO_INCREMENT` column is 0, not the sequence number that is generated automatically when the new row actually is inserted.

By using the `BEGIN ... END` construct, you can define a trigger that executes multiple statements. Within the `BEGIN` block, you also can use other syntax that is permitted within stored routines such as
conditionals and loops. However, just as for stored routines, if you use the `mysql` program to define a trigger that executes multiple statements, it is necessary to redefine the `mysql` statement delimiter so that you can use the `;` statement delimiter within the trigger definition. The following example illustrates these points. It defines an `UPDATE` trigger that checks the new value to be used for updating each row, and modifies the value to be within the range from 0 to 100. This must be a `BEFORE` trigger because the value must be checked before it is used to update the row:

```sql
mysql> delimiter //
mysql> CREATE TRIGGER upd_check BEFORE UPDATE ON account
  -> FOR EACH ROW
  -> BEGIN
  -> IF NEW.amount < 0 THEN
  -> SET NEW.amount = 0;
  -> ELSEIF NEW.amount > 100 THEN
  -> SET NEW.amount = 100;
  -> END IF;
  -> END; //
mysql> delimiter ;
```

It can be easier to define a stored procedure separately and then invoke it from the trigger using a simple `CALL` statement. This is also advantageous if you want to execute the same code from within several triggers.

There are limitations on what can appear in statements that a trigger executes when activated:

- The trigger cannot use the `CALL` statement to invoke stored procedures that return data to the client or that use dynamic SQL. (Stored procedures are permitted to return data to the trigger through `OUT` or `INOUT` parameters.)
- The trigger cannot use statements that explicitly or implicitly begin or end a transaction, such as `START TRANSACTION`, `COMMIT`, or `ROLLBACK`. (`ROLLBACK` to `SAVEPOINT` is permitted because it does not end a transaction.).

See also Section 20.8, “Restrictions on Stored Programs”.

MySQL handles errors during trigger execution as follows:

- If a `BEFORE` trigger fails, the operation on the corresponding row is not performed.
- A `BEFORE` trigger is activated by the `attempt` to insert or modify the row, regardless of whether the attempt subsequently succeeds.
- An `AFTER` trigger is executed only if any `BEFORE` triggers and the row operation execute successfully.
- An error during either a `BEFORE` or `AFTER` trigger results in failure of the entire statement that caused trigger invocation.
- For transactional tables, failure of a statement should cause rollback of all changes performed by the statement. Failure of a trigger causes the statement to fail, so trigger failure also causes rollback. For nontransactional tables, such rollback cannot be done, so although the statement fails, any changes performed prior to the point of the error remain in effect.

Triggers can contain direct references to tables by name, such as the trigger named `testref` shown in this example:

```sql
CREATE TABLE test1(a1 INT);
CREATE TABLE test2(a2 INT);
CREATE TABLE test3(a3 INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
```
CREATE TABLE test4(
    a4 INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    b4 INT DEFAULT 0
);

CREATE TRIGGER testref BEFORE INSERT ON test1
    FOR EACH ROW
    BEGIN
        INSERT INTO test2 SET a2 = NEW.a1;
        DELETE FROM test3 WHERE a3 = NEW.a1;
        UPDATE test4 SET b4 = b4 + 1 WHERE a4 = NEW.a1;
    END;

INSERT INTO test3 (a3) VALUES
    (NULL), (NULL), (NULL), (NULL), (NULL),
    (NULL), (NULL), (NULL), (NULL), (NULL);

INSERT INTO test4 (a4) VALUES
    (0), (0), (0), (0), (0), (0), (0), (0), (0), (0);

Suppose that you insert the following values into table test1 as shown here:

```
mysql> INSERT INTO test1 VALUES
    (1), (3), (1), (7), (1), (8), (4), (4);
Query OK, 8 rows affected (0.01 sec)
Records: 8  Duplicates: 0  Warnings: 0
```

As a result, the four tables contain the following data:

```
mysql> SELECT * FROM test1;
+------+
| a1   |
+------+
|    1 |
|    3 |
|    1 |
|    7 |
|    1 |
|    8 |
|    4 |
|    4 |
+------+
8 rows in set (0.00 sec)

mysql> SELECT * FROM test2;
+------+
| a2   |
+------+
|    1 |
|    3 |
|    1 |
|    7 |
|    1 |
|    8 |
|    4 |
|    4 |
+------+
8 rows in set (0.00 sec)

mysql> SELECT * FROM test3;
```
### 20.3.2 Trigger Metadata

Metadata about triggers can be obtained as follows:

- Query the **TRIGGERS** table of the **INFORMATION_SCHEMA** database. See Section 21.27, “The INFORMATION_SCHEMA TRIGGERS Table”.

- Use the **SHOW CREATE TRIGGER** statement. See Section 13.7.5.13, “SHOW CREATE TRIGGER Syntax”.

- Use the **SHOW TRIGGERS** statement. See Section 13.7.5.39, “SHOW TRIGGERS Syntax”.

### 20.4 Using the Event Scheduler

The *MySQL Event Scheduler* manages the scheduling and execution of events, that is, tasks that run according to a schedule. The following discussion covers the Event Scheduler and is divided into the following sections:

- **Section 20.4.1, “Event Scheduler Overview”**, provides an introduction to and conceptual overview of MySQL Events.

- **Section 20.4.3, “Event Syntax”**, discusses the SQL statements for creating, altering, and dropping MySQL Events.

- **Section 20.4.4, “Event Metadata”**, shows how to obtain information about events and how this information is stored by the MySQL Server.

- **Section 20.4.6, “The Event Scheduler and MySQL Privileges”**, discusses the privileges required to work with events and the ramifications that events have with regard to privileges when executing.

Stored routines require the **event** table in the **mysql** database. This table is created during the MySQL 5.6 installation procedure. If you are upgrading to MySQL 5.6 from an earlier version, be sure to update your grant tables to make sure that the **event** table exists. See Section 2.11, “Upgrading MySQL”. 
Additional Resources

• You may find the MySQL Event Scheduler User Forum of use when working with scheduled events.
• There are some restrictions on the use of events; see Section 20.8, “Restrictions on Stored Programs”.
• Binary logging for events takes place as described in Section 20.7, “Stored Program Binary Logging”.

20.4.1 Event Scheduler Overview

MySQL Events are tasks that run according to a schedule. Therefore, we sometimes refer to them as scheduled events. When you create an event, you are creating a named database object containing one or more SQL statements to be executed at one or more regular intervals, beginning and ending at a specific date and time. Conceptually, this is similar to the idea of the Unix crontab (also known as a “cron job”) or the Windows Task Scheduler.

Scheduled tasks of this type are also sometimes known as “temporal triggers”, implying that these are objects that are triggered by the passage of time. While this is essentially correct, we prefer to use the term events to avoid confusion with triggers of the type discussed in Section 20.3, “Using Triggers”. Events should more specifically not be confused with “temporary triggers”. Whereas a trigger is a database object whose statements are executed in response to a specific type of event that occurs on a given table, a (scheduled) event is an object whose statements are executed in response to the passage of a specified time interval.

While there is no provision in the SQL Standard for event scheduling, there are precedents in other database systems, and you may notice some similarities between these implementations and that found in the MySQL Server.

MySQL Events have the following major features and properties:

• In MySQL, an event is uniquely identified by its name and the schema to which it is assigned.

• An event performs a specific action according to a schedule. This action consists of an SQL statement, which can be a compound statement in a BEGIN ... END block if desired (see Section 13.6, “Compound-Statement Syntax”). An event's timing can be either one-time or recurrent. A one-time event executes one time only. A recurrent event repeats its action at a regular interval, and the schedule for a recurring event can be assigned a specific start day and time, end day and time, both, or neither. (By default, a recurring event's schedule begins as soon as it is created, and continues indefinitely, until it is disabled or dropped.)

If a repeating event does not terminate within its scheduling interval, the result may be multiple instances of the event executing simultaneously. If this is undesirable, you should institute a mechanism to prevent simultaneous instances. For example, you could use the GET_LOCK() function, or row or table locking.

• Users can create, modify, and drop scheduled events using SQL statements intended for these purposes. Syntactically invalid event creation and modification statements fail with an appropriate error message. A user may include statements in an event's action which require privileges that the user does not actually have. The event creation or modification statement succeeds but the event's action fails. See Section 20.4.6, “The Event Scheduler and MySQL Privileges” for details.

• Many of the properties of an event can be set or modified using SQL statements. These properties include the event's name, timing, persistence (that is, whether it is preserved following the expiration of its schedule), status (enabled or disabled), action to be performed, and the schema to which it is assigned. See Section 13.1.2, “ALTER EVENT Syntax”.

The default definer of an event is the user who created the event, unless the event has been altered, in which case the definer is the user who issued the last ALTER EVENT statement affecting that event. An
event can be modified by any user having the EVENT privilege on the database for which the event is defined. See Section 20.4.6, “The Event Scheduler and MySQL Privileges”.

• An event’s action statement may include most SQL statements permitted within stored routines. For restrictions, see Section 20.8, “Restrictions on Stored Programs”.

### 20.4.2 Event Scheduler Configuration

Events are executed by a special event scheduler thread; when we refer to the Event Scheduler, we actually refer to this thread. When running, the event scheduler thread and its current state can be seen by users having the PROCESS privilege in the output of SHOW PROCESSLIST, as shown in the discussion that follows.

The global event_scheduler system variable determines whether the Event Scheduler is enabled and running on the server. It has one of these 3 values, which affect event scheduling as described here:

- **OFF**: The Event Scheduler is stopped. The event scheduler thread does not run, is not shown in the output of SHOW PROCESSLIST, and no scheduled events are executed. OFF is the default value for event_scheduler.

  When the Event Scheduler is stopped (event_scheduler is OFF), it can be started by setting the value of event_scheduler to ON. (See next item.)

- **ON**: The Event Scheduler is started; the event scheduler thread runs and executes all scheduled events.

  When the Event Scheduler is ON, the event scheduler thread is listed in the output of SHOW PROCESSLIST as a daemon process, and its state is represented as shown here:

```sql
mysql> SHOW PROCESSLIST\G
*************************** 1. row ***************************
   Id: 1
   User: root
   Host: localhost
    db: NULL
Command: Query
   Time: 0
   State: NULL
   Info: show processlist
*************************** 2. row ***************************
   Id: 2
   User: event_scheduler
   Host: localhost
    db: NULL
Command: Daemon
   Time: 3
   State: Waiting for next activation
   Info: NULL
2 rows in set (0.00 sec)
```

Event scheduling can be stopped by setting the value of event_scheduler to OFF.

- **DISABLED**: This value renders the Event Scheduler nonoperational. When the Event Scheduler is DISABLED, the event scheduler thread does not run (and so does not appear in the output of SHOW PROCESSLIST). In addition, the Event Scheduler state cannot be changed at runtime.

  If the Event Scheduler status has not been set to DISABLED, event_scheduler can be toggled between ON and OFF (using SET). It is also possible to use 0 for OFF, and 1 for ON when setting this variable. Thus, any of the following 4 statements can be used in the mysql client to turn on the Event Scheduler:
SET GLOBAL event_scheduler = ON;
SET @@GLOBAL.event_scheduler = ON;
SET GLOBAL event_scheduler = 1;
SET @@GLOBAL.event_scheduler = 1;

Similarly, any of these 4 statements can be used to turn off the Event Scheduler:

SET GLOBAL event_scheduler = OFF;
SET @@GLOBAL.event_scheduler = OFF;
SET GLOBAL event_scheduler = 0;
SET @@GLOBAL.event_scheduler = 0;

Although `ON` and `OFF` have numeric equivalents, the value displayed for `event_scheduler` by `SELECT` or `SHOW VARIABLES` is always one of `OFF`, `ON`, or `DISABLED`. `DISABLED` has no numeric equivalent. For this reason, `ON` and `OFF` are usually preferred over `1` and `0` when setting this variable.

Attempting to set `event_scheduler` without specifying it as a global variable causes an error:

```
mysql< SET @@event_scheduler = OFF;
ERROR 1229 (HY000): Variable 'event_scheduler' is a GLOBAL variable and should be set with SET GLOBAL
```

Important

It is possible to set the Event Scheduler to `DISABLED` only at server startup. If `event_scheduler` is `ON` or `OFF`, you cannot set it to `DISABLED` at runtime. Also, if the Event Scheduler is set to `DISABLED` at startup, you cannot change the value of `event_scheduler` at runtime.

To disable the event scheduler, use one of the following two methods:

- As a command-line option when starting the server:

  `--event-scheduler=DISABLED`

- In the server configuration file (`my.cnf`, or `my.ini` on Windows systems), include the line where it will be read by the server (for example, in a `[mysqld]` section):

  `event_scheduler=DISABLED`

To enable the Event Scheduler, restart the server without the `--event-scheduler=DISABLED` command-line option, or after removing or commenting out the line containing `event-scheduler=DISABLED` in the server configuration file, as appropriate. Alternatively, you can use `ON` (or `1`) or `OFF` (or `0`) in place of the `DISABLED` value when starting the server.

Note

You can issue event-manipulation statements when `event_scheduler` is set to `DISABLED`. No warnings or errors are generated in such cases (provided that the statements are themselves valid). However, scheduled events cannot execute until this variable is set to `ON` (or `1`). Once this has been done, the event scheduler thread executes all events whose scheduling conditions are satisfied.

Starting the MySQL server with the `--skip-grant-tables` option causes `event_scheduler` to be set to `DISABLED`, overriding any other value set either on the command line or in the `my.cnf` or `my.ini` file (Bug #26807).
For SQL statements used to create, alter, and drop events, see Section 20.4.3, “Event Syntax”.

MySQL provides an EVENTS table in the INFORMATION_SCHEMA database. This table can be queried to obtain information about scheduled events which have been defined on the server. See Section 20.4.4, “Event Metadata”, and Section 21.8, “The INFORMATION_SCHEMA EVENTS Table”, for more information.

For information regarding event scheduling and the MySQL privilege system, see Section 20.4.6, “The Event Scheduler and MySQL Privileges”.

20.4.3 Event Syntax

MySQL provides several SQL statements for working with scheduled events:

• New events are defined using the CREATE EVENT statement. See Section 13.1.11, “CREATE EVENT Syntax”.

• The definition of an existing event can be changed by means of the ALTER EVENT statement. See Section 13.1.2, “ALTER EVENT Syntax”.

• When a scheduled event is no longer wanted or needed, it can be deleted from the server by its definer using the DROP EVENT statement. See Section 13.1.22, “DROP EVENT Syntax”. Whether an event persists past the end of its schedule also depends on its ON COMPLETION clause, if it has one. See Section 13.1.11, “CREATE EVENT Syntax”.

An event can be dropped by any user having the EVENT privilege for the database on which the event is defined. See Section 20.4.6, “The Event Scheduler and MySQL Privileges”.

20.4.4 Event Metadata

Metadata about events can be obtained as follows:

• Query the event table of the mysql database.

• Query the EVENTS table of the INFORMATION_SCHEMA database. See Section 21.8, “The INFORMATION_SCHEMA EVENTS Table”.

• Use the SHOW CREATE EVENT statement. See Section 13.7.5.9, “SHOW CREATE EVENT Syntax”.

• Use the SHOW EVENTS statement. See Section 13.7.5.19, “SHOW EVENTS Syntax”.

Event Scheduler Time Representation

Each session in MySQL has a session time zone (STZ). This is the session time_zone value that is initialized from the server's global time_zone value when the session begins but may be changed during the session.

The session time zone that is current when a CREATE EVENT or ALTER EVENT statement executes is used to interpret times specified in the event definition. This becomes the event time zone (ETZ); that is, the time zone that is used for event scheduling and is in effect within the event as it executes.

For representation of event information in the mysql.event table, the execute_at, starts, and ends times are converted to UTC and stored along with the event time zone. This enables event execution to proceed as defined regardless of any subsequent changes to the server time zone or daylight saving time effects. The last_executed time is also stored in UTC.

If you select information from mysql.event, the times just mentioned are retrieved as UTC values. These times can also be obtained by selecting from the INFORMATION_SCHEMA EVENTS table or from SHOW EVENTS, but they are reported as ETZ values. Other times available from these sources indicate when
an event was created or last altered; these are displayed as STZ values. The following table summarizes
representation of event times.

<table>
<thead>
<tr>
<th>Value</th>
<th>mysql.event</th>
<th>INFORMATION_SCHEMA.EVENTS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execute at</td>
<td>UTC</td>
<td>ETZ</td>
</tr>
<tr>
<td>Starts</td>
<td>UTC</td>
<td>ETZ</td>
</tr>
<tr>
<td>Ends</td>
<td>UTC</td>
<td>ETZ</td>
</tr>
<tr>
<td>Last executed</td>
<td>UTC</td>
<td>ETZ</td>
</tr>
<tr>
<td>Created</td>
<td>STZ</td>
<td>STZ</td>
</tr>
<tr>
<td>Last altered</td>
<td>STZ</td>
<td>STZ</td>
</tr>
</tbody>
</table>

20.4.5 Event Scheduler Status

The Event Scheduler writes information about event execution that terminates with an error or warning to
the MySQL Server’s error log. See Section 20.4.6, “The Event Scheduler and MySQL Privileges” for an
e example.

To obtain information about the state of the Event Scheduler for debugging and troubleshooting purposes,
run mysqladmin debug (see Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”);
after running this command, the server’s error log contains output relating to the Event Scheduler, similar to
what is shown here:

<table>
<thead>
<tr>
<th>Events status:</th>
</tr>
</thead>
<tbody>
<tr>
<td>LLA = Last Locked At</td>
</tr>
<tr>
<td>LUA = Last Unlocked At</td>
</tr>
<tr>
<td>WOC = Waiting On Condition</td>
</tr>
<tr>
<td>DL = Data Locked</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Event scheduler status:</th>
</tr>
</thead>
<tbody>
<tr>
<td>State : INITIALIZED</td>
</tr>
<tr>
<td>Thread id : 0</td>
</tr>
<tr>
<td>LLA : init_scheduler:313</td>
</tr>
<tr>
<td>LUA : init_scheduler:318</td>
</tr>
<tr>
<td>WOC : NO</td>
</tr>
<tr>
<td>Workers : 0</td>
</tr>
<tr>
<td>Executed : 0</td>
</tr>
<tr>
<td>Data locked: NO</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Event queue status:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Element count : 1</td>
</tr>
<tr>
<td>Data locked : NO</td>
</tr>
<tr>
<td>Attempting lock : NO</td>
</tr>
<tr>
<td>LLA : init_queue:148</td>
</tr>
<tr>
<td>LUA : init_queue:168</td>
</tr>
<tr>
<td>WOC : NO</td>
</tr>
<tr>
<td>Next activation : 0000-00-00 00:00:00</td>
</tr>
</tbody>
</table>

In statements that occur as part of events executed by the Event Scheduler, diagnostics messages (not
only errors, but also warnings) are written to the error log, and, on Windows, to the application event log.
For frequently executed events, it is possible for this to result in many logged messages. For example,
for SELECT ... INTO var_list statements, if the query returns no rows, a warning with error code
1329 occurs (No data), and the variable values remain unchanged. If the query returns multiple rows,
error 1172 occurs (Result consisted of more than one row). For either condition, you can avoid
having the warnings be logged by declaring a condition handler; see Section 13.6.7.2, “DECLARE ...
HANDLER Syntax”. For statements that may retrieve multiple rows, another strategy is to use LIMIT 1 to
limit the result set to a single row.

20.4.6 The Event Scheduler and MySQL Privileges
To enable or disable the execution of scheduled events, it is necessary to set the value of the global `event_scheduler` system variable. This requires privileges sufficient to set global system variables. See Section 5.1.8.1, “System Variable Privileges”.

The `EVENT` privilege governs the creation, modification, and deletion of events. This privilege can be bestowed using `GRANT`. For example, this `GRANT` statement confers the `EVENT` privilege for the schema named `myschema` on the user `jon@ghidora`:

```
GRANT EVENT ON myschema.* TO jon@ghidora;
```

(We assume that this user account already exists, and that we wish for it to remain unchanged otherwise.)

To grant this same user the `EVENT` privilege on all schemas, use the following statement:

```
GRANT EVENT ON *.* TO jon@ghidora;
```

The `EVENT` privilege has global or schema-level scope. Therefore, trying to grant it on a single table results in an error as shown:

```
mysql> GRANT EVENT ON myschema.mytable TO jon@ghidora;
ERROR 1144 (42000): Illegal GRANT/REVOKE command; please consult the manual to see which privileges can be used
```

It is important to understand that an event is executed with the privileges of its definer, and that it cannot perform any actions for which its definer does not have the requisite privileges. For example, suppose that `jon@ghidora` has the `EVENT` privilege for `myschema`. Suppose also that this user has the `SELECT` privilege for `myschema`, but no other privileges for this schema. It is possible for `jon@ghidora` to create a new event such as this one:

```
CREATE EVENT e_store_ts
  ON SCHEDULE EVERY 10 SECOND
  DO
    INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP());
```

The user waits for a minute or so, and then performs a `SELECT * FROM mytable;` query, expecting to see several new rows in the table. Instead, the table is empty. Since the user does not have the `INSERT` privilege for the table in question, the event has no effect.

If you inspect the MySQL error log (hostname.err), you can see that the event is executing, but the action it is attempting to perform fails, as indicated by `RetCode=0`:

```
060209 22:39:44 [Note]     EVEX EXECUTED event newdb.e  [EXPR:10]. RetCode=0  
060209 22:39:54 [Note]     EVEX EXECUTING event newdb.e [EXPR:10]  
060209 22:39:54 [Note]     EVEX EXECUTED event newdb.e  [EXPR:10]. RetCode=0  
060209 22:40:04 [Note]     EVEX EXECUTING event newdb.e [EXPR:10]  
060209 22:40:04 [Note]     EVEX EXECUTED event newdb.e  [EXPR:10]. RetCode=0  
```

Since this user very likely does not have access to the error log, it is possible to verify whether the event's action statement is valid by executing it directly:

```
mysql> INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP());
ERROR 1142 (42000): INSERT command denied to user 'jon'@'ghidora' for table 'mytable'
```
Inspection of the `INFORMATION_SCHEMA.EVENTS` table shows that `e_store_ts` exists and is enabled, but its `LAST_EXECUTED` column is `NULL`:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.EVENTS
    > WHERE EVENT_NAME='e_store_ts'
    > AND EVENT_SCHEMA='myschema'
```

```
*************************** 1. row ***************************
EVENT_CATALOG: NULL
EVENT_SCHEMA: myschema
EVENT_NAME: e_store_ts
DEFINER: jon@ghidora
EVENT_BODY: SQL
EVENT_DEFINITION: INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP())
EVENT_TYPE: RECURRING
EXECUTE_AT: NULL
INTERVAL_VALUE: 5
INTERVAL_FIELD: SECOND
SQL_MODE: NULL
STARTS: 0000-00-00 00:00:00
ENDS: 0000-00-00 00:00:00
STATUS: ENABLED
ON_COMPLETION: NOT PRESERVE
CREATED: 2006-02-09 22:36:06
LAST_ALTERED: 2006-02-09 22:36:06
LAST_EXECUTED: NULL
EVENT_COMMENT: 
1 row in set (0.00 sec)
```

To rescind the `EVENT` privilege, use the `REVOKE` statement. In this example, the `EVENT` privilege on the schema `myschema` is removed from the `jon@ghidora` user account:

```
REVOKE EVENT ON myschema.* FROM jon@ghidora;
```

**Important**

Revoking the `EVENT` privilege from a user does not delete or disable any events that may have been created by that user.

An event is not migrated or dropped as a result of renaming or dropping the user who created it.

Suppose that the user `jon@ghidora` has been granted the `EVENT` and `INSERT` privileges on the `myschema` schema. This user then creates the following event:

```
CREATE EVENT e_insert
    ON SCHEDULE
        EVERY 7 SECOND
    DO
        INSERT INTO myschema.mytable;
```

After this event has been created, `root` revokes the `EVENT` privilege for `jon@ghidora`. However, `e_insert` continues to execute, inserting a new row into `mytable` each seven seconds. The same would be true if `root` had issued either of these statements:

- `DROP USER jon@ghidora;`
- `RENAME USER jon@ghidora TO someotherguy@ghidora;`

You can verify that this is true by examining the `mysql.event` table (discussed later in this section) or the `INFORMATION_SCHEMA.EVENTS` table (see Section 21.8, "The INFORMATION_SCHEMA EVENTS Table") before and after issuing a `DROP USER` or `RENAME USER` statement.
Using Views

Event definitions are stored in the `mysql.event` table. To drop an event created by another user account, the MySQL `root` user (or another user with the necessary privileges) can delete rows from this table. For example, to remove the event `e_insert` shown previously, `root` can use the following statement:

```
DELETE FROM mysql.event
    WHERE db = 'myschema'
    AND name = 'e_insert';
```

It is very important to match the event name and database schema name when deleting rows from the `mysql.event` table. This is because different events of the same name can exist in different schemas.

Users' EVENT privileges are stored in the `Event_priv` columns of the `mysql.user` and `mysql.db` tables. In both cases, this column holds one of the values 'Y' or 'N'. 'N' is the default. `mysql.user.Event_priv` is set to 'Y' for a given user only if that user has the global EVENT privilege (that is, if the privilege was bestowed using `GRANT EVENT ON *.*`). For a schema-level EVENT privilege, `GRANT` creates a row in `mysql.db` and sets that row's `Db` column to the name of the schema, the `User` column to the name of the user, and the `Event_priv` column to 'Y'. There should never be any need to manipulate these tables directly, since the `GRANT EVENT` and `REVOKE EVENT` statements perform the required operations on them.

Five status variables provide counts of event-related operations (but not of statements executed by events; see Section 20.8, “Restrictions on Stored Programs”). These are:

- `Com_create_event`: The number of `CREATE EVENT` statements executed since the last server restart.
- `Com_alter_event`: The number of `ALTER EVENT` statements executed since the last server restart.
- `Com_drop_event`: The number of `DROP EVENT` statements executed since the last server restart.
- `Com_show_create_event`: The number of `SHOW CREATE EVENT` statements executed since the last server restart.
- `Com_show_events`: The number of `SHOW EVENTS` statements executed since the last server restart.

You can view current values for all of these at one time by running the statement `SHOW STATUS LIKE '%event%';`.

20.5 Using Views

MySQL supports views, including updatable views. Views are stored queries that when invoked produce a result set. A view acts as a virtual table.

To use views if you have upgraded to MySQL 5.6 from an older release that did not support views, you should upgrade your grant tables so that they contain the view-related privileges. See Section 4.4.7, “mysql_upgrade — Check and Upgrade MySQL Tables”.

The following discussion describes the syntax for creating and dropping views, and shows some examples of how to use them.

Additional Resources

- You may find the Views User Forum of use when working with views.
- For answers to some commonly asked questions regarding views in MySQL, see Section A.6, “MySQL 5.6 FAQ: Views”.
- There are some restrictions on the use of views; see Section 20.9, “Restrictions on Views”.
20.5.1 View Syntax

The CREATE VIEW statement creates a new view (see Section 13.1.20, “CREATE VIEW Syntax”). To alter the definition of a view or drop a view, use ALTER VIEW (see Section 13.1.9, “ALTER VIEW Syntax”), or DROP VIEW (see Section 13.1.31, “DROP VIEW Syntax”).

A view can be created from many kinds of SELECT statements. It can refer to base tables or other views. It can use joins, UNION, and subqueries. The SELECT need not even refer to any tables. The following example defines a view that selects two columns from another table, as well as an expression calculated from those columns:

```sql
mysql> CREATE TABLE t (qty INT, price INT);
mysql> INSERT INTO t VALUES(3, 50), (5, 60);
mysql> CREATE VIEW v AS SELECT qty, price, qty*price AS value FROM t;
mysql> SELECT * FROM v;
+------+-------+-------+
<table>
<thead>
<tr>
<th>qty</th>
<th>price</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>50</td>
<td>150</td>
</tr>
<tr>
<td>5</td>
<td>60</td>
<td>300</td>
</tr>
</tbody>
</table>
+------+-------+-------+
mysql> SELECT * FROM v WHERE qty = 5;
+------+-------+-------+
<table>
<thead>
<tr>
<th>qty</th>
<th>price</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>60</td>
<td>300</td>
</tr>
</tbody>
</table>
+------+-------+-------+
```

20.5.2 View Processing Algorithms

The optional ALGORITHM clause for CREATE VIEW or ALTER VIEW is a MySQL extension to standard SQL. It affects how MySQL processes the view. ALGORITHM takes three values: MERGE, TEMPTABLE, or UNDEFINED.

- For MERGE, the text of a statement that refers to the view and the view definition are merged such that parts of the view definition replace corresponding parts of the statement.
- For TEMPTABLE, the results from the view are retrieved into a temporary table, which then is used to execute the statement.
- For UNDEFINED, MySQL chooses which algorithm to use. It prefers MERGE over TEMPTABLE if possible, because MERGE is usually more efficient and because a view cannot be updatable if a temporary table is used.
- If no ALGORITHM clause is present, UNDEFINED is the default algorithm.

A reason to specify TEMPTABLE explicitly is that locks can be released on underlying tables after the temporary table has been created and before it is used to finish processing the statement. This might result in quicker lock release than the MERGE algorithm so that other clients that use the view are not blocked as long.

A view algorithm can be UNDEFINED for three reasons:

- No ALGORITHM clause is present in the CREATE VIEW statement.
- The CREATE VIEW statement has an explicit ALGORITHM = UNDEFINED clause.
- ALGORITHM = MERGE is specified for a view that can be processed only with a temporary table. In this case, MySQL generates a warning and sets the algorithm to UNDEFINED.
As mentioned earlier, **MERGE** is handled by merging corresponding parts of a view definition into the statement that refers to the view. The following examples briefly illustrate how the **MERGE** algorithm works. The examples assume that there is a view `v_merge` that has this definition:

```
CREATE ALGORITHM = MERGE VIEW v_merge (vc1, vc2) AS
SELECT c1, c2 FROM t WHERE c3 > 100;
```

**Example 1:** Suppose that we issue this statement:

```
SELECT * FROM v_merge;
```

MySQL handles the statement as follows:

- **v_merge** becomes **t**
- ***** becomes **vc1, vc2**, which corresponds to **c1, c2**
- The view **WHERE** clause is added

The resulting statement to be executed becomes:

```
SELECT c1, c2 FROM t WHERE c3 > 100;
```

**Example 2:** Suppose that we issue this statement:

```
SELECT * FROM v_merge WHERE vc1 < 100;
```

This statement is handled similarly to the previous one, except that **vc1 < 100** becomes **c1 < 100** and the view **WHERE** clause is added to the statement **WHERE** clause using an **AND** connective (and parentheses are added to make sure the parts of the clause are executed with correct precedence). The resulting statement to be executed becomes:

```
SELECT c1, c2 FROM t WHERE (c3 > 100) AND (c1 < 100);
```

Effectively, the statement to be executed has a **WHERE** clause of this form:

```
WHERE (select WHERE) AND (view WHERE)
```

If the **MERGE** algorithm cannot be used, a temporary table must be used instead. **MERGE** cannot be used if the view contains any of the following constructs:

- Aggregate functions (**SUM()**, **MIN()**, **MAX()**, **COUNT()**, and so forth)
- **DISTINCT**
- **GROUP BY**
- **HAVING**
- **LIMIT**
- **UNION** or **UNION ALL**
- Subquery in the select list
- Assignment to user variables
- Refers only to literal values (in this case, there is no underlying table)
20.5.3 Updatable and Insertable Views

Some views are updatable and references to them can be used to specify tables to be updated in data change statements. That is, you can use them in statements such as UPDATE, DELETE, or INSERT to update the contents of the underlying table.

For a view to be updatable, there must be a one-to-one relationship between the rows in the view and the rows in the underlying table. There are also certain other constructs that make a view nonupdatable. To be more specific, a view is not updatable if it contains any of the following:

- Aggregate functions (SUM(), MIN(), MAX(), COUNT(), and so forth)
- DISTINCT
- GROUP BY
- HAVING
- UNION or UNION ALL

Subquery in the select list

- Certain joins (see additional join discussion later in this section)

Reference to nonupdatable view in the FROM clause

Subquery in the WHERE clause that refers to a table in the FROM clause

- Refers only to literal values (in this case, there is no underlying table to update)

- ALGORITHM = TEMPTABLE (use of a temporary table always makes a view nonupdatable)

- Multiple references to any column of a base table

It is sometimes possible for a multiple-table view to be updatable, assuming that it can be processed with the MERGE algorithm. For this to work, the view must use an inner join (not an outer join or a UNION). Also, only a single table in the view definition can be updated, so the SET clause must name only columns from one of the tables in the view. Views that use UNION ALL are not permitted even though they might be theoretically updatable.

With respect to insertability (being updatable with INSERT statements), an updatable view is insertable if it also satisfies these additional requirements for the view columns:

- There must be no duplicate view column names.

- The view must contain all columns in the base table that do not have a default value.

- The view columns must be simple column references. They must not be expressions, such as these:

  3.14159
  col1 + 3
  UPPER(col2)
  col3 / col4
  (subquery)

MySQL sets a flag, called the view updatability flag, at CREATE VIEW time. The flag is set to YES (true) if UPDATE and DELETE (and similar operations) are legal for the view. Otherwise, the flag is set to NO (false). The IS_UPDATABLE column in the INFORMATION_SCHEMA.VIEWS table displays the status of this flag. It means that the server always knows whether a view is updatable.
If a view is not updatable, statements such as `UPDATE`, `DELETE`, and `INSERT` are illegal and are rejected. (Even if a view is updatable, it might not be possible to insert into it, as described elsewhere in this section.)

The updatability of views may be affected by the value of the `updatable_views_with_limit` system variable. See Section 5.1.7, “Server System Variables”.

Earlier discussion in this section pointed out that a view is not insertable if not all columns are simple column references (for example, if it contains columns that are expressions or composite expressions). Although such a view is not insertable, it can be updatable if you update only columns that are not expressions. Consider this view:

```sql
CREATE VIEW v AS SELECT col1, 1 AS col2 FROM t;
```

This view is not insertable because `col2` is an expression. But it is updatable if the update does not try to update `col2`. This update is permissible:

```sql
UPDATE v SET col1 = 0;
```

This update is not permissible because it attempts to update an expression column:

```sql
UPDATE v SET col2 = 0;
```

For a multiple-table updatable view, `INSERT` can work if it inserts into a single table. `DELETE` is not supported.

`INSERT DELAYED` is not supported for views.

If a table contains an `AUTO_INCREMENT` column, inserting into an insertable view on the table that does not include the `AUTO_INCREMENT` column does not change the value of `LAST_INSERT_ID()`, because the side effects of inserting default values into columns not part of the view should not be visible.

### 20.5.4 The View WITH CHECK OPTION Clause

The `WITH CHECK OPTION` clause can be given for an updatable view to prevent inserts to rows for which the `WHERE` clause in the `select_statement` is not true. It also prevents updates to rows for which the `WHERE` clause is true but the update would cause it to be not true (in other words, it prevents visible rows from being updated to nonvisible rows).

In a `WITH CHECK OPTION` clause for an updatable view, the `LOCAL` and `CASCADED` keywords determine the scope of check testing when the view is defined in terms of another view. When neither keyword is given, the default is `CASCADED`. The `LOCAL` keyword restricts the `CHECK OPTION` only to the view being defined. `CASCADED` causes the checks for underlying views to be evaluated as well.

Consider the definitions for the following table and set of views:

```sql
CREATE TABLE t1 (a INT);
CREATE VIEW v1 AS SELECT * FROM t1 WHERE a < 2
  WITH CHECK OPTION;
CREATE VIEW v2 AS SELECT * FROM v1 WHERE a > 0
  WITH LOCAL CHECK OPTION;
CREATE VIEW v3 AS SELECT * FROM v1 WHERE a > 0
  WITH CASCADED CHECK OPTION;
```

Here the `v2` and `v3` views are defined in terms of another view, `v1`. `v2` has a `LOCAL` check option, so inserts are tested only against the `v2` check. `v3` has a `CASCADED` check option, so inserts are tested not
only against its own check, but against those of underlying views. The following statements illustrate these differences:

```sql
mysql> INSERT INTO v2 VALUES (2);
Query OK, 1 row affected (0.00 sec)
mysql> INSERT INTO v3 VALUES (2);
ERROR 1369 (HY000): CHECK OPTION failed 'test.v3'
```

20.5.5 View Metadata

Metadata about views can be obtained as follows:

- Query the `VIEWS` table of the `INFORMATION_SCHEMA` database. See Section 21.29, “The `INFORMATION_SCHEMA VIEWS Table`”.
- Use the `SHOW CREATE VIEW` statement. See Section 13.7.5.14, “SHOW CREATE VIEW Syntax”.

20.6 Stored Object Access Control

Stored programs (procedures, functions, triggers, and events) and views are defined prior to use and, when referenced, execute within a security context that determines their privileges. These privileges are controlled by their `DEFINER` attribute and `SQL SECURITY` characteristic.

- The `DEFINER` Attribute
- The `SQL SECURITY` Characteristic
- Examples
- Risk-Minimization Guidelines

The `DEFINER` Attribute

All stored object definitions can include a `DEFINER` attribute that names a MySQL account. If a definition omits the `DEFINER` attribute, the default definer is the user who creates the object.

MySQL uses the following rules to control which accounts a user can specify in an object `DEFINER` attribute:

- If you have the `SUPER` privilege, you can specify any account as the `DEFINER` value, although a warning is generated if the account does not exist.
- Otherwise, the only permitted account is your own, either specified literally or as `CURRENT_USER` or `CURRENT_USER()`. You cannot set the definer to some other account.

Creating a stored object with a nonexistent `DEFINER` account may have negative consequences:

- For a stored routine, an error occurs at routine execution time if the `SQL SECURITY` value is `DEFINER` but the definer account does not exist.
- For a trigger, it is not a good idea for trigger activation to occur until the account actually does exist. Otherwise, the behavior with respect to privilege checking is undefined.
- For an event, an error occurs at event execution time if the account does not exist.
- For a view, an error occurs when the view is referenced if the `SQL SECURITY` value is `DEFINER` but the definer account does not exist.
The SQL SECURITY Characteristic

Definitions for stored routines (procedures and functions) and views can include an SQL SECURITY characteristic with a value of DEFINER or INVOKER to specify whether the object executes in definer or invoker context. If a definition omits the SQL SECURITY characteristic, the default is definer context.

Triggers and events have no SQL SECURITY characteristic and always execute in definer context. The server invokes these objects automatically as necessary, so there is no invoking user.

Definer and invoker security contexts differ as follows:

- A stored object that executes in definer security context executes with the privileges of the account named by its DEFINER attribute. These privileges may be entirely different from those of the invoking user. The invoker must have appropriate privileges to reference the object (for example, EXECUTE to call a stored procedure or SELECT to select from a view), but during object execution, the invoker's privileges are ignored and only the DEFINER account privileges matter. If the DEFINER account has few privileges, the object is correspondingly limited in the operations it can perform. If the DEFINER account is highly privileged (such as a root account), the object can perform powerful operations no matter who invokes it.

- A stored routine or view that executes in invoker security context can perform only operations for which the invoker has privileges. The DEFINER attribute has no effect during object execution.

Examples

Consider the following stored procedure, which is declared with SQL SECURITY DEFINER to execute in definer security context:

```sql
CREATE DEFINER = 'admin'@'localhost' PROCEDURE p1()
SQL SECURITY DEFINER
BEGIN
  UPDATE t1 SET counter = counter + 1;
END;
```

Any user who has the EXECUTE privilege for `p1` can invoke it with a CALL statement. However, when `p1` executes, it does so in definer security context and thus executes with the privileges of `'admin'@'localhost'`, the account named in the DEFINER attribute. This account must have the EXECUTE privilege for `p1` as well as the UPDATE privilege for the table `t1` referenced within the object body. Otherwise, the procedure fails.

Now consider this stored procedure, which is identical to `p1` except that its SQL SECURITY characteristic is INVOKER:

```sql
CREATE DEFINER = 'admin'@'localhost' PROCEDURE p2()
SQL SECURITY INVOKER
BEGIN
  UPDATE t1 SET counter = counter + 1;
END;
```

Unlike `p1`, `p2` executes in invoker security context and thus with the privileges of the invoking user regardless of the DEFINER attribute value. `p2` fails if the invoker lacks the EXECUTE privilege for `p2` or the UPDATE privilege for the table `t1`.

Risk-Minimization Guidelines

To minimize the risk potential for stored object creation and use, follow these guidelines:
• For a stored routine or view, use `SQL SECURITY INVOKER` in the object definition when possible so that it can be used only by users with permissions appropriate for the operations performed by the object.

• If you create definer-context stored objects while using an account that has the `SUPER` privilege, specify an explicit `DEFINER` attribute that names an account possessing only the privileges required for the operations performed by the object. Specify a highly privileged `DEFINER` account only when absolutely necessary.

• Administrators can prevent users from creating stored objects that specify highly privileged `DEFINER` accounts by not granting them the `SUPER` privilege.

• Definer-context objects should be written keeping in mind that they may be able to access data for which the invoking user has no privileges. In some cases, you can prevent references to these objects by not granting unauthorized users particular privileges:
  - A stored routine cannot be referenced by a user who does not have the `EXECUTE` privilege for it.
  - A view cannot be referenced by a user who does not have the appropriate privilege for it (`SELECT` to select from it, `INSERT` to insert into it, and so forth).

However, no such control exists for triggers and events because they always execute in definer context. The server invokes these objects automatically as necessary; users do not reference them directly:

• A trigger is activated by access to the table with which it is associated, even ordinary table accesses by users with no special privileges.

• An event is executed by the server on a scheduled basis.

In both cases, if the `DEFINER` account is highly privileged, the object may be able to perform sensitive or dangerous operations. This remains true if the privileges needed to create the object are revoked from the account of the user who created it. Administrators should be especially careful about granting users object-creation privileges.

### 20.7 Stored Program Binary Logging

The binary log contains information about SQL statements that modify database contents. This information is stored in the form of “events” that describe the modifications. (Binary log events differ from scheduled event stored objects.) The binary log has two important purposes:

• For replication, the binary log is used on master replication servers as a record of the statements to be sent to slave servers. The master server sends the events contained in its binary log to its slaves, which execute those events to make the same data changes that were made on the master. See Section 17.2, “Replication Implementation”.

• Certain data recovery operations require use of the binary log. After a backup file has been restored, the events in the binary log that were recorded after the backup was made are re-executed. These events bring databases up to date from the point of the backup. See Section 7.3.2, “Using Backups for Recovery”.

However, if logging occurs at the statement level, there are certain binary logging issues with respect to stored programs (stored procedures and functions, triggers, and events):

• In some cases, a statement might affect different sets of rows on master and slave.

• Replicated statements executed on a slave are processed by the slave SQL thread, which has full privileges. It is possible for a procedure to follow different execution paths on master and slave servers.
so a user can write a routine containing a dangerous statement that will execute only on the slave where it is processed by a thread that has full privileges.

- If a stored program that modifies data is nondeterministic, it is not repeatable. This can result in different data on master and slave, or cause restored data to differ from the original data.

This section describes how MySQL handles binary logging for stored programs. It states the current conditions that the implementation places on the use of stored programs, and what you can do to avoid logging problems. It also provides additional information about the reasons for these conditions.

In general, the issues described here result when binary logging occurs at the SQL statement level (statement-based binary logging). If you use row-based binary logging, the log contains changes made to individual rows as a result of executing SQL statements. When routines or triggers execute, row changes are logged, not the statements that make the changes. For stored procedures, this means that the `CALL` statement is not logged. For stored functions, row changes made within the function are logged, not the function invocation. For triggers, row changes made by the trigger are logged. On the slave side, only the row changes are seen, not the stored program invocation.

Mixed format binary logging (`binlog_format=MIXED`) uses statement-based binary logging, except for cases where only row-based binary logging is guaranteed to lead to proper results. With mixed format, when a stored function, stored procedure, trigger, event, or prepared statement contains anything that is not safe for statement-based binary logging, the entire statement is marked as unsafe and logged in row format. The statements used to create and drop procedures, functions, triggers, and events are always safe, and are logged in statement format. For more information about row-based, mixed, and statement-based logging, and how safe and unsafe statements are determined, see Section 17.1.2, "Replication Formats".

Unless noted otherwise, the remarks here assume that binary logging is enabled on the server (see Section 5.4.4, "The Binary Log"). If the binary log is not enabled, replication is not possible, nor is the binary log available for data recovery.

The conditions on the use of stored functions in MySQL can be summarized as follows. These conditions do not apply to stored procedures or Event Scheduler events and they do not apply unless binary logging is enabled.

- To create or alter a stored function, you must have the `SUPER` privilege, in addition to the `CREATE ROUTINE` or `ALTER ROUTINE` privilege that is normally required. (Depending on the `DEFINER` value in the function definition, `SUPER` might be required regardless of whether binary logging is enabled. See Section 13.1.15, "CREATE PROCEDURE and CREATE FUNCTION Syntax").

- When you create a stored function, you must declare either that it is deterministic or that it does not modify data. Otherwise, it may be unsafe for data recovery or replication.

By default, for a `CREATE FUNCTION` statement to be accepted, at least one of `DETERMINISTIC`, `NO SQL`, or `READS SQL DATA` must be specified explicitly. Otherwise an error occurs:

```
ERROR 1418 (HY000): This function has none of DETERMINISTIC, NO SQL, or READS SQL DATA in its declaration and binary logging is enabled (you *might* want to use the less safe log_bin_trust_function_creators variable)
```

This function is deterministic (and does not modify data), so it is safe:

```
CREATE FUNCTION f1(i INT)
RETURNS INT
DETERMINISTIC
READS SQL DATA
```
This function uses `UUID()`, which is not deterministic, so the function also is not deterministic and is not safe:

```sql
CREATE FUNCTION f2()
RETURNS CHAR(36) CHARACTER SET utf8
BEGIN
    RETURN UUID();
END;
```

This function modifies data, so it may not be safe:

```sql
CREATE FUNCTION f3(p_id INT)
RETURNS INT
BEGIN
    UPDATE t SET modtime = NOW() WHERE id = p_id;
    RETURN ROW_COUNT();
END;
```

Assessment of the nature of a function is based on the “honesty” of the creator. MySQL does not check that a function declared `DETERMINISTIC` is free of statements that produce nondeterministic results.

- When you attempt to execute a stored function, if `binlog_format=STATEMENT` is set, the `DETERMINISTIC` keyword must be specified in the function definition. If this is not the case, an error is generated and the function does not run, unless `log_bin_trust_function_creators=1` is specified to override this check (see below). For recursive function calls, the `DETERMINISTIC` keyword is required on the outermost call only. If row-based or mixed binary logging is in use, the statement is accepted and replicated even if the function was defined without the `DETERMINISTIC` keyword.

- Because MySQL does not check if a function really is deterministic at creation time, the invocation of a stored function with the `DETERMINISTIC` keyword might carry out an action that is unsafe for statement-based logging, or invoke a function or procedure containing unsafe statements. If this occurs when `binlog_format=STATEMENT` is set, a warning message is issued. If row-based or mixed binary logging is in use, no warning is issued, and the statement is replicated in row-based format.

- To relax the preceding conditions on function creation (that you must have the `SUPER` privilege and that a function must be declared deterministic or to not modify data), set the global `log_bin_trust_function_creators` system variable to 1. By default, this variable has a value of 0, but you can change it like this:

```
mysql> SET GLOBAL log_bin_trust_function_creators = 1;
```

You can also set this variable at server startup.

If binary logging is not enabled, `log_bin_trust_function_creators` does not apply. `SUPER` is not required for function creation unless, as described previously, the `DEFINER` value in the function definition requires it.

- For information about built-in functions that may be unsafe for replication (and thus cause stored functions that use them to be unsafe as well), see Section 17.4.1, “Replication Features and Issues”.

Triggers are similar to stored functions, so the preceding remarks regarding functions also apply to triggers with the following exception: `CREATE TRIGGER` does not have an optional `DETERMINISTIC` characteristic, so triggers are assumed to be always deterministic. However, this assumption might be invalid in some
cases. For example, the `UUID()` function is nondeterministic (and does not replicate). Be careful about using such functions in triggers.

Triggers can update tables, so error messages similar to those for stored functions occur with `CREATE TRIGGER` if you do not have the required privileges. On the slave side, the slave uses the trigger `DEFINER` attribute to determine which user is considered to be the creator of the trigger.

The rest of this section provides additional detail about the logging implementation and its implications. You need not read it unless you are interested in the background on the rationale for the current logging-related conditions on stored routine use. This discussion applies only for statement-based logging, and not for row-based logging, with the exception of the first item: `CREATE` and `DROP` statements are logged as statements regardless of the logging mode.

- The server writes `CREATE EVENT`, `CREATE PROCEDURE`, `CREATE FUNCTION`, `ALTER EVENT`, `ALTER PROCEDURE`, `ALTER FUNCTION`, `DROP EVENT`, `DROP PROCEDURE`, and `DROP FUNCTION` statements to the binary log.

- A stored function invocation is logged as a `SELECT` statement if the function changes data and occurs within a statement that would not otherwise be logged. This prevents nonreplication of data changes that result from use of stored functions in nonlogged statements. For example, `SELECT` statements are not written to the binary log, but a `SELECT` might invoke a stored function that makes changes. To handle this, a `SELECT func_name()` statement is written to the binary log when the given function makes a change. Suppose that the following statements are executed on the master:

```sql
CREATE FUNCTION f1(a INT) RETURNS INT
BEGIN
  IF (a < 3) THEN
    INSERT INTO t2 VALUES (a);
  END IF;
  RETURN 0;
END;

CREATE TABLE t1 (a INT);
INSERT INTO t1 VALUES (1),(2),(3);
SELECT f1(a) FROM t1;
```

When the `SELECT` statement executes, the function `f1()` is invoked three times. Two of those invocations insert a row, and MySQL logs a `SELECT` statement for each of them. That is, MySQL writes the following statements to the binary log:

```sql
SELECT f1(1);
SELECT f1(2);
```

The server also logs a `SELECT` statement for a stored function invocation when the function invokes a stored procedure that causes an error. In this case, the server writes the `SELECT` statement to the log along with the expected error code. On the slave, if the same error occurs, that is the expected result and replication continues. Otherwise, replication stops.

- Logging stored function invocations rather than the statements executed by a function has a security implication for replication, which arises from two factors:
  - It is possible for a function to follow different execution paths on master and slave servers.
  - Statements executed on a slave are processed by the slave SQL thread which has full privileges.

The implication is that although a user must have the `CREATE ROUTINE` privilege to create a function, the user can write a function containing a dangerous statement that will execute only on the slave where
it is processed by a thread that has full privileges. For example, if the master and slave servers have server ID values of 1 and 2, respectively, a user on the master server could create and invoke an unsafe function `unsafe_func()` as follows:

```sql
mysql> delimiter //
mysql> CREATE FUNCTION unsafe_func () RETURNS INT
    
    -> BEGIN
    -> IF @@server_id=2 THEN dangerous_statement; END IF;
    -> RETURN 1;
    -> END;
    -> //
mysql> delimiter ;
mysql> INSERT INTO t VALUES(unsafe_func());
```

The `CREATE FUNCTION` and `INSERT` statements are written to the binary log, so the slave will execute them. Because the slave SQL thread has full privileges, it will execute the dangerous statement. Thus, the function invocation has different effects on the master and slave and is not replication-safe.

To guard against this danger for servers that have binary logging enabled, stored function creators must have the `SUPER` privilege, in addition to the usual `CREATE ROUTINE` privilege that is required. Similarly, to use `ALTER FUNCTION`, you must have the `SUPER` privilege in addition to the `ALTER ROUTINE` privilege. Without the `SUPER` privilege, an error will occur:

```
ERROR 1419 (HY000): You do not have the SUPER privilege and binary logging is enabled (you *might* want to use the less safe log_bin_trust_function_creators variable)
```

If you do not want to require function creators to have the `SUPER` privilege (for example, if all users with the `CREATE ROUTINE` privilege on your system are experienced application developers), set the global `log_bin_trust_function_creators` system variable to 1. You can also set this variable at server startup. If binary logging is not enabled, `log_bin_trust_function_creators` does not apply. `SUPER` is not required for function creation unless, as described previously, the `DEFINER` value in the function definition requires it.

- If a function that performs updates is nondeterministic, it is not repeatable. This can have two undesirable effects:
  - It will make a slave different from the master.
  - Restored data will be different from the original data.

To deal with these problems, MySQL enforces the following requirement: On a master server, creation and alteration of a function is refused unless you declare the function to be deterministic or to not modify data. Two sets of function characteristics apply here:

- The `DETERMINISTIC` and `NOT DETERMINISTIC` characteristics indicate whether a function always produces the same result for given inputs. The default is `NOT DETERMINISTIC` if neither characteristic is given. To declare that a function is deterministic, you must specify `DETERMINISTIC` explicitly.

- The `CONTAINS SQL`, `NO SQL`, `READS SQL DATA`, and `MODIFIES SQL DATA` characteristics provide information about whether the function reads or writes data. Either `NO SQL` or `READS SQL DATA` indicates that a function does not change data, but you must specify one of these explicitly because the default is `CONTAINS SQL` if no characteristic is given.
By default, for a `CREATE FUNCTION` statement to be accepted, at least one of `DETERMINISTIC`, `NO SQL`, or `READS SQL DATA` must be specified explicitly. Otherwise an error occurs:

```
ERROR 1418 (HY000): This function has none of DETERMINISTIC, NO SQL, or READS SQL DATA in its declaration and binary logging is enabled
(you "might" want to use the less safe log_bin_trust_function_creators variable)
```

If you set `log_bin_trust_function_creators` to 1, the requirement that functions be deterministic or not modify data is dropped.

- Stored procedure calls are logged at the statement level rather than at the `CALL` level. That is, the server does not log the `CALL` statement, it logs those statements within the procedure that actually execute. As a result, the same changes that occur on the master will be observed on slave servers. This prevents problems that could result from a procedure having different execution paths on different machines.

In general, statements executed within a stored procedure are written to the binary log using the same rules that would apply were the statements to be executed in standalone fashion. Some special care is taken when logging procedure statements because statement execution within procedures is not quite the same as in nonprocedure context:

- A statement to be logged might contain references to local procedure variables. These variables do not exist outside of stored procedure context, so a statement that refers to such a variable cannot be logged literally. Instead, each reference to a local variable is replaced by this construct for logging purposes:

```
NAME_CONST(var_name, var_value)
```

`var_name` is the local variable name, and `var_value` is a constant indicating the value that the variable has at the time the statement is logged. `NAME_CONST()` has a value of `var_value`, and a “name” of `var_name`. Thus, if you invoke this function directly, you get a result like this:

```
mysql> SELECT NAME_CONST('myname', 14);
+--------+
| myname |
| 14     |
+--------+
```

`NAME_CONST()` enables a logged standalone statement to be executed on a slave with the same effect as the original statement that was executed on the master within a stored procedure.

The use of `NAME_CONST()` can result in a problem for `CREATE TABLE ... SELECT` statements when the source column expressions refer to local variables. Converting these references to `NAME_CONST()` expressions can result in column names that are different on the master and slave servers, or names that are too long to be legal column identifiers. A workaround is to supply aliases for columns that refer to local variables. Consider this statement when `myvar` has a value of 1:

```
CREATE TABLE t1 SELECT myvar;
```

That will be rewritten as follows:

```
CREATE TABLE t1 SELECT NAME_CONST(myvar, 1);
```
To ensure that the master and slave tables have the same column names, write the statement like this:

```
CREATE TABLE t1 SELECT myvar AS myvar;
```

The rewritten statement becomes:

```
CREATE TABLE t1 SELECT NAME_CONST(myvar, 1) AS myvar;
```

- A statement to be logged might contain references to user-defined variables. To handle this, MySQL writes a `SET` statement to the binary log to make sure that the variable exists on the slave with the same value as on the master. For example, if a statement refers to a variable `@my_var`, that statement will be preceded in the binary log by the following statement, where `value` is the value of `@my_var` on the master:

  ```
  SET @my_var = value;
  ```

- Procedure calls can occur within a committed or rolled-back transaction. Transactional context is accounted for so that the transactional aspects of procedure execution are replicated correctly. That is, the server logs those statements within the procedure that actually execute and modify data, and also logs `BEGIN`, `COMMIT`, and `ROLLBACK` statements as necessary. For example, if a procedure updates only transactional tables and is executed within a transaction that is rolled back, those updates are not logged. If the procedure occurs within a committed transaction, `BEGIN` and `COMMIT` statements are logged with the updates. For a procedure that executes within a transaction that is rolled back, its statements are logged using the same rules that would apply if the statements were executed in standalone fashion:

  - Updates to transactional tables are not logged.
  - Updates to nontransactional tables are logged because rollback does not cancel them.
  - Updates to a mix of transactional and nontransactional tables are logged surrounded by `BEGIN` and `ROLLBACK` so that slaves will make the same changes and rollbacks as on the master.

  - A stored procedure call is not written to the binary log at the statement level if the procedure is invoked from within a stored function. In that case, the only thing logged is the statement that invokes the function (if it occurs within a statement that is logged) or a `DO` statement (if it occurs within a statement that is not logged). For this reason, care should be exercised in the use of stored functions that invoke a procedure, even if the procedure is otherwise safe in itself.

### 20.8 Restrictions on Stored Programs

These restrictions apply to the features described in Chapter 20, *Stored Objects*.

Some of the restrictions noted here apply to all stored routines; that is, both to stored procedures and stored functions. There are also some restrictions specific to stored functions but not to stored procedures.

The restrictions for stored functions also apply to triggers. There are also some restrictions specific to triggers.

The restrictions for stored procedures also apply to the `DO` clause of Event Scheduler event definitions. There are also some restrictions specific to events.
SQL Statements Not Permitted in Stored Routines

Stored routines cannot contain arbitrary SQL statements. The following statements are not permitted:

- The locking statements `LOCK TABLES` and `UNLOCK TABLES`.
- `ALTER VIEW`.
- `LOAD DATA` and `LOAD TABLE`.
- SQL prepared statements (`PREPARE`, `EXECUTE`, `DEALLOCATE PREPARE`) can be used in stored procedures, but not stored functions or triggers. Thus, stored functions and triggers cannot use dynamic SQL (where you construct statements as strings and then execute them).

Generally, statements not permitted in SQL prepared statements are also not permitted in stored programs. For a list of statements supported as prepared statements, see Section 13.5, “Prepared SQL Statement Syntax”. Exceptions are `SIGNAL`, `RESIGNAL`, and `GET DIAGNOSTICS`, which are not permissible as prepared statements but are permitted in stored programs.

Because local variables are in scope only during stored program execution, references to them are not permitted in prepared statements created within a stored program. Prepared statement scope is the current session, not the stored program, so the statement could be executed after the program ends, at which point the variables would no longer be in scope. For example, `SELECT ... INTO local_var` cannot be used as a prepared statement. This restriction also applies to stored procedure and function parameters. See Section 13.5.1, “PREPARE Syntax”.

- Inserts cannot be delayed. `INSERT DELAYED` syntax is accepted, but the statement is handled as a normal `INSERT`.

- Within all stored programs (stored procedures and functions, triggers, and events), the parser treats `BEGIN [WORK]` as the beginning of a `BEGIN ... END` block. To begin a transaction in this context, use `START TRANSACTION` instead.

Restrictions for Stored Functions

The following additional statements or operations are not permitted within stored functions. They are permitted within stored procedures, except stored procedures that are invoked from within a stored function or trigger. For example, if you use `FLUSH` in a stored procedure, that stored procedure cannot be called from a stored function or trigger.

- Statements that perform explicit or implicit commit or rollback. Support for these statements is not required by the SQL standard, which states that each DBMS vendor may decide whether to permit them.

- Statements that return a result set. This includes `SELECT` statements that do not have an `INTO var_list` clause and other statements such as `SHOW`, `EXPLAIN`, and `CHECK TABLE`. A function can process a result set either with `SELECT ... INTO var_list` or by using a cursor and `FETCH` statements. See Section 13.2.9.1, “SELECT ... INTO Syntax”, and Section 13.6.6, “Cursors”.

- `FLUSH` statements.

- Stored functions cannot be used recursively.

- A stored function or trigger cannot modify a table that is already being used (for reading or writing) by the statement that invoked the function or trigger.

- If you refer to a temporary table multiple times in a stored function under different aliases, a `Can't reopen table: 'tbl_name'` error occurs, even if the references occur in different statements within the function.
• **HANDLER ... READ** statements that invoke stored functions can cause replication errors and are disallowed.

**Restrictions for Triggers**

For triggers, the following additional restrictions apply:

• Triggers are not activated by foreign key actions.

• When using row-based replication, triggers on the slave are not activated by statements originating on the master. The triggers on the slave are activated when using statement-based replication. For more information, see Section 17.4.1.33, “Replication and Triggers”.

• The **RETURN** statement is not permitted in triggers, which cannot return a value. To exit a trigger immediately, use the **LEAVE** statement.

• Triggers are not permitted on tables in the **mysql** database. Nor are they permitted on **INFORMATION_SCHEMA** or **performance_schema** tables. Those tables are actually views and triggers are not permitted on views.

• The trigger cache does not detect when metadata of the underlying objects has changed. If a trigger uses a table and the table has changed since the trigger was loaded into the cache, the trigger operates using the outdated metadata.

**Name Conflicts within Stored Routines**

The same identifier might be used for a routine parameter, a local variable, and a table column. Also, the same local variable name can be used in nested blocks. For example:

```sql
CREATE PROCEDURE p (i INT)
BEGIN
  DECLARE i INT DEFAULT 0;
  SELECT i FROM t;
  BEGIN
    DECLARE i INT DEFAULT 1;
    SELECT i FROM t;
  END;
END;
```

In such cases, the identifier is ambiguous and the following precedence rules apply:

• A local variable takes precedence over a routine parameter or table column.

• A routine parameter takes precedence over a table column.

• A local variable in an inner block takes precedence over a local variable in an outer block.

The behavior that variables take precedence over table columns is nonstandard.

**Replication Considerations**

Use of stored routines can cause replication problems. This issue is discussed further in Section 20.7, “Stored Program Binary Logging”.

The **--replicate-wild-do-table=db_name.tbl_name** option applies to tables, views, and triggers. It does not apply to stored procedures and functions, or events. To filter statements operating on the latter objects, use one or more of the **--replicate-*-db** options.
Debugging Considerations

There are no stored routine debugging facilities.

Unsupported Syntax from the SQL:2003 Standard

The MySQL stored routine syntax is based on the SQL:2003 standard. The following items from that standard are not currently supported:

- **UNDO** handlers
- **FOR** loops

Stored Routine Concurrency Considerations

To prevent problems of interaction between sessions, when a client issues a statement, the server uses a snapshot of routines and triggers available for execution of the statement. That is, the server calculates a list of procedures, functions, and triggers that may be used during execution of the statement, loads them, and then proceeds to execute the statement. While the statement executes, it does not see changes to routines performed by other sessions.

For maximum concurrency, stored functions should minimize their side-effects; in particular, updating a table within a stored function can reduce concurrent operations on that table. A stored function acquires table locks before executing, to avoid inconsistency in the binary log due to mismatch of the order in which statements execute and when they appear in the log. When statement-based binary logging is used, statements that invoke a function are recorded rather than the statements executed within the function. Consequently, stored functions that update the same underlying tables do not execute in parallel. In contrast, stored procedures do not acquire table-level locks. All statements executed within stored procedures are written to the binary log, even for statement-based binary logging. See Section 20.7, “Stored Program Binary Logging”.

Event Scheduler Restrictions

The following limitations are specific to the Event Scheduler:

- Event names are handled in case-insensitive fashion. For example, you cannot have two events in the same database with the names `anEvent` and `AnEvent`.
- An event may not be created, altered, or dropped from within a stored program, if the event name is specified by means of a variable. An event also may not create, alter, or drop stored routines or triggers.
- DDL statements on events are prohibited while a `LOCK TABLES` statement is in effect.
- Event timings using the intervals **YEAR**, **QUARTER**, **MONTH**, and **YEAR_MONTH** are resolved in months; those using any other interval are resolved in seconds. There is no way to cause events scheduled to occur at the same second to execute in a given order. In addition—due to rounding, the nature of threaded applications, and the fact that a nonzero length of time is required to create events and to signal their execution—events may be delayed by as much as 1 or 2 seconds. However, the time shown in the `INFORMATION_SCHEMA.EVENTS` table's `LAST_EXECUTED` column or the `mysql.event` table's `last_executed` column is always accurate to within one second of the actual event execution time. (See also Bug #16522.)
- Each execution of the statements contained in the body of an event takes place in a new connection; thus, these statements has no effect in a given user session on the server's statement counts such
as `Com_select` and `Com_insert` that are displayed by `SHOW STATUS`. However, such counts are updated in the global scope. (Bug #16422)

- Events do not support times later than the end of the Unix Epoch; this is approximately the beginning of the year 2038. Such dates are specifically not permitted by the Event Scheduler. (Bug #16396)

- References to stored functions, user-defined functions, and tables in the `ON SCHEDULE` clauses of `CREATE EVENT` and `ALTER EVENT` statements are not supported. These sorts of references are not permitted. (See Bug #22830 for more information.)

**Stored routines and triggers in NDB Cluster.** Stored procedures, stored functions, and triggers are all supported by tables using the NDB storage engine; however, it is important to keep in mind that they do not propagate automatically between MySQL Servers acting as Cluster SQL nodes. This is because of the following:

- Stored routine definitions are kept in tables in the `mysql` system database using the MyISAM storage engine, and so do not participate in clustering.

- The `.TRN` and `.TRG` files containing trigger definitions are not read by the NDB storage engine, and are not copied between Cluster nodes.

Any stored routine or trigger that interacts with NDB Cluster tables must be re-created by running the appropriate `CREATE PROCEDURE`, `CREATE FUNCTION`, or `CREATE TRIGGER` statements on each MySQL Server that participates in the cluster where you wish to use the stored routine or trigger. Similarly, any changes to existing stored routines or triggers must be carried out explicitly on all Cluster SQL nodes, using the appropriate `ALTER` or `DROP` statements on each MySQL Server accessing the cluster.

**Warning**

Do not attempt to work around the issue described in the first item mentioned previously by converting any `mysql` database tables to use the NDB storage engine. Altering the system tables in the `mysql` database is not supported and is very likely to produce undesirable results.

### 20.9 Restrictions on Views

The maximum number of tables that can be referenced in the definition of a view is 61.

View processing is not optimized:

- It is not possible to create an index on a view.

- Indexes can be used for views processed using the merge algorithm. However, a view that is processed with the temptable algorithm is unable to take advantage of indexes on its underlying tables (although indexes can be used during generation of the temporary tables).

Subqueries cannot be used in the `FROM` clause of a view.

There is a general principle that you cannot modify a table and select from the same table in a subquery. See Section 13.2.10.12, "Restrictions on Subqueries".

The same principle also applies if you select from a view that selects from the table, if the view selects from the table in a subquery and the view is evaluated using the merge algorithm. Example:

```sql
CREATE VIEW v1 AS
SELECT * FROM t2 WHERE EXISTS (SELECT 1 FROM t1 WHERE t1.a = t2.a);
```
Restrictions on Views

```sql
UPDATE t1, v2 SET t1.a = 1 WHERE t1.b = v2.b;
```

If the view is evaluated using a temporary table, you can select from the table in the view subquery and still modify that table in the outer query. In this case the view will be stored in a temporary table and thus you are not really selecting from the table in a subquery and modifying it “at the same time.” (This is another reason you might wish to force MySQL to use the temptable algorithm by specifying `ALGORITHM = TEMPTABLE` in the view definition.)

You can use `DROP TABLE` or `ALTER TABLE` to drop or alter a table that is used in a view definition. No warning results from the `DROP` or `ALTER` operation, even though this invalidates the view. Instead, an error occurs later, when the view is used. `CHECK TABLE` can be used to check for views that have been invalidated by `DROP` or `ALTER` operations.

Before MySQL 5.6.5, a view definition is “frozen” by certain statements. If a statement prepared by `PREPARE` refers to a view, the view definition seen each time the statement is executed later will be the definition of the view at the time it was prepared. This is true even if the view definition is changed after the statement is prepared and before it is executed. In the following example, the result returned by the `EXECUTE` statement is a random number, not the current date and time:

```sql
CREATE VIEW v AS SELECT RAND();
PREPARE s FROM 'SELECT * FROM v';
ALTER VIEW v AS SELECT NOW();
EXECUTE s;
```

With regard to view updatability, the overall goal for views is that if any view is theoretically updatable, it should be updatable in practice. MySQL as quickly as possible. Many theoretically updatable views can be updated now, but limitations still exist. For details, see Section 20.5.3, “Updatable and Insertable Views”.

There exists a shortcoming with the current implementation of views. If a user is granted the basic privileges necessary to create a view (the `CREATE VIEW` and `SELECT` privileges), that user will be unable to call `SHOW CREATE VIEW` on that object unless the user is also granted the `SHOW VIEW` privilege.

That shortcoming can lead to problems backing up a database with `mysqldump`, which may fail due to insufficient privileges. This problem is described in Bug #22062.

The workaround to the problem is for the administrator to manually grant the `SHOW VIEW` privilege to users who are granted `CREATE VIEW`, since MySQL doesn't grant it implicitly when views are created.

Views do not have indexes, so index hints do not apply. Use of index hints when selecting from a view is not permitted.

`SHOW CREATE VIEW` displays view definitions using an `AS alias_name` clause for each column. If a column is created from an expression, the default alias is the expression text, which can be quite long. Aliases for column names in `CREATE VIEW` statements are checked against the maximum column length of 64 characters (not the maximum alias length of 256 characters). As a result, views created from the output of `SHOW CREATE VIEW` fail if any column alias exceeds 64 characters. This can cause problems in the following circumstances for views with too-long aliases:

- View definitions fail to replicate to newer slaves that enforce the column-length restriction.
- Dump files created with `mysqldump` cannot be loaded into servers that enforce the column-length restriction.

A workaround for either problem is to modify each problematic view definition to use aliases that provide shorter column names. Then the view will replicate properly, and can be dumped and reloaded without
causing an error. To modify the definition, drop and create the view again with `DROP VIEW` and `CREATE VIEW`, or replace the definition with `CREATE OR REPLACE VIEW`.

For problems that occur when reloading view definitions in dump files, another workaround is to edit the dump file to modify its `CREATE VIEW` statements. However, this does not change the original view definitions, which may cause problems for subsequent dump operations.

21.1 Introduction

**INFORMATION_SCHEMA** provides access to database metadata, information about the MySQL server such as the name of a database or table, the data type of a column, or access privileges. Other terms that are sometimes used for this information are data dictionary and system catalog.

- **INFORMATION_SCHEMA Usage Notes**
- Character Set Considerations
- **INFORMATION_SCHEMA** as Alternative to SHOW Statements
- **INFORMATION_SCHEMA** and Privileges
- Performance Considerations
- Standards Considerations
- Conventions in the INFORMATION_SCHEMA Reference Sections
- Related Information

**INFORMATION_SCHEMA** Usage Notes

**INFORMATION_SCHEMA** is a database within each MySQL instance, the place that stores information about all the other databases that the MySQL server maintains. The **INFORMATION_SCHEMA** database contains several read-only tables. They are actually views, not base tables, so there are no files associated with them, and you cannot set triggers on them. Also, there is no database directory with that name.

Although you can select **INFORMATION_SCHEMA** as the default database with a **USE** statement, you can only read the contents of tables, not perform **INSERT**, **UPDATE**, or **DELETE** operations on them.
Here is an example of a statement that retrieves information from `INFORMATION_SCHEMA`:

```sql
mysql> SELECT table_name, table_type, engine
    FROM information_schema.tables
    WHERE table_schema = 'db5'
    ORDER BY table_name;
+------------+------------+--------+
| table_name | table_type | engine |
+------------+------------+--------+
| fk         | BASE TABLE | InnoDB |
| fk2        | BASE TABLE | InnoDB |
| goto       | BASE TABLE | MyISAM |
| into       | BASE TABLE | MyISAM |
| k          | BASE TABLE | MyISAM |
| kurs       | BASE TABLE | MyISAM |
| loop       | BASE TABLE | MyISAM |
| pk         | BASE TABLE | InnoDB |
| t          | BASE TABLE | MyISAM |
| t2         | BASE TABLE | MyISAM |
| t3         | BASE TABLE | MyISAM |
| t7         | BASE TABLE | MyISAM |
| tables     | BASE TABLE | MyISAM |
| v          | VIEW       | NULL   |
| v2         | VIEW       | NULL   |
| v3         | VIEW       | NULL   |
| v56        | VIEW       | NULL   |
+------------+------------+--------+
17 rows in set (0.01 sec)
```

Explanation: The statement requests a list of all the tables in database `db5`, showing just three pieces of information: the name of the table, its type, and its storage engine.

**Character Set Considerations**

The definition for character columns (for example, `TABLES.TABLE_NAME`) is generally `VARCHAR(N) CHARACTER SET utf8` where `N` is at least 64. MySQL uses the default collation for this character set (`utf8_general_ci`) for all searches, sorts, comparisons, and other string operations on such columns.

Because some MySQL objects are represented as files, searches in `INFORMATION_SCHEMA` string columns can be affected by file system case sensitivity. For more information, see Section 10.8.7, “Using Collation in INFORMATION_SCHEMA Searches”.

**INFORMATION_SCHEMA as Alternative to SHOW Statements**

The `SELECT ... FROM INFORMATION_SCHEMA` statement is intended as a more consistent way to provide access to the information provided by the various `SHOW` statements that MySQL supports (`SHOW DATABASES`, `SHOW TABLES`, and so forth). Using `SELECT` has these advantages, compared to `SHOW`:

- It conforms to Codd’s rules, because all access is done on tables.
- You can use the familiar syntax of the `SELECT` statement, and only need to learn some table and column names.
- The implementor need not worry about adding keywords.
- You can filter, sort, concatenate, and transform the results from `INFORMATION_SCHEMA` queries into whatever format your application needs, such as a data structure or a text representation to parse.
- This technique is more interoperable with other database systems. For example, Oracle Database users are familiar with querying tables in the Oracle data dictionary.
Because `SHOW` is familiar and widely used, the `SHOW` statements remain as an alternative. In fact, along with the implementation of `INFORMATION_SCHEMA`, there are enhancements to `SHOW` as described in Section 21.34, “Extensions to SHOW Statements”.

**INFORMATION_SCHEMA and Privileges**

Each MySQL user has the right to access these tables, but can see only the rows in the tables that correspond to objects for which the user has the proper access privileges. In some cases (for example, the `ROUTINE_DEFINITION` column in the `INFORMATION_SCHEMA Routines` table), users who have insufficient privileges see `NULL`. These restrictions do not apply for InnoDB tables; you can see them with only the `PROCESS` privilege.

The same privileges apply to selecting information from `INFORMATION_SCHEMA` and viewing the same information through `SHOW` statements. In either case, you must have some privilege on an object to see information about it.

**Performance Considerations**

`INFORMATION_SCHEMA` queries that search for information from more than one database might take a long time and impact performance. To check the efficiency of a query, you can use `EXPLAIN`. For information about using `EXPLAIN` output to tune `INFORMATION_SCHEMA` queries, see Section 8.2.3, “Optimizing INFORMATION_SCHEMA Queries”.

**Standards Considerations**

The implementation for the `INFORMATION_SCHEMA` table structures in MySQL follows the ANSI/ISO SQL:2003 standard Part 11 `Schemata`. Our intent is approximate compliance with SQL:2003 core feature F021 Basic information schema.

Users of SQL Server 2000 (which also follows the standard) may notice a strong similarity. However, MySQL has omitted many columns that are not relevant for our implementation, and added columns that are MySQL-specific. One such added column is the `ENGINE` column in the `INFORMATION_SCHEMA TABLES` table.

Although other DBMSs use a variety of names, like `syscat` or `system`, the standard name is `INFORMATION_SCHEMA`.

To avoid using any name that is reserved in the standard or in DB2, SQL Server, or Oracle, we changed the names of some columns marked “MySQL extension”. (For example, we changed `COLLATION` to `TABLE_COLLATION` in the `TABLES` table.) See the list of reserved words near the end of this article: https://web.archive.org/web/20070428032454/http://www.dbazine.com/db2/db2-disarticles/gulutzan5.

**Conventions in the INFORMATION_SCHEMA Reference Sections**

The following sections describe each of the tables and columns in `INFORMATION_SCHEMA`. For each column, there are three pieces of information:

- **"INFORMATION_SCHEMA Name"** indicates the name for the column in the `INFORMATION_SCHEMA` table. This corresponds to the standard SQL name unless the “Remarks” field says “MySQL extension.”

- **"SHOW Name"** indicates the equivalent field name in the closest `SHOW` statement, if there is one.

- **“Remarks”** provides additional information where applicable. If this field is `NULL`, it means that the value of the column is always `NULL`. If this field says “MySQL extension,” the column is a MySQL extension to standard SQL.
Many sections indicate what `SHOW` statement is equivalent to a `SELECT` that retrieves information from `INFORMATION_SCHEMA`. For `SHOW` statements that display information for the default database if you omit a `FROM db_name` clause, you can often select information for the default database by adding an `AND TABLE_SCHEMA = SCHEMA()` condition to the `WHERE` clause of a query that retrieves information from an `INFORMATION_SCHEMA` table.

Related Information

These sections discuss additional `INFORMATION_SCHEMA`-related topics:

- information about `INFORMATION_SCHEMA` tables specific to the InnoDB storage engine: Section 21.30, “INFORMATION_SCHEMA InnoDB Tables”
- information about `INFORMATION_SCHEMA` tables specific to the NDB storage engine (NDB Cluster): Section 21.31, “INFORMATION_SCHEMA NDB Cluster Tables”
- information about `INFORMATION_SCHEMA` tables specific to the thread pool plugin: Section 21.32, “INFORMATION_SCHEMA Thread Pool Tables”
- information about `INFORMATION_SCHEMA` tables specific to the CONNECTION_CONTROL plugin: Section 21.33, “INFORMATION_SCHEMA Connection-Control Tables”
- Answers to questions that are often asked concerning the `INFORMATION_SCHEMA` database: Section A.7, “MySQL 5.6 FAQ: INFORMATION_SCHEMA”
- `INFORMATION_SCHEMA` queries and the optimizer: Section 8.2.3, “Optimizing INFORMATION_SCHEMA Queries”
- The effect of collation on `INFORMATION_SCHEMA` comparisons: Section 10.8.7, “Using Collation in INFORMATION_SCHEMA Searches”

21.2 The INFORMATION_SCHEMA CHARACTER_SETS Table

The `CHARACTER_SETS` table provides information about available character sets.

The `CHARACTER_SETS` table has these columns:

- `CHARACTER_SET_NAME`
  The character set name.
- `DEFAULT_COLLATE_NAME`
  The default collation for the character set.
- `DESCRIPTION`
  A description of the character set.
- `MAXLEN`
  The maximum number of bytes required to store one character.

Notes

Character set information is also available from the `SHOW CHARACTER SET` statement. See Section 13.7.5.4, “SHOW CHARACTER SET Syntax”. The following statements are equivalent:
SELECT * FROM INFORMATION_SCHEMA.CHARACTER_SETS 

[WHERE CHARACTER_SET_NAME LIKE 'wild']

SHOW CHARACTER SET 

[LIKE 'wild']

21.3 The INFORMATION_SCHEMA COLLATIONS Table

The COLLATIONS table provides information about collations for each character set. The COLLATIONS table has these columns:

- COLLATION_NAME
  The collation name.
- CHARACTER_SET_NAME
  The name of the character set with which the collation is associated.
- ID
  The collation ID.
- IS_DEFAULT
  Whether the collation is the default for its character set.
- IS_COMPILED
  Whether the character set is compiled into the server.
- SORTLEN
  This is related to the amount of memory required to sort strings expressed in the character set.

Notes

Collation information is also available from the SHOW COLLATION statement. See Section 13.7.5.5, “SHOW COLLATION Syntax”. The following statements are equivalent:

SELECT COLLATION_NAME FROM INFORMATION_SCHEMA.COLLATIONS 

[WHERE COLLATION_NAME LIKE 'wild']

SHOW COLLATION 

[LIKE 'wild']

21.4 The INFORMATION_SCHEMA COLLATION_CHARACTER_SET_APPLICABILITY Table

The COLLATION_CHARACTER_SET_APPLICABILITY table indicates what character set is applicable for what collation. The COLLATION_CHARACTER_SET_APPLICABILITY table has these columns:

- COLLATION_NAME
  The collation name.
Notes

The name of the character set with which the collation is associated.

Notes

The COLLATION_CHARACTER_SET_APPLICABILITY columns are equivalent to the first two columns displayed by the SHOW COLLATION statement.

21.5 The INFORMATION_SCHEMA COLUMNS Table

The COLUMNS table provides information about columns in tables.

The COLUMNS table has these columns:

- **TABLE_CATALOG**
  The name of the catalog to which the table containing the column belongs. This value is always def.

- **TABLE_SCHEMA**
  The name of the schema (database) to which the table containing the column belongs.

- **TABLE_NAME**
  The name of the table containing the column.

- **COLUMN_NAME**
  The name of the column.

- **ORDINAL_POSITION**
  The position of the column within the table. ORDINAL_POSITION is necessary because you might want to say ORDER BY ORDINAL_POSITION. Unlike SHOW COLUMNS, SELECT from the COLUMNS table does not have automatic ordering.

- **COLUMN_DEFAULT**
  The default value for the column. This is NULL if the column has an explicit default of NULL, or if the column definition includes no DEFAULT clause.

- **IS_NULLABLE**
  The column nullability. The value is YES if NULL values can be stored in the column, NO if not.

- **DATA_TYPE**
  The column data type.

  The DATA_TYPE value is the type name only with no other information. The COLUMN_TYPE value contains the type name and possibly other information such as the precision or length.

- **CHARACTER_MAXIMUM_LENGTH**
  For string columns, the maximum length in characters.

- **CHARACTER_OCTET_LENGTH**
For string columns, the maximum length in bytes.

- **NUMERIC_PRECISION**
  For numeric columns, the numeric precision.

- **NUMERIC_SCALE**
  For numeric columns, the numeric scale.

- **DATETIME_PRECISION**
  For temporal columns, the fractional seconds precision.

- **CHARACTER_SET_NAME**
  For character string columns, the character set name.

- **COLLABATION_NAME**
  For character string columns, the collation name.

- **COLUMN_TYPE**
  The column data type.
  
  The `DATA_TYPE` value is the type name only with no other information. The `COLUMN_TYPE` value contains the type name and possibly other information such as the precision or length.

- **COLUMN_KEY**
  Whether the column is indexed:
  
  - If `COLUMN_KEY` is empty, the column either is not indexed or is indexed only as a secondary column in a multiple-column, nonunique index.
  
  - If `COLUMN_KEY` is `PRI`, the column is a `PRIMARY KEY` or is one of the columns in a multiple-column `PRIMARY KEY`.
  
  - If `COLUMN_KEY` is `UNI`, the column is the first column of a `UNIQUE` index. (A `UNIQUE` index permits multiple `NULL` values, but you can tell whether the column permits `NULL` by checking the `Null` column.)
  
  - If `COLUMN_KEY` is `MUL`, the column is the first column of a nonunique index in which multiple occurrences of a given value are permitted within the column.
  
  If more than one of the `COLUMN_KEY` values applies to a given column of a table, `COLUMN_KEY` displays the one with the highest priority, in the order `PRI`, `UNI`, `MUL`.
  
  A `UNIQUE` index may be displayed as `PRI` if it cannot contain `NULL` values and there is no `PRIMARY KEY` in the table. A `UNIQUE` index may display as `MUL` if several columns form a composite `UNIQUE` index; although the combination of the columns is unique, each column can still hold multiple occurrences of a given value.

- **EXTRA**
  Any additional information that is available about a given column. The value is nonempty in these cases: `auto_increment` for columns that have the `AUTO_INCREMENT` attribute; on
update CURRENT_TIMESTAMP for TIMESTAMP or DATETIME columns that have the ON UPDATE CURRENT_TIMESTAMP attribute.

- PRIVILEGES
  The privileges you have for the column.

- COLUMN_COMMENT
  Any comment included in the column definition.

Notes

- In SHOW COLUMNS, the Type display includes values from several different COLUMNS columns.

- CHARACTER_OCTET_LENGTH should be the same as CHARACTER_MAXIMUM_LENGTH, except for multibyte character sets.

- CHARACTER_SET_NAME can be derived from COLLATION_NAME. For example, if you say SHOW FULL COLUMNS FROM t, and you see in the COLLATION_NAME column a value of latin1_swedish_ci, the character set is what is before the first underscore: latin1.

Column information is also available from the SHOW COLUMNS statement. See Section 13.7.5.6, “SHOW COLUMNS Syntax”. The following statements are nearly equivalent:

```sql
SELECT COLUMN_NAME, DATA_TYPE, IS_NULLABLE, COLUMN_DEFAULT
FROM INFORMATION_SCHEMA.COLUMNS
WHERE table_name = 'tbl_name'
    [AND table_schema = 'db_name']
    [AND column_name LIKE 'wild']

SHOW COLUMNS
FROM tbl_name
    [FROM db_name]
    [LIKE 'wild']
```

21.6 The INFORMATION_SCHEMA COLUMN_PRIVILEGES Table

The COLUMN_PRIVILEGES table provides information about column privileges. It takes its values from the mysql.columns_priv system table.

The COLUMN_PRIVILEGES table has these columns:

- GRANTEE
  The name of the account to which the privilege is granted, in 'user_name'@'host_name' format.

- TABLE_CATALOG
  The name of the catalog to which the table containing the column belongs. This value is always def.

- TABLE_SCHEMA
  The name of the schema (database) to which the table containing the column belongs.

- TABLE_NAME
  The name of the table containing the column.

- COLUMN_NAME
The name of the column.

- **PRIVILEGE_TYPE**

  The privilege granted. The value can be any privilege that can be granted at the column level; see Section 13.7.1.4, “GRANT Syntax”. Each row lists a single privilege, so there is one row per column privilege held by the grantee.

  In the output from `SHOW FULL COLUMNS`, the privileges are all in one column and in lowercase, for example, `select,insert,update,references`. In `COLUMN_PRIVILEGES`, there is one privilege per row, in uppercase.

- **IS_GRANTABLE**

  *YES* if the user has the `GRANT OPTION` privilege, *NO* otherwise. The output does not list `GRANT OPTION` as a separate row with `PRIVILEGE_TYPE='GRANT OPTION'`.

**Notes**

- The `COLUMN_PRIVILEGES` table is a nonstandard `INFORMATION_SCHEMA` table.

  The following statements are *not* equivalent:

  ```
  SELECT ... FROM INFORMATION_SCHEMA.COLUMN_PRIVILEGES
  SHOW GRANTS ...
  ```

21.7 The **INFORMATION_SCHEMA ENGINES** Table

The `ENGINES` table provides information about storage engines. This is particularly useful for checking whether a storage engine is supported, or to see what the default engine is.

The `ENGINES` table has these columns:

- **ENGINE**

  The name of the storage engine.

- **SUPPORT**

  The server's level of support for the storage engine, as shown in the following table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>YES</td>
<td>The engine is supported and is active</td>
</tr>
<tr>
<td>DEFAULT</td>
<td>Like YES, plus this is the default engine</td>
</tr>
<tr>
<td>NO</td>
<td>The engine is not supported</td>
</tr>
<tr>
<td>DISABLED</td>
<td>The engine is supported but has been disabled</td>
</tr>
</tbody>
</table>

A value of *NO* means that the server was compiled without support for the engine, so it cannot be enabled at runtime.

A value of *DISABLED* occurs either because the server was started with an option that disables the engine, or because not all options required to enable it were given. In the latter case, the error log should contain a reason indicating why the option is disabled. See Section 5.4.2, “The Error Log”.
You might also see `DISABLED` for a storage engine if the server was compiled to support it, but was started with a `--skip-engine_name` option. For the NDB storage engine, `DISABLED` means the server was compiled with support for NDB Cluster, but was not started with the `--ndbcluster` option.

All MySQL servers support `MyISAM` tables. It is not possible to disable `MyISAM`.

- **COMMENT**
  A brief description of the storage engine.

- **TRANSACTIONS**
  Whether the storage engine supports transactions.

- **XA**
  Whether the storage engine supports XA transactions.

- **SAVEPOINTS**
  Whether the storage engine supports savepoints.

Notes

- The `ENGINES` table is a nonstandard `INFORMATION_SCHEMA` table.

Storage engine information is also available from the `SHOW ENGINES` statement. See Section 13.7.5.17, “SHOW ENGINES Syntax”. The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.ENGINES
SHOW ENGINES
```

21.8 The `INFORMATION_SCHEMA EVENTS` Table

The `EVENTS` table provides information about Event Manager events, which are discussed in Section 20.4, “Using the Event Scheduler”.

The `EVENTS` table has these columns:

- **EVENT_CATALOG**
  The name of the catalog to which the event belongs. This value is always `def`.

- **EVENT_SCHEMA**
  The name of the schema (database) to which the event belongs.

- **EVENT_NAME**
  The name of the event.

- **DEFINER**
  The account of the user who created the event, in `'user_name'@'host_name'` format.
### The INFORMATION_SCHEMA EVENTS Table

- **TIME_ZONE**
  The event time zone, which is the time zone used for scheduling the event and that is in effect within the event as it executes. The default value is `SYSTEM`.

- **EVENT_BODY**
  The language used for the statements in the event's `DO` clause. The value is always `SQL`.

- **EVENT_DEFINITION**
  The text of the SQL statement making up the event's `DO` clause; in other words, the statement executed by this event.

- **EVENT_TYPE**
  The event repetition type, either `ONE TIME` (transient) or `RECURRING` (repeating).

- **EXECUTE_AT**
  For a one-time event, this is the `DATETIME` value specified in the `AT` clause of the `CREATE EVENT` statement used to create the event, or of the last `ALTER EVENT` statement that modified the event. The value shown in this column reflects the addition or subtraction of any `INTERVAL` value included in the event's `AT` clause. For example, if an event is created using `ON SCHEDULE AT CURRENT_TIMESTAMP + '1:6' DAY_HOUR`, and the event was created at 2018-02-09 14:05:30, the value shown in this column would be `'2018-02-10 20:05:30'`. If the event's timing is determined by an `EVERY` clause instead of an `AT` clause (that is, if the event is recurring), the value of this column is `NULL`.

- **INTERVAL_VALUE**
  For a recurring event, the number of intervals to wait between event executions. For a transient event, the value is always `NULL`.

- **INTERVAL_FIELD**
  The time units used for the interval which a recurring event waits before repeating. For a transient event, the value is always `NULL`.

- **SQL_MODE**
  The SQL mode in effect when the event was created or altered, and under which the event executes. For the permitted values, see Section 5.1.10, “Server SQL Modes”.

- **STARTS**
  The start date and time for a recurring event. This is displayed as a `DATETIME` value, and is `NULL` if no start date and time are defined for the event. For a transient event, this column is always `NULL`. For a recurring event whose definition includes a `STARTS` clause, this column contains the corresponding `DATETIME` value. As with the `EXECUTE_AT` column, this value resolves any expressions used. If there is no `STARTS` clause affecting the timing of the event, this column is `NULL`.

- **ENDS**
  For a recurring event whose definition includes a `ENDS` clause, this column contains the corresponding `DATETIME` value. As with the `EXECUTE_AT` column, this value resolves any expressions used. If there is no `ENDS` clause affecting the timing of the event, this column is `NULL`.

- **STATUS**
The event status. One of `ENABLED`, `DISABLED`, or `SLAVESIDE_DISABLED`. `SLAVESIDE_DISABLED` indicates that the creation of the event occurred on another MySQL server acting as a replication master and replicated to the current MySQL server which is acting as a slave, but the event is not presently being executed on the slave. For more information, see Section 17.4.1.16, "Replication of Invoked Features".

- **ON_COMPLETION**

  One of the two values `PRESERVE` or `NOT PRESERVE`.

- **CREATED**

  The date and time when the event was created. This is a `TIMESTAMP` value.

- **LAST_ALTERED**

  The date and time when the event was last modified. This is a `TIMESTAMP` value. If the event has not been modified since its creation, this value is the same as the `CREATED` value.

- **LAST_EXECUTED**

  The date and time when the event last executed. This is a `DATETIME` value. If the event has never executed, this column is `NULL`.

  `LAST_EXECUTED` indicates when the event started. As a result, the `ENDS` column is never less than `LAST_EXECUTED`.

- **EVENT_COMMENT**

  The text of the comment, if the event has one. If not, this value is empty.

- **ORIGINATOR**

  The server ID of the MySQL server on which the event was created; used in replication. This value may be updated by `ALTER EVENT` to the server ID of the server on which that statement occurs, if executed on a master server. The default value is 0.

- **CHARACTER_SET_CLIENT**

  The session value of the `character_set_client` system variable when the event was created.

- **COLLATION_CONNECTION**

  The session value of the `collation_connection` system variable when the event was created.

- **DATABASE_COLLATION**

  The collation of the database with which the event is associated.

**Notes**

- The `EVENTS` table is a nonstandard `INFORMATION_SCHEMA` table.

- Times in the `EVENTS` table are displayed using the event time zone, the current session time zone, or UTC, as described in Section 20.4.4, "Event Metadata".

- For more information about `SLAVESIDE_DISABLED` and the `ORIGINATOR` column, see Section 17.4.1.16, "Replication of Invoked Features".
Example

Suppose that the user 'jon'@'ghidora' creates an event named e_daily, and then modifies it a few minutes later using an ALTER EVENT statement, as shown here:

DELIMITER |

CREATE EVENT e_daily
    ON SCHEDULE
    EVERY 1 DAY
    COMMENT 'Saves total number of sessions then clears the table each day'
    DO
        BEGIN
            INSERT INTO site_activity.totals (time, total)
                SELECT CURRENT_TIMESTAMP, COUNT(*)
                FROM site_activity.sessions;
            DELETE FROM site_activity.sessions;
        END |

DELIMITER ;

ALTER EVENT e_daily
    ENABLE;

(Note that comments can span multiple lines.)

This user can then run the following SELECT statement, and obtain the output shown:

mysql> SELECT * FROM INFORMATION_SCHEMA.EVENTS
    WHERE EVENT_NAME = 'e_daily'
    AND EVENT_SCHEMA = 'myschema'
G
*************************** 1. row ***************************
EVENT_CATALOG: def
EVENT_SCHEMA: myschema
EVENT_NAME: e_daily
DEFINER: jon@ghidora
TIME_ZONE: SYSTEM
EVENT_BODY: SQL
EVENT_DEFINITION: BEGIN
    INSERT INTO site_activity.totals (time, total)
        SELECT CURRENT_TIMESTAMP, COUNT(*)
        FROM site_activity.sessions;
    DELETE FROM site_activity.sessions;
END
EVENT_TYPE: RECURRING
EXECUTE_AT: NULL
INTERVAL_VALUE: 1
INTERVAL_FIELD: DAY
SQL_MODE: NO_ENGINE_SUBSTITUTION
STARTS: 2018-08-08 11:06:34
ENDS: NULL
STATUS: ENABLED
ON_COMPLETION: NOT PRESERVE
CREATED: 2018-08-08 11:06:34
LAST_ALTERED: 2018-08-08 11:06:34
LAST_EXECUTED: 2018-08-08 16:06:34
EVENT_COMMENT: Saves total number of sessions then clears the table each day
ORIGINATOR: 1
CHARACTER_SET_CLIENT: utf8
COLLATION_CONNECTION: utf8_general_ci
DATABASE_COLLATION: latin1_swedish_ci
Event information is also available from the `SHOW EVENTS` statement. See Section 13.7.5.19, “SHOW EVENTS Syntax”. The following statements are equivalent:

```sql
SELECT
    EVENT_SCHEMA, EVENT_NAME, DEFINER, TIME_ZONE, EVENT_TYPE, EXECUTE_AT,
    INTERVAL_VALUE, INTERVAL_FIELD, STARTS, ENDS, STATUS, ORIGINATOR,
    CHARACTER_SET_CLIENT, COLLATION_CONNECTION, DATABASE_COLLATION
FROM INFORMATION_SCHEMA.EVENTS
WHERE table_schema = 'db_name'
    [AND column_name LIKE 'wild']
```

### 21.9 The INFORMATION_SCHEMA GLOBAL_STATUS and SESSION_STATUS Tables

The `GLOBAL_STATUS` and `SESSION_STATUS` tables provide information about server status variables. Their contents correspond to the information produced by the `SHOW GLOBAL STATUS` and `SHOW SESSION STATUS` statements (see Section 13.7.5.36, “SHOW STATUS Syntax”).

#### Notes

- The `VARIABLE_VALUE` column for each of these tables is defined as `VARCHAR(1024)`.

### 21.10 The INFORMATION_SCHEMA GLOBAL_VARIABLES and SESSION_VARIABLES Tables

The `GLOBAL_VARIABLES` and `SESSION_VARIABLES` tables provide information about server status variables. Their contents correspond to the information produced by the `SHOW GLOBAL VARIABLES` and `SHOW SESSION VARIABLES` statements (see Section 13.7.5.40, “SHOW VARIABLES Syntax”).

#### Notes

- The `VARIABLE_VALUE` column for each of these tables is defined as `VARCHAR(1024)`. For variables with very long values that are not completely displayed, use `SELECT` as a workaround. For example:

  ```sql
  SELECT @@GLOBAL.innodb_data_file_path;
  ```

### 21.11 The INFORMATION_SCHEMA KEY_COLUMN_USAGE Table

The `KEY_COLUMN_USAGE` table describes which key columns have constraints.

The `KEY_COLUMN_USAGE` table has these columns:

- `CONSTRAINT_CATALOG`
  The name of the catalog to which the constraint belongs. This value is always `def`.

- `CONSTRAINT_SCHEMA`
  The name of the schema (database) to which the constraint belongs.

- `CONSTRAINT_NAME`
The name of the constraint.

- **TABLE_CATALOG**
  The name of the catalog to which the table belongs. This value is always *def*.

- **TABLE_SCHEMA**
  The name of the schema (database) to which the table belongs.

- **TABLE_NAME**
  The name of the table that has the constraint.

- **COLUMN_NAME**
  The name of the column that has the constraint.
  
  If the constraint is a foreign key, then this is the column of the foreign key, not the column that the foreign key references.

- **ORDINAL_POSITION**
  The column's position within the constraint, not the column's position within the table. Column positions are numbered beginning with 1.

- **POSITION_IN_UNIQUE_CONSTRAINT**
  NULL for unique and primary-key constraints. For foreign-key constraints, this column is the ordinal position in key of the table that is being referenced.

- **REFERENCED_TABLE_SCHEMA**
  The name of the schema (database) referenced by the constraint.

- **REFERENCED_TABLE_NAME**
  The name of the table referenced by the constraint.

- **REFERENCED_COLUMN_NAME**
  The name of the column referenced by the constraint.

Suppose that there are two tables name *t1* and *t3* that have the following definitions:

```sql
CREATE TABLE t1
(
    s1 INT,
    s2 INT,
    s3 INT,
    PRIMARY KEY(s3)
) ENGINE=InnoDB;

CREATE TABLE t3
(
    s1 INT,
    s2 INT,
    s3 INT,
    KEY(s1),
```
The INFORMATION_SCHEMA OPTIMIZER_TRACE Table

For those two tables, the KEY_COLUMN_USAGE table has two rows:

- One row with CONSTRAINT_NAME = 'PRIMARY', TABLE_NAME = 't1', COLUMN_NAME = 's3',
  ORDINAL_POSITION = 1, POSITION_IN_UNIQUE_CONSTRAINT = NULL.

- One row with CONSTRAINT_NAME = 'CO', TABLE_NAME = 't3', COLUMN_NAME = 's2',
  ORDINAL_POSITION = 1, POSITION_IN_UNIQUE_CONSTRAINT = 1.

21.12 The INFORMATION_SCHEMA OPTIMIZER_TRACE Table

The OPTIMIZER_TRACE table provides information produced by the optimizer tracing capability for traced statements. To enable tracking, use the optimizer_trace system variable. For details, see MySQL Internals: Tracing the Optimizer.

The OPTIMIZER_TRACE table has these columns:

- QUERY
  The text of the traced statement.

- TRACE
  The trace, in JSON format.

- MISSING_BYTES_BEYOND_MAX_MEM_SIZE
  Each remembered trace is a string that is extended as optimization progresses and appends data to it. The optimizer_trace_max_mem_size variable sets a limit on the total amount of memory used by all currently remembered traces. If this limit is reached, the current trace is not extended (and thus is incomplete), and the MISSING_BYTES_BEYOND_MAX_MEM_SIZE column shows the number of bytes missing from the trace.

- INSUFFICIENT_PRIVILEGES
  If a traced query uses views or stored routines that have SQL SECURITY with a value of DEFINER, it may be that a user other than the definer is denied from seeing the trace of the query. In that case, the trace is shown as empty and INSUFFICIENT_PRIVILEGES has a value of 1. Otherwise, the value is 0.

21.13 The INFORMATION_SCHEMA PARAMETERS Table

The PARAMETERS table provides information about parameters for stored routines (stored procedures and stored functions), and about return values for stored functions. The PARAMETERS table does not include built-in SQL functions or user-defined functions (UDFs). Parameter information is similar to the contents of the param_list column in the mysql.proc table.

The PARAMETERS table has these columns:

- SPECIFIC_CATALOG
  The name of the catalog to which the routine containing the parameter belongs. This value is always def.

- SPECIFIC_SCHEMA
  The name of the schema (database) to which the routine containing the parameter belongs.
The INFORMATION_SCHEMA PARAMETERS Table

• **SPECIFIC_NAME**
  The name of the routine containing the parameter.

• **ORDINAL_POSITION**
  For successive parameters of a stored procedure or function, the ORDINAL_POSITION values are 1, 2, 3, and so forth. For a stored function, there is also a row that applies to the function return value (as described by the RETURNS clause). The return value is not a true parameter, so the row that describes it has these unique characteristics:
  - The ORDINAL_POSITION value is 0.
  - The PARAMETER_NAME and PARAMETER_MODE values are NULL because the return value has no name and the mode does not apply.

• **PARAMETER_MODE**
  The mode of the parameter. This value is one of IN, OUT, or INOUT. For a stored function return value, this value is NULL.

• **PARAMETER_NAME**
  The name of the parameter. For a stored function return value, this value is NULL.

• **DATA_TYPE**
  The parameter data type.
  The DATA_TYPE value is the type name only with no other information. The DTD_IDENTIFIER value contains the type name and possibly other information such as the precision or length.

• **CHARACTER_MAXIMUM_LENGTH**
  For string parameters, the maximum length in characters.

• **CHARACTER_OCTET_LENGTH**
  For string parameters, the maximum length in bytes.

• **NUMERIC_PRECISION**
  For numeric parameters, the numeric precision.

• **NUMERIC_SCALE**
  For numeric parameters, the numeric scale.

• **DATETIME_PRECISION**
  For temporal parameters, the fractional seconds precision.

• **CHARACTER_SET_NAME**
  For character string parameters, the character set name.

• **COLLATION_NAME**
  For character string parameters, the collation name.
The INFORMATION_SCHEMA PARTITIONS Table

- **DTD_IDENTIFIER**
  The parameter data type.
  The DATA_TYPE value is the type name only with no other information. The DTD_IDENTIFIER value contains the type name and possibly other information such as the precision or length.

- **ROUTINE_TYPE**
  PROCEDURE for stored procedures, FUNCTION for stored functions.

### 21.14 The INFORMATION_SCHEMA PARTITIONS Table

The PARTITIONS table provides information about table partitions. Each row in this table corresponds to an individual partition or subpartition of a partitioned table. For more information about partitioning tables, see Chapter 19, Partitioning.

The PARTITIONS table has these columns:

- **TABLE_CATALOG**
  The name of the catalog to which the table belongs. This value is always def.

- **TABLE_SCHEMA**
  The name of the database to which the table belongs.

- **TABLE_NAME**
  The name of the table containing the partition.

- **PARTITION_NAME**
  The name of the partition.

- **SUBPARTITION_NAME**
  If the PARTITIONS table row represents a subpartition, the name of subpartition; otherwise NULL.

- **PARTITION_ORDINAL_POSITION**
  All partitions are indexed in the same order as they are defined, with 1 being the number assigned to the first partition. The indexing can change as partitions are added, dropped, and reorganized; the number shown is this column reflects the current order, taking into account any indexing changes.

- **SUBPARTITION_ORDINAL_POSITION**
  Subpartitions within a given partition are also indexed and reindexed in the same manner as partitions are indexed within a table.

- **PARTITION_METHOD**
  One of the values RANGE, LIST, HASH, LINEAR HASH, KEY, or LINEAR KEY; that is, one of the available partitioning types as discussed in Section 19.2, "Partitioning Types".

- **SUBPARTITION_METHOD**
  One of the values HASH, LINEAR HASH, KEY, or LINEAR KEY; that is, one of the available subpartitioning types as discussed in Section 19.2.6, "Subpartitioning".
The INFORMATION_SCHEMA PARTITIONS Table

- **PARTITION_EXPRESSION**
  
The expression for the partitioning function used in the CREATE TABLE or ALTER TABLE statement that created the table's current partitioning scheme.
  
For example, consider a partitioned table created in the test database using this statement:

```sql
CREATE TABLE tp (
    c1 INT,
    c2 INT,
    c3 VARCHAR(25)
) PARTITION BY HASH(c1 + c2)
PARTITIONS 4;
```

The **PARTITION_EXPRESSION** column in a PARTITIONS table row for a partition from this table displays `c1 + c2`, as shown here:

```sql
mysql> SELECT DISTINCT PARTITION_EXPRESSION
       -> FROM INFORMATION_SCHEMA.PARTITIONS
       -> WHERE TABLE_NAME='tp' AND TABLE_SCHEMA='test';
+----------------------+
| PARTITION_EXPRESSION |
+----------------------+
| c1 + c2              |
+----------------------+
```

- **SUBPARTITION_EXPRESSION**
  
This works in the same fashion for the subpartitioning expression that defines the subpartitioning for a table as **PARTITION_EXPRESSION** does for the partitioning expression used to define a table's partitioning.

If the table has no subpartitions, this column is **NULL**.

- **PARTITION_DESCRIPTION**
  
This column is used for RANGE and LIST partitions. For a RANGE partition, it contains the value set in the partition's VALUES LESS THAN clause, which can be either an integer or MAXVALUE. For a LIST partition, this column contains the values defined in the partition's VALUES IN clause, which is a list of comma-separated integer values.

For partitions whose **PARTITION_METHOD** is other than RANGE or LIST, this column is always **NULL**.

- **TABLE_ROWS**
  
The number of table rows in the partition.

For partitioned InnoDB tables, the row count given in the **TABLE_ROWS** column is only an estimated value used in SQL optimization, and may not always be exact.

For NDB tables, you can also obtain this information using the `ndb_desc` utility.

- **AVG_ROW_LENGTH**
  
The average length of the rows stored in this partition or subpartition, in bytes. This is the same as **DATA_LENGTH** divided by **TABLE_ROWS**.

For NDB tables, you can also obtain this information using the `ndb_desc` utility.
• **DATA_LENGTH**
  The total length of all rows stored in this partition or subpartition, in bytes; that is, the total number of bytes stored in the partition or subpartition.
  For **NDB** tables, you can also obtain this information using the `ndb_desc` utility.

• **MAX_DATA_LENGTH**
  The maximum number of bytes that can be stored in this partition or subpartition.
  For **NDB** tables, you can also obtain this information using the `ndb_desc` utility.

• **INDEX_LENGTH**
  The length of the index file for this partition or subpartition, in bytes.
  For partitions of **NDB** tables, whether the tables use implicit or explicit partitioning, the `INDEX_LENGTH` column value is always 0. However, you can obtain equivalent information using the `ndb_desc` utility.

• **DATA_FREE**
  The number of bytes allocated to the partition or subpartition but not used.
  For **NDB** tables, you can also obtain this information using the `ndb_desc` utility.

• **CREATE_TIME**
  The time that the partition or subpartition was created.
  Prior to MySQL 5.6.25, for partitioned **InnoDB** tables, this column was always **NULL**. The correct creation time is shown in MySQL 5.6.25 and later. (Bug #17299181, Bug #69990)

• **UPDATE_TIME**
  The time that the partition or subpartition was last modified.
  For partitioned **InnoDB** tables, the value is always **NULL**.

• **CHECK_TIME**
  The last time that the table to which this partition or subpartition belongs was checked.
  For partitioned **InnoDB** tables, this column is always **NULL**.

• **CHECKSUM**
  The checksum value, if any; otherwise **NULL**.

• **PARTITION_COMMENT**
  The text of the comment, if the partition has one. If not, this value is empty.
  The maximum length for a partition comment is defined as 1024 characters, and the display width of the `PARTITION_COMMENT` column is also 1024, characters to match this limit.

• **NODEGROUP**
  This is the nodegroup to which the partition belongs. This is relevant only to NDB Cluster tables; otherwise, the value is always **0**.
Notes

- **TABLESPACE_NAME**

  The name of the tablespace to which the partition belongs. The value is always `DEFAULT`, unless the table uses the NDB storage engine (see the Notes at the end of this section).

**Notes**

- The PARTITIONS table is a nonstandard INFORMATION_SCHEMA table.

- A table using any storage engine other than NDB and which is not partitioned has one row in the PARTITIONS table. However, the values of the PARTITION_NAME, SUBPARTITION_NAME, PARTITION_ORDINAL_POSITION, SUBPARTITION_ORDINAL_POSITION, PARTITION_METHOD, SUBPARTITION_METHOD, PARTITION_EXPRESSION, SUBPARTITION_EXPRESSION, and PARTITION_DESCRIPTION columns are all NULL. Also, the PARTITION_COMMENT column in this case is blank.

- An NDB table which is not explicitly partitioned has one row in the PARTITIONS table for each data node in the NDB cluster. For each such row:
  - The SUBPARTITION_NAME, SUBPARTITION_ORDINAL_POSITION, SUBPARTITION_METHOD, PARTITION_EXPRESSION, SUBPARTITION_EXPRESSION, CREATE_TIME, UPDATE_TIME, CHECK_TIME, CHECKSUM, and TABLESPACE_NAME columns are all NULL.
  - The PARTITION_METHOD is always KEY.
  - The NODEGROUP column is default.
  - The PARTITION_EXPRESSION and PARTITION_COMMENT columns are empty.

**21.15 The INFORMATION_SCHEMA PLUGINS Table**

The PLUGINS table provides information about server plugins.

The PLUGINS table has these columns:

- **PLUGIN_NAME**

  The name used to refer to the plugin in statements such as INSTALL PLUGIN and UNINSTALL PLUGIN.

- **PLUGIN_VERSION**

  The version from the plugin's general type descriptor.

- **PLUGIN_STATUS**

  The plugin status, one of ACTIVE, INACTIVE, DISABLED, or DELETED.

- **PLUGIN_TYPE**

  The type of plugin, such as STORAGE ENGINE, INFORMATION_SCHEMA, or AUTHENTICATION.

- **PLUGIN_TYPE_VERSION**

  The version from the plugin's type-specific descriptor.

- **PLUGIN_LIBRARY**
The name of the plugin shared library file. This is the name used to refer to the plugin file in statements such as `INSTALL PLUGIN` and `UNINSTALL PLUGIN`. This file is located in the directory named by the `plugin_dir` system variable. If the library name is `NULL`, the plugin is compiled in and cannot be uninstalled with `UNINSTALL PLUGIN`.

- **PLUGIN_LIBRARY_VERSION**
  The plugin API interface version.

- **PLUGIN_AUTHOR**
  The plugin author.

- **PLUGIN_DESCRIPTION**
  A short description of the plugin.

- **PLUGIN_LICENSE**
  How the plugin is licensed (for example, GPL).

- **LOAD_OPTION**
  How the plugin was loaded. The value is `OFF`, `ON`, `FORCE`, or `FORCE_PLUS_PERMANENT`. See Section 5.5.1, “Installing and Uninstalling Plugins”.

Notes

- The `PLUGINS` table is a nonstandard `INFORMATION_SCHEMA` table.
- For plugins installed with `INSTALL PLUGIN`, the `PLUGIN_NAME` and `PLUGIN_LIBRARY` values are also registered in the `mysql.plugin` table.
- For information about plugin data structures that form the basis of the information in the `PLUGINS` table, see Section 24.2, “The MySQL Plugin API”.

Plugin information is also available from the `SHOW PLUGINS` statement. See Section 13.7.5.26, “SHOW PLUGINS Syntax”. These statements are equivalent:

```sql
SELECT PLUGIN_NAME, PLUGIN_STATUS, PLUGIN_TYPE,
       PLUGIN_LIBRARY, PLUGIN_LICENSE
FROM INFORMATION_SCHEMA.PLUGINS;
SHOW PLUGINS;
```

21.16 The INFORMATION_SCHEMA PROCESSLIST Table

The `PROCESSLIST` table provides information about which threads are running.

The `PROCESSLIST` table has these columns:

- **ID**
  The connection identifier. This is the same type of value displayed in the `Id` column of the `SHOW PROCESSLIST` statement, the `PROCESSLIST_ID` column of the Performance Schema `threads` table, and returned by the `CONNECTION_ID()` function.
• **USER**

The MySQL user who issued the statement. A value of *system user* refers to a nonclient thread spawned by the server to handle tasks internally. This could be the I/O or SQL thread used on replication slaves or a delayed-row handler. For *system user*, there is no host specified in the Host column. *unauthenticated user* refers to a thread that has become associated with a client connection but for which authentication of the client user has not yet been done. *event_scheduler* refers to the thread that monitors scheduled events (see Section 20.4, “Using the Event Scheduler”).

• **HOST**

The host name of the client issuing the statement (except for *system user*, for which there is no host). The host name for TCP/IP connections is reported in *host_name:client_port* format to make it easier to determine which client is doing what.

• **DB**

The default database, if one is selected; otherwise **NULL**.

• **COMMAND**

The type of command the thread is executing. For descriptions for thread commands, see Section 8.14, “Examining Thread Information”. The value of this column corresponds to the COM_xxx commands of the client/server protocol and Com_xxx status variables. See Section 5.1.9, “Server Status Variables”.

• **TIME**

The time in seconds that the thread has been in its current state. For a slave SQL thread, the value is the number of seconds between the timestamp of the last replicated event and the real time of the slave machine. See Section 17.2.1, “Replication Implementation Details”.

• **STATE**

An action, event, or state that indicates what the thread is doing. Descriptions for **STATE** values can be found at Section 8.14, “Examining Thread Information”.

Most states correspond to very quick operations. If a thread stays in a given state for many seconds, there might be a problem that needs to be investigated.

For the **SHOW PROCESSLIST** statement, the value of **STATE** is **NULL**.

• **INFO**

The statement the thread is executing, or **NULL** if it is not executing any statement. The statement might be the one sent to the server, or an innermost statement if the statement executes other statements. For example, if a **CALL** statement executes a stored procedure that is executing a **SELECT** statement, the **INFO** value shows the **SELECT** statement.

---

**Notes**

• The **PROCESSLIST** table is a nonstandard **INFORMATION_SCHEMA** table.

• Like the output from the **SHOW PROCESSLIST** statement, the **PROCESSLIST** table shows information only about your own threads, unless you have the **PROCESS** privilege, in which case you will see information about other threads, too. As an anonymous user, you cannot see any rows at all.
• If an SQL statement refers to the `PROCESSLIST` table, MySQL populates the entire table once, when statement execution begins, so there is read consistency during the statement. There is no read consistency for a multi-statement transaction.

Process information is also available from the `mysqladmin processlist` command, the `SHOW PROCESSLIST` statement, and the Performance Schema `threads` table (see Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”, Section 13.7.5.30, “SHOW PROCESSLIST Syntax”, and Section 22.12.10.3, “The threads Table”). In contrast to the `INFORMATION_SCHEMA PROCESSLIST` table and `SHOW PROCESSLIST` statement, which have negative performance consequences because they require a mutex, access to `threads` does not require a mutex and has minimal impact on server performance. The `threads` table also shows information about background threads, which the `PROCESSLIST` table and `SHOW PROCESSLIST` do not. This means that `threads` can be used to monitor activity the other thread information sources cannot.

The following statements are equivalent:

```plaintext
SELECT * FROM INFORMATION_SCHEMA.PROCESSLIST
SHOW FULL PROCESSLIST
```

### 21.17 The INFORMATION_SCHEMA PROFILING Table

The `PROFILING` table provides statement profiling information. Its contents correspond to the information produced by the `SHOW PROFILE` and `SHOW PROFILES` statements (see Section 13.7.5.31, “SHOW PROFILE Syntax”). The table is empty unless the `profiling` session variable is set to 1.

The `PROFILING` table has these columns:

- **QUERY_ID**
  A numeric statement identifier.

- **SEQ**
  A sequence number indicating the display order for rows with the same `QUERY_ID` value.

- **STATE**
  The profiling state to which the row measurements apply.

- **DURATION**
  How long statement execution remained in the given state, in seconds.

- **CPU_USER, CPU_SYSTEM**
  User and system CPU use, in seconds.

- **CONTEXT_VOLUNTARY, CONTEXT_INVOLUNTARY**
  How many voluntary and involuntary context switches occurred.

- **BLOCK_OPS_IN, BLOCK_OPS_OUT**
  The number of block input and output operations.

- **MESSAGES_SENT, MESSAGES_RECEIVED**
The number of communication messages sent and received.

- **PAGE_FAULTS_MAJOR, PAGE_FAULTS_MINOR**
  The number of major and minor page faults.

- **SWAPS**
  How many swaps occurred.

- **SOURCE_FUNCTION, SOURCE_FILE, and SOURCE_LINE**
  Information indicating where in the source code the profiled state executes.

**Notes**

- The **PROFILING** table is a nonstandard **INFORMATION_SCHEMA** table.

  Profiling information is also available from the **SHOW PROFILE** and **SHOW PROFILES** statements. See Section 13.7.5.31, “SHOW PROFILE Syntax”. For example, the following queries are equivalent:

  ```sql
  SHOW PROFILE FOR QUERY 2;
  SELECT STATE, FORMAT(DURATION, 6) AS DURATION
  FROM INFORMATION_SCHEMA.PROFILING
  WHERE QUERY_ID = 2 ORDER BY SEQ;
  ```

21.18 The **INFORMATION_SCHEMA REFERENTIAL_CONSTRAINTS** Table

The **REFERENTIAL_CONSTRAINTS** table provides information about foreign keys.

The **REFERENTIAL_CONSTRAINTS** table has these columns:

- **CONSTRAINT_CATALOG**
  The name of the catalog to which the constraint belongs. This value is always def.

- **CONSTRAINT_SCHEMA**
  The name of the schema (database) to which the constraint belongs.

- **CONSTRAINT_NAME**
  The name of the constraint.

- **UNIQUE_CONSTRAINT_CATALOG**
  The name of the catalog containing the unique constraint that the constraint references. This value is always def.

- **UNIQUE_CONSTRAINT_SCHEMA**
  The name of the schema (database) containing the unique constraint that the constraint references.

- **UNIQUE_CONSTRAINT_NAME**
The name of the unique constraint that the constraint references.

- **MATCH_OPTION**
  The value of the constraint MATCH attribute. The only valid value at this time is **NONE**.

- **UPDATE_RULE**
  The value of the constraint ON UPDATE attribute. The possible values are **CASCADE, SET NULL, SET DEFAULT, RESTRICT, NO ACTION**.

- **DELETE_RULE**
  The value of the constraint ON DELETE attribute. The possible values are **CASCADE, SET NULL, SET DEFAULT, RESTRICT, NO ACTION**.

- **TABLE_NAME**
  The name of the table. This value is the same as in the **TABLE_CONSTRAINTS** table.

- **REFERENCED_TABLE_NAME**
  The name of the table referenced by the constraint.

### 21.19 The INFORMATION_SCHEMA ROUTINES Table

The **ROUTINES** table provides information about stored routines (stored procedures and stored functions). The **ROUTINES** table does not include built-in SQL functions or user-defined functions (UDFs).

The column named “mysql.proc Name” indicates the mysql.proc table column that corresponds to the INFORMATION_SCHEMA ROUTINES table column, if any.

The **ROUTINES** table has these columns:

- **SPECIFIC_NAME**
  The name of the routine.

- **ROUTINE_CATALOG**
  The name of the catalog to which the routine belongs. This value is always **def**.

- **ROUTINE_SCHEMA**
  The name of the schema (database) to which the routine belongs.

- **ROUTINE_NAME**
  The name of the routine.

- **ROUTINE_TYPE**
  **PROCEDURE** for stored procedures, **FUNCTION** for stored functions.

- **DATA_TYPE**
  If the routine is a stored function, the return value data type. If the routine is a stored procedure, this value is empty.
The **DATA_TYPE** value is the type name only with no other information. The **DTD_IDENTIFIER** value contains the type name and possibly other information such as the precision or length.

- **CHARACTER_MAXIMUM_LENGTH**
  For stored function string return values, the maximum length in characters. If the routine is a stored procedure, this value is **NULL**.

- **CHARACTER_OCTET_LENGTH**
  For stored function string return values, the maximum length in bytes. If the routine is a stored procedure, this value is **NULL**.

- **NUMERIC_PRECISION**
  For stored function numeric return values, the numeric precision. If the routine is a stored procedure, this value is **NULL**.

- **NUMERIC_SCALE**
  For stored function numeric return values, the numeric scale. If the routine is a stored procedure, this value is **NULL**.

- **DATETIME_PRECISION**
  For stored function temporal return values, the fractional seconds precision. If the routine is a stored procedure, this value is **NULL**.

- **CHARACTER_SET_NAME**
  For stored function character string return values, the character set name. If the routine is a stored procedure, this value is **NULL**.

- **COLLATION_NAME**
  For stored function character string return values, the collation name. If the routine is a stored procedure, this value is **NULL**.

- **DTD_IDENTIFIER**
  If the routine is a stored function, the return value data type. If the routine is a stored procedure, this value is empty.

  The **DATA_TYPE** value is the type name only with no other information. The **DTD_IDENTIFIER** value contains the type name and possibly other information such as the precision or length.

- **ROUTINE_BODY**
  The language used for the routine definition. This value is always **SQL**.

- **ROUTINE_DEFINITION**
  The text of the SQL statement executed by the routine.

- **EXTERNAL_NAME**
  This value is always **NULL**.
• **EXTERNAL_LANGUAGE**
  The language of the stored routine. MySQL calculates `EXTERNAL_LANGUAGE` thus:
  • If `mysql.proc.language='SQL'`, `EXTERNAL_LANGUAGE` is `NULL`
  • Otherwise, `EXTERNAL_LANGUAGE` is what is in `mysql.proc.language`. However, we do not have external languages yet, so it is always `NULL`.

• **PARAMETER_STYLE**
  This value is always `SQL`.

• **IS_DETERMINISTIC**
  `YES` or `NO`, depending on whether the routine is defined with the `DETERMINISTIC` characteristic.

• **SQL_DATA_ACCESS**
  The data access characteristic for the routine. The value is one of `CONTAINS SQL`, `NO SQL`, `READS SQL DATA`, or `MODIFIES SQL DATA`.

• **SQL_PATH**
  This value is always `NULL`.

• **SECURITY_TYPE**
  The routine `SQL SECURITY` characteristic. The value is one of `DEFINER` or `INVOKER`.

• **CREATED**
  The date and time when the routine was created. This is a `TIMESTAMP` value.

• **LAST_ALTERED**
  The date and time when the routine was last modified. This is a `TIMESTAMP` value. If the routine has not been modified since its creation, this value is the same as the `CREATED` value.

• **SQL_MODE**
  The SQL mode in effect when the routine was created or altered, and under which the routine executes. For the permitted values, see Section 5.1.10, “Server SQL Modes”.

• **ROUTINE_COMMENT**
  The text of the comment, if the routine has one. If not, this value is empty.

• **DEFINER**
  The account of the user who created the routine, in 'user_name'@'host_name' format.

• **CHARACTER_SET_CLIENT**
  The session value of the `character_set_client` system variable when the routine was created.

• **COLLATION_CONNECTION**
  The session value of the `collation_connection` system variable when the routine was created.
• **DATABASE_COLLATION**

  The collation of the database with which the routine is associated.

**Notes**

• Information about stored function return values is also available in the **PARAMETERS** table. The return value row for a stored function can be identified as the row that has an **ORDINAL_POSITION** value of 0.

### 21.20 The INFORMATION_SCHEMA SCHEMATA Table

A schema is a database, so the **SCHEMATA** table provides information about databases.

The **SCHEMATA** table has these columns:

• **CATALOG_NAME**

  The name of the catalog to which the schema belongs. This value is always **def**.

• **SCHEMA_NAME**

  The name of the schema.

• **DEFAULT_CHARACTER_SET_NAME**

  The schema default character set.

• **DEFAULT_COLLATION_NAME**

  The schema default collation.

• **SQL_PATH**

  This value is always **NULL**.

Schema names are also available from the **SHOW DATABASES** statement. See Section 13.7.5.15, “SHOW DATABASES Syntax”. The following statements are equivalent:

```
SELECT SCHEMA_NAME AS 'Database'
FROM INFORMATION_SCHEMA.SCHEMATA
[WHERE SCHEMA_NAME LIKE '%wild%']
SHOW DATABASES
[LIKE '%wild%']
```

You see only those databases for which you have some kind of privilege, unless you have the global **SHOW DATABASES** privilege.

**Caution**

Because a global privilege is considered a privilege for all databases, any global privilege enables a user to see all database names with **SHOW DATABASES** or by examining the **INFORMATION_SCHEMA SCHEMATA** table.

### 21.21 The INFORMATION_SCHEMA SCHEMA_PRIVILEGES Table

The **SCHEMA_PRIVILEGES** table provides information about schema (database) privileges. It takes its values from the **mysql.db** system table.
The `SCHEMA_PRIVILEGES` table has these columns:

- **GRANTEE**
  The name of the account to which the privilege is granted, in `'user_name'@'host_name'` format.

- **TABLE_CATALOG**
  The name of the catalog to which the schema belongs. This value is always `def`.

- **TABLE_SCHEMA**
  The name of the schema.

- **PRIVILEGE_TYPE**
  The privilege granted. The value can be any privilege that can be granted at the schema level; see Section 13.7.1.4, “GRANT Syntax”. Each row lists a single privilege, so there is one row per schema privilege held by the grantee.

- **IS_GRANTABLE**
  `YES` if the user has the GRANT OPTION privilege, `NO` otherwise. The output does not list GRANT OPTION as a separate row with PRIVILEGE_TYPE='GRANT OPTION'.

Notes

- The `SCHEMA_PRIVILEGES` table is a nonstandard INFORMATION_SCHEMA table.

The following statements are *not* equivalent:

```sql
SELECT ... FROM INFORMATION_SCHEMA.SCHEMA_PRIVILEGES
SHOW GRANTS ...
```

21.22 The INFORMATION_SCHEMA STATISTICS Table

The `STATISTICS` table provides information about table indexes.

The `STATISTICS` table has these columns:

- **TABLE_CATALOG**
  The name of the catalog to which the table containing the index belongs. This value is always `def`.

- **TABLE_SCHEMA**
  The name of the schema (database) to which the table containing the index belongs.

- **TABLE_NAME**
  The name of the table containing the index.

- **NON_UNIQUE**
  0 if the index cannot contain duplicates, 1 if it can.

- **INDEX_SCHEMA
The name of the schema (database) to which the index belongs.

- **INDEX_NAME**
  The name of the index. If the index is the primary key, the name is always **PRIMARY**.

- **SEQ_IN_INDEX**
  The column sequence number in the index, starting with 1.

- **COLUMN_NAME**
  The column name. See also the description for the **EXPRESSION** column.

- **COLLATION**
  How the column is sorted in the index. This can have values **A** (ascending), **D** (descending), or **NULL** (not sorted).

- **CARDINALITY**
  An estimate of the number of unique values in the index. To update this number, run **ANALYZE TABLE** or (for **MyISAM** tables) **myisamchk -a**.
  
  **CARDINALITY** is counted based on statistics stored as integers, so the value is not necessarily exact even for small tables. The higher the cardinality, the greater the chance that MySQL uses the index when doing joins.

- **SUB_PART**
  The index prefix. That is, the number of indexed characters if the column is only partly indexed, **NULL** if the entire column is indexed.

  **Note**
  Prefix *limits* are measured in bytes. However, prefix *lengths* for index specifications in **CREATE TABLE**, **ALTER TABLE**, and **CREATE INDEX** statements are interpreted as number of characters for nonbinary string types (**CHAR**, **VARCHAR**, **TEXT**) and number of bytes for binary string types (**BINARY**, **VARBINARY**, **BLOB**). Take this into account when specifying a prefix length for a nonbinary string column that uses a multibyte character set.

  For additional information about index prefixes, see **Section 8.3.4, “Column Indexes”**, and **Section 13.1.13, “CREATE INDEX Syntax”**.

- **PACKED**
  Indicates how the key is packed. **NULL** if it is not.

- **NULLABLE**
  Contains **YES** if the column may contain **NULL** values and **' '** if not.

- **INDEX_TYPE**
  The index method used (**BTREE**, **FULLTEXT**, **HASH**, **RTREE**).
Information about the index not described in its own column, such as *disabled* if the index is disabled.

- **INDEX_COMMENT**

  Any comment provided for the index with a *COMMENT* attribute when the index was created.

**Notes**

- There is no standard *INFORMATION_SCHEMA* table for indexes. The MySQL column list is similar to what SQL Server 2000 returns for *sp_statistics*, except that *QUALIFIER* and *OWNER* are replaced with *CATALOG* and *SCHEMA*, respectively.

Information about table indexes is also available from the *SHOW INDEX* statement. See Section 13.7.5.23, “*SHOW INDEX Syntax*”. The following statements are equivalent:

```sql
SELECT * FROM INFORMATION_SCHEMA.STATISTICS
   WHERE table_name = 'tbl_name'
   AND table_schema = 'db_name'
```

```sql
SHOW INDEX
   FROM tbl_name
   FROM db_name
```

### 21.23 The *INFORMATION_SCHEMA* TABLES Table

The *TABLES* table provides information about tables in databases.

The *TABLES* table has these columns:

- **TABLE_CATALOG**

  The name of the catalog to which the table belongs. This value is always *def*.

- **TABLE_SCHEMA**

  The name of the schema (database) to which the table belongs.

- **TABLE_NAME**

  The name of the table.

- **TABLE_TYPE**

  *BASE TABLE* for a table, *VIEW* for a view, or *SYSTEM VIEW* for an *INFORMATION_SCHEMA* table.

  The *TABLES* table does not list *TEMPORARY* tables.

- **ENGINE**

  For partitioned tables, *ENGINE* shows the name of the storage engine used by all partitions.

- **VERSION**

  The version number of the table’s *.frm* file.
The INFORMATION_SCHEMA TABLES Table

- **ROW_FORMAT**

  The row-storage format (Fixed, Dynamic, Compressed, Redundant, Compact). For MyISAM tables, Dynamic corresponds to what myisamchk -dvv reports as Packed. InnoDB table format is either Redundant or Compact when using the Antelope file format, or Compressed or Dynamic when using the Barracuda file format.

- **TABLE_ROWS**

  The number of rows. Some storage engines, such as MyISAM, store the exact count. For other storage engines, such as InnoDB, this value is an approximation, and may vary from the actual value by as much as 40% to 50%. In such cases, use SELECT COUNT(*) to obtain an accurate count.

  TABLE_ROWS is NULL for INFORMATION_SCHEMA tables.

  For InnoDB tables, the row count is only a rough estimate used in SQL optimization. (This is also true if the InnoDB table is partitioned.)

- **AVG_ROW_LENGTH**

  The average row length.

  Refer to the notes at the end of this section for related information.

- **DATA_LENGTH**

  For MyISAM, DATA_LENGTH is the length of the data file, in bytes.

  For InnoDB, DATA_LENGTH is the approximate amount of memory allocated for the clustered index, in bytes. Specifically, it is the clustered index size, in pages, multiplied by the InnoDB page size.

  Refer to the notes at the end of this section for information regarding other storage engines.

- **MAX_DATA_LENGTH**

  For MyISAM, MAX_DATA_LENGTH is maximum length of the data file. This is the total number of bytes of data that can be stored in the table, given the data pointer size used.

  Unused for InnoDB.

  Refer to the notes at the end of this section for information regarding other storage engines.

- **INDEX_LENGTH**

  For MyISAM, INDEX_LENGTH is the length of the index file, in bytes.

  For InnoDB, INDEX_LENGTH is the approximate amount of memory allocated for non-clustered indexes, in bytes. Specifically, it is the sum of non-clustered index sizes, in pages, multiplied by the InnoDB page size.

  Refer to the notes at the end of this section for information regarding other storage engines.

- **DATA_FREE**

  The number of allocated but unused bytes.

  InnoDB tables report the free space of the tablespace to which the table belongs. For a table located in the shared tablespace, this is the free space of the shared tablespace. If you are using multiple
tables and the table has its own tablespace, the free space is for only that table. Free space means the number of bytes in completely free extents minus a safety margin. Even if free space displays as 0, it may be possible to insert rows as long as new extents need not be allocated.

For NDB Cluster, `DATA_FREE` shows the space allocated on disk for, but not used by, a Disk Data table or fragment on disk. (In-memory data resource usage is reported by the `DATA_LENGTH` column.)

For partitioned tables, this value is only an estimate and may not be absolutely correct. A more accurate method of obtaining this information in such cases is to query the `INFORMATION_SCHEMA PARTITIONS` table, as shown in this example:

```
SELECT SUM(DATA_FREE)
FROM INFORMATION_SCHEMA.PARTITIONS
WHERE TABLE_SCHEMA = 'mydb'
AND   TABLE_NAME   = 'mytable';
```

For more information, see Section 21.14, “The INFORMATION_SCHEMA PARTITIONS Table”.

- **AUTO_INCREMENT**

  The next `AUTO_INCREMENT` value.

- **CREATE_TIME**

  When the table was created.

  Prior to MySQL 5.6.25, for partitioned `InnoDB` tables, the `CREATE_TIME` column shows `NULL`. This column shows the correct table creation time for such tables in MySQL 5.6.25 and later. (Bug #17299181, Bug #69990)

- **UPDATE_TIME**

  When the data file was last updated. For some storage engines, this value is `NULL`. For example, `InnoDB` stores multiple tables in its system tablespace and the data file timestamp does not apply. Even with `file-per-table` mode with each `InnoDB` table in a separate `.ibd` file, change buffering can delay the write to the data file, so the file modification time is different from the time of the last insert, update, or delete. For `MyISAM`, the data file timestamp is used; however, on Windows the timestamp is not updated by updates, so the value is inaccurate.

  For partitioned `InnoDB` tables, `UPDATE_TIME` is always `NULL`.

- **CHECK_TIME**

  When the table was last checked. Not all storage engines update this time, in which case, the value is always `NULL`.

  For partitioned `InnoDB` tables, `CHECK_TIME` is always `NULL`.

- **TABLE_COLLATION**

  The table default collation. The output does not explicitly list the table default character set, but the collation name begins with the character set name.

- **CHECKSUM**

  The live checksum value, if any.

- **CREATE_OPTIONS**
Extra options used with `CREATE TABLE`. The original options from when `CREATE TABLE` was executed are retained and the options reported here may differ from the active table settings and options.

`CREATE_OPTIONS` shows partitioned if the table is partitioned.

- **TABLE_COMMENT**

  The comment used when creating the table (or information as to why MySQL could not access the table information).

**Notes**

- For NDB tables, the output of this statement shows appropriate values for the `AVG_ROW_LENGTH` and `DATA_LENGTH` columns, with the exception that `BLOB` columns are not taken into account.

- For NDB tables, `DATA_LENGTH` includes data stored in main memory only; the `MAX_DATA_LENGTH` and `DATA_FREE` columns apply to Disk Data.

- For NDB Cluster Disk Data tables, `MAX_DATA_LENGTH` shows the space allocated for the disk part of a Disk Data table or fragment. (In-memory data resource usage is reported by the `DATA_LENGTH` column.)

- For MEMORY tables, the `DATA_LENGTH`, `MAX_DATA_LENGTH`, and `INDEX_LENGTH` values approximate the actual amount of allocated memory. The allocation algorithm reserves memory in large amounts to reduce the number of allocation operations.

- For views, all `TABLES` columns are `NULL` except that `TABLE_NAME` indicates the view name and `TABLE_COMMENT` says `VIEW`.

Table information is also available from the `SHOW TABLE STATUS` and `SHOW TABLES` statements. See Section 13.7.5.37, “SHOW TABLE STATUS Syntax”, and Section 13.7.5.38, “SHOW TABLES Syntax”. The following statements are equivalent:

```
SELECT  
    TABLE_NAME, ENGINE, VERSION, ROW_FORMAT, TABLE_ROWS, AVG_ROW_LENGTH,  
    DATA_LENGTH, MAX_DATA_LENGTH, INDEX_LENGTH, DATA_FREE, AUTO_INCREMENT,  
    CREATE_TIME, UPDATE_TIME, CHECK_TIME, TABLE_COLLATION, CHECKSUM,  
    CREATE_OPTIONS, TABLE_COMMENT  
FROM INFORMATION_SCHEMA.TABLES  
WHERE table_schema = 'db_name'  
[AND table_name LIKE 'wild']
```

```
SHOW TABLE STATUS  
FROM db_name  
[LIKE 'wild']
```

The following statements are equivalent:

```
SELECT  
    TABLE_NAME, TABLE_TYPE  
FROM INFORMATION_SCHEMA.TABLES  
WHERE table_schema = 'db_name'  
[AND table_name LIKE 'wild']
```

```
SHOW FULL TABLES  
FROM db_name  
[LIKE 'wild']
```

21.24 The INFORMATION_SCHEMA TABLESPACES Table
The `TABLESPACES` table provides information about active MySQL Cluster tablespaces.

The `TABLESPACES` table has these columns:

- **TABLESPACE_NAME**
  The name of the tablespace.

- **ENGINE**
  The name of the storage engine that uses the tablespace.

- **TABLESPACE_TYPE**
  The tablespace type.

- **LOGFILE_GROUP_NAME**
  The name of the logfile group assigned to the tablespace.

- **EXTENT_SIZE**
  The size in bytes of the extents used by files that belong to the tablespace.

- **AUTOEXTEND_SIZE**
  Unused.

- **MAXIMUM_SIZE**
  Unused.

- **NODEGROUP_ID**
  Unused.

- **TABLESPACE_COMMENT**
  Unused.

**Notes**

- The `TABLESPACES` table is a nonstandard `INFORMATION_SCHEMA` table.

- The `TABLESPACES` table does not provide information about InnoDB tablespaces. For InnoDB tablespace metadata, see the `INFORMATION_SCHEMA INNODB_SYS_TABLESPACES` and `INNODB_SYS_DATAFILES` tables.

### 21.25 The `INFORMATION_SCHEMA` TABLE_CONSTRAINTS Table

The `TABLE_CONSTRAINTS` table describes which tables have constraints.

The `TABLE_CONSTRAINTS` table has these columns:

- **CONSTRAINT_CATALOG**
  The name of the catalog to which the constraint belongs. This value is always `def`.

- **CONSTRAINT_SCHEMA**
The name of the schema (database) to which the constraint belongs.

- **TABLE_SCHEMA**
  The name of the schema (database) to which the table belongs.

- **TABLE_NAME**
  The name of the table.

- **CONSTRAINT_TYPE**
  The type of constraint. The value can be **UNIQUE**, **PRIMARY KEY**, **FOREIGN KEY**, or **CHECK**. This is a **CHAR** (not **ENUM**) column. The **CHECK** value is not available until MySQL supports **CHECK**.

The **UNIQUE** and **PRIMARY KEY** information is about the same as what you get from the **Key_name** column in the output from **SHOW INDEX** when the **Non_unique** column is 0.

### 21.26 The INFORMATION_SCHEMA TABLE_PRIVILEGES Table

The **TABLE_PRIVILEGES** table provides information about table privileges. It takes its values from the **mysql.tables_priv** system table.

The **TABLE_PRIVILEGES** table has these columns:

- **GRANTEE**
  The name of the account to which the privilege is granted, in 'user_name'@'host_name' format.

- **TABLE_CATALOG**
  The name of the catalog to which the table belongs. This value is always **def**.

- **TABLE_SCHEMA**
  The name of the schema (database) to which the table belongs.

- **TABLE_NAME**
  The name of the table.

- **PRIVILEGE_TYPE**
  The privilege granted. The value can be any privilege that can be granted at the table level; see **Section 13.7.1.4, “GRANT Syntax”**. Each row lists a single privilege, so there is one row per table privilege held by the grantee.

- **IS_GRANTABLE**
  **YES** if the user has the **GRANT OPTION** privilege, **NO** otherwise. The output does not list **GRANT OPTION** as a separate row with **PRIVILEGE_TYPE='GRANT OPTION'**.

### Notes

- The **TABLE_PRIVILEGES** table is a nonstandard INFORMATION_SCHEMA table.

The following statements are not equivalent:
SELECT ... FROM INFORMATION_SCHEMA.TABLE_PRIVILEGES
SHOW GRANTS ...

21.27 The INFORMATION_SCHEMA TRIGGERS Table

The TRIGGERS table provides information about triggers. To see information about a table's triggers, you must have the TRIGGER privilege for the table.

The TRIGGERS table has these columns:

• TRIGGER_CATALOG
  The name of the catalog to which the trigger belongs. This value is always def.

• TRIGGER_SCHEMA
  The name of the schema (database) to which the trigger belongs.

• TRIGGER_NAME
  The name of the trigger.

• EVENT_MANIPULATION
  The trigger event. This is the type of operation on the associated table for which the trigger activates. The value is INSERT (a row was inserted), DELETE (a row was deleted), or UPDATE (a row was modified).

• EVENT_OBJECT_CATALOG, EVENT_OBJECT_SCHEMA, and EVENT_OBJECT_TABLE
  As noted in Section 20.3, "Using Triggers", every trigger is associated with exactly one table. These columns indicate the catalog and schema (database) in which this table occurs, and the table name, respectively. The EVENT_OBJECT_CATALOG value is always def.

• ACTION_ORDER
  The ordinal position of the trigger's action within the list of all similar triggers on the same table. This value is always 0 because it is not possible to have more than one trigger with the same EVENT_MANIPULATION and ACTION_TIMING on the same table.

• ACTION_CONDITION
  This value is always NULL.

• ACTION_STATEMENT
  The trigger body; that is, the statement executed when the trigger activates. This text uses UTF-8 encoding.

• ACTION_ORIENTATION
  This value is always ROW.

• ACTION_TIMING
  Whether the trigger activates before or after the triggering event. The value is BEFORE or AFTER.
• **ACTIONREFERENCEOLDTABLE**
  This value is always **NULL**.

• **ACTIONREFERENCENEWTABLE**
  This value is always **NULL**.

• **ACTIONREFERENCEOLDROW** and **ACTIONREFERENCENEWROW**
  The old and new column identifiers, respectively. The **ACTIONREFERENCEOLDROW** value is always **OLD** and the **ACTIONREFERENCENEWROW** value is always **NEW**.

• **CREATED**
  This value is always **NULL**.

• **SQL_MODE**
  The SQL mode in effect when the trigger was created, and under which the trigger executes. For the permitted values, see **Section 5.1.10, “Server SQL Modes”**.

• **DEFINER**
  The account of the user who created the trigger, in **user_name@host_name** format.

• **CHARACTER_SET_CLIENT**
  The session value of the **character_set_client** system variable when the trigger was created.

• **COLLATION_CONNECTION**
  The session value of the **collation_connection** system variable when the trigger was created.

• **DATABASE_COLLATION**
  The collation of the database with which the trigger is associated.

### Example

The following example uses the **ins_sum** trigger defined in **Section 20.3, “Using Triggers”**:

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.TRIGGERS
WHERE TRIGGER_SCHEMA='test' AND TRIGGER_NAME='ins_sum';
```

```
TRIGGER_CATALOG: def
TRIGGER_SCHEMA: test
TRIGGER_NAME: ins_sum
EVENT_MANIPULATION: INSERT
EVENT_OBJECT_CATALOG: def
EVENT_OBJECT_SCHEMA: test
EVENT_OBJECT_TABLE: account
ACTION_ORDER: 0
ACTION_CONDITION: NULL
ACTION_STATEMENT: SET @sum = @sum + NEW.amount
ACTION_ORIENTATION: ROW
ACTION_TIMING: BEFORE
ACTIONREFERENCEOLDTABLE: NULL
ACTIONREFERENCENEWTABLE: NULL
ACTIONREFERENCEOLDROW: OLD
ACTIONREFERENCENEWROW: NEW
```
21.28 The INFORMATION_SCHEMA USER_PRIVILEGES Table

The USER_PRIVILEGES table provides information about global privileges. It takes its values from the mysql.user system table.

The USER_PRIVILEGES table has these columns:

- **GRANTEE**
  The name of the account to which the privilege is granted, in 'user_name'@'host_name' format.

- **TABLE_CATALOG**
  The name of the catalog. This value is always def.

- **PRIVILEGE_TYPE**
  The privilege granted. The value can be any privilege that can be granted at the global level; see Section 13.7.1.4, “GRANT Syntax”. Each row lists a single privilege, so there is one row per global privilege held by the grantee.

- **IS_GRANTABLE**
  YES if the user has the GRANT OPTION privilege, NO otherwise. The output does not list GRANT OPTION as a separate row with PRIVILEGE_TYPE='GRANT OPTION'.

Notes

- The USER_PRIVILEGES table is a nonstandard INFORMATION_SCHEMA table.

The following statements are not equivalent:

```sql
SELECT ... FROM INFORMATION_SCHEMA.USER_PRIVILEGES
SHOW GRANTS ...
```

21.29 The INFORMATION_SCHEMA VIEWS Table

The VIEWS table provides information about views in databases. You must have the SHOW VIEW privilege to access this table.

The VIEWS table has these columns:

- **TABLE_CATALOG**
  The name of the catalog to which the view belongs. This value is always def.

- **TABLE_SCHEMA**
The name of the schema (database) to which the view belongs.

- **TABLE_NAME**
  The name of the view.

- **VIEW_DEFINITION**
  The `SELECT` statement that provides the definition of the view. This column has most of what you see in the `Create Table` column that `SHOW CREATE VIEW` produces. Skip the words before `SELECT` and skip the words `WITH CHECK OPTION`. Suppose that the original statement was:

  ```sql
  CREATE VIEW v AS
  SELECT s2, s1 FROM t
  WHERE s1 > 5
  ORDER BY s1
  WITH CHECK OPTION;
  ```

  Then the view definition looks like this:

  ```sql
  SELECT s2, s1 FROM t WHERE s1 > 5 ORDER BY s1
  ```

- **CHECK_OPTION**
  The value of the `CHECK_OPTION` attribute. The value is one of `NONE`, `CASCADE`, or `LOCAL`.

- **IS_UPDATABLE**
  MySQL sets a flag, called the view updatability flag, at `CREATE VIEW` time. The flag is set to `YES` (true) if `UPDATE` and `DELETE` (and similar operations) are legal for the view. Otherwise, the flag is set to `NO` (false). The `IS_UPDATABLE` column in the `VIEWS` table displays the status of this flag. It means that the server always knows whether a view is updatable.

  If a view is not updatable, statements such `UPDATE`, `DELETE`, and `INSERT` are illegal and are rejected. (Even if a view is updatable, it might not be possible to insert into it; for details, refer to Section 20.5.3, “Updatable and Insertable Views”.)

- **DEFINER**
  The account of the user who created the view, in `'user_name'@'host_name'` format.

- **SECURITY_TYPE**
  The view `SQL SECURITY` characteristic. The value is one of `DEFINER` or `INVOKER`.

- **CHARACTER_SET_CLIENT**
  The session value of the `character_set_client` system variable when the view was created.

- **COLLATION_CONNECTION**
  The session value of the `collation_connection` system variable when the view was created.

### Notes

MySQL permits different `sql_mode` settings to tell the server the type of SQL syntax to support. For example, you might use the `ANSI` SQL mode to ensure MySQL correctly interprets the standard SQL
concatenation operator, the double bar (||), in your queries. If you then create a view that concatenates items, you might worry that changing the sql_mode setting to a value different from ANSI could cause the view to become invalid. But this is not the case. No matter how you write out a view definition, MySQL always stores it the same way, in a canonical form. Here is an example that shows how the server changes a double bar concatenation operator to a CONCAT() function:

```sql
mysql> SET sql_mode = 'ANSI';
Query OK, 0 rows affected (0.00 sec)
mysql> CREATE VIEW test.v AS SELECT 'a' || 'b' as col1;
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT VIEW_DEFINITION FROM INFORMATION_SCHEMA.VIEWS
WHERE TABLE_SCHEMA = 'test' AND TABLE_NAME = 'v';
+----------------------------------+
<table>
<thead>
<tr>
<th>VIEW_DEFINITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>select concat('a','b') AS 'col1'</td>
</tr>
</tbody>
</table>
+----------------------------------+
1 row in set (0.00 sec)
```

The advantage of storing a view definition in canonical form is that changes made later to the value of sql_mode do not affect the results from the view. However, an additional consequence is that comments prior to SELECT are stripped from the definition by the server.

21.30 INFORMATION_SCHEMA InnoDB Tables

This section provides table definitions for InnoDB INFORMATION_SCHEMA tables. For related information and examples, see Section 14.15, “InnoDB INFORMATION_SCHEMA Tables”.

InnoDB INFORMATION_SCHEMA tables can be used to monitor ongoing InnoDB activity, to detect inefficiencies before they turn into issues, or to troubleshoot performance and capacity issues. As your database becomes bigger and busier, running up against the limits of your hardware capacity, you monitor and tune these aspects to keep the database running smoothly.

21.30.1 The INFORMATION_SCHEMA INNODB_BUFFER_PAGE Table

The INNODB_BUFFER_PAGE table provides information about each page in the InnoDB buffer pool. For related usage information and examples, see Section 14.15.5, “InnoDB INFORMATION_SCHEMA Buffer Pool Tables”.

**Warning**

Querying the INNODB_BUFFER_PAGE table can affect performance. Do not query this table on a production system unless you are aware of the performance impact and have determined it to be acceptable. To avoid impacting performance on a production system, reproduce the issue you want to investigate and query buffer pool statistics on a test instance.

The INNODB_BUFFER_PAGE table has these columns:

- **POOL_ID**
  The buffer pool ID. This is an identifier to distinguish between multiple buffer pool instances.

- **BLOCK_ID**
  The buffer pool block ID.
The INFORMATION_SCHEMA INNODB_BUFFER_PAGE Table

- **SPACE**
  The tablespace ID; the same value as INNODB_SYS_TABLES.SPACE.

- **PAGE_NUMBER**
  The page number.

- **PAGE_TYPE**
  The page type. The following table shows the permitted values.

**Table 21.1 INNODB_BUFFER_PAGE.PAGE_TYPE Values**

<table>
<thead>
<tr>
<th>Page Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALLOCATED</td>
<td>Freshly allocated page</td>
</tr>
<tr>
<td>BLOB</td>
<td>Uncompressed BLOB page</td>
</tr>
<tr>
<td>COMPRESSED_BLOB2</td>
<td>Subsequent comp BLOB page</td>
</tr>
<tr>
<td>COMPRESSED_BLOB</td>
<td>First compressed BLOB page</td>
</tr>
<tr>
<td>EXTENT_DESCRIPTOR</td>
<td>Extent descriptor page</td>
</tr>
<tr>
<td>FILE_SPACE_HEADER</td>
<td>File space header</td>
</tr>
<tr>
<td>IBUF_BITMAP</td>
<td>Insert buffer bitmap</td>
</tr>
<tr>
<td>IBUF_FREE_LIST</td>
<td>Insert buffer free list</td>
</tr>
<tr>
<td>IBUF_INDEX</td>
<td>Insert buffer index</td>
</tr>
<tr>
<td>INDEX</td>
<td>B-tree node</td>
</tr>
<tr>
<td>INODE</td>
<td>Index node</td>
</tr>
<tr>
<td>SYSTEM</td>
<td>System page</td>
</tr>
<tr>
<td>TRX_SYSTEM</td>
<td>Transaction system data</td>
</tr>
<tr>
<td>UNDO_LOG</td>
<td>Undo log page</td>
</tr>
<tr>
<td>UNKNOWN</td>
<td>Unknown</td>
</tr>
</tbody>
</table>

- **FLUSH_TYPE**
  The flush type.

- **FIX_COUNT**
  The number of threads using this block within the buffer pool. When zero, the block is eligible to be evicted.

- **IS_HASHED**
  Whether a hash index has been built on this page.

- **NEWEST_MODIFICATION**
  The Log Sequence Number of the youngest modification.

- **OLDEST_MODIFICATION**
  The Log Sequence Number of the oldest modification.
The INFORMATION_SCHEMA INNODB_BUFFER_PAGE Table

- **ACCESS_TIME**
  An abstract number used to judge the first access time of the page.

- **TABLE_NAME**
  The name of the table the page belongs to. This column is applicable only to pages with a PAGE_TYPE value of **INDEX**.

- **INDEX_NAME**
  The name of the index the page belongs to. This can be the name of a clustered index or a secondary index. This column is applicable only to pages with a PAGE_TYPE value of **INDEX**.

- **NUMBER_RECORDS**
  The number of records within the page.

- **DATA_SIZE**
  The sum of the sizes of the records. This column is applicable only to pages with a PAGE_TYPE value of **INDEX**.

- **COMPRESSED_SIZE**
  The compressed page size. **NULL** for pages that are not compressed.

- **PAGE_STATE**
  The page state. The following table shows the permitted values.

<table>
<thead>
<tr>
<th>Page State</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FILE_PAGE</td>
<td>A buffered file page</td>
</tr>
<tr>
<td>MEMORY</td>
<td>Contains a main memory object</td>
</tr>
<tr>
<td>NOT_USED</td>
<td>In the free list</td>
</tr>
<tr>
<td>NULL</td>
<td>Clean compressed pages, compressed pages in the flush list, pages used as buffer pool watch sentinels</td>
</tr>
<tr>
<td>READY_FOR_USE</td>
<td>A free page</td>
</tr>
<tr>
<td>REMOVE_HASH</td>
<td>Hash index should be removed before placing in the free list</td>
</tr>
</tbody>
</table>

- **IO_FIX**
  Whether any I/O is pending for this page: **IO_NONE** = no pending I/O, **IO_READ** = read pending, **IO_WRITE** = write pending.

- **IS_OLD**
  Whether the block is in the sublist of old blocks in the LRU list.

- **FREE_PAGE_CLOCK**
  The value of the freed_page_clock counter when the block was the last placed at the head of the LRU list. The freed_page_clock counter tracks the number of blocks removed from the end of the LRU list.
The INFORMATION_SCHEMA INNODB_BUFFER_PAGE_LRU Table

Example

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE LIMIT 1\G
*************************** 1. row ***************************
POOL_ID: 0
BLOCK_ID: 0
SPACE: 97
PAGE_NUMBER: 2473
PAGE_TYPE: INDEX
FLUSH_TYPE: 1
FIX_COUNT: 0
IS_HASHED: YES
NEWEST_MODIFICATION: 733855581
OLDEST_MODIFICATION: 0
ACCESS_TIME: 3378385672
TABLE_NAME: `employees`.`salaries`
INDEX_NAME: PRIMARY
NUMBER_RECORDS: 468
DATA_SIZE: 14976
COMPRESSED_SIZE: 0
PAGE_STATE: FILE_PAGE
IO_FIX: IO_NONE
IS_OLD: YES
FREE_PAGE_CLOCK: 66

Notes

• This table is useful primarily for expert-level performance monitoring, or when developing performance-related extensions for MySQL.

• You must have the PROCESS privilege to query this table.

• Use the INFORMATION_SCHEMA_COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of this table, including data types and default values.

• When tables, table rows, partitions, or indexes are deleted, associated pages remain in the buffer pool until space is required for other data. The INNODB_BUFFER_PAGE table reports information about these pages until they are evicted from the buffer pool. For more information about how the InnoDB manages buffer pool data, see Section 14.5.1, “Buffer Pool”.

21.30.2 The INFORMATION_SCHEMA INNODB_BUFFER_PAGE_LRU Table

The INNODB_BUFFER_PAGE_LRU table provides information about the pages in the InnoDB buffer pool; in particular, how they are ordered in the LRU list that determines which pages to evict from the buffer pool when it becomes full.

The INNODB_BUFFER_PAGE_LRU table has the same columns as the INNODB_BUFFER_PAGE table, except that the INNODB_BUFFER_PAGE_LRU table has LRU_POSITION and COMPRESSED columns instead of BLOCK_ID and PAGE_STATE columns.

For related usage information and examples, see Section 14.15.5, “InnoDB INFORMATION_SCHEMA Buffer Pool Tables”.

Warning

Querying the INNODB_BUFFER_PAGE_LRU table can affect performance. Do not query this table on a production system unless you are aware of the performance impact and have determined it to be acceptable. To avoid impacting performance on a production system, reproduce the issue you want to investigate and query buffer pool statistics on a test instance.
The **INNODB_BUFFER_PAGE_LRU** table has these columns:

- **POOL_ID**
  
The buffer pool ID. This is an identifier to distinguish between multiple buffer pool instances.

- **LRU_POSITION**
  
The position of the page in the LRU list.

- **SPACE**
  
The tablespace ID; the same value as **INNODB_SYS_TABLES.SPACE**.

- **PAGE_NUMBER**
  
The page number.

- **PAGE_TYPE**
  
The page type. The following table shows the permitted values.

<table>
<thead>
<tr>
<th>Page Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALLOCATED</td>
<td>Freshly allocated page</td>
</tr>
<tr>
<td>BLOB</td>
<td>Uncompressed BLOB page</td>
</tr>
<tr>
<td>COMPRESSED_BLOB2</td>
<td>Subsequent comp BLOB page</td>
</tr>
<tr>
<td>COMPRESSED_BLOB</td>
<td>First compressed BLOB page</td>
</tr>
<tr>
<td>EXTENT_DESCRIPTOR</td>
<td>Extent descriptor page</td>
</tr>
<tr>
<td>FILE_SPACE_HEADER</td>
<td>File space header</td>
</tr>
<tr>
<td>IBUF_BITMAP</td>
<td>Insert buffer bitmap</td>
</tr>
<tr>
<td>IBUF_FREE_LIST</td>
<td>Insert buffer free list</td>
</tr>
<tr>
<td>IBUF_INDEX</td>
<td>Insert buffer index</td>
</tr>
<tr>
<td>INDEX</td>
<td>B-tree node</td>
</tr>
<tr>
<td>INODE</td>
<td>Index node</td>
</tr>
<tr>
<td>SYSTEM</td>
<td>System page</td>
</tr>
<tr>
<td>TRX_SYSTEM</td>
<td>Transaction system data</td>
</tr>
<tr>
<td>UNDO_LOG</td>
<td>Undo log page</td>
</tr>
<tr>
<td>UNKNOWN</td>
<td>Unknown</td>
</tr>
</tbody>
</table>

- **FLUSH_TYPE**
  
The flush type.

- **FIX_COUNT**
  
The number of threads using this block within the buffer pool. When zero, the block is eligible to be evicted.

- **IS_HASHED**
The INFORMATION_SCHEMA INNODB_BUFFER_PAGE_LRU Table

Whether a hash index has been built on this page.

- **NEWEST_MODIFICATION**
  
  The Log Sequence Number of the youngest modification.

- **OLDEST_MODIFICATION**
  
  The Log Sequence Number of the oldest modification.

- **ACCESS_TIME**
  
  An abstract number used to judge the first access time of the page.

- **TABLE_NAME**
  
  The name of the table the page belongs to. This column is applicable only to pages with a **PAGE_TYPE** value of **INDEX**.

- **INDEX_NAME**
  
  The name of the index the page belongs to. This can be the name of a clustered index or a secondary index. This column is applicable only to pages with a **PAGE_TYPE** value of **INDEX**.

- **NUMBER_RECORDS**
  
  The number of records within the page.

- **DATA_SIZE**
  
  The sum of the sizes of the records. This column is applicable only to pages with a **PAGE_TYPE** value of **INDEX**.

- **COMPRESSED_SIZE**
  
  The compressed page size. **NULL** for pages that are not compressed.

- **COMPRESSED**
  
  Whether the page is compressed.

- **IO_FIX**
  
  Whether any I/O is pending for this page: **IO_NONE** = no pending I/O, **IO_READ** = read pending, **IO_WRITE** = write pending.

- **IS_OLD**
  
  Whether the block is in the sublist of old blocks in the LRU list.

- **FREE_PAGE_CLOCK**
  
  The value of the **freed_page_clock** counter when the block was the last placed at the head of the LRU list. The **freed_page_clock** counter tracks the number of blocks removed from the end of the LRU list.

Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE_LRU LIMIT 1\G
```
Notes

- This table is useful primarily for expert-level performance monitoring, or when developing performance-related extensions for MySQL.
- You must have the PROCESS privilege to query this table.
- Use the INFORMATION_SCHEMA COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of this table, including data types and default values.
- Querying this table can require MySQL to allocate a large block of contiguous memory, more than 64 bytes times the number of active pages in the buffer pool. This allocation could potentially cause an out-of-memory error, especially for systems with multi-gigabyte buffer pools.
- Querying this table requires MySQL to lock the data structure representing the buffer pool while traversing the LRU list, which can reduce concurrency, especially for systems with multi-gigabyte buffer pools.
- When tables, table rows, partitions, or indexes are deleted, associated pages remain in the buffer pool until space is required for other data. The INNODB_BUFFER_PAGE_LRU table reports information about these pages until they are evicted from the buffer pool. For more information about how the InnoDB manages buffer pool data, see Section 14.5.1, “Buffer Pool”.

21.30.3 The INFORMATION_SCHEMA INNODB_BUFFER_POOL_STATS Table

The INNODB_BUFFER_POOL_STATS table provides much of the same buffer pool information provided in SHOW ENGINE INNODB STATUS output. Much of the same information may also be obtained using InnoDB buffer pool server status variables.

The idea of making pages in the buffer pool “young” or “not young” refers to transferring them between the sublists at the head and tail of the buffer pool data structure. Pages made “young” take longer to age out of the buffer pool, while pages made “not young” are moved much closer to the point of eviction.

For related usage information and examples, see Section 14.15.5, “InnoDB INFORMATION_SCHEMA Buffer Pool Tables”.

The INNODB_BUFFER_POOL_STATS table has these columns:

- POOL_ID

<table>
<thead>
<tr>
<th>POOL_ID</th>
<th>LRU_POSITION</th>
<th>SPACE</th>
<th>PAGE_NUMBER</th>
<th>PAGE_TYPE</th>
<th>FLUSH_TYPE</th>
<th>FIX_COUNT</th>
<th>IS_HASHED</th>
<th>NEWEST_MODIFICATION</th>
<th>OLDEST_MODIFICATION</th>
<th>ACCESS_TIME</th>
<th>TABLE_NAME</th>
<th>INDEX_NAME</th>
<th>NUMBER_RECORDS</th>
<th>DATA_SIZE</th>
<th>COMPRESSED_SIZE</th>
<th>COMPRESSED</th>
<th>IO_FIX</th>
<th>IS_OLD</th>
<th>FREE_PAGE_CLOCK</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>97</td>
<td>1984</td>
<td>INDEX</td>
<td>1</td>
<td>0</td>
<td>YES</td>
<td>719490396</td>
<td>0</td>
<td>3378383796</td>
<td><code>employees</code>.<code>salaries</code></td>
<td>PRIMARY</td>
<td>468</td>
<td>14976</td>
<td>0</td>
<td>NO</td>
<td>IO_NONE</td>
<td>YES</td>
<td>0</td>
</tr>
</tbody>
</table>

**Notes**

- This table is useful primarily for expert-level performance monitoring, or when developing performance-related extensions for MySQL.
- You must have the PROCESS privilege to query this table.
- Use the INFORMATION_SCHEMA COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of this table, including data types and default values.
- Querying this table can require MySQL to allocate a large block of contiguous memory, more than 64 bytes times the number of active pages in the buffer pool. This allocation could potentially cause an out-of-memory error, especially for systems with multi-gigabyte buffer pools.
- Querying this table requires MySQL to lock the data structure representing the buffer pool while traversing the LRU list, which can reduce concurrency, especially for systems with multi-gigabyte buffer pools.
- When tables, table rows, partitions, or indexes are deleted, associated pages remain in the buffer pool until space is required for other data. The INNODB_BUFFER_PAGE_LRU table reports information about these pages until they are evicted from the buffer pool. For more information about how the InnoDB manages buffer pool data, see Section 14.5.1, “Buffer Pool”.

**21.30.3 The INFORMATION_SCHEMA INNODB_BUFFER_POOL_STATS Table**

The INNODB_BUFFER_POOL_STATS table provides much of the same buffer pool information provided in SHOW ENGINE INNODB STATUS output. Much of the same information may also be obtained using InnoDB buffer pool server status variables.

The idea of making pages in the buffer pool “young” or “not young” refers to transferring them between the sublists at the head and tail of the buffer pool data structure. Pages made “young” take longer to age out of the buffer pool, while pages made “not young” are moved much closer to the point of eviction.

For related usage information and examples, see Section 14.15.5, “InnoDB INFORMATION_SCHEMA Buffer Pool Tables”.

The INNODB_BUFFER_POOL_STATS table has these columns:

- POOL_ID
The buffer pool ID. This is an identifier to distinguish between multiple buffer pool instances.

- **POOL_SIZE**
  The InnoDB buffer pool size in pages.

- **FREE_BUFFERS**
  The number of free pages in the InnoDB buffer pool.

- **DATABASE_PAGES**
  The number of pages in the InnoDB buffer pool containing data. This number includes both dirty and clean pages.

- **OLD_DATABASE_PAGES**
  The number of pages in the old buffer pool sublist.

- **MODIFIED_DATABASE_PAGES**
  The number of modified (dirty) database pages.

- **PENDING_DECOMPRESS**
  The number of pages pending decompression.

- **PENDING_READS**
  The number of pending reads.

- **PENDING_FLUSH_LRU**
  The number of pages pending flush in the LRU.

- **PENDING_FLUSH_LIST**
  The number of pages pending flush in the flush list.

- **PAGES_MADE_YOUNG**
  The number of pages made young.

- **PAGES_NOT_MADE_YOUNG**
  The number of pages not made young.

- **PAGES_MADE_YOUNG_RATE**
  The number of pages made young per second (pages made young since the last printout / time elapsed).

- **PAGES_MADE_NOT_YOUNG_RATE**
  The number of pages not made per second (pages not made young since the last printout / time elapsed).

- **NUMBER_PAGES_READ**
  The number of pages read.
The INFORMATION_SCHEMA INNODB_BUFFER_POOL_STATS Table

- NUMBER_PAGES_CREATED
  The number of pages created.
- NUMBER_PAGES_WRITTEN
  The number of pages written.
- PAGES_READ_RATE
  The number of pages read per second (pages read since the last printout / time elapsed).
- PAGES_CREATE_RATE
  The number of pages created per second (pages created since the last printout / time elapsed).
- PAGES_WRITTEN_RATE
  The number of pages written per second (pages written since the last printout / time elapsed).
- NUMBER_PAGES_GET
  The number of logical read requests.
- HIT_RATE
  The buffer pool hit rate.
- YOUNG_MAKE_PER_THOUSAND_GETS
  The number of pages made young per thousand gets.
- NOT_YOUNG_MAKE_PER_THOUSAND_GETS
  The number of pages not made young per thousand gets.
- NUMBER_PAGES_READ_AHEAD
  The number of pages read ahead.
- NUMBER_READ_AHEAD_EVICTED
  The number of pages read into the InnoDB buffer pool by the read-ahead background thread that were subsequently evicted without having been accessed by queries.
- READ_AHEAD_RATE
  The read-ahead rate per second (pages read ahead since the last printout / time elapsed).
- READ_AHEAD_EVICTED_RATE
  The number of read-ahead pages evicted without access per second (read-ahead pages not accessed since the last printout / time elapsed).
- LRU_IO_TOTAL
  Total LRU I/O.
- LRU_IO_CURRENT
  LRU I/O for the current interval.
The INFORMATION_SCHEMA INNODB_CMP and INNODB_CMP_RESET Tables

- **UNCOMPRESS_TOTAL**
  The total number of pages decompressed.

- **UNCOMPRESS_CURRENT**
  The number of pages decompressed in the current interval.

**Example**

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_BUFFER_POOL_STATS;
```

| POOL_ID: 0 |
|---|---|
| POOL_SIZE: 8192 |
| FREE_BUFFERS: 1 |
| DATABASE_PAGES: 8085 |
| OLD_DATABASE_PAGES: 2964 |
| MODIFIED_DATABASE_PAGES: 0 |
| PENDING_DECOMPRESS: 0 |
| PENDING_READS: 0 |
| PENDING_FLUSH_LRU: 0 |
| PENDING_FLUSH_LIST: 0 |
| PAGES_MADE_YOUNG: 22821 |
| PAGES_NOT_MADE_YOUNG: 3544303 |
| UNCOMPRESS_TOTAL: 0 |
| UNCOMPRESS_CURRENT: 0 |

**Notes**

- This table is useful primarily for expert-level performance monitoring, or when developing performance-related extensions for MySQL.

- You must have the **PROCESS** privilege to query this table.

- Use the **INFORMATION_SCHEMA COLUMNS** table or the **SHOW COLUMNS** statement to view additional information about the columns of this table, including data types and default values.

**21.30.4 The INFORMATION_SCHEMA INNODB_CMP and INNODB_CMP_RESET Tables**

The **INNODB_CMP** and **INNODB_CMP_RESET** tables provide status information on operations related to compressed InnoDB tables.

The **INNODB_CMP** and **INNODB_CMP_RESET** tables have these columns:
• **PAGE_SIZE**
  The compressed page size in bytes.

• **COMPRESS_OPS**
  The number of times a B-tree page of size `PAGE_SIZE` has been compressed. Pages are compressed whenever an empty page is created or the space for the uncompressed modification log runs out.

• **COMPRESS_OPS_OK**
  The number of times a B-tree page of size `PAGE_SIZE` has been successfully compressed. This count should never exceed `COMPRESS_OPS`.

• **COMPRESS_TIME**
  The total time in seconds used for attempts to compress B-tree pages of size `PAGE_SIZE`.

• **UNCOMPRESS_OPS**
  The number of times a B-tree page of size `PAGE_SIZE` has been uncompressed. B-tree pages are uncompressed whenever compression fails or at first access when the uncompressed page does not exist in the buffer pool.

• **UNCOMPRESS_TIME**
  The total time in seconds used for uncompressing B-tree pages of the size `PAGE_SIZE`.

**Example**

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_CMP;
```

```
*************************** 1. row ***************************
  page_size: 1024
  compress_ops: 0
  compress_ops_ok: 0
  compress_time: 0
  uncompress_ops: 0
  uncompress_time: 0

*************************** 2. row ***************************
  page_size: 2048
  compress_ops: 0
  compress_ops_ok: 0
  compress_time: 0

The INFORMATION_SCHEMA INNODB_CMPMEM and INNODB_CMPMEM_RESET Tables

compress_ops_ok: 0
compress_time: 0
uncompress_ops: 0
uncompress_time: 0

Notes

- Use these tables to measure the effectiveness of InnoDB table compression in your database.
- You must have the PROCESS privilege to query this table.
- Use the INFORMATION_SCHEMA COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of this table, including data types and default values.
- For usage information, see Section 14.9.4, “Monitoring InnoDB Table Compression at Runtime” and Section 14.15.1.3, “Using the Compression Information Schema Tables”. For general information about InnoDB table compression, see Section 14.9, “InnoDB Table Compression”.

21.30.5 The INFORMATION_SCHEMA INNODB_CMPMEM and INNODB_CMPMEM_RESET Tables

The INNODB_CMPMEM and INNODB_CMPMEM_RESET tables provide status information on compressed pages within the InnoDB buffer pool.

The INNODB_CMPMEM and INNODB_CMPMEM_RESET tables have these columns:

- **PAGE_SIZE**
  The block size in bytes. Each record of this table describes blocks of this size.

- **BUFFER_POOL_INSTANCE**
  A unique identifier for the buffer pool instance.

- **PAGES_USED**
  The number of blocks of size PAGE_SIZE that are currently in use.

- **PAGES_FREE**
  The number of blocks of size PAGE_SIZE that are currently available for allocation. This column shows the external fragmentation in the memory pool. Ideally, these numbers should be at most 1.

- **RELOCATION_OPS**
  The number of times a block of size PAGE_SIZE has been relocated. The buddy system can relocate the allocated “buddy neighbor” of a freed block when it tries to form a bigger freed block. Reading from the INNODB_CMPMEM_RESET table resets this count.

- **RELOCATION_TIME**
  The total time in microseconds used for relocating blocks of size PAGE_SIZE. Reading from the table INNODB_CMPMEM_RESET resets this count.

Example
The INFORMATION_SCHEMA INNODB_CMP_PER_INDEX and INNODB_CMP_PER_INDEX_RESET Tables

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_CMPMEM\G
*************************** 1. row ***************************
<table>
<thead>
<tr>
<th>page_size</th>
<th>buffer_pool_instance</th>
<th>pages_used</th>
<th>pages_free</th>

<td>0</td>
</tr>
</tbody>
</table>

Notes

- Use these tables to measure the effectiveness of InnoDB table compression in your database.
- You must have the PROCESS privilege to query this table.
- Use the INFORMATION_SCHEMA.COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of this table, including data types and default values.
- For usage information, see Section 14.9.4, “Monitoring InnoDB Table Compression at Runtime” and Section 14.15.1.3, “Using the Compression Information Schema Tables”. For general information about InnoDB table compression, see Section 14.9, “InnoDB Table Compression”.

21.30.6 The INFORMATION_SCHEMA INNODB_CMP_PER_INDEX and INNODB_CMP_PER_INDEX_RESET Tables

The INNODB_CMP_PER_INDEX and INNODB_CMP_PER_INDEX_RESET tables provide status information on operations related to compressed InnoDB tables and indexes, with separate statistics for each combination of database, table, and index, to help you evaluate the performance and usefulness of compression for specific tables.

For a compressed InnoDB table, both the table data and all the secondary indexes are compressed. In this context, the table data is treated as just another index, one that happens to contain all the columns: the clustered index.
The INFORMATION_SCHEMA INNODB_CMP_PER_INDEX and INNODB_CMP_PER_INDEX_RESET tables have these columns:

- **DATABASE_NAME**
  The schema (database) containing the applicable table.

- **TABLE_NAME**
  The table to monitor for compression statistics.

- **INDEX_NAME**
  The index to monitor for compression statistics.

- **COMPRESS_OPS**
  The number of compression operations attempted. Pages are compressed whenever an empty page is created or the space for the uncompressed modification log runs out.

- **COMPRESS_OPS_OK**
  The number of successful compression operations. Subtract from the COMPRESS_OPS value to get the number of compression failures. Divide by the COMPRESS_OPS value to get the percentage of compression failures.

- **COMPRESS_TIME**
  The total time in seconds used for compressing data in this index.

- **UNCOMPRESS_OPS**
  The number of uncompression operations performed. Compressed InnoDB pages are uncompressed whenever compression fails, or the first time a compressed page is accessed in the buffer pool and the uncompressed page does not exist.

- **UNCOMPRESS_TIME**
  The total time in seconds used for uncompressing data in this index.

**Example**

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_CMP_PER_INDEX\G
*************************** 1. row ***************************
database_name: employees
table_name: salaries
index_name: PRIMARY
compress_ops: 0
compress_ops_ok: 0
compress_time: 0
uncompress_ops: 23451
uncompress_time: 4
*************************** 2. row ***************************
database_name: employees
table_name: salaries
index_name: emp_no
compress_ops: 0
compress_ops_ok: 0
compress_time: 0
uncompress_ops: 1597
uncompress_time: 0
```
The INFORMATION_SCHEMA INNODB_FT_BEING_DELETED Table

Notes

- Use these tables to measure the effectiveness of InnoDB table compression for specific tables, indexes, or both.

- You must have the PROCESS privilege to query these tables.

- Use the INFORMATION_SCHEMA COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of these tables, including data types and default values.

- Because collecting separate measurements for every index imposes substantial performance overhead, INNODB_CMP_PER_INDEX and INNODB_CMP_PER_INDEX_RESET statistics are not gathered by default. You must enable the innodb_cmp_per_index_enabled system variable before performing the operations on compressed tables that you want to monitor.

- For usage information, see Section 14.9.4, “Monitoring InnoDB Table Compression at Runtime” and Section 14.15.1.3, “Using the Compression Information Schema Tables”. For general information about InnoDB table compression, see Section 14.9, “InnoDB Table Compression”.

21.30.7 The INFORMATION_SCHEMA INNODB_FT_BEING_DELETED Table

The INNODB_FT_BEING_DELETED table provides a snapshot of the INNODB_FT_DELETED table; it is used only during an OPTIMIZE TABLE maintenance operation. When OPTIMIZE TABLE is run, the INNODB_FT_BEING_DELETED table is emptied, and DOC_ID values are removed from the INNODB_FT_DELETED table. Because the contents of INNODB_FT_BEING_DELETED typically have a short lifetime, this table has limited utility for monitoring or debugging. For information about running OPTIMIZE TABLE on tables with FULLTEXT indexes, see Section 12.9.6, “Fine-Tuning MySQL Full-Text Search”.

This table is empty initially. Before querying it, set the value of the innodb_ft_aux_table system variable to the name (including the database name) of the table that contains the FULLTEXT index; for example test/articles. The output appears similar to the example provided for the INNODB_FT_DELETED table.

For related usage information and examples, see Section 14.15.4, “InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables”.

The INNODB_FT_BEING_DELETED table has these columns:

- **DOC_ID**

  The document ID of the row that is in the process of being deleted. This value might reflect the value of an ID column that you defined for the underlying table, or it can be a sequence value generated by InnoDB when the table contains no suitable column. This value is used when you do text searches, to skip rows in the INNODB_FT_INDEX_TABLE table before data for deleted rows is physically removed from the FULLTEXT index by an OPTIMIZE TABLE statement. For more information, see Optimizing InnoDB Full-Text Indexes.

Notes

- You must have the PROCESS privilege to query this table.

- Use the INFORMATION_SCHEMA COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of this table, including data types and default values.

- For more information about InnoDB FULLTEXT search, see Section 14.6.2.3, “InnoDB FULLTEXT Indexes”, and Section 12.9, “Full-Text Search Functions”. 
21.30.8 The INFORMATION_SCHEMA INNODB_FT_CONFIG Table

The `INNODB_FT_CONFIG` table provides metadata about the FULLTEXT index and associated processing for an InnoDB table.

This table is empty initially. Before querying it, set the value of the `innodb_ft_aux_table` system variable to the name (including the database name) of the table that contains the FULLTEXT index; for example `test/articles`.

For related usage information and examples, see Section 14.15.4, “InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables”.

The `INNODB_FT_CONFIG` table has these columns:

- **KEY**
  
  The name designating an item of metadata for an InnoDB table containing a FULLTEXT index.

  The values for this column might change, depending on the needs for performance tuning and debugging for InnoDB full-text processing. The key names and their meanings include:

  - `optimize_checkpoint_limit`: The number of seconds after which an OPTIMIZE TABLE run stops.
  - `synced_doc_id`: The next DOC_ID to be issued.
  - `stopword_table_name`: The database/table name for a user-defined stopword table. The VALUE column is empty if there is no user-defined stopword table.
  - `use_stopword`: Indicates whether a stopword table is used, which is defined when the FULLTEXT index is created.

- **VALUE**
  
  The value associated with the corresponding KEY column, reflecting some limit or current value for an aspect of a FULLTEXT index for an InnoDB table.

**Example**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_CONFIG;
+---------------------------+-------------------+
| KEY                       | VALUE             |
+---------------------------+-------------------+
| optimize_checkpoint_limit | 180               |
| synced_doc_id             | 0                 |
| stopword_table_name       | test/my_stopwords |
| use_stopword              | 1                 |
+---------------------------+-------------------+
```

**Notes**

- This table is intended only for internal configuration. It is not intended for statistical information purposes.
- You must have the PROCESS privilege to query this table.
- Use the INFORMATION_SCHEMA COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of this table, including data types and default values.
• For more information about InnoDB FULLTEXT search, see Section 14.6.2.3, “InnoDB FULLTEXT Indexes”, and Section 12.9, “Full-Text Search Functions”.

21.30.9 The INFORMATION_SCHEMA INNODB_FT_DEFAULT_STOPWORD Table

The INNODB_FT_DEFAULT_STOPWORD table holds a list of stopwords that are used by default when creating a FULLTEXT index on InnoDB tables. For information about the default InnoDB stopword list and how to define your own stopword lists, see Section 12.9.4, “Full-Text Stopwords”.

For related usage information and examples, see Section 14.15.4, “InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables”.

The INNODB_FT_DEFAULT_STOPWORD table has these columns:

• value

A word that is used by default as a stopword for FULLTEXT indexes on InnoDB tables. This is not used if you override the default stopword processing with either the innodb_ft_server_stopword_table or the innodb_ft_user_stopword_table system variable.

Example

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_DEFAULT_STOPWORD;

<p>| | |
| -------- |        |
|--------- |</p>
<table>
<thead>
<tr>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
</tr>
<tr>
<td>about</td>
</tr>
<tr>
<td>an</td>
</tr>
<tr>
<td>are</td>
</tr>
<tr>
<td>as</td>
</tr>
<tr>
<td>at</td>
</tr>
<tr>
<td>be</td>
</tr>
<tr>
<td>by</td>
</tr>
<tr>
<td>com</td>
</tr>
<tr>
<td>de</td>
</tr>
<tr>
<td>en</td>
</tr>
<tr>
<td>for</td>
</tr>
<tr>
<td>from</td>
</tr>
<tr>
<td>how</td>
</tr>
<tr>
<td>i</td>
</tr>
<tr>
<td>in</td>
</tr>
<tr>
<td>is</td>
</tr>
<tr>
<td>it</td>
</tr>
<tr>
<td>la</td>
</tr>
<tr>
<td>of</td>
</tr>
<tr>
<td>on</td>
</tr>
<tr>
<td>or</td>
</tr>
<tr>
<td>that</td>
</tr>
<tr>
<td>the</td>
</tr>
<tr>
<td>this</td>
</tr>
<tr>
<td>to</td>
</tr>
<tr>
<td>was</td>
</tr>
<tr>
<td>what</td>
</tr>
<tr>
<td>when</td>
</tr>
<tr>
<td>where</td>
</tr>
<tr>
<td>who</td>
</tr>
<tr>
<td>will</td>
</tr>
<tr>
<td>with</td>
</tr>
<tr>
<td>und</td>
</tr>
</tbody>
</table>
The INFORMATION_SCHEMA INNODB_FT_DELETED Table

21.30.10 The INFORMATION_SCHEMA INNODB_FT_DELETED Table

The INNODB_FT_DELETED table stores rows that are deleted from the FULLTEXT index for an InnoDB table. To avoid expensive index reorganization during DML operations for an InnoDB FULLTEXT index, the information about newly deleted words is stored separately, filtered out of search results when you do a text search, and removed from the main search index only when you issue an OPTIMIZE TABLE statement for the InnoDB table. For more information, see Optimizing InnoDB Full-Text Indexes.

This table is empty initially. Before querying it, set the value of the innodb_ft_aux_table system variable to the name (including the database name) of the table that contains the FULLTEXT index; for example test/articles.

For related usage information and examples, see Section 14.15.4, “InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables”.

The INNODB_FT_DELETED table has these columns:

- **DOC_ID**

  The document ID of the newly deleted row. This value might reflect the value of an ID column that you defined for the underlying table, or it can be a sequence value generated by InnoDB when the table contains no suitable column. This value is used when you do text searches, to skip rows in the INNODB_FT_INDEX_TABLE table before data for deleted rows is physically removed from the FULLTEXT index by an OPTIMIZE TABLE statement. For more information, see Optimizing InnoDB Full-Text Indexes.

Example

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_DELETED;
+--------+
| DOC_ID |
+--------+
|      6 |
|      7 |
|      8 |
+--------+
```

Notes

- You must have the PROCESS privilege to query this table.
- Use the INFORMATION_SCHEMA COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of this table, including data types and default values.
The INFORMATION_SCHEMA INNODB_FT_INDEX_CACHE Table

For more information about InnoDB FULLTEXT search, see Section 14.6.2.3, “InnoDB FULLTEXT Indexes”, and Section 12.9, “Full-Text Search Functions”.

21.30.11 The INFORMATION_SCHEMA INNODB_FT_INDEX_CACHE Table

The INNODB_FT_INDEX_CACHE table provides token information about newly inserted rows in a FULLTEXT index. To avoid expensive index reorganization during DML operations, the information about newly indexed words is stored separately, and combined with the main search index only when OPTIMIZE TABLE is run, when the server is shut down, or when the cache size exceeds a limit defined by the innodb_ft_cache_size or innodb_ft_total_cache_size system variable.

This table is empty initially. Before querying it, set the value of the innodb_ft_aux_table system variable to the name (including the database name) of the table that contains the FULLTEXT index; for example test/articles.

For related usage information and examples, see Section 14.15.4, “InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables”.

The INNODB_FT_INDEX_CACHE table has these columns:

- **WORD**
  A word extracted from the text of a newly inserted row.

- **FIRST_DOC_ID**
  The first document ID in which this word appears in the FULLTEXT index.

- **LAST_DOC_ID**
  The last document ID in which this word appears in the FULLTEXT index.

- **DOC_COUNT**
  The number of rows in which this word appears in the FULLTEXT index. The same word can occur several times within the cache table, once for each combination of DOC_ID and POSITION values.

- **DOC_ID**
  The document ID of the newly inserted row. This value might reflect the value of an ID column that you defined for the underlying table, or it can be a sequence value generated by InnoDB when the table contains no suitable column.

- **POSITION**
  The position of this particular instance of the word within the relevant document identified by the DOC_ID value. The value does not represent an absolute position; it is an offset added to the POSITION of the previous instance of that word.

Notes

- This table is empty initially. Before querying it, set the value of the innodb_ft_aux_table system variable to the name (including the database name) of the table that contains the FULLTEXT index; for example test/articles. The following example demonstrates how to use the innodb_ft_aux_table system variable to show information about a FULLTEXT index for a specified table.

```
mysql> USE test;
```
The INFORMATION_SCHEMA INNODB_FT_INDEX_TABLE Table

```sql
mysql> CREATE TABLE articles (  
    id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,  
    title VARCHAR(200),  
    body TEXT,  
    FULLTEXT (title, body)  
) ENGINE=InnoDB;

mysql> INSERT INTO articles (title, body) VALUES  
    ('MySQL Tutorial', 'DBMS stands for Database ...'),  
    ('How To Use MySQL Well', 'After you went through a ...'),  
    ('Optimizing MySQL', 'In this tutorial we will show ...'),  
    ('1001 MySQL Tricks', '1. Never run mysqld as root. 2. ...'),  
    ('MySQL vs. YourSQL', 'In the following database comparison ...'),  
    ('MySQL Security', 'When configured properly, MySQL ...');

mysql> SET GLOBAL innodb_ft_aux_table = 'test/articles';

mysql> SELECT WORD, DOC_COUNT, DOC_ID, POSITION  
FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE LIMIT 5;
```

<table>
<thead>
<tr>
<th>WORD</th>
<th>DOC_COUNT</th>
<th>DOC_ID</th>
<th>POSITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>1001</td>
<td></td>
<td>4</td>
<td>0</td>
</tr>
<tr>
<td>after</td>
<td></td>
<td>2</td>
<td>22</td>
</tr>
<tr>
<td>comparison</td>
<td></td>
<td>5</td>
<td>44</td>
</tr>
<tr>
<td>configured</td>
<td></td>
<td>6</td>
<td>20</td>
</tr>
<tr>
<td>database</td>
<td></td>
<td>1</td>
<td>31</td>
</tr>
</tbody>
</table>

- You must have the `PROCESS` privilege to query this table.
- Use the `INFORMATION_SCHEMA COLUMNS` table or the `SHOW COLUMNS` statement to view additional information about the columns of this table, including data types and default values.
- For more information about InnoDB FULLTEXT search, see Section 14.6.2.3, “InnoDB FULLTEXT Indexes”, and Section 12.9, “Full-Text Search Functions”.

### 21.30.12 The INFORMATION_SCHEMA INNODB_FT_INDEX_TABLE Table

The `INNODB_FT_INDEX_TABLE` table provides information about the inverted index used to process text searches against the `FULLTEXT` index of an InnoDB table.

This table is empty initially. Before querying it, set the value of the `innodb_ft_aux_table` system variable to the name (including the database name) of the table that contains the `FULLTEXT` index; for example `test/articles`.

For related usage information and examples, see Section 14.15.4, “InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables”.

The `INNODB_FT_INDEX_TABLE` table has these columns:

- **WORD**
  A word extracted from the text of the columns that are part of a `FULLTEXT`.

- **FIRST_DOC_ID**
  The first document ID in which this word appears in the `FULLTEXT` index.

- **LAST_DOC_ID**
  The last document ID in which this word appears in the `FULLTEXT` index.
The INFORMATION_SCHEMA INNODB_FT_INDEX_TABLE Table

- **DOC_COUNT**
  
The number of rows in which this word appears in the FULLTEXT index. The same word can occur several times within the cache table, once for each combination of DOC_ID and POSITION values.

- **DOC_ID**
  
The document ID of the row containing the word. This value might reflect the value of an ID column that you defined for the underlying table, or it can be a sequence value generated by InnoDB when the table contains no suitable column.

- **POSITION**
  
The position of this particular instance of the word within the relevant document identified by the DOC_ID value.

**Notes**

- This table is empty initially. Before querying it, set the value of the innodb_ft_aux_table system variable to the name (including the database name) of the table that contains the FULLTEXT index; for example `test/articles`. The following example demonstrates how to use the innodb_ft_aux_table system variable to show information about a FULLTEXT index for a specified table. Before information for newly inserted rows appears in INNODB_FT_INDEX_TABLE, the FULLTEXT index cache must be flushed to disk. This is accomplished by running an OPTIMIZE TABLE operation on the indexed table with the innodb_optimize_fulltext_only system variable enabled. (The example disables that variable again at the end because it is intended to be enabled only temporarily.)

```
mysql> USE test;
mysql> CREATE TABLE articles (
  id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
  title VARCHAR(200),
  body TEXT,
  FULLTEXT (title,body)
) ENGINE=InnoDB;
mysql> INSERT INTO articles (title,body) VALUES
  ('MySQL Tutorial','DBMS stands for DataBase ...'),
  ('How To Use MySQL Well','After you went through a ...'),
  ('Optimizing MySQL','In this tutorial we will show ...'),
  ('1001 MySQL Tricks','1. Never run mysqld as root. 2. ...'),
  ('MySQL vs. YourSQL','In the following database comparison ...'),
  ('MySQL Security','When configured properly, MySQL ...');
mysql> SET GLOBAL innodb_optimize_fulltext_only=ON;
mysql> OPTIMIZE TABLE articles;
+---------------+----------+----------+----------+
<table>
<thead>
<tr>
<th>Table</th>
<th>Op</th>
<th>Msg_type</th>
<th>Msg_text</th>
</tr>
</thead>
<tbody>
<tr>
<td>test.articles</td>
<td>optimize</td>
<td>status</td>
<td>OK</td>
</tr>
</tbody>
</table>
+---------------+----------+----------+----------+
mysql> SET GLOBAL innodb_ft_aux_table = 'test/articles';
mysql> SELECT WORD, DOC_COUNT, DOC_ID, POSITION
  FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_TABLE LIMIT 5;
```

<table>
<thead>
<tr>
<th>WORD</th>
<th>DOC_COUNT</th>
<th>DOC_ID</th>
<th>POSITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>1001</td>
<td>1</td>
<td>4</td>
<td>0</td>
</tr>
<tr>
<td>after</td>
<td>1</td>
<td>2</td>
<td>22</td>
</tr>
</tbody>
</table>
The INFORMATION_SCHEMA INNODB_LOCKS Table

| comparison | 1 | 5 | 44 |
| configured | 1 | 6 | 20 |
| database   | 2 | 1 | 31 |

mysql> SET GLOBAL innodb_optimize_fulltext_only=OFF;

• You must have the PROCESS privilege to query this table.

• Use the INFORMATION_SCHEMA COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of this table, including data types and default values.

• For more information about InnoDB FULLTEXT search, see Section 14.6.2.3, “InnoDB FULLTEXT Indexes”, and Section 12.9, “Full-Text Search Functions”.

21.30.13 The INFORMATION_SCHEMA INNODB_LOCKS Table

The INNODB_LOCKS table provides information about each lock that an InnoDB transaction has requested but not yet acquired, and each lock that a transaction holds that is blocking another transaction.

The INNODB_LOCKS table has these columns:

• LOCK_ID

  A unique lock ID number, internal to InnoDB. Treat it as an opaque string. Although LOCK_ID currently contains TRX_ID, the format of the data in LOCK_ID is subject to change at any time. Do not write applications that parse the LOCK_ID value.

• LOCK_TRX_ID

  The ID of the transaction holding the lock. To obtain details about the transaction, join this column with the TRX_ID column of the INNODB_TRX table.

• LOCK_MODE

  How the lock is requested. Permitted lock mode descriptors are S, X, IS, IX, GAP, AUTO_INC, and UNKNOWN. Lock mode descriptors may be used in combination to identify particular lock modes. For information about InnoDB lock modes, see Section 14.7.1, “InnoDB Locking”.

• LOCK_TYPE

  The type of lock. Permitted values are RECORD for a row-level lock, TABLE for a table-level lock.

• LOCK_TABLE

  The name of the table that has been locked or contains locked records.

• LOCK_INDEX

  The name of the index, if LOCK_TYPE is RECORD; otherwise NULL.

• LOCK_SPACE

  The tablespace ID of the locked record, if LOCK_TYPE is RECORD; otherwise NULL.

• LOCK_PAGE

  The page number of the locked record, if LOCK_TYPE is RECORD; otherwise NULL.
The heap number of the locked record within the page, if `LOCK_TYPE` is `RECORD`; otherwise `NULL`.

- **LOCK_DATA**

The data associated with the lock, if any. A value is shown if the `LOCK_TYPE` is `RECORD`, otherwise the value is `NULL`. Primary key values of the locked record are shown for a lock placed on the primary key index. Secondary index values of the locked record are shown for a lock placed on a unique secondary index. Secondary index values are shown with primary key values appended if the secondary index is not unique. If there is no primary key, `LOCK_DATA` shows either the key values of a selected unique index or the unique InnoDB internal row ID number, according to the rules governing InnoDB clustered index use (see Section 14.6.2.1, “Clustered and Secondary Indexes”). `LOCK_DATA` reports “supremum pseudo-record” for a lock taken on a supremum pseudo-record. If the page containing the locked record is not in the buffer pool because it was written to disk while the lock was held, InnoDB does not fetch the page from disk. Instead, `LOCK_DATA` reports `NULL`.

**Example**

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_LOCKS
G
*************************** 1. row ***************************
   lock_id: 3723:72:3:2
lock_trx_id: 3723
lock_mode: X
lock_type: RECORD
lock_table: 'mysql'.'t'
lock_index: PRIMARY
lock_space: 72
lock_page: 3
lock_rec: 2
lock_data: 1, 9

*************************** 2. row ***************************
   lock_id: 3722:72:3:2
lock_trx_id: 3722
lock_mode: S
lock_type: RECORD
lock_table: 'mysql'.'t'
lock_index: PRIMARY
lock_space: 72
lock_page: 3
lock_rec: 2
lock_data: 1, 9
```

**Notes**

- Use this table to help diagnose performance problems that occur during times of heavy concurrent load. Its contents are updated as described in Section 14.15.2.3, “Persistence and Consistency of InnoDB Transaction and Locking Information”.

- You must have the `PROCESS` privilege to query this table.

- Use the `INFORMATION_SCHEMA.COLUMNS` table or the `SHOW COLUMNS` statement to view additional information about the columns of this table, including data types and default values.

- For usage information, see Section 14.15.2.1, “Using InnoDB Transaction and Locking Information”.

**21.30.14 The INFORMATION_SCHEMA INNODB LOCK WAITS Table**

The `INNODB_LOCK_WAITS` table contains one or more rows for each blocked InnoDB transaction, indicating the lock it has requested and any locks that are blocking that request.
The **INNODB_LOCK_WAITS** table has these columns:

- **REQUESTING_TRX_ID**
  The ID of the requesting (blocked) transaction.

- **REQUESTED_LOCK_ID**
  The ID of the lock for which a transaction is waiting. To obtain details about the lock, join this column with the **LOCK_ID** column of the **INNODB_LOCKS** table.

- **BLOCKING_TRX_ID**
  The ID of the blocking transaction.

- **BLOCKING_LOCK_ID**
  The ID of a lock held by a transaction blocking another transaction from proceeding. To obtain details about the lock, join this column with the **LOCK_ID** column of the **INNODB_LOCKS** table.

Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_LOCK_WAITS\G
*************************** 1. row ***************************
requesting_trx_id: 3396
requested_lock_id: 3396:91:3:2
blocking_trx_id: 3395
blocking_lock_id: 3395:91:3:2
```

Notes

- Use this table to help diagnose performance problems that occur during times of heavy concurrent load. Its contents are updated as described in [Section 14.15.2.3, “Persistence and Consistency of InnoDB Transaction and Locking Information”](#).

- You must have the **PROCESS** privilege to query this table.

- Use the **INFORMATION_SCHEMA COLUMNS** table or the **SHOW COLUMNS** statement to view additional information about the columns of this table, including data types and default values.

- For usage information, see [Section 14.15.2.1, “Using InnoDB Transaction and Locking Information”](#).

### 21.30.15 The INFORMATION_SCHEMA INNODB_METRICS Table

The **INNODB_METRICS** table provides a wide variety of InnoDB performance information, complementing the specific focus areas of the Performance Schema tables for InnoDB. With simple queries, you can check the overall health of the system. With more detailed queries, you can diagnose issues such as performance bottlenecks, resource shortages, and application issues.

Each monitor represents a point within the InnoDB source code that is instrumented to gather counter information. Each counter can be started, stopped, and reset. You can also perform these actions for a group of counters using their common module name.

By default, relatively little data is collected. To start, stop, and reset counters, set one of the system variables `innodb_monitor_enable`, `innodb_monitor_disable`, `innodb_monitor_reset`, or `innodb_monitor_reset_all`, using the name of the counter, the name of the module, a wildcard match for such a name using the “%” character, or the special keyword **all**.

For usage information, see [Section 14.15.6, “InnoDB INFORMATION_SCHEMA Metrics Table”](#).
The INNODB_METRICS table has these columns:

- **NAME**
  A unique name for the counter.

- **SUBSYSTEM**
  The aspect of InnoDB that the metric applies to.

- **COUNT**
  The value since the counter was enabled.

- **MAX_COUNT**
  The maximum value since the counter was enabled.

- **MIN_COUNT**
  The minimum value since the counter was enabled.

- **AVG_COUNT**
  The average value since the counter was enabled.

- **COUNT_RESET**
  The counter value since it was last reset. (The _RESET columns act like the lap counter on a stopwatch: you can measure the activity during some time interval, while the cumulative figures are still available in COUNT, MAX_COUNT, and so on.)

- **MAX_COUNT_RESET**
  The maximum counter value since it was last reset.

- **MIN_COUNT_RESET**
  The minimum counter value since it was last reset.

- **AVG_COUNT_RESET**
  The average counter value since it was last reset.

- **TIME_ENABLED**
  The timestamp of the last start.

- **TIME_DISABLED**
  The timestamp of the last stop.

- **TIME_ELAPSED**
  The elapsed time in seconds since the counter started.

- **TIME_RESET**
  The timestamp of the last reset.

- **STATUS**
The INFORMATION_SCHEMA INNODB_SYS_COLUMNS Table

Whether the counter is still running (enabled) or stopped (disabled).

- **TYPE**

  Whether the item is a cumulative counter, or measures the current value of some resource.

- **COMMENT**

  The counter description.

**Example**

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME='dml Inserts'
```

```
*************************** 1. row ***************************
NAME: dml Inserts
SUBSYSTEM: dml
COUNT: 3
MAX_COUNT: 3
MIN_COUNT: NULL
AVG_COUNT: 0.046153846153846156
COUNT_RESET: 3
MAX_COUNT_RESET: 3
MIN_COUNT_RESET: NULL
AVG_COUNT_RESET: NULL
TIME_ENABLED: 2014-12-04 14:18:28
TIME_DISABLED: NULL
TIME_ELAPSED: 65
TIME_RESET: NULL
STATUS: enabled
TYPE: status_counter
COMMENT: Number of rows inserted
```

**Notes**

- You must have the **PROCESS** privilege to query this table.

- Use the INFORMATION_SCHEMA_COLUMNS table or the **SHOW COLUMNS** statement to view additional information about the columns of this table, including data types and default values.

**21.30.16 The INFORMATION_SCHEMA INNODB_SYS_COLUMNS Table**

The **INNODB_SYS_COLUMNS** table provides metadata about InnoDB table columns, equivalent to the information from the **SYS_COLUMNS** table in the InnoDB data dictionary.

For related usage information and examples, see Section 14.15.3, “InnoDB INFORMATION_SCHEMA System Tables”.

The **INNODB_SYS_COLUMNS** table has these columns:

- **TABLE_ID**

  An identifier representing the table associated with the column; the same value as **INNODB_SYS_TABLES.TABLE_ID**.

- **NAME**

  The name of the column. These names can be uppercase or lowercase depending on the **lower_case_table_names** setting. There are no special system-reserved names for columns.

- **POS**
The ordinal position of the column within the table, starting from 0 and incrementing sequentially. When a column is dropped, the remaining columns are reordered so that the sequence has no gaps.

- **MTYPE**

  Stands for “main type”. A numeric identifier for the column type. 1 = VARCHAR, 2 = CHAR, 3 = FIXBINARY, 4 = BINARY, 5 = BLOB, 6 = INT, 7 = SYS_CHILD, 8 = SYS, 9 = FLOAT, 10 = DOUBLE, 11 = DECIMAL, 12 = VARMYSQL, 13 = MYSQL.

- **PRTYPE**

  The InnoDB “precise type”, a binary value with bits representing MySQL data type, character set code, and nullability.

- **LEN**

  The column length, for example 4 for INT and 8 for BIGINT. For character columns in multibyte character sets, this length value is the maximum length in bytes needed to represent a definition such as VARCHAR(N); that is, it might be 2*N, 3*N, and so on depending on the character encoding.

### Example

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_COLUMNS where TABLE_ID = 71\G
*************************** 1. row ***************************
TABLE_ID: 71
  NAME: col1
  POS: 0
  MTYPE: 6
  PRTYPE: 1027
  LEN: 4
*************************** 2. row ***************************
TABLE_ID: 71
  NAME: col2
  POS: 1
  MTYPE: 2
  PRTYPE: 524542
  LEN: 10
*************************** 3. row ***************************
TABLE_ID: 71
  NAME: col3
  POS: 2
  MTYPE: 1
  PRTYPE: 524303
  LEN: 10
```

### Notes

- You must have the PROCESS privilege to query this table.

- Use the INFORMATION_SCHEMA_COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of this table, including data types and default values.

### 21.30.17 The INFORMATION_SCHEMA INNODB_SYS_DATAFILES Table

The INNODB_SYS_DATAFILES table provides data file path information for InnoDB tablespaces, equivalent to the information in the SYS_DATAFILES table in the InnoDB data dictionary.

For related usage information and examples, see Section 14.15.3, “InnoDB INFORMATION_SCHEMA System Tables”.
The **INNODB_SYS_DATAFILES** table has these columns:

- **SPACE**

  The tablespace ID.

- **PATH**

  The tablespace data file path. If a file-per-table tablespace is created in a location outside the MySQL data directory, the path value is a fully qualified directory path. Otherwise, the path is relative to the data directory.

**Example**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_DATAFILES WHERE SPACE = 57\G
*************************** 1. row ***************************
SPACE: 57
PATH: ./test/t1.ibd
```

**Notes**

- You must have the **PROCESS** privilege to query this table.

- Use the **INFORMATION_SCHEMA COLUMNS** table or the **SHOW COLUMNS** statement to view additional information about the columns of this table, including data types and default values.

### 21.30.18 The INFORMATION_SCHEMA INNODB_SYS_FIELDS Table

The **INNODB_SYS_FIELDS** table provides metadata about the key columns (fields) of InnoDB indexes, equivalent to the information from the **SYS_FIELDS** table in the InnoDB data dictionary.

For related usage information and examples, see Section 14.15.3, "InnoDB INFORMATION_SCHEMA System Tables".

The **INNODB_SYS_FIELDS** table has these columns:

- **INDEX_ID**

  An identifier for the index associated with this key field; the same value as **INNODB_SYS_INDEXES.INDEX_ID**.

- **NAME**

  The name of the original column from the table; the same value as **INNODB_SYS_COLUMNS.NAME**.

- **POS**

  The ordinal position of the key field within the index, starting from 0 and incrementing sequentially. When a column is dropped, the remaining columns are reordered so that the sequence has no gaps.

**Example**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_FIELDS WHERE INDEX_ID = 117\G
*************************** 1. row ***************************
INDEX_ID: 117
NAME: col1
POS: 0
```
The INFORMATION_SCHEMA INNODB_SYS_FOREIGN Table

Notes

• You must have the PROCESS privilege to query this table.

• Use the INFORMATION_SCHEMA COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of this table, including data types and default values.

21.30.19 The INFORMATION_SCHEMA INNODB_SYS_FOREIGN Table

The INNODB_SYS_FOREIGN table provides metadata about InnoDB foreign keys, equivalent to the information from the SYS_FOREIGN table in the InnoDB data dictionary.

For related usage information and examples, see Section 14.15.3, “InnoDB INFORMATION_SCHEMA System Tables”.

The INNODB_SYS_FOREIGN table has these columns:

• ID
  The name (not a numeric value) of the foreign key index, preceded by the schema (database) name (for example, test/products_fkey).

• FOR_NAME
  The name of the child table in this foreign key relationship.

• REF_NAME
  The name of the parent table in this foreign key relationship.

• N_COLS
  The number of columns in the foreign key index.

• TYPE
  A collection of bit flags with information about the foreign key column, ORed together. 0 = ON DELETE/UPDATE RESTRICT, 1 = ON DELETE CASCADE, 2 = ON DELETE SET NULL, 4 = ON UPDATE CASCADE, 8 = ON UPDATE SET NULL, 16 = ON DELETE NO ACTION, 32 = ON UPDATE NO ACTION.

Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_FOREIGN\G
*************************** 1. row ***************************
ID: test/fk1
FOR_NAME: test/child
REF_NAME: test/parent
N_COLS: 1
TYPE: 1
```

Notes

• You must have the PROCESS privilege to query this table.

• Use the INFORMATION_SCHEMA COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of this table, including data types and default values.

21.30.20 The INFORMATION_SCHEMA INNODB_SYS_FOREIGN_COLS Table
The **INNODB_SYS_FOREIGN_COLS** table provides status information about the columns of InnoDB foreign keys, equivalent to the information from the **SYS_FOREIGN_COLS** table in the InnoDB data dictionary.

For related usage information and examples, see Section 14.15.3, “InnoDB INFORMATION_SCHEMA System Tables”.

The **INNODB_SYS_FOREIGN_COLS** table has these columns:

- **ID**: The foreign key index associated with this index key field, using the same value as **INNODB_SYS_FOREIGN.ID**.
- **FOR_COL_NAME**: The name of the associated column in the child table.
- **REF_COL_NAME**: The name of the associated column in the parent table.
- **POS**: The ordinal position of this key field within the foreign key index, starting from 0.

**Example**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_FOREIGN_COLS WHERE ID = 'test/fk1'
+-----------------------+
| ID                    |
| FOR_COL_NAME          |
| REF_COL_NAME          |
| POS                   |
+-----------------------+
| test/fk1              |
| parent_id             |
| id                    |
| 0                     |
```

**Notes**

- You must have the **PROCESS** privilege to query this table.
- Use the **INFORMATION_SCHEMA COLUMNS** table or the **SHOW COLUMNS** statement to view additional information about the columns of this table, including data types and default values.

### 21.30.21 The INFORMATION_SCHEMA INNODB_SYS_INDEXES Table

The **INNODB_SYS_INDEXES** table provides metadata about InnoDB indexes, equivalent to the information in the internal **SYS_INDEXES** table in the InnoDB data dictionary.

For related usage information and examples, see Section 14.15.3, “InnoDB INFORMATION_SCHEMA System Tables”.

The **INNODB_SYS_INDEXES** table has these columns:

- **INDEX_ID**: An identifier for the index. Index identifiers are unique across all the databases in an instance.
- **NAME**: The name of the index. Most indexes created implicitly by InnoDB have consistent names but the index names are not necessarily unique. Examples: **PRIMARY** for a primary key index, **GEN_CLUST_INDEX** for
the index representing a primary key when one is not specified, and ID_IND, FOR_IND, and REF_IND for foreign key constraints.

- **TABLE_ID**
  An identifier representing the table associated with the index; the same value as INNODB_SYS_TABLES.TABLE_ID.

- **TYPE**
  A numeric value derived from bit-level information that identifies the index type. 0 = nonunique secondary index; 1 = automatically generated clustered index (GEN_CLUST_INDEX); 2 = unique nonclustered index; 3 = clustered index; 32 = full-text index

- **N_FIELDS**
  The number of columns in the index key. For GEN_CLUST_INDEX indexes, this value is 0 because the index is created using an artificial value rather than a real table column.

- **PAGE_NO**
  The root page number of the index B-tree. For full-text indexes, the PAGE_NO column is unused and set to -1 (FIL_NULL) because the full-text index is laid out in several B-trees (auxiliary tables).

- **SPACE**
  An identifier for the tablespace where the index resides. 0 means the InnoDB system tablespace. Any other number represents a table created with a separate .ibd file in file-per-table mode. This identifier stays the same after a TRUNCATE TABLE statement. Because all indexes for a table reside in the same tablespace as the table, this value is not necessarily unique.

**Example**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_INDEXES WHERE TABLE_ID = 74\G
*************************** 1. row ***************************
INDEX_ID: 116
NAME: GEN_CLUST_INDEX
TABLE_ID: 74
TYPE: 1
N_FIELDS: 0
PAGE_NO: 3
SPACE: 60
*************************** 2. row ***************************
INDEX_ID: 117
NAME: i1
TABLE_ID: 74
TYPE: 0
N_FIELDS: 1
PAGE_NO: 4
SPACE: 60
```

**Notes**

- You must have the PROCESS privilege to query this table.

- Use the INFORMATION_SCHEMA COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of this table, including data types and default values.

**21.30.22 The INFORMATION_SCHEMA INNODB_SYS_TABLES Table**
The `INNODB_SYS_TABLES` table provides metadata about InnoDB tables, equivalent to the information from the `SYS_TABLES` table in the InnoDB data dictionary.

For related usage information and examples, see Section 14.15.3, “InnoDB INFORMATION_SCHEMA System Tables”.

The `INNODB_SYS_TABLES` table has these columns:

- **TABLE_ID**
  An identifier for the InnoDB table. This value is unique across all databases in the instance.

- **NAME**
  The name of the table, preceded by the schema (database) name where appropriate (for example, `test/t1`). Names of databases and user tables are in the same case as they were originally defined, possibly influenced by the `lower_case_table_names` setting.

- **FLAG**
  A numeric value that represents bit-level information about table format and storage characteristics.

- **N_COLS**
  The number of columns in the table. The number reported includes three hidden columns that are created by InnoDB (`DB_ROW_ID`, `DB_TRX_ID`, and `DB_ROLL_PTR`).

- **SPACE**
  An identifier for the tablespace where the table resides. 0 means the InnoDB system tablespace. Any other number represents a table created in file-per-table mode with a separate `.ibd` file. This identifier stays the same after a `TRUNCATE TABLE` statement. Other than the zero value, this identifier is unique for tables across all the databases in the instance.

- **FILE_FORMAT**
  The table’s file format (Antelope or Barracuda).

- **ROW_FORMAT**
  The table’s row format (Compact, Redundant, Dynamic, or Compressed).

- **ZIP_PAGE_SIZE**
  The zip page size. Applies only to tables with a row format of Compressed.

**Example**

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE TABLE_ID = 74\G
*************************** 1. row ***************************
TABLE_ID: 74
NAME: test/t1
FLAG: 1
N_COLS: 6
SPACE: 60
FILE_FORMAT: Antelope
ROW_FORMAT: Compact
ZIP_PAGE_SIZE: 0
```
The INFORMATION_SCHEMA INNODB_SYS_TABLESPACES Table

Notes

• You must have the PROCESS privilege to query this table.

• Use the INFORMATION_SCHEMA COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of this table, including data types and default values.

21.30.23 The INFORMATION_SCHEMA INNODB_SYS_TABLESPACES Table

The INNODB_SYS_TABLESPACES table provides metadata about InnoDB tablespaces, equivalent to the information in the SYS_TABLESPACES table in the InnoDB data dictionary.

For related usage information and examples, see Section 14.15.3, “InnoDB INFORMATION_SCHEMA System Tables”.

The INNODB_SYS_TABLESPACES table has these columns:

• SPACE
  The tablespace ID.

• NAME
  The schema (database) and table name.

• FLAG
  A numeric value that represents bit-level information about tablespace format and storage characteristics.

• FILE_FORMAT
  The tablespace file format (for example, Antelope or Barracuda). The data in this field is interpreted from the tablespace flags information that resides in the .ibd file. For more information about InnoDB file formats, see Section 14.10, “InnoDB File-Format Management”.

• ROW_FORMAT
  The tablespace row format (Compact or Redundant, Dynamic, or Compressed). The data in this column is interpreted from the tablespace flags information that resides in the .ibd file.

• PAGE_SIZE
  The tablespace page size. The data in this column is interpreted from the tablespace flags information that resides in the .ibd file.

• ZIP_PAGE_SIZE
  The tablespace zip page size. The data in this column is interpreted from the tablespace flags information that resides in the .ibd file.

Example

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES WHERE SPACE = 57
*************************** 1. row ***************************
SPACE: 57
NAME: test/t1
FLAG: 0
Notes

- You must have the `PROCESS` privilege to query this table.
- Use the `INFORMATION_SCHEMA COLUMNS` table or the `SHOW COLUMNS` statement to view additional information about the columns of this table, including data types and default values.
- Because tablespace flags are always zero for all Antelope file formats (unlike table flags), there is no way to determine from this flag integer if the tablespace row format is Redundant or Compact. As a result, the possible values for the `ROW_FORMAT` field are “Compact or Redundant”, “Compressed”, or “Dynamic.”

21.30.24 The `INFORMATION_SCHEMA INNODB_SYS_TABLESTATS` View

The `INNODB_SYS_TABLESTATS` table provides a view of low-level status information about InnoDB tables. This data is used by the MySQL optimizer to calculate which index to use when querying an InnoDB table. This information is derived from in-memory data structures rather than data stored on disk. There is no corresponding internal InnoDB system table.

InnoDB tables are represented in this view if they have been opened since the last server restart and have not aged out of the table cache. Tables for which persistent stats are available are always represented in this view.

Table statistics are updated only for `DELETE` or `UPDATE` operations that modify indexed columns. Statistics are not updated by operations that modify only nonindexed columns.

`ANALYZE TABLE` clears table statistics and sets the `STATS_INITIALIZED` column to `Uninitialized`. Statistics are collected again the next time the table is accessed.

For related usage information and examples, see Section 14.15.3, “InnoDB INFORMATION_SCHEMA System Tables”.

The `INNODB_SYS_TABLESTATS` table has these columns:

- **TABLE_ID**
  
  An identifier representing the table for which statistics are available; the same value as `INNODB_SYS_TABLES.TABLE_ID`.

- **NAME**
  
  The name of the table; the same value as `INNODB_SYS_TABLES.NAME`.

- **STATS_INITIALIZED**
  
  The value is `Initialized` if the statistics are already collected, `Uninitialized` if not.

- **NUM_ROWS**
  
  The current estimated number of rows in the table. Updated after each DML operation. The value could be imprecise if uncommitted transactions are inserting into or deleting from the table.

- **CLUST_INDEX_SIZE**
The number of pages on disk that store the clustered index, which holds the InnoDB table data in primary key order. This value might be null if no statistics are collected yet for the table.

- **OTHER_INDEX_SIZE**

  The number of pages on disk that store all secondary indexes for the table. This value might be null if no statistics are collected yet for the table.

- **MODIFIED_COUNTER**

  The number of rows modified by DML operations, such as INSERT, UPDATE, DELETE, and also cascade operations from foreign keys. This column is reset each time table statistics are recalculated.

- **AUTOINC**

  The next number to be issued for any auto-increment-based operation. The rate at which the AUTOINC value changes depends on how many times auto-increment numbers have been requested and how many numbers are granted per request.

- **REF_COUNT**

  When this counter reaches zero, the table metadata can be evicted from the table cache.

### Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLESTATS where TABLE_ID = 71
+--------------------------+
| TABLE_ID: 71             |
| NAME: test/t1            |
| STATS_INITIALIZED:        |
| Initialized              |
| NUM_ROWS: 1              |
| CLUST_INDEX_SIZE: 1      |
| OTHER_INDEX_SIZE: 0      |
| MODIFIED_COUNTER: 1      |
| AUTOINC: 0               |
| REF_COUNT: 1             |
```

### Notes

- This table is useful primarily for expert-level performance monitoring, or when developing performance-related extensions for MySQL.
- You must have the PROCESS privilege to query this table.
- Use the INFORMATION_SCHEMA COLUMNS table or the SHOW COLUMNS statement to view additional information about the columns of this table, including data types and default values.

### 21.30.25 The INFORMATION_SCHEMA INNODB_TRX Table

The INNODB_TRX table provides information about every transaction (excluding read-only transactions) currently executing inside InnoDB, including whether the transaction is waiting for a lock, when the transaction started, and the SQL statement the transaction is executing, if any.

For usage information, see Section 14.15.2.1, “Using InnoDB Transaction and Locking Information”.

The INNODB_TRX table has these columns:

- **TRX_ID**
A unique transaction ID number, internal to InnoDB. (Starting in MySQL 5.6, these IDs are not created for transactions that are read only and nonlocking. For details, see Section 8.5.3, “Optimizing InnoDB Read-Only Transactions”.)

- **TRX_WEIGHT**
  
  The weight of a transaction, reflecting (but not necessarily the exact count of) the number of rows altered and the number of rows locked by the transaction. To resolve a deadlock, InnoDB selects the transaction with the smallest weight as the “victim” to roll back. Transactions that have changed nontransactional tables are considered heavier than others, regardless of the number of altered and locked rows.

- **TRX_STATE**
  
  The transaction execution state. Permitted values are RUNNING, LOCK WAIT, ROLLING BACK, and COMMITTING.

- **TRX_STARTED**
  
  The transaction start time.

- **TRX_REQUESTED_LOCK_ID**
  
  The ID of the lock the transaction is currently waiting for, if TRX_STATE is LOCK WAIT; otherwise NULL. To obtain details about the lock, join this column with the LOCK_ID column of the INNODB_LOCKS table.

- **TRX_WAIT_STARTED**
  
  The time when the transaction started waiting on the lock, if TRX_STATE is LOCK WAIT; otherwise NULL.

- **TRX_MYSQL_THREAD_ID**
  
  The MySQL thread ID. To obtain details about the thread, join this column with the ID column of the INFORMATION_SCHEMA PROCESSLIST table, but see Section 14.15.2.3, “Persistence and Consistency of InnoDB Transaction and Locking Information”.

- **TRX_QUERY**
  
  The SQL statement that is being executed by the transaction.

- **TRX_OPERATION_STATE**
  
  The transaction’s current operation, if any; otherwise NULL.

- **TRX_TABLES_IN_USE**
  
  The number of InnoDB tables used while processing the current SQL statement of this transaction.

- **TRX_TABLES_LOCKED**
  
  The number of InnoDB tables that the current SQL statement has row locks on. (Because these are row locks, not table locks, the tables can usually still be read from and written to by multiple transactions, despite some rows being locked.)

- **TRX_LOCK_STRUCTS**
  
  The number of locks reserved by the transaction.
• **TRX_LOCK_MEMORY_BYTES**
  The total size taken up by the lock structures of this transaction in memory.

• **TRX_ROWS_LOCKED**
  The approximate number or rows locked by this transaction. The value might include delete-marked rows that are physically present but not visible to the transaction.

• **TRX_ROWS_MODIFIED**
  The number of modified and inserted rows in this transaction.

• **TRX_CONCURRENCY_TICKETS**
  A value indicating how much work the current transaction can do before being swapped out, as specified by the `innodb_concurrency_tickets` system variable.

• **TRX_ISOLATION_LEVEL**
  The isolation level of the current transaction.

• **TRX_UNIQUE_CHECKS**
  Whether unique checks are turned on or off for the current transaction. For example, they might be turned off during a bulk data load.

• **TRX_FOREIGN_KEY_CHECKS**
  Whether foreign key checks are turned on or off for the current transaction. For example, they might be turned off during a bulk data load.

• **TRX_LAST_FOREIGN_KEY_ERROR**
  The detailed error message for the last foreign key error, if any; otherwise **NULL**.

• **TRX_ADAPTIVE_HASH_LATCHED**
  Whether the adaptive hash index is locked by the current transaction. (Only a single transaction at a time can modify the adaptive hash index.)

• **TRX_ADAPTIVE_HASH_TIMEOUT**
  Whether to relinquish the search latch immediately for the adaptive hash index, or reserve it across calls from MySQL. When there is no adaptive hash index contention, this value remains zero and statements reserve the latch until they finish. During times of contention, it counts down to zero, and statements release the latch immediately after each row lookup.

• **TRX_IS_READ_ONLY**
  A value of 1 indicates the transaction is read only.

• **TRX_AUTOCOMMIT_NON_LOCKING**
  A value of 1 indicates the transaction is a **SELECT** statement that does not use the **FOR UPDATE** or **LOCK IN SHARED MODE** clauses, and is executing with autocommit enabled so that the transaction will contain only this one statement. When this column and **TRX_IS_READ_ONLY** are both 1, InnoDB optimizes the transaction to reduce the overhead associated with transactions that change table data.
Example

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TRX;
*************************** 1. row ***************************
  trx_id: 3298
  trx_state: RUNNING

Notes

- Use this table to help diagnose performance problems that occur during times of heavy concurrent load. Its contents are updated as described in Section 14.15.2.3, “Persistence and Consistency of InnoDB Transaction and Locking Information”.
- You must have the `PROCESS` privilege to query this table.
- Use the `INFORMATION_SCHEMA COLUMNS` table or the `SHOW COLUMNS` statement to view additional information about the columns of this table, including data types and default values.

### 21.31 INFORMATION_SCHEMA NDB Cluster Tables

The following sections provide information about `INFORMATION_SCHEMA` tables which are specific to NDB Cluster. (The `FILES` table is available in standard MySQL 5.6 but is not used there.) The `ndb_transid_mysql_connection_map` table is implemented as an `INFORMATION_SCHEMA` plugin available only in NDB Cluster binaries or source, and does not exist in MySQL Server 5.6.

Additional statistical and other data about NDB Cluster transactions, operations, threads, blocks, and other aspects of performance can be obtained from the tables in the `ndbinfo` database. For information about these tables, see Section 18.5.10, “ndbinfo: The NDB Cluster Information Database”.

#### 21.31.1 The INFORMATION_SCHEMA FILES Table

The `FILES` table provides information about the files in which MySQL NDB Disk Data tables are stored.

The `FILES` table has these columns:

- **FILE_ID**

  A file identifier. `FILE_ID` column values are auto-generated.
The INFORMATION_SCHEMA FILES Table

- **FILE_NAME**
  The name of an UNDO log file created by CREATE LOGFILE GROUP or ALTER LOGFILE GROUP, or of a data file created by CREATE TABLESPACE or ALTER TABLESPACE.

- **FILE_TYPE**
  One of the values UNDO LOG, DATAFILE, or TABLESPACE.

- **TABLESPACE_NAME**
  The name of the tablespace with which the file is associated.

- **TABLE_CATALOG**
  This value is always empty.

- **TABLE_SCHEMA**
  This value is always NULL.

- **TABLE_NAME**
  The name of the Disk Data table with which the file is associated, if any.

- **LOGFILE_GROUP_NAME**
  The name of the log file group to which the log file or data file belongs.

- **LOGFILE_GROUP_NUMBER**
  For an UNDO log file, the auto-generated ID number of the log file group to which the log file belongs.

- **ENGINE**
  For an NDB Cluster Disk Data log file or data file, this value always NDB or NDBCLUSTER.

- **FULLTEXT_KEYS**
  For an NDB Cluster Disk Data log file or data file, this value is always empty.

- **DELETED_ROWS**
  This value is always NULL.

- **UPDATE_COUNT**
  This value is always NULL.

- **FREE_EXTENTS**
  The number of extents which have not yet been used by the file.

- **TOTAL_EXTENTS**
  The total number of extents allocated to the file.

- **EXTENT_SIZE**
  The size of an extent for the file in bytes.
The INFORMATION_SCHEMA FILES Table

- **INITIAL_SIZE**
  The size of the file in bytes. This is the same value that was used in the `INITIAL_SIZE` clause of the `CREATE LOGFILE GROUP`, `ALTER LOGFILE GROUP`, `CREATE TABLESPACE`, or `ALTER TABLESPACE` statement used to create the file.

- **MAXIMUM_SIZE**
  For NDB Cluster Disk Data files, this value is always the same as the `INITIAL_SIZE` value.

- **AUTOEXTEND_SIZE**
  For NDB Cluster Disk Data files, this value is always empty.

- **CREATION_TIME**
  The date and time when the file was created.

- **LAST_UPDATE_TIME**
  The date and time when the file was last modified.

- **LAST_ACCESS_TIME**
  The date and time when the file was last accessed by the server.

- **RECOVER_TIME**
  For NDB Cluster Disk Data files, this value is always 0.

- **TRANSACTION_COUNTER**
  For NDB Cluster Disk Data files, this value is always 0.

- **VERSION**
  For NDB Cluster Disk Data files, this value is always NULL.

- **ROW_FORMAT**
  For NDB Cluster Disk Data files, this value is always NULL.

- **TABLE_ROWS**
  For NDB Cluster Disk Data files, this value is always NULL.

- **AVG_ROW_LENGTH**
  For NDB Cluster Disk Data files, this value is always NULL.

- **DATA_LENGTH**
  For NDB Cluster Disk Data files, this value is always NULL.

- **MAX_DATA_LENGTH**
  For NDB Cluster Disk Data files, this value is always NULL.

- **INDEX_LENGTH**
  For NDB Cluster Disk Data files, this value is always NULL.
The INFORMATION_SCHEMA FILES Table

- **DATA_FREE**
  For NDB Cluster Disk Data files, this value is always **NULL**.

- **CREATE_TIME**
  For NDB Cluster Disk Data files, this value is always **NULL**.

- **UPDATE_TIME**
  For NDB Cluster Disk Data files, this value is always **NULL**.

- **CHECK_TIME**
  For NDB Cluster Disk Data files, this value is always **NULL**.

- **CHECKSUM**
  For NDB Cluster Disk Data files, this value is always **NULL**.

- **STATUS**
  For NDB Cluster Disk Data files, this value is always **NORMAL**.

- **EXTRA**
  For NDB Cluster Disk Data files, the **EXTRA** column shows which data node the file belongs to (each data node having its own copy), as well as the size of its undo buffer. Suppose that you use this statement on an NDB Cluster with four data nodes:

  ```sql
  CREATE LOGFILE GROUP mygroup
  ADD UNDOFILE 'new_undo.dat'
  INITIAL_SIZE 2G
  ENGINE NDB;
  ```

  After running the **CREATE LOGFILE GROUP** statement successfully, you should see a result similar to the one shown here for this query against the **FILES** table:

  ```sql
  mysql> SELECT LOGFILE_GROUP_NAME, FILE_TYPE, EXTRA
    FROM INFORMATION_SCHEMA.FILES
    WHERE FILE_NAME = 'new_undo.dat';
  ```

<table>
<thead>
<tr>
<th>LOGFILE_GROUP_NAME</th>
<th>FILE_TYPE</th>
<th>EXTRA</th>
</tr>
</thead>
<tbody>
<tr>
<td>mygroup</td>
<td>UNDO LOG</td>
<td>CLUSTER_NODE=5;UNDO_BUFFER_SIZE=8388608</td>
</tr>
<tr>
<td>mygroup</td>
<td>UNDO LOG</td>
<td>CLUSTER_NODE=6;UNDO_BUFFER_SIZE=8388608</td>
</tr>
<tr>
<td>mygroup</td>
<td>UNDO LOG</td>
<td>CLUSTER_NODE=7;UNDO_BUFFER_SIZE=8388608</td>
</tr>
<tr>
<td>mygroup</td>
<td>UNDO LOG</td>
<td>CLUSTER_NODE=8;UNDO_BUFFER_SIZE=8388608</td>
</tr>
</tbody>
</table>

**Notes**

- The **FILES** table is a nonstandard **INFORMATION_SCHEMA** table.

**NDB Notes**

- This table provides information about Disk Data files only: you cannot use it for determining disk space allocation or availability for individual NDB tables. However, it is possible to see how much space is allocated for each NDB table having data stored on disk—as well as how much remains available for
The INFORMATION_SCHEMA FILES Table

storage of data on disk for that table—using ndb_desc. For more information, see Section 18.4.10, "ndb_desc — Describe NDB Tables".

- The CREATION_TIME, LAST_UPDATE_TIME, and LAST_ACCESSED values are as reported by the operating system, and are not supplied by the NDB storage engine. Where no value is provided by the operating system, these columns display 0000-00-00 00:00:00.

- The difference between the TOTAL EXTENTS and FREE_EXTENTS columns is the number of extents currently in use by the file:

```
SELECT TOTAL_EXTENTS - FREE_EXTENTS AS extents_used
FROM INFORMATION_SCHEMA.FILES
WHERE FILE_NAME = 'myfile.dat';
```

To approximate the amount of disk space in use by the file, multiply that difference by the value of the EXTENT_SIZE column, which gives the size of an extent for the file in bytes:

```
SELECT (TOTAL_EXTENTS - FREE_EXTENTS) * EXTENT_SIZE AS bytes_used
FROM INFORMATION_SCHEMA.FILES
WHERE FILE_NAME = 'myfile.dat';
```

Similarly, you can estimate the amount of space that remains available in a given file by multiplying FREE_EXTENTS by EXTENT_SIZE:

```
SELECT FREE_EXTENTS * EXTENT_SIZE AS bytes_free
FROM INFORMATION_SCHEMA.FILES
WHERE FILE_NAME = 'myfile.dat';
```

Important

The byte values produced by the preceding queries are approximations only, and their precision is inversely proportional to the value of EXTENT_SIZE. That is, the larger EXTENT_SIZE becomes, the less accurate the approximations are.

It is also important to remember that once an extent is used, it cannot be freed again without dropping the data file of which it is a part. This means that deletes from a Disk Data table do not release disk space.

The extent size can be set in a CREATE TABLESPACE statement. For more information, see Section 13.1.18, “CREATE TABLESPACE Syntax”.

- An additional row is present in the FILES table following the creation of a logfile group. This row has NULL for the value of the FILE_NAME column. For this row, the value of the FILE_ID column is always 0, that of the FILE_TYPE column is always UNDO_LOG, and that of the STATUS column is always NORMAL. The value of the ENGINE column is always NDBCLUSTER.

The FREE_EXTENTS column in this row shows the total number of free extents available to all undo files belonging to a given log file group whose name and number are shown in the LOGFILE_GROUP_NAME and LOGFILE_GROUP_NUMBER columns, respectively.

Suppose there are no existing log file groups on your NDB Cluster, and you create one using the following statement:

```
mysql> CREATE LOGFILE GROUP lg1
    ADD UNDOFILE 'undofile.dat'
    INITIAL_SIZE = 16M
```
The INFORMATION_SCHEMA FILES Table

**UNDO BUFFER SIZE = 1M**
**ENGINE = NDB;**

You can now see this **NULL** row when you query the **FILES** table:

```sql
mysql> SELECT DISTINCT
FILE_NAME AS File,
FREE_EXTENTS AS Free,
TOTAL_EXTENTS AS Total,
EXTENT_SIZE AS Size,
INITIAL_SIZE AS Initial
FROM INFORMATION_SCHEMA.FILES;
```

<table>
<thead>
<tr>
<th>File</th>
<th>Free</th>
<th>Total</th>
<th>Size</th>
<th>Initial</th>
</tr>
</thead>
<tbody>
<tr>
<td>undofile.dat</td>
<td>NULL</td>
<td>4194304</td>
<td>4</td>
<td>16777216</td>
</tr>
<tr>
<td>NULL</td>
<td>4184068</td>
<td>NULL</td>
<td>4</td>
<td>NULL</td>
</tr>
</tbody>
</table>

The total number of free extents available for undo logging is always somewhat less than the sum of the **TOTAL_EXTENTS** column values for all undo files in the log file group due to overhead required for maintaining the undo files. This can be seen by adding a second undo file to the log file group, then repeating the previous query against the **FILES** table:

```sql
mysql> ALTER LOGFILE GROUP lg1
ADD UNDOFILE 'undofile02.dat'
INITIAL_SIZE = 4M
ENGINE = NDB;
```

```sql
mysql> SELECT DISTINCT
FILE_NAME AS File,
FREE_EXTENTS AS Free,
TOTAL_EXTENTS AS Total,
EXTENT_SIZE AS Size,
INITIAL_SIZE AS Initial
FROM INFORMATION_SCHEMA.FILES;
```

<table>
<thead>
<tr>
<th>File</th>
<th>Free</th>
<th>Total</th>
<th>Size</th>
<th>Initial</th>
</tr>
</thead>
<tbody>
<tr>
<td>undofile.dat</td>
<td>NULL</td>
<td>4194304</td>
<td>4</td>
<td>16777216</td>
</tr>
<tr>
<td>undofile02.dat</td>
<td>NULL</td>
<td>1048576</td>
<td>4</td>
<td>4194304</td>
</tr>
<tr>
<td>NULL</td>
<td>5223944</td>
<td>NULL</td>
<td>4</td>
<td>NULL</td>
</tr>
</tbody>
</table>

The amount of free space in bytes which is available for undo logging by Disk Data tables using this log file group can be approximated by multiplying the number of free extents by the initial size:

```sql
mysql> SELECT
FREE_EXTENTS AS 'Free Extents',
FREE_EXTENTS * EXTENT_SIZE AS 'Free Bytes'
FROM INFORMATION_SCHEMA.FILES
WHERE LOGFILE_GROUP_NAME = 'lg1'
AND FILE_NAME IS NULL;
```

<table>
<thead>
<tr>
<th>Free Extents</th>
<th>Free Bytes</th>
</tr>
</thead>
<tbody>
<tr>
<td>5223944</td>
<td>20895776</td>
</tr>
</tbody>
</table>

If you create an NDB Cluster Disk Data table and then insert some rows into it, you can see approximately how much space remains for undo logging afterward, for example:
The INFORMATION_SCHEMA ndb_transid_mysql_connection_map Table

mysql> CREATE TABLESPACE ts1
   ADD DATAFILE 'data1.dat'
   USE LOGFILE GROUP lg1
   INITIAL_SIZE 512M
   ENGINE = NDB;

mysql> CREATE TABLE dd (  
   c1 INT NOT NULL PRIMARY KEY,
   c2 INT,
   c3 DATE  
)
   TABLESPACE ts1 STORAGE DISK
   ENGINE = NDB;

mysql> INSERT INTO dd VALUES  
   (NULL, 1234567890, '2007-02-02'),
   (NULL, 1126789005, '2007-02-03'),
   (NULL, 1357924680, '2007-02-04'),
   (NULL, 1642097531, '2007-02-05');

mysql> SELECT  
   FREE_EXTENTS AS 'Free Extents',
   FREE_EXTENTS * EXTENT_SIZE AS 'Free Bytes'
   FROM INFORMATION_SCHEMA.FILES
   WHERE LOGFILE_GROUP_NAME = 'lg1'
   AND FILE_NAME IS NULL;

+--------------+------------+
| Free Extents | Free Bytes |
+--------------+------------+
| 5207565      | 20830260   |
+--------------+------------+

• An additional row is present in the FILES table for any NDB Cluster tablespace, whether or not any data files are associated with the tablespace. This row has NULL for the value of the FILE_NAME column. For this row, the value of the FILE_ID column is always 0, that of the FILE_TYPE column is always TABLESPACE, and that of the STATUS column is always NORMAL. The value of the ENGINE column is always NDBCLUSTER.

• For additional information, and examples of creating and dropping NDB Cluster Disk Data objects, see Section 18.5.12, “NDB Cluster Disk Data Tables”.

21.31.2 The INFORMATION_SCHEMA ndb_transid_mysql_connection_map Table

The ndb_transid_mysql_connection_map table provides a mapping between NDB transactions, NDB transaction coordinators, and MySQL Servers attached to an NDB Cluster as API nodes. This information is used when populating the server_operations and server_transactions tables of the ndbinfo NDB Cluster information database.

The ndb_transid_mysql_connection_map table has these columns:

• mysql_connection_id
  The MySQL server connection ID.

• node_id
  The transaction coordinator node ID.

• ndb_transid
The **NDB** transaction ID.

**Notes**

The `mysql_connection_id` value is the same as the connection or session ID shown in the output of `SHOW PROCESSLIST`.

There are no `SHOW` statements associated with this table.

This is a nonstandard table, specific to NDB Cluster. It is implemented as an **INFORMATION_SCHEMA** plugin; you can verify that it is supported by checking the output of `SHOW PLUGINS`. If `ndb_transid_mysql_connection_map` support is enabled, the output from this statement includes a plugin having this name, of type `INFORMATION_SCHEMA`, and having status `ACTIVE`, as shown here (using emphasized text):

```sql
mysql> SHOW PLUGINS;
+----------------------------------+--------+--------------------+---------+---------+
| Name                             | Status | Type               | Library | License |
+----------------------------------+--------+--------------------+---------+---------+
| binlog                           | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| mysql_native_password            | ACTIVE | AUTHENTICATION     | NULL    | GPL     |
| mysql_old_password               | ACTIVE | AUTHENTICATION     | NULL    | GPL     |
| CSV                              | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| MEMORY                           | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| MRG_MyISAM                       | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| MyISAM                           | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| PERFORMANCE_SCHEMA               | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| BLACKHOLE                        | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| ARCHIVE                          | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| ndbcluster                       | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| ndbinfo                          | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| ndb_transid_mysql_connection_map | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| InnoDB                           | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
| INNODB_TRX                       | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_LOCKS                     | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_LOCK_WAITS                | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_CMP                       | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_CMP_RESET                 | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_CMPMEM                    | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| INNODB_CMPMEM_RESET              | ACTIVE | INFORMATION SCHEMA | NULL    | GPL     |
| partition                        | ACTIVE | STORAGE ENGINE     | NULL    | GPL     |
+----------------------------------+--------+--------------------+---------+---------+
22 rows in set (0.00 sec)
```

The plugin is enabled by default. You can disable it (or force the server not to run unless the plugin starts) by starting the server with the `--ndb-transid-mysql-connection-map` option. If the plugin is disabled, the status is shown by `SHOW PLUGINS` as `DISABLED`. The plugin cannot be enabled or disabled at runtime.

Although the names of this table and its columns are displayed using lowercase, you can use uppercase or lowercase when referring to them in SQL statements.

For this table to be created, the MySQL Server must be a binary supplied with the NDB Cluster distribution, or one built from the NDB Cluster sources with `NDB` storage engine support enabled. It is not available in the standard MySQL 5.6 Server.

### 21.32 INFORMATION_SCHEMA Thread Pool Tables
The following sections describe the INFORMATION_SCHEMA tables associated with the thread pool plugin (see Section 5.5.3, “MySQL Enterprise Thread Pool”). They provide information about thread pool operation:

- **TP_THREAD_GROUP_STATE**: Information about thread pool thread group states
- **TP_THREAD_GROUP_STATS**: Thread group statistics
- **TP_THREAD_STATE**: Information about thread pool thread states

Rows in these tables represent snapshots in time. In the case of TP_THREAD_STATE, all rows for a thread group comprise a snapshot in time. Thus, the MySQL server holds the mutex of the thread group while producing the snapshot. But it does not hold mutexes on all thread groups at the same time, to prevent a statement against TP_THREAD_STATE from blocking the entire MySQL server.

The thread pool INFORMATION_SCHEMA tables are implemented by individual plugins and the decision whether to load one can be made independently of the others (see Section 5.5.3.2, “Thread Pool Installation”). However, the content of all the tables depends on the thread pool plugin being enabled. If a table plugin is enabled but the thread pool plugin is not, the table becomes visible and can be accessed but will be empty.

### 21.32.1 The INFORMATION_SCHEMA TP_THREAD_GROUP_STATE Table

The TP_THREAD_GROUP_STATE table has one row per thread group in the thread pool. Each row provides information about the current state of a group.

The TP_THREAD_GROUP_STATE table has these columns:

- **TP_GROUP_ID**
  The thread group ID. This is a unique key within the table.

- **CONSUMER_THREADS**
  The number of consumer threads. There is at most one thread ready to start executing if the active threads become stalled or blocked.

- **RESERVE_THREADS**
  The number of threads in the reserved state. This means that they will not be started until there is a need to wake a new thread and there is no consumer thread. This is where most threads end up when the thread group has created more threads than needed for normal operation. Often a thread group needs additional threads for a short while and then does not need them again for a while. In this case, they go into the reserved state and remain until needed again. They take up some extra memory resources, but no extra computing resources.

- **CONNECT_THREAD_COUNT**
  The number of threads that are processing or waiting to process connection initialization and authentication. There can be a maximum of four connection threads per thread group; these threads expire after a period of inactivity.

  This column was added in MySQL 5.6.36.

- **CONNECTION_COUNT**
  The number of connections using this thread group.
• **QUEUED_QUERIES**

  The number of statements waiting in the high-priority queue.

• **QUEUED_TRANSACTIONS**

  The number of statements waiting in the low-priority queue. These are the initial statements for transactions that have not started, so they also represent queued transactions.

• **STALL_LIMIT**

  The value of the `thread_pool_stall_limit` system variable for the thread group. This is the same value for all thread groups.

• **PRIO_KICKUP_TIMER**

  The value of the `thread_pool_prio_kickup_timer` system variable for the thread group. This is the same value for all thread groups.

• **ALGORITHM**

  The value of the `thread_pool_algorithm` system variable for the thread group. This is the same value for all thread groups.

• **THREAD_COUNT**

  The number of threads started in the thread pool as part of this thread group.

• **ACTIVE_THREAD_COUNT**

  The number of threads active in executing statements.

• **STALLLED_THREAD_COUNT**

  The number of stalled statements in the thread group. A stalled statement could be executing, but from a thread pool perspective it is stalled and making no progress. A long-running statement quickly ends up in this category.

• **WAITING_THREAD_NUMBER**

  If there is a thread handling the polling of statements in the thread group, this specifies the thread number within this thread group. It is possible that this thread could be executing a statement.

• **OLDEST_QUEUED**

  How long in milliseconds the oldest queued statement has been waiting for execution.

• **MAX_THREAD_IDS_IN_GROUP**

  The maximum thread ID of the threads in the group. This is the same as `MAX(TP_THREAD_NUMBER)` for the threads when selected from the `TP_THREAD_STATE` table. That is, these two queries are equivalent:

  ```sql
  SELECT TP_GROUP_ID, MAX_THREAD_IDS_IN_GROUP
  FROM TP_THREAD_GROUP_STATE;
  
  SELECT TP_GROUP_ID, MAX(TP_THREAD_NUMBER)
  FROM TP_THREAD_STATE GROUP BY TP_GROUP_ID;
  ```

### 21.32.2 The INFORMATION_SCHEMA TP_THREAD_GROUP_STATS Table
The **TP_THREAD_GROUP_STATS** table reports statistics per thread group. There is one row per group. The **TP_THREAD_GROUP_STATS** table has these columns:

- **TP_GROUP_ID**
  The thread group ID. This is a unique key within the table.

- **CONNECTIONS_STARTED**
  The number of connections started.

- **CONNECTIONS_CLOSED**
  The number of connections closed.

- **QUERIES_EXECUTED**
  The number of statements executed. This number is incremented when a statement starts executing, not when it finishes.

- **QUERIES_QUEUED**
  The number of statements received that were queued for execution. This does not count statements that the thread group was able to begin executing immediately without queuing, which can happen under the conditions described in Section 5.5.3.3, "Thread Pool Operation".

- **THREADS_STARTED**
  The number of threads started.

- **PRIO_KICKUPS**
  The number of statements that have been moved from low-priority queue to high-priority queue based on the value of the `thread_pool_prio_kickup_timer` system variable. If this number increases quickly, consider increasing the value of that variable. A quickly increasing counter means that the priority system is not keeping transactions from starting too early. For InnoDB, this most likely means deteriorating performance due to too many concurrent transactions.

- **STALLED QUERIES_EXECUTED**
  The number of statements that have become defined as stalled due to executing for longer than the value of the `thread_pool_stall_limit` system variable.

- **BECOME_CONSUMER_THREAD**
  The number of times thread have been assigned the consumer thread role.

- **BECOME_reserve_THREAD**
  The number of times threads have been assigned the reserve thread role.

- **BECOME_WAITING_THREAD**
  The number of times threads have been assigned the waiter thread role. When statements are queued, this happens very often, even in normal operation, so rapid increases in this value are normal in the case of a highly loaded system where statements are queued up.

- **WAKE_THREAD_STALL_CHECKER**
The TP_THREAD_STATE table has one row per thread created by the thread pool to handle connections.

The TP_THREAD_STATE table has these columns:

- **TP_GROUP_ID**
  - The thread group ID.
• **TP_THREAD_NUMBER**

The ID of the thread within its thread group. **TP_GROUP_ID** and **TP_THREAD_NUMBER** together provide a unique key within the table.

• **PROCESS_COUNT**

The 10ms interval in which the statement that uses this thread is currently executing. 0 means no statement is executing, 1 means it is in the first 10ms, and so forth.

• **WAIT_TYPE**

The type of wait for the thread. **NULL** means the thread is not blocked. Otherwise, the thread is blocked by a call to **thd_wait_begin()** and the value specifies the type of wait. The **xxx_WAIT** columns of the **TP_THREAD_GROUP_STATS** table accumulate counts for each wait type.

The **WAIT_TYPE** value is a string that describes the type of wait, as shown in the following table.

<table>
<thead>
<tr>
<th>Wait Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>THD_WAIT_SLEEP</td>
<td>Waiting for sleep</td>
</tr>
<tr>
<td>THD_WAIT_DISKIO</td>
<td>Waiting for Disk IO</td>
</tr>
<tr>
<td>THD_WAIT_ROW_LOCK</td>
<td>Waiting for row lock</td>
</tr>
<tr>
<td>THD_WAIT_GLOBAL_LOCK</td>
<td>Waiting for global lock</td>
</tr>
<tr>
<td>THD_WAIT_META_DATA_LOCK</td>
<td>Waiting for metadata lock</td>
</tr>
<tr>
<td>THD_WAIT_TABLE_LOCK</td>
<td>Waiting for table lock</td>
</tr>
<tr>
<td>THD_WAIT_USER_LOCK</td>
<td>Waiting for user lock</td>
</tr>
<tr>
<td>THD_WAIT_BINLOG</td>
<td>Waiting for binlog</td>
</tr>
<tr>
<td>THD_WAIT_GROUP_COMMIT</td>
<td>Waiting for group commit</td>
</tr>
<tr>
<td>THD_WAIT_SYNC</td>
<td>Waiting for fsync</td>
</tr>
</tbody>
</table>

### 21.33 INFORMATION_SCHEMA Connection-Control Tables

The following sections describe the **INFORMATION_SCHEMA** tables associated with the **CONNECTION_CONTROL** plugin.

#### 21.33.1 The INFORMATION_SCHEMA CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS Table

This table provides information about the current number of consecutive failed connection attempts per client user/host combination. The table was added in MySQL 5.6.35.

**CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS** has these columns:

• **USERHOST**

The user/host combination of a client that has failed connection attempts, in 'user_name'@'host_name' format.

• **FAILED_ATTEMPTS**
The current number of consecutive failed connection attempts for the `USERHOST` value. This counts all failed attempts, regardless of whether they were delayed. The number of attempts for which the server added a delay to its response is the difference between the `FAILED_ATTEMPTS` value and the `connection_control_failed_connections_threshold` system variable value.

Notes

- The `CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS` plugin must be activated for this table to be available, and the `CONNECTION_CONTROL` plugin must be activated or the table contents will always be empty. See Section 6.4.2, “The Connection-Control Plugins”.

- The table contains rows only for clients that have had one or more consecutive failed connection attempts without a subsequent successful attempt. When a client connects successfully, its failed-connection count is reset to zero and the server removes any row corresponding to the client.

- Assigning a value to the `connection_control_failed_connections_threshold` system variable at runtime resets all accumulated failed-connection counters to zero, which causes the table to become empty.

### 21.34 Extensions to SHOW Statements

Some extensions to `SHOW` statements accompany the implementation of `INFORMATION_SCHEMA`:

- `SHOW` can be used to get information about the structure of `INFORMATION_SCHEMA` itself.

- Several `SHOW` statements accept a `WHERE` clause that provides more flexibility in specifying which rows to display.

`INFORMATION_SCHEMA` is an information database, so its name is included in the output from `SHOW DATABASES`. Similarly, `SHOW TABLES` can be used with `INFORMATION_SCHEMA` to obtain a list of its tables:

```sql
mysql> SHOW TABLES FROM INFORMATION_SCHEMA;
+---------------------------------------+
| Tables_in_INFORMATION_SCHEMA          |
+---------------------------------------+
| CHARACTER_SETS                        |
| COLLATIONS                            |
| COLLATION_CHARACTER_SET_APPLICABILITY |
| COLUMNS                               |
| COLUMN_PRIVILEGES                     |
| ENGINES                               |
| EVENTS                                |
| FILES                                 |
| GLOBAL_STATUS                         |
| GLOBAL_VARIABLES                      |
| KEY_COLUMN_USAGE                      |
| PARTITIONS                            |
| PLUGINS                               |
| PROCESSLIST                           |
| REFERENTIAL_CONSTRAINTS               |
| ROUTINES                              |
| SCHEMATA                              |
| SCHEMA_PRIVILEGES                     |
| SESSION_STATUS                        |
| SESSION_VARIABLES                     |
| STATISTICS                             |
| TABLES                                |
| TABLE_CONSTRAINTS                     |
```
### Extensions to SHOW Statements

**SHOW COLUMNS** and **DESCRIBE** can display information about the columns in individual **INFORMATION_SCHEMA** tables.

**SHOW** statements that accept a `LIKE` clause to limit the rows displayed also permit a `WHERE` clause that specifies more general conditions that selected rows must satisfy:

```sql
SHOW CHARACTER SET
SHOW COLLATION
SHOW COLUMNS
SHOW DATABASES
SHOW FUNCTION STATUS
SHOW INDEX
SHOW PROCEDURE STATUS
SHOW STATUS
SHOW TABLE STATUS
SHOW TABLES
SHOW TRIGGERS
SHOW VARIABLES
```

The `WHERE` clause, if present, is evaluated against the column names displayed by the `SHOW` statement. For example, the `SHOW CHARACTER SET` statement produces these output columns:

```sql
mysql> SHOW CHARACTER SET;
+----------+-----------------------------+---------------------+--------+
| Charset  | Description                 | Default collation   | Maxlen |
+----------+-----------------------------+---------------------+--------+
| big5     | Big5 Traditional Chinese    | big5_chinese_ci     |      2 |
| dec8     | DEC West European           | dec8_swedish_ci     |      1 |
| cp850    | DOS West European           | cp850_general_ci    |      1 |
| hp8      | HP West European            | hp8_english_ci      |      1 |
| koi8r    | KOI8-R Relcom Russian       | koi8r_general_ci    |      1 |
| latin1   | cp1252 West European        | latin1_swedish_ci   |      1 |
| latin2   | ISO 8859-2 Central European | latin2_general_ci   |      1 |
| ...      |                             |                     |        |
```

To use a `WHERE` clause with `SHOW CHARACTER SET`, you would refer to those column names. As an example, the following statement displays information about character sets for which the default collation contains the string **'japanese'**:

```sql
mysql> SHOW CHARACTER SET WHERE `Default collation` LIKE '%japanese%';
+----------+-----------------------------+---------------------+--------+
| Charset  | Description                 | Default collation   | Maxlen |
+----------+-----------------------------+---------------------+--------+
| ujis     | EUC-JP Japanese             | ujis_japanese_ci     |      3 |
| sjis     | Shift-JIS Japanese          | sjis_japanese_ci     |      2 |
| cp932    | SJIS for Windows Japanese   | cp932_japanese_ci    |      2 |
| eucjcms  | UJIS for Windows Japanese   | eucjcms_japanese_ci  |      3 |
+----------+-----------------------------+---------------------+--------+
```

This statement displays the multibyte character sets:

```sql
mysql> SHOW CHARACTER SET WHERE Maxlen > 1;
+----------+-----------------------------+---------------------+--------+
| Charset  | Description                 | Default collation   | Maxlen |
+----------+-----------------------------+---------------------+--------+
```

The MySQL Performance Schema is a feature for monitoring MySQL Server execution at a low level. The Performance Schema has these characteristics:

• The Performance Schema provides a way to inspect internal execution of the server at runtime. It is implemented using the PERFORMANCE_SCHEMA storage engine and the performance_schema database. The Performance Schema focuses primarily on performance data. This differs from INFORMATION_SCHEMA, which serves for inspection of metadata.
• The Performance Schema monitors server events. An “event” is anything the server does that takes time and has been instrumented so that timing information can be collected. In general, an event could be a function call, a wait for the operating system, a stage of an SQL statement execution such as parsing or sorting, or an entire statement or group of statements. Event collection provides access to information about synchronization calls (such as for mutexes) file and table I/O, table locks, and so forth for the server and for several storage engines.

• Performance Schema events are distinct from events written to the server’s binary log (which describe data modifications) and Event Scheduler events (which are a type of stored program).

• Performance Schema events are specific to a given instance of the MySQL Server. Performance Schema tables are considered local to the server, and changes to them are not replicated or written to the binary log.

• Current events are available, as well as event histories and summaries. This enables you to determine how many times instrumented activities were performed and how much time they took. Event information is available to show the activities of specific threads, or activity associated with particular objects such as a mutex or file.

• The `PERFORMANCE_SCHEMA` storage engine collects event data using “instrumentation points” in server source code.

• Collected events are stored in tables in the `performance_schema` database. These tables can be queried using `SELECT` statements like other tables.

• Performance Schema configuration can be modified dynamically by updating tables in the `performance_schema` database through SQL statements. Configuration changes affect data collection immediately.

• Tables in the Performance Schema are in-memory tables that use no persistent on-disk storage. The contents are repopulated beginning at server startup and discarded at server shutdown.

• Monitoring is available on all platforms supported by MySQL.

  Some limitations might apply: The types of timers might vary per platform. Instruments that apply to storage engines might not be implemented for all storage engines. Instrumentation of each third-party engine is the responsibility of the engine maintainer. See also Section 22.19, “Restrictions on Performance Schema”.

• Data collection is implemented by modifying the server source code to add instrumentation. There are no separate threads associated with the Performance Schema, unlike other features such as replication or the Event Scheduler.

The Performance Schema is intended to provide access to useful information about server execution while having minimal impact on server performance. The implementation follows these design goals:

• Activating the Performance Schema causes no changes in server behavior. For example, it does not cause thread scheduling to change, and it does not cause query execution plans (as shown by `EXPLAIN`) to change.

• No memory allocation is done beyond that which occurs during server startup. By using early allocation of structures with a fixed size, it is never necessary to resize or reallocate them, which is critical for achieving good runtime performance.

• Server monitoring occurs continuously and unobtrusively with very little overhead. Activating the Performance Schema does not make the server unusable.

• The parser is unchanged. There are no new keywords or statements.
Performance Schema Quick Start

- Execution of server code proceeds normally even if the Performance Schema fails internally.
- When there is a choice between performing processing during event collection initially or during event retrieval later, priority is given to making collection faster. This is because collection is ongoing whereas retrieval is on demand and might never happen at all.
- It is easy to add new instrumentation points.
- Instrumentation is versioned. If the instrumentation implementation changes, previously instrumented code will continue to work. This benefits developers of third-party plugins because it is not necessary to upgrade each plugin to stay synchronized with the latest Performance Schema changes.

Note

The MySQL sys schema is a set of objects that provides convenient access to data collected by the Performance Schema. In MySQL 5.7, the sys schema is installed by default. For MySQL 5.6, you can obtain it from the schema development website at https://github.com/mysql/mysql-sys. For usage instructions, see MySQL sys Schema.

22.1 Performance Schema Quick Start

This section briefly introduces the Performance Schema with examples that show how to use it. For additional examples, see Section 22.18, “Using the Performance Schema to Diagnose Problems”.

For the Performance Schema to be available, support for it must have been configured when MySQL was built. You can verify whether this is the case by checking the server’s help output. If the Performance Schema is available, the output will mention several variables with names that begin with performance_schema:

```
shell> mysqld --verbose --help
...
   --performance_schema  Enable the performance schema.
   --performance_schema_events_waits_history_long_size=#
                     Number of rows in events_waits_history_long.
...
```

If such variables do not appear in the output, your server has not been built to support the Performance Schema. In this case, see Section 22.2, “Performance Schema Build Configuration”.

Assuming that the Performance Schema is available, it is enabled by default. To enable or disable it explicitly, start the server with the performance_schema variable set to an appropriate value. For example, use these lines in your my.cnf file:

```
[mysqld]
performance_schema=ON
```

When the server starts, it sees performance_schema and attempts to initialize the Performance Schema. To verify successful initialization, use this statement:

```
mysql> SHOW VARIABLES LIKE 'performance_schema';
+------------------------+-------+
| Variable_name          | Value |
+------------------------+-------+
| performance_schema     | ON    |
+------------------------+-------+
```
A value of **ON** means that the Performance Schema initialized successfully and is ready for use. A value of **OFF** means that some error occurred. Check the server error log for information about what went wrong.

The Performance Schema is implemented as a storage engine. If this engine is available (which you should already have checked earlier), you should see it listed with a **SUPPORT** value of **YES** in the output from the `INFORMATION_SCHEMA.ENGINES` table or the `SHOW ENGINES` statement:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.ENGINES
    WHERE ENGINE='PERFORMANCE_SCHEMA';
```

```
*************************** 1. row ***************************
  ENGINE: PERFORMANCE_SCHEMA
  SUPPORT: YES
  COMMENT: Performance Schema
  TRANSACTIONS: NO
  XA: NO
  SAVEPOINTS: NO
```

```
mysql> SHOW ENGINES;
```

```
... Engine: PERFORMANCE_SCHEMA  Support: YES Comment: Performance Schema
    Transactions: NO
    XA: NO
    Savepoints: NO
...```

The **PERFORMANCE_SCHEMA** storage engine operates on tables in the **performance_schema** database. You can make **performance_schema** the default database so that references to its tables need not be qualified with the database name:

```
mysql> USE performance_schema;
```

Performance Schema tables are stored in the **performance_schema** database. Information about the structure of this database and its tables can be obtained, as for any other database, by selecting from the `INFORMATION_SCHEMA` database or by using `SHOW` statements. For example, use either of these statements to see what Performance Schema tables exist:

```
mysql> SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
    WHERE TABLE_SCHEMA = 'performance_schema';
```

```
+-------------------------------------+
<table>
<thead>
<tr>
<th>TABLE_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>accounts</td>
</tr>

</tr>
<tr>
<td>file_instances</td>
</tr>
<tr>
<td>file_summary_by_event_name</td>
</tr>
<tr>
<td>file_summary_by_instance</td>
</tr>
</tbody>
</table>
```

The number of Performance Schema tables increases over time as implementation of additional instrumentation proceeds.

The name of the `performance_schema` database is lowercase, as are the names of tables within it. Queries should specify the names in lowercase.

To see the structure of individual tables, use `SHOW CREATE TABLE`:

```
mysql> SHOW CREATE TABLE performance_schema.setup_consumers;
```

Table structure is also available by selecting from tables such as `INFORMATION_SCHEMA.COLUMNS` or by using statements such as `SHOW COLUMNS`.

Tables in the `performance_schema` database can be grouped according to the type of information in them: Current events, event histories and summaries, object instances, and setup (configuration) information. The following examples illustrate a few uses for these tables. For detailed information about the tables in each group, see Section 22.12, “Performance Schema Table Descriptions”.

Initially, not all instruments and consumers are enabled, so the performance schema does not collect all events. To turn all of these on and enable event timing, execute two statements (the row counts may differ depending on MySQL version):
To see what the server is doing at the moment, examine the `events_waits_current` table. It contains one row per thread showing each thread’s most recent monitored event:

```sql
mysql> SELECT * FROM performance_schema.events_waits_current\G
*************************** 1. row ***************************
THREAD_ID: 0
EVENT_ID: 5523
END_EVENT_ID: 5523
EVENT_NAME: wait/synch/mutex/mysys/THR_LOCK::mutex
SOURCE: thr_lock.c:525
TIMER_START: 201660494489586
TIMER_END: 201660494576112
TIMER_WAIT: 86526
SPINS: NULL
OBJECT_SCHEMA: NULL
OBJECT_NAME: NULL
INDEX_NAME: NULL
OBJECT_TYPE: NULL
OBJECT_INSTANCE_BEGIN: 142270668
NESTING_EVENT_ID: NULL
NESTING_EVENT_TYPE: NULL
OPERATION: lock
NUMBER_OF_BYTES: NULL
FLAGS: 0
...```

This event indicates that thread 0 was waiting for 86,526 picoseconds to acquire a lock on `THR_LOCK::mutex`, a mutex in the `mysys` subsystem. The first few columns provide the following information:

- The ID columns indicate which thread the event comes from and the event number.

- `EVENT_NAME` indicates what was instrumented and `SOURCE` indicates which source file contains the instrumented code.

- The timer columns show when the event started and stopped and how long it took. If an event is still in progress, the `TIMER_END` and `TIMER_WAIT` values are `NULL`. Timer values are approximate and expressed in picoseconds. For information about timers and event time collection, see Section 22.4.1, “Performance Schema Event Timing”.

The history tables contain the same kind of rows as the current-events table but have more rows and show what the server has been doing “recently” rather than “currently.” The `events_waits_history` and `events_waits_history_long` tables contain the most recent 10 events per thread and most recent 10,000 events, respectively. For example, to see information for recent events produced by thread 13, do this:

```sql
mysql> SELECT EVENT_ID, EVENT_NAME, TIMER_WAIT
  FROM performance_schema.events_waits_history
  WHERE THREAD_ID = 13
  ORDER BY EVENT_ID;
```

<table>
<thead>
<tr>
<th>EVENT_ID</th>
<th>EVENT_NAME</th>
<th>TIMER_WAIT</th>
</tr>
</thead>
</table>

...
As new events are added to a history table, older events are discarded if the table is full.

Summary tables provide aggregated information for all events over time. The tables in this group summarize event data in different ways. To see which instruments have been executed the most times or have taken the most wait time, sort the `events_waits_summary_global_by_event_name` table on the `COUNT_STAR` or `SUM_TIMER_WAIT` column, which correspond to a `COUNT(*)` or `SUM(TIMER_WAIT)` value, respectively, calculated over all events:

```sql
mysql> SELECT EVENT_NAME, COUNT_STAR
FROM performance_schema.events_waits_summary_global_by_event_name
ORDER BY COUNT_STAR DESC LIMIT 10;
```

<table>
<thead>
<tr>
<th>EVENT_NAME</th>
<th>COUNT_STAR</th>
</tr>
</thead>
<tbody>

<td>wait/synch/mutex/mysys/THR_LOCK::mutex</td>
<td>89</td>
</tr>
<tr>
<td>wait/synch/mutex/mysys/LOCK_open</td>
<td>88</td>
</tr>
</tbody>
</table>

```sql
mysql> SELECT EVENT_NAME, SUM_TIMER_WAIT
FROM performance_schema.events_waits_summary_global_by_event_name
ORDER BY SUM_TIMER_WAIT DESC LIMIT 10;
```

<table>
<thead>
<tr>
<th>EVENT_NAME</th>
<th>SUM_TIMER_WAIT</th>
</tr>
</thead>
<tbody>
<tr>

<td>86027823</td>
</tr>
<tr>
<td>wait/io/file/sql/pid</td>
<td>72591750</td>
</tr>
</tbody>
</table>

These results show that the `THR_LOCK_malloc` mutex is “hot,” both in terms of how often it is used and amount of time that threads wait attempting to acquire it.

**Note**

The `THR_LOCK_malloc` mutex is used only in debug builds. In production builds it is not hot because it is nonexistent.
Instance tables document what types of objects are instrumented. An instrumented object, when used by the server, produces an event. These tables provide event names and explanatory notes or status information. For example, the `file_instances` table lists instances of instruments for file I/O operations and their associated files:

```sql
mysql> SELECT * FROM performance_schema.file_instances;
+---------------------+---------------------+----------+
| FILE_NAME           | EVENT_NAME          | OPEN_COUNT |
+---------------------+---------------------+----------+
| /opt/mysql-log/60500/binlog.000007 | wait/io/file/sql/binlog | 0        |
| /opt/mysql/60500/data/mysql/tables_priv.MYI | wait/io/file/myisam/kfile | 1        |
| /opt/mysql/60500/data/mysql/columns_priv.MYI | wait/io/file/myisam/kfile | 1        |
| ...                 |                     |          |
```

Setup tables are used to configure and display monitoring characteristics. For example, `setup_instruments` lists the set of instruments for which events can be collected and shows which of them are enabled:

```sql
mysql> SELECT * FROM performance_schema.setup_instruments;
+----------------------------------------+---------+-------+
| NAME                                   | ENABLED | TIMED |
|----------------------------------------+---------+-------|
| ...                                    |         |       |
| stage/sql/end                          | NO      | NO    |
| stage/sql/executing                    | NO      | NO    |
| stage/sql/init                         | NO      | NO    |
| stage/sql/insert                       | NO      | NO    |
| ...                                    |         |       |
| statement/sql/load                     | YES     | YES   |
| statement/sql/grant                    | YES     | YES   |
| statement/sql/check                    | YES     | YES   |
| statement/sql/flush                    | YES     | YES   |
| ...                                    |         |       |
| wait/synch/mutex/sql/LOCK_global_read_lock | YES     | YES   |
| wait/synch/mutex/sql/LOCK_global_system_variables | YES | YES |
| wait/synch/mutex/sql/LOCK_lock_db      | YES     | YES   |
| wait/synch/mutex/sql/LOCK_manager      | YES     | YES   |
| ...                                    |         |       |
| wait/synch/rwlock/sql/LOCK_grant       | YES     | YES   |
| wait/synch/rwlock/sql/LOGGER::LOCK_logger | YES   | YES   |
| wait/synch/rwlock/sql/LOCK_sys_init_connect | YES | YES |
| wait/synch/rwlock/sql/LOCK_sys_init_slave | YES | YES |
| ...                                    |         |       |
| wait/io/file/sql/binlog                | YES     | YES   |
| wait/io/file/sql/binlog_index          | YES     | YES   |
| wait/io/file/sql/casetest              | YES     | YES   |
| wait/io/file/sql/dbopt                 | YES     | YES   |
| ...                                    |         |       |
```

To understand how to interpret instrument names, see Section 22.6, “Performance Schema Instrument Naming Conventions”.

To control whether events are collected for an instrument, set its `ENABLED` value to `YES` or `NO`. For example:
The Performance Schema uses collected events to update tables in the `performance_schema` database, which act as “consumers” of event information. The `setup_consumers` table lists the available consumers and which are enabled:

```sql
mysql> SELECT * FROM performance_schema.setup_consumers;
+--------------------------------+---------+
| NAME                           | ENABLED |
+--------------------------------+---------+
| events_stages_current          | NO      |
| events_stages_history          | NO      |
| events_stages_history_long     | NO      |
| events_statements_current      | YES     |
| events_statements_history      | NO      |
| events_statements_history_long | NO      |
| events_waits_current           | NO      |
| events_waits_history           | NO      |
| events_waits_history_long      | NO      |
| global_instrumentation         | YES     |
| thread_instrumentation         | YES     |
| statements_digest              | YES     |
+--------------------------------+---------+
```

To control whether the Performance Schema maintains a consumer as a destination for event information, set its `ENABLED` value.

For more information about the setup tables and how to use them to control event collection, see Section 22.4.2, “Performance Schema Event Filtering”.

There are some miscellaneous tables that do not fall into any of the previous groups. For example, `performance_timers` lists the available event timers and their characteristics. For information about timers, see Section 22.4.1, “Performance Schema Event Timing”.

### 22.2 Performance Schema Build Configuration

For the Performance Schema to be available, it must be configured into the MySQL server at build time. Binary MySQL distributions provided by Oracle Corporation are configured to support the Performance Schema. If you use a binary MySQL distribution from another provider, check with the provider whether the distribution has been appropriately configured.

If you build MySQL from a source distribution, enable the Performance Schema by running `CMake` with the `WITH_PERFSCHEMA_STORAGE_ENGINE` option enabled:

```bash
shell> cmake . -DWITH_PERFSCHEMA_STORAGE_ENGINE=1
```

Configuring MySQL with the `WITHOUT_PERFSCHEMA_STORAGE_ENGINE=1` option prevents inclusion of the Performance Schema, so if you want it included, do not use this option. See Section 2.9.7, “MySQL Source-Configuration Options”.

If you install MySQL over a previous installation that was configured without the Performance Schema (or with an older version of the Performance Schema that has missing or out-of-date tables). One indication of this issue is the presence of messages such as the following in the error log:
Performance Schema Startup Configuration

To correct that problem, perform the MySQL upgrade procedure. See Section 2.11, “Upgrading MySQL.”

To verify whether a server was built with Performance Schema support, check its help output. If the Performance Schema is available, the output will mention several variables with names that begin with performance_schema:

```
shell> mysqld --verbose --help
...  
--performance_schema
   --performance_schema_events_waits_history_long_size=#
       Number of rows in events_waits_history_long.
...
```

You can also connect to the server and look for a line that names the PERFORMANCE_SCHEMA storage engine in the output from SHOW ENGINES:

```
mysql> SHOW ENGINES\G
...  
   Engine: PERFORMANCE_SCHEMA
   Support: YES
   Comment: Performance Schema
   Transactions: NO
   XA: NO
   Savepoints: NO
...
```

If the Performance Schema was not configured into the server at build time, no row for PERFORMANCE_SCHEMA will appear in the output from SHOW ENGINES. You might see performance_schema listed in the output from SHOW DATABASES, but it will have no tables and you will not be able to use it.

A line for PERFORMANCE_SCHEMA in the SHOW ENGINES output means that the Performance Schema is available, not that it is enabled. To enable it, you must do so at server startup, as described in the next section.

### 22.3 Performance Schema Startup Configuration

To use the MySQL Performance Schema, it must be enabled at server startup to enable event collection to occur.

Assuming that the Performance Schema is available, it is enabled by default. To enable or disable it explicitly, start the server with the performance_schema variable set to an appropriate value. For example, use these lines in your `my.cnf` file:

```
[mysqld]
performance_schema=ON
```

If the server is unable to allocate any internal buffer during Performance Schema initialization, the Performance Schema disables itself and sets performance_schema to OFF, and the server runs without instrumentation.
The Performance Schema also permits instrument and consumer configuration at server startup.

To control an instrument at server startup, use an option of this form:

```
--performance-schema-instrument='instrument_name=value'
```

Here, `instrument_name` is an instrument name such as `wait/synch/mutex/sql/LOCK_open`, and `value` is one of these values:

- **OFF**, **FALSE**, or **0**: Disable the instrument
- **ON**, **TRUE**, or **1**: Enable and time the instrument
- **COUNTED**: Enable and count (rather than time) the instrument

Each `--performance-schema-instrument` option can specify only one instrument name, but multiple instances of the option can be given to configure multiple instruments. In addition, patterns are permitted in instrument names to configure instruments that match the pattern. To configure all condition synchronization instruments as enabled and counted, use this option:

```
--performance-schema-instrument='wait/synch/cond/%=COUNTED'
```

To disable all instruments, use this option:

```
--performance-schema-instrument='%=OFF'
```

Longer instrument name strings take precedence over shorter pattern names, regardless of order. For information about specifying patterns to select instruments, see Section 22.4.9, “Naming Instruments or Consumers for Filtering Operations”.

An unrecognized instrument name is ignored. It is possible that a plugin installed later may create the instrument, at which time the name is recognized and configured.

To control a consumer at server startup, use an option of this form:

```
--performance-schema-consumer-consumer_name=value
```

Here, `consumer_name` is a consumer name such as `events_waits_history`, and `value` is one of these values:

- **OFF**, **FALSE**, or **0**: Do not collect events for the consumer
- **ON**, **TRUE**, or **1**: Collect events for the consumer

For example, to enable the `events_waits_history` consumer, use this option:

```
--performance-schema-consumer-events-waits-history=ON
```

The permitted consumer names can be found by examining the `setup_consumers` table. Patterns are not permitted. Consumer names in the `setup_consumers` table use underscores, but for consumers set at startup, dashes and underscores within the name are equivalent.

The Performance Schema includes several system variables that provide configuration information:
The `performance_schema` variable is ON or OFF to indicate whether the Performance Schema is enabled or disabled. The other variables indicate table sizes (number of rows) or memory allocation values.

### Note

With the Performance Schema enabled, the number of Performance Schema instances affects the server memory footprint, perhaps to a large extent. It may be necessary to tune the values of Performance Schema system variables to find the number of instances that balances insufficient instrumentation against excessive memory consumption.

To change the value of Performance Schema system variables, set them at server startup. For example, put the following lines in a `my.cnf` file to change the sizes of the history tables for wait events:

```ini
[mysqld]
performance_schema
performance_schema_events_waits_history_size=20
performance_schema_events_waits_history_long_size=15000
```

The Performance Schema automatically sizes the values of several of its parameters at server startup if they are not set explicitly. For example, it sizes the parameters that control the sizes of the events waits tables this way. To see which parameters are autosized under this policy, use `mysqld --verbose --help` and look for those with a default value of −1, or see Section 22.15, “Performance Schema System Variables”.

For each autosized parameter that is not set at server startup, the Performance Schema determines how to set its value based on the value of the following system values, which are considered as “hints” about how you have configured your MySQL server:

```ini
max_connections
open_files_limit
table_definition_cache
table_open_cache
```

To override autosizing for a given parameter, set it to a value other than −1 at startup. In this case, the Performance Schema assigns it the specified value.

At runtime, `SHOW VARIABLES` displays the actual values that autosized parameters were set to.
If the Performance Schema is disabled, its autosized parameters remain set to \(-1\) and `SHOW VARIABLES` displays \(-1\).

### 22.4 Performance Schema Runtime Configuration

Specific Performance Schema features can be enabled at runtime to control which types of event collection occur.

Performance Schema setup tables contain information about monitoring configuration:

```sql
mysql> SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
  WHERE TABLE_SCHEMA = 'performance_schema'
  AND TABLE_NAME LIKE 'setup%';
+-------------------+
| TABLE_NAME        |
+-------------------+
| setup_actors      |
| setup_consumers   |
| setup_instruments |
| setup_objects     |
| setup_timers      |
+-------------------+
```

You can examine the contents of these tables to obtain information about Performance Schema monitoring characteristics. If you have the `UPDATE` privilege, you can change Performance Schema operation by modifying setup tables to affect how monitoring occurs. For additional details about these tables, see Section 22.12.2, “Performance Schema Setup Tables”.

To see which event timers are selected, query the `setup_timers` tables:

```sql
mysql> SELECT * FROM performance_schema.setup_timers;
+-----------+-------------+
| NAME      | TIMER_NAME  |
+-----------+-------------+
| idle      | MICROSECOND |
| wait      | CYCLE       |
| stage     | NANOSECOND  |
| statement | NANOSECOND  |
+-----------+-------------+
```

The `NAME` value indicates the type of instrument to which the timer applies, and `TIMER_NAME` indicates which timer applies to those instruments. The timer applies to instruments where their name begins with a component matching the `NAME` value.

To change the timer, update the `NAME` value. For example, to use the `NANOSECOND` timer for the `wait` timer:

```sql
mysql> UPDATE performance_schema.setup_timers
    SET TIMER_NAME = 'NANOSECOND'
    WHERE NAME = 'wait';
mysql> SELECT * FROM performance_schema.setup_timers;
+-----------+-------------+
| NAME      | TIMER_NAME  |
+-----------+-------------+
| idle      | MICROSECOND |
| wait      | NANOSECOND  |
| stage     | NANOSECOND  |
| statement | NANOSECOND  |
+-----------+-------------+
```
Performance Schema Event Timing

For discussion of timers, see Section 22.4.1, “Performance Schema Event Timing”.

The `setup_instruments` and `setup_consumers` tables list the instruments for which events can be collected and the types of consumers for which event information actually is collected, respectively. Other setup tables enable further modification of the monitoring configuration. Section 22.4.2, “Performance Schema Event Filtering”, discusses how you can modify these tables to affect event collection.

If there are Performance Schema configuration changes that must be made at runtime using SQL statements and you would like these changes to take effect each time the server starts, put the statements in a file and start the server with the `init_file` system variable set to name the file. This strategy can also be useful if you have multiple monitoring configurations, each tailored to produce a different kind of monitoring, such as casual server health monitoring, incident investigation, application behavior troubleshooting, and so forth. Put the statements for each monitoring configuration into their own file and specify the appropriate file as the `init_file` value when you start the server.

### 22.4.1 Performance Schema Event Timing

Events are collected by means of instrumentation added to the server source code. Instruments time events, which is how the Performance Schema provides an idea of how long events take. It is also possible to configure instruments not to collect timing information. This section discusses the available timers and their characteristics, and how timing values are represented in events.

**Performance Schema Timers**

Two Performance Schema tables provide timer information:

- `performance_timers` lists the available timers and their characteristics.
- `setup_timers` indicates which timers are used for which instruments.

Each timer row in `setup_timers` must refer to one of the timers listed in `performance_timers`.

Timers vary in precision and amount of overhead. To see what timers are available and their characteristics, check the `performance_timers` table:

```sql
mysql> SELECT * FROM performance_schema.performance_timers;
```

<table>
<thead>
<tr>
<th>TIMER_NAME</th>
<th>TIMER_FREQUENCY</th>
<th>TIMER_RESOLUTION</th>
<th>TIMER_OVERHEAD</th>
</tr>
</thead>
<tbody>
<tr>
<td>CYCLE</td>
<td>2389029850</td>
<td>1</td>
<td>72</td>
</tr>
<tr>
<td>NANOSECOND</td>
<td>1000000000</td>
<td>1</td>
<td>112</td>
</tr>
<tr>
<td>MICROSECOND</td>
<td>1000000</td>
<td>1</td>
<td>136</td>
</tr>
<tr>
<td>MILISECOND</td>
<td>1036</td>
<td>1</td>
<td>168</td>
</tr>
<tr>
<td>TICK</td>
<td>105</td>
<td>1</td>
<td>2416</td>
</tr>
</tbody>
</table>

If the values associated with a given timer name are `NULL`, that timer is not supported on your platform. The rows that do not contain `NULL` indicate which timers you can use in `setup_timers`.

The columns have these meanings:

- The `TIMER_NAME` column shows the names of the available timers. `CYCLE` refers to the timer that is based on the CPU (processor) cycle counter. The timers in `setup_timers` that you can use are those that do not have `NULL` in the other columns. If the values associated with a given timer name are `NULL`, that timer is not supported on your platform.
• **TIMER_FREQUENCY** indicates the number of timer units per second. For a cycle timer, the frequency is generally related to the CPU speed. The value shown was obtained on a system with a 2.4GHz processor. The other timers are based on fixed fractions of seconds. For **TICK**, the frequency may vary by platform (for example, some use 100 ticks/second, others 1000 ticks/second).

• **TIMER_RESOLUTION** indicates the number of timer units by which timer values increase at a time. If a timer has a resolution of 10, its value increases by 10 each time.

• **TIMER_OVERHEAD** is the minimal number of cycles of overhead to obtain one timing with the given timer. The overhead per event is twice the value displayed because the timer is invoked at the beginning and end of the event.

To see which timers are in effect or to change timers, access the `setup_timers` table:

```sql
mysql> SELECT * FROM performance_schema.setup_timers;
+-----------+-------------+
| NAME      | TIMER_NAME  |
+-----------+-------------+
| idle      | MICROSECOND |
| wait      | CYCLE       |
| stage     | NANOSECOND  |
| statement | NANOSECOND  |
+-----------+-------------+

mysql> UPDATE performance_schema.setup_timers
SET TIMER_NAME = 'MICROSECOND'
WHERE NAME = 'idle';

mysql> SELECT * FROM performance_schema.setup_timers;
+-----------+-------------+
| NAME      | TIMER_NAME  |
+-----------+-------------+
| idle      | MICROSECOND |
| wait      | CYCLE       |
| stage     | NANOSECOND  |
| statement | NANOSECOND  |
+-----------+-------------+
```

By default, the Performance Schema uses the best timer available for each instrument type, but you can select a different one.

To time wait events, the most important criterion is to reduce overhead, at the possible expense of the timer accuracy, so using the **CYCLE** timer is the best.

The time a statement (or stage) takes to execute is in general orders of magnitude larger than the time it takes to execute a single wait. To time statements, the most important criterion is to have an accurate measure, which is not affected by changes in processor frequency, so using a timer which is not based on cycles is the best. The default timer for statements is **NANOSECOND**. The extra “overhead” compared to the **CYCLE** timer is not significant, because the overhead caused by calling a timer twice (once when the statement starts, once when it ends) is orders of magnitude less compared to the CPU time used to execute the statement itself. Using the **CYCLE** timer has no benefit here, only drawbacks.

The precision offered by the cycle counter depends on processor speed. If the processor runs at 1 GHz (one billion cycles/second) or higher, the cycle counter delivers sub-nanosecond precision. Using the cycle counter is much cheaper than getting the actual time of day. For example, the standard `gettimeofday()` function can take hundreds of cycles, which is an unacceptable overhead for data gathering that may occur thousands or millions of times per second.

Cycle counters also have disadvantages:
End users expect to see timings in wall-clock units, such as fractions of a second. Converting from cycles to fractions of seconds can be expensive. For this reason, the conversion is a quick and fairly rough multiplication operation.

Processor cycle rate might change, such as when a laptop goes into power-saving mode or when a CPU slows down to reduce heat generation. If a processor’s cycle rate fluctuates, conversion from cycles to real-time units is subject to error.

Cycle counters might be unreliable or unavailable depending on the processor or the operating system. For example, on Pentiums, the instruction is `RDTSC` (an assembly-language rather than a C instruction) and it is theoretically possible for the operating system to prevent user-mode programs from using it.

Some processor details related to out-of-order execution or multiprocessor synchronization might cause the counter to seem fast or slow by up to 1000 cycles.

MySQL works with cycle counters on x86 (Windows, macOS, Linux, Solaris, and other Unix flavors), PowerPC, and IA-64.

**Performance Schema Timer Representation in Events**

Rows in Performance Schema tables that store current events and historical events have three columns to represent timing information: `TIMER_START` and `TIMER_END` indicate when an event started and finished, and `TIMER_WAIT` indicates event duration.

The `setup_instruments` table has an `ENABLED` column to indicate the instruments for which to collect events. The table also has a `TIMED` column to indicate which instruments are timed. If an instrument is not enabled, it produces no events. If an enabled instrument is not timed, events produced by the instrument have `NULL` for the `TIMER_START`, `TIMER_END`, and `TIMER_WAIT` timer values. This in turn causes those values to be ignored when calculating aggregate time values in summary tables (sum, minimum, maximum, and average).

Internally, times within events are stored in units given by the timer in effect when event timing begins. For display when events are retrieved from Performance Schema tables, times are shown in picoseconds (trillionths of a second) to normalize them to a standard unit, regardless of which timer is selected.

Modifications to the `setup_timers` table affect monitoring immediately. Events already in progress may use the original timer for the begin time and the new timer for the end time. To avoid unpredictable results after you make timer changes, use `TRUNCATE TABLE` to reset Performance Schema statistics.

The timer baseline ("time zero") occurs at Performance Schema initialization during server startup. `TIMER_START` and `TIMER_END` values in events represent picoseconds since the baseline. `TIMER_WAIT` values are durations in picoseconds.

Picosecond values in events are approximate. Their accuracy is subject to the usual forms of error associated with conversion from one unit to another. If the `CYCLE` timer is used and the processor rate varies, there might be drift. For these reasons, it is not reasonable to look at the `TIMER_START` value for an event as an accurate measure of time elapsed since server startup. On the other hand, it is reasonable to use `TIMER_START` or `TIMER_WAIT` values in `ORDER BY` clauses to order events by start time or duration.

The choice of picoseconds in events rather than a value such as microseconds has a performance basis. One implementation goal was to show results in a uniform time unit, regardless of the timer. In an ideal world this time unit would look like a wall-clock unit and be reasonably precise; in other words, microseconds. But to convert cycles or nanoseconds to microseconds, it would be necessary to perform a division for every instrumentation. Division is expensive on many platforms. Multiplication is not expensive, so that is what is used. Therefore, the time unit is an integer multiple of the highest possible `TIMER_FREQUENCY` value, using a multiplier large enough to ensure that there is no major precision
loss. The result is that the time unit is “picoseconds.” This precision is spurious, but the decision enables overhead to be minimized.

Before MySQL 5.6.26, while a wait, stage, or statement event is executing, the respective current-event tables display the event with `TIMER_START` populated, but with `TIMER_END` and `TIMER_WAIT` set to `NULL`:

```plaintext
events_waits_current
events_stages_current
events_statements_current
```

As of MySQL 5.6.26, current-event timing provides more information. To make it possible to determine how long a not-yet-completed event has been running, the timer columns are set as follows:

- **`TIMER_START`** is populated.
- **`TIMER_END`** is populated with the current timer value.
- **`TIMER_WAIT`** is populated with the time elapsed so far (`TIMER_END - TIMER_START`).

Events that have not yet completed have an `END_EVENT_ID` value of `NULL`. To assess time elapsed so far for an event, use the `TIMER_WAIT` column. Therefore, to identify events that have not yet completed and have taken longer than `N` picoseconds thus far, monitoring applications can use this expression in queries:

```sql
WHERE END_EVENT_ID IS NULL AND TIMER_WAIT > N
```

Event identification as just described assumes that the corresponding instruments have `ENABLED` and `TIMED` set to `YES` and that the relevant consumers are enabled.

### 22.4.2 Performance Schema Event Filtering

Events are processed in a producer/consumer fashion:

- Instrumented code is the source for events and produces events to be collected. The `setup_instruments` table lists the instruments for which events can be collected, whether they are enabled, and (for enabled instruments) whether to collect timing information:

```sql
mysql> SELECT * FROM performance_schema.setup_instruments;
```

- Performance Schema tables are the destinations for events and consume events. The `setup_consumers` table lists the types of consumers to which event information can be sent and whether they are enabled:

```sql
mysql> SELECT * FROM performance_schema.setup_consumers;
```
Filtering can be done at different stages of performance monitoring:

- **Pre-filtering.** This is done by modifying Performance Schema configuration so that only certain types of events are collected from producers, and collected events update only certain consumers. To do this, enable or disable instruments or consumers. Pre-filtering is done by the Performance Schema and has a global effect that applies to all users.

Reasons to use pre-filtering:

- To reduce overhead. Performance Schema overhead should be minimal even with all instruments enabled, but perhaps you want to reduce it further. Or you do not care about timing events and want to disable the timing code to eliminate timing overhead.

- To avoid filling the current-events or history tables with events in which you have no interest. Pre-filtering leaves more “room” in these tables for instances of rows for enabled instrument types. If you enable only file instruments with pre-filtering, no rows are collected for nonfile instruments. With post-filtering, nonfile events are collected, leaving fewer rows for file events.

- To avoid maintaining some kinds of event tables. If you disable a consumer, the server does not spend time maintaining destinations for that consumer. For example, if you do not care about event histories, you can disable the history table consumers to improve performance.

- **Post-filtering.** This involves the use of `WHERE` clauses in queries that select information from Performance Schema tables, to specify which of the available events you want to see. Post-filtering is performed on a per-user basis because individual users select which of the available events are of interest.

Reasons to use post-filtering:

- To avoid making decisions for individual users about which event information is of interest.

- To use the Performance Schema to investigate a performance issue when the restrictions to impose using pre-filtering are not known in advance.

The following sections provide more detail about pre-filtering and provide guidelines for naming instruments or consumers in filtering operations. For information about writing queries to retrieve information (post-filtering), see Section 22.5, “Performance Schema Queries”.

### 22.4.3 Event Pre-Filtering

Pre-filtering is done by the Performance Schema and has a global effect that applies to all users. Pre-filtering can be applied to either the producer or consumer stage of event processing:
• To configure pre-filtering at the producer stage, several tables can be used:

  • `setup_instruments` indicates which instruments are available. An instrument disabled in this table produces no events regardless of the contents of the other production-related setup tables. An instrument enabled in this table is permitted to produce events, subject to the contents of the other tables.

  • `setup_objects` controls whether the Performance Schema monitors particular table objects.

  • `threads` indicates whether monitoring is enabled for each server thread.

  • `setup_actors` determines the initial monitoring state for new foreground threads.

• To configure pre-filtering at the consumer stage, modify the `setup_consumers` table. This determines the destinations to which events are sent. `setup_consumers` also implicitly affects event production. If a given event will not be sent to any destination (that is, will not be consumed), the Performance Schema does not produce it.

Modifications to any of these tables affect monitoring immediately, with some exceptions:

• Modifications to some instruments in the `setup_instruments` table are effective only at server startup; changing them at runtime has no effect. This affects primarily mutexes, conditions, and rwlocks in the server, although there may be other instruments for which this is true.

• Modifications to the `setup_actors` table affect only foreground threads created subsequent to the modification, not existing threads.

When you change the monitoring configuration, the Performance Schema does not flush the history tables. Events already collected remain in the current-events and history tables until displaced by newer events. If you disable instruments, you might need to wait a while before events for them are displaced by newer events of interest. Alternatively, use `TRUNCATE TABLE` to empty the history tables.

After making instrumentation changes, you might want to truncate the summary tables. Generally, the effect is to reset the summary columns to 0 or `NULL`, not to remove rows. This enables you to clear collected values and restart aggregation. That might be useful, for example, after you have made a runtime configuration change. Exceptions to this truncation behavior are noted in individual summary table sections.

The following sections describe how to use specific tables to control Performance Schema pre-filtering.

### 22.4.4 Pre-Filtering by Instrument

The `setup_instruments` table lists the available instruments:

```sql
mysql> SELECT * FROM performance_schema.setup_instruments;
```

```
+---------------------------------------------------+---------+-------+
| NAME                                              | ENABLED | TIMED |
|---------------------------------------------------|---------+-------|
| stage/sql/end                                     | NO      | NO    |
| stage/sql/executing                               | NO      | NO    |
| stage/sql/init                                    | NO      | NO    |
| stage/sql/insert                                  | NO      | NO    |
| statement/sql/load                                | YES     | YES   |
| statement/sql/grant                               | YES     | YES   |
| statement/sql/check                               | YES     | YES   |
| statement/sql/flush                               | YES     | YES   |
```

After making instrumentation changes, you might want to truncate the summary tables. Generally, the effect is to reset the summary columns to 0 or `NULL`, not to remove rows. This enables you to clear collected values and restart aggregation. That might be useful, for example, after you have made a runtime configuration change. Exceptions to this truncation behavior are noted in individual summary table sections.

The following sections describe how to use specific tables to control Performance Schema pre-filtering.
To control whether an instrument is enabled, set its `ENABLED` column to `YES` or `NO`. To configure whether to collect timing information for an enabled instrument, set its `TIMED` value to `YES` or `NO`. Setting the `TIMED` column affects Performance Schema table contents as described in Section 22.4.1, “Performance Schema Event Timing”.

Modifications to most `setup_instruments` rows affect monitoring immediately. For some instruments, modifications are effective only at server startup; changing them at runtime has no effect. This affects primarily mutexes, conditions, and rwlocks in the server, although there may be other instruments for which this is true.

The `setup_instruments` table provides the most basic form of control over event production. To further refine event production based on the type of object or thread being monitored, other tables may be used as described in Section 22.4.3, “Event Pre-Filtering”.

The following examples demonstrate possible operations on the `setup_instruments` table. These changes, like other pre-filtering operations, affect all users. Some of these queries use the `LIKE` operator and a pattern match instrument names. For additional information about specifying patterns to select instruments, see Section 22.4.9, “Naming Instruments or Consumers for Filtering Operations”.

• Disable all instruments:

```sql
UPDATE performance_schema.setup_instruments
SET ENABLED = 'NO';
```

Now no events will be collected.

• Disable all file instruments, adding them to the current set of disabled instruments:

```sql
UPDATE performance_schema.setup_instruments
SET ENABLED = 'NO'
WHERE NAME LIKE 'wait/io/file/%';
```

• Disable only file instruments, enable all other instruments:

```sql
UPDATE performance_schema.setup_instruments
SET ENABLED = IF(NAME LIKE 'wait/io/file/%', 'NO', 'YES');
```

• Enable all but those instruments in the `mysys` library:

```sql
UPDATE performance_schema.setup_instruments
SET ENABLED = CASE WHEN NAME LIKE '%/mysys/%' THEN 'YES' ELSE 'NO' END;
```
• Disable a specific instrument:

```
UPDATE performance_schema.setup_instruments
SET ENABLED = 'NO'
WHERE NAME = 'wait/synch/mutex/mysys/TMPDIR_mutex';
```

• To toggle the state of an instrument, “flip” its ENABLED value:

```
UPDATE performance_schema.setup_instruments
SET ENABLED = IF(ENABLED = 'YES', 'NO', 'YES')
WHERE NAME = 'wait/synch/mutex/mysys/TMPDIR_mutex';
```

• Disable timing for all events:

```
UPDATE performance_schema.setup_instruments
SET TIMED = 'NO';
```

### 22.4.5 Pre-Filtering by Object

The `setup_objects` table controls whether the Performance Schema monitors particular table objects. The initial `setup_objects` contents look like this:

```
mysql> SELECT * FROM performance_schema.setup_objects;
+-------------+--------------------+-------------+---------+-------+
<table>
<thead>
<tr>
<th>OBJECT_TYPE</th>
<th>OBJECT_SCHEMA</th>
<th>OBJECT_NAME</th>
<th>ENABLED</th>
<th>TIMED</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLE</td>
<td>mysql</td>
<td>%</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>TABLE</td>
<td>performance_schema</td>
<td>%</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>TABLE</td>
<td>information_schema</td>
<td>%</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>TABLE</td>
<td>%</td>
<td>%</td>
<td>YES</td>
<td>YES</td>
</tr>
</tbody>
</table>
+-------------+--------------------+-------------+---------+-------+
```

Modifications to the `setup_objects` table affect object monitoring immediately.

The **OBJECT_TYPE** column indicates the type of object to which a row applies. **TABLE** filtering affects table I/O events (```wait/io/table/sql/handler```) instrument) and table lock events (```wait/lock/table/sql/handler``` instrument).

The **OBJECT_SCHEMA** and **OBJECT_NAME** columns should contain a literal schema or table name, or '%', to match any name.

The **ENABLED** column indicates whether matching objects are monitored, and **TIMED** indicates whether to collect timing information. Setting the **TIMED** column affects Performance Schema table contents as described in Section 22.4.1, “Performance Schema Event Timing”.

The effect of the default object configuration is to instrument all tables except those in the **mysql**, **INFORMATION_SCHEMA**, and **performance_schema** databases. (Tables in the **INFORMATION_SCHEMA** database are not instrumented regardless of the contents of `setup_objects`; the row for `information_schema.%` simply makes this default explicit.)

When the Performance Schema checks for a match in `setup_objects`, it tries to find more specific matches first. For rows that match a given **OBJECT_TYPE**, the Performance Schema checks rows in this order:

• Rows with **OBJECT_SCHEMA='literal'** and **OBJECT_NAME='literal'**.
• Rows with **OBJECT_SCHEMA='literal'** and **OBJECT_NAME='%'.**
Pre-Filtering by Thread

- Rows with `OBJECT_SCHEMA='%'` and `OBJECT_NAME='%'`.

For example, with a table `db1.t1`, the Performance Schema looks in `TABLE` rows for a match for 'db1' and 't1', then for 'db1' and '%', then for '%' and '%'. The order in which matching occurs matters because different matching `setup_objects` rows can have different `ENABLED` and `TIMED` values.

For table-related events, the Performance Schema combines the contents of `setup_objects` with `setup_instruments` to determine whether to enable instruments and whether to time enabled instruments:

- For tables that match a row in `setup_objects`, table instruments produce events only if `ENABLED` is `YES` in both `setup_instruments` and `setup_objects`.

- The `TIMED` values in the two tables are combined, so that timing information is collected only when both values are `YES`.

Suppose that `setup_objects` contains the following `TABLE` rows that apply to `db1`, `db2`, and `db3`:

<table>
<thead>
<tr>
<th>OBJECT_TYPE</th>
<th>OBJECT_SCHEMA</th>
<th>OBJECT_NAME</th>
<th>ENABLED</th>
<th>TIMED</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLE</td>
<td>db1</td>
<td>t1</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>TABLE</td>
<td>db1</td>
<td>t2</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>TABLE</td>
<td>db2</td>
<td>%</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>TABLE</td>
<td>db3</td>
<td>%</td>
<td>NO</td>
<td>NO</td>
</tr>
<tr>
<td>TABLE</td>
<td>%</td>
<td>%</td>
<td>YES</td>
<td>YES</td>
</tr>
</tbody>
</table>

If a table-related instrument in `setup_instruments` has an `ENABLED` value of `NO`, events for the object are not monitored. If the `ENABLED` value is `YES`, event monitoring occurs according to the `ENABLED` value in the relevant `setup_objects` row:

- `db1.t1` events are monitored
- `db1.t2` events are not monitored
- `db2.t3` events are monitored
- `db3.t4` events are not monitored
- `db4.t5` events are monitored

Similar logic applies for combining the `TIMED` columns from the `setup_instruments` and `setup_objects` tables to determine whether to collect event timing information.

If a persistent table and a temporary table have the same name, matching against `setup_objects` rows occurs the same way for both. It is not possible to enable monitoring for one table but not the other. However, each table is instrumented separately.

### 22.4.6 Pre-Filtering by Thread

The `threads` table contains a row for each server thread. Each row contains information about a thread and indicates whether monitoring is enabled for it. For the Performance Schema to monitor a thread, these things must be true:

- The `thread_instrumentation` consumer in the `setup_consumers` table must be `YES`.
- The `threads.INSTRUMENTED` column must be `YES`.  

3326
Pre-Filtering by Thread

- Monitoring occurs only for those thread events produced from instruments that are enabled in the `setup_instruments` table.

The `INSTRUMENTED` column in the `threads` table indicates the monitoring state for each thread. For foreground threads (resulting from client connections), the initial `INSTRUMENTED` value is determined by whether the user account associated with the thread matches any row in the `setup_actors` table.

For background threads, there is no associated user. `INSTRUMENTED` is `YES` by default and `setup_actors` is not consulted.

The initial `setup_actors` contents look like this:

```
mysql> SELECT * FROM performance_schema.setup_actors;
+------+-----+-----+
| HOST | USER | ROLE |
| %    | %    | %    |
+------+-----+-----+
```

The `HOST` and `USER` columns should contain a literal host or user name, or ` '%' ` to match any name.

The Performance Schema uses the `HOST` and `USER` columns to match each new foreground thread. (`ROLE` is unused.) The `INSTRUMENTED` value for the thread becomes `YES` if any row matches, `NO` otherwise. This enables instrumenting to be applied selectively per host, user, or combination of host and user.

By default, monitoring is enabled for all new foreground threads because the `setup_actors` table initially contains a row with ` '%' ` for both `HOST` and `USER`. To perform more limited matching such as to enable monitoring only for some foreground threads, you must delete this row because it matches any connection.

Suppose that you modify `setup_actors` as follows:

```
TRUNCATE TABLE performance_schema.setup_actors;
```

Now `setup_actors` is empty and there are no rows that could match incoming connections. Consequently, the Performance Schema sets the `INSTRUMENTED` column to `NO` for all new foreground threads.

Suppose that you further modify `setup_actors`:

```
INSERT INTO performance_schema.setup_actors
VALUES('localhost','joe','%');
INSERT INTO performance_schema.setup_actors
VALUES('%','sam','%');
```

Now the Performance Schema determines how to set the `INSTRUMENTED` value for new connection threads as follows:

- If `joe` connects from the local host, the connection matches the first inserted row.
- If `joe` connects from any other host, there is no match.
- If `sam` connects from any host, the connection matches the second inserted row.
- For any other connection, there is no match.

Modifications to the `setup_actors` table affect only foreground threads created subsequent to the modification, not existing threads. To affect existing threads, modify the `INSTRUMENTED` column of `threads` table rows.
Pre-Filtering by Consumer

22.4.7 Pre-Filtering by Consumer

The `setup_consumers` table lists the available consumer types and which are enabled:

```
mysql> SELECT * FROM performance_schema.setup_consumers;
+--------------------------------+---------+
| NAME                           | ENABLED |
+--------------------------------+---------+
| events_stages_current          | NO      |
| events_stages_history          | NO      |
| events_stages_history_long     | NO      |
| events_statements_current      | YES     |
| events_statements_history      | NO      |
| events_statements_history_long | NO      |
| events_waits_current           | NO      |
| events_waits_history           | NO      |
| events_waits_history_long      | NO      |
| global_instrumentation         | YES     |
| thread_instrumentation         | YES     |
| statements_digest              | YES     |
+--------------------------------+---------+
```

Modify the `setup_consumers` table to affect pre-filtering at the consumer stage and determine the destinations to which events are sent. To enable or disable a consumer, set its `ENABLED` value to `YES` or `NO`.

Modifications to the `setup_consumers` table affect monitoring immediately.

If you disable a consumer, the server does not spend time maintaining destinations for that consumer. For example, if you do not care about historical event information, disable the history consumers:

```
UPDATE performance_schema.setup_consumers
SET ENABLED = 'NO'
WHERE NAME LIKE '%history%';
```

The consumer settings in the `setup_consumers` table form a hierarchy from higher levels to lower. The following principles apply:

- Destinations associated with a consumer receive no events unless the Performance Schema checks the consumer and the consumer is enabled.
- A consumer is checked only if all consumers it depends on (if any) are enabled.
- If a consumer is not checked, or is checked but is disabled, other consumers that depend on it are not checked.
- Dependent consumers may have their own dependent consumers.
- If an event would not be sent to any destination, the Performance Schema does not produce it.

The following lists describe the available consumer values. For discussion of several representative consumer configurations and their effect on instrumentation, see Section 22.4.8, “Example Consumer Configurations”.

- Global and Thread Consumers
- Wait Event Consumers
- Stage Event Consumers
Pre-Filtering by Consumer

- **Statement Event Consumers**
- **Statement Digest Consumer**

**Global and Thread Consumers**

- `<global_instrumentation>` is the highest level consumer. If `global_instrumentation` is NO, it disables global instrumentation. All other settings are lower level and are not checked; it does not matter what they are set to. No global or per thread information is maintained and no individual events are collected in the current-events or event-history tables. If `global_instrumentation` is YES, the Performance Schema maintains information for global states and also checks the `thread_instrumentation` consumer.

- `thread_instrumentation` is checked only if `global_instrumentation` is YES. Otherwise, if `thread_instrumentation` is NO, it disables thread-specific instrumentation and all lower-level settings are ignored. No information is maintained per thread and no individual events are collected in the current-events or event-history tables. If `thread_instrumentation` is YES, the Performance Schema maintains thread-specific information and also checks `events_xxx_current` consumers.

**Wait Event Consumers**

These consumers require both `global_instrumentation` and `thread_instrumentation` to be YES or they are not checked. If checked, they act as follows:

- `events_waits_current`, if NO, disables collection of individual wait events in the `events_waits_current` table. If YES, it enables wait event collection and the Performance Schema checks the `events_waits_history` and `events_waits_history_long` consumers.

- `events_waits_history` is not checked if `event_waits_current` is NO. Otherwise, an `events_waits_history` value of NO or YES disables or enables collection of wait events in the `events_waits_history` table.

- `events_waits_history_long` is not checked if `event_waits_current` is NO. Otherwise, an `events_waits_history_long` value of NO or YES disables or enables collection of wait events in the `events_waits_history_long` table.

**Stage Event Consumers**

These consumers require both `global_instrumentation` and `thread_instrumentation` to be YES or they are not checked. If checked, they act as follows:

- `events_stages_current`, if NO, disables collection of individual stage events in the `events_stages_current` table. If YES, it enables stage event collection and the Performance Schema checks the `events_stages_history` and `events_stages_history_long` consumers.

- `events_stages_history` is not checked if `event_stages_current` is NO. Otherwise, an `events_stages_history` value of NO or YES disables or enables collection of stage events in the `events_stages_history` table.

- `events_stages_history_long` is not checked if `event_stages_current` is NO. Otherwise, an `events_stages_history_long` value of NO or YES disables or enables collection of stage events in the `events_stages_history_long` table.

**Statement Event Consumers**

These consumers require both `global_instrumentation` and `thread_instrumentation` to be YES or they are not checked. If checked, they act as follows:
Example Consumer Configurations

- `events_statements_current`, if `NO`, disables collection of individual statement events in the `events_statements_current` table. If `YES`, it enables statement event collection and the Performance Schema checks the `events_statements_history` and `events_statements_history_long` consumers.

- `events_statements_history` is not checked if `events_statements_current` is `NO`. Otherwise, an `events_statements_history` value of `NO` or `YES` disables or enables collection of statement events in the `events_statements_history` table.

- `events_statements_history_long` is not checked if `events_statements_current` is `NO`. Otherwise, an `events_statements_history_long` value of `NO` or `YES` disables or enables collection of statement events in the `events_statements_history_long` table.

Statement Digest Consumer

The `statements_digest` consumer requires `global_instrumentation` to be `YES` or it is not checked. There is no dependency on the statement event consumers, so you can obtain statistics per digest without having to collect statistics in `events_statements_current`, which is advantageous in terms of overhead. Conversely, you can get detailed statements in `events_statements_current` without digests (the `DIGEST` and `DIGEST_TEXT` columns will be `NULL`).

For more information about statement digesting, see Section 22.10, “Performance Schema Statement Digests”.

22.4.8 Example Consumer Configurations

The consumer settings in the `setup_consumers` table form a hierarchy from higher levels to lower. The following discussion describes how consumers work, showing specific configurations and their effects as consumer settings are enabled progressively from high to low. The consumer values shown are representative. The general principles described here apply to other consumer values that may be available.

The configuration descriptions occur in order of increasing functionality and overhead. If you do not need the information provided by enabling lower-level settings, disable them and the Performance Schema will execute less code on your behalf and you will have less information to sift through.

The `setup_consumers` table contains the following hierarchy of values:

global_instrumentation
thread_instrumentation
events_waits_current	envents_waits_history	envents_waits_history_long
events_stages_current	envents_stages_history	envents_stages_history_long
events_statements_current	envents_statements_history	envents_statements_history_long
statements_digest

Note

In the consumer hierarchy, the consumers for waits, stages, and statements are all at the same level. This differs from the event nesting hierarchy, for which wait events nest within stage events, which nest within statement events.
If a given consumer setting is NO, the Performance Schema disables the instrumentation associated with the consumer and ignores all lower-level settings. If a given setting is YES, the Performance Schema enables the instrumentation associated with it and checks the settings at the next lowest level. For a description of the rules for each consumer, see Section 22.4.7, “Pre-Filtering by Consumer”.

For example, if global_instrumentation is enabled, thread_instrumentation is checked. If thread_instrumentation is enabled, the events_xxx_current consumers are checked. If of these events_waits_current is enabled, events_waits_history and events_waits_history_long are checked.

Each of the following configuration descriptions indicates which setup elements the Performance Schema checks and which output tables it maintains (that is, for which tables it collects information).

- No Instrumentation
- Global Instrumentation Only
- Global and Thread Instrumentation Only
- Global, Thread, and Current-Event Instrumentation
- Global, Thread, Current-Event, and Event-History instrumentation

### No Instrumentation

**Server configuration state:**

```
mysql> SELECT * FROM performance_schema.setup_consumers;
+--------------------------+---------+
| NAME                     | ENABLED |
+--------------------------+---------+
| global_instrumentation   | NO      |
|                          |         |
|                          |         |
+--------------------------+---------+
```

In this configuration, nothing is instrumented.

**Setup elements checked:**

- Table `setup_consumers`, consumer `global_instrumentation`

**Output tables maintained:**

- None

### Global Instrumentation Only

**Server configuration state:**

```
mysql> SELECT * FROM performance_schema.setup_consumers;
+--------------------------+---------+
| NAME                     | ENABLED |
+--------------------------+---------+
| global_instrumentation   | YES     |
| thread_instrumentation   | NO      |
|                          |         |
|                          |         |
+--------------------------+---------+
```

**Output tables maintained:**

- None
In this configuration, instrumentation is maintained only for global states. Per-thread instrumentation is disabled.

Additional setup elements checked, relative to the preceding configuration:

- Table `setup_consumers`, consumer `thread_instrumentation`
- Table `setup_instruments`
- Table `setup_objects`
- Table `setup_timers`

Additional output tables maintained, relative to the preceding configuration:

- `mutex_instances`
- `rwlock_instances`
- `cond_instances`
- `file_instances`
- `users`
- `hosts`
- `accounts`
- `socket_summary_by_event_name`
- `file_summary_by_instance`
- `file_summary_by_event_name`
- `objects_summary_global_by_type`
- `table_lock_waits_summary_by_table`
- `table_io_waits_summary_by_index_usage`
- `table_io_waits_summary_by_table`
- `events_waits_summary_by_instance`
- `events_waits_summary_global_by_event_name`
- `events_stages_summary_global_by_event_name`
- `events_statements_summary_global_by_event_name`

### Global and Thread Instrumentation Only

Server configuration state:

```sql
mysql> SELECT * FROM performance_schema.setup_consumers;
+--------------------------------+---------+
| NAME                           | ENABLED |
+--------------------------------+---------+
```

3332
### Example Consumer Configurations

<table>
<thead>
<tr>
<th>global_instrumentation</th>
<th>YES</th>
</tr>
</thead>
<tbody>
<tr>
<td>thread_instrumentation</td>
<td>YES</td>
</tr>
<tr>
<td>events_waits_current</td>
<td>NO</td>
</tr>
<tr>
<td>...</td>
<td></td>
</tr>
<tr>
<td>events_stages_current</td>
<td>NO</td>
</tr>
<tr>
<td>...</td>
<td></td>
</tr>
<tr>
<td>events_statements_current</td>
<td>YES</td>
</tr>
<tr>
<td>...</td>
<td></td>
</tr>
</tbody>
</table>

In this configuration, instrumentation is maintained globally and per thread. No individual events are collected in the current-events or event-history tables.

Additional setup elements checked, relative to the preceding configuration:

- **Table** `setup_consumers`, consumers `events_xxx_current`, where `xxx` is `waits`, `stages`, `statements`

- **Table** `setup_actors`

- **Column** `threads.instrumented`

Additional output tables maintained, relative to the preceding configuration:

- `events_xxx_summary_by_yyy_by_event_name`, where `xxx` is `waits`, `stages`, `statements`; and `yyy` is `thread`, `user`, `host`, `account`

### Global, Thread, and Current-Event Instrumentation

Server configuration state:

```
mysql> SELECT * FROM performance_schema.setup_consumers;
```

<table>
<thead>
<tr>
<th>NAME</th>
<th>ENABLED</th>
</tr>
</thead>
<tbody>
<tr>
<td>global_instrumentation</td>
<td>YES</td>
</tr>
<tr>
<td>thread_instrumentation</td>
<td>YES</td>
</tr>
<tr>
<td>events_waits_current</td>
<td>NO</td>
</tr>
<tr>
<td>events_waits_history</td>
<td>NO</td>
</tr>
<tr>
<td>events_waits_history_long</td>
<td>NO</td>
</tr>
<tr>
<td>events_stages_current</td>
<td>YES</td>
</tr>
<tr>
<td>events_stages_history</td>
<td>NO</td>
</tr>
<tr>
<td>events_stages_history_long</td>
<td>NO</td>
</tr>
<tr>
<td>events_statements_current</td>
<td>YES</td>
</tr>
<tr>
<td>events_statements_history</td>
<td>NO</td>
</tr>
<tr>
<td>events_statements_history_long</td>
<td>NO</td>
</tr>
<tr>
<td>...</td>
<td></td>
</tr>
</tbody>
</table>

In this configuration, instrumentation is maintained globally and per thread. Individual events are collected in the current-events table, but not in the event-history tables.

Additional setup elements checked, relative to the preceding configuration:

- **Consumers** `events_xxx_history`, where `xxx` is `waits`, `stages`, `statements`

- **Consumers** `events_xxx_history_long`, where `xxx` is `waits`, `stages`, `statements`

Additional output tables maintained, relative to the preceding configuration:
Example Consumer Configurations

- `events_xxx_current`, where `xxx` is `waits, stages, statements`

**Global, Thread, Current-Event, and Event-History instrumentation**

The preceding configuration collects no event history because the `events_xxx_history` and `events_xxx_history_long` consumers are disabled. Those consumers can be enabled separately or together to collect event history per thread, globally, or both.

This configuration collects event history per thread, but not globally:

```sql
mysql> SELECT * FROM performance_schema.setup_consumers;
```

```
+--------------------------------+---------+
| NAME                           | ENABLED |
+--------------------------------+---------+
| global_instrumentation         | YES     |
| thread_instrumentation         | YES     |
| events_waits_current           | YES     |
| events_waits_history           | YES     |
| events_waits_history_long      | NO      |
| events_stages_current          | YES     |
| events_stages_history          | YES     |
| events_stages_history_long     | YES     |
| events_statements_current      | YES     |
| events_statements_history      | YES     |
| events_statements_history_long | NO      |
```

Event-history tables maintained for this configuration:

- `events_xxx_history`, where `xxx` is `waits, stages, statements`

This configuration collects event history globally, but not per thread:

```sql
mysql> SELECT * FROM performance_schema.setup_consumers;
```

```
+--------------------------------+---------+
| NAME                           | ENABLED |
+--------------------------------+---------+
| global_instrumentation         | YES     |
| thread_instrumentation         | YES     |
| events_waits_current           | YES     |
| events_waits_history           | NO      |
| events_waits_history_long      | YES     |
| events_stages_current          | YES     |
| events_stages_history          | NO      |
| events_stages_history_long     | YES     |
```

Event-history tables maintained for this configuration:

- `events_xxx_history_long`, where `xxx` is `waits, stages, statements`

This configuration collects event history per thread and globally:

```sql
mysql> SELECT * FROM performance_schema.setup_consumers;
```

```
+--------------------------------+---------+
| NAME                           | ENABLED |
+--------------------------------+---------+
| global_instrumentation         | YES     |
| thread_instrumentation         | YES     |
| events_waits_current           | YES     |
| events_waits_history           | NO      |
| events_waits_history_long      | YES     |
| events_stages_current          | YES     |
| events_stages_history          | NO      |
| events_stages_history_long     | YES     |
```
Event-history tables maintained for this configuration:

- `events_xxx_history`, where `xxx` is `waits`, `stages`, `statements`
- `events_xxx_history_long`, where `xxx` is `waits`, `stages`, `statements`

### 22.4.9 Naming Instruments or Consumers for Filtering Operations

Names given for filtering operations can be as specific or general as required. To indicate a single instrument or consumer, specify its name in full:

```sql
UPDATE performance_schema.setup_instruments
SET ENABLED = 'NO'
WHERE NAME = 'wait/synch/mutex/myisammrg/MYRG_INFO::mutex';
```

```sql
UPDATE performance_schema.setup_consumers
SET ENABLED = 'NO'
WHERE NAME = 'events_waits_current';
```

To specify a group of instruments or consumers, use a pattern that matches the group members:

```sql
UPDATE performance_schema.setup_instruments
SET ENABLED = 'NO'
WHERE NAME LIKE 'wait/synch/mutex/%';
```

```sql
UPDATE performance_schema.setup_consumers
SET ENABLED = 'NO'
WHERE NAME LIKE '%history%';
```

If you use a pattern, it should be chosen so that it matches all the items of interest and no others. For example, to select all file I/O instruments, it is better to use a pattern that includes the entire instrument name prefix:

```sql
... WHERE NAME LIKE 'wait/io/file/%';
```

A pattern of `/file/%` will match other instruments that have a component of `/file/` anywhere in the name. Even less suitable is the pattern `/file%` because it will match instruments with `file` anywhere in the name, such as `wait/synch/mutex/sql/LOCK_des_key_file`.

To check which instrument or consumer names a pattern matches, perform a simple test:

```sql
SELECT NAME FROM performance_schema.setup_instruments
```
Determining What Is Instrumented

WHERE NAME LIKE 'pattern';
SELECT NAME FROM performance_schema.setup_consumers
WHERE NAME LIKE 'pattern';

For information about the types of names that are supported, see Section 22.6, “Performance Schema Instrument Naming Conventions”.

22.4.10 Determining What Is Instrumented

It is always possible to determine what instruments the Performance Schema includes by checking the setup_instruments table. For example, to see what file-related events are instrumented for the InnoDB storage engine, use this query:

mysql> SELECT * FROM performance_schema.setup_instruments
WHERE NAME LIKE 'wait/io/file/innodb/%';
+--------------------------------------+---------+-------+
| NAME                                 | ENABLED | TIMED |
+--------------------------------------+---------+-------+
| wait/io/file/innodb/innodb_data_file | YES     | YES   |
| wait/io/file/innodb/innodb_log_file  | YES     | YES   |
| wait/io/file/innodb/innodb_temp_file | YES     | YES   |
+--------------------------------------+---------+-------+

An exhaustive description of precisely what is instrumented is not given in this documentation, for several reasons:

• What is instrumented is the server code. Changes to this code occur often, which also affects the set of instruments.

• It is not practical to list all the instruments because there are hundreds of them.

• As described earlier, it is possible to find out by querying the setup_instruments table. This information is always up to date for your version of MySQL, also includes instrumentation for instrumented plugins you might have installed that are not part of the core server, and can be used by automated tools.

22.5 Performance Schema Queries

Pre-filtering limits which event information is collected and is independent of any particular user. By contrast, post-filtering is performed by individual users through the use of queries with appropriate WHERE clauses that restrict what event information to select from the events available after pre-filtering has been applied.

In Section 22.4.3, “Event Pre-Filtering”, an example showed how to pre-filter for file instruments. If the event tables contain both file and nonfile information, post-filtering is another way to see information only for file events. Add a WHERE clause to queries to restrict event selection appropriately:

mysql> SELECT THREAD_ID, NUMBER_OF_BYTES
FROM performance_schema.events_waits_history
WHERE EVENT_NAME LIKE 'wait/io/file/%'
AND NUMBER_OFgetBytes IS NOT NULL;
+-----------+-----------------+
<table>
<thead>
<tr>
<th>THREAD_ID</th>
<th>NUMBER_OFBYTES</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>66</td>
</tr>
<tr>
<td>11</td>
<td>47</td>
</tr>
<tr>
<td>11</td>
<td>139</td>
</tr>
</tbody>
</table>
22.6 Performance Schema Instrument Naming Conventions

An instrument name consists of a sequence of components separated by `/` characters. Example names:

```
wait/io/file/myisam/log
wait/io/file/mysys/charset
wait/lock/table/sql/handler
wait/synch/cond/mysys/COND_alarm
wait/synch/cond/sql/BINLOG::update_cond
wait/synch/mutex/mysys/BITMAP_mutex
wait/synch/rwlock/sql/LOCK_delete
wait/synch/cond/sql/MYSQL::cond
wait/synch/cond/sql/cond
stage/sql/closing tables
stage/sql/Sorting result
statement/com/Execute
statement/com/Query
statement/sql/create_table
statement/sql/lock_tables
```

The instrument name space has a tree-like structure. The components of an instrument name from left to right provide a progression from more general to more specific. The number of components a name has depends on the type of instrument.

The interpretation of a given component in a name depends on the components to the left of it. For example, `myisam` appears in both of the following names, but `myisam` in the first name is related to file I/O, whereas in the second it is related to a synchronization instrument:

```
wait/io/file/myisam/log
wait/synch/cond/myisam/COND_THREAD::cond
```

Instrument names consist of a prefix with a structure defined by the Performance Schema implementation and a suffix defined by the developer implementing the instrument code. The top-level component of an instrument prefix indicates the type of instrument. This component also determines which event timer in the `setup_timers` table applies to the instrument. For the prefix part of instrument names, the top level indicates the type of instrument.

The suffix part of instrument names comes from the code for the instruments themselves. Suffixes may include levels such as these:

- A name for the major component (a server module such as `myisam`, `innodb`, `mysys`, or `sql`) or a plugin name.
- The name of a variable in the code, in the form `XXX` (a global variable) or `CCC::MMM` (a member `MMM` in class `CCC`). Examples: `COND_thread_cache`, `THR_LOCK_myisam`, `BINLOG::LOCK_index`.

- **Top-Level Instrument Components**
- **Idle Instrument Components**
- **Stage Instrument Components**
- **Statement Instrument Components**
- **Wait Instrument Components**
Top-Level Instrument Components

- **idle**: An instrumented idle event. This instrument has no further components.
- **stage**: An instrumented stage event.
- **statement**: An instrumented statement event.
- **wait**: An instrumented wait event.

Idle Instrument Components

The `idle` instrument is used for idle events, which The Performance Schema generates as discussed in the description of the `socket_instances.STATE` column in Section 22.12.3.5, “The `socket_instances` Table”.

Stage Instrument Components

Stage instruments have names of the form `stage/code_area/stage_name`, where `code_area` is a value such as `sql` or `myisam`, and `stage_name` indicates the stage of statement processing, such as `Sorting result` or `Sending data`. Stages correspond to the thread states displayed by `SHOW PROCESSLIST` or that are visible in the `INFORMATION_SCHEMA.PROCESSLIST` table.

Statement Instrument Components

- **statement/abstract/***: An abstract instrument for statement operations. Abstract instruments are used during the early stages of statement classification before the exact statement type is known, then changed to a more specific statement instrument when the type is known. For a description of this process, see Section 22.12.6, “Performance Schema Statement Event Tables”.

- **statement/com**: An instrumented command operation. These have names corresponding to `COM_` operations (see the `mysql_com.h` header file and `sql/sql_parse.cc`. For example, the `statement/com/Connect` and `statement/com/Init DB` instruments correspond to the `COM_CONNECT` and `COM_INIT_DB` commands.

- **statement/sql**: An instrumented SQL statement operation. For example, the `statement/sql/create_db` and `statement/sql/select` instruments are used for `CREATE DATABASE` and `SELECT` statements.

Wait Instrument Components

- **wait/io**
  An instrumented I/O operation.

- **wait/io/file**
  An instrumented file I/O operation. For files, the wait is the time waiting for the file operation to complete (for example, a call to `fwrite()`). Due to caching, the physical file I/O on the disk might not happen within this call.

- **wait/io/socket**
  An instrumented socket operation. Socket instruments have names of the form `wait/io/socket/sql/socket_type`. The server has a listening socket for each network protocol that it supports.
The instruments associated with listening sockets for TCP/IP or Unix socket file connections have a `socket_type` value of `server_tcip_socket` or `server_unix_socket`, respectively. When a listening socket detects a connection, the server transfers the connection to a new socket managed by a separate thread. The instrument for the new connection thread has a `socket_type` value of `client_connection`.

• **wait/io/table**

An instrumented table I/O operation. These include row-level accesses to persistent base tables or temporary tables. Operations that affect rows are fetch, insert, update, and delete. For a view, waits are associated with base tables referenced by the view.

Unlike most waits, a table I/O wait can include other waits. For example, table I/O might include file I/O or memory operations. Thus, `events_waits_current` for a table I/O wait usually has two rows. For more information, see Section 22.8, “Performance Schema Atom and Molecule Events”.

Some row operations might cause multiple table I/O waits. For example, an insert might activate a trigger that causes an update.

• **wait/lock**

An instrumented lock operation.

• **wait/lock/table**

An instrumented table lock operation.

• **wait/synch**

An instrumented synchronization object. For synchronization objects, the `TIMER_WAIT` time includes the amount of time blocked while attempting to acquire a lock on the object, if any.

• **wait/synch/cond**

A condition is used by one thread to signal to other threads that something they were waiting for has happened. If a single thread was waiting for a condition, it can wake up and proceed with its execution. If several threads were waiting, they can all wake up and compete for the resource for which they were waiting.

• **wait/synch/mutex**

A mutual exclusion object used to permit access to a resource (such as a section of executable code) while preventing other threads from accessing the resource.

• **wait/synch/rwlock**

A read/write lock object used to lock a specific variable for access while preventing its use by other threads. A shared read lock can be acquired simultaneously by multiple threads. An exclusive write lock can be acquired by only one thread at a time.

### 22.7 Performance Schema Status Monitoring

There are several status variables associated with the Performance Schema:

```
mysql> SHOW STATUS LIKE 'perf%';
+-----------------------------------------------+-------+
```
### Performance Schema Status Monitoring

<table>
<thead>
<tr>
<th>Variable_name</th>
<th>Value</th>

<tr>
<td>Performance_schema_users_lost</td>
<td>0</td>
</tr>
</tbody>
</table>

The Performance Schema status variables provide information about instrumentation that could not be loaded or created due to memory constraints. Names for these variables have several forms:

- **Performance_schema_xxx_classes_lost** indicates how many instruments of type **xxx** could not be loaded.
- **Performance_schema_xxx_instances_lost** indicates how many instances of object type **xxx** could not be created.
- **Performance_schema_xxx_handles_lost** indicates how many instances of object type **xxx** could not be opened.
- **Performance_schema_locker_lost** indicates how many events are “lost” or not recorded.

For example, if a mutex is instrumented in the server source but the server cannot allocate memory for the instrumentation at runtime, it increments **Performance_schema_mutex_classes_lost**. The mutex still functions as a synchronization object (that is, the server continues to function normally), but performance data for it will not be collected. If the instrument can be allocated, it can be used for initializing instrumented mutex instances. For a singleton mutex such as a global mutex, there will be only one instance. Other mutexes have an instance per connection, or per page in various caches and data buffers, so the number of instances varies over time. Increasing the maximum number of connections or the maximum size of some buffers will increase the maximum number of instances that might be allocated at once. If the server cannot create a given instrumented mutex instance, it increments **Performance_schema_mutex_instances_lost**.

Suppose that the following conditions hold:

- The server was started with the `--performance_schema_max_mutex_classes=200` option and thus has room for 200 mutex instruments.
- 150 mutex instruments have been loaded already.
- The plugin named plugin_a contains 40 mutex instruments.
- The plugin named plugin_b contains 20 mutex instruments.
The server allocates mutex instruments for the plugins depending on how many they need and how many are available, as illustrated by the following sequence of statements:

```
INSTALL PLUGIN plugin_a
```

The server now has $150+40 = 190$ mutex instruments.

```
UNINSTALL PLUGIN plugin_a;
```

The server still has 190 instruments. All the historical data generated by the plugin code is still available, but new events for the instruments are not collected.

```
INSTALL PLUGIN plugin_a;
```

The server detects that the 40 instruments are already defined, so no new instruments are created, and previously assigned internal memory buffers are reused. The server still has 190 instruments.

```
INSTALL PLUGIN plugin_b;
```

The server has room for $200-190 = 10$ instruments (in this case, mutex classes), and sees that the plugin contains 20 new instruments. 10 instruments are loaded, and 10 are discarded or “lost.” The `Performance_schema_mutex_classes_lost` indicates the number of instruments (mutex classes) lost:

```
mysql> SHOW STATUS LIKE "perf\*mutex_classes_lost";
+---------------------------------------+-------+
<table>
<thead>
<tr>
<th>Variable_name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Performance_schema_mutex_classes_lost</td>
<td>10</td>
</tr>
</tbody>
</table>
+---------------------------------------+-------+
1 row in set (0.10 sec)
```

The instrumentation still works and collects (partial) data for `plugin_b`.

When the server cannot create a mutex instrument, these results occur:

- No row for the instrument is inserted into the `setup_instruments` table.
- `Performance_schema_mutex_classes_lost` increases by 1.
- `Performance_schema_mutex_instances_lost` does not change. (When the mutex instrument is not created, it cannot be used to create instrumented mutex instances later.)

The pattern just described applies to all types of instruments, not just mutexes.

A value of `Performance_schema_mutex_classes_lost` greater than 0 can happen in two cases:

- To save a few bytes of memory, you start the server with `-- performance_schema_max_mutex_classes=N`, where $N$ is less than the default value. The default value is chosen to be sufficient to load all the plugins provided in the MySQL distribution, but this can be reduced if some plugins are never loaded. For example, you might choose not to load some of the storage engines in the distribution.

- You load a third-party plugin that is instrumented for the Performance Schema but do not allow for the plugin's instrumentation memory requirements when you start the server. Because it comes from a third party, the instrument memory consumption of this engine is not accounted for in the default value chosen for `performance_schema_max_mutex_classes`. 
If the server has insufficient resources for the plugin's instruments and you do not explicitly allocate more using `--performance_schema_max_mutex_classes=N`, loading the plugin leads to starvation of instruments.

If the value chosen for `performance_schema_max_mutex_classes` is too small, no error is reported in the error log and there is no failure at runtime. However, the content of the tables in the `performance_schema` database will miss events. The `performance_schema_mutex_classes_lost` status variable is the only visible sign to indicate that some events were dropped internally due to failure to create instruments.

If an instrument is not lost, it is known to the Performance Schema, and is used when instrumenting instances. For example, `wait/synch/mutex/sql/LOCK_delete` is the name of a mutex instrument in the `setup_instruments` table. This single instrument is used when creating a mutex in the code (in `THD::LOCK_delete`) however many instances of the mutex are needed as the server runs. In this case, `LOCK_delete` is a mutex that is per connection (`THD`), so if a server has 1000 connections, there are 1000 threads, and 1000 instrumented `LOCK_delete` mutex instances (`THD::LOCK_delete`).

If the server does not have room for all these 1000 instrumented mutexes (instances), some mutexes are created with instrumentation, and some are created without instrumentation. If the server can create only 800 instances, 200 instances are lost. The server continues to run, but increments `performance_schema_mutex_instances_lost` by 200 to indicate that instances could not be created.

A value of `performance_schema_mutex_instances_lost` greater than 0 can happen when the code initializes more mutexes at runtime than were allocated for `--performance_schema_max_mutex_instances=N`.

The bottom line is that if `SHOW STATUS LIKE 'perf%'` says that nothing was lost (all values are zero), the Performance Schema data is accurate and can be relied upon. If something was lost, the data is incomplete, and the Performance Schema could not record everything given the insufficient amount of memory it was given to use. In this case, the specific `performance_schema_`xxx_lost` variable indicates the problem area.

It might be appropriate in some cases to cause deliberate instrument starvation. For example, if you do not care about performance data for file I/O, you can start the server with all Performance Schema parameters related to file I/O set to 0. No memory will be allocated for file-related classes, instances, or handles, and all file events will be lost.

Use `SHOW ENGINE PERFORMANCE_SCHEMA STATUS` to inspect the internal operation of the Performance Schema code:

```
mysql> SHOW ENGINE PERFORMANCE_SCHEMA STATUS\G
... 3. row ***********************************************
| Type: performance_schema |
| Name: events_waits_history.row_size |
| Status: 76 |
4. row ***********************************************
| Type: performance_schema |
| Name: events_waits_history.row_count |
| Status: 10000 |
5. row ***********************************************
| Type: performance_schema |
| Name: events_waits_history.memory |
| Status: 760000 |
... 57. row ***********************************************
```
For a table I/O event, there are usually two rows in `events_waits_current`, not one. For example, a row fetch might result in rows like this:

<table>
<thead>
<tr>
<th>Row#</th>
<th>EVENT_NAME</th>
<th>TIMER_START</th>
<th>TIMER_END</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>wait/io/file/myisam/dfile</td>
<td>10001</td>
<td>10002</td>
</tr>
<tr>
<td>2</td>
<td>wait/io/table/sql/handler</td>
<td>10000</td>
<td>NULL</td>
</tr>
</tbody>
</table>

The row fetch causes a file read. In the example, the table I/O fetch event started before the file I/O event but has not finished (its `TIMER_END` value is `NULL`). The file I/O event is “nested” within the table I/O event.

This occurs because, unlike other “atomic” wait events such as for mutexes or file I/O, table I/O events are “molecular” and include (overlap with) other events. In `events_waits_current`, the table I/O event usually has two rows:

- One row for the most recent table I/O wait event
- One row for the most recent wait event of any kind

Usually, but not always, the “of any kind” wait event differs from the table I/O event. As each subsidiary event completes, it disappears from `events_waits_current`. At this point, and until the next subsidiary event begins, the table I/O wait is also the most recent wait of any kind.

### 22.9 Performance Schema Tables for Current and Historical Events

For wait, stage, and statement events, the Performance Schema can monitor and store current events. In addition, when events end, the Performance Schema can store them in history tables. For each event type, the Performance Schema uses three tables for storing current and historical events. The tables have names of the following forms, where `xxx` indicates the event type (`waits`, `stages`, `statements`):

- `events_xxx_current`: The “current events” table stores the current monitored event for each thread (one row per thread).
- `events_xxx_history`: The “recent history” table stores the most recent events that have ended per thread (up to a maximum number of rows per thread).
- `events_xxx_history_long`: The “long history” table stores the most recent events that have ended globally (across all threads, up to a maximum number of rows per table).

The `_current` table for each event type contains one row per thread, so there is no system variable for configuring its maximum size. The Performance Schema autosizes the history tables, or the sizes can be configured explicitly at server startup using table-specific system variables, as indicated in the sections that describe the individual history tables. Typical autosized values are 10 rows per thread for `_history` tables, and 10,000 rows total for `_history_long` tables.

For each event type, the `_current`, `_history`, and `_history_long` tables have the same columns.
The `_current` tables show what is currently happening within the server. When a current event ends, it is removed from its `_current` table.

The `_history` and `_history_long` tables show what has happened in the recent past. When the history tables become full, old events are discarded as new events are added. Rows expire from the `_history` and `_history_long` tables in different ways because the tables serve different purposes:

- `_history` is meant to investigate individual threads, independently of the global server load.
- `_history_long` is meant to investigate the server globally, not each thread.

The difference between the two types of history tables relates to the data retention policy. Both tables contain the same data when an event is first seen. However, data within each table expires differently over time, so that data might be preserved for a longer or shorter time in each table:

- For `_history`, when the table contains the maximum number of rows for a given thread, the oldest thread row is discarded when a new row for that thread is added.
- For `_history_long`, when the table becomes full, the oldest row is discarded when a new row is added, regardless of which thread generated either row.

When a thread ends, all its rows are discarded from the `_history` table but not from the `_history_long` table.

The following example illustrates the differences in how events are added to and discarded from the two types of history tables. The principles apply equally to all event types. The example is based on these assumptions:

- The Performance Schema is configured to retain 10 rows per thread in the `_history` table and 10,000 rows total in the `_history_long` table.
- Thread A generates 1 event per second.
- Thread B generates 100 events per second.
- No other threads are running.

After 5 seconds of execution:

- A and B have generated 5 and 500 events, respectively.
- `_history` contains 5 rows for A and 10 rows for B. Because storage per thread is limited to 10 rows, no rows have been discarded for A, whereas 490 rows have been discarded for B.
- `_history_long` contains 5 rows for A and 500 rows for B. Because the table has a maximum size of 10,000 rows, no rows have been discarded for either thread.

After 5 minutes (300 seconds) of execution:

- A and B have generated 300 and 30,000 events, respectively.
- `_history` contains 10 rows for A and 10 rows for B. Because storage per thread is limited to 10 rows, 290 rows have been discarded for A, whereas 29,990 rows have been discarded for B. Rows for A include data up to 10 seconds old, whereas rows for B include data up to only .1 seconds old.
- `_history_long` contains 10,000 rows. Because A and B together generate 101 events per second, the table contains data up to approximately 10,000/101 = 99 seconds old, with a mix of rows approximately 100 to 1 from B as opposed to A.
22.10 Performance Schema Statement Digests

The MySQL server is capable of maintaining statement digest information. The digesting process converts each SQL statement to normalized form (the statement digest) and computes an MD5 hash value (the digest hash value) from the normalized result. Normalization permits statements that are similar to be grouped and summarized to expose information about the types of statements the server is executing and how often they occur. This section describes how statement digesting occurs and how it can be useful.

As of 5.6.24, digesting occurs in the parser regardless of whether the Performance Schema is available, so that other server components such as MySQL Enterprise Firewall have access to statement digests. Before MySQL 5.6.24, statement digesting was a function of the Performance Schema.

- Statement Digest General Concepts
- Statement Digests in the Performance Schema
- Statement Digest Memory Use

Statement Digest General Concepts

When the parser receives an SQL statement, it computes a statement digest if that digest is needed, which is true if any of the following conditions are true:

- Performance Schema digest instrumentation is enabled
- MySQL Enterprise Firewall is enabled

The `max_digest_length` system variable value determines the maximum number of bytes available per session for computation of normalized statement digests. Once that amount of space is used during digest computation, truncation occurs: no further tokens from a parsed statement are collected or figure into its digest value. Statements that differ only after that many bytes of parsed tokens produce the same normalized statement digest and are considered identical if compared or if aggregated for digest statistics.

After the normalized statement has been computed, an MD5 hash value is computed from it. In addition:

- If MySQL Enterprise Firewall is enabled, it is called and the digest as computed is available to it.

- If the Performance Schema has digest instrumentation enabled, it makes a copy of the normalized statement digest, allocating a maximum of `performance_schema_max_digest_length` bytes for it. Consequently, if `performance_schema_max_digest_length` is less than `max_digest_length`, the copy is truncated relative to the original. The copy of the normalized statement digest is stored in the appropriate Performance Schema tables, along with the MD5 hash value computed from the original normalized statement. (If the Performance Schema truncates its copy of the normalized statement digest relative to the original, it does not recompute the MD5 hash value.)

In MySQL 5.6.24 and 5.6.25, `performance_schema_max_digest_length` is not available and `max_digest_length` applies to all digest computation. Before MySQL 5.6.24, neither `max_digest_length` nor `performance_schema_max_digest_length` are available and a fixed maximum of 1024 bytes applies to all digest computation.

Statement normalization transforms the statement text to a more standardized digest string representation that preserves the general statement structure while removing information not essential to the structure:

- Object identifiers such as database and table names are preserved.
- Literal values are converted to parameter markers. A normalized statement does not retain information such as names, passwords, dates, and so forth.
• Comments are removed and whitespace is adjusted.

Consider these statements:

```
SELECT * FROM orders WHERE customer_id=10 AND quantity>20
SELECT * FROM orders WHERE customer_id = 20 AND quantity > 100
```

To normalize these statements, the parser replaces data values by `?` and adjusts whitespace. Both statements yield the same normalized form and thus are considered “the same”:

```
SELECT * FROM orders WHERE customer_id = ? AND quantity > ?
```

The normalized statement contains less information but is still representative of the original statement. Other similar statements that have different data values have the same normalized form.

Now consider these statements:

```
SELECT * FROM customers WHERE customer_id = 1000
SELECT * FROM orders WHERE customer_id = 1000
```

In this case, the normalized statements differ because the object identifiers differ:

```
SELECT * FROM customers WHERE customer_id = ?
SELECT * FROM orders WHERE customer_id = ?
```

If normalization produces a statement that exceeds the space available in the digest buffer (as determined by `max_digest_length`), truncation occurs and the text ends with “...”. Long normalized statements that differ only in the part that occurs following the “...” are considered the same. Consider these statements:

```
SELECT * FROM mytable WHERE cola = 10 AND colb = 20
SELECT * FROM mytable WHERE cola = 10 AND colc = 20
```

If the cutoff happens to be right after the `AND`, both statements have this normalized form:

```
SELECT * FROM mytable WHERE cola = ? AND ...
```

In this case, the difference in the second column name is lost and both statements are considered the same.

**Statement Digests in the Performance Schema**

In the Performance Schema, statement digesting involves these components:

- A `statements_digest` consumer in the `setup_consumers` table controls whether the Performance Schema maintains digest information. See Statement Digest Consumer.

- The statement event tables (`events_statements_current`, `events_statements_history`, and `events_statements_history_long`) have columns for storing normalized statement digests and the corresponding digest MD5 hash values:

  - `DIGEST_TEXT` is the text of the normalized statement digest. This is a copy of the original normalized statement that was computed to a maximum of `max_digest_length` bytes, further truncated as necessary to `performance_schema_max_digest_length` bytes.

  - `DIGEST` is the digest MD5 hash value computed from the original normalized statement.
Statement Digest Memory Use

See Section 22.12.6, “Performance Schema Statement Event Tables”.

- The `events_statements_summary_by_digest` summary table provides aggregated statement digest information. This table aggregates information for statements per `SCHEMA_NAME` and `DIGEST` combination. The Performance Schema uses MD5 hash values for aggregation because they are fast to compute and have a favorable statistical distribution that minimizes collisions. See Section 22.12.9.3, “Statement Summary Tables”.

The statement event tables also have an `SQL_TEXT` column that contains the original SQL statement. The maximum space available for statement display is 1024 bytes.

The `performance_schema_max_digest_length` system variable determines the maximum number of bytes available per statement for digest value storage in the Performance Schema. However, the display length of statement digests may be longer than the available buffer size due to internal encoding of statement components such as keywords and literal values. Consequently, values selected from the `DIGEST_TEXT` column of statement event tables may appear to exceed the `performance_schema_max_digest_length` value.

The `events_statements_summary_by_digest` summary table provides a profile of the statements executed by the server. It shows what kinds of statements an application is executing and how often. An application developer can use this information together with other information in the table to assess the application's performance characteristics. For example, table columns that show wait times, lock times, or index use may highlight types of queries that are inefficient. This gives the developer insight into which parts of the application need attention.

The `events_statements_summary_by_digest` summary table has a fixed size. By default the Performance Schema estimates the size to use at startup. To specify the table size explicitly, set the `performance_schema_digests_size` system variable at server startup. If the table becomes full, the Performance Schema groups statements that have `SCHEMA_NAME` and `DIGEST` values not matching existing values in the table in a special row with `SCHEMA_NAME` and `DIGEST` set to `NULL`. This permits all statements to be counted. However, if the special row accounts for a significant percentage of the statements executed, it might be desirable to increase the summary table size by increasing `performance_schema_digests_size`.

**Statement Digest Memory Use**

For applications that generate very long statements that differ only at the end, increasing `max_digest_length` enables computation of digests that distinguish statements that would otherwise aggregate to the same digest. Conversely, decreasing `max_digest_length` causes the server to devote less memory to digest storage but increases the likelihood of longer statements aggregating to the same digest. Administrators should keep in mind that larger values result in correspondingly increased memory requirements, particularly for workloads that involve large numbers of simultaneous sessions (the server allocates `max_digest_length` bytes per session).

As described previously, normalized statement digests as computed by the parser are constrained to a maximum of `max_digest_length` bytes, whereas normalized statement digests stored in the Performance Schema use `performance_schema_max_digest_length` bytes. The following memory-use considerations apply regarding the relative values of `max_digest_length` and `performance_schema_max_digest_length`:

- If `max_digest_length` is less than `performance_schema_max_digest_length`:
  - Server components other than the Performance Schema use normalized statement digests that take up to `max_digest_length` bytes.
• The Performance Schema does not further truncate normalized statement digests that it stores, but allocates more memory than \texttt{max_digest_length} bytes per digest, which is unnecessary.

• If \texttt{max_digest_length} equals \texttt{performance_schema_max_digest_length}:

  • Server components other than the Performance Schema use normalized statement digests that take up to \texttt{max_digest_length} bytes.

  • The Performance Schema does not further truncate normalized statement digests that it stores, and allocates the same amount of memory as \texttt{max_digest_length} bytes per digest.

• If \texttt{max_digest_length} is greater than \texttt{performance_schema_max_digest_length}:

  • Server components other than the Performance Schema use normalized statement digests that take up to \texttt{max_digest_length} bytes.

  • The Performance Schema further truncates normalized statement digests that it stores, and allocates less memory than \texttt{max_digest_length} bytes per digest.

Because the Performance Schema statement event tables might store many digests, setting \texttt{performance_schema_max_digest_length} smaller than \texttt{max_digest_length} enables administrators to balance these factors:

• The need to have long normalized statement digests available for server components outside the Performance Schema

• Many concurrent sessions, each of which allocates digest-computation memory

• The need to limit memory consumption by the Performance Schema statement event tables when storing many statement digests

The \texttt{performance_schema_max_digest_length} setting is not per session, it is per statement, and a session can store multiple statements in the \texttt{events_statements_history} table. A typical number of statements in this table is 10 per session, so each session will consume 10 times the memory indicated by the \texttt{performance_schema_max_digest_length} value, for this table alone.

Also, there are many statements (and digests) collected globally, most notably in the \texttt{events_statements_history_long} table. Here, too, \( N \) statements stored will consume \( N \) times the memory indicated by the \texttt{performance_schema_max_digest_length} value.

\section*{22.11 Performance Schema General Table Characteristics}

The name of the \texttt{performance_schema} database is lowercase, as are the names of tables within it. Queries should specify the names in lowercase.

Many tables in the \texttt{performance_schema} database are read only and cannot be modified:

```
mysql> TRUNCATE TABLE performance_schema.setup_instruments;
ERROR 1683 (HY000): Invalid performance_schema usage.
```

Some of the setup tables have columns that can be modified to affect Performance Schema operation; some also permit rows to be inserted or deleted. Truncation is permitted to clear collected events, so \texttt{TRUNCATE TABLE} can be used on tables containing those kinds of information, such as tables named with a prefix of \texttt{events_waits_}.  

3348
Summary tables can be truncated with \texttt{TRUNCATE TABLE}. Generally, the effect is to reset the summary columns to 0 or \texttt{NULL}, not to remove rows. This enables you to clear collected values and restart aggregation. That might be useful, for example, after you have made a runtime configuration change. Exceptions to this truncation behavior are noted in individual summary table sections.

Privileges are as for other databases and tables:

- To retrieve from \textit{performance_schema} tables, you must have the \texttt{SELECT} privilege.
- To change those columns that can be modified, you must have the \texttt{UPDATE} privilege.
- To truncate tables that can be truncated, you must have the \texttt{DROP} privilege.

Because only a limited set of privileges apply to Performance Schema tables, attempts to use \texttt{GRANT ALL} as shorthand for granting privileges at the database or table level fail with an error:

```sql
mysql> GRANT ALL ON performance_schema.*
       TO 'u1'@'localhost';
ERROR 1044 (42000): Access denied for user 'root'@'localhost'
to database 'performance_schema'
```

Instead, grant exactly the desired privileges:

```sql
mysql> GRANT SELECT ON performance_schema.*
       TO 'u1'@'localhost';
Query OK, 0 rows affected (0.03 sec)
mysql> GRANT SELECT, UPDATE ON performance_schema.setup_instruments
       TO 'u2'@'localhost';
Query OK, 0 rows affected (0.02 sec)
```

### 22.12 Performance Schema Table Descriptions

Tables in the \textit{performance_schema} database can be grouped as follows:

- Setup tables. These tables are used to configure and display monitoring characteristics.
- Current events tables. The \texttt{events_waits_current} table contains the most recent event for each thread. Other similar tables contain current events at different levels of the event hierarchy: \texttt{events_stages_current} for stage events, and \texttt{events_statements_current} for statement events.
- History tables. These tables have the same structure as the current events tables, but contain more rows. For example, for wait events, \texttt{events_waits_history} table contains the most recent 10 events per thread. \texttt{events_waits_history_long} contains the most recent 10,000 events. Other similar tables exist for stage and statement histories.
- Summary tables. These tables contain information aggregated over groups of events, including those that have been discarded from the history tables.
• Instance tables. These tables document what types of objects are instrumented. An instrumented object, when used by the server, produces an event. These tables provide event names and explanatory notes or status information.

• Miscellaneous tables. These do not fall into any of the other table groups.

### 22.12.1 Performance Schema Table Index

The following table lists each Performance Schema table and provides a short description of each one.

**Table 22.1 Performance Schema Tables**

<table>
<thead>
<tr>
<th>Table Name</th>

#### 22.12.2 Performance Schema Setup Tables

The setup tables provide information about the current instrumentation and enable the monitoring configuration to be changed. For this reason, some columns in these tables can be changed if you have the `UPDATE` privilege.

The use of tables rather than individual variables for setup information provides a high degree of flexibility in modifying Performance Schema configuration. For example, you can use a single statement with standard SQL syntax to make multiple simultaneous configuration changes.

These setup tables are available:

- **setup_actors**: How to initialize monitoring for new foreground threads
- **setup_consumers**: The destinations to which event information can be sent and stored
- **setup_instruments**: The classes of instrumented objects for which events can be collected
• setup_objects: Which objects should be monitored

• setup_timers: The current event timer

22.12.2.1 The setup_actors Table

The setup_actors table contains information that determines whether to enable monitoring for new foreground server threads (threads associated with client connections). This table has a maximum size of 100 rows by default. To change the table size, modify the performance_schema_setup_actors_size system variable at server startup.

For each new foreground thread, the Performance Schema matches the user and host for the thread against the rows of the setup_actors table. If a row from that table matches, its ENABLED column value is used to set the INSTRUMENTED column of the threads table row for the thread. This enables instrumenting to be applied selectively per host, user, or account (user and host combination). If there is no match, the INSTRUMENTED column for the thread is set to NO.

For background threads, there is no associated user. INSTRUMENTED is YES by default and setup_actors is not consulted.

The initial contents of the setup_actors table match any user and host combination, so monitoring is enabled by default for all foreground threads:

```
mysql> SELECT * FROM performance_schema.setup_actors;
+---------+---------+-------+
| HOST    | USER    | ROLE  |
| %       | %       | %     |
+---------+---------+-------+
```

For information about how to use the setup_actors table to affect event monitoring, see Section 22.4.6, “Pre-Filtering by Thread”.

Modifications to the setup_actors table affect only foreground threads created subsequent to the modification, not existing threads. To affect existing threads, modify the INSTRUMENTED column of threads table rows.

The setup_actors table has these columns:

• HOST

The host name. This should be a literal name, or '%' to mean “any host.”

• USER

The user name. This should be a literal name, or '%' to mean “any user.”

• ROLE

Unused.

TRUNCATE TABLE is permitted for the setup_actors table. It removes the rows.

22.12.2.2 The setup_consumers Table

The setup_consumers table lists the types of consumers for which event information can be stored and which are enabled:
mysql> SELECT * FROM performance_schema.setup_consumers;
+--------------------------------+---------+
| NAME                           | ENABLED |
+--------------------------------+---------+
| events_stages_current          | NO      |
| events_stages_history          | NO      |
| events_stages_history_long     | NO      |
| events_statements_current      | YES     |
| events_statements_history      | NO      |
| events_statements_history_long | NO      |
| events_waits_current           | NO      |
| events_waits_history           | NO      |
| events_waits_history_long      | NO      |
| global_instrumentation         | YES     |
| thread_instrumentation         | YES     |
| statements_digest              | YES     |
+--------------------------------+---------+

The consumer settings in the `setup_consumers` table form a hierarchy from higher levels to lower. For detailed information about the effect of enabling different consumers, see Section 22.4.7, “Pre-Filtering by Consumer”.

Modifications to the `setup_consumers` table affect monitoring immediately.

The `setup_consumers` table has these columns:

- **NAME**
  The consumer name.

- **ENABLED**
  Whether the consumer is enabled. The value is **YES** or **NO**. This column can be modified. If you disable a consumer, the server does not spend time adding event information to it.

  **TRUNCATE TABLE** is not permitted for the `setup_consumers` table.

### 22.12.2.3 The setup_instruments Table

The `setup_instruments` table lists classes of instrumented objects for which events can be collected:

```sql
mysql> SELECT * FROM performance_schema.setup_instruments;
+-------------------------------------+---------+-------+
| NAME                                | ENABLED | TIMED |
+-------------------------------------+---------+-------+
| ...                                 | ...     | ...   |
| stage/sql/end                       | NO      | NO    |
| stage/sql/executing                 | NO      | NO    |
| stage/sql/init                      | NO      | NO    |
| stage/sql/insert                    | NO      | NO    |
| ...                                 | ...     | ...   |
| statement/sql/load                  | YES     | YES   |
| statement/sql/grant                 | YES     | YES   |
| statement/sql/check                 | YES     | YES   |
| statement/sql/flush                  | YES     | YES   |
| ...                                 | ...     | ...   |
| wait/synch/mutex/sql/LOCK_global_read_lock | YES     | YES   |
| wait/synch/mutex/sql/LOCK_global_system_variables | YES     | YES   |
| wait/synch/mutex/sql/LOCK_lock_db    | YES     | YES   |
| wait/synch/mutex/sql/LOCK_manager   | YES     | YES   |
| ...                                 | ...     | ...   |
| wait/synch/rwlock/sql/LOCK_grant    | YES     | YES   |
```
Performance Schema Setup Tables

| wait/synch/rwlock/sql/LOGGER::LOCK_logger         | YES     | YES   |
| wait/synch/rwlock/sql/LOCK_sys_init_connect       | YES     | YES   |
| wait/synch/rwlock/sql/LOCK_sys_init_slave         | YES     | YES   |
| wait/io/file/sql/binlog                           | YES     | YES   |
| wait/io/file/sql/binlog_index                     | YES     | YES   |
| wait/io/file/sql/casetest                         | YES     | YES   |
| wait/io/file/sql/dbopt                            | YES     | YES   |

Each instrument added to the source code provides a row for the `setup_instruments` table, even when the instrumented code is not executed. When an instrument is enabled and executed, instrumented instances are created, which are visible in the `xxx_instances` tables, such as `file_instances` or `rwlock_instances`.

Modifications to most `setup_instruments` rows affect monitoring immediately. For some instruments, modifications are effective only at server startup; changing them at runtime has no effect. This affects primarily mutexes, conditions, and rwlocks in the server, although there may be other instruments for which this is true.

For more information about the role of the `setup_instruments` table in event filtering, see Section 22.4.3, “Event Pre-Filtering”.

The `setup_instruments` table has these columns:

• **NAME**

  The instrument name. Instrument names may have multiple parts and form a hierarchy, as discussed in Section 22.6, “Performance Schema Instrument Naming Conventions”. Events produced from execution of an instrument have an `EVENT_NAME` value that is taken from the instrument `NAME` value. (Events do not really have a “name,” but this provides a way to associate events with instruments.)

• **ENABLED**

  Whether the instrument is enabled. The value is YES or NO. A disabled instrument produces no events. This column can be modified, although setting `ENABLED` has no effect for instruments that have already been created.

• **TIMED**

  Whether the instrument is timed. The value is YES or NO. This column can be modified, although setting `TIMED` has no effect for instruments that have already been created.

  If an enabled instrument is not timed, the instrument code is enabled, but the timer is not. Events produced by the instrument have NULL for the `TIMER_START`, `TIMER_END`, and `TIMER_WAIT` timer values. This in turn causes those values to be ignored when calculating the sum, minimum, maximum, and average time values in summary tables.

  `TRUNCATE TABLE` is not permitted for the `setup_instruments` table.

22.12.2.4 The `setup_objects` Table

The `setup_objects` table controls whether the Performance Schema monitors particular objects. This table has a maximum size of 100 rows by default. To change the table size, modify the `performance_schema_setup_objects_size` system variable at server startup.

The initial `setup_objects` contents look like this:
Modifications to the setup_objects table affect object monitoring immediately.

For object types listed in setup_objects, the Performance Schema uses the table to how to monitor them. Object matching is based on the OBJECT_SCHEMA and OBJECT_NAME columns. Objects for which there is no match are not monitored.

The effect of the default object configuration is to instrument all tables except those in the mysql, INFORMATION_SCHEMA, and performance_schema databases. (Tables in the INFORMATION_SCHEMA database are not instrumented regardless of the contents of setup_objects; the row for information_schema.% simply makes this default explicit.)

When the Performance Schema checks for a match in setup_objects, it tries to find more specific matches first. For example, with a table db1.t1, it looks for a match for 'db1' and 't1', then for 'db1' and '%', then for '%' and '%'. The order in which matching occurs matters because different matching setup_objects rows can have different ENABLED and TIMED values.

Rows can be inserted into or deleted from setup_objects by users with the INSERT or DELETE privilege on the table. For existing rows, only the ENABLED and TIMED columns can be modified, by users with the UPDATE privilege on the table.

For more information about the role of the setup_objects table in event filtering, see Section 22.4.3, “Event Pre-Filtering”.

The setup_objects table has these columns:

- **OBJECT_TYPE**
  
  The type of object to instrument. This is always 'TABLE' (base table).

  TABLE filtering affects table I/O events (wait/io/table/sql/handler instrument) and table lock events (wait/lock/table/sql/handler instrument).

- **OBJECT_SCHEMA**
  
  The schema that contains the object. This should be a literal name, or '%' to mean “any schema.”

- **OBJECT_NAME**
  
  The name of the instrumented object. This should be a literal name, or '%' to mean “any object.”

- **ENABLED**
  
  Whether events for the object are instrumented. The value is YES or NO. This column can be modified.

- **TIMED**
  
  Whether events for the object are timed. The value is YES or NO. This column can be modified.

TRUNCATE TABLE is permitted for the setup_objects table. It removes the rows.
22.12.2.5 The setup_timers Table

The setup_timers table shows the currently selected event timers:

```
mysql> SELECT * FROM performance_schema.setup_timers;
+-----------+-------------+
| NAME      | TIMER_NAME  |
+-----------+-------------+
| idle      | MICROSECOND |
| wait      | CYCLE       |
| stage     | NANOSECOND  |
| statement | NANOSECOND  |
+-----------+-------------+
```

The setup_timers.TIMER_NAME value can be changed to select a different timer. The value can be any of the values in the performance_timers.TIMER_NAME column. For an explanation of how event timing occurs, see Section 22.4.1, “Performance Schema Event Timing”.

Modifications to the setup_timers table affect monitoring immediately. Events already in progress may use the original timer for the begin time and the new timer for the end time. To avoid unpredictable results after you make timer changes, use TRUNCATE TABLE to reset Performance Schema statistics.

The setup_timers table has these columns:

- **NAME**
  The type of instrument the timer is used for.

- **TIMER_NAME**
  The timer that applies to the instrument type. This column can be modified.

TRUNCATE TABLE is not permitted for the setup_timers table.

22.12.3 Performance Schema Instance Tables

Instance tables document what types of objects are instrumented. They provide event names and explanatory notes or status information:

- **cond_instances**: Condition synchronization object instances
- **file_instances**: File instances
- **mutex_instances**: Mutex synchronization object instances
- **rwlock_instances**: Lock synchronization object instances
- **socket_instances**: Active connection instances

These tables list instrumented synchronization objects, files, and connections. There are three types of synchronization objects: cond, mutex, and rwlock. Each instance table has an EVENT_NAME or NAME column to indicate the instrument associated with each row. Instrument names may have multiple parts and form a hierarchy, as discussed in Section 22.6, “Performance Schema Instrument Naming Conventions”.

The mutex_instances.LOCKED_BY_THREAD_ID and rwlock_instances.WRITE_LOCKED_BY_THREAD_ID columns are extremely important for investigating performance bottlenecks or deadlocks. For examples of how to use them for this purpose, see Section 22.18, “Using the Performance Schema to Diagnose Problems”
22.12.3.1 The cond_instances Table

The `cond_instances` table lists all the conditions seen by the Performance Schema while the server executes. A condition is a synchronization mechanism used in the code to signal that a specific event has happened, so that a thread waiting for this condition can resume work.

When a thread is waiting for something to happen, the condition name is an indication of what the thread is waiting for, but there is no immediate way to tell which other thread, or threads, will cause the condition to happen.

The `cond_instances` table has these columns:

- **NAME**
  The instrument name associated with the condition.

- **OBJECT_INSTANCE_BEGIN**
  The address in memory of the instrumented condition.

**TRUNCATE TABLE** is not permitted for the `cond_instances` table.

22.12.3.2 The file_instances Table

The `file_instances` table lists all the files seen by the Performance Schema when executing file I/O instrumentation. If a file on disk has never been opened, it will not be in `file_instances`. When a file is deleted from the disk, it is also removed from the `file_instances` table.

The `file_instances` table has these columns:

- **FILE_NAME**
  The file name.

- **EVENT_NAME**
  The instrument name associated with the file.

- **OPEN_COUNT**
  The count of open handles on the file. If a file was opened and then closed, it was opened 1 time, but `OPEN_COUNT` will be 0. To list all the files currently opened by the server, use `WHERE OPEN_COUNT > 0`.

**TRUNCATE TABLE** is not permitted for the `file_instances` table.

22.12.3.3 The mutex_instances Table

The `mutex_instances` table lists all the mutexes seen by the Performance Schema while the server executes. A mutex is a synchronization mechanism used in the code to enforce that only one thread at a given time can have access to some common resource. The resource is said to be “protected” by the mutex.

When two threads executing in the server (for example, two user sessions executing a query simultaneously) do need to access the same resource (a file, a buffer, or some piece of data), these two threads will compete against each other, so that the first query to obtain a lock on the mutex will cause the other query to wait until the first is done and unlocks the mutex.
The work performed while holding a mutex is said to be in a “critical section,” and multiple queries do execute this critical section in a serialized way (one at a time), which is a potential bottleneck.

The `mutex_instances` table has these columns:

- **NAME**
  The instrument name associated with the mutex.

- **OBJECT_INSTANCE_BEGIN**
  The address in memory of the instrumented mutex.

- **LOCKED_BY_THREAD_ID**
  When a thread currently has a mutex locked, `LOCKED_BY_THREAD_ID` is the `THREAD_ID` of the locking thread, otherwise it is `NULL`.

`TRUNCATE TABLE` is not permitted for the `mutex_instances` table.

For every mutex instrumented in the code, the Performance Schema provides the following information.

- The `setup_instruments` table lists the name of the instrumentation point, with the prefix `wait/synch/mutex/`.

- When some code creates a mutex, a row is added to the `mutex_instances` table. The `OBJECT_INSTANCE_BEGIN` column is a property that uniquely identifies the mutex.

- When a thread attempts to lock a mutex, the `events_waits_current` table shows a row for that thread, indicating that it is waiting on a mutex (in the `EVENT_NAME` column), and indicating which mutex is waited on (in the `OBJECT_INSTANCE_BEGIN` column).

- When a thread succeeds in locking a mutex:
  - `events_waits_current` shows that the wait on the mutex is completed (in the `TIMER_END` and `TIMER_WAIT` columns)
  - The completed wait event is added to the `events_waits_history` and `events_waits_history_long` tables
  - `mutex_instances` shows that the mutex is now owned by the thread (in the `THREAD_ID` column).

- When a thread unlocks a mutex, `mutex_instances` shows that the mutex now has no owner (the `THREAD_ID` column is `NULL`).

- When a mutex object is destroyed, the corresponding row is removed from `mutex_instances`.

By performing queries on both of the following tables, a monitoring application or a DBA can detect bottlenecks or deadlocks between threads that involve mutexes:

- `events_waits_current`, to see what mutex a thread is waiting for
- `mutex_instances`, to see which other thread currently owns a mutex

### 22.12.3.4 The `rwlock_instances` Table

The `rwlock_instances` table lists all the `rwlock` instances (read write locks) seen by the Performance Schema while the server executes. An `rwlock` is a synchronization mechanism used in the code to enforce that threads at a given time can have access to some common resource following certain rules.
The resource is said to be “protected” by the `rwlock`. The access is either shared (many threads can have a read lock at the same time) or exclusive (only one thread can have a write lock at a given time).

Depending on how many threads are requesting a lock, and the nature of the locks requested, access can be either granted in shared mode, granted in exclusive mode, or not granted at all, waiting for other threads to finish first.

The `rwlock_instances` table has these columns:

- **NAME**
  
  The instrument name associated with the lock.

- **OBJECT_INSTANCE_BEGIN**
  
  The address in memory of the instrumented lock.

- **WRITE_LOCKED_BY_THREAD_ID**
  
  When a thread currently has an `rwlock` locked in exclusive (write) mode, `WRITE_LOCKED_BY_THREAD_ID` is the `THREAD_ID` of the locking thread, otherwise it is `NULL`.

- **READ_LOCKED_BY_COUNT**
  
  When a thread currently has an `rwlock` locked in shared (read) mode, `READ_LOCKED_BY_COUNT` is incremented by 1. This is a counter only, so it cannot be used directly to find which thread holds a read lock, but it can be used to see whether there is a read contention on an `rwlock`, and see how many readers are currently active.

`TRUNCATE TABLE` is not permitted for the `rwlock_instances` table.

By performing queries on both of the following tables, a monitoring application or a DBA may detect some bottlenecks or deadlocks between threads that involve locks:

- `events_waits_current`, to see what `rwlock` a thread is waiting for
- `rwlock_instances`, to see which other thread currently owns an `rwlock`

There is a limitation: The `rwlock_instances` can be used only to identify the thread holding a write lock, but not the threads holding a read lock.

### 22.12.3.5 The `socket_instances` Table

The `socket_instances` table provides a real-time snapshot of the active connections to the MySQL server. The table contains one row per TCP/IP or Unix socket file connection. Information available in this table provides a real-time snapshot of the active connections to the server. (Additional information is available in socket summary tables, including network activity such as socket operations and number of bytes transmitted and received; see Section 22.12.9.7, “Socket Summary Tables”).

```sql
mysql> SELECT * FROM performance_schema.socket_instances\G
*************************** 1. row ***************************
EVENT_NAME: wait/io/socket/sql/server_unix_socket
OBJECT_INSTANCE_BEGIN: 4316619408
THREAD_ID: 1
SOCKET_ID: 16
IP: 
PORT: 0
STATE: ACTIVE
*************************** 2. row ***************************
```
Socket instruments have names of the form `wait/io/socket/sql/socket_type` and are used like this:

1. The server has a listening socket for each network protocol that it supports. The instruments associated with listening sockets for TCP/IP or Unix socket file connections have a `socket_type` value of `server_tcpip_socket` or `server_unix_socket`, respectively.

2. When a listening socket detects a connection, the server transfers the connection to a new socket managed by a separate thread. The instrument for the new connection thread has a `socket_type` value of `client_connection`.

3. When a connection terminates, the row in `socket_instances` corresponding to it is deleted.

The `socket_instances` table has these columns:

- **EVENT_NAME**
  The name of the `wait/io/socket/*` instrument that produced the event. This is a `NAME` value from the `setup_instruments` table. Instrument names may have multiple parts and form a hierarchy, as discussed in Section 22.6, “Performance Schema Instrument Naming Conventions”.

- **OBJECT_INSTANCE_BEGIN**
  This column uniquely identifies the socket. The value is the address of an object in memory.

- **THREAD_ID**
  The internal thread identifier assigned by the server. Each socket is managed by a single thread, so each socket can be mapped to a thread which can be mapped to a server process.

- **SOCKET_ID**
  The internal file handle assigned to the socket.

- **IP**
  The client IP address. The value may be either an IPv4 or IPv6 address, or blank to indicate a Unix socket file connection.

- **PORT**
  The TCP/IP port number, in the range from 0 to 65535.

- **STATE**
The socket status, either IDLE or ACTIVE. Wait times for active sockets are tracked using the corresponding socket instrument. Wait times for idle sockets are tracked using the idle instrument.

A socket is idle if it is waiting for a request from the client. When a socket becomes idle, the event row in socket_instances that is tracking the socket switches from a status of ACTIVE to IDLE. The EVENT_NAME value remains wait/io/socket/*, but timing for the instrument is suspended. Instead, an event is generated in the events_waits_current table with an EVENT_NAME value of idle.

When the next request is received, the idle event terminates, the socket instance switches from IDLE to ACTIVE, and timing of the socket instrument resumes.

TRUNCATE TABLE is not permitted for the socket_instances table.

The IP:PORT column combination value identifies the connection. This combination value is used in the OBJECT_NAME column of the events_waits_xxx tables, to identify the connection from which socket events come:

- For the Unix domain listener socket (server_unix_socket), the port is 0, and the IP is ''.
- For client connections via the Unix domain listener (client_connection), the port is 0, and the IP is ''.
- For the TCP/IP server listener socket (server_tcppip_socket), the port is always the master port (for example, 3306), and the IP is always 0.0.0.0.
- For client connections via the TCP/IP listener (client_connection), the port is whatever the server assigns, but never 0. The IP is the IP of the originating host (127.0.0.1 or ::1 for the local host)

### 22.12.4 Performance Schema Wait Event Tables

The Performance Schema instruments waits, which are events that take time. Within the event hierarchy, wait events nest within stage events, which nest within statement events.

These tables store wait events:

- events_waits_current: The current wait event for each thread.
- events_waits_history: The most recent wait events that have ended per thread.
- events_waits_history_long: The most recent wait events that have ended globally (across all threads).

The following sections describe the wait event tables. There are also summary tables that aggregate information about wait events; see Section 22.12.9.1, “Wait Event Summary Tables”.

For more information about the relationship between the three wait event tables, see Section 22.9, “Performance Schema Tables for Current and Historical Events”.

### Configuring Wait Event Collection

To control whether to collect wait events, set the state of the relevant instruments and consumers:

- The setup_instruments table contains instruments with names that begin with wait. Use these instruments to enable or disable collection of individual wait event classes.
- The setup_consumers table contains consumer values with names corresponding to the current and historical wait event table names. Use these consumers to filter collection of wait events.
Some wait instruments are enabled by default; others are disabled. For example:

```
mysql> SELECT * FROM performance_schema.setup_instruments
     WHERE NAME LIKE 'wait/io/file/innodb%';
+--------------------------------------+---------+-------+
| NAME                                 | ENABLED | TIMED |
+--------------------------------------+---------+-------+
| wait/io/file/innodb/innodb_data_file | YES     | YES   |
| wait/io/file/innodb/innodb_log_file  | YES     | YES   |
| wait/io/file/innodb/innodb_temp_file | YES     | YES   |
+--------------------------------------+---------+-------+
mysql> SELECT * FROM performance_schema.setup_instruments
     WHERE NAME LIKE 'wait/io/socket/%';
+----------------------------------------+---------+-------+
| NAME                                   | ENABLED | TIMED |
+----------------------------------------+---------+-------+
| wait/io/socket/sql/server_tcpip_socket | NO      | NO    |
| wait/io/socket/sql/server_unix_socket  | NO      | NO    |
| wait/io/socket/sql/client_connection   | NO      | NO    |
+----------------------------------------+---------+-------+
```

The wait consumers are disabled by default:

```
mysql> SELECT * FROM performance_schema.setup_consumers
     WHERE NAME LIKE 'events_waits%';
+---------------------------+---------+
| NAME                      | ENABLED |
+---------------------------+---------+
| events_waits_current      | NO      |
| events_waits_history      | NO      |
| events_waits_history_long | NO      |
+---------------------------+---------+
```

To control wait event collection at server startup, use lines like these in your `my.cnf` file:

- **Enable:**
  ```
  [mysqld]
  performance-schema-instrument='wait/%=ON'
  performance-schema-consumer-events-waits-current=ON
  performance-schema-consumer-events-waits-history=ON
  performance-schema-consumer-events-waits-history-long=ON
  ```

- **Disable:**
  ```
  [mysqld]
  performance-schema-instrument='wait/%=OFF'
  performance-schema-consumer-events-waits-current=OFF
  performance-schema-consumer-events-waits-history=OFF
  performance-schema-consumer-events-waits-history-long=OFF
  ```

To control wait event collection at runtime, update the `setup_instruments` and `setup_consumers` tables:

- **Enable:**
  ```
  UPDATE performance_schema.setup_instruments
  SET ENABLED = 'YES', TIMED = 'YES'
  WHERE NAME = 'wait/%';
  ```
Performance Schema Wait Event Tables

UPDATE performance_schema.setup_consumers
SET ENABLED = 'YES'
WHERE NAME LIKE 'events_waits%';

• Disable:

UPDATE performance_schema.setup_instruments
SET ENABLED = 'NO', TIMED = 'NO'
WHERE NAME = 'wait/%';
UPDATE performance_schema.setup_consumers
SET ENABLED = 'NO'
WHERE NAME LIKE 'events_waits%';

To collect only specific wait events, enable only the corresponding wait instruments. To collect wait events
only for specific wait event tables, enable the wait instruments but only the wait consumers corresponding
to the desired tables.

The setup_timers table contains a row with a NAME value of wait that indicates the unit for wait event
timing. The default unit is CYCLE:

mysql> SELECT * 
FROM performance_schema.setup_timers
WHERE NAME = 'wait';
+------+------------+
| NAME | TIMER_NAME |
+------+------------+
| wait | CYCLE      |

To change the timing unit, modify the TIMER_NAME value:

UPDATE performance_schema.setup_timers
SET TIMER_NAME = 'NANOSECOND'
WHERE NAME = 'wait';

For additional information about configuring event collection, see Section 22.3, “Performance Schema
Startup Configuration”, and Section 22.4, “Performance Schema Runtime Configuration”.

22.12.4.1 The events_waits_current Table

The events_waits_current table contains current wait events. The table stores one row per thread
showing the current status of the thread’s most recent monitored wait event, so there is no system variable
for configuring the table size.

Of the tables that contain wait event rows, events_waits_current is the most fundamental. Other
tables that contain wait event rows are logically derived from the current events. For example, the
events_waits_history and events_waits_history_long tables are collections of the most recent
wait events that have ended, up to a maximum number of rows per thread and globally across all threads,
respectively.

For more information about the relationship between the three wait event tables, see Section 22.9,
“Performance Schema Tables for Current and Historical Events”.

For information about configuring whether to collect wait events, see Section 22.12.4, “Performance
Schema Wait Event Tables”. 
The `events_waits_current` table has these columns:

- **THREAD_ID, EVENT_ID**
  
  The thread associated with the event and the thread current event number when the event starts. The `THREAD_ID` and `EVENT_ID` values taken together uniquely identify the row. No two rows have the same pair of values.

- **END_EVENT_ID**
  
  This column is set to `NULL` when the event starts and updated to the thread current event number when the event ends.

- **EVENT_NAME**
  
  The name of the instrument that produced the event. This is a `NAME` value from the `setup_instruments` table. Instrument names may have multiple parts and form a hierarchy, as discussed in Section 22.6, “Performance Schema Instrument Naming Conventions”.

- **SOURCE**
  
  The name of the source file containing the instrumented code that produced the event and the line number in the file at which the instrumentation occurs. This enables you to check the source to determine exactly what code is involved. For example, if a mutex or lock is being blocked, you can check the context in which this occurs.

- **TIMER_START, TIMER_END, TIMER_WAIT**
  
  Timing information for the event. The unit for these values is picoseconds (trillionths of a second). The `TIMER_START` and `TIMER_END` values indicate when event timing started and ended. `TIMER_WAIT` is the event elapsed time (duration).

  If an event has not finished, `TIMER_END` and `TIMER_WAIT` are `NULL` before MySQL 5.6.26. As of 5.6.26, `TIMER_END` is the current timer value and `TIMER_WAIT` is the time elapsed so far (`TIMER_END - TIMER_START`).

  If an event is produced from an instrument that has `TIMED = NO`, timing information is not collected, and `TIMER_START`, `TIMER_END`, and `TIMER_WAIT` are all `NULL`.

  For discussion of picoseconds as the unit for event times and factors that affect time values, see Section 22.4.1, “Performance Schema Event Timing”.

- **SPINS**
  
  For a mutex, the number of spin rounds. If the value is `NULL`, the code does not use spin rounds or spinning is not instrumented.

- **OBJECT_SCHEMA, OBJECT_NAME, OBJECT_TYPE, OBJECT_INSTANCE_BEGIN**
  
  These columns identify the object “being acted on.” What that means depends on the object type.

  For a synchronization object (`cond, mutex, rwlock`):

  - `OBJECT_SCHEMA, OBJECT_NAME, and OBJECT_TYPE` are `NULL`.

  - `OBJECT_INSTANCE_BEGIN` is the address of the synchronization object in memory.

  For a file I/O object:
• **OBJECT_SCHEMA** is **NULL**.

• **OBJECT_NAME** is the file name.

• **OBJECT_TYPE** is **FILE**.

• **OBJECT_INSTANCE_BEGIN** is an address in memory.

For a socket object:

• **OBJECT_NAME** is the **IP:PORT** value for the socket.

• **OBJECT_INSTANCE_BEGIN** is an address in memory.

For a table I/O object:

• **OBJECT_SCHEMA** is the name of the schema that contains the table.

• **OBJECT_NAME** is the table name.

• **OBJECT_TYPE** is **TABLE** for a persistent base table or **TEMPORARY TABLE** for a temporary table.

• **OBJECT_INSTANCE_BEGIN** is an address in memory.

An **OBJECT_INSTANCE_BEGIN** value itself has no meaning, except that different values indicate different objects. **OBJECT_INSTANCE_BEGIN** can be used for debugging. For example, it can be used with **GROUP BY OBJECT_INSTANCE_BEGIN** to see whether the load on 1,000 mutexes (that protect, say, 1,000 pages or blocks of data) is spread evenly or just hitting a few bottlenecks. This can help you correlate with other sources of information if you see the same object address in a log file or another debugging or performance tool.

• **INDEX_NAME**

The name of the index used. **PRIMARY** indicates the table primary index. **NULL** means that no index was used.

• **NESTING_EVENT_ID**

The **EVENT_ID** value of the event within which this event is nested.

• **NESTING_EVENT_TYPE**

The nesting event type. The value is **STATEMENT**, **STAGE**, or **WAIT**.

• **OPERATION**

The type of operation performed, such as **lock**, **read**, or **write**.

• **NUMBER_OF_BYTES**

The number of bytes read or written by the operation. For table I/O waits (events for the **wait/io/table/sql/handler** instrument), **NUMBER_OF_BYTES** is **NULL**.

• **FLAGS**

Reserved for future use.

**TRUNCATE TABLE** is permitted for the **events_waits_current** table. It removes the rows.
22.12.4.2 The events_waits_history Table

The `events_waits_history` table contains the $N$ most recent wait events that have ended per thread. Wait events are not added to the table until they have ended. When the table contains the maximum number of rows for a given thread, the oldest thread row is discarded when a new row for that thread is added. When a thread ends, all its rows are discarded.

The Performance Schema autosizes the value of $N$ during server startup. To set the number of rows per thread explicitly, set the `performance_schema_events_waits_history_size` system variable at server startup.

The `events_waits_history` table has the same columns as `events_waits_current`. See Section 22.12.4.1, “The events_waits_current Table”.

`TRUNCATE TABLE` is permitted for the `events_waits_history` table. It removes the rows.

For more information about the relationship between the three wait event tables, see Section 22.9, “Performance Schema Tables for Current and Historical Events”.

For information about configuring whether to collect wait events, see Section 22.12.4, “Performance Schema Wait Event Tables”.

22.12.4.3 The events_waits_history_long Table

The `events_waits_history_long` table contains $N$ the most recent wait events that have ended globally, across all threads. Wait events are not added to the table until they have ended. When the table becomes full, the oldest row is discarded when a new row is added, regardless of which thread generated either row.

The Performance Schema autosizes the value of $N$ during server startup. To set the table size explicitly, set the `performance_schema_events_waits_history_long_size` system variable at server startup.

The `events_waits_history_long` table has the same columns as `events_waits_current`. See Section 22.12.4.1, “The events_waits_current Table”.

`TRUNCATE TABLE` is permitted for the `events_waits_history_long` table. It removes the rows.

For more information about the relationship between the three wait event tables, see Section 22.9, “Performance Schema Tables for Current and Historical Events”.

For information about configuring whether to collect wait events, see Section 22.12.4, “Performance Schema Wait Event Tables”.

22.12.5 Performance Schema Stage Event Tables

The Performance Schema instruments stages, which are steps during the statement-execution process, such as parsing a statement, opening a table, or performing a `filesort` operation. Stages correspond to the thread states displayed by `SHOW PROCESSTLIST` or that are visible in the `INFORMATION_SCHEMA.PROCESSLIST` table. Stages begin and end when state values change.

Within the event hierarchy, wait events nest within stage events, which nest within statement events.

These tables store stage events:

- `events_stages_current`: The current stage event for each thread.
• **events_stages_history**: The most recent stage events that have ended per thread.

• **events_stages_history_long**: The most recent stage events that have ended globally (across all threads).

The following sections describe the stage event tables. There are also summary tables that aggregate information about stage events; see Section 22.12.9.2, “Stage Summary Tables”.

For more information about the relationship between the three stage event tables, see Section 22.9, “Performance Schema Tables for Current and Historical Events”.

### Configuring Stage Event Collection

To control whether to collect stage events, set the state of the relevant instruments and consumers:

• The `setup_instruments` table contains instruments with names that begin with `stage`. Use these instruments to enable or disable collection of individual stage event classes.

• The `setup_consumers` table contains consumer values with names corresponding to the current and historical stage event table names. Use these consumers to filter collection of stage events.

The stage instruments are disabled by default. For example:

```sql
mysql> SELECT *
FROM performance_schema.setup_instruments
WHERE NAME RLIKE 'stage/sql/[a-c]';
```

```
| NAME                                               | ENABLED | TIMED |
|----------------------------------------------------+---------+-------|
| stage/sql/After create                             | NO      | NO    |
| stage/sql/allocating local table                   | NO      | NO    |
| stage/sql/altering table                           | NO      | NO    |
| stage/sql/committing alter table to storage engine  | NO      | NO    |
| stage/sql/Changing master                          | NO      | NO    |
| stage/sql/Checking master version                   | NO      | NO    |
| stage/sql/checking permissions                      | NO      | NO    |
| stage/sql/checking privileges on cached query       | NO      | NO    |
| stage/sql/checking query cache for query           | NO      | NO    |
| stage/sql/cleaning up                               | NO      | NO    |
| stage/sql/closing tables                            | NO      | NO    |
| stage/sql/Connecting to master                      | NO      | NO    |
| stage/sql/converting HEAP to MyISAM                 | NO      | NO    |
| stage/sql/Copying to group table                    | NO      | NO    |
| stage/sql/Copying to tmp table                      | NO      | NO    |
| stage/sql/copy to tmp table                         | NO      | NO    |
| stage/sql/Creating delayed handler                  | NO      | NO    |
| stage/sql/Creating sort index                       | NO      | NO    |
| stage/sql/Creating table                            | NO      | NO    |
| stage/sql/Creating tmp table                        | NO      | NO    |
```

The stage consumers are disabled by default:

```sql
mysql> SELECT *
FROM performance_schema.setup_consumers
WHERE NAME LIKE 'events_stages%';
```

```
| NAME                       | ENABLED |
|----------------------------+---------|
| events_stages_current      | NO      |
| events_stages_history      | NO      |
```
To control stage event collection at server startup, use lines like these in your *my.cnf* file:

- **Enable:**

```sql
[mysqld]
performance-schema-instrument='stage/%=ON'
performance-schema-consumer-events-stages-current=ON
performance-schema-consumer-events-stages-history=ON
performance-schema-consumer-events-stages-history-long=ON
```

- **Disable:**

```sql
[mysqld]
performance-schema-instrument='stage/%=OFF'
performance-schema-consumer-events-stages-current=OFF
performance-schema-consumer-events-stages-history=OFF
performance-schema-consumer-events-stages-history-long=OFF
```

To control stage event collection at runtime, update the *setup_instruments* and *setup_consumers* tables:

- **Enable:**

```sql
UPDATE performance_schema.setup_instruments
SET ENABLED = 'YES', TIMED = 'YES'
WHERE NAME = 'stage/%';

UPDATE performance_schema.setup_consumers
SET ENABLED = 'YES'
WHERE NAME LIKE 'events_stages%';
```

- **Disable:**

```sql
UPDATE performance_schema.setup_instruments
SET ENABLED = 'NO', TIMED = 'NO'
WHERE NAME = 'stage/%';

UPDATE performance_schema.setup_consumers
SET ENABLED = 'NO'
WHERE NAME LIKE 'events_stages%';
```

To collect only specific stage events, enable only the corresponding stage instruments. To collect stage events only for specific stage event tables, enable the stage instruments but only the stage consumers corresponding to the desired tables.

- **Enable:**

```sql
UPDATE performance_schema.setup_instruments
SET ENABLED = 'YES', TIMED = 'YES'
WHERE NAME = 'stage/%';

UPDATE performance_schema.setup_consumers
SET ENABLED = 'YES'
WHERE NAME LIKE 'events_stages%';
```

- **Disable:**

```sql
UPDATE performance_schema.setup_instruments
SET ENABLED = 'NO', TIMED = 'NO'
WHERE NAME = 'stage/%';

UPDATE performance_schema.setup_consumers
SET ENABLED = 'NO'
WHERE NAME LIKE 'events_stages%';
```

The *setup_timers* table contains a row with a *NAME* value of *stage* that indicates the unit for stage event timing. The default unit is *NANOSECOND*:

```sql
mysql> SELECT * FROM performance_schema.setup_timers WHERE NAME = 'stage';
+---------+------------+
| NAME    | TIMER_NAME |
|---------+------------+
| stage   | NANOSECOND |
```

3368
To change the timing unit, modify the `TIMER_NAME` value:

```
UPDATE performance_schema.setup_timers
SET TIMER_NAME = 'MICROSECOND'
WHERE NAME = 'stage';
```

For additional information about configuring event collection, see Section 22.3, “Performance Schema Startup Configuration”, and Section 22.4, “Performance Schema Runtime Configuration”.

### 22.12.5.1 The `events_stages_current` Table

The `events_stages_current` table contains current stage events. The table stores one row per thread showing the current status of the thread’s most recent monitored stage event, so there is no system variable for configuring the table size.

Of the tables that contain stage event rows, `events_stages_current` is the most fundamental. Other tables that contain stage event rows are logically derived from the current events. For example, the `events_stages_history` and `events_stages_history_long` tables are collections of the most recent stage events that have ended, up to a maximum number of rows per thread and globally across all threads, respectively.

For more information about the relationship between the three stage event tables, see Section 22.9, “Performance Schema Tables for Current and Historical Events”.

For information about configuring whether to collect stage events, see Section 22.12.5, “Performance Schema Stage Event Tables”.

The `events_stages_current` table has these columns:

- **THREAD_ID, EVENT_ID**
  
  The thread associated with the event and the thread current event number when the event starts. The `THREAD_ID` and `EVENT_ID` values taken together uniquely identify the row. No two rows have the same pair of values.

- **END_EVENT_ID**
  
  This column is set to `NULL` when the event starts and updated to the thread current event number when the event ends.

- **EVENT_NAME**
  
  The name of the instrument that produced the event. This is a `NAME` value from the `setup_instruments` table. Instrument names may have multiple parts and form a hierarchy, as discussed in Section 22.6, “Performance Schema Instrument Naming Conventions”.

- **SOURCE**
  
  The name of the source file containing the instrumented code that produced the event and the line number in the file at which the instrumentation occurs. This enables you to check the source to determine exactly what code is involved.

- **TIMER_START, TIMER_END, TIMER_WAIT**
  
  Timing information for the event. The unit for these values is picoseconds (trillionths of a second). The `TIMER_START` and `TIMER_END` values indicate when event timing started and ended. `TIMER_WAIT` is the event elapsed time (duration).
If an event has not finished, `TIMER_END` and `TIMER_WAIT` are `NULL` before MySQL 5.6.26. As of 5.6.26, `TIMER_END` is the current timer value and `TIMER_WAIT` is the time elapsed so far (`TIMER_END - TIMER_START`).

If an event is produced from an instrument that has `TIMED = NO`, timing information is not collected, and `TIMER_START`, `TIMER_END`, and `TIMER_WAIT` are all `NULL`.

For discussion of picoseconds as the unit for event times and factors that affect time values, see Section 22.4.1, “Performance Schema Event Timing”.

- **NESTING_EVENT_ID**

  The `EVENT_ID` value of the event within which this event is nested. The nesting event for a stage event is usually a statement event.

- **NESTING_EVENT_TYPE**

  The nesting event type. The value is `STATEMENT`, `STAGE`, or `WAIT`.

`TRUNCATE TABLE` is permitted for the `events_stages_current` table. It removes the rows.

### 22.12.5.2 The `events_stages_history` Table

The `events_stages_history` table contains the `N` most recent stage events that have ended per thread. Stage events are not added to the table until they have ended. When the table contains the maximum number of rows for a given thread, the oldest thread row is discarded when a new row for that thread is added. When a thread ends, all its rows are discarded.

The Performance Schema autosizes the value of `N` during server startup. To set the number of rows per thread explicitly, set the `performance_schema_events_stages_history_size` system variable at server startup.

The `events_stages_history` table has the same columns as `events_stages_current`. See Section 22.12.5.1, “The `events_stages_current` Table”.

`TRUNCATE TABLE` is permitted for the `events_stages_history` table. It removes the rows.

For more information about the relationship between the three stage event tables, see Section 22.9, “Performance Schema Tables for Current and Historical Events”.

For information about configuring whether to collect stage events, see Section 22.12.5, “Performance Schema Stage Event Tables”.

### 22.12.5.3 The `events_stages_history_long` Table

The `events_stages_history_long` table contains the `N` most recent stage events that have ended globally, across all threads. Stage events are not added to the table until they have ended. When the table becomes full, the oldest row is discarded when a new row is added, regardless of which thread generated either row.

The Performance Schema autosizes the value of `N` during server startup. To set the table size explicitly, set the `performance_schema_events_stages_history_long_size` system variable at server startup.

The `events_stages_history_long` table has the same columns as `events_stages_current`. See Section 22.12.5.1, “The `events_stages_current` Table”.
TRUNCATE TABLE is permitted for the events_stages_history_long table. It removes the rows.

For more information about the relationship between the three stage event tables, see Section 22.9, “Performance Schema Tables for Current and Historical Events”.

For information about configuring whether to collect stage events, see Section 22.12.5, “Performance Schema Stage Event Tables”.

22.12.6 Performance Schema Statement Event Tables

The Performance Schema instruments statement execution. Statement events occur at a high level of the event hierarchy: Wait events nest within stage events, which nest within statement events.

These tables store statement events:

• **events_statements_current**: The current statement event for each thread.

• **events_statements_history**: The most recent statement events that have ended per thread.

• **events_statements_history_long**: The most recent statement events that have ended globally (across all threads).

The following sections describe the statement event tables. There are also summary tables that aggregate information about statement events; see Section 22.12.9.3, “Statement Summary Tables”.

For more information about the relationship between the three events_statements_XXX event tables, see Section 22.9, “Performance Schema Tables for Current and Historical Events”.

Configuring Statement Event Collation

To control whether to collect statement events, set the state of the relevant instruments and consumers:

- The setup_instruments table contains instruments with names that begin with statement. Use these instruments to enable or disable collection of individual statement event classes.

- The setup_consumers table contains consumer values with names corresponding to the current and historical statement event table names, and the statement digest consumer. Use these consumers to filter collection of statement events and statement digesting.

The statement instruments are enabled by default, and the events_statements_current and statements_digest statement consumers are enabled by default:

```sql
mysql> SELECT * FROM performance_schema.setup_instruments
    WHERE NAME LIKE 'statement/%';
+---------------------------------------------+---------+-------+
| NAME                                        | ENABLED | TIMED |
+---------------------------------------------+---------+-------+
| statement/sql/select                        | YES     | YES   |
| statement/sql/create_table                  | YES     | YES   |
| statement/sql/create_index                  | YES     | YES   |
| ...                                         |         |       |
| statement/sp/stmt                           | YES     | YES   |
| statement/sp/set                            | YES     | YES   |
| statement/sp/set_trigger_field              | YES     | YES   |
| statement/scheduler/event                   | YES     | YES   |
| statement/com.Sleep                         | YES     | YES   |
| statement/com/Quit                          | YES     | YES   |
| statement/com/Init_DB                       | YES     | YES   |
```
Performance Schema Statement Event Tables

<table>
<thead>
<tr>
<th>statement/abstract/Query</th>
<th>YES</th>
<th>YES</th>
</tr>
</thead>
<tbody>
<tr>
<td>statement/abstract/new_packet</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>statement/abstract/relay_log</td>
<td>YES</td>
<td>YES</td>
</tr>
</tbody>
</table>

mysql> SELECT * FROM performance_schema.setup_consumers WHERE NAME LIKE '%statements%';

+--------------------------------+---------+
| NAME                           | ENABLED |
|--------------------------------+---------+
| events_statements_current      | YES     |
| events_statements_history      | NO      |
| events_statements_history_long | NO      |
| statements_digest              | YES     |

To control statement event collection at server startup, use lines like these in your `my.cnf` file:

- **Enable**:
  ```
  [mysqld]
  performance-schema-instrument='statement/%=ON'
  performance-schema-consumer-events-statements-current=ON
  performance-schema-consumer-events-statements-history=ON
  performance-schema-consumer-events-statements-history-long=ON
  performance-schema-consumer-statements-digest=ON
  ```

- **Disable**:
  ```
  [mysqld]
  performance-schema-instrument='statement/%=OFF'
  performance-schema-consumer-events-statements-current=OFF
  performance-schema-consumer-events-statements-history=OFF
  performance-schema-consumer-events-statements-history-long=OFF
  performance-schema-consumer-statements-digest=OFF
  ```

To control statement event collection at runtime, update the `setup_instruments` and `setup_consumers` tables:

- **Enable**:
  ```
  UPDATE performance_schema.setup_instruments
  SET ENABLED = 'YES', TIMED = 'YES'
  WHERE NAME LIKE '%statement/%';
  UPDATE performance_schema.setup_consumers
  SET ENABLED = 'YES'
  WHERE NAME LIKE '%statements%';
  ```

- **Disable**:
  ```
  UPDATE performance_schema.setup_instruments
  SET ENABLED = 'NO', TIMED = 'NO'
  WHERE NAME LIKE '%statement/%';
  UPDATE performance_schema.setup_consumers
  SET ENABLED = 'NO'
  WHERE NAME LIKE '%statements%';
  ```
To collect only specific statement events, enable only the corresponding statement instruments. To collect statement events only for specific statement event tables, enable the statement instruments but only the statement consumers corresponding to the desired tables.

The `setup_timers` table contains a row with a `NAME` value of `statement` that indicates the unit for statement event timing. The default unit is `NANOSECOND`:

```sql
mysql> SELECT * FROM performance_schema.setup_timers WHERE NAME = 'statement';
+-----------+------------+
| NAME      | TIMER_NAME |
+-----------+------------+
| statement | NANOSECOND |
+-----------+------------+
```

To change the timing unit, modify the `TIMER_NAME` value:

```
UPDATE performance_schema.setup_timers SET TIMER_NAME = 'MICROSECOND' WHERE NAME = 'statement';
```

For additional information about configuring event collection, see Section 22.3, “Performance Schema Startup Configuration”, and Section 22.4, “Performance Schema Runtime Configuration”.

**Statement Monitoring**

Statement monitoring begins from the moment the server sees that activity is requested on a thread, to the moment when all activity has ceased. Typically, this means from the time the server gets the first packet from the client to the time the server has finished sending the response. Monitoring occurs only for top-level statements. Statements within stored programs and subqueries are not seen separately.

When the Performance Schema instruments a request (server command or SQL statement), it uses instrument names that proceed in stages from more general (or “abstract”) to more specific until it arrives at a final instrument name.

Final instrument names correspond to server commands and SQL statements:

- Server commands correspond to the `COM_xxx` codes defined in the `mysql_com.h` header file and processed in `sql/sql_parse.cc`. Examples are `COM_PING` and `COM_QUIT`. Instruments for commands have names that begin with `statement/com`, such as `statement/com/Ping` and `statement/com/Quit`.

- SQL statements are expressed as text, such as `DELETE FROM t1` or `SELECT * FROM t2`. Instruments for SQL statements have names that begin with `statement/sql`, such as `statement/sql/delete` and `statement/sql/select`.

Some final instrument names are specific to error handling:

- `statement/com/Error` accounts for messages received by the server that are out of band. It can be used to detect commands sent by clients that the server does not understand. This may be helpful for purposes such as identifying clients that are misconfigured or using a version of MySQL more recent than that of the server, or clients that are attempting to attack the server.

- `statement/sql/error` accounts for SQL statements that fail to parse. It can be used to detect malformed queries sent by clients. A query that fails to parse differs from a query that parses but fails due to an error during execution. For example, `SELECT * FROM` is malformed, and the `statement/`
The sql/error instrument is used. By contrast, SELECT * parses but fails with a No tables used error. In this case, statement/sql/select is used and the statement event contains information to indicate the nature of the error.

A request can be obtained from any of these sources:

- As a command or statement request from a client, which sends the request as packets
- As a statement string read from the relay log on a replication slave

The details for a request are not initially known and the Performance Schema proceeds from abstract to specific instrument names in a sequence that depends on the source of the request.

For a request received from a client:

1. When the server detects a new packet at the socket level, a new statement is started with an abstract instrument name of statement/abstract/new_packet.

2. When the server reads the packet number, it knows more about the type of request received, and the Performance Schema refines the instrument name. For example, if the request is a COM_PING packet, the instrument name becomes statement/com/Ping and that is the final name. If the request is a COM_QUERY packet, it is known to correspond to an SQL statement but not the particular type of statement. In this case, the instrument changes from one abstract name to a more specific but still abstract name, statement/abstract/Query, and the request requires further classification.

3. If the request is a statement, the statement text is read and given to the parser. After parsing, the exact statement type is known. If the request is, for example, an INSERT statement, the Performance Schema refines the instrument name from statement/abstract/Query to statement/sql/insert, which is the final name.

For a request read as a statement from the relay log on a replication slave:

1. Statements in the relay log are stored as text and are read as such. There is no network protocol, so the statement/abstract/new_packet instrument is not used. Instead, the initial instrument is statement/abstract/relay_log.

2. When the statement is parsed, the exact statement type is known. If the request is, for example, an INSERT statement, the Performance Schema refines the instrument name from statement/abstract/Query to statement/sql/insert, which is the final name.

The preceding description applies only for statement-based replication. For row-based replication, table I/O done on the slave as it processes row changes can be instrumented, but row events in the relay log do not appear as discrete statements.

For statistics to be collected for statements, it is not sufficient to enable only the final statement/sql/* instruments used for individual statement types. The abstract statement/abstract/* instruments must be enabled as well. This should not normally be an issue because all statement instruments are enabled by default. However, an application that enables or disables statement instruments selectively must take into account that disabling abstract instruments also disables statistics collection for the individual statement instruments. For example, to collect statistics for INSERT statements, statement/sql/insert must be enabled, but also statement/abstract/new_packet and statement/abstract/Query. Similarly, for replicated statements to be instrumented, statement/abstract/relay_log must be enabled.

No statistics are aggregated for abstract instruments such as statement/abstract/Query because no statement is ever classified with an abstract instrument as the final statement name.
The abstract instrument names in the preceding discussion are as of MySQL 5.6.15. In earlier 5.6 versions, there was some renaming before those names were settled on:

- `statement/abstract/new_packet` was `statement/com/` in MySQL 5.6.14, `statement/com/` in MySQL 5.6.13, and `statement/com/` before that.
- `statement/abstract/Query` was `statement/com/Query` before MySQL 5.6.15.
- `statement/abstract/relay_log` was `statement/rpl/relay_log` from MySQL 5.6.13 to 5.6.14 and did not exist before that.

### 22.12.6.1 The `events_statements_current` Table

The `events_statements_current` table contains current statement events. The table stores one row per thread showing the current status of the thread's most recent monitored statement event, so there is no system variable for configuring the table size.

Of the tables that contain statement event rows, `events_statements_current` is the most fundamental. Other tables that contain statement event rows are logically derived from the current events. For example, the `events_statements_history` and `events_statements_history_long` tables are collections of the most recent statement events that have ended, up to a maximum number of rows per thread and globally across all threads, respectively.

For more information about the relationship between the three `events_statements_***` event tables, see Section 22.9, “Performance Schema Tables for Current and Historical Events”.

For information about configuring whether to collect statement events, see Section 22.12.6, “Performance Schema Statement Event Tables”.

The `events_statements_current` table has these columns:

- **THREAD_ID, EVENT_ID**
  
The thread associated with the event and the thread current event number when the event starts. The `THREAD_ID` and `EVENT_ID` values taken together uniquely identify the row. No two rows have the same pair of values.

- **END_EVENT_ID**
  
  This column is set to `NULL` when the event starts and updated to the thread current event number when the event ends.

- **EVENT_NAME**
  
The name of the instrument from which the event was collected. This is a `NAME` value from the `setup_instruments` table. Instrument names may have multiple parts and form a hierarchy, as discussed in Section 22.6, “Performance Schema Instrument Naming Conventions”.

  For SQL statements, the `EVENT_NAME` value initially is `statement/com/Query` until the statement is parsed, then changes to a more appropriate value, as described in Section 22.12.6, “Performance Schema Statement Event Tables”.

- **SOURCE**
  
The name of the source file containing the instrumented code that produced the event and the line number in the file at which the instrumentation occurs. This enables you to check the source to determine exactly what code is involved.
• **TIMER_START, TIMER_END, TIMER_WAIT**

Timing information for the event. The unit for these values is picoseconds (trillionths of a second). The `TIMER_START` and `TIMER_END` values indicate when event timing started and ended. `TIMER_WAIT` is the event elapsed time (duration).

If an event has not finished, `TIMER_END` and `TIMER_WAIT` are `NULL` before MySQL 5.6.26. As of 5.6.26, `TIMER_END` is the current timer value and `TIMER_WAIT` is the time elapsed so far (`TIMER_END - TIMER_START`).

If an event is produced from an instrument that has `TIMED = NO`, timing information is not collected, and `TIMER_START`, `TIMER_END`, and `TIMER_WAIT` are all `NULL`.

For discussion of picoseconds as the unit for event times and factors that affect time values, see Section 22.4.1, “Performance Schema Event Timing”.

• **LOCK_TIME**

The time spent waiting for table locks. This value is computed in microseconds but normalized to picoseconds for easier comparison with other Performance Schema timers.

• **SQL_TEXT**

The text of the SQL statement. For a command not associated with an SQL statement, the value is `NULL`. The maximum space available for statement display is 1024 bytes.

• **DIGEST**

The statement digest MD5 value as a string of 32 hexadecimal characters, or `NULL` if the `statements_digest` consumer is `no`. For more information about statement digesting, see Section 22.10, “Performance Schema Statement Digests”.

• **DIGEST_TEXT**

The normalized statement digest text, or `NULL` if the `statements_digest` consumer is `no`. For more information about statement digesting, see Section 22.10, “Performance Schema Statement Digests”.

The `performance_schema_max_digest_length` system variable determines the maximum number of bytes available per session for digest value storage. However, the display length of statement digests may be longer than the available buffer size due to encoding of statement components such as keywords and literal values in digest buffer. Consequently, values selected from the `DIGEST_TEXT` column of statement event tables may appear to exceed the `performance_schema_max_digest_length` value.

`performance_schema_max_digest_length` was added in MySQL 5.6.26. In MySQL 5.6.24 and 5.6.25, `performance_schema_max_digest_length` is not available and the `max_digest_length` value determines the maximum number of bytes available for digest value storage. Before MySQL 5.6.24, neither `max_digest_length` nor `performance_schema_max_digest_length` are available and a fixed maximum of 1024 bytes is available for digest value storage.

• **CURRENT_SCHEMA**

The default database for the statement, `NULL` if there is none.

• **OBJECT_SCHEMA, OBJECT_NAME, OBJECT_TYPE**

Reserved. Always `NULL`.
Performance Schema Statement Event Tables

- **OBJECT_INSTANCE_BEGIN**
  This column identifies the statement. The value is the address of an object in memory.

- **MYSQL_ERRNO**
  The statement error number, from the statement diagnostics area.

- **RETURNED_SQLSTATE**
  The statement SQLSTATE value, from the statement diagnostics area.

- **MESSAGE_TEXT**
  The statement error message, from the statement diagnostics area.

- **ERRORS**
  Whether an error occurred for the statement. The value is 0 if the SQLSTATE value begins with `00` (completion) or `01` (warning). The value is 1 is the SQLSTATE value is anything else.

- **WARNINGS**
  The number of warnings, from the statement diagnostics area.

- **ROWS_AFFECTED**
  The number of rows affected by the statement. For a description of the meaning of “affected,” see Section 23.8.7.1, “mysql_affected_rows(“).

- **ROWS_SENT**
  The number of rows returned by the statement.

- **ROWS_EXAMINED**
  The number of rows examined by the server layer (not counting any processing internal to storage engines).

- **CREATED_TMP_DISK_TABLES**
  Like the `Created_tmp_disk_tables` status variable, but specific to the statement.

- **CREATED_TMP_TABLES**
  Like the `Created_tmp_tables` status variable, but specific to the statement.

- **SELECT_FULL_JOIN**
  Like the `Select_full_join` status variable, but specific to the statement.

- **SELECT_FULL_RANGE_JOIN**
  Like the `Select_full_range_join` status variable, but specific to the statement.

- **SELECT_RANGE**
  Like the `Select_range` status variable, but specific to the statement.

- **SELECT_RANGE_CHECK**
Like the `Select_range_check` status variable, but specific to the statement.

- **SELECT_SCAN**
  Like the `Select_scan` status variable, but specific to the statement.

- **SORT_MERGE_PASSES**
  Like the `Sort_merge_passes` status variable, but specific to the statement.

- **SORT_RANGE**
  Like the `Sort_range` status variable, but specific to the statement.

- **SORT_ROWS**
  Like the `Sort_rows` status variable, but specific to the statement.

- **SORT_SCAN**
  Like the `Sort_scan` status variable, but specific to the statement.

- **NO_INDEX_USED**
  1 if the statement performed a table scan without using an index, 0 otherwise.

- **NO_GOOD_INDEX_USED**
  1 if the server found no good index to use for the statement, 0 otherwise. For additional information, see the description of the `Extra` column from `EXPLAIN` output for the `Range checked for each record value` in Section 8.8.2, “EXPLAIN Output Format”.

- **NESTING_EVENT_ID, NESTING_EVENT_TYPE**
  Reserved. Always `NULL`.

`TRUNCATE TABLE` is permitted for the `events_statements_current` table. It removes the rows.

### 22.12.6.2 The `events_statements_history` Table

The `events_statements_history` table contains the `N` most recent statement events that have ended per thread. Statement events are not added to the table until they have ended. When the table contains the maximum number of rows for a given thread, the oldest thread row is discarded when a new row for that thread is added. When a thread ends, all its rows are discarded.

The Performance Schema autosizes the value of `N` during server startup. To set the number of rows per thread explicitly, set the `performance_schema_events_statements_history_size` system variable at server startup.

The `events_statements_history` table has the same columns as `events_statements_current`. See Section 22.12.6.1, “The `events_statements_current` Table”.

`TRUNCATE TABLE` is permitted for the `events_statements_history` table. It removes the rows.

For more information about the relationship between the three `events_statements_XXX` event tables, see Section 22.9, “Performance Schema Tables for Current and Historical Events”.

3378
Performance Schema Connection Tables

For information about configuring whether to collect statement events, see Section 22.12.6, “Performance Schema Statement Event Tables”.

22.12.6.3 The events_statements_history_long Table

The `events_statements_history_long` table contains the $N$ most recent statement events that have ended globally, across all threads. Statement events are not added to the table until they have ended. When the table becomes full, the oldest row is discarded when a new row is added, regardless of which thread generated either row.

The value of $N$ is autosized at server startup. To set the table size explicitly, set the `performance_schema_events_statements_history_long_size` system variable at server startup.

The `events_statements_history_long` table has the same columns as `events_statements_current`. See Section 22.12.6.1, “The events_statements_current Table”.

`TRUNCATE TABLE` is permitted for the `events_statements_history_long` table. It removes the rows.

For more information about the relationship between the three `events_statements_`xxx event tables, see Section 22.9, “Performance Schema Tables for Current and Historical Events”.

For information about configuring whether to collect statement events, see Section 22.12.6, “Performance Schema Statement Event Tables”.

22.12.7 Performance Schema Connection Tables

When a client connects to the MySQL server, it does so under a particular user name and from a particular host. The Performance Schema provides statistics about these connections, tracking them per account (user and host combination) as well as separately per user name and host name, using these tables:

- **accounts**: Connection statistics per client account
- **hosts**: Connection statistics per client host name
- **users**: Connection statistics per client user name

The meaning of “account” in the connection tables is similar to its meaning in the MySQL grant tables in the `mysql` system database, in the sense that the term refers to a combination of user and host values. They differ in that, for grant tables, the host part of an account can be a pattern, whereas for Performance Schema tables, the host value is always a specific nonpattern host name.

Each connection table has `CURRENT_CONNECTIONS` and `TOTAL_CONNECTIONS` columns to track the current and total number of connections per “tracking value” on which its statistics are based. The tables differ in what they use for the tracking value. The `accounts` table has `USER` and `HOST` columns to track connections per user and host combination. The `users` and `hosts` tables have a `USER` and `HOST` column, respectively, to track connections per user name and host name.

The Performance Schema also counts internal threads and threads for user sessions that failed to authenticate, using rows with `USER` and `HOST` column values of `NULL`.

Suppose that clients named `user1` and `user2` each connect one time from `hosta` and `hostb`. The Performance Schema tracks the connections as follows:

- The `accounts` table has four rows, for the `user1/hosta`, `user1/hostb`, `user2/hosta`, and `user2/hostb` account values, each row counting one connection per account.
• The **hosts** table has two rows, for **hosta** and **hostb**, each row counting two connections per host name.

• The **users** table has two rows, for **user1** and **user2**, each row counting two connections per user name.

When a client connects, the Performance Schema determines which row in each connection table applies, using the tracking value appropriate to each table. If there is no such row, one is added. Then the Performance Schema increments by one the **CURRENT_CONNECTIONS** and **TOTAL_CONNECTIONS** columns in that row.

When a client disconnects, the Performance Schema decrements by one the **CURRENT_CONNECTIONS** column in the row and leaves the **TOTAL_CONNECTIONS** column unchanged.

**TRUNCATE TABLE** is permitted for connection tables. It has these effects:

• Rows are removed for accounts, hosts, or users that have no current connections (rows with **CURRENT_CONNECTIONS** = 0).

• Nonremoved rows are reset to count only current connections: For rows with **CURRENT_CONNECTIONS** > 0, **TOTAL_CONNECTIONS** is reset to **CURRENT_CONNECTIONS**.

• Summary tables that depend on the connection table are implicitly truncated, as described later in this section.

The Performance Schema maintains summary tables that aggregate connection statistics for various event types by account, host, or user. These tables have **_summary_by_account**, **_summary_by_host**, or **_summary_by_user** in the name. To identify them, use this query:

```sql
mysql> SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
    WHERE TABLE_SCHEMA = 'performance_schema'
    AND TABLE_NAME REGEXP '_summary_by_(account|host|user)'
    ORDER BY TABLE_NAME;
```

For details about individual connection summary tables, consult the section that describes tables for the summarized event type:

• Wait event summaries: Section 22.12.9.1, “Wait Event Summary Tables”

• Stage event summaries: Section 22.12.9.2, “Stage Summary Tables”

• Statement event summaries: Section 22.12.9.3, “Statement Summary Tables”

**TRUNCATE TABLE** is permitted for connection summary tables. It removes rows for accounts, hosts, or users with no connections, and resets the summary columns to zero for the remaining rows. In addition, each summary table that is aggregated by account, host, user, or thread is implicitly truncated.
by truncation of the connection table on which it depends. The following table describes the relationship
between connection table truncation and implicitly truncated tables.

Table 22.2 Implicit Effects of Connection Table Truncation

<table>
<thead>
<tr>
<th>Truncated Connection Table</th>
<th>Implicitly Truncated Summary Tables</th>
</tr>
</thead>
<tbody>
<tr>
<td>accounts</td>
<td>Tables with names containing _summary_by_account, _summary_by_thread</td>
</tr>
<tr>
<td>hosts</td>
<td>Tables with names containing _summary_by_account, _summary_by_host, _summary_by_thread</td>
</tr>
<tr>
<td>users</td>
<td>Tables with names containing _summary_by_account, _summary_by_user, _summary_by_thread</td>
</tr>
</tbody>
</table>

Truncating a _summary_global summary table also implicitly truncates its corresponding connection and
thread summary tables. For example, truncating events_waits_summary_global_by_event_name
implicitly truncates the wait event summary tables that are aggregated by account, host, user, or thread.

22.12.7.1 The accounts Table

The accounts table contains a row for each account that has connected to the MySQL server. For each
account, the table counts the current and total number of connections. The table size is autosized at server
startup. To set the table size explicitly, set the performance_schema_accounts_size system variable
at server startup. To disable account statistics, set this variable to 0.

The accounts table has the following columns. For a description of how the Performance Schema
maintains rows in this table, including the effect of TRUNCATE TABLE, see Section 22.12.7, “Performance
Schema Connection Tables”:

• USER
  The client user name for the connection. This is NULL for an internal thread, or for a user session that
  failed to authenticate.

• HOST
  The host from which the client connected. This is NULL for an internal thread, or for a user session that
  failed to authenticate.

• CURRENT_CONNECTIONS
  The current number of connections for the account.

• TOTAL_CONNECTIONS
  The total number of connections for the account.

22.12.7.2 The hosts Table

The hosts table contains a row for each host from which clients have connected to the MySQL server. For
each host name, the table counts the current and total number of connections. The table size is autosized
at server startup. To set the table size explicitly, set the performance_schema_hosts_size system variable
at server startup. To disable host statistics, set this variable to 0.

The hosts table has the following columns. For a description of how the Performance Schema maintains
rows in this table, including the effect of TRUNCATE TABLE, see Section 22.12.7, “Performance Schema
Connection Tables”.

3381
Performance Schema Connection Attribute Tables

- **HOST**
The host from which the client connected. This is NULL for an internal thread, or for a user session that failed to authenticate.

- **CURRENT_CONNECTIONS**
The current number of connections for the host.

- **TOTAL_CONNECTIONS**
The total number of connections for the host.

### 22.12.7.3 The users Table

The `users` table contains a row for each user who has connected to the MySQL server. For each user name, the table counts the current and total number of connections. The table size is autosized at server startup. To set the table size explicitly, set the `performance_schema_users_size` system variable at server startup. To disable user statistics, set this variable to 0.

The `users` table has the following columns. For a description of how the Performance Schema maintains rows in this table, including the effect of `TRUNCATE TABLE`, see Section 22.12.7, “Performance Schema Connection Tables”.

- **USER**
The client user name for the connection. This is NULL for an internal thread, or for a user session that failed to authenticate.

- **CURRENT_CONNECTIONS**
The current number of connections for the user.

- **TOTAL_CONNECTIONS**
The total number of connections for the user.

### 22.12.8 Performance Schema Connection Attribute Tables

Connection attributes are key-value pairs that application programs can pass to the server at connect time. For applications based on the C API implemented by the `libmysqlclient` client library, the `mysql_options()` and `mysql_options4()` functions define the connection attribute set. Other MySQL Connectors may provide their own attribute-definition methods.

These Performance Schema tables expose attribute information:

- **session_account_connect_attrs**: Connection attributes for the current session, and other sessions associated with the session account

- **session_connect_attrs**: Connection attributes for all sessions

Attribute names that begin with an underscore (_) are reserved for internal use and should not be created by application programs. This convention permits new attributes to be introduced by MySQL without colliding with application attributes, and enables application programs to define their own attributes that do not collide with internal attributes.

- **Available Connection Attributes**
• **Connection Attribute Limits**

**Available Connection Attributes**

The set of connection attributes visible within a given connection varies depending on factors such as your platform, MySQL Connector used to establish the connection, or client program.

The `libmysqlclient` client library (provided in MySQL and MySQL Connector/C distributions) sets these attributes:

- `_client_name`: The client name (`libmysql` for the client library).
- `_client_version`: The client library version.
- `_os`: The operating system (for example, `Linux`, `Win64`).
- `_pid`: The client process ID.
- `_platform`: The machine platform (for example, `x86_64`).
- `_thread`: The client thread ID (Windows only).

Other MySQL Connectors may define their own connection attributes.

MySQL Connector/J defines these attributes:

- `_client_license`: The connector license type.
- `_runtime_vendor`: The Java runtime environment (JRE) vendor.
- `_runtime_version`: The Java runtime environment (JRE) version.

MySQL Connector/NET defines these attributes:

- `_client_version`: The client library version.
- `_os`: The operating system (for example, `Linux`, `Win64`).
- `_pid`: The client process ID.
- `_platform`: The machine platform (for example, `x86_64`).
- `_program_name`: The client name.
- `_thread`: The client thread ID (Windows only).

PHP defines attributes that depend on how it was compiled:

- Compiled using `libmysqlclient`: The standard `libmysqlclient` attributes, described previously.
- Compiled using `mysqlnd`: Only the `_client_name` attribute, with a value of `mysqlnd`.

Many MySQL client programs set a `program_name` attribute with a value equal to the client name. For example, `mysqladmin` and `mysqldump` set `program_name` to `mysqladmin` and `mysqldump`, respectively.

Some MySQL client programs define additional attributes:

- `mysqlbinlog`: 
  - `_client_role:binary_log_listener`
• Replication slave connections:
  • program_name: mysqld
  • _client_role: binary_log_listener
• FEDERATED storage engine connections:
  • program_name: mysqld
  • _client_role: federated_storage

Connection Attribute Limits

There are limits on the amount of connection attribute data transmitted from client to server:

• A fixed limit imposed by the client prior to connect time.
• A fixed limit imposed by the server at connect time.
• A configurable limit imposed by the Performance Schema at connect time.

For connections initiated using the C API, the libmysqlclient library imposes a limit of 64KB on the aggregate size of connection attribute data on the client side: Calls to mysql_options() that cause this limit to be exceeded produce a CR_INVALID_PARAMETER_NO error. Other MySQL Connectors may impose their own client-side limits on how much connection attribute data can be transmitted to the server.

On the server side, these size checks on connection attribute data occur:

• The server imposes a limit of 64KB on the aggregate size of connection attribute data it will accept. If a client attempts to send more than 64KB of attribute data, the server rejects the connection.
• For accepted connections, the Performance Schema checks aggregate attribute size against the value of the performance_schema_session_connect_attrs_size system variable. If attribute size exceeds this value, these actions take place:
  • The Performance Schema truncates the attribute data and increments the Performance_schema_session_connect_attrs_lost status variable, which indicates the number of connections for which attribute truncation occurred.
  • The Performance Schema writes a message to the error log if the log_warnings system variable is greater than zero:

   [Warning] Connection attributes of length \( N \) were truncated

22.12.8.1 The session_account_connect_attrs Table

Application programs can provide key-value connection attributes to be passed to the server at connect time. For descriptions of common attributes, see Section 22.12.8, “Performance Schema Connection Attribute Tables”.

The session_account_connect_attrs table contains connection attributes only for the current session, and other sessions associated with the session account. To see connection attributes for all sessions, use the session_connect_attrs table.

The session_account_connect_attrs table contains these columns:

• PROCESSLIST_ID
The connection identifier for the session.

- **ATTR_NAME**
  The attribute name.

- **ATTR_VALUE**
  The attribute value.

- **ORDINAL_POSITION**
  The order in which the attribute was added to the set of connection attributes.

**TRUNCATE TABLE** is not permitted for the `session_account_connect_attrs` table.

### 22.12.8.2 The `session_connect_attrs` Table

Application programs can provide key-value connection attributes to be passed to the server at connect time. For descriptions of common attributes, see Section 22.12.8, “Performance Schema Connection Attribute Tables”.

The `session_connect_attrs` table contains connection attributes for all sessions. To see connection attributes only for the current session, and other sessions associated with the session account, use the `session_account_connect_attrs` table.

The `session_connect_attrs` table contains these columns:

- **PROCESSLIST_ID**
  The connection identifier for the session.

- **ATTR_NAME**
  The attribute name.

- **ATTR_VALUE**
  The attribute value.

- **ORDINAL_POSITION**
  The order in which the attribute was added to the set of connection attributes.

**TRUNCATE TABLE** is not permitted for the `session_connect_attrs` table.

### 22.12.9 Performance Schema Summary Tables

Summary tables provide aggregated information for terminated events over time. The tables in this group summarize event data in different ways.

**Wait Event Summaries**

- **events_waits_summary_by_account_by_event_name**: Wait events per account and event name
- **events_waits_summary_by_host_by_event_name**: Wait events per host name and event name
- **events_waits_summary_by_instance**: Wait events per instance
Performance Schema Summary Tables

• `events_waits_summary_by_thread_by_event_name`: Wait events per thread and event name
• `events_waits_summary_by_user_by_event_name`: Wait events per user name and event name
• `events_waits_summary_global_by_event_name`: Wait events per event name

Stage Summaries

• `events_stages_summary_by_account_by_event_name`: Stage events per account and event name
• `events_stages_summary_by_host_by_event_name`: Stage events per host name and event name
• `events_stages_summary_by_thread_by_event_name`: Stage waits per thread and event name
• `events_stages_summary_by_user_by_event_name`: Stage events per user name and event name
• `events_stages_summary_global_by_event_name`: Stage waits per event name

Statement Summaries

• `events_statements_summary_by_account_by_event_name`: Statement events per account and event name
• `events_statements_summary_by_digest`: Statement events per schema and digest value
• `events_statements_summary_by_host_by_event_name`: Statement events per host name and event name
• `events_statements_summary_by_thread_by_event_name`: Statement events per thread and event name
• `events_statements_summary_by_user_by_event_name`: Statement events per user name and event name
• `events_statements_summary_global_by_event_name`: Statement events per event name

Object Wait Summaries

• `objects_summary_global_by_type`: Object summaries

File I/O Summaries

• `file_summary_by_event_name`: File events per event name
• `file_summary_by_instance`: File events per file instance

Table I/O and Lock Wait Summaries

• `table_io_waits_summary_by_index_usage`: Table I/O waits per index
• `table_io_waits_summary_by_table`: Table I/O waits per table
• `table_lock_waits_summary_by_table`: Table lock waits per table

Socket Summaries

• `socket_summary_by_instance`: Socket waits and I/O per instance
Performance Schema Summary Tables

- **socket_summary_by_event_name**: Socket waits and I/O per event name

Each summary table has grouping columns that determine how to group the data to be aggregated, and summary columns that contain the aggregated values. Tables that summarize events in similar ways often have similar sets of summary columns and differ only in the grouping columns used to determine how events are aggregated.

Summary tables can be truncated with `TRUNCATE TABLE`. Generally, the effect is to reset the summary columns to 0 or `NULL`, not to remove rows. This enables you to clear collected values and restart aggregation. That might be useful, for example, after you have made a runtime configuration change. Exceptions to this truncation behavior are noted in individual summary table sections.

### 22.12.9.1 Wait Event Summary Tables

The Performance Schema maintains tables for collecting current and recent wait events, and aggregates that information in summary tables. Section 22.12.4, “Performance Schema Wait Event Tables” describes the events on which wait summaries are based. See that discussion for information about the content of wait events, the current and recent wait event tables, and how to control wait event collection, which is disabled by default.

Example wait event summary information:

```sql
mysql> SELECT *
                   FROM performance_schema.events_waits_summary_global_by_event_name\G
...
********************** 6. row **********************
   EVENT_NAME: wait/synch/mutex/sql/BINARY_LOG::LOCK_index
   COUNT_STAR: 8
   SUM_TIMER_WAIT: 2119302
   MIN_TIMER_WAIT: 196092
   AVG_TIMER_WAIT: 264912
   MAX_TIMER_WAIT: 569421
...
********************** 9. row **********************
   EVENT_NAME: wait/synch/mutex/sql/hash_filo::lock
   COUNT_STAR: 69
   SUM_TIMER_WAIT: 16848828
   MIN_TIMER_WAIT: 0
   AVG_TIMER_WAIT: 244185
   MAX_TIMER_WAIT: 735345
...
```

Each wait event summary table has one or more grouping columns to indicate how the table aggregates events. Event names refer to names of event instruments in the `setup_instruments` table:

- **events_waits_summary_by_account_by_event_name** has EVENT_NAME, USER, and HOST columns. Each row summarizes events for a given account (user and host combination) and event name.

- **events_waits_summary_by_host_by_event_name** has EVENT_NAME and HOST columns. Each row summarizes events for a given host and event name.

- **events_waits_summary_by_instance** has EVENT_NAME and OBJECT_INSTANCE_BEGIN columns. Each row summarizes events for a given event name and object. If an instrument is used to create multiple instances, each instance has a unique OBJECT_INSTANCE_BEGIN value and is summarized separately in this table.

- **events_waits_summary_by_thread_by_event_name** has THREAD_ID and EVENT_NAME columns. Each row summarizes events for a given thread and event name.
Performance Schema Summary Tables

- **events_waits_summary_by_user_by_event_name** has EVENT_NAME and USER columns. Each row summarizes events for a given user and event name.

- **events_waits_summary_global_by_event_name** has an EVENT_NAME column. Each row summarizes events for a given event name. An instrument might be used to create multiple instances of the instrumented object. For example, if there is an instrument for a mutex that is created for each connection, there are as many instances as there are connections. The summary row for the instrument summarizes over all these instances.

Each wait event summary table has these summary columns containing aggregated values:

- **COUNT_STAR**
  The number of summarized events. This value includes all events, whether timed or nontimed.

- **SUM_TIMER_WAIT**
  The total wait time of the summarized timed events. This value is calculated only for timed events because nontimed events have a wait time of NULL. The same is true for the other xxx_TIMER_WAIT values.

- **MIN_TIMER_WAIT**
  The minimum wait time of the summarized timed events.

- **AVG_TIMER_WAIT**
  The average wait time of the summarized timed events.

- **MAX_TIMER_WAIT**
  The maximum wait time of the summarized timed events.

**TRUNCATE TABLE** is permitted for wait summary tables. It has these effects:

- For summary tables not aggregated by account, host, or user, truncation resets the summary columns to zero rather than removing rows.

- For summary tables aggregated by account, host, or user, truncation removes rows for accounts, hosts, or users with no connections, and resets the summary columns to zero for the remaining rows.

In addition, each wait summary table that is aggregated by account, host, user, or thread is implicitly truncated by truncation of the connection table on which it depends, or truncation of **events_waits_summary_global_by_event_name**. For details, see **Section 22.12.7, “Performance Schema Connection Tables”**.

### 22.12.9.2 Stage Summary Tables

The Performance Schema maintains tables for collecting current and recent stage events, and aggregates that information in summary tables. **Section 22.12.5, “Performance Schema Stage Event Tables”** describes the events on which stage summaries are based. See that discussion for information about the content of stage events, the current and historical stage event tables, and how to control stage event collection, which is disabled by default.

Example stage event summary information:

```
mysql> SELECT * FROM performance_schema.events_stages_summary_global_by_event_name;
```
Performance Schema Summary Tables

Each stage summary table has one or more grouping columns to indicate how the table aggregates events. Event names refer to names of event instruments in the `setup_instruments` table:

- `events_stages_summary_by_account_by_event_name` has `EVENT_NAME`, `USER`, and `HOST` columns. Each row summarizes events for a given account (user and host combination) and event name.

- `events_stages_summary_by_host_by_event_name` has `EVENT_NAME` and `HOST` columns. Each row summarizes events for a given host and event name.

- `events_stages_summary_by_thread_by_event_name` has `THREAD_ID` and `EVENT_NAME` columns. Each row summarizes events for a given thread and event name.

- `events_stages_summary_by_user_by_event_name` has `EVENT_NAME` and `USER` columns. Each row summarizes events for a given user and event name.

- `events_stages_summary_global_by_event_name` has an `EVENT_NAME` column. Each row summarizes events for a given event name.

Each stage summary table has these summary columns containing aggregated values: `COUNT_STAR`, `SUM_TIMER_WAIT`, `MIN_TIMER_WAIT`, `AVG_TIMER_WAIT`, and `MAX_TIMER_WAIT`. These columns are analogous to the columns of the same names in the wait event summary tables (see Section 22.12.9.1, "Wait Event Summary Tables"), except that the stage summary tables aggregate events from `events_stages_current` rather than `events_waits_current`.

`TRUNCATE TABLE` is permitted for stage summary tables. It has these effects:

- For summary tables not aggregated by account, host, or user, truncation resets the summary columns to zero rather than removing rows.

- For summary tables aggregated by account, host, or user, truncation removes rows for accounts, hosts, or users with no connections, and resets the summary columns to zero for the remaining rows.

In addition, each stage summary table that is aggregated by account, host, user, or thread is implicitly truncated by truncation of the connection table on which it depends, or truncation of `events_stages_summary_global_by_event_name`. For details, see Section 22.12.7, "Performance Schema Connection Tables".

22.12.9.3 Statement Summary Tables

The Performance Schema maintains tables for collecting current and recent statement events, and aggregates that information in summary tables. Section 22.12.6, "Performance Schema Statement
Event Tables” describes the events on which statement summaries are based. See that discussion for information about the content of statement events, the current and historical statement event tables, and how to control statement event collection, which is partially disabled by default.

Example statement event summary information:

```
mysql> SELECT * FROM performance_schema.events_statements_summary_global_by_event_name;
+-----------------+-------------------+------------------------+------------------+
<table>
<thead>
<tr>
<th>EVENT_NAME</th>
<th>COUNT_STAR</th>
<th>SUM_TIMER_WAIT</th>
<th>MIN_TIMER_WAIT</th>
</tr>
</thead>
<tbody>
<tr>
<td>statement/sql/select</td>
<td>25</td>
<td>1535983999000</td>
<td>209823000</td>
</tr>
<tr>
<td>AVG_TIMER_WAIT</td>
<td>61439359000</td>
<td>1363397650000</td>
<td></td>
</tr>
<tr>
<td>MAX_TIMER_WAIT</td>
<td>20186000000</td>
<td></td>
<td></td>
</tr>
<tr>
<td>SUM_LOCK_TIME</td>
<td>20186000000</td>
<td></td>
<td></td>
</tr>

<tr>
<td>SUM_NO_GOOD_INDEX_USED</td>
<td>0</td>
<td></td>
<td></td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

Each statement summary table has one or more grouping columns to indicate how the table aggregates events. Event names refer to names of event instruments in the `setup_instruments` table:

- `events_statements_summary_by_account_by_event_name` has `EVENT_NAME`, `USER`, and `HOST` columns. Each row summarizes events for a given account (user and host combination) and event name.

- `events_statements_summary_by_digest` has `SCHEMA_NAME` and `DIGEST` columns. Each row summarizes events per schema and digest value. (The `DIGEST_TEXT` column contains the corresponding normalized statement digest text, but is neither a grouping nor a summary column.)

The maximum number of rows in the table is autosized at server startup. To set this maximum explicitly, set the `performance_schema_digests_size` system variable at server startup.

- `events_statements_summary_by_host_by_event_name` has `EVENT_NAME` and `HOST` columns. Each row summarizes events for a given host and event name.

- `events_statements_summary_by_thread_by_event_name` has `THREAD_ID` and `EVENT_NAME` columns. Each row summarizes events for a given thread and event name.

- `events_statements_summary_by_user_by_event_name` has `EVENT_NAME` and `USER` columns. Each row summarizes events for a given user and event name.

- `events_statements_summary_global_by_event_name` has an `EVENT_NAME` column. Each row summarizes events for a given event name.
Each statement summary table has these summary columns containing aggregated values:

- COUNT_STAR, SUM_TIMER_WAIT, MIN_TIMER_WAIT, AVG_TIMER_WAIT, MAX_TIMER_WAIT

These columns are analogous to the columns of the same names in the wait event summary tables (see Section 22.12.9.1, “Wait Event Summary Tables”), except that the statement summary tables aggregate events from events_statements_current rather than events_waits_current.

- SUM_xxx

The aggregate of the corresponding xxx column in the events_statements_current table. For example, the SUM_LOCK_TIME and SUM_ERRORS columns in statement summary tables are the aggregates of the LOCK_TIME and ERRORS columns in events_statements_current table.

The events_statements_summary_by_digest table has these additional summary columns:

- FIRST_SEEN, LAST_SEEN

Timestamps indicating when statements with the given digest value were first seen and most recently seen.

TRUNCATE TABLE is permitted for statement summary tables. It has these effects:

- For events_statements_summary_by_digest, it removes the rows.

- For other summary tables not aggregated by account, host, or user, truncation resets the summary columns to zero rather than removing rows.

- For other summary tables aggregated by account, host, or user, truncation removes rows for accounts, hosts, or users with no connections, and resets the summary columns to zero for the remaining rows.

In addition, each statement summary table that is aggregated by account, host, user, or thread is implicitly truncated by truncation of the connection table on which it depends, or truncation of events_statements_summary_global_by_event_name. For details, see Section 22.12.7, “Performance Schema Connection Tables”.

Statement Digest Aggregation Rules

If the statements_digest consumer is enabled, aggregation into events_statements_summary_by_digest occurs as follows when a statement completes. Aggregation is based on the DIGEST value computed for the statement.

- If a events_statements_summary_by_digest row already exists with the digest value for the statement that just completed, statistics for the statement are aggregated to that row. The LAST_SEEN column is updated to the current time.

- If no row has the digest value for the statement that just completed, and the table is not full, a new row is created for the statement. The FIRST_SEEN and LAST_SEEN columns are initialized with the current time.

- If no row has the statement digest value for the statement that just completed, and the table is full, the statistics for the statement that just completed are added to a special “catch-all” row with DIGEST = NULL, which is created if necessary. If the row is created, the FIRST_SEEN and LAST_SEEN columns are initialized with the current time. Otherwise, the LAST_SEEN column is updated with the current time.

The row with DIGEST = NULL is maintained because Performance Schema tables have a maximum size due to memory constraints. The DIGEST = NULL row permits digests that do not match other rows to be
counted even if the summary table is full, using a common “other” bucket. This row helps you estimate whether the digest summary is representative:

- **A `DIGEST = NULL` row that has a `COUNT_STAR` value that represents 5% of all digests shows that the digest summary table is very representative; the other rows cover 95% of the statements seen.**

- **A `DIGEST = NULL` row that has a `COUNT_STAR` value that represents 50% of all digests shows that the digest summary table is not very representative; the other rows cover only half the statements seen. Most likely the DBA should increase the maximum table size so that more of the rows counted in the `DIGEST = NULL` row would be counted using more specific rows instead. To do this, set the `performance_schema_digests_size` system variable to a larger value at server startup. The default size is 200.

### 22.12.9.4 Object Wait Summary Table

The Performance Schema maintains the `objects_summary_global_by_type` table for aggregating object wait events.

Example object wait event summary information:

```sql
mysql> SELECT * FROM performance_schema.objects_summary_global_by_type\G
... ******************* 3. row *******************
<table>
<thead>
<tr>
<th>OBJECT_TYPE</th>
<th>OBJECT_SCHEMA</th>
<th>OBJECT_NAME</th>
<th>COUNT_STAR</th>
<th>SUM_TIMER_WAIT</th>
<th>MIN_TIMER_WAIT</th>
<th>AVG_TIMER_WAIT</th>
<th>MAX_TIMER_WAIT</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLE</td>
<td>test</td>
<td>t</td>
<td>3</td>
<td>263126976</td>
<td>1522272</td>

</table>
```

The `objects_summary_global_by_type` table has these grouping columns to indicate how the table aggregates events: `OBJECT_TYPE`, `OBJECT_SCHEMA`, and `OBJECT_NAME`. Each row summarizes events for the given object.

`objects_summary_global_by_type` has the same summary columns as the `events_waits_summary_by_xxx` tables. See Section 22.12.9.1, “Wait Event Summary Tables”.

**TRUNCATE TABLE** is permitted for the object summary table. It resets the summary columns to zero rather than removing rows.

### 22.12.9.5 File I/O Summary Tables

The Performance Schema maintains file I/O summary tables that aggregate information about I/O operations.

Example file I/O event summary information:
Each file I/O summary table has one or more grouping columns to indicate how the table aggregates events. Event names refer to names of event instruments in the `setup_instruments` table:

- `file_summary_by_event_name` has an `EVENT_NAME` column. Each row summarizes events for a given event name.
- `file_summary_by_instance` has `FILE_NAME`, `EVENT_NAME`, and `OBJECT_INSTANCE_BEGIN` columns. Each row summarizes events for a given file and event name.

Each file I/O summary table has the following summary columns containing aggregated values. Some columns are more general and have values that are the same as the sum of the values of more fine-grained columns. In this way, aggregations at higher levels are available directly without the need for user-defined views that sum lower-level columns.

- `COUNT_STAR`, `SUM_TIMER_WAIT`, `MIN_TIMER_WAIT`, `AVG_TIMER_WAIT`, `MAX_TIMER_WAIT` These columns aggregate all I/O operations.
- `COUNT_READ`, `SUM_TIMER_READ`, `MIN_TIMER_READ`, `AVG_TIMER_READ`, `MAX_TIMER_READ`, `SUM_NUMBER_OF_BYTES_READ` These columns aggregate all read operations, including `FGETS`, `FGETC`, `FREAD`, and `READ`.
- `COUNT_WRITE`, `SUM_TIMER_WRITE`, `MIN_TIMER_WRITE`, `AVG_TIMER_WRITE`, `MAX_TIMER_WRITE`, `SUM_NUMBER_OF_BYTES_WRITE` These columns aggregate all write operations, including `FPUTS`, `FPUTC`, `PRINTF`, `VFPRINTF`, `FWRITE`, and `FWRITE`.
- `COUNT_MISC`, `SUM_TIMER_MISC`, `MIN_TIMER_MISC`, `AVG_TIMER_MISC`, `MAX_TIMER_MISC` These columns aggregate all other I/O operations, including `CREATE`, `DELETE`, `OPEN`, `CLOSE`, `STREAM_OPEN`, `STREAM_CLOSE`, `SEEK`, `TELL`, `FLUSH`, `STAT`, `FSTAT`, `CHSIZE`, `RENAME`, and `SYNC`. There are no byte counts for these operations.

`TRUNCATE TABLE` is permitted for file I/O summary tables. It resets the summary columns to zero rather than removing rows.
The MySQL server uses several techniques to avoid I/O operations by caching information read from files, so it is possible that statements you might expect to result in I/O events will not. You may be able to ensure that I/O does occur by flushing caches or restarting the server to reset its state.

22.12.9.6 Table I/O and Lock Wait Summary Tables

The following sections describe the table I/O and lock wait summary tables:

- **table_io_waits_summary_by_index_usage**: Table I/O waits per index
- **table_io_waits_summary_by_table**: Table I/O waits per table
- **table_lock_waits_summary_by_table**: Table lock waits per table

The **table_io_waits_summary_by_table** Table

The **table_io_waits_summary_by_table** table aggregates all table I/O wait events, as generated by the `wait/io/table/sql/handler` instrument. The grouping is by table.

The **table_io_waits_summary_by_table** table has these grouping columns to indicate how the table aggregates events: **OBJECT_TYPE**, **OBJECT_SCHEMA**, and **OBJECT_NAME**. These columns have the same meaning as in the **events_waits_current** table. They identify the table to which the row applies.

**table_io_waits_summary_by_table** has the following summary columns containing aggregated values. As indicated in the column descriptions, some columns are more general and have values that are the same as the sum of the values of more fine-grained columns. For example, columns that aggregate all writes hold the sum of the corresponding columns that aggregate inserts, updates, and deletes. In this way, aggregations at higher levels are available directly without the need for user-defined views that sum lower-level columns.

- **COUNT_STAR**, **SUM_TIMER_WAIT**, **MIN_TIMER_WAIT**, **AVG_TIMER_WAIT**, **MAX_TIMER_WAIT**
  These columns aggregate all I/O operations. They are the same as the sum of the corresponding **xxx_READ** and **xxx_WRITE** columns.

- **COUNT_READ**, **SUM_TIMER_READ**, **MIN_TIMER_READ**, **AVG_TIMER_READ**, **MAX_TIMER_READ**
  These columns aggregate all read operations. They are the same as the sum of the corresponding **xxx.FETCH** columns.

- **COUNT_WRITE**, **SUM_TIMER_WRITE**, **MIN_TIMER_WRITE**, **AVG_TIMER_WRITE**, **MAX_TIMER_WRITE**
  These columns aggregate all write operations. They are the same as the sum of the corresponding **xxx_INSERT**, **xxx_UPDATE**, and **xxx.DELETE** columns.

- **COUNT_FETCH**, **SUM_TIMER_FETCH**, **MIN_TIMER_FETCH**, **AVG_TIMER_FETCH**, **MAX_TIMER_FETCH**
  These columns aggregate all fetch operations.

- **COUNT_INSERT**, **SUM_TIMER_INSERT**, **MIN_TIMER_INSERT**, **AVG_TIMER_INSERT**, **MAX_TIMER_INSERT**
  These columns aggregate all insert operations.

- **COUNT_UPDATE**, **SUM_TIMER_UPDATE**, **MIN_TIMER_UPDATE**, **AVG_TIMER_UPDATE**, **MAX_TIMER_UPDATE**
  These columns aggregate all update operations.
Performance Schema Summary Tables

- COUNT_DELETE, SUM_TIMER_DELETE, MIN_TIMER_DELETE, AVG_TIMER_DELETE, MAX_TIMER_DELETE

These columns aggregate all delete operations.

TRUNCATE TABLE is permitted for table I/O summary tables. It resets the summary columns to zero rather than removing rows. Truncating this table also truncates the table_io_waits_summary_by_index_usage table.

The table_io_waits_summary_by_index_usage Table

The table_io_waits_summary_by_index_usage table aggregates all table index I/O wait events, as generated by the wait/io/table/sql/handler instrument. The grouping is by table index.

The columns of table_io_waits_summary_by_index_usage are nearly identical to table_io_waits_summary_by_table. The only difference is the additional group column, INDEX_NAME, which corresponds to the name of the index that was used when the table I/O wait event was recorded:

- A value of PRIMARY indicates that table I/O used the primary index.
- A value of NULL means that table I/O used no index.
- Inserts are counted against INDEX_NAME = NULL.

TRUNCATE TABLE is permitted for table I/O summary tables. It resets the summary columns to zero rather than removing rows. This table is also truncated by truncation of the table_io_waits_summary_by_table table. A DDL operation that changes the index structure of a table may cause the per-index statistics to be reset.

The table_lock_waits_summary_by_table Table

The table_lock_waits_summary_by_table table aggregates all table lock wait events, as generated by the wait/lock/table/sql/handler instrument. The grouping is by table.

This table contains information about internal and external locks:

- An internal lock corresponds to a lock in the SQL layer. This is currently implemented by a call to thr_lock(). In event rows, these locks are distinguished by the OPERATION column, which has one of these values:
  
<table>
<thead>
<tr>
<th>Operation</th>
</tr>
</thead>
<tbody>
<tr>
<td>read normal</td>
</tr>
<tr>
<td>read with shared locks</td>
</tr>
<tr>
<td>read high priority</td>
</tr>
<tr>
<td>read no insert</td>
</tr>
<tr>
<td>write allow write</td>
</tr>
<tr>
<td>write concurrent insert</td>
</tr>
<tr>
<td>write delayed</td>
</tr>
<tr>
<td>write low priority</td>
</tr>
<tr>
<td>write normal</td>
</tr>
</tbody>
</table>

- An external lock corresponds to a lock in the storage engine layer. This is currently implemented by a call to handler::external_lock(). In event rows, these locks are distinguished by the OPERATION column, which has one of these values:

<table>
<thead>
<tr>
<th>Operation</th>
</tr>
</thead>
<tbody>
<tr>
<td>read external</td>
</tr>
<tr>
<td>write external</td>
</tr>
</tbody>
</table>
The `table_lock_waits_summary_by_table` table has these grouping columns to indicate how the table aggregates events: `OBJECT_TYPE`, `OBJECT_SCHEMA`, and `OBJECT_NAME`. These columns have the same meaning as in the `events_waits_current` table. They identify the table to which the row applies.

`table_lock_waits_summary_by_table` has the following summary columns containing aggregated values. As indicated in the column descriptions, some columns are more general and have values that are the same as the sum of the values of more fine-grained columns. For example, columns that aggregate all locks hold the sum of the corresponding columns that aggregate read and write locks. In this way, aggregations at higher levels are available directly without the need for user-defined views that sum lower-level columns.

- **COUNT_STAR, SUM_TIMER_WAIT, MIN_TIMER_WAIT, AVG_TIMER_WAIT, MAX_TIMER_WAIT**

  These columns aggregate all lock operations. They are the same as the sum of the corresponding `xxx_READ` and `xxx_WRITE` columns.

- **COUNT_READ, SUM_TIMER_READ, MIN_TIMER_READ, AVG_TIMER_READ, MAX_TIMER_READ**

  These columns aggregate all read-lock operations. They are the same as the sum of the corresponding `xxx_READ_NORMAL`, `xxx_READ_WITH_SHARED_LOCKS`, `xxx_READ_HIGH_PRIORITY`, and `xxx_READ_NO_INSERT` columns.

- **COUNT_WRITE, SUM_TIMER_WRITE, MIN_TIMER_WRITE, AVG_TIMER_WRITE, MAX_TIMER_WRITE**

  These columns aggregate all write-lock operations. They are the same as the sum of the corresponding `xxx_WRITE_ALLOW_WRITE`, `xxx_WRITE_CONCURRENT_INSERT`, `xxx_WRITE_DELAYED`, `xxx_WRITE_LOW_PRIORITY`, and `xxx_WRITE_NORMAL` columns.

- **COUNT_READ_NORMAL, SUM_TIMER_READ_NORMAL, MIN_TIMER_READ_NORMAL, AVG_TIMER_READ_NORMAL, MAX_TIMER_READ_NORMAL**

  These columns aggregate internal read locks.

- **COUNT_READ_WITH_SHARED_LOCKS, SUM_TIMER_READ_WITH_SHARED_LOCKS, MIN_TIMER_READ_WITH_SHARED_LOCKS, AVG_TIMER_READ_WITH_SHARED_LOCKS, MAX_TIMER_READ_WITH_SHARED_LOCKS**

  These columns aggregate internal read locks.

- **COUNT_READ_HIGH_PRIORITY, SUM_TIMER_READ_HIGH_PRIORITY, MIN_TIMER_READ_HIGH_PRIORITY, AVG_TIMER_READ_HIGH_PRIORITY, MAX_TIMER_READ_HIGH_PRIORITY**

  These columns aggregate internal read locks.

- **COUNT_READ_NO_INSERT, SUM_TIMER_READ_NO_INSERT, MIN_TIMER_READ_NO_INSERT, AVG_TIMER_READ_NO_INSERT, MAX_TIMER_READ_NO_INSERT**

  These columns aggregate internal read locks.

- **COUNT_READ_EXTERNAL, SUM_TIMER_READ_EXTERNAL, MIN_TIMER_READ_EXTERNAL, AVG_TIMER_READ_EXTERNAL, MAX_TIMER_READ_EXTERNAL**

  These columns aggregate external read locks.

- **COUNT_WRITE_ALLOW_WRITE, SUM_TIMER_WRITE_ALLOW_WRITE, MIN_TIMER_WRITE_ALLOW_WRITE, AVG_TIMER_WRITE_ALLOW_WRITE, MAX_TIMER_WRITE_ALLOW_WRITE**

  These columns aggregate external read locks.
These columns aggregate internal write locks.

- `COUNT_WRITE_CONCURRENT_INSERT`, `SUM_TIMER_WRITE_CONCURRENT_INSERT`, `MIN_TIMER_WRITE_CONCURRENT_INSERT`, `AVG_TIMER_WRITE_CONCURRENT_INSERT`, `MAX_TIMER_WRITE_CONCURRENT_INSERT`

These columns aggregate internal write locks.

- `COUNT_WRITE_DELAYED`, `SUM_TIMER_WRITE_DELAYED`, `MIN_TIMER_WRITE_DELAYED`, `AVG_TIMER_WRITE_DELAYED`, `MAX_TIMER_WRITE_DELAYED`

`DELAYED` inserts are deprecated, so these columns will be removed in a future release.

- `COUNT_WRITE_LOW_PRIORITY`, `SUM_TIMER_WRITE_LOW_PRIORITY`, `MIN_TIMER_WRITE_LOW_PRIORITY`, `AVG_TIMER_WRITE_LOW_PRIORITY`, `MAX_TIMER_WRITE_LOW_PRIORITY`

These columns aggregate internal write locks.

- `COUNT_WRITE_NORMAL`, `SUM_TIMER_WRITE_NORMAL`, `MIN_TIMER_WRITE_NORMAL`, `AVG_TIMER_WRITE_NORMAL`, `MAX_TIMER_WRITE_NORMAL`

These columns aggregate internal write locks.

- `COUNT_WRITE_EXTERNAL`, `SUM_TIMER_WRITE_EXTERNAL`, `MIN_TIMER_WRITE_EXTERNAL`, `AVG_TIMER_WRITE_EXTERNAL`, `MAX_TIMER_WRITE_EXTERNAL`

These columns aggregate external write locks.

`TRUNCATE TABLE` is permitted for table lock summary tables. It resets the summary columns to zero rather than removing rows.

**22.12.9.7 Socket Summary Tables**

The Performance Schema maintains socket summary tables, which aggregate timer and byte count information for socket operations:

- `socket_summary_by_event_name`: Aggregate timer and byte count statistics generated by the `wait/io/socket/*` instruments for all socket I/O operations, per socket instrument.

- `socket_summary_by_instance`: Aggregate timer and byte count statistics generated by the `wait/io/socket/*` instruments for all socket I/O operations, per socket instance. When a connection terminates, the row in `socket_summary_by_instance` corresponding to it is deleted.

The socket summary tables do not aggregate waits generated by `idle` events while sockets are waiting for the next request from the client. For `idle` event aggregations, use the wait-event summary tables; see Section 22.12.9.1, “Wait Event Summary Tables”.

Each socket summary table has one or more grouping columns to indicate how the table aggregates events. Event names refer to names of event instruments in the `setup_instruments` table:

- `socket_summary_by_event_name` has an `EVENT_NAME` column. Each row summarizes events for a given event name.

- `socket_summary_by_instance` has an `OBJECT_INSTANCE_BEGIN` column. Each row summarizes events for a given object.
Each socket summary table has these summary columns containing aggregated values:

- **COUNT_STAR**, **SUM_TIMER_WAIT**, **MIN_TIMER_WAIT**, **AVG_TIMER_WAIT**, **MAX_TIMER_WAIT**
  These columns aggregate all operations.

- **COUNT_READ**, **SUM_TIMER_READ**, **MIN_TIMER_READ**, **AVG_TIMER_READ**, **MAX_TIMER_READ**, **SUM_NUMBER_OF_BYTES_READ**
  These columns aggregate all receive operations (**RECV**, **RECVFROM**, and **RECVMSG**).

- **COUNT_WRITE**, **SUM_TIMER_WRITE**, **MIN_TIMER_WRITE**, **AVG_TIMER_WRITE**, **MAX_TIMER_WRITE**, **SUM_NUMBER_OF_BYTES_WRITE**
  These columns aggregate all send operations (**SEND**, **SENDTO**, and **SENDMSG**).

- **COUNT_MISC**, **SUM_TIMER_MISC**, **MIN_TIMER_MISC**, **AVG_TIMER_MISC**, **MAX_TIMER_MISC**
  These columns aggregate all other socket operations, such as **CONNECT**, **LISTEN**, **ACCEPT**, **CLOSE**, and **SHUTDOWN**. There are no byte counts for these operations.

The `socket_summary_by_instance` table also has an **EVENT_NAME** column that indicates the class of the socket: **client_connection**, **server_tcpip_socket**, **server_unix_socket**. This column can be grouped on to isolate, for example, client activity from that of the server listening sockets.

**TRUNCATE TABLE** is permitted for socket summary tables. Except for **events_statements_summary_by_digest**, it resets the summary columns to zero rather than removing rows.

### 22.12.10 Performance Schema Miscellaneous Tables

The following sections describe tables that do not fall into the table categories discussed in the preceding sections:

- **host_cache**: Information from the internal host cache
- **performance_timers**: Which event timers are available
- **threads**: Information about server threads

#### 22.12.10.1 The host_cache Table

The `host_cache` table provides access to the contents of the host cache, which contains client host name and IP address information and is used to avoid Domain Name System (DNS) lookups. The `host_cache_size` system variable controls the size of the host cache, as well as the size of the `host_cache` table that exposes the cache contents. For operational and configuration information about the host cache, see Section 8.12.5.2, "DNS Lookup Optimization and the Host Cache".

Because the `host_cache` table exposes the contents of the host cache, it can be examined using **SELECT** statements. This may help you diagnose the causes of connection problems. The Performance Schema must be enabled or this table is empty.

The `host_cache` table has these columns:

- **IP**
  The IP address of the client that connected to the server, expressed as a string.

- **HOST**
The resolved DNS host name for that client IP, or NULL if the name is unknown.

- **HOST_VALIDATED**

Whether the IP-to-host name-to-IP DNS resolution was performed successfully for the client IP. If HOST_VALIDATED is YES, the HOST column is used as the host name corresponding to the IP so that additional calls to DNS can be avoided. While HOST_VALIDATED is NO, DNS resolution is attempted for each connection attempt, until it eventually completes with either a valid result or a permanent error. This information enables the server to avoid caching bad or missing host names during temporary DNS failures, which would negatively affect clients forever.

- **SUM_CONNECT_ERRORS**

The number of connection errors that are deemed “blocking” (assessed against the max_connect_errors system variable). Only protocol handshake errors are counted, and only for hosts that passed validation (HOST_VALIDATED = YES).

Once SUM_CONNECT_ERRORS for a given host reaches the value of max_connect_errors, new connections from that host are blocked. The SUM_CONNECT_ERRORS value can exceed the max_connect_errors value because multiple connection attempts from a host can occur simultaneously while the host is not blocked. Any or all of them can fail, independently incrementing SUM_CONNECT_ERRORS, possibly beyond the value of max_connect_errors.

Suppose that max_connect_errors is 200 and SUM_CONNECT_ERRORS for a given host is 199. If 10 clients attempt to connect from that host simultaneously, none of them are blocked because SUM_CONNECT_ERRORS has not reached 200. If blocking errors occur for five of the clients, SUM_CONNECT_ERRORS is increased by one for each client, for a resulting SUM_CONNECT_ERRORS value of 204. The other five clients succeed and are not blocked because the value of SUM_CONNECT_ERRORS when their connection attempts began had not reached 200. New connections from the host that begin after SUM_CONNECT_ERRORS reaches 200 are blocked.

- **COUNT_HOST_BLOCKED_ERRORS**

The number of connections that were blocked because SUM_CONNECT_ERRORS exceeded the value of the max_connect_errors system variable.

- **COUNT_NAMEINFO_TRANSIENT_ERRORS**

The number of transient errors during IP-to-host name DNS resolution.

- **COUNT_NAMEINFO_PERMANENT_ERRORS**

The number of permanent errors during IP-to-host name DNS resolution.

- **COUNT_FORMAT_ERRORS**

The number of host name format errors. MySQL does not perform matching of Host column values in the mysql.user system table against host names for which one or more of the initial components of the name are entirely numeric, such as 1.2.example.com. The client IP address is used instead. For the rationale why this type of matching does not occur, see Section 6.2.4, “Specifying Account Names”.

- **COUNT_ADDRINFO_TRANSIENT_ERRORS**

The number of transient errors during host name-to-IP reverse DNS resolution.

- **COUNT_ADDRINFO_PERMANENT_ERRORS**
The number of permanent errors during host name-to-IP reverse DNS resolution.

- **COUNT_FCRDNS_ERRORS**
  
  The number of forward-confirmed reverse DNS errors. These errors occur when IP-to-host name-to-IP DNS resolution produces an IP address that does not match the client originating IP address.

- **COUNT_HOST_ACL_ERRORS**
  
  The number of errors that occur because no users are permitted to connect from the client host. In such cases, the server returns `ER_HOST_NOT_PRIVILEGED` and does not even ask for a user name or password.

- **COUNT_NO_AUTH_PLUGIN_ERRORS**
  
  The number of errors due to requests for an unavailable authentication plugin. A plugin can be unavailable if, for example, it was never loaded or a load attempt failed.

- **COUNT_AUTH_PLUGIN_ERRORS**
  
  The number of errors reported by authentication plugins.

  An authentication plugin can report different error codes to indicate the root cause of a failure. Depending on the type of error, one of these columns is incremented: `COUNT_AUTHENTICATION_ERRORS`, `COUNT_AUTH_PLUGIN_ERRORS`, `COUNT_HANDSHAKE_ERRORS`. New return codes are an optional extension to the existing plugin API. Unknown or unexpected plugin errors are counted in the `COUNT_AUTH_PLUGIN_ERRORS` column.

- **COUNT_HANDSHAKE_ERRORS**
  
  The number of errors detected at the wire protocol level.

- **COUNT_PROXY_USER_ERRORS**
  
  The number of errors detected when proxy user A is proxied to another user B who does not exist.

- **COUNT_PROXY_USER_ACL_ERRORS**
  
  The number of errors detected when proxy user A is proxied to another user B who does exist but for whom A does not have the PROXY privilege.

- **COUNT_AUTHENTICATION_ERRORS**
  
  The number of errors caused by failed authentication.

- **COUNT_SSL_ERRORS**
  
  The number of errors due to SSL problems.

- **COUNT_MAX_USER_CONNECTIONS_ERRORS**
  
  The number of errors caused by exceeding per-user connection quotas. See Section 6.2.13, “Setting Account Resource Limits”.

- **COUNT_MAX_USER_CONNECTIONS_PER_HOUR_ERRORS**
  
  The number of errors caused by exceeding per-user connections-per-hour quotas. See Section 6.2.13, “Setting Account Resource Limits”.
• **COUNT_DEFAULT_DATABASE_ERRORS**

  The number of errors related to the default database. For example, the database does not exist or the user has no privileges to access it.

• **COUNT_INIT_CONNECT_ERRORS**

  The number of errors caused by execution failures of statements in the `init_connect` system variable value.

• **COUNT_LOCAL_ERRORS**

  The number of errors local to the server implementation and not related to the network, authentication, or authorization. For example, out-of-memory conditions fall into this category.

• **COUNT_UNKNOWN_ERRORS**

  The number of other, unknown errors not accounted for by other columns in this table. This column is reserved for future use, in case new error conditions must be reported, and if preserving the backward compatibility and structure of the `host_cache` table is required.

• **FIRST_SEEN**

  The timestamp of the first connection attempt seen from the client in the IP column.

• **LAST_SEEN**

  The timestamp of the most recent connection attempt seen from the client in the IP column.

• **FIRST_ERROR_SEEN**

  The timestamp of the first error seen from the client in the IP column.

• **LAST_ERROR_SEEN**

  The timestamp of the most recent error seen from the client in the IP column.

The FLUSH HOSTS statement, TRUNCATE TABLE host_cache statement, and mysqladmin flush-hosts command have the same effect: They clear the host cache, remove all rows from the host_cache table that exposes the cache contents, and unblock any blocked hosts (see Section B.4.2.6, “Host ‘host_name’ is blocked”). FLUSH HOSTS and mysqladmin flush-hosts require the RELOAD privilege. TRUNCATE TABLE requires the DROP privilege for the host_cache table.

### 22.12.10.2 The performance_timers Table

The `performance_timers` table shows which event timers are available:

```
mysql> SELECT * FROM performance_schema.performance_timers;
+-------------+-----------------+-----------------+-----------------+
<table>
<thead>
<tr>
<th>TIMER_NAME</th>
<th>TIMER_FREQUENCY</th>
<th>TIMER_RESOLUTION</th>
<th>TIMER_OVERHEAD</th>
</tr>
</thead>
<tbody>
<tr>
<td>CYCLE</td>
<td>2389029850</td>
<td>1</td>
<td>72</td>
</tr>
<tr>
<td>NANOSECOND</td>
<td>1000000000</td>
<td>1</td>
<td>112</td>
</tr>
<tr>
<td>MICROSECOND</td>
<td>1000000</td>
<td>1</td>
<td>136</td>
</tr>
<tr>
<td>MILLISECOND</td>
<td>1036</td>
<td>1</td>
<td>168</td>
</tr>
<tr>
<td>TICK</td>
<td>105</td>
<td>1</td>
<td>2416</td>
</tr>
</tbody>
</table>
+-------------+-----------------+-----------------+-----------------+
```

3401
If the values associated with a given timer name are NULL, that timer is not supported on your platform. The rows that do not contain NULL indicate which timers you can use in setup_timers. For an explanation of how event timing occurs, see Section 22.4.1, “Performance Schema Event Timing”.

The performance_timers table has these columns:

• TIMER_NAME
The name by which to refer to the timer when configuring the setup_timers table.

• TIMER_FREQUENCY
The number of timer units per second. For a cycle timer, the frequency is generally related to the CPU speed. For example, on a system with a 2.4GHz processor, the CYCLE may be close to 240000000.

• TIMER_RESOLUTION
Indicates the number of timer units by which timer values increase. If a timer has a resolution of 10, its value increases by 10 each time.

• TIMER_OVERHEAD
The minimal number of cycles of overhead to obtain one timing with the given timer. The Performance Schema determines this value by invoking the timer 20 times during initialization and picking the smallest value. The total overhead really is twice this amount because the instrumentation invokes the timer at the start and end of each event. The timer code is called only for timed events, so this overhead does not apply for nontimed events.

TRUNCATE TABLE is not permitted for the performance_timers table.

22.12.10.3 The threads Table

The threads table contains a row for each server thread. Each row contains information about a thread and indicates whether monitoring is enabled for it:

```
mysql> SELECT * FROM performance_schema.threads\G
*************************** 1. row ***************************
    THREAD_ID: 1
         NAME: thread/sql/main
          TYPE: BACKGROUND
   PROCESSLIST_ID: NULL
   PROCESSLIST_USER: NULL
   PROCESSLIST_HOST: NULL
   PROCESSLIST_DB: NULL
PROCESSLIST_COMMAND: NULL
   PROCESSLIST_TIME: 80284
   PROCESSLIST_STATE: NULL
   PROCESSLIST_INFO: NULL
  PARENT_THREAD_ID: NULL
           ROLE: NULL
       INSTRUMENTED: YES

...                  4. row ***************************
    THREAD_ID: 51
         NAME: thread/sql/one_connection
          TYPE: FOREGROUND
   PROCESSLIST_ID: 34
   PROCESSLIST_USER: isabella
   PROCESSLIST_HOST: localhost
   PROCESSLIST_DB: performance_schema
PROCESSLIST_COMMAND: Query
```
When the Performance Schema initializes, it populates the `threads` table based on the threads in existence then. Thereafter, a new row is added each time the server creates a thread.

The `INSTRUMENTED` column value for new threads is determined by the contents of the `setup_actors` table. For information about how to use the `setup_actors` table to control this column, see Section 22.4.6, “Pre-Filtering by Thread”.

Removal of rows from the `threads` table occurs when threads end. For a thread associated with a client session, removal occurs when the session ends. If a client has auto-reconnect enabled and the session reconnects after a disconnect, the session becomes associated with a new row in the `threads` table that has a different `PROCESSLIST_ID` value. The initial `INSTRUMENTED` value for the new thread may be different from that of the original thread: The `setup_actors` table may have changed in the meantime, and if the `INSTRUMENTED` value for the original thread was changed after it was initialized, that change does not carry over to the new thread.

The `threads` table columns with names having a prefix of `PROCESSLIST_` provide information similar to that available from the `INFORMATION_SCHEMA.PROCESSLIST` table or the `SHOW PROCESSLIST` statement. Thus, all three sources provide thread-monitoring information. Use of `threads` differs from use of the other two sources in these ways:

- Access to `threads` does not require a mutex and has minimal impact on server performance. `INFORMATION_SCHEMA.PROCESSLIST` and `SHOW PROCESSLIST` have negative performance consequences because they require a mutex.

- `threads` provides additional information for each thread, such as whether it is a foreground or background thread, and the location within the server associated with the thread.

- `threads` provides information about background threads, so it can be used to monitor activity the other thread information sources cannot.

- You can enable or disable thread monitoring (that is, whether events executed by the thread are instrumented). To control the initial `INSTRUMENTED` value for new foreground threads, use the `setup_actors` table. To control monitoring of existing threads, set the `INSTRUMENTED` column of `threads` table rows. (For more information about the conditions under which thread monitoring occurs, see the description of the `INSTRUMENTED` column.)

For these reasons, DBAs who perform server monitoring using `INFORMATION_SCHEMA.PROCESSLIST` or `SHOW PROCESSLIST` may wish to monitor using the `threads` table instead.

**Note**

For `INFORMATION_SCHEMA.PROCESSLIST` and `SHOW PROCESSLIST`, information about threads for other users is shown only if the current user has the `PROCESS` privilege. That is not true of the `threads` table; all rows are shown to any user who has the `SELECT` privilege for the table. Users who should not be able to see threads for other users should not be given that privilege.

The `threads` table has these columns:

- `THREAD_ID`
A unique thread identifier.

- **NAME**
  The name associated with the thread instrumentation code in the server. For example, `thread/sql/one_connection` corresponds to the thread function in the code responsible for handling a user connection, and `thread/sql/main` stands for the `main()` function of the server.

- **TYPE**
  The thread type, either **FOREGROUND** or **BACKGROUND**. User connection threads are foreground threads. Threads associated with internal server activity are background threads. Examples are internal InnoDB threads, “binlog dump” threads sending information to slaves, and slave I/O and SQL threads.

- **PROCESSLIST_ID**
  For threads that are displayed in the **INFORMATION_SCHEMA.PROCESSLIST** table, this is the same value displayed in the **ID** column of that table. It is also the value displayed in the **Id** column of **SHOW PROCESSLIST** output, and the value that **CONNECTION_ID()** would return within that thread.

  For background threads (threads not associated with a user connection), **PROCESSLIST_ID** is **NULL**, so the values are not unique.

- **PROCESSLIST_USER**
  The user associated with a foreground thread, **NULL** for a background thread.

- **PROCESSLIST_HOST**
  The host name of the client associated with a foreground thread, **NULL** for a background thread.

  Unlike the **HOST** column of the **INFORMATION_SCHEMA.PROCESSLIST** table or the **Host** column of **SHOW PROCESSLIST** output, the **PROCESSLIST_HOST** column does not include the port number for TCP/IP connections. To obtain this information from the Performance Schema, enable the socket instrumentation (which is not enabled by default) and examine the **socket_instances** table:

  ```sql
  mysql> SELECT * FROM performance_schema.setup_instruments
  WHERE NAME LIKE 'wait/io/socket%';
  +----------------------------------------+---------+-------+
  | NAME                                   | ENABLED | TIMED |
  +----------------------------------------+---------+-------+
  | wait/io/socket/sql/server_tcpip_socket | NO      | NO    |
  | wait/io/socket/sql/server_unix_socket  | NO      | NO    |
  | wait/io/socket/sql/client_connection   | NO      | NO    |
  +----------------------------------------+---------+-------+
  3 rows in set (0.01 sec)

  mysql> UPDATE performance_schema.setup_instruments
  SET ENABLED='YES'
  WHERE NAME LIKE 'wait/io/socket%';
  Query OK, 3 rows affected (0.00 sec)
  Rows matched: 3  Changed: 3  Warnings: 0

  mysql> SELECT * FROM performance_schema.socket_instances\G
  *************************** 1. row ***************************
  EVENT_NAME: wait/io/socket/sql/client_connection
  OBJECT_INSTANCE_BEGIN: 140612577298432
  THREAD_ID: 31
  SOCKET_ID: 53
  IP: ::ffff:127.0.0.1
PORT: 55642
STATE: ACTIVE

• PROCESSLIST_DB
  The default database for the thread, or NULL if there is none.

• PROCESSLIST_COMMAND
  For foreground threads, the type of command the thread is executing on behalf of the client, or Sleep if the session is idle. For descriptions of thread commands, see Section 8.14, “Examining Thread Information”. The value of this column corresponds to the COM_XXX commands of the client/server protocol and Com_XXX status variables. See Section 5.1.9, “Server Status Variables”

Background threads do not execute commands on behalf of clients, so this column may be NULL.

• PROCESSLIST_TIME
  The time in seconds that the thread has been in its current state.

• PROCESSLIST_STATE
  An action, event, or state that indicates what the thread is doing. For descriptions of PROCESSLIST_STATE values, see Section 8.14, “Examining Thread Information”. If the value if NULL, the thread may correspond to an idle client session or the work it is doing is not instrumented with stages.

Most states correspond to very quick operations. If a thread stays in a given state for many seconds, there might be a problem that bears investigation.

• PROCESSLIST_INFO
  The statement the thread is executing, or NULL if it is not executing any statement. The statement might be the one sent to the server, or an innermost statement if the statement executes other statements. For example, if a CALL statement executes a stored procedure that is executing a SELECT statement, the PROCESSLIST_INFO value shows the SELECT statement.

• PARENT_THREAD_ID
  If this thread is a subthread (spawned by another thread), this is the THREAD_ID value of the spawning thread. Thread spawning occurs, for example, to handle insertion of rows from INSERT DELAYED statements.

• ROLE
  Unused.

• INSTRUMENTED
  Whether events executed by the thread are instrumented. The value is YES or NO.

• For foreground threads, the initial INSTRUMENTED value is determined by whether the user account associated with the thread matches any row in the setup_actors table. Matching is based on the values of the PROCESSLIST_USER and PROCESSLIST_HOST columns.

If the thread spawns a subthread, matching occurs again for the threads table row created for the subthread.
• For background threads, **INSTRUMENTED** is **YES** by default. **setup_actors** is not consulted because there is no associated user for background threads.

• For any thread, its **INSTRUMENTED** value can be changed during the lifetime of the thread. This is the only **threads** table column that can be modified.

For monitoring of events executed by the thread to occur, these things must be true:

• The **thread_instrumentation** consumer in the **setup_consumers** table must be **YES**.

• The **threads.INSTRUMENTED** column must be **YES**.

• Monitoring occurs only for those thread events produced from instruments that have the **ENABLED** column set to **YES** in the **setup_instruments** table.

**TRUNCATE TABLE** is not permitted for the **threads** table.

22.14 Performance Schema Command Options

Performance Schema parameters can be specified at server startup on the command line or in option files to configure Performance Schema instruments and consumers. Runtime configuration is also possible in many cases (see Section 22.4, “Performance Schema Runtime Configuration”), but startup configuration must be used when runtime configuration is too late to affect instruments that have already been initialized during the startup process.

Performance Schema consumers and instruments can be configured at startup using the following syntax. For additional details, see Section 22.3, “Performance Schema Startup Configuration”.

- **--performance-schema-consumer-consumer_name=value**

Configure a Performance Schema consumer. Consumer names in the `setup_consumers` table use underscores, but for consumers set at startup, dashes and underscores within the name are equivalent. Options for configuring individual consumers are detailed later in this section.
• `--performance-schema-instrument=instrument_name=value`

Configure a Performance Schema instrument. The name may be given as a pattern to configure instruments that match the pattern.

The following items configure individual consumers:

• `--performance-schema-consumer-events-stages-current=value`
  Configure the `events-stages-current` consumer.

• `--performance-schema-consumer-events-stages-history=value`
  Configure the `events-stages-history` consumer.

• `--performance-schema-consumer-events-stages-history-long=value`
  Configure the `events-stages-history-long` consumer.

• `--performance-schema-consumer-events-statements-current=value`
  Configure the `events-statements-current` consumer.

• `--performance-schema-consumer-events-statements-history=value`
  Configure the `events-statements-history` consumer.

• `--performance-schema-consumer-events-statements-history-long=value`
  Configure the `events-statements-history-long` consumer.

• `--performance-schema-consumer-events-waits-current=value`
  Configure the `events-waits-current` consumer.

• `--performance-schema-consumer-events-waits-history=value`
  Configure the `events-waits-history` consumer.

• `--performance-schema-consumer-events-waits-history-long=value`
  Configure the `events-waits-history-long` consumer.

• `--performance-schema-consumer-global-instrumentation=value`
  Configure the `global-instrumentation` consumer.

• `--performance-schema-consumer-statements-digest=value`
  Configure the `statements-digest` consumer.

• `--performance-schema-consumer-thread-instrumentation=value`
  Configure the `thread-instrumentation` consumer.

22.15 Performance Schema System Variables

The Performance Schema implements several system variables that provide configuration information:
Performance Schema system variables can be set at server startup on the command line or in option files, and many can be set at runtime. See Section 22.13, “Performance Schema Option and Variable Reference”.

The Performance Schema automatically sizes the values of several of its parameters at server startup if they are not set explicitly. For more information, see Section 22.3, “Performance Schema Startup Configuration”.

Performance Schema system variables have the following meanings:

- **performance_schema**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--performance-schema [=OFF</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>performance_schema</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value (&gt;= 5.6.6)</td>
<td>ON</td>
</tr>
<tr>
<td>Default Value (&lt;= 5.6.5)</td>
<td>OFF</td>
</tr>
</tbody>
</table>
The value of this variable is **ON** or **OFF** to indicate whether the Performance Schema is enabled. By default, the value is **ON**. At server startup, you can specify this variable with no value or a value of **ON** or 1 to enable it, or with a value of **OFF** or 0 to disable it.

- **performance_schema_accounts_size**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--performance-schema-accounts-size=#</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.3</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>performance_schema_accounts_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value (&gt;= 5.6.6)</td>
<td>-1 (signifies autosizing; do not assign this literal value)</td>
</tr>
<tr>
<td>Default Value (&lt;= 5.6.5)</td>
<td>10</td>
</tr>
<tr>
<td>Minimum Value (&gt;= 5.6.6)</td>
<td>-1 (signifies autosizing; do not assign this literal value)</td>
</tr>
<tr>
<td>Minimum Value (&lt;= 5.6.5)</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1048576</td>
</tr>
</tbody>
</table>

The number of rows in the `accounts` table. If this variable is 0, the Performance Schema does not maintain connection statistics in the `accounts` table.

- **performance_schema_digests_size**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--performance-schema-digests-size=#</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.5</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>performance_schema_digests_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>-1 (signifies autosizing; do not assign this literal value)</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>-1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1048576</td>
</tr>
</tbody>
</table>

The maximum number of rows in the `events_statements_summary_by_digest` table. If this maximum is exceeded such that a digest cannot be instrumented, the Performance Schema increments the `Performance_schema_digest_lost` status variable.

For more information about statement digesting, see Section 22.10, “Performance Schema Statement Digests”.

- **performance_schema_events_stages_history_long_size**
### Performance Schema System Variables

<table>
<thead>
<tr>
<th>Property</th>

<tr>
<td>Default Value (&gt;= 5.6.6)</td>
<td>-1 (signifies autosizing; do not assign this literal value)</td>
</tr>
<tr>
<td>Default Value (&lt;= 5.6.5)</td>
<td>10</td>
</tr>
<tr>
<td>Minimum Value (&gt;= 5.6.6)</td>
<td>-1 (signifies autosizing; do not assign this literal value)</td>
</tr>
<tr>
<td>Minimum Value (&lt;= 5.6.5)</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1048576</td>
</tr>
</tbody>
</table>

The number of rows in the `hosts` table. If this variable is 0, the Performance Schema does not maintain connection statistics in the `hosts` table.

- `performance_schema_max_cond_classes`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--performance-schema-max-cond-classes=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>performance_schema_max_cond_classes</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>80</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>256</td>
</tr>
</tbody>
</table>

The maximum number of condition instruments. For information about how to set and use this variable, see Section 22.7, “Performance Schema Status Monitoring”.

- `performance_schema_max_cond_instances`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--performance-schema-max-cond-instances=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>performance_schema_max_cond_instances</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value (&gt;= 5.6.6)</td>
<td>-1 (signifies autosizing; do not assign this literal value)</td>
</tr>
<tr>
<td>Default Value (&lt;= 5.6.5)</td>
<td>1000</td>
</tr>
</tbody>
</table>

The maximum number of instrumented condition objects. For information about how to set and use this variable, see Section 22.7, “Performance Schema Status Monitoring”.

- `performance_schema_max_digest_length`
### Performance Schema System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--performance-schema-max-digest-length=#</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.26</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>performance_schema_max_digest_length</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1024</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1048576</td>
</tr>
</tbody>
</table>

The maximum number of bytes of memory reserved per statement for computation of normalized statement digest values in the Performance Schema. This variable is related to `max_digest_length`; see the description of that variable in Section 5.1.7, “Server System Variables”.

For more information about statement digesting, including considerations regarding memory use, see Section 22.10, “Performance Schema Statement Digests”.

- **performance_schema_max_file_classes**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--performance-schema-max-file-classes=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>performance_schema_max_file_classes</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>50</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>256</td>
</tr>
</tbody>
</table>

The maximum number of file instruments. For information about how to set and use this variable, see Section 22.7, “Performance Schema Status Monitoring”.

- **performance_schema_max_file_handles**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--performance-schema-max-file-handles=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>performance_schema_max_file_handles</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>32768</td>
</tr>
</tbody>
</table>

The maximum number of opened file objects. For information about how to set and use this variable, see Section 22.7, “Performance Schema Status Monitoring”.

---

---
The value of `performance_schema_max_file_handles` should be greater than the value of `open_files_limit`: `open_files_limit` affects the maximum number of open file handles the server can support and `performance_schema_max_file_handles` affects how many of these file handles can be instrumented.

- **performance_schema_max_file_instances**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--performance-schema-max-file-instances=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>performance_schema_max_file_instances</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value ((\geq 5.6.6))</td>
<td>(-1) (signifies autosizing; do not assign this literal value)</td>
</tr>
<tr>
<td>Default Value ((\leq 5.6.5))</td>
<td>(10000)</td>
</tr>
</tbody>
</table>

The maximum number of instrumented file objects. For information about how to set and use this variable, see Section 22.7, “Performance Schema Status Monitoring”.

- **performance_schema_max_mutex_classes**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--performance-schema-max-mutex-classes=#</code></td>
</tr>
<tr>
<td>System Variable</td>

</tbody>
</table>

The maximum number of socket instruments. For information about how to set and use this variable, see Section 22.7, “Performance Schema Status Monitoring”.

- **performance_schema_max_socket_instances**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--performance-schema-max-socket-instances=#</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.3</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>performance_schema_max_socket_instances</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value (&gt;= 5.6.6)</td>
<td>-1 (signifies autosizing; do not assign this literal value)</td>
</tr>
<tr>
<td>Default Value (&lt;= 5.6.5)</td>
<td>1000</td>
</tr>
</tbody>
</table>

The maximum number of instrumented socket objects. For information about how to set and use this variable, see Section 22.7, “Performance Schema Status Monitoring”.

- **performance_schema_max_stage_classes**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--performance-schema-max-stage-classes=#</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.3</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>performance_schema_max_stage_classes</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>150</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>256</td>
</tr>
</tbody>
</table>

The maximum number of stage instruments. For information about how to set and use this variable, see Section 22.7, “Performance Schema Status Monitoring”.

- **performance_schema_max_statement_classes**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--performance-schema-max-statement-classes=#</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.3</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>performance_schema_max_statement_classes</code></td>
</tr>
</tbody>
</table>
The maximum number of statement instruments. For information about how to set and use this variable, see Section 22.7, “Performance Schema Status Monitoring”.

The default value is calculated at server build time based on the number of commands in the client/server protocol and the number of SQL statement types supported by the server.

This variable should not be changed, unless to set it to 0 to disable all statement instrumentation and save all memory associated with it. Setting the variable to nonzero values other than the default has no benefit; in particular, values larger than the default cause more memory to be allocated than is needed.

- `performance_schema_max_table_handles`

The maximum number of opened table objects. For information about how to set and use this variable, see Section 22.7, “Performance Schema Status Monitoring”.

- `performance_schema_max_table_instances`

The maximum number of instrumented table objects. For information about how to set and use this variable, see Section 22.7, “Performance Schema Status Monitoring”.

- `performance_schema_max_thread_classes`
### Performance Schema System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--performance-schema-max-thread-classes=#</td>
</tr>
<tr>
<td>System Variable</td>
<td>performance_schema_max_thread_classes</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>50</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>256</td>
</tr>
</tbody>
</table>

The maximum number of thread instruments. For information about how to set and use this variable, see Section 22.7, “Performance Schema Status Monitoring”.

- `performance_schema_max_thread_instances`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--performance-schema-max-thread-instances=#</td>
</tr>
<tr>
<td>System Variable</td>
<td>performance_schema_max_thread_instances</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value ((\geq 5.6.6))</td>
<td>-1 (signifies autosizing; do not assign this literal value)</td>
</tr>
<tr>
<td>Default Value ((\leq 5.6.5))</td>
<td>1000</td>
</tr>
</tbody>
</table>

The maximum number of instrumented thread objects. The value controls the size of the `threads` table. If this maximum is exceeded such that a thread cannot be instrumented, the Performance Schema increments the `performance_schema_thread_instances_lost` status variable. For information about how to set and use this variable, see Section 22.7, “Performance Schema Status Monitoring”.

- `max_connections` system variable affects how many threads are run in the server.
- `performance_schema_max_thread_instances` affects how many of these running threads can be instrumented. The default value of `performance_schema_max_thread_instances` is autosized based on the value of `max_connections`.

- `performance_schema_session_connect_attrs_size`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--performance-schema-session-connect-attrs-size=#</td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.6</td>
</tr>
<tr>
<td>System Variable</td>
<td>performance_schema_session_connect_attrs_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>-1 (signifies autosizing; do not assign this literal value)</td>
</tr>
</tbody>
</table>
Performance Schema System Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum Value</td>
<td>-1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1048576</td>
</tr>
</tbody>
</table>

The amount of preallocated memory per thread reserved to hold connection attribute key-value pairs. If the aggregate size of connection attribute data sent by a client is larger than this amount, the Performance Schema truncates the attribute data, increments the `performance_schema_session_connect_attrs_lost` status variable, and writes a message to the error log indicating that truncation occurred if the `log_warnings` system variable value is greater than zero.

The default value of `performance_schema_session_connect_attrs_size` is autosized at server startup. This value may be small, so if truncation occurs (`performance_schema_session_connect_attrs_lost` becomes nonzero), you may wish to set `performance_schema_session_connect_attrs_size` explicitly to a larger value.

Although the maximum permitted `performance_schema_session_connect_attrs_size` value is 1MB, the effective maximum is 64KB because the server imposes a limit of 64KB on the aggregate size of connection attribute data it will accept. If a client attempts to send more than 64KB of attribute data, the server rejects the connection. For more information, see Section 22.12.8, "Performance Schema Connection Attribute Tables".

- **performance_schema_setup_actors_size**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--performance-schema-setup-actors-size=#</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.1</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>performance_schema_setup_actors_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>100</td>
</tr>
</tbody>
</table>

The number of rows in the `setup_actors` table.

- **performance_schema_setup_objects_size**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--performance-schema-setup-objects-size=#</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.1</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>performance_schema_setup_objects_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>100</td>
</tr>
</tbody>
</table>

The number of rows in the `setup_objects` table.

- **performance_schema_users_size**
The number of rows in the `users` table. If this variable is 0, the Performance Schema does not maintain connection statistics in the `users` table.

### 22.16 Performance Schema Status Variables

The Performance Schema implements several status variables that provide information about instrumentation that could not be loaded or created due to memory constraints:

```sql
mysql> SHOW STATUS LIKE 'perf%';
+-------------------------------------------+-------+
| Variable_name                             | Value |
+-------------------------------------------+-------+
| Performance_schema_accounts_lost          | 0     |
| Performance_schema_cond_classes_lost      | 0     |
| Performance_schema_cond_instances_lost    | 0     |
| Performance_schema_file_classes_lost      | 0     |
| Performance_schema_file_handles_lost      | 0     |
| Performance_schema_file_instances_lost    | 0     |
| Performance_schema_hosts_lost             | 0     |
| Performance_schema_locker_lost            | 0     |
| Performance_schema_mutex_classes_lost     | 0     |
| Performance_schema_mutex_instances_lost   | 0     |
| Performance_schema_rwlock_classes_lost    | 0     |
| Performance_schema_rwlock_instances_lost  | 0     |
| Performance_schema_socket_classes_lost    | 0     |
| Performance_schema_socket_instances_lost  | 0     |
| Performance_schema_stage_classes_lost     | 0     |
| Performance_schema_statement_classes_lost | 0     |
| Performance_schema_table_handles_lost     | 0     |
| Performance_schema_table_instances_lost   | 0     |
| Performance_schema_thread_classes_lost    | 0     |
| Performance_schema_thread_instances_lost  | 0     |
| Performance_schema_users_lost             | 0     |
+-------------------------------------------+-------+
```

For information on using these variables to check Performance Schema status, see Section 22.7, “Performance Schema Status Monitoring”.

Performance Schema status variables have the following meanings:

- `Performance_schema_accounts_lost`
The number of times a row could not be added to the `accounts` table because it was full.

- **Performance_schema_cond_classes_lost**
  How many condition instruments could not be loaded.

- **Performance_schema_cond_instances_lost**
  How many condition instrument instances could not be created.

- **Performance_schema_digest_lost**
  The number of digest instances that could not be instrumented in the `events_statements_summary_by_digest` table. This can be nonzero if the value of `performance_schema_digests_size` is too small.

- **Performance_schema_file_classes_lost**
  How many file instruments could not be loaded.

- **Performance_schema_file_handles_lost**
  How many file instrument instances could not be opened.

- **Performance_schema_file_instances_lost**
  How many file instrument instances could not be created.

- **Performance_schema_hosts_lost**
  The number of times a row could not be added to the `hosts` table because it was full.

- **Performance_schema_locker_lost**
  How many events are “lost” or not recorded, due to the following conditions:
  - Events are recursive (for example, waiting for A caused a wait on B, which caused a wait on C).
  - The depth of the nested events stack is greater than the limit imposed by the implementation.
  Events recorded by the Performance Schema are not recursive, so this variable should always be 0.

- **Performance_schema_mutex_classes_lost**
  How many mutex instruments could not be loaded.

- **Performance_schema_mutex_instances_lost**
  How many mutex instrument instances could not be created.

- **Performance_schema_rwlock_classes_lost**
  How many rwlock instruments could not be loaded.

- **Performance_schema_rwlock_instances_lost**
  How many rwlock instrument instances could not be created.

- **Performance_schema_session_connect_attrs_lost**
The number of connections for which connection attribute truncation has occurred. For a given connection, if the client sends connection attribute key-value pairs for which the aggregate size is larger than the reserved storage permitted by the value of the `performance_schema_session_connect_attrs_size` system variable, the Performance Schema truncates the attribute data and increments `Performance_schema_session_connect_attrs_lost`. If this value is nonzero, you may wish to set `performance_schema_session_connect_attrs_size` to a larger value.

For more information about connection attributes, see Section 22.12.8, “Performance Schema Connection Attribute Tables”.

- **Performance_schema_socket_classes_lost**
  How many socket instruments could not be loaded.

- **Performance_schema_socket_instances_lost**
  How many socket instrument instances could not be created.

- **Performance_schema_stage_classes_lost**
  How many stage instruments could not be loaded.

- **Performance_schema_statement_classes_lost**
  How many statement instruments could not be loaded.

- **Performance_schema_table_handles_lost**
  How many table instrument instances could not be opened.

- **Performance_schema_table_instances_lost**
  How many table instrument instances could not be created.

- **Performance_schema_thread_classes_lost**
  How many thread instruments could not be loaded.

- **Performance_schema_thread_instances_lost**
  The number of thread instances that could not be instrumented in the `threads` table. This can be nonzero if the value of `performance_schema_max_thread_instances` is too small.

- **Performance_schema_users_lost**
  The number of times a row could not be added to the `users` table because it was full.

### 22.17 Performance Schema and Plugins

Removing a plugin with `UNINSTALL PLUGIN` does not affect information already collected for code in that plugin. Time spent executing the code while the plugin was loaded was still spent even if the plugin is unloaded later. The associated event information, including aggregate information, remains readable in `performance_schema` database tables. For additional information about the effect of plugin installation and removal, see Section 22.7, “Performance Schema Status Monitoring”.
A plugin implementor who instruments plugin code should document its instrumentation characteristics to enable those who load the plugin to account for its requirements. For example, a third-party storage engine should include in its documentation how much memory the engine needs for mutex and other instruments.

22.18 Using the Performance Schema to Diagnose Problems

The Performance Schema is a tool to help a DBA do performance tuning by taking real measurements instead of “wild guesses.” This section demonstrates some ways to use the Performance Schema for this purpose. The discussion here relies on the use of event filtering, which is described in Section 22.4.2, “Performance Schema Event Filtering”.

The following example provides one methodology that you can use to analyze a repeatable problem, such as investigating a performance bottleneck. To begin, you should have a repeatable use case where performance is deemed “too slow” and needs optimization, and you should enable all instrumentation (no pre-filtering at all).

1. Run the use case.
2. Using the Performance Schema tables, analyze the root cause of the performance problem. This analysis will rely heavily on post-filtering.
3. For problem areas that are ruled out, disable the corresponding instruments. For example, if analysis shows that the issue is not related to file I/O in a particular storage engine, disable the file I/O instruments for that engine. Then truncate the history and summary tables to remove previously collected events.
4. Repeat the process at step 1.

At each iteration, the Performance Schema output, particularly the `events_waits_history_long` table, will contain less and less “noise” caused by nonsignificant instruments, and given that this table has a fixed size, will contain more and more data relevant to the analysis of the problem at hand.

At each iteration, investigation should lead closer and closer to the root cause of the problem, as the “signal/noise” ratio will improve, making analysis easier.

5. Once a root cause of performance bottleneck is identified, take the appropriate corrective action, such as:
   - Tune the server parameters (cache sizes, memory, and so forth).
   - Tune a query by writing it differently,
   - Tune the database schema (tables, indexes, and so forth).
   - Tune the code (this applies to storage engine or server developers only).
6. Start again at step 1, to see the effects of the changes on performance.

The `mutex_instances.LOCKED_BY_THREAD_ID` and `rwlock_instances.WRITE_LOCKED_BY_THREAD_ID` columns are extremely important for investigating performance bottlenecks or deadlocks. This is made possible by Performance Schema instrumentation as follows:

1. Suppose that thread 1 is stuck waiting for a mutex.
2. You can determine what the thread is waiting for:
Say the query result identifies that the thread is waiting for mutex A, found in `events_waits_current.OBJECT_INSTANCE_BEGIN`.

3. You can determine which thread is holding mutex A:

   ```sql
   SELECT * FROM performance_schema.mutex_instances
   WHERE OBJECT_INSTANCE_BEGIN = 'mutex_A';
   ```

   Say the query result identifies that it is thread 2 holding mutex A, as found in `mutex_instances.LOCKED_BY_THREAD_ID`.

4. You can see what thread 2 is doing:

   ```sql
   SELECT * FROM performance_schema.events_waits_current
   WHERE THREAD_ID = 'thread_2';
   ```

22.18.1 Query Profiling Using Performance Schema

The following example demonstrates how to use Performance Schema statement events and stage events to retrieve data comparable to profiling information provided by `SHOW PROFILES` and `SHOW PROFILE` statements.

In this example, statement and stage event data is collected in the `events_statements_history_long` and `events_stages_history_long` tables. On a busy server with many active foreground threads, data could age out of the history tables before you are able to retrieve the information you want to analyze. If you encounter this problem, options include:

- Running the query on a test instance where there is less foreground thread activity.
- Disabling instrumentation for other existing foreground threads by setting the `INSTRUMENTED` field of the `threads` table to `NO` for other thread records. For example, the following statement disables instrumentation for all foreground threads except the `test_user` thread:

  ```sql
  mysql> UPDATE performance_schema.threads
  SET INSTRUMENTED = 'NO'
  WHERE TYPE='FOREGROUND' AND PROCESSLIST_USER NOT LIKE 'test_user';
  ```

However, be aware that new threads are always instrumented by default.

- Increasing the number of rows in the `events_statements_history_long` and `events_stages_history_long` tables. The `performance_schema_events_statements_history_size` and `performance_schema_events_stages_history_size` configuration options are autosized by default but can also be set explicitly at startup. You can view current settings by running `SHOW VARIABLES`. For information about autosized Performance Schema parameters, see Section 22.3, “Performance Schema Startup Configuration”.

Performance Schema displays event timer information in picoseconds (trillionths of a second) to normalize timing data to a standard unit. In the following example, `TIMER_WAIT` values are divided by 1000000000000 to show data in units of seconds. Values are also truncated to 6 decimal places to display data in the same format as `SHOW PROFILES` and `SHOW PROFILE` statements.
1. Ensure that statement and stage instrumentation is enabled by updating the `setup_instruments` table. Some instruments may already be enabled by default.

```sql
mysql> UPDATE performance_schema.setup_instruments
    SET ENABLED = 'YES', TIMED = 'YES'
    WHERE NAME LIKE '%statement/%';

mysql> UPDATE performance_schema.setup_instruments
    SET ENABLED = 'YES', TIMED = 'YES'
    WHERE NAME LIKE '%stage/%';
```

2. Ensure that `events_statements_*` and `events_stages_*` consumers are enabled. Some consumers may already be enabled by default.

```sql
mysql> UPDATE performance_schema.setup_consumers
    SET ENABLED = 'YES'
    WHERE NAME LIKE '%events_statements_%';

mysql> UPDATE performance_schema.setup_consumers
    SET ENABLED = 'YES'
    WHERE NAME LIKE '%events_stages_%';
```

3. Run the statement that you want to profile. For example:

```sql
mysql> SELECT * FROM employees.employees WHERE emp_no = 10001;
```

```
+--------+------------+------------+-----------+--------+------------+
<table>
<thead>
<tr>
<th>emp_no</th>
<th>birth_date</th>
<th>first_name</th>
<th>last_name</th>
<th>gender</th>
<th>hire_date</th>
</tr>
</thead>
<tbody>
<tr>
<td>10001</td>
<td>1953-09-02</td>
<td>Georgi</td>
<td>Facello</td>
<td>M</td>
<td>1986-06-26</td>
</tr>
</tbody>
</table>
+--------+------------+------------+-----------+--------+------------+
```

4. Identify the `EVENT_ID` of the statement by querying the `events_statements_history_long` table. This step is similar to running `SHOW PROFILES` to identify the `Query_ID`. The following query produces output similar to `SHOW PROFILES`:

```sql
mysql> SELECT EVENT_ID, TRUNCATE(TIMER_WAIT/1000000000000,6) as Duration, SQL_TEXT
    FROM performance_schema.events_statements_history_long WHERE SQL_TEXT like '%10001%';
```

```
+----------+----------+--------------------------------------------------------+
| event_id | duration | sql_text                                               |
|----------|----------|--------------------------------------------------------+
|       31 | 0.028310 | SELECT * FROM employees.employees WHERE emp_no = 10001 |
+----------+----------+--------------------------------------------------------+
```

5. Query the `events_stages_history_long` table to retrieve the statement's stage events. Stages are linked to statements using event nesting. Each stage event record has a `NESTING_EVENT_ID` column that contains the `EVENT_ID` of the parent statement.

```sql
mysql> SELECT event_name AS Stage, TRUNCATE(TIMER_WAIT/1000000000000,6) AS Duration
    FROM performance_schema.events_stages_history_long WHERE NESTING_EVENT_ID=31;
```

```
+----------------+------------+
| Stage           | Duration   |
|----------------+------------|
| stage/sql/starting | 0.0000080  |
| stage/sql/checking permissions | 0.000005  |
| stage/sql/Opening tables | 0.027759  |
| stage/sql/init | 0.000052   |
| stage/sql/System lock | 0.000009  |
| stage/sql/optimizing | 0.000006  |
| stage/sql/statistics | 0.000082  |
| stage/sql/preparing | 0.000008  |
```
### 22.19 Restrictions on Performance Schema

The Performance Schema avoids using mutexes to collect or produce data, so there are no guarantees of consistency and results can sometimes be incorrect. Event values in `performance_schema` tables are nondeterministic and nonrepeatable.

If you save event information in another table, you should not assume that the original events will still be available later. For example, if you select events from a `performance_schema` table into a temporary table, intending to join that table with the original table later, there might be no matches.

`mysqldump` and `BACKUP DATABASE` ignore tables in the `performance_schema` database.

Tables in the `performance_schema` database cannot be locked with `LOCK TABLES`, except the `setup_`xxx tables.

Tables in the `performance_schema` database cannot be indexed.

Results for queries that refer to tables in the `performance_schema` database are not saved in the query cache.

Tables in the `performance_schema` database are not replicated.

The Performance Schema is not available in `libmysql`, the embedded server.

The types of timers might vary per platform. The `performance_timers` table shows which event timers are available. If the values in this table for a given timer name are `NULL`, that timer is not supported on your platform.

Instruments that apply to storage engines might not be implemented for all storage engines. Instrumentation of each third-party engine is the responsibility of the engine maintainers.

MySQL Connectors provide connectivity to the MySQL server for client programs. APIs provide low-
level access to the MySQL protocol and MySQL resources. Both Connectors and the APIs enable you to
connect and execute MySQL statements from another language or environment, including ODBC, Java
(JDBC), Perl, Python, PHP, Ruby, and native C and embedded MySQL instances.
MySQL Connectors

Oracle develops a number of connectors:

• **Connector/C** is a standalone replacement for the MySQL Client Library (*libmysqlclient*), to be used for C applications.

• **Connector/C++** enables C++ applications to connect to MySQL.

• **Connector/J** provides driver support for connecting to MySQL from Java applications using the standard Java Database Connectivity (JDBC) API.

• **Connector/NET** enables developers to create .NET applications that connect to MySQL. Connector/NET implements a fully functional ADO.NET interface and provides support for use with ADO.NET aware tools. Applications that use Connector/NET can be written in any supported .NET language.

**MySQL for Visual Studio** works with Connector/NET and Microsoft Visual Studio 2012, 2013, 2015, and 2017. MySQL for Visual Studio provides access to MySQL objects and data from Visual Studio. As a Visual Studio package, it integrates directly into Server Explorer providing the ability to create new connections and work with MySQL database objects.

• **Connector/ODBC** provides driver support for connecting to MySQL using the Open Database Connectivity (ODBC) API. Support is available for ODBC connectivity from Windows, Unix, and OS X platforms.

• **Connector/Python** provides driver support for connecting to MySQL from Python applications using an API that is compliant with the Python DB API version 2.0. No additional Python modules or MySQL client libraries are required.

The MySQL C API

For direct access to using MySQL natively within a C application, there are two methods:

• The **C API** provides low-level access to the MySQL client/server protocol through the *libmysqlclient* client library. This is the primary method used to connect to an instance of the MySQL server, and is used both by MySQL command-line clients and many of the MySQL Connectors and third-party APIs detailed here.

  *libmysqlclient* is included in MySQL distributions and in Connector/C distributions.

• **libmysqld** is an embedded MySQL server library that enables you to embed an instance of the MySQL server into your C applications.

  *libmysqld* is included in MySQL distributions, but not in Connector/C distributions.

See also Section 23.8.1, “MySQL C API Implementations”.

To access MySQL from a C application, or to build an interface to MySQL for a language not supported by the Connectors or APIs in this chapter, the **C API** is where to start. A number of programmer's utilities are available to help with the process; see Section 4.7, “MySQL Program Development Utilities”.

Third-Party MySQL APIs

The remaining APIs described in this chapter provide an interface to MySQL from specific application languages. These third-party solutions are not developed or supported by Oracle. Basic information on their usage and abilities is provided here for reference purposes only.
All the third-party language APIs are developed using one of two methods, using `libmysqlclient` or by implementing a `native driver`. The two solutions offer different benefits:

- Using `libmysqlclient` offers complete compatibility with MySQL because it uses the same libraries as the MySQL client applications. However, the feature set is limited to the implementation and interfaces exposed through `libmysqlclient` and the performance may be lower as data is copied between the native language, and the MySQL API components.

- **Native drivers** are an implementation of the MySQL network protocol entirely within the host language or environment. Native drivers are fast, as there is less copying of data between components, and they can offer advanced functionality not available through the standard MySQL API. Native drivers are also easier for end users to build and deploy because no copy of the MySQL client libraries is needed to build the native driver components.

Table 23.1, “MySQL APIs and Interfaces” lists many of the libraries and interfaces available for MySQL.

### 23.1 MySQL Connector/C

The MySQL Connector/C manual is published in standalone form, not as part of the MySQL Reference Manual. For information, see these documents:

- Main manual: MySQL Connector/C Developer Guide
- Release notes: MySQL Connector/C Release Notes

### 23.2 MySQL Connector/C++

The MySQL Connector/C++ manual is published in standalone form, not as part of the MySQL Reference Manual. For information, see these documents:

- Main manual: MySQL Connector/C++ 8.0 Developer Guide
- Release notes: MySQL Connector/C++ Release Notes

### 23.3 MySQL Connector/J

The MySQL Connector/J manual is published in standalone form, not as part of the MySQL Reference Manual. For information, see these documents:

- Main manual: MySQL Connector/J Developer Guide
- Release notes: MySQL Connector/J Release Notes
23.4 MySQL Connector/NET

The MySQL Connector/NET manual is published in standalone form, not as part of the MySQL Reference Manual. For information, see these documents:

- Main manual: MySQL Connector/NET Developer Guide
- Release notes: MySQL Connector/NET Release Notes

23.5 MySQL Connector/ODBC

The MySQL Connector/ODBC manual is published in standalone form, not as part of the MySQL Reference Manual. For information, see these documents:

- Main manual: MySQL Connector/ODBC Developer Guide
- Release notes: MySQL Connector/ODBC Release Notes

23.6 MySQL Connector/Python

The MySQL Connector/Python manual is published in standalone form, not as part of the MySQL Reference Manual. For information, see these documents:

- Main manual: MySQL Connector/Python Developer Guide
- Release notes: MySQL Connector/Python Release Notes

23.7 libmysqld, the Embedded MySQL Server Library

The embedded MySQL server library makes it possible to run a full-featured MySQL server inside a client application. The main benefits are increased speed and more simple management for embedded applications.

The embedded server library is based on the client/server version of MySQL, which is written in C/C++. Consequently, the embedded server also is written in C/C++. There is no embedded server available in other languages.

The API is identical for the embedded MySQL version and the client/server version. To change a threaded application to use the embedded library, you normally only have to add calls to the following functions.

**Table 23.2 MySQL Embedded Server Library Functions**

<table>
<thead>
<tr>
<th>Function</th>
<th>When to Call</th>
</tr>
</thead>
<tbody>
<tr>
<td>mysql_library_init()</td>
<td>Call it before any other MySQL function is called, preferably early in the main() function.</td>
</tr>
<tr>
<td>mysql_library_end()</td>
<td>Call it before your program exits.</td>
</tr>
<tr>
<td>mysql_thread_init()</td>
<td>Call it in each thread you create that accesses MySQL.</td>
</tr>
<tr>
<td>mysql_thread_end()</td>
<td>Call it before calling pthread_exit().</td>
</tr>
</tbody>
</table>

Then, link your code with libmysqld.a instead of libmysqlclient.a. To ensure binary compatibility between your application and the server library, always compile your application against headers for the same series of MySQL that was used to compile the server library. For example, if libmysqld was compiled against MySQL 5.5 headers, do not compile your application against MySQL 5.6 headers, or vice versa.
Because the `mysql_library_xxx()` functions are also included in `libmysqlclient.a`, you can change between the embedded and the client/server version by just linking your application with the right library. See Section 23.8.7.40, “mysql_library_init()”.

One difference between the embedded server and the standalone server is that for the embedded server, authentication for connections is disabled by default.

### 23.7.1 Compiling Programs with libmysqld

In precompiled binary MySQL distributions that include `libmysqld`, the embedded server library, MySQL builds the library using the appropriate vendor compiler if there is one.

To get a `libmysqld` library if you build MySQL from source yourself, you should configure MySQL with the `--with-embedded-server=1` option. See Section 2.9.7, “MySQL Source-Configuration Options”.

When you link your program with `libmysqld`, you must also include the system-specific `pthread` libraries and some libraries that the MySQL server uses. You can get the full list of libraries by executing `mysql_config --libmysqld-libs`.

The correct flags for compiling and linking a threaded program must be used, even if you do not directly call any thread functions in your code.

To compile a C program to include the necessary files to embed the MySQL server library into an executable version of a program, the compiler will need to know where to find various files and need instructions on how to compile the program. The following example shows how a program could be compiled from the command line, assuming that you are using `gcc`, use the GNU C compiler:

```
gcc mysql_test.c -o mysql_test `'/usr/local/mysql/bin/mysql_config --include --libmysqld-libs'`
```

Immediately following the `gcc` command is the name of the C program source file. After it, the `-o` option is given to indicate that the file name that follows is the name that the compiler is to give to the output file, the compiled program. The next line of code tells the compiler to obtain the location of the include files and libraries and other settings for the system on which it is compiled. The `mysql_config` command is contained in backticks, not single quotation marks.

On some non-`gcc` platforms, the embedded library depends on C++ runtime libraries and linking against the embedded library might result in missing-symbol errors. To solve this, link using a C++ compiler or explicitly list the required libraries on the link command line.

### 23.7.2 Restrictions When Using the Embedded MySQL Server

The embedded server has the following limitations:

- No user-defined functions (UDFs).
- No stack trace on core dump.
- You cannot set this up as a master or a slave (no replication).
- Very large result sets may be unusable on low memory systems.
- You cannot connect to an embedded server from an outside process with sockets or TCP/IP. However, you can connect to an intermediate application, which in turn can connect to an embedded server on the behalf of a remote client or outside process.
- `libmysqld` does not support encrypted connections. An implication is that if an application linked against `libmysqld` establishes a connection to a remote server, the connection cannot be encrypted.
InnoDB is not reentrant in the embedded server and cannot be used for multiple connections, either successively or simultaneously.

The Event Scheduler is not available. Because of this, the `event_scheduler` system variable is disabled.

The Performance Schema is not available.

Some of these limitations can be changed by editing the `mysql_embed.h` include file and recompiling MySQL.

### 23.7.3 Options with the Embedded Server

Any options that may be given with the `mysqld` server daemon, may be used with an embedded server library. Server options may be given in an array as an argument to the `mysql_library_init()`, which initializes the server. They also may be given in an option file like `my.cnf`. To specify an option file for a C program, use the `--defaults-file` option as one of the elements of the second argument of the `mysql_library_init()` function. See Section 23.8.7.40, "`mysql_library_init()`", for more information on the `mysql_library_init()` function.

Using option files can make it easier to switch between a client/server application and one where MySQL is embedded. Put common options under the `[server]` group. These are read by both MySQL versions. Client/server-specific options should go under the `[mysqld]` section. Put options specific to the embedded MySQL server library in the `[embedded]` section. Options specific to applications go under section labeled `[ApplicationName_SERVER]`. See Section 4.2.2.2, “Using Option Files”.

### 23.7.4 Embedded Server Examples

These two example programs should work without any changes on a Linux or FreeBSD system. For other operating systems, minor changes are needed, mostly with file paths. These examples are designed to give enough details for you to understand the problem, without the clutter that is a necessary part of a real application. The first example is very straightforward. The second example is a little more advanced with some error checking. The first is followed by a command-line entry for compiling the program. The second is followed by a GNUmake file that may be used for compiling instead.

**Example 1**

`test1_libmysqld.c`

```c
#include <stdio.h>
#include <stdlib.h>
#include <stdarg.h>
#include "mysql.h"
MYSQL *mysql;
MYSQL_RES *results;
MYSQL_ROW record;
static char *server_options[] = \\n    { "mysql_test", "--defaults-file=my.cnf", NULL };
int num_elements = (sizeof(server_options) / sizeof(char *)) - 1;
static char *server_groups[] = { "libmysqld_server", "libmysqld_client", NULL };
int main(void)
{
    mysql_library_init(num_elements, server_options, server_groups);
    mysql = mysql_init(NULL);
    mysql_options(mysql, MYSQL_READ_DEFAULT_GROUP, "libmysqld_client");
```
Example 2

To try the example, create an test2_libmysqld directory at the same level as the MySQL source directory. Save the test2_libmysqld.c source and the GNUmakefile in the directory, and run GNU make from inside the test2_libmysqld directory.

test2_libmysqld.c

/*
 * A simple example client, using the embedded MySQL server library
 */

#include <mysql.h>
#include <stdarg.h>
#include <stdio.h>
#include <stdlib.h>

MYSQL *db_connect(const char *dbname);
void db_disconnect(MYSQL *db);
void db_do_query(MYSQL *db, const char *query);

const char *server_groups[] = {
    "test2_libmysqld_SERVER", "embedded", "server", NULL
};

int main(int argc, char **argv)
{
    MYSQL *one, *two;

    /* mysql_library_init() must be called before any other mysql
     * functions.
     * You can use mysql_library_init(0, NULL, NULL), and it
     * initializes the server using groups = {
     *     "server", "embedded", NULL
     * }.
     * In your $HOME/.my.cnf file, you probably want to put:
     */
Embedded Server Examples

```
[test2_libmysqld_SERVER]
language = /path/to/source/of/mysql/sql/share/english

* You could, of course, modify argc and argv before passing
* them to this function. Or you could create new ones in any
* way you like. But all of the arguments in argv (except for
* argv[0], which is the program name) should be valid options
* for the MySQL server.
* *
* If you link this client against the normal mysqlclient
* library, this function is just a stub that does nothing. */
mysql_library_init(argc, argv, (char **)server_groups);

one = db_connect("test");
two = db_connect(NULL);

db_do_query(one, "SHOW TABLE STATUS");
db_do_query(two, "SHOW DATABASES");

mysql_close(two);
mysql_close(one);

/* This must be called after all other mysql functions */
mysql_library_end();

The C API provides low-level access to the MySQL client/server protocol and enables C programs to access database contents. The C API code is distributed with MySQL and implemented in the `libmysqlclient` library. See Section 23.8.1, “MySQL C API Implementations”.

Most other client APIs use the `libmysqlclient` library to communicate with the MySQL server. (Exceptions are Connector/J and Connector/NET.) This means that, for example, you can take advantage of many of the same environment variables that are used by other client programs because they are referenced from the library. For a list of these variables, see Section 4.1, “Overview of MySQL Programs”.

For instructions on building client programs using the C API, see Section 23.8.4.1, “Building C API Client Programs”. For programming with threads, see Section 23.8.4.2, “Writing C API Threaded Client Programs”. To create a standalone application which includes the “server” and “client” in the same program (and does not communicate with an external MySQL server), see Section 23.7, “libmysqld, the Embedded MySQL Server Library”.

Note

If, after an upgrade, you experience problems with compiled client programs, such as `Commands out of sync` or unexpected core dumps, the programs were probably compiled using old header or library files. In this case, check the date of the `mysql.h` file and `libmysqlclient.a` library used for compilation to verify that they are from the new MySQL distribution. If not, recompile the programs with the new headers and libraries. Recompilation might also be necessary for programs compiled against the shared client library if the library major version number has changed (for example, from `libmysqlclient.so.17` to `libmysqlclient.so.18`). For additional compatibility information, see Section 23.8.4.3, “Running C API Client Programs”.

Clients have a maximum communication buffer size. The size of the buffer that is allocated initially (16KB) is automatically increased up to the maximum size (16MB by default). Because buffer sizes are increased only as demand warrants, simply increasing the maximum limit does not in itself cause more resources to be used. This size check is mostly a precaution against erroneous statements and communication packets.

The communication buffer must be large enough to contain a single SQL statement (for client-to-server traffic) and one row of returned data (for server-to-client traffic). Each session’s communication buffer is dynamically enlarged to handle any query or row up to the maximum limit. For example, if you have `BLOB` values that contain up to 16MB of data, you must have a communication buffer limit of at least 16MB (in both server and client). The default maximum built into the client library is 1GB, but the default maximum in the server is 1MB. You can increase this by changing the value of the `max_allowed_packet` parameter at server startup. See Section 5.1.1, “Configuring the Server”.

The MySQL server shrinks each communication buffer to `net_buffer_length` bytes after each query. For clients, the size of the buffer associated with a connection is not decreased until the connection is closed, at which time client memory is reclaimed.

23.8.1 MySQL C API Implementations

The MySQL C API is a C-based API that client applications written in C can use to communicate with MySQL Server. Client programs refer to C API header files at compile time and link to a C API library file at link time. The library comes in two versions, depending on how the application is intended to communicate with the server:
Simultaneous MySQL Server and Connector/C Installations

• **libmysqlclient**: The client version of the library, used for applications that communicate over a network connection as a client of a standalone server process.

• **libmysqld**: The embedded server version of the library, used for applications intended to include an embedded MySQL server within the application itself. The application communicates with its own private server instance.

Both libraries have the same interface. In terms of C API calls, an application communicates with a standalone server the same way it communicates with an embedded server. A given client can be built to communicate with a standalone or embedded server, depending on whether it is linked against **libmysqlclient** or **libmysqld** at build time.

There are two ways to obtain the C API header and library files required to build C API client programs:

• Install a MySQL Server distribution. Server distributions include both **libmysqlclient** and **libmysqld**.

• Install a Connector/C distribution. Connector/C distributions include only **libmysqlclient**. They do not include **libmysqld**.

For both MySQL Server and Connector/C, you can install a binary distribution that contains the C API files pre-built, or you can use a source distribution and build the C API files yourself.

Normally, you install either a MySQL Server distribution or a Connector/C distribution, but not both. For information about issues involved with simultaneous MySQL Server and Connector/C installations, see Section 23.8.2, “Simultaneous MySQL Server and Connector/C Installations”.

The names of the library files to use when linking C API client applications depend on the library type and platform for which a distribution is built:

• On Unix (and Unix-like) systems, the static library is **libmysqlclient.a**. The dynamic library is **libmysqlclient.so** on most Unix systems and **libmysqlclient.dylib** on OS X.

  For distributions that include embedded server libraries, the corresponding library names begin with **libmysqld** rather than **libmysqlclient**.

• On Windows, the static library is **mysqlclient.lib** and the dynamic library is **libmysql.dll**. Windows distributions also include **libmysql.lib**, a static import library needed for using the dynamic library.

  For distributions that include embedded server libraries, the corresponding library names are **mysqlserver.lib**, **libmysqld.dll**, and **libmysqld.lib**.

  Windows distributions also include a set of debug libraries. These have the same names as the nondebug libraries, but are located in the **lib/debug** library. You must use the debug libraries when compiling clients built using the debug C runtime.

On Unix, you may also see libraries that include _r in the names. Before MySQL 5.5, these were built as thread-safe (re-entrant) libraries separately from the non-_r libraries. As of 5.5, both libraries are the same and the _r names are symbolic links to the corresponding non-_r names. There is no need to use the _r libraries. For example, if you use **mysql_config** to obtain linker flags, you can use **mysql_config --libs** in all cases, even for threaded clients. There is no need to use **mysql_config --libs_r**.

### 23.8.2 Simultaneous MySQL Server and Connector/C Installations

MySQL Server and Connector/C installation packages both provide the files needed to build and run MySQL C API client programs. This section discusses when it is possible to install both products on the
same system. For some packaging formats, this is possible without conflict. For others, both products cannot be installed at the same time.

This discussion assumes the use of similar package types for both products (for example, RPM packages for both products). It does not try to describe coexistence between packaging types (for example, use of RPM packages for one product and a tar file package for the other). Nor does it describe coexistence of packages provided by Oracle and those provided by third-party vendors.

If you install both products, it may be necessary to adjust your development tools or runtime environment to choose one set of header files and libraries over the other. See Section 23.8.4.1, “Building C API Client Programs”, and Section 23.8.4.3, “Running C API Client Programs”.

tar and Zip file packages install under the directory into which you unpack them. For example, you can unpack MySQL Server and Connector/C tar packages under /usr/local and they will unpack into distinct directory names without conflict.

Windows MSI installers use their own installation directory, so MySQL Server and Connector/C installers do not conflict.

OS X DMG packages install under the same parent directory but in a different subdirectory, so there is no conflict. For example:

```
/usr/local/mysql-5.6.11-osx10.7-x86_64/
/usr/local/mysql-connector-c-6.1.0-osx10.7-x86/
```

Solaris PKG packages install under the same parent directory but in a different subdirectory, so there is no conflict. For example:

```
/opt/mysql/mysql
/opt/mysql/connector-c
```

The Solaris Connector/C installer does not create any symlinks from system directories such as /usr/bin or /usr/lib into the installation directory. That must be done manually if desired after installation.

For RPM installations, there are several types of RPM packages. MySQL Server shared and devel RPM packages are similar to the corresponding Connector/C RPM packages. These RPM package types cannot coexist because the MySQL Server and Connector/C RPM packages use the same installation locations for the client library-related files. This means the following conditions hold:

- If MySQL Server shared and devel RPM packages are installed, they provide the C API headers and libraries, and there is no need to install the Connector/C RPM packages. To install the Connector/C packages anyway, you must first remove the corresponding MySQL Server packages.
- To install MySQL Server RPM packages if you already have Connector/C RPM packages installed, you must first remove the Connector/C RPM packages.

MySQL Server RPM packages other than shared and devel do not conflict with Connector/C packages and can be installed if Connector/C is installed. This includes the main server RPM that includes the `mysqld` server itself.

### 23.8.3 Example C API Client Programs

Many of the clients in MySQL source distributions are written in C, such as `mysql`, `mysqladmin`, and `mysqlshow`. If you are looking for examples that demonstrate how to use the C API, take a look at these clients: Obtain a source distribution and look in its `client` directory. See Section 2.1.2, “How to Get MySQL”.
23.8.4 Building and Running C API Client Programs

The following sections provide information on building client programs that use the C API. Topics include compiling and linking clients, writing threaded clients, and troubleshooting runtime problems.

23.8.4.1 Building C API Client Programs

This section provides guidelines for compiling C programs that use the MySQL C API.

Compiling MySQL Clients on Unix

The examples here use gcc as the compiler. A different compiler might be appropriate on some systems (for example, clang on OS X or FreeBSD, or Sun Studio on Solaris). Adjust the examples as necessary.

You may need to specify an -I option when you compile client programs that use MySQL header files, so that the compiler can find them. For example, if the header files are installed in /usr/local/mysql/include, use this option in the compile command:

```
-I/usr/local/mysql/include
```

MySQL clients must be linked using the -lmysqlclient option in the link command. You may also need to specify a -L option to tell the linker where to find the library. For example, if the library is installed in /usr/local/mysql/lib, use these options in the link command:

```
-L/usr/local/mysql/lib -lmysqlclient
```

The path names may differ on your system. Adjust the -I and -L options as necessary.

To make it simpler to compile MySQL programs on Unix, use the mysql_config script. See Section 4.7.2, "mysql_config — Display Options for Compiling Clients".

mysql_config displays the options needed for compiling or linking:

```
shell> mysql_config --cflags
shell> mysql_config --libs
```

You can run those commands to get the proper options and add them manually to compilation or link commands. Alternatively, include the output from mysql_config directly within command lines using backticks:

```
shell> gcc -c `mysql_config --cflags` proname.c
shell> gcc -o proname proname.o `mysql_config --libs`
```

On Unix, linking uses dynamic libraries by default. To link to the static client library instead, add its path name to the link command. For example, if the library is located in /usr/local/mysql/lib, link like this:

```
shell> gcc -o proname proname.o /usr/local/mysql/lib/libmysqlclient.a
```

Or use mysql_config to provide the library name:

```
shell> gcc -o proname proname.o `mysql_config --variable=pkglibdir'/libmysqlclient.a
```

mysql_config does not currently provide a way to list all libraries needed for static linking, so it might be necessary to name additional libraries on the link command (for example, -lnsl -lsocket on Solaris).
To get an idea which libraries to add, use `mysql_config --libs` and `ldd libmysqlclient.so` (or `otool -L libmysqlclient.dylib` on OS X).

**Compiling MySQL Clients on Microsoft Windows**

To specify header and library file locations, use the facilities provided by your development environment.

To build C API clients on Windows, you must link in the C client library, as well as the Windows ws2_32 sockets library and Secur32 security library.

You link your code with either the dynamic or static C client library. On Windows, the static library is named `mysqlclient.lib` and the dynamic library is named `libmysql.dll`. In addition, the `libmysql.lib` static import library is needed for using the dynamic library. If the static C client library is used, the client application must be compiled with the same version of Visual Studio used to compile the C client library (which is Visual Studio 2010 for the static C client library built by Oracle).

![Note]

The MySQL Connector/C is a standalone, drop-in replacement of the MySQL C client libraries that come with the MySQL server distribution. The Oracle-built MySQL Connector/C contains currently two versions of the static client library, one built with Visual Studio 2013 and the other one with Visual Studio 2015; use the one that matches the Visual Studio version you use to compile your application.

When using the Oracle-built MySQL C client library (or MySQL Connector/C), following these rules when it comes to linking the C runtime for your client application:

- For the Community version of the MySQL C client library (or the Community version of MySQL Connector/C):
  - *For version 5.6.35 and before* (or MySQL Connector/C Community 6.1.9 and before):
    - If linking to the static C client library, link statically to the C runtime (use the `/MT` compiler option).
    - If linking to the dynamic C client library, link either statically or dynamically to the C runtime (use either `/MT` or `/MD` compiler option).
  - *For version 5.6.36 and later* (or MySQL Connector/C Community 6.1.10 and later): Always link dynamically to the C runtime (use the `/MD` compiler option), whether you are linking to the static or dynamic C client library. Also, target hosts running the client application need to have the Visual C++ Redistributable for Visual Studio 2010 installed if you are using the C client libraries, or the Visual C++ Redistributable for Visual Studio 2015 installed if you are using MySQL Connector/C. The redistributable packages are available at the [Microsoft Download Center](https://www.microsoft.com/en-us/download/details.aspx?id=10442).

- For the Commercial version of the MySQL C client library (or the Commercial version of MySQL Connector/C):
  - If linking to the static C client library, link statically to the C runtime (use the `/MT` compiler option).
  - If linking to the dynamic C client library, link either statically or dynamically to the C runtime (use either `/MT` or `/MD` compiler option).

In general, when linking to a static MySQL C client library, the client library and the client application must use the same compiler option when it comes to linking the C runtime—that is, if your C client library is compiled with the `/MT` option, your client application should also be compiled with the `/MT` option, and so on (see the MSDN page describing the C library linking options for more details). Follow this rule when you are building your own static MySQL C client library (or MySQL Connector/C) from source and linking your client application to it.
Building and Running C API Client Programs

Note

Debug Mode: Because of the above-mentioned rule, you cannot build your application in debug mode (with the /MTd or /MDd compiler option) and link it to the static C client library built by Oracle, which is not built with the debug options; instead, you will have to build the static client library from source with the debug options.

Troubleshooting Problems Linking to the MySQL Client Library

The MySQL client library includes SSL support built in. If your application requires -lssl or -lcrypto from the OpenSSL libraries at link time, you must specify them before -lmysqlclient.

If the linker cannot find the MySQL client library, you might get undefined-reference errors for symbols that start with mysql_, such as those shown here:

```
/tmp/ccFKsdPa.o: In function `main':
/tmp/ccFKsdPa.o(.text+0xb): undefined reference to `mysql_init'
/tmp/ccFKsdPa.o(.text+0x31): undefined reference to `mysql_real_connect'
/tmp/ccFKsdPa.o(.text+0x69): undefined reference to `mysql_error'
/tmp/ccFKsdPa.o(.text+0x9a): undefined reference to `mysql_close'
```

You should be able to solve this problem by adding -ldir_path -lmysqlclient at the end of your link command, where dir_path represents the path name of the directory where the client library is located. To determine the correct directory, try this command:

```
shell> mysql_config --libs
```

The output from mysql_config might indicate other libraries that should be specified on the link command as well. You can include mysql_config output directly in your compile or link command using backticks. For example:

```
shell> gcc -o progname progname.o `mysql_config --libs`
```

If an error occurs at link time that the floor symbol is undefined, link to the math library by adding -lm to the end of the compile/link line. Similarly, if you get undefined-reference errors for other functions that should exist on your system, such as connect(), check the manual page for the function in question to determine which libraries you should add to the link command.

If you get undefined-reference errors such as the following for functions that do not exist on your system, it usually means that your MySQL client library was compiled on a system that is not 100% compatible with yours:

```
mf_format.o(.text+0x201): undefined reference to `__lxstat'
```

In this case, you should download the latest MySQL or Connector/C source distribution and compile the MySQL client library yourself. See Section 2.9, “Installing MySQL from Source”, and MySQL Connector/C Developer Guide.

23.8.4.2 Writing C API Threaded Client Programs

The client library is almost thread-safe. The biggest problem is that the subroutines in sql/net_serv.cc that read from sockets are not interrupt-safe. This was done with the thought that you might want to have your own alarm that can break a long read to a server. If you install interrupt handlers for the SIGPIPE interrupt, socket handling should be thread-safe.
To avoid aborting the program when a connection terminates, MySQL blocks SIGPIPE on the first call to mysql_library_init(), mysql_init(), or mysql_connect(). To use your own SIGPIPE handler, first call mysql_library_init(), then install your handler.

If “undefined symbol” errors occur when linking against the libmysqlclient client library, in most cases this is because you have not included the thread libraries on the link/compile command.

The client library is thread-safe per connection. You can let two threads share the same connection with the following caveats:

- Multiple threads cannot send a query to the MySQL server at the same time on the same connection. In particular, you must ensure that between calls to mysql_query() and mysql_store_result() in one thread, no other thread uses the same connection. You must have a mutex lock around your pair of mysql_query() and mysql_store_result() calls. After mysql_store_result() returns, the lock can be released and other threads may query the same connection.

If you use POSIX threads, you can use pthread_mutex_lock() and pthread_mutex_unlock() to establish and release a mutex lock.

- Many threads can access different result sets that are retrieved with mysql_store_result().

- To use mysql_use_result(), you must ensure that no other thread is using the same connection until the result set is closed. However, it really is best for threaded clients that share the same connection to use mysql_store_result().

You need to know the following if you have a thread that did not create the connection to the MySQL database but is calling MySQL functions:

When you call mysql_init(), MySQL creates a thread-specific variable for the thread that is used by the debug library (among other things). If you call a MySQL function before the thread has called mysql_init(), the thread does not have the necessary thread-specific variables in place and you are likely to end up with a core dump sooner or later. To avoid problems, you must do the following:

1. Call mysql_library_init() before any other MySQL functions. It is not thread-safe, so call it before threads are created, or protect the call with a mutex.

2. Arrange for mysql_thread_init() to be called early in the thread handler before calling any MySQL function. If you call mysql_init(), it will call mysql_thread_init() for you.

3. In the thread, call mysql_thread_end() before calling pthread_exit(). This frees the memory used by MySQL thread-specific variables.

The preceding notes regarding mysql_init() also apply to mysql_connect(), which calls mysql_init().

23.8.4.3 Running C API Client Programs

If, after an upgrade, you experience problems with compiled client programs, such as Commands out of sync or unexpected core dumps, the programs were probably compiled using old header or library files. In this case, check the date of the mysql.h file and libmysqlclient.a library used for compilation to verify that they are from the new MySQL distribution. If not, recompile the programs with the new headers and libraries. Recompilation might also be necessary for programs compiled against the shared client library if the library major version number has changed (for example, from libmysqlclient.so.17 to libmysqlclient.so.18).

The major client library version determines compatibility. (For example, for libmysqlclient.so.18.1.0, the major version is 18.) For this reason, the libraries shipped with newer versions of MySQL are drop-in replacements for older versions that have the same major number. As long
as the major library version is the same, you can upgrade the library and old applications should continue to work with it.

Undefined-reference errors might occur at runtime when you try to execute a MySQL program. If these errors specify symbols that start with `mysql_` or indicate that the `libmysqlclient` library cannot be found, it means that your system cannot find the shared `libmysqlclient.so` library. The solution to this problem is to tell your system to search for shared libraries in the directory where that library is located. Use whichever of the following methods is appropriate for your system:

- Add the path of the directory where `libmysqlclient.so` is located to the `LD_LIBRARY_PATH` or `LD_LIBRARY` environment variable.
- On OS X, add the path of the directory where `libmysqlclient.dylib` is located to the `DYLD_LIBRARY_PATH` environment variable.
- Copy the shared-library files (such as `libmysqlclient.so`) to some directory that is searched by your system, such as `/lib`, and update the shared library information by executing `ldconfig`. Be sure to copy all related files. A shared library might exist under several names, using symlinks to provide the alternate names.

If the application is linked to the embedded server library, runtime error messages will indicate the `libmysqld` rather than `libmysqlclient` library, but the solution to the problem is the same as just described.

### 23.8.4.4 C API Server and Client Library Versions

The string and numeric forms of the MySQL server version are available at compile time as the values of the `MYSQL_SERVER_VERSION` and `MYSQL_VERSION_ID` macros, and at runtime as the values of the `mysql_get_server_info()` and `mysql_get_server_version()` functions.

The client library version is the MySQL version. For Connector/C, this is the MySQL version on which the Connector/C distribution is based. The string and numeric forms of this version are available at compile time as the values of the `MYSQL_SERVER_VERSION` and `MYSQL_VERSION_ID` macros, and at runtime as the values of the `mysql_get_client_info()` and `mysql_get_client_version()` functions.

### 23.8.5 C API Data Structures

This section describes C API data structures other than those used for prepared statements. For information about the latter, see Section 23.8.9, “C API Prepared Statement Data Structures”.

- **MYSQL**
  This structure represents handler for one database connection. It is used for almost all MySQL functions. Do not try to make a copy of a `MYSQL` structure. There is no guarantee that such a copy will be usable.

- **MYSQL_RES**
  This structure represents the result of a query that returns rows (`SELECT`, `SHOW`, `DESCRIBE`, `EXPLAIN`). The information returned from a query is called the *result set* in the remainder of this section.

- **MYSQL_ROW**
  This is a type-safe representation of one row of data. It is currently implemented as an array of counted byte strings. (You cannot treat these as null-terminated strings if field values may contain binary data, because such values may contain null bytes internally.) Rows are obtained by calling `mysql_fetch_row()`.

- **MYSQL_FIELD**
This structure contains metadata: information about a field, such as the field's name, type, and size. Its members are described in more detail later in this section. You may obtain the `MYSQL_FIELD` structures for each field by calling `mysql_fetch_field()` repeatedly. Field values are not part of this structure; they are contained in a `MYSQL_ROW` structure.

- **MYSQL_FIELD_OFFSET**
  
  This is a type-safe representation of an offset into a MySQL field list. (Used by `mysql_field_seek()`.) Offsets are field numbers within a row, beginning at zero.

- **my_ulonglong**
  
  The type used for the number of rows and for `mysql_affected_rows()`, `mysql_num_rows()`, and `mysql_insert_id()`. This type provides a range of 0 to 1.84e19.

  Some functions that return a row count using this type return -1 as an unsigned value to indicate an error or exceptional condition. You can check for -1 by comparing the return value to `(my_ulonglong)-1` (or to `(my_ulonglong)-0`, which is equivalent).

  On some systems, attempting to print a value of type `my_ulonglong` does not work. To print such a value, convert it to `unsigned long` and use a `%lu` print format. Example:

  ```c
  printf("Number of rows: \%lu\n",
         (unsigned long) mysql_num_rows(result));
  ```

- **my_bool**
  
  A boolean type, for values that are true (nonzero) or false (zero).

The `MYSQL_FIELD` structure contains the members described in the following list. The definitions apply primarily for columns of result sets such as those produced by `SELECT` statements. `MYSQL_FIELD` structures are also used to provide metadata for `OUT` and `INOUT` parameters returned from stored procedures executed using prepared `CALL` statements. For such parameters, some of the structure members have a meaning different from the meaning for column values.

- **char * name**
  
  The name of the field, as a null-terminated string. If the field was given an alias with an `AS` clause, the value of `name` is the alias. For a procedure parameter, the parameter name.

- **char * org_name**
  
  The name of the field, as a null-terminated string. Aliases are ignored. For expressions, the value is an empty string. For a procedure parameter, the parameter name.

- **char * table**
  
  The name of the table containing this field, if it is not a calculated field. For calculated fields, the `table` value is an empty string. If the column is selected from a view, `table` names the view. If the table or view was given an alias with an `AS` clause, the value of `table` is the alias. For a `UNION`, the value is the empty string. For a procedure parameter, the procedure name.

- **char * org_table**
  
  The name of the table, as a null-terminated string. Aliases are ignored. If the column is selected from a view, `org_table` names the view. For a `UNION`, the value is the empty string. For a procedure parameter, the procedure name.
• **char * db**

  The name of the database that the field comes from, as a null-terminated string. If the field is a calculated field, `db` is an empty string. For a **UNION**, the value is the empty string. For a procedure parameter, the name of the database containing the procedure.

• **char * catalog**

  The catalog name. This value is always "def".

• **char * def**

  The default value of this field, as a null-terminated string. This is set only if you use `mysql_list_fields()`.

• **unsigned long length**

  The width of the field. This corresponds to the display length, in bytes.

  The server determines the `length` value before it generates the result set, so this is the minimum length required for a data type capable of holding the largest possible value from the result column, without knowing in advance the actual values that will be produced by the query for the result set.

• **unsigned long max_length**

  The maximum width of the field for the result set (the length in bytes of the longest field value for the rows actually in the result set). If you use `mysql_store_result()` or `mysql_list_fields()`, this contains the maximum length for the field. If you use `mysql_use_result()`, the value of this variable is zero.

  The value of `max_length` is the length of the string representation of the values in the result set. For example, if you retrieve a **FLOAT** column and the “widest” value is `-12.345`, `max_length` is 7 (the length of `-12.345`).

  If you are using prepared statements, `max_length` is not set by default because for the binary protocol the lengths of the values depend on the types of the values in the result set. (See Section 23.8.9, “C API Prepared Statement Data Structures”.) If you want the `max_length` values anyway, enable the `STMT_ATTR_UPDATE_MAX_LENGTH` option with `mysql_stmt_attr_set()` and the lengths will be set when you call `mysql_stmt_store_result()` (See Section 23.8.11.3, “mysql_stmt_attr_set()”, and Section 23.8.11.28, “mysql_stmt_store_result()”).

• **unsigned int name_length**

  The length of `name`.

• **unsigned int org_name_length**

  The length of `org_name`.

• **unsigned int table_length**

  The length of `table`.

• **unsigned int org_table_length**

  The length of `org_table`.

• **unsigned int db_length**
The length of `db`.

- `unsigned int catalog_length`

  The length of `catalog`.

- `unsigned int def_length`

  The length of `def`.

- `unsigned int flags`

  Bit-flags that describe the field. The `flags` value may have zero or more of the bits set that are shown in the following table.

<table>
<thead>
<tr>
<th>Flag Value</th>
<th>Flag Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NOT_NULL_FLAG</td>
<td>Field cannot be NULL</td>
</tr>
<tr>
<td>PRI_KEY_FLAG</td>
<td>Field is part of a primary key</td>
</tr>
<tr>
<td>UNIQUE_KEY_FLAG</td>
<td>Field is part of a unique key</td>
</tr>
<tr>
<td>MULTIPLE_KEY_FLAG</td>
<td>Field is part of a nonunique key</td>
</tr>
<tr>
<td>UNSIGNED_FLAG</td>
<td>Field has the UNSIGNED attribute</td>
</tr>
<tr>
<td>ZEROFILL_FLAG</td>
<td>Field has the ZEROFILL attribute</td>
</tr>
<tr>
<td>BINARY_FLAG</td>
<td>Field has the BINARY attribute</td>
</tr>
<tr>
<td>AUTO_INCREMENT_FLAG</td>
<td>Field has the AUTO_INCREMENT attribute</td>
</tr>
<tr>
<td>ENUM_FLAG</td>
<td>Field is an ENUM</td>
</tr>
<tr>
<td>SET_FLAG</td>
<td>Field is a SET</td>
</tr>
<tr>
<td>BLOB_FLAG</td>
<td>Field is a BLOB or TEXT (deprecated)</td>
</tr>
<tr>
<td>TIMESTAMP_FLAG</td>
<td>Field is a TIMESTAMP (deprecated)</td>
</tr>
<tr>
<td>NUM_FLAG</td>
<td>Field is numeric; see additional notes following table</td>
</tr>
<tr>
<td>NO_DEFAULT_VALUE_FLAG</td>
<td>Field has no default value; see additional notes following table</td>
</tr>
</tbody>
</table>

Some of these flags indicate data type information and are superseded by or used in conjunction with the `MYSQL_TYPE_xxx` value in the `field->type` member described later:

- To check for BLOB or TIMESTAMP values, check whether `type` is `MYSQL_TYPE_BLOB` or `MYSQL_TYPE_TIMESTAMP`. (The BLOB_FLAG and TIMESTAMP_FLAG flags are unneeded.)

- ENUM and SET values are returned as strings. For these, check that the `type` value is `MYSQL_TYPE_STRING` and that the ENUM_FLAG or SET_FLAG flag is set in the flags value.

NUM_FLAG indicates that a column is numeric. This includes columns with a type of `MYSQL_TYPE_DECIMAL`, `MYSQL_TYPE_NEWDECIMAL`, `MYSQL_TYPE_TINY`, `MYSQL_TYPE_SHORT`, `MYSQL_TYPE_LONG`, `MYSQL_TYPE_FLOAT`, `MYSQL_TYPE_DOUBLE`, `MYSQL_TYPE_NULL`, `MYSQL_TYPE_LONGLONG`, `MYSQL_TYPE_INT24`, and `MYSQL_TYPE_YEAR`.

NO_DEFAULT_VALUE_FLAG indicates that a column has no DEFAULT clause in its definition. This does not apply to NULL columns (because such columns have a default of NULL), or to AUTO_INCREMENT columns (which have an implied default value).
The following example illustrates a typical use of the `flags` value:

```c
if (field->flags & NOT_NULL_FLAG)
    printf("Field cannot be null\n");
```

You may use the convenience macros shown in the following table to determine the boolean status of the `flags` value.

<table>
<thead>
<tr>
<th>Flag Status</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>IS_NOT_NULL(flags)</code></td>
<td>True if this field is defined as NOT NULL</td>
</tr>
<tr>
<td><code>IS_PRI_KEY(flags)</code></td>
<td>True if this field is a primary key</td>
</tr>
<tr>
<td><code>IS_BLOB(flags)</code></td>
<td>False if this field is a BLOB or TEXT (deprecated; test <code>field-&gt;type</code> instead)</td>
</tr>
</tbody>
</table>

- **unsigned int decimals**
  
The number of decimals for numeric fields, and the fractional seconds precision for temporal fields.

- **unsigned int charsetnr**
  
  An ID number that indicates the character set/collation pair for the field.

  Normally, character values in result sets are converted to the character set indicated by the `character_set_results` system variable. In this case, `charsetnr` corresponds to the character set indicated by that variable. Character set conversion can be suppressed by setting `character_set_results` to `NULL`. In this case, `charsetnr` corresponds to the character set of the original table column or expression. See also Section 10.4, “Connection Character Sets and Collations”.

  To distinguish between binary and nonbinary data for string data types, check whether the `charsetnr` value is 63. If so, the character set is `binary`, which indicates binary rather than nonbinary data. This enables you to distinguish `BINARY` from `CHAR`, `VARBINARY` from `VARCHAR`, and the `BLOB` types from the `TEXT` types.

  `charsetnr` values are the same as those displayed in the `Id` column of the `SHOW COLLATION` statement or the `ID` column of the `INFORMATION_SCHEMA.COLLATIONS` table. You can use those information sources to see which character set and collation specific `charsetnr` values indicate:

```
mysql> SHOW COLLATION WHERE Id = 63;
+------------+---------+----+---------+----------+---------+
| Collation  | Charset | Id | Default | Compiled | Sortlen |
|------------+---------+----+---------+----------+---------+
| binary     | binary  | 63 | Yes     | Yes      | 1       |
+------------+---------+----+---------+----------+---------+
```

```
mysql> SELECT COLLATION_NAME, CHARACTER_SET_NAME
    FROM INFORMATION_SCHEMA.COLLATIONS WHERE ID = 33;
+-----------------+--------------------+
| COLLATION_NAME   | CHARACTER_SET_NAME |
| utf8_general_ci | utf8               |
+-----------------+--------------------+
```

- **enum enum_field_types type**
The type of the field. The `type` value may be one of the `MYSQL_TYPE_` symbols shown in the following table.

<table>
<thead>
<tr>
<th>Type Value</th>
<th>Type Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>MYSQL_TYPE_TINY</code></td>
<td>TINYINT field</td>
</tr>
<tr>
<td><code>MYSQL_TYPE_SHORT</code></td>
<td>SMALLINT field</td>
</tr>
<tr>
<td><code>MYSQL_TYPE_LONG</code></td>
<td>INTEGER field</td>
</tr>
<tr>
<td><code>MYSQL_TYPE_INT24</code></td>
<td>MEDIUMINT field</td>
</tr>
<tr>
<td><code>MYSQL_TYPE_LONGLONG</code></td>
<td>BIGINT field</td>
</tr>
<tr>
<td><code>MYSQL_TYPE_DECIMAL</code></td>
<td>DECIMAL or NUMERIC field</td>
</tr>
<tr>
<td><code>MYSQL_TYPE_NEWDECIMAL</code></td>
<td>Precision math DECIMAL or NUMERIC</td>
</tr>
<tr>
<td><code>MYSQL_TYPE_FLOAT</code></td>
<td>FLOAT field</td>
</tr>
<tr>
<td><code>MYSQL_TYPE_DOUBLE</code></td>
<td>DOUBLE or REAL field</td>
</tr>
<tr>
<td><code>MYSQL_TYPE_BIT</code></td>
<td>BIT field</td>
</tr>
<tr>
<td><code>MYSQL_TYPE_TIMESTAMP</code></td>
<td>TIMESTAMP field</td>
</tr>
<tr>
<td><code>MYSQL_TYPE_DATE</code></td>
<td>DATE field</td>
</tr>
<tr>
<td><code>MYSQL_TYPE_TIME</code></td>
<td>TIME field</td>
</tr>
<tr>
<td><code>MYSQL_TYPE_DATETIME</code></td>
<td>DATETIME field</td>
</tr>
<tr>
<td><code>MYSQL_TYPE_YEAR</code></td>
<td>YEAR field</td>
</tr>
<tr>
<td><code>MYSQL_TYPE_STRING</code></td>
<td>CHAR or BINARY field</td>
</tr>
<tr>
<td><code>MYSQL_TYPE_VAR_STRING</code></td>
<td>VARCHAR or VARBINARY field</td>
</tr>
<tr>
<td><code>MYSQL_TYPE_BLOB</code></td>
<td>BLOB or TEXT field (use <code>max_length</code> to determine the maximum length)</td>
</tr>
<tr>
<td><code>MYSQL_TYPE_SET</code></td>
<td>SET field</td>
</tr>
<tr>
<td><code>MYSQL_TYPE_ENUM</code></td>
<td>ENUM field</td>
</tr>
<tr>
<td><code>MYSQL_TYPE_GEOMETRY</code></td>
<td>Spatial field</td>
</tr>
<tr>
<td><code>MYSQL_TYPE_NULL</code></td>
<td>NULL-type field</td>
</tr>
</tbody>
</table>

The `MYSQL_TYPE_TIME2`, `MYSQL_TYPE_DATETIME2`, and `MYSQL_TYPE_TIMESTAMP2`) type codes are used only on the server side. Clients see the `MYSQL_TYPE_TIME`, `MYSQL_TYPE_DATETIME`, and `MYSQL_TYPE_TIMESTAMP` codes.

You can use the `IS_NUM()` macro to test whether a field has a numeric type. Pass the `type` value to `IS_NUM()` and it evaluates to TRUE if the field is numeric:

```c
if (IS_NUM(field->type))
    printf("Field is numeric\n");
```

`ENUM` and `SET` values are returned as strings. For these, check that the `type` value is `MYSQL_TYPE_STRING` and that the `ENUM_FLAG` or `SET_FLAG` flag is set in the `flags` value.

23.8.6 C API Function Overview

The following list summarizes the functions available in the C API. For greater detail, see the descriptions in Section 23.8.7, "C API Function Descriptions".
C API Function Overview

- **my_init()**: Initializes global variables and the thread handler in thread-safe programs.
- **mysql_affected_rows()**: Returns the number of rows changed/deleted/inserted by the last `UPDATE`, `DELETE`, or `INSERT` query.
- **mysql-autocommit()**: Toggles autocommit mode on/off.
- **mysql-change_user()**: Changes the user and database on an open connection.
- **mysql-character_set_name()**: Returns the default character set name for the current connection.
- **mysql-client-find-plugin()**: Returns a pointer to a plugin.
- **mysql-client-register_plugin()**: Registers a plugin.
- **mysql-close()**: Closes a server connection.
- **mysql-commit()**: Commits the transaction.
- **mysql-connect()**: Connects to a MySQL server. This function is deprecated; use `mysql_real_connect()` instead.
- **mysql-create_db()**: Creates a database. This function is deprecated; use the SQL statement `CREATE DATABASE` instead.
- **mysql-data_seek()**: Seeks to an arbitrary row number in a query result set.
- **mysql-debug()**: Does a `DBUG_PUSH` with the given string.
- **mysql-drop_db()**: Drops a database. This function is deprecated; use the SQL statement `DROP DATABASE` instead.
- **mysql_dump_debug_info()**: Causes the server to write debug information to the log.
- **mysql_eof()**: Determines whether the last row of a result set has been read. This function is deprecated; use `mysql_errno()` or `mysql_error()` instead.
- **mysql_errno()**: Returns the error number for the most recently invoked MySQL function.
- **mysql_error()**: Returns the error message for the most recently invoked MySQL function.
- **mysql-escape_string()**: Escapes special characters in a string for use in an SQL statement.
- **mysql_fetch_field()**: Returns the type of the next table field.
- **mysql_fetch_field_direct()**: Returns the type of a table field, given a field number.
- **mysql_fetch_fields()**: Returns an array of all field structures.
- **mysql_fetch_lengths()**: Returns the lengths of all columns in the current row.
- **mysql_fetch_row()**: Fetches the next row from the result set.
- **mysql_field_count()**: Returns the number of result columns for the most recent statement.
- **mysql-field-seek()**: Puts the column cursor on a specified column.
- **mysql-field-tell()**: Returns the position of the field cursor used for the last `mysql_fetch_field()`.
- **mysql-free_result()**: Frees memory used by a result set.
• **mysql_get_character_set_info()**: Returns information about default character set.
• **mysql_get_client_info()**: Returns client version information as a string.
• **mysql_get_client_version()**: Returns client version information as an integer.
• **mysql_get_host_info()**: Returns a string describing the connection.
• **mysql_get_proto_info()**: Returns the protocol version used by the connection.
• **mysql_get_server_info()**: Returns the server version number.
• **mysql_get_server_version()**: Returns the server version number as an integer.
• **mysql_get_ssl_cipher()**: Returns the current SSL cipher.
• **mysql_hex_string()**: Encodes a string in hexadecimal format.
• **mysql_info()**: Returns information about the most recently executed query.
• **mysql_init()**: Gets or initializes a `MYSQL` structure.
• **mysql_insert_id()**: Returns the ID generated for an `AUTO_INCREMENT` column by the previous query.
• **mysql_kill()**: Kills a given thread.
• **mysql_library_end()**: Finalizes the MySQL C API library.
• **mysql_library_init()**: Initializes the MySQL C API library.
• **mysql_list_dbs()**: Returns database names matching a simple regular expression.
• **mysql_list_fields()**: Returns field names matching a simple regular expression.
• **mysql_list_processes()**: Returns a list of the current server threads.
• **mysql_list_tables()**: Returns table names matching a simple regular expression.
• **mysql_load_plugin()**: Loads a plugin.
• **mysql_load_plugin_v()**: Loads a plugin.
• **mysql_more_results()**: Checks whether any more results exist.
• **mysql_next_result()**: Returns/initiates the next result in multiple-result executions.
• **mysql_num_fields()**: Returns the number of columns in a result set.
• **mysql_num_rows()**: Returns the number of rows in a result set.
• **mysql_options()**: Sets connect options for `mysql_real_connect()`.
• **mysql_options4()**: Sets connect options for `mysql_real_connect()`.
• **mysql_ping()**: Checks whether the connection to the server is working, reconnecting as necessary.
• **mysql_plugin_options()**: Sets a plugin option.
• **mysql_query()**: Executes an SQL query specified as a null-terminated string.
• **mysql_real_connect()**: Connects to a MySQL server.
C API Function Overview

- **mysql_real_escape_string()**: Escapes special characters in a string for use in an SQL statement, taking into account the current character set of the connection.
- **mysql_real_query()**: Executes an SQL query specified as a counted string.
- **mysql_refresh()**: Flushes or resets tables and caches.
- **mysql_reload()**: Tells the server to reload the grant tables.
- **mysql_rollback()**: Rolls back the transaction.
- **mysql_row_seek()**: Seeks to a row offset in a result set, using value returned from **mysql_row_tell()**.
- **mysql_row_tell()**: Returns the row cursor position.
- **mysql_select_db()**: Selects a database.
- **mysql_server_end()**: Finalizes the MySQL C API library.
- **mysql_server_init()**: Initializes the MySQL C API library.
- **mysql_set_character_set()**: Sets the default character set for the current connection.
- **mysql_set_local_infile_default()**: Sets the **LOAD DATA LOCAL** handler callbacks to their default values.
- **mysql_set_local_infile_handler()**: Installs application-specific **LOAD DATA LOCAL** handler callbacks.
- **mysql_set_server_option()**: Sets an option for the connection (like **multi-statements**).
- **mysql_sqlstate()**: Returns the SQLSTATE error code for the last error.
- **mysql_shutdown()**: Shuts down the database server.
- **mysql_ssl_set()**: Prepares to establish an SSL connection to the server.
- **mysql_stat()**: Returns the server status as a string.
- **mysql_store_result()**: Retrieves a complete result set to the client.
- **mysql_thread_end()**: Finalizes a thread handler.
- **mysql_thread_id()**: Returns the current thread ID.
- **mysql_thread_init()**: Initializes a thread handler.
- **mysql_thread_safe()**: Returns 1 if the clients are compiled as thread-safe.
- **mysql_use_result()**: Initiates a row-by-row result set retrieval.
- **mysql_warning_count()**: Returns the warning count for the previous SQL statement.

Application programs should use this general outline for interacting with MySQL:

1. Initialize the MySQL client library by calling **mysql_library_init()**. This function exists in both the **libmysqlclient** C client library and the **libmysqld** embedded server library, so it is used whether you build a regular client program by linking with the **-libmysqlclient** flag, or an embedded server application by linking with the **-libmysqld** flag.
2. Initialize a connection handler by calling `mysql_init()` and connect to the server by calling `mysql_real_connect()`.

3. Issue SQL statements and process their results. (The following discussion provides more information about how to do this.)

4. Close the connection to the MySQL server by calling `mysql_close()`.

5. End use of the MySQL client library by calling `mysql_library_end()`.

The purpose of calling `mysql_library_init()` and `mysql_library_end()` is to provide proper initialization and finalization of the MySQL client library. For applications that are linked with the client library, they provide improved memory management. If you do not call `mysql_library_end()`, a block of memory remains allocated. (This does not increase the amount of memory used by the application, but some memory leak detectors will complain about it.) For applications that are linked with the embedded server, these calls start and stop the server.

In a nonmultithreaded environment, the call to `mysql_library_init()` may be omitted, because `mysql_init()` will invoke it automatically as necessary. However, `mysql_library_init()` is not thread-safe in a multithreaded environment, and thus neither is `mysql_init()`, which calls `mysql_library_init()`. You must either call `mysql_library_init()` prior to spawning any threads, or else use a mutex to protect the call, whether you invoke `mysql_library_init()` or indirectly through `mysql_init()`. This should be done prior to any other client library call.

To connect to the server, call `mysql_init()` to initialize a connection handler, then call `mysql_real_connect()` with that handler (along with other information such as the host name, user name, and password). Upon connection, `mysql_real_connect()` sets the `reconnect` flag (part of the `MYSQL` structure) to a value of 1 in versions of the API older than 5.0.3, or 0 in newer versions. A value of 1 for this flag indicates that if a statement cannot be performed because of a lost connection, to try reconnecting to the server before giving up. You can use the `MYSQL_OPT_RECONNECT` option to `mysql_options()` to control reconnection behavior. When you are done with the connection, call `mysql_close()` to terminate it. Do not use the handler after it has been closed.

While a connection is active, the client may send SQL statements to the server using `mysql_query()` or `mysql_real_query()`. The difference between the two is that `mysql_query()` expects the query to be specified as a null-terminated string whereas `mysql_real_query()` expects a counted string. If the string contains binary data (which may include null bytes), you must use `mysql_real_query()`.

For each non-`SELECT` query (for example, `INSERT`, `UPDATE`, `DELETE`), you can find out how many rows were changed (affected) by calling `mysql_affected_rows()`.

For `SELECT` queries, you retrieve the selected rows as a result set. (Note that some statements are `SELECT`-like in that they return rows. These include `SHOW`, `DESCRIBE`, and `EXPLAIN`. Treat these statements the same way as `SELECT` statements.)

There are two ways for a client to process result sets. One way is to retrieve the entire result set all at once by calling `mysql_store_result()`. This function acquires from the server all the rows returned by the query and stores them in the client. The second way is for the client to initiate a row-by-row result set retrieval by calling `mysql_use_result()`. This function initializes the retrieval, but does not actually get any rows from the server.

In both cases, you access rows by calling `mysql_fetch_row()`. With `mysql_store_result()`, `mysql_fetch_row()` accesses rows that have previously been fetched from the server. With `mysql_use_result()`, `mysql_fetch_row()` actually retrieves the row from the server. Information about the size of the data in each row is available by calling `mysql_fetch_lengths()`.

After you are done with a result set, call `mysql_free_result()` to free the memory used for it.
The two retrieval mechanisms are complementary. Choose the approach that is most appropriate for each client application. In practice, clients tend to use `mysql_store_result()` more commonly.

An advantage of `mysql_store_result()` is that because the rows have all been fetched to the client, you not only can access rows sequentially, you can move back and forth in the result set using `mysql_data_seek()` or `mysql_row_seek()` to change the current row position within the result set. You can also find out how many rows there are by calling `mysql_num_rows()`. On the other hand, the memory requirements for `mysql_store_result()` may be very high for large result sets and you are more likely to encounter out-of-memory conditions.

An advantage of `mysql_use_result()` is that the client requires less memory for the result set because it maintains only one row at a time (and because there is less allocation overhead, `mysql_use_result()` can be faster). Disadvantages are that you must process each row quickly to avoid tying up the server, you do not have random access to rows within the result set (you can only access rows sequentially), and the number of rows in the result set is unknown until you have retrieved them all. Furthermore, you must retrieve all the rows even if you determine in mid-retrieval that you've found the information you were looking for.

The API makes it possible for clients to respond appropriately to statements (retrieving rows only as necessary) without knowing whether the statement is a `SELECT`. You can do this by calling `mysql_store_result()` after each `mysql_query()` (or `mysql_real_query()`). If the result set call succeeds, the statement was a `SELECT` and you can read the rows. If the result set call fails, call `mysql_field_count()` to determine whether a result was actually to be expected. If `mysql_field_count()` returns zero, the statement returned no data (indicating that it was an `INSERT`, `UPDATE`, `DELETE`, and so forth), and was not expected to return rows. If `mysql_field_count()` is nonzero, the statement should have returned rows, but did not. This indicates that the statement was a `SELECT` that failed. See the description for `mysql_field_count()` for an example of how this can be done.

Both `mysql_store_result()` and `mysql_use_result()` enable you to obtain information about the fields that make up the result set (the number of fields, their names and types, and so forth). You can access field information sequentially within the row by calling `mysql_fetch_field()` repeatedly, or by field number within the row by calling `mysql_fetch_field_direct()`. The current field cursor position may be changed by calling `mysql_field_seek()`. Setting the field cursor affects subsequent calls to `mysql_fetch_field()`. You can also get information for fields all at once by calling `mysql_fetch_fields()`.

For detecting and reporting errors, MySQL provides access to error information by means of the `mysql_errno()` and `mysql_error()` functions. These return the error code or error message for the most recently invoked function that can succeed or fail, enabling you to determine when an error occurred and what it was.

### 23.8.7 C API Function Descriptions

This section describes C API functions other than those used for prepared statements or the replication stream interface. For information about those, see Section 23.8.11, “C API Prepared Statement Function Descriptions”, and C API Binary Log Function Descriptions.

In the descriptions here, a parameter or return value of `NULL` means `NULL` in the sense of the C programming language, not a MySQL `NULL` value.

Functions that return a value generally return a pointer or an integer. Unless specified otherwise, functions returning a pointer return a non-`NULL` value to indicate success or a `NULL` value to indicate an error, and functions returning an integer return zero to indicate success or nonzero to indicate an error. Note that “nonzero” means just that. Unless the function description says otherwise, do not test against a value other than zero:
When a function returns an error, the **Errors** subsection of the function description lists the possible types of errors. You can find out which of these occurred by calling `mysql_errno()`. A string representation of the error may be obtained by calling `mysql_error()`.

### 23.8.7.1 `mysql_affected_rows()`

```c
my_ulonglong mysql_affected_rows(MYSQL *mysql)
```

#### Description

`mysql_affected_rows()` may be called immediately after executing a statement with `mysql_query()` or `mysql_real_query()`. It returns the number of rows changed, deleted, or inserted by the last statement if it was an `UPDATE`, `DELETE`, or `INSERT`. For `SELECT` statements, `mysql_affected_rows()` works like `mysql_num_rows()`.

For `UPDATE` statements, the affected-rows value by default is the number of rows actually changed. If you specify the `CLIENT_FOUND_ROWS` flag to `mysql_real_connect()` when connecting to `mysqld`, the affected-rows value is the number of rows “found”; that is, matched by the `WHERE` clause.

For `REPLACE` statements, the affected-rows value is 2 if the new row replaced an old row, because in this case, one row was inserted after the duplicate was deleted.

For `INSERT ... ON DUPLICATE KEY UPDATE` statements, the affected-rows value per row is 1 if the row is inserted as a new row, 2 if an existing row is updated, and 0 if an existing row is set to its current values. If you specify the `CLIENT_FOUND_ROWS` flag, the affected-rows value is 1 (not 0) if an existing row is set to its current values.

Following a `CALL` statement for a stored procedure, `mysql_affected_rows()` returns the value that it would return for the last statement executed within the procedure, or 0 if that statement would return -1. Within the procedure, you can use `ROW_COUNT()` at the SQL level to obtain the affected-rows value for individual statements.

In MySQL 5.6, `mysql_affected_rows()` returns a meaningful value for a wider range of statements. For details, see the description for `ROW_COUNT()` in Section 12.15, “Information Functions”.

#### Return Values

An integer greater than zero indicates the number of rows affected or retrieved. Zero indicates that no records were updated for an `UPDATE` statement, no rows matched the `WHERE` clause in the query or that no query has yet been executed. -1 indicates that the query returned an error or that, for a `SELECT` query, `mysql_affected_rows()` was called prior to calling `mysql_store_result()`.

Because `mysql_affected_rows()` returns an unsigned value, you can check for -1 by comparing the return value to `(my_ulonglong)-1` (or to `(my_ulonglong)~0`, which is equivalent).

#### Errors

None.
Example

```c
char *stmt = "UPDATE products SET cost=cost*1.25
WHERE group=10";
mysql_query(&mysql,stmt);
printf("%ld products updated",
(long) mysql_affected_rows(&mysql));
```

23.8.7.2 mysql_autocommit()

```c
my_bool mysql_autocommit(MYSQL *mysql, my_bool mode)
```

**Description**

Sets autocommit mode on if `mode` is 1, off if `mode` is 0.

**Return Values**

Zero for success. Nonzero if an error occurred.

**Errors**

None.

23.8.7.3 mysql_change_user()

```c
my_bool mysql_change_user(MYSQL *mysql, const char *user, const char *password, const char *db)
```

**Description**

Changes the user and causes the database specified by `db` to become the default (current) database on the connection specified by `mysql`. In subsequent queries, this database is the default for table references that include no explicit database specifier.

`mysql_change_user()` fails if the connected user cannot be authenticated or does not have permission to use the database. In this case, the user and database are not changed.

Pass a `db` parameter of `NULL` if you do not want to have a default database.

This function resets the session state as if one had done a new connect and reauthenticated. (See Section 23.8.20, “C API Automatic Reconnection Control”.) It always performs a `ROLLBACK` of any active transactions, closes and drops all temporary tables, and unlocks all locked tables. Session system variables are reset to the values of the corresponding global system variables. Prepared statements are released and `HANDLER` variables are closed. Locks acquired with `GET_LOCK()` are released. These effects occur even if the user did not change.

**Return Values**

Zero for success. Nonzero if an error occurred.

**Errors**

The same that you can get from `mysql_real_connect()`, plus:

- `CR_COMMANDS_OUT_OF_SYNC`

  Commands were executed in an improper order.
• **CR_SERVER_GONE_ERROR**
  The MySQL server has gone away.

• **CR_SERVER_LOST**
  The connection to the server was lost during the query.

• **CR_UNKNOWN_ERROR**
  An unknown error occurred.

• **ER_UNKNOWN_COM_ERROR**
  The MySQL server does not implement this command (probably an old server).

• **ER_ACCESS_DENIED_ERROR**
  The user or password was wrong.

• **ER_BAD_DB_ERROR**
  The database did not exist.

• **ER_DBACCESS_DENIED_ERROR**
  The user did not have access rights to the database.

• **ER_WRONG_DB_NAME**
  The database name was too long.

**Example**

```c
if (mysql_change_user(&mysql, "user", "password", "new_database"))
{
    fprintf(stderr, "Failed to change user. Error: %s\n",
            mysql_error(&mysql));
}
```

**23.8.7.4 mysql_character_set_name()**

```c
const char *mysql_character_set_name(MYSQL *mysql)
```

**Description**

Returns the default character set name for the current connection.

**Return Values**

The default character set name

**Errors**

None.

**23.8.7.5 mysql_close()**

```c
void mysql_close(MYSQL *mysql)
```
C API Function Descriptions

Description

Closes a previously opened connection. `mysql_close()` also deallocates the connection handler pointed to by `mysql` if the handler was allocated automatically by `mysql_init()` or `mysql_connect()`. Do not use the handler after it has been closed.

Return Values

None.

Errors

None.

23.8.7.6 `mysql_commit()`

```c
my_bool mysql_commit(MYSQL *mysql)
```

Description

Commits the current transaction.

The action of this function is subject to the value of the `completion_type` system variable. In particular, if the value of `completion_type` is `RELEASE` (or 2), the server performs a release after terminating a transaction and closes the client connection. Call `mysql_close()` from the client program to close the connection from the client side.

Return Values

Zero for success. Nonzero if an error occurred.

Errors

None.

23.8.7.7 `mysql_connect()`

```c
MYSQL *mysql_connect(MYSQL *mysql, const char *host, const char *user, const char *passwd)
```

Description

This function is deprecated. Use `mysql_real_connect()` instead.

`mysql_connect()` attempts to establish a connection to a MySQL database engine running on `host`. `mysql_connect()` must complete successfully before you can execute any of the other API functions, with the exception of `mysql_get_client_info()`.

The meanings of the parameters are the same as for the corresponding parameters for `mysql_real_connect()` with the difference that the connection parameter may be `NULL`. In this case, the C API allocates memory for the connection structure automatically and frees it when you call `mysql_close()`. The disadvantage of this approach is that you cannot retrieve an error message if the connection fails. (To get error information from `mysql_errno()` or `mysql_error()`, you must provide a valid `MYSQL` pointer.)

Return Values

Same as for `mysql_real_connect()`.
Errors

Same as for `mysql_real_connect()`.

23.8.7.8 `mysql_create_db()`

```c
int mysql_create_db(MYSQL *mysql, const char *db)
```

**Description**

Creates the database named by the `db` parameter.

This function is deprecated. Use `mysql_query()` to issue an SQL `CREATE DATABASE` statement instead.

**Return Values**

Zero for success. Nonzero if an error occurred.

**Errors**

- `CR_COMMANDS_OUT_OF_SYNC`
  
  Commands were executed in an improper order.

- `CR_SERVER_GONE_ERROR`
  
  The MySQL server has gone away.

- `CR_SERVER_LOST`
  
  The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`
  
  An unknown error occurred.

**Example**

```c
if(mysql_create_db(&mysql, "my_database"))
{
    fprintf(stderr, "Failed to create new database. Error: %s\n",
            mysql_error(&mysql));
}
```

23.8.7.9 `mysql_data_seek()`

```c
void mysql_data_seek(MYSQL_RES *result, my_ulonglong offset)
```

**Description**

Seeks to an arbitrary row in a query result set. The `offset` value is a row number. Specify a value in the range from 0 to `mysql_num_rows(result)-1`.

This function requires that the result set structure contains the entire result of the query, so `mysql_data_seek()` may be used only in conjunction with `mysql_store_result()`, not with `mysql_use_result()`.
C API Function Descriptions

Return Values

None.

Errors

None.

23.8.7.10 mysql_debug()

```c
void mysql_debug(const char *debug)
```

Description

Does a `DBUG_PUSH` with the given string. `mysql_debug()` uses the Fred Fish debug library. To use this function, you must compile the client library to support debugging. See Section 24.5.3, "The DBUG Package".

Return Values

None.

Errors

None.

Example

The call shown here causes the client library to generate a trace file in `/tmp/client.trace` on the client machine:

```c
mysql_debug("d:t:O,/tmp/client.trace");
```

23.8.7.11 mysql_drop_db()

```c
int mysql_drop_db(MYSQL *mysql, const char *db)
```

Description

Drops the database named by the `db` parameter.

This function is deprecated. Use `mysql_query()` to issue an SQL `DROP DATABASE` statement instead.

Return Values

Zero for success. Nonzero if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`
  
  Commands were executed in an improper order.

- `CR_SERVER_GONE_ERROR`
  
  The MySQL server has gone away.
• **CR_SERVER_LOST**
  The connection to the server was lost during the query.

• **CR_UNKNOWN_ERROR**
  An unknown error occurred.

**Example**

```c
if(mysql_drop_db(&mysql, "my_database"))
    fprintf(stderr, "Failed to drop the database: Error: %s\n",
            mysql_error(&mysql));
```

**23.8.7.12 mysql_dump_debug_info()**

```c
int mysql_dump_debug_info(MYSQL *mysql)
```

**Description**

Instructs the server to write debugging information to the error log. The connected user must have the `SUPER` privilege.

**Return Values**

Zero for success. Nonzero if an error occurred.

**Errors**

• **CR_COMMANDS_OUT_OF_SYNC**
  Commands were executed in an improper order.

• **CR_SERVER_GONE_ERROR**
  The MySQL server has gone away.

• **CR_SERVER_LOST**
  The connection to the server was lost during the query.

• **CR_UNKNOWN_ERROR**
  An unknown error occurred.

**23.8.7.13 mysql_eof()**

```c
my_bool mysql_eof(MYSQL_RES *result)
```

**Description**

This function is deprecated. `mysql_errno()` or `mysql_error()` may be used instead.

`mysql_eof()` determines whether the last row of a result set has been read.

If you acquire a result set from a successful call to `mysql_store_result()`, the client receives the entire set in one operation. In this case, a NULL return from `mysql_fetch_row()` always means the
end of the result set has been reached and it is unnecessary to call `mysql_eof()`. When used with `mysql_store_result()`, `mysql_eof()` always returns true.

On the other hand, if you use `mysql_use_result()` to initiate a result set retrieval, the rows of the set are obtained from the server one by one as you call `mysql_fetch_row()` repeatedly. Because an error may occur on the connection during this process, a NULL return value from `mysql_fetch_row()` does not necessarily mean the end of the result set was reached normally. In this case, you can use `mysql_eof()` to determine what happened. `mysql_eof()` returns a nonzero value if the end of the result set was reached and zero if an error occurred.

Historically, `mysql_eof()` predates the standard MySQL error functions `mysql_errno()` and `mysql_error()`. Because those error functions provide the same information, their use is preferred over `mysql_eof()`, which is deprecated. (In fact, they provide more information, because `mysql_eof()` returns only a boolean value whereas the error functions indicate a reason for the error when one occurs.)

**Return Values**

Zero for success. Nonzero if the end of the result set has been reached.

**Errors**

None.

**Example**

The following example shows how you might use `mysql_eof()`:

```c
mysql_query(&mysql,"SELECT * FROM some_table");
result = mysql_use_result(&mysql);
while((row = mysql_fetch_row(result)))
{
    // do something with data
}
if(!mysql_eof(result))  // mysql_fetch_row() failed due to an error
{
    fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
}
```

However, you can achieve the same effect with the standard MySQL error functions:

```c
mysql_query(&mysql,"SELECT * FROM some_table");
result = mysql_use_result(&mysql);
while((row = mysql_fetch_row(result)))
{
    // do something with data
}
if(mysql_errno(&mysql))  // mysql_fetch_row() failed due to an error
{
    fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
}
```

---

**23.8.7.14 mysql_errno()**

```c
unsigned int mysql_errno(MYSQL *mysql)
```

**Description**

For the connection specified by `mysql`, `mysql_errno()` returns the error code for the most recently invoked API function that can succeed or fail. A return value of zero means that no error occurred. Client
error message numbers are listed in the MySQL errmsg.h header file. Server error message numbers are listed in mysql_error.h. Errors also are listed at Appendix B, Errors, Error Codes, and Common Problems.

Note
Some functions such as mysql_fetch_row() do not set mysql_errno() if they succeed. A rule of thumb is that all functions that have to ask the server for information reset mysql_errno() if they succeed.

MySQL-specific error numbers returned by mysql_errno() differ from SQLSTATE values returned by mysql_sqlstate(). For example, the mysql client program displays errors using the following format, where 1146 is the mysql_errno() value and '42S02' is the corresponding mysql_sqlstate() value:

```
shell> SELECT * FROM no_such_table;
ERROR 1146 (42S02): Table 'test.no_such_table' doesn't exist
```

Return Values
An error code value for the last mysql_XXX() call, if it failed. zero means no error occurred.

Errors
None.

23.8.7.15 mysql_error()

```
const char *mysql_error(MYSQL *mysql)
```

Description
For the connection specified by mysql, mysql_error() returns a null-terminated string containing the error message for the most recently invoked API function that failed. If a function did not fail, the return value of mysql_error() may be the previous error or an empty string to indicate no error.

A rule of thumb is that all functions that have to ask the server for information reset mysql_errno() if they succeed.

For functions that reset mysql_errno(), either of these two tests can be used to check for an error:

```
if(*mysql_error(&mysql))
{
    // an error occurred
}
if(mysql_error(&mysql)[0])
{
    // an error occurred
}
```

The language of the client error messages may be changed by recompiling the MySQL client library. You can choose error messages in several different languages. See Section 10.12, “Setting the Error Message Language”.

Return Values
A null-terminated character string that describes the error. An empty string if no error occurred.
Errors

None.

23.8.7.16 mysql_escape_string()

Note

This function should not be used. Use `mysql_real_escape_string()` instead.

`mysql_escape_string()` is identical to `mysql_real_escape_string()` except that `mysql_real_escape_string()` takes a connection handler as its first argument and escapes the string according to the current character set. `mysql_escape_string()` does not take a connection argument and does not respect the current character set.

23.8.7.17 mysql_fetch_field()

```c
MYSQL_FIELD *mysql_fetch_field(MYSQL_RES *result)
```

Description

Returns the definition of one column of a result set as a `MYSQL_FIELD` structure. Call this function repeatedly to retrieve information about all columns in the result set. `mysql_fetch_field()` returns `NULL` when no more fields are left.

`mysql_fetch_field()` is reset to return information about the first field each time you execute a new `SELECT` query. The field returned by `mysql_fetch_field()` is also affected by calls to `mysql_field_seek()`.

If you've called `mysql_query()` to perform a `SELECT` on a table but have not called `mysql_store_result()`, MySQL returns the default blob length (8KB) if you call `mysql_fetch_field()` to ask for the length of a `BLOB` field. (The 8KB size is chosen because MySQL does not know the maximum length for the `BLOB`. This should be made configurable sometime.) Once you've retrieved the result set, `field->max_length` contains the length of the largest value for this column in the specific query.

Return Values

The `MYSQL_FIELD` structure for the current column. `NULL` if no columns are left.

Errors

None.

Example

```c
MYSQL_FIELD *field;
while((field = mysql_fetch_field(result)))
{
    printf("field name %s\n", field->name);
}
```

23.8.7.18 mysql_fetch_field_direct()

```c
MYSQL_FIELD *mysql_fetch_field_direct(MYSQL_RES *result, unsigned int fieldnr)
```
Description

Given a field number `fieldnr` for a column within a result set, returns that column’s field definition as a `MYSQL_FIELD` structure. Use this function to retrieve the definition for an arbitrary column. Specify a value for `fieldnr` in the range from 0 to `mysql_num_fields(result)-1`.

Return Values

The `MYSQL_FIELD` structure for the specified column.

Errors

None.

Example

```c
unsigned int num_fields;
unsigned int i;
MYSQL_FIELD *field;

num_fields = mysql_num_fields(result);
for(i = 0; i < num_fields; i++)
{
    field = mysql_fetch_field_direct(result, i);
    printf("Field %u is %s\n", i, field->name);
}
```

23.8.7.19 `mysql_fetch_fields()`

`MYSQL_FIELD *mysql_fetch_fields(MYSQL_RES *result)`

Description

Returns an array of all `MYSQL_FIELD` structures for a result set. Each structure provides the field definition for one column of the result set.

Return Values

An array of `MYSQL_FIELD` structures for all columns of a result set.

Errors

None.

Example

```c
unsigned int num_fields;
unsigned int i;
MYSQL_FIELD *fields;

num_fields = mysql_num_fields(result);
fields = mysql_fetch_fields(result);
for(i = 0; i < num_fields; i++)
{
    printf("Field %u is %s\n", i, fields[i].name);
}
```

23.8.7.20 `mysql_fetch_lengths()`
unsigned long *mysql_fetch_lengths(MYSQL_RES *result)

Description

Returns the lengths of the columns of the current row within a result set. If you plan to copy field values, this length information is also useful for optimization, because you can avoid calling strlen(). In addition, if the result set contains binary data, you must use this function to determine the size of the data, because strlen() returns incorrect results for any field containing null characters.

The length for empty columns and for columns containing NULL values is zero. To see how to distinguish these two cases, see the description for mysql_fetch_row().

Return Values

An array of unsigned long integers representing the size of each column (not including any terminating null bytes). NULL if an error occurred.

Errors

mysql_fetch_lengths() is valid only for the current row of the result set. It returns NULL if you call it before calling mysql_fetch_row() or after retrieving all rows in the result.

Example

MYSQL_ROW row;
unsigned long *lengths;
unsigned int num_fields;
unsigned int i;

row = mysql_fetch_row(result);
if (row)
{
    num_fields = mysql_num_fields(result);
    lengths = mysql_fetch_lengths(result);
    for(i = 0; i < num_fields; i++)
    {
        printf("Column %u is %lu bytes in length.\n", i, lengths[i]);
    }
}

23.8.7.21 mysql_fetch_row()

MYSQL_ROW mysql_fetch_row(MYSQL_RES *result)

Description

mysql_fetch_row() retrieves the next row of a result set:

• When used after mysql_store_result(), mysql_fetch_row() returns NULL if there are no more rows to retrieve.

• When used after mysql_use_result(), mysql_fetch_row() returns NULL if there are no more rows to retrieve or an error occurred.

The number of values in the row is given by mysql_num_fields(result). If row holds the return value from a call to mysql_fetch_row(), pointers to the values are accessed as row[0] to row[mysql_num_fields(result)-1]. NULL values in the row are indicated by NULL pointers.
The lengths of the field values in the row may be obtained by calling `mysql_fetch_lengths()`. Empty fields and fields containing `NULL` both have length 0; you can distinguish these by checking the pointer for the field value. If the pointer is `NULL`, the field is `NULL`; otherwise, the field is empty.

**Return Values**

A `MYSQL_ROW` structure for the next row, or `NULL`. The meaning of a `NULL` return depends on which function was called preceding `mysql_fetch_row()`:

- When used after `mysql_store_result()`, `mysql_fetch_row()` returns `NULL` if there are no more rows to retrieve.
- When used after `mysql_use_result()`, `mysql_fetch_row()` returns `NULL` if there are no more rows to retrieve or an error occurred. To determine whether an error occurred, check whether `mysql_error()` returns a nonempty string or `mysql_errno()` returns nonzero.

**Errors**

Errors are not reset between calls to `mysql_fetch_row()`

- **CR_SERVER_LOST**
  The connection to the server was lost during the query.
- **CR_UNKNOWN_ERROR**
  An unknown error occurred.

**Example**

```c
MYSQL_ROW row;
unsigned int num_fields;
unsigned int i;

num_fields = mysql_num_fields(result);
while ((row = mysql_fetch_row(result)))
{
  unsigned long *lengths;
  lengths = mysql_fetch_lengths(result);
  for(i = 0; i < num_fields; i++)
  {
    printf("[%.s] ", (int) lengths[i],
    row[i] ? row[i] : "NULL");
  }
  printf("\n");
}
```

**23.8.7.22 mysql_field_count()**

```c
unsigned int mysql_field_count(MYSQL *mysql)
```

**Description**

Returns the number of columns for the most recent query on the connection.

The normal use of this function is when `mysql_store_result()` returned `NULL` (and thus you have no result set pointer). In this case, you can call `mysql_field_count()` to determine whether `mysql_store_result()` should have produced a nonempty result. This enables the client program to
take proper action without knowing whether the query was a `SELECT` (or `SELECT`-like) statement. The example shown here illustrates how this may be done.

See Section 23.8.21.1, “Why `mysql_store_result()` Sometimes Returns NULL After `mysql_query()` Returns Success”.

Return Values

An unsigned integer representing the number of columns in a result set.

Errors

None.

Example

```c
MYSQL_RES *result;
unsigned int num_fields;
unsigned int num_rows;

if (mysql_query(&mysql,query_string))
{
    // error
}
else // query succeeded, process any data returned by it
{
    result = mysql_store_result(&mysql);
    if (result)  // there are rows
    {
        num_fields = mysql_num_fields(result);
        // retrieve rows, then call mysql_free_result(result)
    }
    else  // `mysql_store_result()` returned nothing; should it have?
    {
        if(mysql_field_count(&mysql) == 0)
        {
            // query does not return data
            // (it was not a SELECT)
            num_rows = mysql_affected_rows(&mysql);
        }
        else // `mysql_store_result()` should have returned data
        {
            fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
        }
    }
}
```

An alternative is to replace the `mysql_field_count(&mysql)` call with `mysql_errno(&mysql)`. In this case, you are checking directly for an error from `mysql_store_result()` rather than inferring from the value of `mysql_field_count()` whether the statement was a `SELECT`.

### 23.8.7.23 `mysql_field_seek()`

`MYSQL_FIELD_OFFSET mysql_field_seek(MYSQL_RES *result, MYSQL_FIELD_OFFSET offset)`

Description

Sets the field cursor to the given offset. The next call to `mysql_fetch_field()` retrieves the field definition of the column associated with that offset.
To seek to the beginning of a row, pass an offset value of zero.

Return Values

The previous value of the field cursor.

Errors

None.

23.8.7.24 mysql_field_tell()

MYSQL_FIELD_OFFSET mysql_field_tell(MYSQL_RES *result)

Description

Returns the position of the field cursor used for the last mysql_fetch_field(). This value can be used as an argument to mysql_field_seek().

Return Values

The current offset of the field cursor.

Errors

None.

23.8.7.25 mysql_free_result()

void mysql_free_result(MYSQL_RES *result)

Description

mysql_free_result() frees the memory allocated for a result set by mysql_store_result(), mysql_use_result(), mysql_list_dbs(), and so forth. When you are done with a result set, you must free the memory it uses by calling mysql_free_result().

Do not attempt to access a result set after freeing it.

Return Values

None.

Errors

None.

23.8.7.26 mysql_get_character_set_info()

void mysql_get_character_set_info(MYSQL *mysql, MY_CHARSET_INFO *cs)

Description

This function provides information about the default client character set. The default character set may be changed with the mysql_set_character_set() function.
Example

This example shows the fields that are available in the `MY_CHARSET_INFO` structure:

```c
if (!mysql_set_character_set(&mysql, "utf8"))
{
    MY_CHARSET_INFO cs;
    mysql_get_character_set_info(&mysql, &cs);
    printf("character set information:
"n);
    printf("character set+collation number: %d\n", cs.number);
    printf("character set name: %s\n", cs.name);
    printf("collation name: %s\n", cs.csname);
    printf("comment: %s\n", cs.comment);
    printf("directory: %s\n", cs.dir);
    printf("multi byte character min. length: %d\n", cs.mbminlen);
    printf("multi byte character max. length: %d\n", cs.mbmaxlen);
}
```

23.8.7.27 mysql_get_client_info()

```c
const char *mysql_get_client_info(void)
```

Description

Returns a string that represents the MySQL client library version (for example, "5.6.47").

The function value is the MySQL version. For Connector/C, this is the MySQL version on which the Connector/C distribution is based. For more information, see Section 23.8.4.4, “C API Server and Client Library Versions”.

Return Values

A character string that represents the MySQL client library version.

Errors

None.

23.8.7.28 mysql_get_client_version()

```c
unsigned long mysql_get_client_version(void)
```

Description

Returns an integer that represents the MySQL client library version. The value has the format `XYZZ` where `X` is the major version, `YY` is the release level (or minor version), and `ZZ` is the sub-version within the release level:

```
major_version*10000 + release_level*100 + sub_version
```

For example, "5.6.47" is returned as 50647.

The function value is the MySQL version. For Connector/C, this is the MySQL version on which the Connector/C distribution is based. For more information, see Section 23.8.4.4, “C API Server and Client Library Versions”.

Return Values

An integer that represents the MySQL client library version.
Errors
None.

23.8.7.29 mysql_get_host_info()

const char *mysql_get_host_info(MYSQL *mysql)

Description
Returns a string describing the type of connection in use, including the server host name.

Return Values
A character string representing the server host name and the connection type.

Errors
None.

23.8.7.30 mysql_get_proto_info()

unsigned int mysql_get_proto_info(MYSQL *mysql)

Description
Returns the protocol version used by current connection.

Return Values
An unsigned integer representing the protocol version used by the current connection.

Errors
None.

23.8.7.31 mysql_get_server_info()

const char *mysql_get_server_info(MYSQL *mysql)

Description
Returns a string that represents the MySQL server version (for example, "5.6.47").

Return Values
A character string that represents the MySQL server version.

Errors
None.

23.8.7.32 mysql_get_server_version()

unsigned long mysql_get_server_version(MYSQL *mysql)
C API Function Descriptions

Description

Returns an integer that represents the MySQL server version. The value has the format \texttt{XYYZZ} where \(X\) is the major version, \(YY\) is the release level (or minor version), and \(ZZ\) is the sub-version within the release level:

\[
\text{major_version} \times 10000 + \text{release_level} \times 100 + \text{sub_version}
\]

For example, "5.6.47" is returned as \(50647\).

This function is useful in client programs for determining whether some version-specific server capability exists.

Return Values

An integer that represents the MySQL server version.

Errors

None.

23.8.7.33 mysql_get_ssl_cipher()

\texttt{const char *mysql_get_ssl_cipher(MYSQL *mysql)}

Description

\texttt{mysql_get_ssl_cipher()} returns the encryption cipher used for the given connection to the server. \texttt{mysql} is the connection handler returned from \texttt{mysql_init()}.

Return Values

A string naming the encryption cipher used for the connection, or \texttt{NULL} if the connection is not encrypted.

23.8.7.34 mysql_hex_string()

\texttt{unsigned long mysql_hex_string(char *to, const char *from, unsigned long length)}

Description

This function creates a legal SQL string for use in an SQL statement. See Section 9.1.1, "String Literals".

The string in the \texttt{from} argument is encoded in hexadecimal format, with each character encoded as two hexadecimal digits. The result is placed in the \texttt{to} argument, followed by a terminating null byte.

The string pointed to by \texttt{from} must be \texttt{length} bytes long. You must allocate the \texttt{to} buffer to be at least \texttt{length*2+1} bytes long. When \texttt{mysql_hex_string()} returns, the contents of \texttt{to} is a null-terminated string. The return value is the length of the encoded string, not including the terminating null byte.

The return value can be placed into an SQL statement using either \texttt{X'value'} or \texttt{0xvalue} format. However, the return value does not include the \texttt{X'...'} or \texttt{0x}. The caller must supply whichever of those is desired.

Example
The `strmov()` function used in the example is included in the `libmysqlclient` library and works like `strcpy()` but returns a pointer to the terminating null of the first parameter.

**Return Values**

The length of the encoded string that is placed into `to`, not including the terminating null character.

**Errors**

None.

**23.8.7.35 mysql_info()**

```c
const char *mysql_info(MYSQL *mysql)
```

**Description**

Retrieves a string providing information about the most recently executed statement, but only for the statements listed here. For other statements, `mysql_info()` returns NULL. The format of the string varies depending on the type of statement, as described here. The numbers are illustrative only; the string contains values appropriate for the statement.

- **INSERT INTO ... SELECT ...**
  
  String format: Records: 100 Duplicates: 0 Warnings: 0

- **INSERT INTO ... VALUES (...),(...),(...)...**
  
  String format: Records: 3 Duplicates: 0 Warnings: 0

- **LOAD DATA**
  
  String format: Records: 1 Deleted: 0 Skipped: 0 Warnings: 0

- **ALTER TABLE**
  
  String format: Records: 3 Duplicates: 0 Warnings: 0

- **UPDATE**
  
  String format: Rows matched: 40 Changed: 40 Warnings: 0

`mysql_info()` returns a non-NULL value for `INSERT ... VALUES` only for the multiple-row form of the statement (that is, only if multiple value lists are specified).
Return Values

A character string representing additional information about the most recently executed statement. NULL if no information is available for the statement.

Errors

None.

23.8.7.36 mysql_init()

MYSQL *mysql_init(MYSQL *mysql)

Description

Allocates or initializes a MYSQL object suitable for mysql_real_connect(). If mysql is a NULL pointer, the function allocates, initializes, and returns a new object. Otherwise, the object is initialized and the address of the object is returned. If mysql_init() allocates a new object, it is freed when mysql_close() is called to close the connection.

In a nonmultithreaded environment, mysql_init() invokes mysql_library_init() automatically as necessary. However, mysql_library_init() is not thread-safe in a multithreaded environment, and thus neither is mysql_init(). Before calling mysql_init(), either call mysql_library_init() prior to spawning any threads, or use a mutex to protect the mysql_library_init() call. This should be done prior to any other client library call.

Return Values

An initialized MYSQL* handler. NULL if there was insufficient memory to allocate a new object.

Errors

In case of insufficient memory, NULL is returned.

23.8.7.37 mysql_insert_id()

my_ulonglong mysql_insert_id(MYSQL *mysql)

Description

Returns the value generated for an AUTO_INCREMENT column by the previous INSERT or UPDATE statement. Use this function after you have performed an INSERT statement into a table that contains an AUTO_INCREMENT field, or have used INSERT or UPDATE to set a column value with LAST_INSERT_ID(expr).

The return value of mysql_insert_id() is always zero unless explicitly updated under one of the following conditions:

• INSERT statements that store a value into an AUTO_INCREMENT column. This is true whether the value is automatically generated by storing the special values NULL or 0 into the column, or is an explicit nonspecial value.

• In the case of a multiple-row INSERT statement, mysql_insert_id() returns the first automatically generated AUTO_INCREMENT value that was successfully inserted.

If no rows are successfully inserted, mysql_insert_id() returns 0.
• If an INSERT ... SELECT statement is executed, and no automatically generated value is successfully inserted, mysql_insert_id() returns the ID of the last inserted row.

• If an INSERT ... SELECT statement uses LAST_INSERT_ID(expr), mysql_insert_id() returns expr.

• INSERT statements that generate an AUTO_INCREMENT value by inserting LAST_INSERT_ID(expr) into any column or by updating any column to LAST_INSERT_ID(expr).

• If the previous statement returned an error, the value of mysql_insert_id() is undefined.

The return value of mysql_insert_id() can be simplified to the following sequence:

1. If there is an AUTO_INCREMENT column, and an automatically generated value was successfully inserted, return the first such value.

2. If LAST_INSERT_ID(expr) occurred in the statement, return expr, even if there was an AUTO_INCREMENT column in the affected table.

3. The return value varies depending on the statement used. When called after an INSERT statement:
   • If there is an AUTO_INCREMENT column in the table, and there were some explicit values for this column that were successfully inserted into the table, return the last of the explicit values.

When called after an INSERT ... ON DUPLICATE KEY UPDATE statement:
   • If there is an AUTO_INCREMENT column in the table and there were some explicit successfully inserted values or some updated values, return the last of the inserted or updated values.

mysql_insert_id() returns 0 if the previous statement does not use an AUTO_INCREMENT value. If you need to save the value for later, be sure to call mysql_insert_id() immediately after the statement that generates the value.

The value of mysql_insert_id() is affected only by statements issued within the current client connection. It is not affected by statements issued by other clients.

The LAST_INSERT_ID() SQL function will contain the value of the first automatically generated value that was successfully inserted. LAST_INSERT_ID() is not reset between statements because the value of that function is maintained in the server. Another difference from mysql_insert_id() is that LAST_INSERT_ID() is not updated if you set an AUTO_INCREMENT column to a specific nonspecial value. See Section 12.15, “Information Functions”.

mysql_insert_id() returns 0 following a CALL statement for a stored procedure that generates an AUTO_INCREMENT value because in this case mysql_insert_id() applies to CALL and not the statement within the procedure. Within the procedure, you can use LAST_INSERT_ID() at the SQL level to obtain the AUTO_INCREMENT value.

The reason for the differences between LAST_INSERT_ID() and mysql_insert_id() is that LAST_INSERT_ID() is made easy to use in scripts while mysql_insert_id() tries to provide more exact information about what happens to the AUTO_INCREMENT column.

Return Values

Described in the preceding discussion.

Errors

None.
23.8.7.38 mysql_kill()

```c
int mysql_kill(MYSQL *mysql, unsigned long pid)
```

**Description**

Asks the server to kill the thread specified by `pid`.

This function is deprecated. Use `mysql_query()` to issue an SQL KILL statement instead.

`mysql_kill()` cannot handle values larger than 32 bits, but to guard against killing the wrong thread returns an error in these cases:

- If given an ID larger than 32 bits, `mysql_kill()` returns a `ER_INVALID_CONN_HANDLE` error.
- After the server's internal thread ID counter reaches a value larger than 32 bits, it returns an `ER_DATA_OUT_OF_RANGE` error for any `mysql_kill()` invocation and `mysqlKill()` fails.

**Return Values**

Zero for success. Nonzero if an error occurred.

**Errors**

- `CR_COMMANDS_OUT_OF_SYNC`
  
  Commands were executed in an improper order.

- `CR_INVALID_CONN_HANDLE`
  
  The `pid` was larger than 32 bits.

- `CR_SERVER_GONE_ERROR`
  
  The MySQL server has gone away.

- `CR_SERVER_LOST`
  
  The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`
  
  An unknown error occurred.

- `ER_DATA_OUT_OF_RANGE`
  
  The server's internal thread ID counter has reached a value larger than 32 bits, at which point it rejects all `mysql_kill()` invocations.

23.8.7.39 mysql_library_end()

```c
void mysql_library_end(void)
```

**Description**

This function finalizes the MySQL library. Call it when you are done using the library (for example, after disconnecting from the server). The action taken by the call depends on whether your application is linked to the MySQL client library or the MySQL embedded server library. For a client program linked against the
libmysqlclient library by using the `\-lmysqlclient` flag, `mysql_library_end()` performs some memory management to clean up. For an embedded server application linked against the libmysqld library by using the `\-lmysqld` flag, `mysql_library_end()` shuts down the embedded server and then cleans up.

Note

To avoid memory leaks after the application is done using the library (for example, after closing the connection to the server), be sure to call `mysql_library_end()` explicitly. This enables memory management to be performed to clean up and free resources used by the library.

For usage information, see Section 23.8.6, “C API Function Overview”, and Section 23.8.7.40, “mysql_library_init()”.

23.8.7.40 mysql_library_init()

```
int mysql_library_init(int argc, char **argv, char **groups)
```

Description

Call this function to initialize the MySQL client library before you call any other MySQL function, whether your application is a regular client program or uses the embedded server. If the application uses the embedded server, this call starts the server and initializes any subsystems (mysys, InnoDB, and so forth) that the server uses.

Note

To avoid memory leaks after the application is done using the library (for example, after closing the connection to the server), be sure to call `mysql_library_end()` explicitly. This enables memory management to be performed to clean up and free resources used by the library. See Section 23.8.7.39, “mysql_library_end()”.

The choice of whether the application operates as a regular client or uses the embedded server depends on whether you use the libmysqlclient or libmysqld library at link time to produce the final executable. For additional information, see Section 23.8.6, “C API Function Overview”.

In a nonmultithreaded environment, the call to `mysql_library_init()` may be omitted, because `mysql_init()` will invoke it automatically as necessary. However, `mysql_library_init()` is not thread-safe in a multithreaded environment, and thus neither is `mysql_init()`, which calls `mysql_library_init()`. You must either call `mysql_library_init()` prior to spawning any threads, or else use a mutex to protect the call, whether you invoke `mysql_library_init()` or indirectly through `mysql_init()`. Do this prior to any other client library call.

The `argc` and `argv` arguments are analogous to the arguments to `main()`, and enable passing of options to the embedded server. For convenience, `argc` may be 0 (zero) if there are no command-line arguments for the server. This is the usual case for applications intended for use only as regular (nonembedded) clients, and the call typically is written as `mysql_library_init(0, NULL, NULL).

```
#include <mysql.h>
#include <stdlib.h>

int main(void) {
    if (mysql_library_init(0, NULL, NULL)) {
        fprintf(stderr, "could not initialize MySQL client library\n");
        exit(1);
    }
}
```
When arguments are to be passed (argc is greater than 0), the first element of argv is ignored (it typically contains the program name). mysql_library_init() makes a copy of the arguments so it is safe to destroy argv or groups after the call.

For embedded applications, if you want to connect to an external server without starting the embedded server, you have to specify a negative value for argc.

The groups argument is an array of strings that indicate the groups in option files from which to read options. See Section 4.2.2.2, “Using Option Files”. Make the final entry in the array NULL. For convenience, if the groups argument itself is NULL, the [server] and [embedded] groups are used by default.

```c
#include <mysql.h>
#include <stdlib.h>

static char *server_args[] = {
    "this_program",       /* this string is not used */
    "--datadir=./",
    "--key_buffer_size=32M"
};
static char *server_groups[] = {
    "embedded",
    "server",
    "this_program_SERVER",
    (char *)NULL
};

int main(void) {
    if (mysql_library_init(sizeof(server_args) / sizeof(char *),
        server_args, server_groups)) {  
        fprintf(stderr, "could not initialize MySQL client library\n");
        exit(1);
    }
    /* Use any MySQL API functions here */
    mysql_library_end();
    return EXIT_SUCCESS;
}
```

Return Values

Zero for success. Nonzero if an error occurred.

23.8.7.41 mysql_list_dbs()

```c
MYSQL_RES *mysql_list_dbs(MYSQL *mysql, const char *wild)
```

Description

Returns a result set consisting of database names on the server that match the simple regular expression specified by the wild parameter. wild may contain the wildcard characters % or _, or may be a NULL pointer to match all databases. Calling mysql_list_dbs() is similar to executing the query SHOW DATABASES [LIKE wild].
You must free the result set with `mysql_free_result()`.

**Return Values**

A `MYSQL_RES` result set for success. `NULL` if an error occurred.

**Errors**

- **CR_COMMANDS_OUT_OF_SYNC**
  Commands were executed in an improper order.

- **CR_OUT_OF_MEMORY**
  Out of memory.

- **CR_SERVER_GONE_ERROR**
  The MySQL server has gone away.

- **CR_SERVER_LOST**
  The connection to the server was lost during the query.

- **CR_UNKNOWN_ERROR**
  An unknown error occurred.

### 23.8.7.42 mysql_list_fields()

```c
MYSQL_RES *mysql_list_fields(MYSQL *mysql, const char *table, const char *wild)
```

**Description**

Returns an empty result set for which the metadata provides information about the columns in the given table that match the simple regular expression specified by the `wild` parameter. `wild` may contain the wildcard characters `%` or `_`, or may be a `NULL` pointer to match all fields. Calling `mysql_list_fields()` is similar to executing the query `SHOW COLUMNS FROM tbl_name [LIKE wild].`

It is preferable to use `SHOW COLUMNS FROM tbl_name` instead of `mysql_list_fields()`.

You must free the result set with `mysql_free_result()`.

**Return Values**

A `MYSQL_RES` result set for success. `NULL` if an error occurred.

**Errors**

- **CR_COMMANDS_OUT_OF_SYNC**
  Commands were executed in an improper order.

- **CR_SERVER_GONE_ERROR**
  The MySQL server has gone away.

- **CR_SERVER_LOST**
The connection to the server was lost during the query.

- **CR_UNKNOWN_ERROR**
  An unknown error occurred.

### Example

```c
int i;
MYSQL_RES *tbl_cols = mysql_list_fields(mysql, "mytbl", "f%");
unsigned int field_cnt = mysql_num_fields(tbl_cols);
printf("Number of columns: %d\n", field_cnt);
for (i=0; i < field_cnt; ++i)
{
    /* col describes i-th column of the table */
    MYSQL_FIELD *col = mysql_fetch_field_direct(tbl_cols, i);
    printf ("Column %d: %s\n", i, col->name);
}
mysql_free_result(tbl_cols);
```

### 23.8.7.43 `mysql_list_processes()`

**MYSQL_RES *mysql_list_processes(MYSQL *mysql)**

**Description**

Returns a result set describing the current server threads. This is the same kind of information as that reported by `mysqladmin processlist` or a `SHOW PROCESSLIST` query.

You must free the result set with `mysql_free_result()`.

**Return Values**

A `MYSQL_RES` result set for success. `NULL` if an error occurred.

**Errors**

- **CR_COMMANDS_OUT_OF_SYNC**
  Commands were executed in an improper order.

- **CR_SERVER_GONE_ERROR**
  The MySQL server has gone away.

- **CR_SERVER_LOST**
  The connection to the server was lost during the query.

- **CR_UNKNOWN_ERROR**
  An unknown error occurred.

### 23.8.7.44 `mysql_list_tables()`

**MYSQL_RES *mysql_list_tables(MYSQL *mysql, const char *wild)**
Description

Returns a result set consisting of table names in the current database that match the simple regular expression specified by the `wild` parameter. `wild` may contain the wildcard characters % or _, or may be a NULL pointer to match all tables. Calling `mysql_list_tables()` is similar to executing the query `SHOW TABLES [LIKE wild]`.

You must free the result set with `mysql_free_result()`.

Return Values

A `MYSQL_RES` result set for success. NULL if an error occurred.

Errors

- **CR_COMMANDS_OUT_OF_SYNC**
  Commands were executed in an improper order.
- **CR_SERVER_GONE_ERROR**
  The MySQL server has gone away.
- **CR_SERVER_LOST**
  The connection to the server was lost during the query.
- **CR_UNKNOWN_ERROR**
  An unknown error occurred.

23.8.7.45 `mysql_more_results()`

```c
my_bool mysql_more_results(MYSQL *mysql)
```

Description

This function is used when you execute multiple statements specified as a single statement string, or when you execute `CALL` statements, which can return multiple result sets.

`mysql_more_results()` true if more results exist from the currently executed statement, in which case the application must call `mysql_next_result()` to fetch the results.

Return Values

TRUE (1) if more results exist. FALSE (0) if no more results exist.

In most cases, you can call `mysql_next_result()` instead to test whether more results exist and initiate retrieval if so.

See Section 23.8.16, “C API Multiple Statement Execution Support”, and Section 23.8.7.46, “mysql_next_result()”.

Errors

None.

23.8.7.46 `mysql_next_result()`
int mysql_next_result(MYSQL *mysql)

Description

mysql_next_result() is used when you execute multiple statements specified as a single statement string, or when you use CALL statements to execute stored procedures, which can return multiple result sets.

mysql_next_result() reads the next statement result and returns a status to indicate whether more results exist. If mysql_next_result() returns an error, there are no more results.

Before each call to mysql_next_result(), you must call mysql_free_result() for the current statement if it is a statement that returned a result set (rather than just a result status).

After calling mysql_next_result() the state of the connection is as if you had called mysql_store_result(), mysql_warning_count(), mysql_affected_rows(), and so forth.

If your program uses CALL statements to execute stored procedures, the CLIENT_MULTI_RESULTS flag must be enabled. This is because each CALL returns a result to indicate the call status, in addition to any result sets that might be returned by statements executed within the procedure. Because CALL can return multiple results, process them using a loop that calls mysql_next_result() to determine whether there are more results.

CLIENT_MULTI_RESULTS can be enabled when you call mysql_real_connect(), either explicitly by passing the CLIENT_MULTI_RESULTS flag itself, or implicitly by passing CLIENT_MULTI_STATEMENTS (which also enables CLIENT_MULTI_RESULTS). In MySQL 5.6, CLIENT_MULTI_RESULTS is enabled by default.

It is also possible to test whether there are more results by calling mysql_more_results(). However, this function does not change the connection state, so if it returns true, you must still call mysql_next_result() to advance to the next result.

For an example that shows how to use mysql_next_result(), see Section 23.8.16, “C API Multiple Statement Execution Support”.

Return Values

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Successful and there are more results</td>
</tr>
<tr>
<td>-1</td>
<td>Successful and there are no more results</td>
</tr>
<tr>
<td>&gt;0</td>
<td>An error occurred</td>
</tr>
</tbody>
</table>

Errors

- CR_COMMANDS_OUT_OF_SYNC
  Commands were executed in an improper order. For example, if you did not call mysql_use_result() for a previous result set.

- CR_SERVER_GONE_ERROR
  The MySQL server has gone away.

- CR_SERVER_LOST
  The connection to the server was lost during the query.
• **CR_UNKNOWN_ERROR**
  
  An unknown error occurred.

### 23.8.7.47 mysql_num_fields()

```c
unsigned int mysql_num_fields(MYSQL_RES *result)
```

To pass a `MYSQL*` argument instead, use `unsigned int mysql_field_count(MYSQL *mysql)`.

**Description**

Returns the number of columns in a result set.

You can get the number of columns either from a pointer to a result set or to a connection handler. You would use the connection handler if `mysql_store_result()` or `mysql_use_result()` returned `NULL` (and thus you have no result set pointer). In this case, you can call `mysql_field_count()` to determine whether `mysql_store_result()` should have produced a nonempty result. This enables the client program to take proper action without knowing whether the query was a `SELECT` (or `SELECT`-like) statement. The example shown here illustrates how this may be done.

See [Section 23.8.21.1, “Why mysql_store_result() Sometimes Returns NULL After mysql_query() Returns Success”](#).

**Return Values**

An unsigned integer representing the number of columns in a result set.

**Errors**

None.

**Example**

```c
MYSQL_RES *result;
unsigned int num_fields;
unsigned int num_rows;

if (mysql_query(&mysql, query_string))
{
    // error
}
else // query succeeded, process any data returned by it
{
    result = mysql_store_result(&mysql);
    if (result) // there are rows
    {
        num_fields = mysql_num_fields(result);
        // retrieve rows, then call mysql_free_result(result)
    }
    else // mysql_store_result() returned nothing; should it have?
    {
        if (mysql_errno(&mysql))
        {
            fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
        }
        else if (mysql_field_count(&mysql) == 0)
        {
            // query does not return data
            // (it was not a SELECT)
            num_rows = mysql_affected_rows(&mysql);
        }
    }
}
An alternative (if you know that your query should have returned a result set) is to replace the
`mysql_errno(&mysql)` call with a check whether `mysql_field_count(&mysql)` returns 0. This
happens only if something went wrong.

### 23.8.7.48 mysql_num_rows()

```c
my_ulonglong mysql_num_rows(MYSQL_RES *result)
```

**Description**

Returns the number of rows in the result set.

The use of `mysql_num_rows()` depends on whether you use `mysql_store_result()`
or `mysql_use_result()` to return the result set. If you use `mysql_store_result()`,
`mysql_num_rows()` may be called immediately. If you use `mysql_use_result()`,
`mysql_num_rows()` does not return the correct value until all the rows in the result set have been
retrieved.

`mysql_num_rows()` is intended for use with statements that return a result set, such as `SELECT`. For
statements such as `INSERT`, `UPDATE`, or `DELETE`, the number of affected rows can be obtained with
`mysql_affected_rows()`.

**Return Values**

The number of rows in the result set.

**Errors**

None.

### 23.8.7.49 mysql_options()

```c
int mysql_options(MYSQL *mysql, enum mysql_option option, const void *arg)
```

**Description**

Can be used to set extra connect options and affect behavior for a connection. This function may be called
multiple times to set several options.

Call `mysql_options()` after `mysql_init()` and before `mysql_connect()` or
`mysql_real_connect()`.

The `option` argument is the option that you want to set; the `arg` argument is the value for the option. If
the option is an integer, specify a pointer to the value of the integer as the `arg` argument.

Options for information such as SSL certificate and key files are used to establish an encrypted connection
if such connections are available, but do not enforce any requirement that the connection obtained be
encrypted. To require an encrypted connection, use the technique described in Section 23.8.15, “C API
Encrypted Connection Support”.

The following list describes the possible options, their effect, and how `arg` is used for each option. For
option descriptions that indicate `arg` is unused, its value is irrelevant; it is conventional to pass 0. Several
of the options apply only when the application is linked against the `libmysqld` embedded server library
and are unused for applications linked against the `libmysqlclient` client library.
• **MYSQL_DEFAULT_AUTH** (argument type: `char *`)

  The name of the authentication plugin to use.

• **MYSQL_ENABLE_CLEARTEXT_PLUGIN** (argument type: `my_bool *`)

  Enable the `mysql_clear_password` cleartext authentication plugin. See Section 6.4.1.5, “Client-Side Cleartext Pluggable Authentication”.

• **MYSQL_INIT_COMMAND** (argument type: `char *`)

  SQL statement to execute when connecting to the MySQL server. Automatically re-executed if reconnection occurs.

• **MYSQL_OPT_BIND** (argument: `char *`)

  The network interface from which to connect to the server. This is used when the client host has multiple network interfaces. The argument is a host name or IP address (specified as a string).

• **MYSQL_OPT_CAN_HANDLE_EXPIRED_PASSWORDS** (argument type: `my_bool *`)

  Indicate whether the client can handle expired passwords. See Section 6.2.10, “Server Handling of Expired Passwords”.

• **MYSQL_OPT_COMPRESS** (argument: not used)

  Compress all information sent between the client and the server if possible. See Section 4.2.5, “Connection Compression Control”.

• **MYSQL_OPT_CONNECT_ATTR_DELETE** (argument type: `char *`)

  Given a key name, this option deletes a key-value pair from the current set of connection attributes to pass to the server at connect time. The argument is a pointer to a null-terminated string naming the key. Comparison of the key name with existing keys is case-sensitive.

  See also the description for the `MYSQL_OPT_CONNECT_ATTR_RESET` option, as well as the description for the `MYSQL_OPT_CONNECT_ATTR_ADD` option in the description of the `mysql_options4()` function. That function description also includes a usage example.

  The Performance Schema exposes connection attributes through the `session_connect_attrs` and `session_account_connect_attrs` tables. See Section 22.12.8, “Performance Schema Connection Attribute Tables”.

• **MYSQL_OPT_CONNECT_ATTR_RESET** (argument not used)

  This option resets (clears) the current set of connection attributes to pass to the server at connect time.

  See also the description for the `MYSQL_OPT_CONNECT_ATTR_DELETE` option, as well as the description for the `MYSQL_OPT_CONNECT_ATTR_ADD` option in the description of the `mysql_options4()` function. That function description also includes a usage example.

  The Performance Schema exposes connection attributes through the `session_connect_attrs` and `session_account_connect_attrs` tables. See Section 22.12.8, “Performance Schema Connection Attribute Tables”.

• **MYSQL_OPT_CONNECT_TIMEOUT** (argument type: `unsigned int *`)

  The connect timeout in seconds.
• **MYSQL_OPT_GUESS_CONNECTION** (argument: not used)

For an application linked against the `libmysqld` embedded server library, this option enables the library to guess whether to use the embedded server or a remote server. “Guess” means that if the host name is set and is not `localhost`, it uses a remote server. This behavior is the default. `MYSQL_OPT_USE_EMBEDDED_CONNECTION` and `MYSQL_OPT_USE_REMOTE_CONNECTION` can be used to override it. This option is ignored for applications linked against the `libmysqlclient` client library.

• **MYSQL_OPT_LOCAL_INFILE** (argument type: optional pointer to `unsigned int`)

This option affects client-side LOCAL capability for LOAD DATA operations. By default, LOCAL capability is determined by the default compiled into the MySQL client library (see Section 13.2.6, “LOAD DATA Syntax”). To control this capability explicitly, invoke `mysql_options()` to set the `MYSQL_OPT_LOCAL_INFILE` option:

- LOCAL is disabled if the pointer points to an `unsigned int` that has a zero value.
- LOCAL is enabled if no pointer is given or if the pointer points to an `unsigned int` that has a nonzero value.

Successful use of a LOCAL load operation by a client also requires that the server permits it.

• **MYSQL_OPT_NAMED_PIPE** (argument: not used)

Use a named pipe to connect to the MySQL server on Windows, if the server permits named-pipe connections.

• **MYSQL_OPT_PROTOCOL** (argument type: `unsigned int *`)

Type of protocol to use. Specify one of the enum values of `mysql_protocol_type` defined in `mysql.h`.

• **MYSQL_OPT_READ_TIMEOUT** (argument type: `unsigned int *`)

The timeout in seconds for each attempt to read from the server. There are retries if necessary, so the total effective timeout value is three times the option value. You can set the value so that a lost connection can be detected earlier than the TCP/IP `Close_Wait_Timeout` value of 10 minutes.

Implementation of this timeout uses mechanisms that may not be available on all platforms. On such a platform, a client that issues a read call might under certain circumstances wait without timing out. For example, a client might not time out if the server is not responding because it is waiting for a “disk full” condition to clear.

• **MYSQL_OPT_RECONNECT** (argument type: `my_bool *`)

Enable or disable automatic reconnection to the server if the connection is found to have been lost. Reconnect is off by default; this option provides a way to set reconnection behavior explicitly. See Section 23.8.20, “C API Automatic Reconnection Control”.

• **MYSQL_OPT_RETRY_COUNT** (argument type: `unsigned int *`)

The retry count for I/O-related system calls that are interrupted while connecting to the server or communicating with it. If this option is not specified, the default value is 1 (1 retry if the initial call is interrupted for 2 tries total).

This option can be used only by clients that link against a C client library compiled with NDB Cluster support. It is available as of MySQL NDB Cluster 7.4.11.
• **MYSQL_OPT_SSL_CA** *(argument type: char *)

The path name of the Certificate Authority (CA) certificate file. This option, if used, must specify the same certificate used by the server.

• **MYSQL_OPT_SSL_CAPATH** *(argument type: char *)

The path name of the directory that contains trusted SSL CA certificate files.

• **MYSQL_OPT_SSL_CERT** *(argument type: char *)

The path name of the client public key certificate file.

• **MYSQL_OPT_SSL_CIPHER** *(argument type: char *)

The list of permissible ciphers for SSL encryption.

• **MYSQL_OPT_SSL_CRL** *(argument type: char *)

The path name of the file containing certificate revocation lists.

• **MYSQL_OPT_SSL_CRLPATH** *(argument type: char *)

The path name of the directory that contains files containing certificate revocation lists.

• **MYSQL_OPT_SSL_KEY** *(argument type: char *)

The path name of the client private key file.

• **MYSQL_OPT_SSL_MODE** *(argument type: unsigned int *)

The security state to use for the connection to the server. The only permitted argument value is **SSL_MODE_REQUIRED** (require an encrypted connection). If set, this option causes **mysql_real_connect()** to fail if an encrypted connection cannot be obtained, without falling back to an unencrypted connection. Thus, **mysql_real_connect()** returns an error if the server does not support SSL or the client is not configured to use SSL. For more information about the security states, see the description of **--ssl-mode** in Command Options for Encrypted Connections.

To require an encrypted connection in MySQL 5.6, the standard MySQL client programs call **mysql_options()** to set **MYSQL_OPT_SSL_MODE** if the **--ssl-mode=REQUIRED** command-line option was specified. Third-party applications that must be able to require encrypted connections can use the technique described in Section 23.8.15, “C API Encrypted Connection Support”.

This option was added in MySQL 5.6.36.

• **MYSQL_OPT_SSL_VERIFY_SERVER_CERT** *(argument type: my_bool *)

Enable or disable verification of the server’s Common Name identity in its certificate against the host name used when connecting to the server. The connection is rejected if there is a mismatch. For encrypted connections, this feature can be used to prevent man-in-the-middle attacks. Identity verification is disabled by default.

• **MYSQL_OPT_USE_EMBEDDED_CONNECTION** *(argument: not used)*

For an application linked against the **libmysqld** embedded server library, this option forces the use of the embedded server for the connection. It is ignored for applications linked against the **libmysqlclient** client library.

• **MYSQL_OPT_USE_REMOTE_CONNECTION** *(argument: not used)*
For an application linked against the `libmysqld` embedded server library, this option forces the use of a remote server for the connection. It is ignored for applications linked against the `libmysqlclient` client library.

- **MYSQL_OPT_USE_RESULT** (argument: not used)

  This option is unused.

- **MYSQL_OPT_WRITE_TIMEOUT** (argument type: `unsigned int *`)

  The timeout in seconds for each attempt to write to the server. There is a retry if necessary, so the total effective timeout value is two times the option value.

- **MYSQL_PLUGIN_DIR** (argument type: `char *`)

  The directory in which to look for client plugins.

- **MYSQL_READ_DEFAULT_FILE** (argument type: `char *`)

  Read options from the named option file instead of from `my.cnf`.

- **MYSQL_READ_DEFAULT_GROUP** (argument type: `char *`)

  Read options from the named group from `my.cnf` or the file specified with `MYSQL_READ_DEFAULT_FILE`.

- **MYSQL_REPORT_DATA_TRUNCATION** (argument type: `my_bool *`)

  Enable or disable reporting of data truncation errors for prepared statements using the `error` member of `MYSQL_BIND` structures. (Default: enabled.)

- **MYSQL_SECURE_AUTH** (argument type: `my_bool *`)

  Whether to connect to a server that does not support the password hashing used in MySQL 4.1.1 and later. This option is enabled by default.

- **MYSQL_SERVER_PUBLIC_KEY** (argument type: `char *`)

  The path name to a file containing a client-side copy of the public key required by the server for RSA key pair-based password exchange. The file must be in PEM format. This option applies to clients that connect to the server using an account that authenticates with the `sha256_password` authentication plugin. This option is ignored for accounts that do not authenticate with one of those plugins. It is also ignored if RSA-based password exchange is not used, as is the case when the client connects to the server using a secure connection.

  For information about the `sha256_password` plugin, see Section 6.4.1.4, “SHA-256 Pluggable Authentication”.

- **MYSQL_SET_CHARSET_DIR** (argument type: `char *`)

  The path name of the directory that contains character set definition files.

- **MYSQL_SET_CHARSET_NAME** (argument type: `char *`)

  The name of the character set to use as the default character set. The argument can be `MYSQL_AUTODETECT_CHARSET_NAME` to cause the character set to be autodetected based on the operating system setting (see Section 10.4, “Connection Character Sets and Collations”).
- **MYSQL_SET_CLIENT_IP** (argument type: `char *`)

  For an application linked against the `libmysqld` embedded server library (when `libmysqld` is compiled with authentication support), this option means that the user is considered to have connected from the specified IP address (specified as a string) for authentication purposes. It is ignored for applications linked against the `libmysqlclient` client library.

- **MYSQL_SHARED_MEMORY_BASE_NAME** (argument type: `char *`)

  The name of the shared-memory object for communication to the server on Windows, if the server supports shared-memory connections. Specify the same value as used for the `shared_memory_base_name` system variable of the `mysqld` server you want to connect to.

The client group is always read if you use `MYSQL_READ_DEFAULT_FILE` or `MYSQL_READ_DEFAULT_GROUP`.

The specified group in the option file may contain the following options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>character-sets-dir=dir</code></td>
<td>The directory where character sets are installed.</td>
</tr>
<tr>
<td><code>compress</code></td>
<td>Use the compressed client/server protocol.</td>
</tr>
<tr>
<td><code>connect-timeout=seconds</code></td>
<td>The connect timeout in seconds. On Linux this timeout is also used for waiting for the first answer from the server.</td>
</tr>
<tr>
<td><code>database=db_name</code></td>
<td>Connect to this database if no database was specified in the connect command.</td>
</tr>
<tr>
<td><code>debug</code></td>
<td>Debug options.</td>
</tr>
<tr>
<td><code>default-character-set=charset_name</code></td>
<td>The default character set to use.</td>
</tr>
<tr>
<td><code>disable-local-infile</code></td>
<td>Disable use of LOAD DATA LOCAL.</td>
</tr>
<tr>
<td><code>enable-cleartext-plugin</code></td>
<td>Enable the <code>mysql_clear_password</code> cleartext authentication plugin.</td>
</tr>
<tr>
<td><code>host=host_name</code></td>
<td>Default host name.</td>
</tr>
<tr>
<td><code>init-command=stmt</code></td>
<td>Statement to execute when connecting to MySQL server. Automatically re-executed if reconnection occurs.</td>
</tr>
<tr>
<td><code>interactive-timeout=seconds</code></td>
<td>Same as specifying CLIENT_INTERACTIVE to <code>mysql_real_connect()</code>. See Section 23.8.7.53, &quot;mysql_real_connect()&quot;.</td>
</tr>
<tr>
<td>`local-infile=[0</td>
<td>1]`</td>
</tr>
<tr>
<td><code>max_allowed_packet=bytes</code></td>
<td>Maximum size of packet that client can read from server.</td>
</tr>
<tr>
<td><code>multi-queries,multi-results</code></td>
<td>Enable multiple result sets from multiple-statement executions or stored procedures.</td>
</tr>
<tr>
<td><code>multi-statements</code></td>
<td>Enable the client to send multiple statements in a single string (separated by <code>;</code> characters).</td>
</tr>
<tr>
<td><code>password=password</code></td>
<td>Default password.</td>
</tr>
<tr>
<td><code>pipe</code></td>
<td>Use named pipes to connect to a MySQL server on Windows.</td>
</tr>
<tr>
<td><code>port=port_num</code></td>
<td>Default port number.</td>
</tr>
</tbody>
</table>
### Option Function Descriptions

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>`protocol={TCP</td>
<td>SOCKET</td>
</tr>
<tr>
<td><code>return-found-rows</code></td>
<td>Tell <code>mysql_info()</code> to return found rows instead of updated rows when using <code>UPDATE</code>.</td>
</tr>
<tr>
<td><code>shared-memory-base-name=name</code></td>
<td>Shared-memory name to use to connect to server.</td>
</tr>
<tr>
<td>`socket={file_name</td>
<td>pipe_name}`</td>
</tr>
<tr>
<td><code>ssl-ca=file_name</code></td>
<td>Certificate Authority file.</td>
</tr>
<tr>
<td><code>ssl-capath=dir_name</code></td>
<td>Certificate Authority directory.</td>
</tr>
<tr>
<td><code>ssl-cert=file_name</code></td>
<td>Certificate file.</td>
</tr>
<tr>
<td><code>ssl-cipher=cipher_list</code></td>
<td>Permissible SSL ciphers.</td>
</tr>
<tr>
<td><code>ssl-key=file_name</code></td>
<td>Key file.</td>
</tr>
<tr>
<td><code>timeout=seconds</code></td>
<td>Like <code>connect-timeout</code>.</td>
</tr>
<tr>
<td><code>user</code></td>
<td>Default user.</td>
</tr>
</tbody>
</table>

`timeout` has been replaced by `connect-timeout`, but `timeout` is still supported for backward compatibility.

For more information about option files used by MySQL programs, see Section 4.2.2.2, “Using Option Files”.

### Return Values

Zero for success. Nonzero if you specify an unknown option.

### Example

The following `mysql_options()` calls request the use of compression in the client/server protocol, cause options to be read from the `[odbc]` group in option files, and disable transaction autocommit mode:

```c
MYSQL mysql;
mysql_init(&mysql);
mysql_options(&mysql, MYSQL_OPT_COMPRESS, 0);
mysql_options(&mysql, MYSQL_READ_DEFAULT_GROUP, "odbc");
mysql_options(&mysql, MYSQL_INIT_COMMAND, "SET autocommit=0");
if (!mysql_real_connect(&mysql, "host", "user", "passwd", "database", 0, NULL, 0))
{
    fprintf(stderr, "Failed to connect to database: Error: %s\n",
            mysql_error(&mysql));
}
```

### 23.8.7.50 mysql_options4()

```c
int mysql_options4(MYSQL *mysql, enum mysql_option option, const void *arg1, const void *arg2)
```

### Description

`mysql_options4()` is similar to `mysql_options()` but has an extra fourth argument so that two values can be passed for the option specified in the second argument.
The following list describes the permitted options, their effect, and how arg1 and arg2 are used.

- **MYSQL_OPT_CONNECT_ATTR_ADD** *(argument types: char *, char *)*

  This option adds an attribute key-value pair to the current set of connection attributes to pass to the server at connect time. Both arguments are pointers to null-terminated strings. The first and second strings indicate the key and value, respectively. If the key is empty or already exists in the current set of connection attributes, an error occurs. Comparison of the key name with existing keys is case-sensitive.

  Key names that begin with an underscore (_) are reserved for internal use and should not be created by application programs. This convention permits new attributes to be introduced by MySQL without colliding with application attributes.

  mysql_options4() imposes a limit of 64KB on the aggregate size of connection attribute data it will accept. For calls that cause this limit to be exceeded, a **CR_INVALID_PARAMETER_NO** error occurs. Attribute size-limit checks also occur on the server side. For details, see Section 22.12.8, “Performance Schema Connection Attribute Tables”, which also describes how the Performance Schema exposes connection attributes through the **session_connect_attrs** and **session_account_connect_attrs** tables.

  See also the descriptions for the **MYSQL_OPT_CONNECT_ATTR_RESET** and **MYSQL_OPT_CONNECT_ATTR_DELETE** options in the description of the mysql_options() function.

**Return Values**

Zero for success. Nonzero if you specify an unknown option.

**Errors**

- **CR_DUPLICATE_CONNECTION_ATTR**

  A duplicate attribute name was specified.

- **CR_INVALID_PARAMETER_NO**

  A key name was empty or the amount of key-value connection attribute data exceeds 64KB limit.

- **CR_OUT_OF_MEMORY**

  Out of memory.

**Example**

This example demonstrates the calls that specify connection attributes:

```c
MYSQL mysql;
mysql_init(&mysql);
mysql_options(&mysql,MYSQL_OPT_CONNECT_ATTR_RESET, 0);
mysql_options4(&mysql,MYSQL_OPT_CONNECT_ATTR_ADD, "key1", "value1");
mysql_options4(&mysql,MYSQL_OPT_CONNECT_ATTR_ADD, "key2", "value2");
mysql_options4(&mysql,MYSQL_OPT_CONNECT_ATTR_ADD, "key3", "value3");
mysql_options(&mysql,MYSQL_OPT_CONNECT_ATTR_DELETE, "key1");
if (!mysql_real_connect(&mysql,"host","user","passwd","database",0,NULL,0))
{
    fprintf(stderr, "Failed to connect to database: Error: %s\n",
            mysql_error(&mysql));
}
```
23.8.7.51 mysql_ping()

```c
int mysql_ping(MYSQL *mysql)
```

**Description**

Checks whether the connection to the server is working. If the connection has gone down and auto-reconnect is enabled an attempt to reconnect is made. If the connection is down and auto-reconnect is disabled, `mysql_ping()` returns an error.

Auto-reconnect is disabled by default. To enable it, call `mysql_options()` with the `MYSQL_OPT_RECONNECT` option. For details, see Section 23.8.7.49, "mysql_options()".

`mysql_ping()` can be used by clients that remain idle for a long while, to check whether the server has closed the connection and reconnect if necessary.

If `mysql_ping()` does cause a reconnect, there is no explicit indication of it. To determine whether a reconnect occurs, call `mysql_thread_id()` to get the original connection identifier before calling `mysql_ping()`, then call `mysql_thread_id()` again to see whether the identifier has changed.

If reconnect occurs, some characteristics of the connection will have been reset. For details about these characteristics, see Section 23.8.20, "C API Automatic Reconnection Control".

**Return Values**

Zero if the connection to the server is active. Nonzero if an error occurred. A nonzero return does not indicate whether the MySQL server itself is down; the connection might be broken for other reasons such as network problems.

**Errors**

- `CR_COMMANDS_OUT_OF_SYNC`
  
  Commands were executed in an improper order.

- `CR_SERVER_GONE_ERROR`
  
  The MySQL server has gone away.

- `CR_UNKNOWN_ERROR`
  
  An unknown error occurred.

23.8.7.52 mysql_query()

```c
int mysql_query(MYSQL *mysql, const char *stmt_str)
```

**Description**

Executes the SQL statement pointed to by the null-terminated string `stmt_str`. Normally, the string must consist of a single SQL statement without a terminating semicolon (`;`) or `\g`. If multiple-statement execution has been enabled, the string can contain several statements separated by semicolons. See Section 23.8.16, "C API Multiple Statement Execution Support".

`mysql_query()` cannot be used for statements that contain binary data; you must use `mysql_real_query()` instead. (Binary data may contain the `\0` character, which `mysql_query()` interprets as the end of the statement string.)
If you want to know whether the statement returns a result set, you can use `mysql_field_count()` to check for this. See Section 23.8.7.22, “mysql_field_count()”.

**Return Values**

Zero for success. Nonzero if an error occurred.

**Errors**

- **CR_COMMANDS_OUT_OF_SYNC**
  Commands were executed in an improper order.

- **CR_SERVER_GONE_ERROR**
  The MySQL server has gone away.

- **CR_SERVER_LOST**
  The connection to the server was lost during the query.

- **CR_UNKNOWN_ERROR**
  An unknown error occurred.

### 23.8.7.53 mysql_real_connect()

```c
MYSQL *mysql_real_connect(MYSQL *mysql, const char *host, const char *user, const char *passwd, const char *db, unsigned int port, const char *unix_socket, unsigned long client_flag)
```

**Description**

`mysql_real_connect()` attempts to establish a connection to a MySQL database engine running on `host`. `mysql_real_connect()` must complete successfully before you can execute any other API functions that require a valid `MYSQL` connection handler structure.

The parameters are specified as follows:

- For the first parameter, specify the address of an existing `MYSQL` structure. Before calling `mysql_real_connect()`, call `mysql_init()` to initialize the `MYSQL` structure. You can change a lot of connect options with the `mysql_options()` call. See Section 23.8.7.49, “mysql_options()”.

- The value of `host` may be either a host name or an IP address. The client attempts to connect as follows:

  - If `host` is `NULL` or the string "localhost", a connection to the local host is assumed:
    - On Windows, the client connects using a shared-memory connection, if the server has shared-memory connections enabled.
    - On Unix, the client connects using a Unix socket file. The `unix_socket` parameter or the `MYSQL_UNIX_PORT` environment variable may be used to specify the socket name.
    - On Windows, if `host` is ".", or TCP/IP is not enabled and no `unix_socket` is specified or the host is empty, the client connects using a named pipe, if the server has named-pipe connections enabled. If named-pipe connections are not enabled, an error occurs.
  - Otherwise, TCP/IP is used.
You can also influence the type of connection to use with the `MYSQL_OPT_PROTOCOL` or `MYSQL_OPT_NAMED_PIPE` options to `mysql_options()`. The type of connection must be supported by the server.

- The `user` parameter contains the user's MySQL login ID. If `user` is `NULL` or the empty string '', the current user is assumed. Under Unix, this is the current login name. Under Windows ODBC, the current user name must be specified explicitly. See the Connector/ODBC section of Chapter 23, Connectors and APIs.

- The `passwd` parameter contains the password for `user`. If `passwd` is `NULL`, only entries in the `user` table for the user that have a blank (empty) password field are checked for a match. This enables the database administrator to set up the MySQL privilege system in such a way that users get different privileges depending on whether they have specified a password.

  **Note**
  
  Do not attempt to encrypt the password before calling `mysql_real_connect()`; password encryption is handled automatically by the client API.

- The `user` and `passwd` parameters use whatever character set has been configured for the `MYSQL` object. By default, this is `latin1`, but can be changed by calling `mysql_options(mysql, MYSQL_SET_CHARSET_NAME, "charset_name")` prior to connecting.

- `db` is the database name. If `db` is not `NULL`, the connection sets the default database to this value.

- If `port` is not 0, the value is used as the port number for the TCP/IP connection. Note that the `host` parameter determines the type of the connection.

- If `unix_socket` is not `NULL`, the string specifies the socket or named pipe to use. Note that the `host` parameter determines the type of the connection.

- The value of `client_flag` is usually 0, but can be set to a combination of the following flags to enable certain features:

  - `CAN_HANDLE_EXPIRED_PASSWORDS`: The client can handle expired passwords. For more information, see Section 6.2.10, “Server Handling of Expired Passwords”.

  - `CLIENT_COMPRESS`: Use compression in the client/server protocol.

  - `CLIENT_FOUND_ROWS`: Return the number of found (matched) rows, not the number of changed rows.

  - `CLIENT_IGNORE_SIGPIPE`: Prevents the client library from installing a `SIGPIPE` signal handler. This can be used to avoid conflicts with a handler that the application has already installed.

  - `CLIENT_IGNORE_SPACE`: Permit spaces after function names. Makes all function names reserved words.

  - `CLIENT_INTERACTIVE`: Permit `interactive_timeout` seconds of inactivity (rather than `wait_timeout` seconds) before closing the connection. The client's session `wait_timeout` variable is set to the value of the session `interactive_timeout` variable.

  - `CLIENT_LOCAL_FILES`: Enable `LOAD DATA LOCAL` handling.

  - `CLIENT_MULTI_RESULTS`: Tell the server that the client can handle multiple result sets from multiple-statement executions or stored procedures. This flag is automatically enabled if
**CLIENT_MULTI_STATEMENTS** is enabled. See the note following this table for more information about this flag.

- **CLIENT_MULTI_STATEMENTS**: Tell the server that the client may send multiple statements in a single string (separated by ; characters). If this flag is not set, multiple-statement execution is disabled. See the note following this table for more information about this flag.

- **CLIENT_NO_SCHEMA**: Do not permit db_name.tbl_name.col_name syntax. This is for ODBC. It causes the parser to generate an error if you use that syntax, which is useful for trapping bugs in some ODBC programs.

- **CLIENT_ODBC**: Unused.

- **CLIENT_SSL**: Use SSL (encrypted protocol). Do not set this option within an application program; it is set internally in the client library. Instead, use `mysql_options()` or `mysql_ssl_set()` before calling `mysql_real_connect()`.

- **CLIENT_REMEMBER_OPTIONS**: Remember options specified by calls to `mysql_options()`. Without this option, if `mysql_real_connect()` fails, you must repeat the `mysql_options()` calls before trying to connect again. With this option, the `mysql_options()` calls need not be repeated.

If your program uses **CALL** statements to execute stored procedures, the **CLIENT_MULTI_RESULTS** flag must be enabled. This is because each **CALL** returns a result to indicate the call status, in addition to any result sets that might be returned by statements executed within the procedure. Because **CALL** can return multiple results, process them using a loop that calls `mysql_next_result()` to determine whether there are more results.

**CLIENT_MULTI_RESULTS** can be enabled when you call `mysql_real_connect()`, either explicitly by passing the **CLIENT_MULTI_RESULTS** flag itself, or implicitly by passing **CLIENT_MULTI_STATEMENTS** (which also enables **CLIENT_MULTI_RESULTS**). In MySQL 5.6, **CLIENT_MULTI_RESULTS** is enabled by default.

If you enable **CLIENT_MULTI_STATEMENTS** or **CLIENT_MULTI_RESULTS**, process the result for every call to `mysql_query()` or `mysql_real_query()` by using a loop that calls `mysql_next_result()` to determine whether there are more results. For an example, see Section 23.8.16, “C API Multiple Statement Execution Support”.

For some parameters, it is possible to have the value taken from an option file rather than from an explicit value in the `mysql_real_connect()` call. To do this, call `mysql_options()` with the **MYSQL_READ_DEFAULT_FILE** or **MYSQL_READ_DEFAULT_GROUP** option before calling `mysql_real_connect()`. Then, in the `mysql_real_connect()` call, specify the “no-value” value for each parameter to be read from an option file:

- For **host**, specify a value of **NULL** or the empty string (""").
- For **user**, specify a value of **NULL** or the empty string.
- For **passwd**, specify a value of **NULL**. (For the password, a value of the empty string in the `mysql_real_connect()` call cannot be overridden in an option file, because the empty string indicates explicitly that the MySQL account must have an empty password.)
- For **db**, specify a value of **NULL** or the empty string.
- For **port**, specify a value of 0.
- For **unix_socket**, specify a value of **NULL**.
If no value is found in an option file for a parameter, its default value is used as indicated in the descriptions given earlier in this section.

Return Values

A `MYSQL*` connection handler if the connection was successful, `NULL` if the connection was unsuccessful. For a successful connection, the return value is the same as the value of the first parameter.

Errors

- **CR_CONN_HOST_ERROR**
  Failed to connect to the MySQL server.

- **CR_CONNECTION_ERROR**
  Failed to connect to the local MySQL server.

- **CR_IPSOCK_ERROR**
  Failed to create an IP socket.

- **CR_OUT_OF_MEMORY**
  Out of memory.

- **CR_SOCKET_CREATE_ERROR**
  Failed to create a Unix socket.

- **CR_UNKNOWN_HOST**
  Failed to find the IP address for the host name.

- **CR_VERSION_ERROR**
  A protocol mismatch resulted from attempting to connect to a server with a client library that uses a different protocol version.

- **CR_NAMEDPIPEOPEN_ERROR**
  Failed to create a named pipe on Windows.

- **CR_NAMEDPIPEWAIT_ERROR**
  Failed to wait for a named pipe on Windows.

- **CR_NAMEDPIPEGETSTATE_ERROR**
  Failed to get a pipe handler on Windows.

- **CR_SERVER_LOST**
  If `connect_timeout > 0` and it took longer than `connect_timeout` seconds to connect to the server or if the server died while executing the `init-command`.

- **CR_ALREADY_CONNECTED**
  The `MYSQL` connection handler is already connected.
Example

```c
MYSQL mysql;

mysql_init(&mysql);
mysql_options(&mysql, MYSQL_READ_DEFAULT_GROUP, "your_prog_name");
if (!mysql_real_connect(&mysql, "host", "user", "passwd", "database", 0, NULL, 0))
{
    fprintf(stderr, "Failed to connect to database: Error: %s\n",
            mysql_error(&mysql));
}
```

By using `mysql_options()` the MySQL client library reads the [client] and [your_prog_name] sections in the `my.cnf` file which ensures that your program works, even if someone has set up MySQL in some nonstandard way.

Upon connection, `mysql_real_connect()` sets the reconnect flag (part of the `MYSQL` structure) to a value of 1 in versions of the API older than 5.0.3, or 0 in newer versions. A value of 1 for this flag indicates that if a statement cannot be performed because of a lost connection, to try reconnecting to the server before giving up. You can use the `MYSQL_OPT_RECONNECT` option to `mysql_options()` to control reconnection behavior.

### 23.8.7.54 mysql_real_escape_string()

```c
unsigned long mysql_real_escape_string(MYSQL *mysql, char *to, const char *from, unsigned long length)
```

**Description**

This function creates a legal SQL string for use in an SQL statement. See Section 9.1.1, “String Literals”.

The `mysql` argument must be a valid, open connection because character escaping depends on the character set in use by the server.

The string in the `from` argument is encoded to produce an escaped SQL string, taking into account the current character set of the connection. The result is placed in the `to` argument, followed by a terminating null byte.

Characters encoded are `\`, `'`, `"`, NUL (ASCII 0), `\n`, `\r`, and Control+Z. Strictly speaking, MySQL requires only that backslash and the quote character used to quote the string in the query be escaped. `mysql_real_escape_string()` quotes the other characters to make them easier to read in log files. For comparison, see the quoting rules for literal strings and the `QUOTE()` SQL function in Section 9.1.1, “String Literals”, and Section 12.5, “String Functions and Operators”.

The string pointed to by `from` must be `length` bytes long. You must allocate the `to` buffer to be at least `length*2+1` bytes long. (In the worst case, each character may need to be encoded as using two bytes, and there must be room for the terminating null byte.) When `mysql_real_escape_string()` returns, the contents of `to` is a null-terminated string. The return value is the length of the encoded string, not including the terminating null byte.

If you must change the character set of the connection, use the `mysql_set_character_set()` function rather than executing a `SET NAMES` (or `SET CHARACTER SET`) statement. `mysql_set_character_set()` works like `SET NAMES` but also affects the character set used by `mysql_real_escape_string()`, which `SET NAMES` does not.

**Example**

The following example inserts two escaped strings into an `INSERT` statement, each within single quote characters:
char query[1000], *end;

end = strmov(query,"INSERT INTO test_table VALUES(");
*end++ = '\"';
end += mysql_real_escape_string(&mysql,end,"What is this",12);
*end++ = '\"';
*end++ = ',
*end++ = '\"';
end += mysql_real_escape_string(&mysql,end,"binary data: \0\r\n",16);
*end++ = '\"';
*end++ = ');};

if (mysql_real_query(&mysql,query,(unsigned int) (end - query)))
{
    fprintf(stderr, "Failed to insert row, Error: %s\n",
            mysql_error(&mysql));
}

The `strmov()` function used in the example is included in the `libmysqlclient` library and works like `strcpy()` but returns a pointer to the terminating null of the first parameter.

### Return Values

The length of the encoded string that is placed into the `to` argument, not including the terminating null character.

### Errors

None.

23.8.7.55 **mysql_real_query()**

```c
int mysql_real_query(MYSQL *mysql, const char *stmt_str, unsigned long length)
```

**Description**

`mysql_real_query()` executes the SQL statement pointed to by `stmt_str`, a string `length` bytes long. Normally, the string must consist of a single SQL statement without a terminating semicolon (\;) or \g. If multiple-statement execution has been enabled, the string can contain several statements separated by semicolons. See Section 23.8.16, “C API Multiple Statement Execution Support”.

`mysql_query()` cannot be used for statements that contain binary data; you must use `mysql_real_query()` instead. (Binary data may contain the `\0` character, which `mysql_query()` interprets as the end of the statement string.) In addition, `mysql_real_query()` is faster than `mysql_query()` because it does not call `strlen()` on the statement string.

If you want to know whether the statement returns a result set, you can use `mysql_field_count()` to check for this. See Section 23.8.7.22, “mysql_field_count()”.

### Return Values

Zero for success. Nonzero if an error occurred.

### Errors

- **CR_COMMANDS_OUT_OF_SYNC**
  
  Commands were executed in an improper order.

- **CR_SERVER_GONE_ERROR**
The MySQL server has gone away.

- **CR_SERVER_LOST**
  The connection to the server was lost during the query.

- **CR_UNKNOWN_ERROR**
  An unknown error occurred.

### 23.8.7.56 mysql_refresh()

```c
int mysql_refresh(MYSQL *mysql, unsigned int options)
```

**Description**

This function flushes tables or caches, or resets replication server information. The connected user must have the `RELOAD` privilege.

The `options` argument is a bitmask composed from any combination of the following values. Multiple values can be OR'ed together to perform multiple operations with a single call.

- **REFRESH_GRANT**
  Refresh the grant tables, like `FLUSH PRIVILEGES`.

- **REFRESH_LOG**
  Flush the logs, like `FLUSH LOGS`.

- **REFRESH_TABLES**
  Flush the table cache, like `FLUSH TABLES`.

- **REFRESH_HOSTS**
  Flush the host cache, like `FLUSH HOSTS`.

- **REFRESH_STATUS**
  Reset status variables, like `FLUSH STATUS`.

- **REFRESH_THREADS**
  Flush the thread cache.

- **REFRESH_SLAVE**
  On a slave replication server, reset the master server information and restart the slave, like `RESET SLAVE`.

- **REFRESH_MASTER**
  On a master replication server, remove the binary log files listed in the binary log index and truncate the index file, like `RESET MASTER`.

**Return Values**

Zero for success. Nonzero if an error occurred.
Errors

- **CR_COMMANDS_OUT_OF_SYNC**
  Commands were executed in an improper order.
- **CR_SERVER_GONE_ERROR**
  The MySQL server has gone away.
- **CR_SERVER_LOST**
  The connection to the server was lost during the query.
- **CR_UNKNOWN_ERROR**
  An unknown error occurred.

### 23.8.7.57 mysql_reload()

```c
int mysql_reload(MYSQL *mysql)
```

**Description**

Asks the MySQL server to reload the grant tables. The connected user must have the `RELOAD` privilege.

This function is deprecated. Use `mysql_query()` to issue an SQL `FLUSH PRIVILEGES` statement instead.

**Return Values**

Zero for success. Nonzero if an error occurred.

**Errors**

- **CR_COMMANDS_OUT_OF_SYNC**
  Commands were executed in an improper order.
- **CR_SERVER_GONE_ERROR**
  The MySQL server has gone away.
- **CR_SERVER_LOST**
  The connection to the server was lost during the query.
- **CR_UNKNOWN_ERROR**
  An unknown error occurred.

### 23.8.7.58 mysql_rollback()

```c
my_bool mysql_rollback(MYSQL *mysql)
```

**Description**

Rolls back the current transaction.
The action of this function is subject to the value of the `completion_type` system variable. In particular, if the value of `completion_type` is `RELEASE` (or 2), the server performs a release after terminating a transaction and closes the client connection. Call `mysql_close()` from the client program to close the connection from the client side.

**Return Values**

Zero for success. Nonzero if an error occurred.

**Errors**

None.

### 23.8.7.59 `mysql_row_seek()`

```c
MYSQL_ROW_OFFSET mysql_row_seek(MYSQL_RES *result, MYSQL_ROW_OFFSET offset)
```

**Description**

Sets the row cursor to an arbitrary row in a query result set. The `offset` value is a row offset, typically a value returned from `mysql_row_tell()` or from `mysql_row_seek()`. This value is not a row number; to seek to a row within a result set by number, use `mysql_data_seek()` instead.

This function requires that the result set structure contains the entire result of the query, so `mysql_row_seek()` may be used only in conjunction with `mysql_store_result()`, not with `mysql_use_result()`.

**Return Values**

The previous value of the row cursor. This value may be passed to a subsequent call to `mysql_row_seek()`.

**Errors**

None.

### 23.8.7.60 `mysql_row_tell()`

```c
MYSQL_ROW_OFFSET mysql_row_tell(MYSQL_RES *result)
```

**Description**

Returns the current position of the row cursor for the last `mysql_fetch_row()`. This value can be used as an argument to `mysql_row_seek()`.

Use `mysql_row_tell()` only after `mysql_store_result()`, not after `mysql_use_result()`.

**Return Values**

The current offset of the row cursor.

**Errors**

None.

### 23.8.7.61 `mysql_select_db()`

```c
int mysql_select_db(MYSQL *mysql, const char *db)
```
**Description**

Causes the database specified by `db` to become the default (current) database on the connection specified by `mysql`. In subsequent queries, this database is the default for table references that include no explicit database specifier.

`mysql_select_db()` fails unless the connected user can be authenticated as having permission to use the database or some object within it.

**Return Values**

Zero for success. Nonzero if an error occurred.

**Errors**

- **CR_COMMANDS_OUT_OF_SYNC**
  
  Commands were executed in an improper order.

- **CR_SERVER_GONE_ERROR**
  
  The MySQL server has gone away.

- **CR_SERVER_LOST**
  
  The connection to the server was lost during the query.

- **CR_UNKNOWN_ERROR**
  
  An unknown error occurred.

---

### 23.8.7.62 `mysql_set_character_set()`

```c
int mysql_set_character_set(MYSQL *mysql, const char *csname)
```

**Description**

This function is used to set the default character set for the current connection. The string `csname` specifies a valid character set name. The connection collation becomes the default collation of the character set. This function works like the `SET NAMES` statement, but also sets the value of `mysql->charset`, and thus affects the character set used by `mysql_real_escape_string()`.

**Return Values**

Zero for success. Nonzero if an error occurred.

**Example**

```c
MYSQL mysql;
mysql_init(&mysql);
if (!mysql_real_connect(&mysql,"host","user","passwd","database",0,NULL,0))
    
    fprintf(stderr, "Failed to connect to database: Error: %s\n", mysql_error(&mysql));

if (!mysql_set_character_set(&mysql, "utf8"))
```

23.8.7.63 mysql_set_local_infile_default()

```c
void mysql_set_local_infile_default(MYSQL *mysql);
```

**Description**

Sets the `LOAD DATA LOCAL` callback functions to the defaults used internally by the C client library. The library calls this function automatically if `mysql_set_local_infile_handler()` has not been called or does not supply valid functions for each of its callbacks.

**Return Values**

None.

**Errors**

None.

23.8.7.64 mysql_set_local_infile_handler()

```c
void mysql_set_local_infile_handler(MYSQL *mysql, int (*local_infile_init)(void **ptr, const char *filename, void *userdata), int (*local_infile_read)(void *ptr, char *buf, unsigned int buf_len), void (*local_infile_end)(void *), int (*local_infile_error)(void *, char*, unsigned int), void *userdata);
```

**Description**

This function installs callbacks to be used during the execution of `LOAD DATA LOCAL` statements. It enables application programs to exert control over local (client-side) data file reading. The arguments are the connection handler, a set of pointers to callback functions, and a pointer to a data area that the callbacks can use to share information. To use `mysql_set_local_infile_handler()`, you must write the following callback functions:

```c
int local_infile_init(void **ptr, const char *filename, void *userdata);
```

The initialization function. This is called once to do any setup necessary, open the data file, allocate data structures, and so forth. The first `void**` argument is a pointer to a pointer. You can set the pointer (that is, `*ptr`) to a value that will be passed to each of the other callbacks (as a `void*`). The callbacks can use this pointed-to value to maintain state information. The `userdata` argument is the same value that is passed to `mysql_set_local_infile_handler()`.

Make the initialization function return zero for success, nonzero for an error.

```c
int local_infile_read(void *ptr, char *buf, unsigned int buf_len);
```

The data-reading function. This is called repeatedly to read the data file. `buf` points to the buffer where the read data is stored, and `buf_len` is the maximum number of bytes that the callback can read and store in the buffer. (It can read fewer bytes, but should not read more.)
The return value is the number of bytes read, or zero when no more data could be read (this indicates EOF). Return a value less than zero if an error occurs.

```c
void
local_infile_end(void *ptr)
```

The termination function. This is called once after `local_infile_read()` has returned zero (EOF) or an error. Within this function, deallocate any memory allocated by `local_infile_init()` and perform any other cleanup necessary. It is invoked even if the initialization function returns an error.

```c
int
local_infile_error(void *ptr,
    char *error_msg,
    unsigned int error_msg_len);
```

The error-handling function. This is called to get a textual error message to return to the user in case any of your other functions returns an error. `error_msg` points to the buffer into which the message is written, and `error_msg_len` is the length of the buffer. Write the message as a null-terminated string, at most `error_msg_len−1` bytes long.

The return value is the error number.

Typically, the other callbacks store the error message in the data structure pointed to by `ptr`, so that `local_infile_error()` can copy the message from there into `error_msg`.

After calling `mysql_set_local_infile_handler()` in your C code and passing pointers to your callback functions, you can then issue a `LOAD DATA LOCAL` statement (for example, by using `mysql_query()`). The client library automatically invokes your callbacks. The file name specified in `LOAD DATA LOCAL` will be passed as the second parameter to the `local_infile_init()` callback.

**Return Values**

None.

**Errors**

None.

### 23.8.7.65 `mysql_set_server_option()`

```c
int mysql_set_server_option(MYSQL *mysql, enum enum_mysql_set_option option)
```

**Description**

Enables or disables an option for the connection. `option` can have one of the following values.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MYSQL_OPTION_MULTI_STATEMENTS_ON</td>
<td>Enable multiple-statement support</td>
</tr>
<tr>
<td>MYSQL_OPTION_MULTI_STATEMENTS_OFF</td>
<td>Disable multiple-statement support</td>
</tr>
</tbody>
</table>

If you enable multiple-statement support, you should retrieve results from calls to `mysql_query()` or `mysql_real_query()` by using a loop that calls `mysql_next_result()` to determine whether there are more results. For an example, see Section 23.8.16, “C API Multiple Statement Execution Support”.

Enabling multiple-statement support with `MYSQL_OPTION_MULTI_STATEMENTS_ON` does not have quite the same effect as enabling it by passing the `CLIENT_MULTI_STATEMENTS` flag to
mysql_real_connect(): CLIENT_MULTI_STATEMENTS also enables CLIENT_MULTI_RESULTS. If you are using the CALL SQL statement in your programs, multiple-result support must be enabled; this means that MYSQL_OPTION_MULTI_STATEMENTS_ON by itself is insufficient to permit the use of CALL.

**Return Values**

Zero for success. Nonzero if an error occurred.

**Errors**

- CR_COMMANDS_OUT_OF_SYNC
  
  Commands were executed in an improper order.

- CR_SERVER_GONE_ERROR
  
  The MySQL server has gone away.

- CR_SERVER_LOST
  
  The connection to the server was lost during the query.

- ER_UNKNOWN_COM_ERROR
  
  The server did not support mysql_set_server_option() (which is the case that the server is older than 4.1.1) or the server did not support the option one tried to set.

**23.8.7.66 mysql_shutdown()**

```c
int mysql_shutdown(MYSQL *mysql, enum mysql_enum_shutdown_level shutdown_level)
```

**Description**

Asks the database server to shut down. The connected user must have the SHUTDOWN privilege. MySQL servers support only one type of shutdown; shutdown_level must be equal to SHUTDOWN_DEFAULT. Dynamically linked executables which have been compiled with older versions of the `libmysqlclient` headers and call `mysql_shutdown()` need to be used with the old `libmysqlclient` dynamic library.

The shutdown process is described in Section 5.1.15, “The Server Shutdown Process”.

**Return Values**

Zero for success. Nonzero if an error occurred.

**Errors**

- CR_COMMANDS_OUT_OF_SYNC
  
  Commands were executed in an improper order.

- CR_SERVER_GONE_ERROR
  
  The MySQL server has gone away.

- CR_SERVER_LOST
  
  The connection to the server was lost during the query.
• CR_UNKNOWN_ERROR
  An unknown error occurred.

23.8.7.67 mysql_sqlstate()

    const char *mysql_sqlstate(MYSQL *mysql)

Description

Returns a null-terminated string containing the SQLSTATE error code for the most recently executed SQL statement. The error code consists of five characters. '00000' means “no error.” The values are specified by ANSI SQL and ODBC. For a list of possible values, see Appendix B, Errors, Error Codes, and Common Problems.

SQLSTATE values returned by mysql_sqlstate() differ from MySQL-specific error numbers returned by mysql_errno(). For example, the mysql client program displays errors using the following format, where 1146 is the mysql_errno() value and '42S02' is the corresponding mysql_sqlstate() value:

```
shell> SELECT * FROM no_such_table;
ERROR 1146 (42S02): Table 'test.no_such_table' doesn't exist
```

Not all MySQL error numbers are mapped to SQLSTATE error codes. The value 'HY000' (general error) is used for unmapped error numbers.

If you call mysql_sqlstate() after mysql_real_connect() fails, mysql_sqlstate() might not return a useful value. For example, this happens if a host is blocked by the server and the connection is closed without any SQLSTATE value being sent to the client.

Return Values

A null-terminated character string containing the SQLSTATE error code.

See Also

See Section 23.8.7.14, “mysql_errno()”, Section 23.8.7.15, “mysql_error()”, and Section 23.8.11.27, “mysql_stmt_sqlstate()”.

23.8.7.68 mysql_ssl_set()

    my_bool mysql_ssl_set(MYSQL *mysql, const char *key, const char *cert, const char *ca, const char *capath, const char *cipher)

Description

mysql_ssl_set() is used for establishing encrypted connections using SSL. The mysql argument must be a valid connection handler. Any unused SSL arguments may be given as NULL.

If used, mysql_ssl_set() must be called before mysql_real_connect(). mysql_ssl_set() does nothing unless SSL support is enabled in the client library.

mysql_ssl_set() specifies SSL information such as certificate and key files for establishing an encrypted connection if such connections are available, but does not enforce any requirement that the connection obtained be encrypted. To require an encrypted connection, use the technique described in Section 23.8.15, “C API Encrypted Connection Support”.
For additional security relative to that provided by the default encryption, clients can supply a CA certificate matching the one used by the server and enable host name identity verification. In this way, the server and client place their trust in the same CA certificate and the client verifies that the host to which it connected is the one intended. For details, see Section 23.8.15, “C API Encrypted Connection Support”.

`mysql_ssl_set()` is a convenience function that is essentially equivalent to this set of `mysql_options()` calls:

```c
mysql_options(mysql, MYSQL_OPT_SSL_KEY,    key);
mysql_options(mysql, MYSQL_OPT_SSL_CERT,   cert);
mysql_options(mysql, MYSQL_OPT_SSL_CA,     ca);
mysql_options(mysql, MYSQL_OPT_SSL_CAPATH, capath);
mysql_options(mysql, MYSQL_OPT_SSL_CIPHER, cipher);
```

Because of that equivalence, applications can, instead of calling `mysql_ssl_set()`, call `mysql_options()` directly, omitting calls for those options for which the option value is NULL. Moreover, `mysql_options()` offers encrypted-connection options not available using `mysql_ssl_set()`, such as `MYSQL_OPT_SSL_MODE` to specify the security state of the connection.

Arguments:

- **mysql**: The connection handler returned from `mysql_init()`.
- **key**: The path name of the client private key file.
- **cert**: The path name of the client public key certificate file.
- **ca**: The path name of the Certificate Authority (CA) certificate file. This option, if used, must specify the same certificate used by the server.
- **capath**: The path name of the directory that contains trusted SSL CA certificate files.
- **cipher**: The list of permissible ciphers for SSL encryption.

Return Values

This function always returns 0. If SSL setup is incorrect, a subsequent `mysql_real_connect()` call returns an error when you attempt to connect.

23.8.7.69 mysql_stat()

```c
const char *mysql_stat(MYSQL *mysql)
```

Description

Returns a character string containing information similar to that provided by the `mysqladmin status` command. This includes uptime in seconds and the number of running threads, questions, reloads, and open tables.

Return Values

A character string describing the server status. `NULL` if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`

  Commands were executed in an improper order.
C API Function Descriptions

• **CR_SERVER_GONE_ERROR**
  The MySQL server has gone away.

• **CR_SERVER_LOST**
  The connection to the server was lost during the query.

• **CR_UNKNOWN_ERROR**
  An unknown error occurred.

### 23.8.7.70 mysql_store_result()

```c
MYSQL_RES *mysql_store_result(MYSQL *mysql)
```

**Description**

After invoking `mysql_query()` or `mysql_real_query()`, you must call `mysql_store_result()` or `mysql_use_result()` for every statement that successfully produces a result set (SELECT, SHOW, DESCRIBE, EXPLAIN, CHECK TABLE, and so forth). You must also call `mysql_free_result()` after you are done with the result set.

You need not call `mysql_store_result()` or `mysql_use_result()` for other statements, but it does not do any harm or cause any notable performance degradation if you call `mysql_store_result()` in all cases. You can detect whether the statement has a result set by checking whether `mysql_store_result()` returns a nonzero value (more about this later).

If you enable multiple-statement support, you should retrieve results from calls to `mysql_query()` or `mysql_real_query()` by using a loop that calls `mysql_next_result()` to determine whether there are more results. For an example, see Section 23.8.16, “C API Multiple Statement Execution Support”.

If you want to know whether a statement should return a result set, you can use `mysql_field_count()` to check for this. See Section 23.8.7.22, “mysql_field_count()”.

`mysql_store_result()` reads the entire result of a query to the client, allocates a `MYSQL_RES` structure, and places the result into this structure.

`mysql_store_result()` returns NULL if the statement did not return a result set (for example, if it was an INSERT statement), or an error occurred and reading of the result set failed.

An empty result set is returned if there are no rows returned. (An empty result set differs from a null pointer as a return value.)

After you have called `mysql_store_result()` and gotten back a result that is not a null pointer, you can call `mysql_num_rows()` to find out how many rows are in the result set.

You can call `mysql_fetch_row()` to fetch rows from the result set, or `mysql_row_seek()` and `mysql_row_tell()` to obtain or set the current row position within the result set.

See Section 23.8.21.1, “Why mysql_store_result() Sometimes Returns NULL After mysql_query() Returns Success”.

**Return Values**

A pointer to a `MYSQL_RES` result structure with the results. NULL if the statement did not return a result set or an error occurred. To determine whether an error occurred, check whether `mysql_error()` returns a nonempty string, `mysql_errno()` returns nonzero, or `mysql_field_count()` returns zero.
23.8.7.71 mysql_thread_id()

`unsigned long mysql_thread_id(MYSQL *mysql)`

**Description**

Returns the thread ID of the current connection. This value can be used as an argument to `mysql_kill()` to kill the thread.

If the connection is lost and you reconnect with `mysql_ping()`, the thread ID changes. This means you should not get the thread ID and store it for later. You should get it when you need it.

**Note**

This function does not work correctly if thread IDs become larger than 32 bits, which can occur on some systems. To avoid problems with `mysql_thread_id()`, do not use it. To get the connection ID, execute a `SELECT CONNECTION_ID()` query and retrieve the result.

**Return Values**

The thread ID of the current connection.

**Errors**

None.

23.8.7.72 mysql_use_result()

`MYSQL_RES *mysql_use_result(MYSQL *mysql)`

**Description**

After invoking `mysql_query()` or `mysql_real_query()`, you must call `mysql_store_result()` or `mysql_use_result()` for every statement that successfully produces a result set (SELECT, SHOW,
DESCRIBE, EXPLAIN, CHECK TABLE, and so forth). You must also call mysql_free_result() after you are done with the result set.

mysql_use_result() initiates a result set retrieval but does not actually read the result set into the client like mysql_store_result() does. Instead, each row must be retrieved individually by making calls to mysql_fetch_row(). This reads the result of a query directly from the server without storing it in a temporary table or local buffer, which is somewhat faster and uses much less memory than mysql_store_result(). The client allocates memory only for the current row and a communication buffer that may grow up to max_allowed_packet bytes.

On the other hand, you should not use mysql_use_result() for locking reads if you are doing a lot of processing for each row on the client side, or if the output is sent to a screen on which the user may type a ^S (stop scroll). This ties up the server and prevent other threads from updating any tables from which the data is being fetched.

When using mysql_use_result(), you must execute mysql_fetch_row() until a NULL value is returned, otherwise, the unfetched rows are returned as part of the result set for your next query. The C API gives the error Commands out of sync; you can't run this command now if you forget to do this!

You may not use mysql_data_seek(), mysql_row_seek(), mysql_row_tell(), mysql_num_rows(), or mysql_affected_rows() with a result returned from mysql_use_result(), nor may you issue other queries until mysql_use_result() has finished. (However, after you have fetched all the rows, mysql_num_rows() accurately returns the number of rows fetched.)

You must call mysql_free_result() once you are done with the result set.

When using the libmysqld embedded server, the memory benefits are essentially lost because memory usage incrementally increases with each row retrieved until mysql_free_result() is called.

**Return Values**

A MYSQL_RES result structure. NULL if an error occurred.

**Errors**

mysql_use_result() resets mysql_error() and mysql_errno() if it succeeds.

- **CR_Commands out of Sync**
  
  Commands were executed in an improper order.

- **CR_Out of Memory**
  
  Out of memory.

- **CR_Server Gone Error**
  
  The MySQL server has gone away.

- **CR_Server Lost**
  
  The connection to the server was lost during the query.

- **CR_Unknown Error**
  
  An unknown error occurred.
23.8.7.73 mysql_warning_count()

    unsigned int mysql_warning_count(MYSQL *mysql)

Description

Returns the number of errors, warnings, and notes generated during execution of the previous SQL
statement.

Return Values

The warning count.

Errors

None.

23.8.8 C API Prepared Statements

The MySQL client/server protocol provides for the use of prepared statements. This capability uses
the MYSQL_STMT statement handler data structure returned by the mysql_stmt_init() initialization
function. Prepared execution is an efficient way to execute a statement more than once. The statement
is first parsed to prepare it for execution. Then it is executed one or more times at a later time, using the
statement handler returned by the initialization function.

Prepared execution is faster than direct execution for statements executed more than once, primarily
because the query is parsed only once. In the case of direct execution, the query is parsed every time it is
executed. Prepared execution also can provide a reduction of network traffic because for each execution of
the prepared statement, it is necessary only to send the data for the parameters.

Prepared statements might not provide a performance increase in some situations. For best results,
test your application both with prepared and nonprepared statements and choose whichever yields best
performance.

Another advantage of prepared statements is that it uses a binary protocol that makes data transfer
between client and server more efficient.

For a list of SQL statements that can be used as prepared statements, see Section 13.5, "Prepared SQL
Statement Syntax".

Metadata changes to tables or views referred to by prepared statements are detected and cause automatic
repreparation of the statement when it is next executed. For more information, see Section 8.10.4,
"Caching of Prepared Statements and Stored Programs".

23.8.9 C API Prepared Statement Data Structures

Prepared statements use several data structures:

- To obtain a statement handler, pass a MYSQL connection handler to mysql_stmt_init(), which
  returns a pointer to a MYSQL_STMT data structure. This structure is used for further operations with the
  statement. To specify the statement to prepare, pass the MYSQL_STMT pointer and the statement string
to mysql_stmt_prepare().

- To provide input parameters for a prepared statement, set up MYSQL_BIND structures and pass them to
  mysql_stmt_bind_param(). To receive output column values, set up MYSQL_BIND structures and
  pass them to mysql_stmt_bind_result().
• The **MYSQL_TIME** structure is used to transfer temporal data in both directions.

The following discussion describes the prepared statement data types in detail. For examples that show how to use them, see Section 23.8.11.10, “mysql_stmt_execute()”, and Section 23.8.11.11, “mysql_stmt_fetch()”.

• **MYSQL_STMT**

This structure is a handler for a prepared statement. A handler is created by calling `mysql_stmt_init()`, which returns a pointer to a **MYSQL_STMT**. The handler is used for all subsequent operations with the statement until you close it with `mysql_stmt_close()`, at which point the handler becomes invalid and should no longer be used.

The **MYSQL_STMT** structure has no members intended for application use. Applications should not try to copy a **MYSQL_STMT** structure. There is no guarantee that such a copy will be usable.

Multiple statement handlers can be associated with a single connection. The limit on the number of handlers depends on the available system resources.

• **MYSQL_BIND**

This structure is used both for statement input (data values sent to the server) and output (result values returned from the server):

- For input, use **MYSQL_BIND** structures with `mysql_stmt_bind_param()` to bind parameter data values to buffers for use by `mysql_stmt_execute()`.

- For output, use **MYSQL_BIND** structures with `mysql_stmt_bind_result()` to bind buffers to result set columns, for use in fetching rows with `mysql_stmt_fetch()`.

To use a **MYSQL_BIND** structure, zero its contents to initialize it, then set its members appropriately. For example, to declare and initialize an array of three **MYSQL_BIND** structures, use this code:

```c
MYSQL_BIND bind[3];
memset(bind, 0, sizeof(bind));
```

The **MYSQL_BIND** structure contains the following members for use by application programs. For several of the members, the manner of use depends on whether the structure is used for input or output.

- **enum enum_field_types buffer_type**

  The type of the buffer. This member indicates the data type of the C language variable bound to a statement parameter or result set column. For input, `buffer_type` indicates the type of the variable containing the value to be sent to the server. For output, it indicates the type of the variable into which a value received from the server should be stored. For permissible `buffer_type` values, see Section 23.8.9.1, “C API Prepared Statement Type Codes”.

- **void *buffer**

  A pointer to the buffer to be used for data transfer. This is the address of a C language variable.

For input, `buffer` is a pointer to the variable in which you store the data value for a statement parameter. When you call `mysql_stmt_execute()`, MySQL use the value stored in the variable in place of the corresponding parameter marker in the statement (specified with `?` in the statement string).
For output, `buffer` is a pointer to the variable in which to return a result set column value. When you call `mysql_stmt_fetch()`, MySQL stores a column value from the current row of the result set in this variable. You can access the value when the call returns.

To minimize the need for MySQL to perform type conversions between C language values on the client side and SQL values on the server side, use C variables that have types similar to those of the corresponding SQL values:

- For numeric data types, `buffer` should point to a variable of the proper numeric C type. For integer variables (which can be `char` for single-byte values or an integer type for larger values), you should also indicate whether the variable has the `unsigned` attribute by setting the `is_unsigned` member, described later.

- For character (nonbinary) and binary string data types, `buffer` should point to a character buffer.

- For date and time data types, `buffer` should point to a `MYSQL_TIME` structure.

For guidelines about mapping between C types and SQL types and notes about type conversions, see Section 23.8.9.1, "C API Prepared Statement Type Codes", and Section 23.8.9.2, "C API Prepared Statement Type Conversions".

- `unsigned long buffer_length`

  The actual size of `*buffer` in bytes. This indicates the maximum amount of data that can be stored in the buffer. For character and binary C data, the `buffer_length` value specifies the length of `*buffer` when used with `mysql_stmt_bind_param()` to specify input values, or the maximum number of output data bytes that can be fetched into the buffer when used with `mysql_stmt_bind_result()`.

- `unsigned long *length`

  A pointer to an `unsigned long` variable that indicates the actual number of bytes of data stored in `*buffer`. For character or binary C data, `*length` is used by `mysql_stmt_execute()`.

  For input parameter data binding, set `*length` to indicate the actual length of the parameter value stored in `*buffer`. This is used by `mysql_stmt_execute()`.

  For output value binding, MySQL sets `*length` when you call `mysql_stmt_fetch()`. The `mysql_stmt_fetch()` return value determines how to interpret the length:

  - If the return value is 0, `*length` indicates the actual length of the parameter value.

  - If the return value is `MYSQL_DATA_TRUNCATED`, `*length` indicates the nontruncated length of the parameter value. In this case, the minimum of `*length` and `buffer_length` indicates the actual length of the value.

  `length` is ignored for numeric and temporal data types because the `buffer_type` value determines the length of the data value.

  If you must determine the length of a returned value before fetching it, see Section 23.8.11.11, "mysql_stmt_fetch()", for some strategies.

- `my_bool *is_null`

  This member points to a `my_bool` variable that is true if a value is `NULL`, false if it is not `NULL`. For input, set `*is_null` to true to indicate that you are passing a `NULL` value as a statement parameter.
**is_null** is a pointer to a boolean scalar, not a boolean scalar, to provide flexibility in how you specify NULL values:

- If your data values are always NULL, use **MYSQL_TYPE_NULL** as the buffer_type value when you bind the column. The other **MYSQL_BIND** members, including **is_null**, do not matter.

- If your data values are always NOT NULL, set **is_null** = *(my_bool*) 0, and set the other members appropriately for the variable you are binding.

- In all other cases, set the other members appropriately and set **is_null** to the address of a **my_bool** variable. Set that variable’s value to true or false appropriately between executions to indicate whether the corresponding data value is NULL or NOT NULL, respectively.

For output, when you fetch a row, MySQL sets the value pointed to by **is_null** to true or false according to whether the result set column value returned from the statement is or is not NULL.

- **my_bool is_unsigned**

  This member applies for C variables with data types that can be unsigned (char, short int, int, long long int). Set **is_unsigned** to true if the variable pointed to by buffer is unsigned and false otherwise. For example, if you bind a signed char variable to buffer, specify a type code of **MYSQL_TYPE_TINY** and set **is_unsigned** to false. If you bind an unsigned char instead, the type code is the same but **is_unsigned** should be true. (For char, it is not defined whether it is signed or unsigned, so it is best to be explicit about signedness by using signed char or unsigned char.)

**is_unsigned** applies only to the C language variable on the client side. It indicates nothing about the signedness of the corresponding SQL value on the server side. For example, if you use an int variable to supply a value for a BIGINT UNSIGNED column, **is_unsigned** should be false because int is a signed type. If you use an unsigned int variable to supply a value for a BIGINT column, **is_unsigned** should be true because unsigned int is an unsigned type. MySQL performs the proper conversion between signed and unsigned values in both directions, although a warning occurs if truncation results.

- **my_bool *error**

  For output, set this member to point to a **my_bool** variable to have truncation information for the parameter stored there after a row fetching operation. When truncation reporting is enabled, **mysql_stmt_fetch()** returns **MYSQL_DATA_TRUNCATED** and **error** is true in the **MYSQL_BIND** structures for parameters in which truncation occurred. Truncation indicates loss of sign or significant digits, or that a string was too long to fit in a column. Truncation reporting is enabled by default, but can be controlled by calling **mysql_options()** with the **MYSQL_REPORT_DATA_TRUNCATION** option.

- **MYSQL_TIME**

  This structure is used to send and receive DATE, TIME, DATETIME, and TIMESTAMP data directly to and from the server. Set the buffer member to point to a **MYSQL_TIME** structure, and set the buffer_type member of a **MYSQL_BIND** structure to one of the temporal types (**MYSQL_TYPE_TIME**, **MYSQL_TYPE_DATE**, **MYSQL_TYPE_DATETIME**, **MYSQL_TYPE_TIMESTAMP**).

The **MYSQL_TIME** structure contains the members listed in the following table.

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>unsigned int year</td>
<td>The year</td>
</tr>
</tbody>
</table>

3516
<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>unsigned int month</td>
<td>The month of the year</td>
</tr>
<tr>
<td>unsigned int day</td>
<td>The day of the month</td>
</tr>
<tr>
<td>unsigned int hour</td>
<td>The hour of the day</td>
</tr>
<tr>
<td>unsigned int minute</td>
<td>The minute of the hour</td>
</tr>
<tr>
<td>unsigned int second</td>
<td>The second of the minute</td>
</tr>
<tr>
<td>my_bool neg</td>
<td>A boolean flag indicating whether the time is negative</td>
</tr>
<tr>
<td>unsigned long second_part</td>
<td>The fractional part of the second in microseconds</td>
</tr>
</tbody>
</table>

Only those parts of a MYSQL_TIME structure that apply to a given type of temporal value are used. The year, month, and day elements are used for DATE, DATETIME, and TIMESTAMP values. The hour, minute, and second elements are used for TIME, DATETIME, and TIMESTAMP values. See Section 23.8.17, “C API Prepared Statement Handling of Date and Time Values”.

### 23.8.9.1 C API Prepared Statement Type Codes

The buffer_type member of MYSQL_BIND structures indicates the data type of the C language variable bound to a statement parameter or result set column. For input, buffer_type indicates the type of the variable containing the value to be sent to the server. For output, it indicates the type of the variable into which a value received from the server should be stored.

The following table shows the permissible values for the buffer_type member of MYSQL_BIND structures for input values sent to the server. The table shows the C variable types that you can use, the corresponding type codes, and the SQL data types for which the supplied value can be used without conversion. Choose the buffer_type value according to the data type of the C language variable that you are binding. For the integer types, you should also set the is_unsigned member to indicate whether the variable is signed or unsigned.

<table>
<thead>
<tr>
<th>Input Variable C Type</th>
<th>buffer_type Value</th>
<th>SQL Type of Destination Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>signed char</td>
<td>MYSQL_TYPE_TINY</td>
<td>TINYINT</td>
</tr>
<tr>
<td>short int</td>
<td>MYSQL_TYPE_SHORT</td>
<td>SMALLINT</td>
</tr>
<tr>
<td>int</td>
<td>MYSQL_TYPE_LONG</td>
<td>INT</td>
</tr>
<tr>
<td>long long int</td>
<td>MYSQL_TYPE_LONGLONG</td>
<td>BIGINT</td>
</tr>
<tr>
<td>float</td>
<td>MYSQL_TYPE_FLOAT</td>
<td>FLOAT</td>
</tr>
<tr>
<td>double</td>
<td>MYSQL_TYPE_DOUBLE</td>
<td>DOUBLE</td>
</tr>
<tr>
<td>MYSQL_TIME</td>
<td>MYSQL_TYPE_TIME</td>
<td>TIME</td>
</tr>
<tr>
<td>MYSQL_TIME</td>
<td>MYSQL_TYPE_DATE</td>
<td>DATE</td>
</tr>
<tr>
<td>MYSQL_TIME</td>
<td>MYSQL_TYPE_DATETIME</td>
<td>DATETIME</td>
</tr>
<tr>
<td>MYSQL_TIME</td>
<td>MYSQL_TYPE_TIMESTAMP</td>
<td>TIMESTAMP</td>
</tr>
<tr>
<td>char[]</td>
<td>MYSQL_TYPE_STRING</td>
<td>TEXT, CHAR, VARCHAR</td>
</tr>
<tr>
<td>char[]</td>
<td>MYSQL_TYPE_BLOB</td>
<td>BLOB, BINARY, VARBINARY</td>
</tr>
<tr>
<td>MYSQL_TYPE_NULL</td>
<td>NULL</td>
<td></td>
</tr>
</tbody>
</table>

Use MYSQL_TYPE_NULL as indicated in the description for the is_null member in Section 23.8.9, “C API Prepared Statement Data Structures”.

3517
For input string data, use `MYSQL_TYPE_STRING` or `MYSQL_TYPE_BLOB` depending on whether the value is a character (nonbinary) or binary string:

- `MYSQL_TYPE_STRING` indicates character input string data. The value is assumed to be in the character set indicated by the `character_set_client` system variable. If the server stores the value into a column with a different character set, it converts the value to that character set.

- `MYSQL_TYPE_BLOB` indicates binary input string data. The value is treated as having the `binary` character set. That is, it is treated as a byte string and no conversion occurs.

The following table shows the permissible values for the `buffer_type` member of `MYSQL_BIND` structures for output values received from the server. The table shows the SQL types of received values, the corresponding type codes that such values have in result set metadata, and the recommended C language data types to bind to the `MYSQL_BIND` structure to receive the SQL values without conversion. Choose the `buffer_type` value according to the data type of the C language variable that you are binding. For the integer types, you should also set the `is_unsigned` member to indicate whether the variable is signed or unsigned.

<table>
<thead>
<tr>
<th>SQL Type of Received Value</th>
<th><code>buffer_type</code> Value</th>
<th>Output Variable C Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>TINYINT</td>
<td>MYSQL_TYPE_TINY</td>
<td>signed char</td>
</tr>
<tr>
<td>SMALLINT</td>
<td>MYSQL_TYPE_SHORT</td>
<td>short int</td>
</tr>
<tr>
<td>MEDIUMINT</td>
<td>MYSQL_TYPE_INT24</td>
<td>int</td>
</tr>
<tr>
<td>INT</td>
<td>MYSQL_TYPE_LONG</td>
<td>int</td>
</tr>
<tr>
<td>BIGINT</td>
<td>MYSQL_TYPE_LONGLONG</td>
<td>long long int</td>
</tr>
<tr>
<td>FLOAT</td>
<td>MYSQL_TYPE_FLOAT</td>
<td>float</td>
</tr>
<tr>
<td>DOUBLE</td>
<td>MYSQL_TYPE_DOUBLE</td>
<td>double</td>
</tr>
<tr>
<td>DECIMAL</td>
<td>MYSQL_TYPE_NEWDECIMAL</td>
<td>char[]</td>
</tr>
<tr>
<td>YEAR</td>
<td>MYSQL_TYPE_SHORT</td>
<td>short int</td>
</tr>
<tr>
<td>TIME</td>
<td>MYSQL_TYPE_TIME</td>
<td>MYSQL_TIME</td>
</tr>
<tr>
<td>DATE</td>
<td>MYSQL_TYPE_DATE</td>
<td>MYSQL_TIME</td>
</tr>
<tr>
<td>DATETIME</td>
<td>MYSQL_TYPE_DATETIME</td>
<td>MYSQL_TIME</td>
</tr>
<tr>
<td>TIMESTAMP</td>
<td>MYSQL_TYPE_TIMESTAMP</td>
<td>MYSQL_TIME</td>
</tr>
<tr>
<td>CHAR, BINARY</td>
<td>MYSQL_TYPE_STRING</td>
<td>char[]</td>
</tr>
<tr>
<td>VARCHAR, VARBINARY</td>
<td>MYSQL_TYPE_VAR_STRING</td>
<td>char[]</td>
</tr>
<tr>
<td>TINYBLOB, TINYTEXT</td>
<td>MYSQL_TYPE_TINY_BLOB</td>
<td>char[]</td>
</tr>
<tr>
<td>BLOB, TEXT</td>
<td>MYSQL_TYPE_BLOB</td>
<td>char[]</td>
</tr>
<tr>
<td>MEDIUMBLOB, MEDIUMTEXT</td>
<td>MYSQL_TYPE_MEDIUM_BLOB</td>
<td>char[]</td>
</tr>
<tr>
<td>LONGBLOB, LONGTEXT</td>
<td>MYSQL_TYPE_LONG_BLOB</td>
<td>char[]</td>
</tr>
<tr>
<td>BIT</td>
<td>MYSQL_TYPE_BIT</td>
<td>char[]</td>
</tr>
</tbody>
</table>

### 23.8.9.2 C API Prepared Statement Type Conversions

Prepared statements transmit data between the client and server using C language variables on the client side that correspond to SQL values on the server side. If there is a mismatch between the C variable type on the client side and the corresponding SQL value type on the server side, MySQL performs implicit type conversions in both directions.
MySQL knows the type code for the SQL value on the server side. The `buffer_type` value in the `MYSQL_BIND` structure indicates the type code of the C variable that holds the value on the client side. The two codes together tell MySQL what conversion must be performed, if any. Here are some examples:

- If you use `MYSQL_TYPE_LONG` with an `int` variable to pass an integer value to the server that is to be stored into a `FLOAT` column, MySQL converts the value to floating-point format before storing it.

- If you fetch an SQL `MEDIUMINT` column value, but specify a `buffer_type` value of `MYSQL_TYPE_LONGLONG` and use a C variable of type `long long int` as the destination buffer, MySQL converts the `MEDIUMINT` value (which requires less than 8 bytes) for storage into the `long long int` (an 8-byte variable).

- If you fetch a numeric column with a value of 255 into a `char[4]` character array and specify a `buffer_type` value of `MYSQL_TYPE_STRING`, the resulting value in the array is a 4-byte string `'255\0'`.

- MySQL returns `DECIMAL` values as the string representation of the original server-side value, which is why the corresponding C type is `char[]`. For example, `12.345` is returned to the client as `'12.345'`. If you specify `MYSQL_TYPE_NEWDECIMAL` and bind a string buffer to the `MYSQL_BIND` structure, `mysql_stmt_fetch()` stores the value in the buffer as a string without conversion. If instead you specify a numeric variable and type code, `mysql_stmt_fetch()` converts the string-format `DECIMAL` value to numeric form.

- For the `MYSQL_TYPE_BIT` type code, `BIT` values are returned into a string buffer, which is why the corresponding C type is `char[]`. The value represents a bit string that requires interpretation on the client side. To return the value as a type that is easier to deal with, you can cause the value to be cast to integer using either of the following types of expressions:

```sql
SELECT bit_col + 0 FROM t
SELECT CAST(bit_col AS UNSIGNED) FROM t
```

To retrieve the value, bind an integer variable large enough to hold the value and specify the appropriate corresponding integer type code.

Before binding variables to the `MYSQL_BIND` structures that are to be used for fetching column values, you can check the type codes for each column of the result set. This might be desirable if you want to determine which variable types would be best to use to avoid type conversions. To get the type codes, call `mysql_stmt_result_metadata()` after executing the prepared statement with `mysql_stmt_execute()`. The metadata provides access to the type codes for the result set as described in Section 23.8.11.23, “`mysql_stmt_result_metadata()`”, and Section 23.8.5, “C API Data Structures”.

To determine whether output string values in a result set returned from the server contain binary or nonbinary data, check whether the `charsetnr` value of the result set metadata is 63 (see Section 23.8.5, “C API Data Structures”). If so, the character set is `binary`, which indicates binary rather than nonbinary data. This enables you to distinguish `BINARY` from `CHAR`, `VARBINARY` from `VARCHAR`, and the `BLOB` types from the `TEXT` types.

If you cause the `max_length` member of the `MYSQL_FIELD` column metadata structures to be set (by calling `mysql_stmt_attr_set()`), be aware that the `max_length` values for the result set indicate the lengths of the longest string representation of the result values, not the lengths of the binary representation. That is, `max_length` does not necessarily correspond to the size of the buffers needed to fetch the values with the binary protocol used for prepared statements. Choose the size of the buffers according to the types of the variables into which you fetch the values. For example, a `TINYINT` column containing the value -128 might have a `max_length` value of 4. But the binary representation of any...
TINYINT value requires only 1 byte for storage, so you can supply a signed char variable in which to store the value and set is_unsigned to indicate that values are signed.

Metadata changes to tables or views referred to by prepared statements are detected and cause automatic repreparation of the statement when it is next executed. For more information, see Section 8.10.4, “Caching of Prepared Statements and Stored Programs”.

23.8.10 C API Prepared Statement Function Overview

The following list summarizes the functions available for prepared statement processing. For greater detail, see the descriptions in Section 23.8.11, “C API Prepared Statement Function Descriptions”.

- **mysql_stmt_affected_rows()**: Returns the number of rows changed, deleted, or inserted by prepared UPDATE, DELETE, or INSERT statement.
- **mysql_stmt_attr_get()**: Gets the value of an attribute for a prepared statement.
- **mysql_stmt_attr_set()**: Sets an attribute for a prepared statement.
- **mysql_stmt_bind_param()**: Associates application data buffers with the parameter markers in a prepared SQL statement.
- **mysql_stmt_bind_result()**: Associates application data buffers with columns in a result set.
- **mysql_stmt_close()**: Frees memory used by a prepared statement.
- **mysql_stmt_data_seek()**: Seeks to an arbitrary row number in a statement result set.
- **mysql_stmt_errno()**: Returns the error number for the last statement execution.
- **mysql_stmt_error()**: Returns the error message for the last statement execution.
- **mysql_stmt_execute()**: Executes a prepared statement.
- **mysql_stmt_fetch()**: Fetches the next row of data from a result set and returns data for all bound columns.
- **mysql_stmt_fetch_column()**: Fetches data for one column of the current row of a result set.
- **mysql_stmt_field_count()**: Returns the number of result columns for the most recent statement.
- **mysql_stmt_free_result()**: Frees the resources allocated to a statement handler.
- **mysql_stmt_init()**: Allocates memory for a MYSQL_STMT structure and initializes it.
- **mysql_stmt_insert_id()**: Returns the ID generated for an AUTO_INCREMENT column by a prepared statement.
- **mysql_stmt_next_result()**: Returns/initiates the next result in a multiple-result execution.
- **mysql_stmt_num_rows()**: Returns the row count from a buffered statement result set.
- **mysql_stmt_param_count()**: Returns the number of parameters in a prepared statement.
- **mysql_stmt_param_metadata()**: Returns parameter metadata in the form of a result set. (This function actually does nothing.)
- **mysql_stmt_prepare()**: Prepares an SQL statement string for execution.
- **mysql_stmt_reset()**: Resets the statement buffers in the server.
- **mysql_stmt_result_metadata()**: Returns prepared statement metadata in the form of a result set.
• `mysql_stmt_row_seek()`: Seeks to a row offset in a statement result set, using value returned from `mysql_stmt_row_tell()`.
• `mysql_stmt_row_tell()`: Returns the statement row cursor position.
• `mysql_stmt_send_long_data()`: Sends long data in chunks to server.
• `mysql_stmt_sqlstate()`: Returns the SQLSTATE error code for the last statement execution.
• `mysql_stmt_store_result()`: Retrieves a complete result set to the client.

Call `mysql_stmt_init()` to create a statement handler, then `mysql_stmt_prepare()` to prepare the statement string, `mysql_stmt_bind_param()` to supply the parameter data, and `mysql_stmt_execute()` to execute the statement. You can repeat the `mysql_stmt_execute()` by changing parameter values in the respective buffers supplied through `mysql_stmt_bind_param()`.

You can send text or binary data in chunks to server using `mysql_stmt_send_long_data()`. See Section 23.8.11.26, “mysql_stmt_send_long_data()”.

If the statement is a `SELECT` or any other statement that produces a result set, `mysql_stmt_prepare()` also returns the result set metadata information in the form of a `MYSQL_RES` result set through `mysql_stmt_result_metadata()`.

You can supply the result buffers using `mysql_stmt_bind_result()`, so that the `mysql_stmt_fetch()` automatically returns data to these buffers. This is row-by-row fetching.

When statement execution has been completed, close the statement handler using `mysql_stmt_close()` so that all resources associated with it can be freed. At that point the handler becomes invalid and should no longer be used.

If you obtained a `SELECT` statement’s result set metadata by calling `mysql_stmt_result_metadata()`, you should also free the metadata using `mysql_free_result()`.

### Execution Steps

To prepare and execute a statement, an application follows these steps:

1. Create a prepared statement handler with `mysql_stmt_init()`. To prepare the statement on the server, call `mysql_stmt_prepare()` and pass it a string containing the SQL statement.

2. If the statement will produce a result set, call `mysql_stmt_result_metadata()` to obtain the result set metadata. This metadata is itself in the form of a `MYSQL_RES` result set through `mysql_stmt_result_metadata()`.

3. Set the values of any parameters using `mysql_stmt_bind_param()`. All parameters must be set. Otherwise, statement execution returns an error or produces unexpected results.

4. Call `mysql_stmt_execute()` to execute the statement.

5. If the statement produces a result set, bind the data buffers to use for retrieving the row values by calling `mysql_stmt_bind_result()`.

6. Fetch the data into the buffers row by row by calling `mysql_stmt_fetch()` repeatedly until no more rows are found.

7. Repeat steps 3 through 6 as necessary, by changing the parameter values and re-executing the statement.

When `mysql_stmt_prepare()` is called, the MySQL client/server protocol performs these actions:
• The server parses the statement and sends the okay status back to the client by assigning a statement ID. It also sends total number of parameters, a column count, and its metadata if it is a result set oriented statement. All syntax and semantics of the statement are checked by the server during this call.

• The client uses this statement ID for the further operations, so that the server can identify the statement from among its pool of statements.

When `mysql_stmt_execute()` is called, the MySQL client/server protocol performs these actions:

• The client uses the statement handler and sends the parameter data to the server.

• The server identifies the statement using the ID provided by the client, replaces the parameter markers with the newly supplied data, and executes the statement. If the statement produces a result set, the server sends the data back to the client. Otherwise, it sends an okay status and the number of rows changed, deleted, or inserted.

When `mysql_stmt_fetch()` is called, the MySQL client/server protocol performs these actions:

• The client reads the data from the current row of the result set and places it into the application data buffers by doing the necessary conversions. If the application buffer type is same as that of the field type returned from the server, the conversions are straightforward.

If an error occurs, you can get the statement error number, error message, and SQLSTATE code using `mysql_stmt_errno()`, `mysql_stmt_error()`, and `mysql_stmt_sqlstate()`, respectively.

### Prepared Statement Logging

For prepared statements that are executed with the `mysql_stmt_prepare()` and `mysql_stmt_execute()` C API functions, the server writes `Prepare` and `Execute` lines to the general query log so that you can tell when statements are prepared and executed.

Suppose that you prepare and execute a statement as follows:

1. Call `mysql_stmt_prepare()` to prepare the statement string "SELECT ?".
2. Call `mysql_stmt_bind_param()` to bind the value 3 to the parameter in the prepared statement.
3. Call `mysql_stmt_execute()` to execute the prepared statement.

As a result of the preceding calls, the server writes the following lines to the general query log:

<table>
<thead>
<tr>
<th>Prepare</th>
<th>[1] SELECT ?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execute</td>
<td>[1] SELECT 3</td>
</tr>
</tbody>
</table>

Each `Prepare` and `Execute` line in the log is tagged with a `[N]` statement identifier so that you can keep track of which prepared statement is being logged. `N` is a positive integer. If there are multiple prepared statements active simultaneously for the client, `N` may be greater than 1. Each `Execute` lines shows a prepared statement after substitution of data values for ? parameters.

### 23.8.11 C API Prepared Statement Function Descriptions

To prepare and execute queries, use the functions described in detail in the following sections.

All functions that operate with a `MYSQL_STMT` structure begin with the prefix `mysql_stmt_`.

To create a `MYSQL_STMT` handler, use the `mysql_stmt_init()` function.

#### 23.8.11.1 `mysql_stmt_affected_rows()`

```c
my_ulonglong mysql_stmt_affected_rows(MYSQL_STMT *stmt)
```
Description

`mysql_stmt_affected_rows()` may be called immediately after executing a statement with `mysql_stmt_execute()`. It is like `mysql_affected_rows()` but for prepared statements. For a description of what the affected-rows value returned by this function means, see Section 23.8.7.1, "mysql_affected_rows()".

Errors

None.

Example

See the Example in Section 23.8.11.10, "mysql_stmt_execute()".

23.8.11.2 `mysql_stmt_attr_get()`

```
my_bool mysql_stmt_attr_get(MYSQL_STMT *stmt, enum enum_stmt_attr_type option, void *arg)
```

Description

Can be used to get the current value for a statement attribute.

The `option` argument is the option that you want to get; the `arg` should point to a variable that should contain the option value. If the option is an integer, `arg` should point to the value of the integer.

See Section 23.8.11.3, "mysql_stmt_attr_set()", for a list of options and option types.

Return Values

Zero for success. Nonzero if `option` is unknown.

Errors

None.

23.8.11.3 `mysql_stmt_attr_set()`

```
my_bool mysql_stmt_attr_set(MYSQL_STMT *stmt, enum enum_stmt_attr_type option, const void *arg)
```

Description

Can be used to affect behavior for a prepared statement. This function may be called multiple times to set several options.

The `option` argument is the option that you want to set. The `arg` argument is the value for the option. `arg` should point to a variable that is set to the desired attribute value. The variable type is as indicated in the following table.

The following table shows the possible `option` values.

<table>
<thead>
<tr>
<th>Option</th>
<th>Argument Type</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>STMT_ATTR_UPDATE_MAX_LENGTH</td>
<td>my_bool *</td>
<td>If set to 1, causes <code>mysql_stmt_store_result()</code> to update the metadata <code>MYSQL_FIELD-&gt;max_length</code> value.</td>
</tr>
</tbody>
</table>
### Option Argument Type Function

<table>
<thead>
<tr>
<th>Option</th>
<th>Argument Type</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>STMT_ATTR_CURSOR_TYPE</td>
<td>unsigned long *</td>
<td>Type of cursor to open for statement when <code>mysql_stmt_execute()</code> is invoked. *arg can be CURSOR_TYPE_NO_CURSOR (the default) or CURSOR_TYPE_READ_ONLY.</td>
</tr>
<tr>
<td>STMT_ATTR_PREFETCH_ROWS</td>
<td>unsigned long *</td>
<td>Number of rows to fetch from server at a time when using a cursor. *arg can be in the range from 1 to the maximum value of unsigned long. The default is 1.</td>
</tr>
</tbody>
</table>

If you use the `STMT_ATTR_CURSOR_TYPE` option with CURSOR_TYPE_READ_ONLY, a cursor is opened for the statement when you invoke `mysql_stmt_execute()`. If there is already an open cursor from a previous `mysql_stmt_execute()` call, it closes the cursor before opening a new one. `mysql_stmt_reset()` also closes any open cursor before preparing the statement for re-execution. `mysql_stmt_free_result()` closes any open cursor.

If you open a cursor for a prepared statement, `mysql_stmt_store_result()` is unnecessary, because that function causes the result set to be buffered on the client side.

#### Return Values

Zero for success. Nonzero if option is unknown.

#### Errors

None.

#### Example

The following example opens a cursor for a prepared statement and sets the number of rows to fetch at a time to 5:

```c
MYSQL_STMT *stmt;
int rc;
unsigned long type;
unsigned long prefetch_rows = 5;

stmt = mysql_stmt_init(mysql);
type = (unsigned long) CURSOR_TYPE_READ_ONLY;
rc = mysql_stmt_attr_set(stmt, STMT_ATTR_CURSOR_TYPE, (void*) &type);
/* ... check return value ... */
rc = mysql_stmt_attr_set(stmt, STMT_ATTR_PREFETCH_ROWS, (void*) &prefetch_rows);
/* ... check return value ... */
```

#### 23.8.11.4 mysql_stmt_bind_param()

```c
my_bool mysql_stmt_bind_param(MYSQL_STMT *stmt, MYSQL_BIND *bind)
```

#### Description

`mysql_stmt_bind_param()` is used to bind input data for the parameter markers in the SQL statement that was passed to `mysql_stmt_prepare()`. It uses `MYSQL_BIND` structures to supply the data. `bind` is the address of an array of `MYSQL_BIND` structures. The client library expects the array to contain one element for each ? parameter marker that is present in the query.
Suppose that you prepare the following statement:

```
INSERT INTO mytbl VALUES(?,?,?)
```

When you bind the parameters, the array of `MYSQL_BIND` structures must contain three elements, and can be declared like this:

```
MYSQL_BIND bind[3];
```

Section 23.8.9, “C API Prepared Statement Data Structures”, describes the members of each `MYSQL_BIND` element and how they should be set to provide input values.

Return Values

Zero for success. Nonzero if an error occurred.

Errors

- **CR_UNSUPPORTED_PARAM_TYPE**
  
  The conversion is not supported. Possibly the `buffer_type` value is invalid or is not one of the supported types.

- **CR_OUT_OF_MEMORY**
  
  Out of memory.

- **CR_UNKNOWN_ERROR**
  
  An unknown error occurred.

Example

See the Example in Section 23.8.11.10, “mysql_stmt_execute()”.

23.8.11.5 `mysql_stmt_bind_result()`

```
my_bool mysql_stmt_bind_result(MYSQL_STMT *stmt, MYSQL_BIND *bind)
```

Description

`mysql_stmt_bind_result()` is used to associate (that is, bind) output columns in the result set to data buffers and length buffers. When `mysql_stmt_fetch()` is called to fetch data, the MySQL client/server protocol places the data for the bound columns into the specified buffers.

All columns must be bound to buffers prior to calling `mysql_stmt_fetch()`. `bind` is the address of an array of `MYSQL_BIND` structures. The client library expects the array to contain one element for each column of the result set. If you do not bind columns to `MYSQL_BIND` structures, `mysql_stmt_fetch()` simply ignores the data fetch. The buffers should be large enough to hold the data values, because the protocol does not return data values in chunks.

A column can be bound or rebound at any time, even after a result set has been partially retrieved. The new binding takes effect the next time `mysql_stmt_fetch()` is called. Suppose that an application binds the columns in a result set and calls `mysql_stmt_fetch()`. The client/server protocol returns data in the bound buffers. Then suppose that the application binds the columns to a different set of buffers. The protocol places data into the newly bound buffers when the next call to `mysql_stmt_fetch()` occurs.
To bind a column, an application calls `mysql_stmt_bind_result()` and passes the type, address, and length of the output buffer into which the value should be stored. Section 23.8.9, “C API Prepared Statement Data Structures”, describes the members of each `MYSQL_BIND` element and how they should be set to receive output values.

**Return Values**

Zero for success. Nonzero if an error occurred.

**Errors**

- **CR_UNSUPPORTED_PARAM_TYPE**
  
The conversion is not supported. Possibly the `buffer_type` value is invalid or is not one of the supported types.

- **CR_OUT_OF_MEMORY**
  
  Out of memory.

- **CR_UNKNOWN_ERROR**
  
  An unknown error occurred.

**Example**

See the Example in Section 23.8.11.11, “mysql_stmt_fetch()”.

### 23.8.11.6 mysql_stmt_close()

**my_bool mysql_stmt_close(MYSQL_STMT *stmt)**

**Description**

Closes the prepared statement. `mysql_stmt_close()` also deallocates the statement handler pointed to by `stmt`, which at that point becomes invalid and should no longer be used. For a failed `mysql_stmt_close()` call, do not call `mysql_stmt_error()`, or `mysql_stmt_errno()`, or `mysql_stmt_sqlstate()` to obtain error information because `mysql_stmt_close()` makes the statement handler invalid. Call `mysql_error()`, `mysql_errno()`, or `mysql_sqlstate()` instead.

If the current statement has pending or unread results, this function cancels them so that the next query can be executed.

**Return Values**

Zero for success. Nonzero if an error occurred.

**Errors**

- **CR_SERVER_GONE_ERROR**
  
The MySQL server has gone away.

- **CR_UNKNOWN_ERROR**
  
  An unknown error occurred.

**Example**

See the Example in Section 23.8.11.10, “mysql_stmt_execute()”. 
23.8.11.7 mysql_stmt_data_seek()

```c
void mysql_stmt_data_seek(MYSQL_STMT *stmt, my_ulonglong offset)
```

**Description**

Seeks to an arbitrary row in a statement result set. The `offset` value is a row number and should be in the range from 0 to `mysql_stmt_num_rows(stmt)-1`.

This function requires that the statement result set structure contains the entire result of the last executed query, so `mysql_stmt_data_seek()` may be used only in conjunction with `mysql_stmt_store_result()`.

**Return Values**

None.

**Errors**

None.

23.8.11.8 mysql_stmt_errno()

```c
unsigned int mysql_stmt_errno(MYSQL_STMT *stmt)
```

**Description**

For the statement specified by `stmt`, `mysql_stmt_errno()` returns the error code for the most recently invoked statement API function that can succeed or fail. A return value of zero means that no error occurred. Client error message numbers are listed in the MySQL `errmsg.h` header file. Server error message numbers are listed in `mysqld_error.h`. Errors also are listed at Appendix B, Errors, Error Codes, and Common Problems.

If the failed statement API function was `mysql_stmt_close()`, do not call or `mysql_stmt_errno()` to obtain error information because `mysql_stmt_close()` makes the statement handler invalid. Call `mysql_errno()` instead.

**Return Values**

An error code value. Zero if no error occurred.

**Errors**

None.

23.8.11.9 mysql_stmt_error()

```c
const char *mysql_stmt_error(MYSQL_STMT *stmt)
```

**Description**

For the statement specified by `stmt`, `mysql_stmt_error()` returns a null-terminated string containing the error message for the most recently invoked statement API function that can succeed or fail. An empty string ("") is returned if no error occurred. Either of these two tests can be used to check for an error:

```c
if(*mysql_stmt_errno(stmt))
{
    // an error occurred
}
```
if (mysql_stmt_error(stmt)[0])
{
  // an error occurred
}

If the failed statement API function was `mysql_stmt_close()`, do not call `mysql_stmt_error()` to obtain error information because `mysql_stmt_close()` makes the statement handler invalid. Call `mysql_error()` instead.

The language of the client error messages may be changed by recompiling the MySQL client library. You can choose error messages in several different languages.

**Return Values**

A character string that describes the error. An empty string if no error occurred.

**Errors**

None.

**23.8.11.10 mysql_stmt_execute()**

```c
int mysql_stmt_execute(MYSQL_STMT *stmt)
```

**Description**

`mysql_stmt_execute()` executes the prepared query associated with the statement handler. The currently bound parameter marker values are sent to server during this call, and the server replaces the markers with this newly supplied data.

Statement processing following `mysql_stmt_execute()` depends on the type of statement:

- For an `UPDATE`, `DELETE`, or `INSERT`, the number of changed, deleted, or inserted rows can be found by calling `mysql_stmt_affected_rows()`.

- For a statement such as `SELECT` that generates a result set, you must call `mysql_stmt_fetch()` to fetch the data prior to calling any other functions that result in query processing. For more information on how to fetch the results, refer to Section 23.8.11.11, “mysql_stmt_fetch()”.

  Do not following invocation of `mysql_stmt_execute()` with a call to `mysql_store_result()` or `mysql_use_result()`. Those functions are not intended for processing results from prepared statements.

  For statements that generate a result set, you can request that `mysql_stmt_execute()` open a cursor for the statement by calling `mysql_stmt_attr_set()` before executing the statement. If you execute a statement multiple times, `mysql_stmt_execute()` closes any open cursor before opening a new one.

  Metadata changes to tables or views referred to by prepared statements are detected and cause automatic repreparation of the statement when it is next executed. For more information, see Section 8.10.4, “Caching of Prepared Statements and Stored Programs”.

**Return Values**

Zero for success. Nonzero if an error occurred.

**Errors**

- `CR_COMMANDS_OUT_OF_SYNC` Commands were executed in an improper order.
• **CR_OUT_OF_MEMORY**
  Out of memory.

• **CR_SERVER_GONE_ERROR**
  The MySQL server has gone away.

• **CR_SERVER_LOST**
  The connection to the server was lost during the query.

• **CR_UNKNOWN_ERROR**
  An unknown error occurred.

**Example**

The following example demonstrates how to create and populate a table using `mysql_stmt_init()`, `mysql_stmt_prepare()`, `mysql_stmt_param_count()`, `mysql_stmt_bind_param()`, `mysql_stmt_execute()`, and `mysql_stmt_affected_rows()`. The `mysql` variable is assumed to be a valid connection handler. For an example that shows how to retrieve data, see Section 23.8.11.11, "mysql_stmt_fetch()".

```c
#define STRING_SIZE 50
#define DROP_SAMPLE_TABLE "DROP TABLE IF EXISTS test_table"
#define CREATE_SAMPLE_TABLE "CREATE TABLE test_table(col1 INT, \ 
                           col2 VARCHAR(40), \ 
                           col3 SMALLINT, \ 
                           col4 TIMESTAMP)"
#define INSERT_SAMPLE "INSERT INTO \ 
                    test_table(col1,col2,col3) \ 
                    VALUES(?,?,?)"

MYSQL_STMT *stmt;
MYSQL_BIND bind[3];
my_ulonglong affected_rows;
int param_count;
short small_data;
int int_data;
char str_data[STRING_SIZE];
unsigned long str_length;
my_bool is_null;

if (mysql_query(mysql, DROP_SAMPLE_TABLE))
{
    fprintf(stderr, " DROP TABLE failed\n");
    fprintf(stderr, " %s\n", mysql_error(mysql));
    exit(0);
}

if (mysql_query(mysql, CREATE_SAMPLE_TABLE))
{
    fprintf(stderr, " CREATE TABLE failed\n");
    fprintf(stderr, " %s\n", mysql_error(mysql));
    exit(0);
}

/* Prepare an INSERT query with 3 parameters */
/* (the TIMESTAMP column is not named; the server */
/* sets it to the current date and time) */
stmt = mysql_stmt_init(mysql);
```
if (!stmt)
{
    fprintf(stderr, " mysql_stmt_init(), out of memory\n");
    exit(0);
}
if (mysql_stmt_prepare(stmt, INSERT_SAMPLE, strlen(INSERT_SAMPLE)))
{
    fprintf(stderr, " mysql_stmt_prepare(), INSERT failed\n");
    fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
    exit(0);
}
fprintf(stdout, " prepare, INSERT successful\n");

/* Get the parameter count from the statement */
param_count= mysql_stmt_param_count(stmt);
fprintf(stdout, " total parameters in INSERT: %d\n", param_count);

if (param_count != 3) /* validate parameter count */
{
    fprintf(stderr, " invalid parameter count returned by MySQL\n");
    exit(0);
}

/* Bind the data for all 3 parameters */
memset(bind, 0, sizeof(bind));

/* INTEGER PARAM */
/* This is a number type, so there is no need to specify buffer_length */
bind[0].buffer_type= MYSQL_TYPE_LONG;
bind[0].buffer= (char *)&int_data;
bind[0].is_null= 0;
bind[0].length= 0;

/* STRING PARAM */
bind[1].buffer_type= MYSQL_TYPE_STRING;
bind[1].buffer= (char *)str_data;
bind[1].buffer_length= STRING_SIZE;
bind[1].is_null= 0;
bind[1].length= &str_length;

/* SMALLINT PARAM */
bind[2].buffer_type= MYSQL_TYPE_SHORT;
bind[2].buffer= (char *)&small_data;
bind[2].is_null= &is_null;
bind[2].length= 0;

/* Bind the buffers */
if (mysql_stmt_bind_param(stmt, bind))
{
    fprintf(stderr, " mysql_stmt_bind_param() failed\n");
    fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
    exit(0);
}

/* Specify the data values for the first row */
int_data= 10;             /* integer */
strncpy(str_data, "MySQL", STRING_SIZE); /* string */

/* INSERT SMALLINT data as NULL */
is_null= 1;

/* Execute the INSERT statement - 1*/
if (mysql_stmt_execute(stmt))
fprintf(stderr, " mysql_stmt_execute(), 1 failed\n")
fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
exit(0);
}

/* Get the number of affected rows */
affected_rows= mysql_stmt_affected_rows(stmt);
fprintf(stdout, " total affected rows(insert 1): %lu\n",
(unsigned long) affected_rows);
if (affected_rows != 1) /* validate affected rows */
{
  fprintf(stderr, " invalid affected rows by MySQL\n");
  exit(0);
}

/* Specify data values for second row, 
then re-execute the statement */
int_data= 1000;
strncpy(str_data, "The most popular Open Source database",
STRING_SIZE);
str_length= strlen(str_data);
small_data= 1000;         /* smallint */
is_null= 0;               /* reset */

/* Execute the INSERT statement - 2*/
if (mysql_stmt_execute(stmt))
{
  fprintf(stderr, " mysql_stmt_execute, 2 failed\n");
  fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
  exit(0);
}

/* Get the total rows affected */
affected_rows= mysql_stmt_affected_rows(stmt);
fprintf(stdout, " total affected rows(insert 2): %lu\n",
(unsigned long) affected_rows);
if (affected_rows != 1) /* validate affected rows */
{
  fprintf(stderr, " invalid affected rows by MySQL\n");
  exit(0);
}

/* Close the statement */
if (mysql_stmt_close(stmt))
{
  /* mysql_stmt_close() invalidates stmt, so call */
  /* mysql_error(mysql) rather than mysql_stmt_error(stmt) */
  fprintf(stderr, " failed while closing the statement\n");
  fprintf(stderr, " %s\n", mysql_error(mysql));
  exit(0);
}

Note
For complete examples on the use of prepared statement functions, refer to the file
tests/mysql_client_test.c. This file can be obtained from a MySQL source
distribution or from the source repository (see Section 2.9, "Installing MySQL from 
Source").

23.8.11.11 mysql_stmt_fetch()

int mysql_stmt_fetch(MYSQL_STMT *stmt)
Description

`mysql_stmt_fetch()` returns the next row in the result set. It can be called only while the result set exists; that is, after a call to `mysql_stmt_execute()` for a statement such as `SELECT` that produces a result set.

`mysql_stmt_fetch()` returns row data using the buffers bound by `mysql_stmt_bind_result()`. It returns the data in those buffers for all the columns in the current row set and the lengths are returned to the `length` pointer. All columns must be bound by the application before it calls `mysql_stmt_fetch()`.

`mysql_stmt_fetch()` typically occurs within a loop, to ensure that all result set rows are fetched. For example:

```c
int status;
while (1)
{
    status = mysql_stmt_fetch(stmt);
    if (status == 1 || status == MYSQL_NO_DATA)
        break;
/* handle current row here */
}
/* if desired, handle status == 1 case and display error here */
```

By default, result sets are fetched unbuffered a row at a time from the server. To buffer the entire result set on the client, call `mysql_stmt_store_result()` after binding the data buffers and before calling `mysql_stmt_fetch()`.

If a fetched data value is a `NULL` value, the `*is_null` value of the corresponding `MYSQL_BIND` structure contains TRUE (1). Otherwise, the data and its length are returned in the `*buffer` and `*length` elements based on the buffer type specified by the application. Each numeric and temporal type has a fixed length, as listed in the following table. The length of the string types depends on the length of the actual data value, as indicated by `data_length`.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
</tr>
</thead>
<tbody>
<tr>
<td>MYSQL_TYPE_TINY</td>
<td>1</td>
</tr>
<tr>
<td>MYSQL_TYPE_SHORT</td>
<td>2</td>
</tr>
<tr>
<td>MYSQL_TYPE_LONG</td>
<td>4</td>
</tr>
<tr>
<td>MYSQL_TYPE_LONGLONG</td>
<td>8</td>
</tr>
<tr>
<td>MYSQL_TYPE_FLOAT</td>
<td>4</td>
</tr>
<tr>
<td>MYSQL_TYPE_DOUBLE</td>
<td>8</td>
</tr>
<tr>
<td>MYSQL_TYPE_TIME</td>
<td><code>sizeof(MYSQL_TIME)</code></td>
</tr>
<tr>
<td>MYSQL_TYPE_DATE</td>
<td><code>sizeof(MYSQL_TIME)</code></td>
</tr>
<tr>
<td>MYSQL_TYPE_DATETIME</td>
<td><code>sizeof(MYSQL_TIME)</code></td>
</tr>
<tr>
<td>MYSQL_TYPE_STRING</td>
<td><code>data_length</code></td>
</tr>
<tr>
<td>MYSQL_TYPE_BLOB</td>
<td><code>data_length</code></td>
</tr>
</tbody>
</table>

In some cases, you might want to determine the length of a column value before fetching it with `mysql_stmt_fetch()`. For example, the value might be a long string or `BLOB` value for which you want to know how much space must be allocated. To accomplish this, use one of these strategies:
- Before invoking `mysql_stmt_fetch()` to retrieve individual rows, pass `STMT_ATTR_UPDATE_MAX_LENGTH` to `mysql_stmt_attr_set()`, then invoke `mysql_stmt_store_result()` to buffer the entire result on the client side. Setting the `STMT_ATTR_UPDATE_MAX_LENGTH` attribute causes the maximal length of column values to be indicated by the `max_length` member of the result set metadata returned by `mysql_stmt_result_metadata()`.

- Invoke `mysql_stmt_fetch()` with a zero-length buffer for the column in question and a pointer in which the real length can be stored. Then use the real length with `mysql_stmt_fetch_column()`.

```c
real_length= 0;
bind[0].buffer= 0;
bind[0].buffer_length= 0;
bind[0].length= &real_length
mysql_stmt_bind_result(stmt, bind);

mysql_stmt_fetch(stmt);
if (real_length > 0)
{
    data= malloc(real_length);
    bind[0].buffer= data;
    bind[0].buffer_length= real_length;
    mysql_stmt_fetch_column(stmt, bind, 0, 0);
}
```

**Return Values**

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Success, the data has been fetched to application data buffers.</td>
</tr>
<tr>
<td>1</td>
<td>Error occurred. Error code and message can be obtained by calling <code>mysql_stmt_errno()</code> and <code>mysql_stmt_error()</code>.</td>
</tr>
<tr>
<td>MYSQL_NO_DATA</td>
<td>Success, no more data exists</td>
</tr>
<tr>
<td>MYSQL_DATA_TRUNCATED</td>
<td>Data truncation occurred</td>
</tr>
</tbody>
</table>

`MYSQL_DATA_TRUNCATED` is returned when truncation reporting is enabled. To determine which column values were truncated when this value is returned, check the `error` members of the `MYSQL_BIND` structures used for fetching values. Truncation reporting is enabled by default, but can be controlled by calling `mysql_options()` with the `MYSQL_REPORT_DATA_TRUNCATION` option.

**Errors**

- **CR_COMMANDS_OUT_OF_SYNC**

  Commands were executed in an improper order.

  Although `mysql_stmt_fetch()` can produce this error, it is more likely to occur for the following C API call if `mysql_stmt_fetch()` is not called enough times to read the entire result set (that is, enough times to return `MYSQL_NO_DATA`).

- **CR_OUT_OF_MEMORY**

  Out of memory.

- **CR_SERVER_GONE_ERROR**

  The MySQL server has gone away.
• **CR_SERVER_LOST**
  The connection to the server was lost during the query.

• **CR_UNKNOWN_ERROR**
  An unknown error occurred.

• **CR_UNSUPPORTED_PARAM_TYPE**
  The buffer type is `MYSQL_TYPE_DATE`, `MYSQL_TYPE_TIME`, `MYSQL_TYPE_DATETIME`, or `MYSQL_TYPE_TIMESTAMP`, but the data type is not `DATE`, `TIME`, `DATETIME`, or `TIMESTAMP`.

• All other unsupported conversion errors are returned from `mysql_stmt_bind_result()`.

**Example**

The following example demonstrates how to fetch data from a table using `mysql_stmt_result_metadata()`, `mysql_stmt_bind_result()`, and `mysql_stmt_fetch()`.

(This example expects to retrieve the two rows inserted by the example shown in Section 23.8.11.10, “mysql_stmt_execute()”.) The `mysql` variable is assumed to be a valid connection handler.

```c
#define STRING_SIZE 50
#define SELECT_SAMPLE "SELECT col1, col2, col3, col4 
    FROM test_table"

MYSQL_STMT    *stmt;
MYSQL_BIND    bind[4];
MYSQL_RES     *prepare_meta_result;
MYSQL_TIME    ts;
unsigned long length[4];
int           param_count, column_count, row_count;
short         small_data;
int           int_data;
char          str_data[STRING_SIZE];
my_bool       is_null[4];
my_bool       error[4];

/* Prepare a SELECT query to fetch data from test_table */
stmt = mysql_stmt_init(mysql);
if (!stmt)
    {fprintf(stderr, " mysql_stmt_init(), out of memory\n");
     exit(0);}
if (mysql_stmt_prepare(stmt, SELECT_SAMPLE, strlen(SELECT_SAMPLE)))
    {
        fprintf(stderr, " mysql_stmt_prepare(), SELECT failed\n");
        fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
        exit(0);
    }
fprintf(stdout, " prepare, SELECT successful\n");
/* Get the parameter count from the statement */
param_count= mysql_stmt_param_count(stmt);
if (param_count != 0) /* validate parameter count */
    {
        fprintf(stderr, " invalid parameter count returned by MySQL\n");
        exit(0);
    }
}````
/* Fetch result set meta information */
prepare_meta_result = mysql_stmt_result_metadata(stmt);
if (!prepare_meta_result)
{
    fprintf(stderr,
        " mysql_stmt_result_metadata(), \" \
        returned no meta information\n\n"");
    fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
    exit(0);
}
/* Get total columns in the query */
column_count = mysql_num_fields(prepare_meta_result);
fprintf(stdout,
    " total columns in SELECT statement: %d\n", \
    column_count);

    if (is_null[3])
        fprintf(stdout, " NULL\n");
    else
        fprintf(stdout, " %04d-%02d-%02d %02d:%02d:%02d (%ld)\n",
            ts.year, ts.month, ts.day,
            ts.hour, ts.minute, ts.second,
            length[3]);
    fprintf(stdout, "\n");
}

/* Validate rows fetched */
fprintf(stdout, " total rows fetched: %d\n", row_count);
if (row_count != 2)
{
    fprintf(stderr, " MySQL failed to return all rows\n");
    exit(0);
}

/* Free the prepared result metadata */
mysql_free_result(prepare_meta_result);

/* Close the statement */
if (mysql_stmt_close(stmt))
{
    /* mysql_stmt_close() invalidates stmt, so call          */
    /* mysql_error(mysql) rather than mysql_stmt_error(stmt) */
    fprintf(stderr, " failed while closing the statement\n");
    fprintf(stderr, " %s\n", mysql_error(mysql));
    exit(0);
}

23.8.11.12 mysql_stmt_fetch_column()

int mysql_stmt_fetch_column(MYSQL_STMT *stmt, MYSQL_BIND *bind, unsigned int
column, unsigned long offset)

Description

Fetches one column from the current result set row. bind provides the buffer where data should be
placed. It should be set up the same way as for mysql_stmt_bind_result(). column indicates which
column to fetch. The first column is numbered 0. offset is the offset within the data value at which to
begin retrieving data. This can be used for fetching the data value in pieces. The beginning of the value is
offset 0.

Return Values

Zero for success. Nonzero if an error occurred.

Errors

• CR_INVALID_PARAMETER_NO
  Invalid column number.

• CR_NO_DATA
  The end of the result set has already been reached.

23.8.11.13 mysql_stmt_field_count()

unsigned int mysql_stmt_field_count(MYSQL_STMT *stmt)

Description

Returns the number of columns for the most recent statement for the statement handler. This value is zero
for statements such as INSERT or DELETE that do not produce result sets.

mysql_stmt_field_count() can be called after you have prepared a statement by invoking
mysql_stmt_prepare().

Return Values

An unsigned integer representing the number of columns in a result set.

Errors

None.

23.8.11.14 mysql_stmt_free_result()
my_bool mysql_stmt_free_result(MYSQL_STMT *stmt)

Description

Releases memory associated with the result set produced by execution of the prepared statement. If there is a cursor open for the statement, mysql_stmt_free_result() closes it.

Return Values

Zero for success. Nonzero if an error occurred.

23.8.11.15 mysql_stmt_init()

MYSQL_STMT *mysql_stmt_init(MYSQL *mysql)

Description

Creates and returns a MYSQL_STMT handler. The handler should be freed with mysql_stmt_close(), at which point the handler becomes invalid and should no longer be used.

See also Section 23.8.9, "C API Prepared Statement Data Structures", for more information.

Return Values

A pointer to a MYSQL_STMT structure in case of success. NULL if out of memory.

Errors

• CR_OUT_OF_MEMORY

Out of memory.

23.8.11.16 mysql_stmt_insert_id()

my_ulonglong mysql_stmt_insert_id(MYSQL_STMT *stmt)

Description

Returns the value generated for an AUTO_INCREMENT column by the prepared INSERT or UPDATE statement. Use this function after you have executed a prepared INSERT statement on a table which contains an AUTO_INCREMENT field.

See Section 23.8.7.37, "mysql_insert_id()", for more information.

Return Values

Value for AUTO_INCREMENT column which was automatically generated or explicitly set during execution of prepared statement, or value generated by LAST_INSERT_ID(expr) function. Return value is undefined if statement does not set AUTO_INCREMENT value.

Errors

None.

23.8.11.17 mysql_stmt_next_result()
C API Prepared Statement Function Descriptions

```c
int mysql_stmt_next_result(MYSQL_STMT *mysql)
```

**Description**

This function is used when you use prepared `CALL` statements to execute stored procedures, which can return multiple result sets. Use a loop that calls `mysql_stmt_next_result()` to determine whether there are more results. If a procedure has `OUT` or `INOUT` parameters, their values will be returned as a single-row result set following any other result sets. The values will appear in the order in which they are declared in the procedure parameter list.

For information about the effect of unhandled conditions on procedure parameters, see Section 13.6.7.8, “Condition Handling and OUT or INOUT Parameters”.

`mysql_stmt_next_result()` returns a status to indicate whether more results exist. If `mysql_stmt_next_result()` returns an error, there are no more results.

Before each call to `mysql_stmt_next_result()`, you must call `mysql_stmt_free_result()` for the current result if it produced a result set (rather than just a result status).

After calling `mysql_stmt_next_result()` the state of the connection is as if you had called `mysql_stmt_execute()`, `mysql_stmt_affected_rows()`, and so forth.

It is also possible to test whether there are more results by calling `mysql_more_results()`. However, this function does not change the connection state, so if it returns true, you must still call `mysql_stmt_next_result()` to advance to the next result.

For an example that shows how to use `mysql_stmt_next_result()`, see Section 23.8.18, “C API Prepared CALL Statement Support”.

**Return Values**

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Successful and there are more results</td>
</tr>
<tr>
<td>-1</td>
<td>Successful and there are no more results</td>
</tr>
<tr>
<td>&gt;0</td>
<td>An error occurred</td>
</tr>
</tbody>
</table>

**Errors**

- `CR_COMMANDS_OUT_OF_SYNC`
  
  Commands were executed in an improper order.

- `CR_SERVER_GONE_ERROR`
  
  The MySQL server has gone away.

- `CR_SERVER_LOST`
  
  The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`
  
  An unknown error occurred.
23.8.11.18 mysql_stmt_num_rows()

    my_ulonglong mysql_stmt_num_rows(MYSQL_STMT *stmt)

Description

Returns the number of rows in the result set.

The use of mysql_stmt_num_rows() depends on whether you used mysql_stmt_store_result() to buffer the entire result set in the statement handler. If you use mysql_stmt_store_result(), mysql_stmt_num_rows() may be called immediately. Otherwise, the row count is unavailable unless you count the rows as you fetch them.

mysql_stmt_num_rows() is intended for use with statements that return a result set, such as SELECT. For statements such as INSERT, UPDATE, or DELETE, the number of affected rows can be obtained with mysql_stmt_affected_rows().

Return Values

The number of rows in the result set.

Errors

None.

23.8.11.19 mysql_stmt_param_count()

    unsigned long mysql_stmt_param_count(MYSQL_STMT *stmt)

Description

Returns the number of parameter markers present in the prepared statement.

Return Values

An unsigned long integer representing the number of parameters in a statement.

Errors

None.

Example

See the Example in Section 23.8.11.10, "mysql_stmt_execute()".

23.8.11.20 mysql_stmt_param_metadata()

    MYSQL_RES *mysql_stmt_param_metadata(MYSQL_STMT *stmt)

This function currently does nothing.

23.8.11.21 mysql_stmt_prepare()

    int mysql_stmt_prepare(MYSQL_STMT *stmt, const char *stmt_str, unsigned long length)
Description

Given the statement handler returned by `mysql_stmt_init()`, prepares the SQL statement pointed to by the string `stmt_str` and returns a status value. The string length should be given by the `length` argument. The string must consist of a single SQL statement. You should not add a terminating semicolon (`;`) or `\g` to the statement.

The application can include one or more parameter markers in the SQL statement by embedding question mark (`?`) characters into the SQL string at the appropriate positions.

The markers are legal only in certain places in SQL statements. For example, they are permitted in the `VALUES()` list of an `INSERT` statement (to specify column values for a row), or in a comparison with a column in a `WHERE` clause to specify a comparison value. However, they are not permitted for identifiers (such as table or column names), or to specify both operands of a binary operator such as the `=` equal sign. The latter restriction is necessary because it would be impossible to determine the parameter type. In general, parameters are legal only in Data Manipulation Language (DML) statements, and not in Data Definition Language (DDL) statements.

The parameter markers must be bound to application variables using `mysql_stmt_bind_param()` before executing the statement.

Metadata changes to tables or views referred to by prepared statements are detected and cause automatic repreparation of the statement when it is next executed. For more information, see Section 8.10.4, “Caching of Prepared Statements and Stored Programs”.

Return Values

Zero for success. Nonzero if an error occurred.

Errors

- **CR_COMMANDS_OUT_OF_SYNC**
  
  Commands were executed in an improper order.

- **CR_OUT_OF_MEMORY**
  
  Out of memory.

- **CR_SERVER_GONE_ERROR**
  
  The MySQL server has gone away.

- **CR_SERVER_LOST**
  
  The connection to the server was lost during the query.

- **CR_UNKNOWN_ERROR**
  
  An unknown error occurred.

If the prepare operation was unsuccessful (that is, `mysql_stmt_prepare()` returns nonzero), the error message can be obtained by calling `mysql_stmt_error()`.

Example

See the Example in Section 23.8.11.10, "mysql_stmt_execute()".
23.8.11.22 mysql_stmt_reset()

```c
my_bool mysql_stmt_reset(MYSQL_STMT *stmt)
```

**Description**

Resets a prepared statement on client and server to state after prepare. It resets the statement on the server, data sent using `mysql_stmt_send_long_data()`, unbuffered result sets and current errors. It does not clear bindings or stored result sets. Stored result sets will be cleared when executing the prepared statement (or closing it).

To re-prepare the statement with another query, use `mysql_stmt_prepare()`.

**Return Values**

Zero for success. Nonzero if an error occurred.

**Errors**

- `CR_COMMANDS_OUT_OF_SYNC`
  
  Commands were executed in an improper order.

- `CR_SERVER_GONE_ERROR`
  
  The MySQL server has gone away.

- `CR_SERVER_LOST`
  
  The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`
  
  An unknown error occurred.

23.8.11.23 mysql_stmt_result_metadata()

```c
MYSQL_RES *mysql_stmt_result_metadata(MYSQL_STMT *stmt)
```

**Description**

If a statement passed to `mysql_stmt_prepare()` is one that produces a result set, `mysql_stmt_result_metadata()` returns the result set metadata in the form of a pointer to a `MYSQL_RES` structure that can be used to process the meta information such as number of fields and individual field information. This result set pointer can be passed as an argument to any of the field-based API functions that process result set metadata, such as:

- `mysql_num_fields()`

- `mysql_fetch_field()`

- `mysql_fetch_field_direct()`

- `mysql_fetch_fields()`

- `mysql_field_count()`

- `mysql_field_seek()`
• `mysql_field_tell()`
• `mysql_free_result()`

The result set structure should be freed when you are done with it, which you can do by passing it to `mysql_free_result()`. This is similar to the way you free a result set obtained from a call to `mysql_store_result()`.

The result set returned by `mysql_stmt_result_metadata()` contains only metadata. It does not contain any row results. The rows are obtained by using the statement handler with `mysql_stmt_fetch()`.

### Return Values

A `MYSQL_RES` result structure. `NULL` if no meta information exists for the prepared query.

### Errors

- **CR_OUT_OF_MEMORY**
  
  Out of memory.
- **CR_UNKNOWN_ERROR**
  
  An unknown error occurred.

### Example

See the Example in Section 23.8.11.11, "mysql_stmt_fetch()".

### 23.8.11.24 `mysql_stmt_row_seek()`

```c
MYSQLForRow_OFFSET mysql_stmt_row_seek(MYSQL_STMT *stmt, MYSQLForRow_OFFSET offset)
```

### Description

Sets the row cursor to an arbitrary row in a statement result set. The `offset` value is a row offset that should be a value returned from `mysql_stmt_row_tell()` or from `mysql_stmt_row_seek()`. This value is not a row number; if you want to seek to a row within a result set by number, use `mysql_stmt_data_seek()` instead.

This function requires that the result set structure contains the entire result of the query, so `mysql_stmt_row_seek()` may be used only in conjunction with `mysql_stmt_store_result()`.

### Return Values

The previous value of the row cursor. This value may be passed to a subsequent call to `mysql_stmt_row_seek()`.

### Errors

None.

### 23.8.11.25 `mysql_stmt_row_tell()`

```c
MYSQLForRow_OFFSET mysql_stmt_row_tell(MYSQL_STMT *stmt)
```
Description

Returns the current position of the row cursor for the last `mysql_stmt_fetch()`. This value can be used as an argument to `mysql_stmt_row_seek()`.

You should use `mysql_stmt_row_tell()` only after `mysql_stmt_store_result()`.

Return Values

The current offset of the row cursor.

Errors

None.

23.8.11.26 `mysql_stmt_send_long_data()`

`my_bool mysql_stmt_send_long_data(MYSQL_STMT *stmt, unsigned int parameter_number, const char *data, unsigned long length)`

Description

Enables an application to send parameter data to the server in pieces (or “chunks”). Call this function after `mysql_stmt_bind_param()` and before `mysql_stmt_execute()`. It can be called multiple times to send the parts of a character or binary data value for a column, which must be one of the `TEXT` or `BLOB` data types.

`parameter_number` indicates which parameter to associate the data with. Parameters are numbered beginning with 0. `data` is a pointer to a buffer containing data to be sent, and `length` indicates the number of bytes in the buffer.

Note

The next `mysql_stmt_execute()` call ignores the bind buffer for all parameters that have been used with `mysql_stmt_send_long_data()` since last `mysql_stmt_execute()` or `mysql_stmt_reset()`.

If you want to reset/forget the sent data, you can do it with `mysql_stmt_reset()`. See Section 23.8.11.22, "`mysql_stmt_reset()`".

The `max_allowed_packet` system variable controls the maximum size of parameter values that can be sent with `mysql_stmt_send_long_data()`.

Return Values

Zero for success. Nonzero if an error occurred.

Errors

- **CR_INVALID_BUFFER_USE**
  
The parameter does not have a string or binary type.

- **CR_INVALID_PARAMETER_NO**
  
  Invalid parameter number.
• CR_COMMANDS_OUT_OF_SYNC
  Commands were executed in an improper order.

• CR_SERVER_GONE_ERROR
  The MySQL server has gone away.

• CR_OUT_OF_MEMORY
  Out of memory.

• CR_UNKNOWN_ERROR
  An unknown error occurred.

Example

The following example demonstrates how to send the data for a TEXT column in chunks. It inserts the data value 'MySQL - The most popular Open Source database' into the text_column column. The mysql variable is assumed to be a valid connection handler.

```c
#define INSERT_QUERY "INSERT INTO \n  test_long_data(text_column) VALUES(?)"

MYSQL_BIND bind[1];
long       length;

stmt = mysql_stmt_init(mysql);
if (!stmt)
{
  fprintf(stderr, " mysql_stmt_init(), out of memory\n");
  exit(0);
}
if (mysql_stmt_prepare(stmt, INSERT_QUERY, strlen(INSERT_QUERY)))
{
  fprintf(stderr, "\n mysql_stmt_prepare(), INSERT failed\n  %s", mysql_stmt_error(stmt));
  exit(0);
}
memset(bind, 0, sizeof(bind));
bind[0].buffer_type= MYSQL_TYPE_STRING;
bind[0].length= &length;
bind[0].is_null= 0;
/* Bind the buffers */
if (mysql_stmt_bind_param(stmt, bind))
{
  fprintf(stderr, "\n param bind failed\n  %s", mysql_stmt_error(stmt));
  exit(0);
}
/* Supply data in chunks to server */
if (mysql_stmt_send_long_data(stmt,0,"MySQL",5))
{
  fprintf(stderr, "\n send_long_data failed\n  %s", mysql_stmt_error(stmt));
  exit(0);
}
/* Supply the next piece of data */
if (mysql_stmt_send_long_data(stmt,0,\
                           "- The most popular Open Source database",15))
{
  fprintf(stderr, "\n send_long_data failed\n  %s", mysql_stmt_error(stmt));
  exit(0);
}
```
23.8.11.27 mysql_stmt_sqlstate()

    const char *mysql_stmt_sqlstate(MYSQL_STMT *stmt)

Description

For the statement specified by stmt, mysql_stmt_sqlstate() returns a null-terminated string containing the SQLSTATE error code for the most recently invoked prepared statement API function that can succeed or fail. The error code consists of five characters. "00000" means "no error." The values are specified by ANSI SQL and ODBC. For a list of possible values, see Appendix B, Errors, Error Codes, and Common Problems.

Not all MySQL errors are mapped to SQLSTATE codes. The value "HY000" (general error) is used for unmapped errors.

If the failed statement API function was mysql_stmt_close(), do not call mysql_stmt_sqlstate() to obtain error information because mysql_stmt_close() makes the statement handler invalid. Call mysql_sqlstate() instead.

Return Values

A null-terminated character string containing the SQLSTATE error code.

23.8.11.28 mysql_stmt_store_result()

    int mysql_stmt_store_result(MYSQL_STMT *stmt)

Description

Result sets are produced by calling mysql_stmt_execute() to executed prepared statements for SQL statements such as SELECT, SHOW, DESCRIBE, and EXPLAIN. By default, result sets for successfully executed prepared statements are not buffered on the client and mysql_stmt_fetch() fetches them one at a time from the server. To cause the complete result set to be buffered on the client, call mysql_stmt_store_result() after binding data buffers with mysql_stmt_bind_result() and before calling mysql_stmt_fetch() to fetch rows. (For an example, see Section 23.8.11.11, "mysql_stmt_fetch()".)

mysql_stmt_store_result() is optional for result set processing, unless you will call mysql_stmt_data_seek(), mysql_stmt_row_seek(), or mysql_stmt_row_tell(). Those functions require a seekable result set.

It is unnecessary to call mysql_stmt_store_result() after executing an SQL statement that does not produce a result set, but if you do, it does not harm or cause any notable performance problem.
detect whether the statement produced a result set by checking if `mysql_stmt_result_metadata()` returns NULL. For more information, refer to Section 23.8.11.23, “mysql_stmt_result_metadata()”.

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
</table>
| MySQL does not by default calculate `MYSQL_FIELD->max_length` for all columns in `mysql_stmt_store_result()` because calculating this would slow down `mysql_stmt_store_result()` considerably and most applications do not need `max_length`. If you want `max_length` to be updated, you can call `mysql_stmt_attr_set(MYSQL_STMT, STM T_ATTR_UPDATE_MAX_LENGTH, &flag)` to enable this. See Section 23.8.11.3, “mysql_stmt_attr_set()”.

Return Values
Zero for success. Nonzero if an error occurred.

Errors
- `CR_COMMANDS_OUT_OF_SYNC`
  Commands were executed in an improper order.
- `CR_OUT_OF_MEMORY`
  Out of memory.
- `CR_SERVER_GONE_ERROR`
  The MySQL server has gone away.
- `CR_SERVER_LOST`
  The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`
  An unknown error occurred.

23.8.12 C API Threaded Function Descriptions
To create a threaded client, use the functions described in the following sections. See also Section 23.8.4.2, “Writing C API Threaded Client Programs”.

23.8.12.1 my_init()

    void my_init(void)

Description
`my_init()` initializes some global variables that MySQL needs. It also calls `mysql_thread_init()` for this thread.

It is necessary for `my_init()` to be called early in the initialization phase of a program's use of the MySQL client library. However, `my_init()` is automatically called by `mysql_init()`, `mysql_library_init()`, `mysql_server_init()`, and `mysql_connect()`. If you ensure that your program invokes one of those functions before any other MySQL calls, there is no need to invoke `my_init()` explicitly.
To access the prototype for `my_init()`, your program should include these header files:

```
#include <my_global.h>
#include <my_sys.h>
```

### Return Values
None.

#### 23.8.12.2 mysql_thread_end()

`void mysql_thread_end(void)`

**Description**

This function needs to be called before calling `pthread_exit()` to free memory allocated by `mysql_thread_init()`.

`mysql_thread_end()` *is not invoked automatically by the client library*. It must be called explicitly to avoid a memory leak.

**Return Values**
None.

#### 23.8.12.3 mysql_thread_init()

`my_bool mysql_thread_init(void)`

**Description**

This function must be called early within each created thread to initialize thread-specific variables. However, you may not necessarily need to invoke it explicitly: `mysql_thread_init()` *is automatically called by my_init()*, which itself is automatically called by `mysql_init()`, `mysql_library_init()`, `mysql_server_init()`, and `mysql_connect()`. If you invoke any of those functions, `mysql_thread_init()` is called for you.

**Return Values**
Zero for success. Nonzero if an error occurred.

#### 23.8.12.4 mysql_thread_safe()

`unsigned int mysql_thread_safe(void)`

**Description**

This function indicates whether the client library is compiled as thread-safe.

**Return Values**
1 if the client library is thread-safe, 0 otherwise.

### 23.8.13 C API Embedded Server Function Descriptions

MySQL applications can be written to use an embedded server. See Section 23.7, "libmysqld, the Embedded MySQL Server Library". To write such an application, you must link it against the
libmysqld library by using the -lmysqld flag rather than linking it against the libmysqlclient client library by using the -lmysqlclient flag. However, the calls to initialize and finalize the library are the same whether you write a client application or one that uses the embedded server: Call mysql_library_init() to initialize the library and mysql_library_end() when you are done with it. See Section 23.8.6, “C API Function Overview”.

23.8.13.1 mysql_server_end()

   void mysql_server_end(void)

Description

This function finalizes the MySQL library, which should be done when you are done using the library. However, mysql_server_end() is deprecated and mysql_library_end() should be used instead. See Section 23.8.7.39, “mysql_library_end()”.

Note

To avoid memory leaks after the application is done using the library (for example, after closing the connection to the server), be sure to call mysql_server_end() (or mysql_library_end()) explicitly. This enables memory management to be performed to clean up and free resources used by the library.

Return Values

None.

23.8.13.2 mysql_server_init()

   int mysql_server_init(int argc, char **argv, char **groups)

Description

This function initializes the MySQL client library, which must be done before you call any other MySQL function. However, mysql_server_init() is deprecated and you should call mysql_library_init() instead. See Section 23.8.7.40, “mysql_library_init()”.

Note

To avoid memory leaks after the application is done using the library (for example, after closing the connection to the server), be sure to call mysql_server_end() (or mysql_library_end()) explicitly. This enables memory management to be performed to clean up and free resources used by the library. See Section 23.8.7.39, “mysql_library_end()”.

Return Values

Zero for success. Nonzero if an error occurred.

23.8.14 C API Client Plugin Functions

This section describes functions used for the client-side plugin API. They enable management of client plugins. For a description of the st_mysql_client_plugin structure used by these functions, see Client Plugin Descriptors.
It is unlikely that a client program needs to call the functions in this section. For example, a client that supports the use of authentication plugins normally causes a plugin to be loaded by calling `mysql_options()` to set the `MYSQL_DEFAULT_AUTH` and `MYSQL_PLUGIN_DIR` options:

```c
char *plugin_dir = "path_to_plugin_dir";
char *default_auth = "plugin_name";
/* ... process command-line options ... */
mysql_options(&mysql, MYSQL_PLUGIN_DIR, plugin_dir);
mysql_options(&mysql, MYSQL_DEFAULT_AUTH, default_auth);
```

Typically, the program will also accept `--plugin-dir` and `--default-auth` options that enable users to override the default values.

### 23.8.14.1 `mysql_client_find_plugin()`

```c
struct st_mysql_client_plugin *mysql_client_find_plugin(MYSQL *mysql, const char *name, int type)
```

**Description**

Returns a pointer to a loaded plugin, loading the plugin first if necessary. An error occurs if the type is invalid or the plugin cannot be found or loaded.

Specify the parameters as follows:

- **mysql**: A pointer to a `MYSQL` structure. The plugin API does not require a connection to a MySQL server, but this structure must be properly initialized. The structure is used to obtain connection-related information.
- **name**: The plugin name.
- **type**: The plugin type.

**Return Values**

A pointer to the plugin for success. `NULL` if an error occurred.

**Errors**

To check for errors, call the `mysql_error()` or `mysql_errno()` function. See Section 23.8.7.15, “mysql_error()”, and Section 23.8.7.14, “mysql_errno()”.

**Example**

```c
MYSQL mysql;
struct st_mysql_client_plugin *p;
if ((p = mysql_client_find_plugin(&mysql, "myplugin", MYSQL_CLIENT_AUTHENTICATION_PLUGIN, 0)))
    [printf("Plugin version: %d.%d.%d\n", p->version[0], p->version[1], p->version[2]);
```

### 23.8.14.2 `mysql_client_register_plugin()`
struct st_mysql_client_plugin *mysql_client_register_plugin(MYSQL *mysql, struct st_mysql_client_plugin *plugin)

Description

Adds a plugin structure to the list of loaded plugins. An error occurs if the plugin is already loaded.

Specify the parameters as follows:

• mysql: A pointer to a MYSQL structure. The plugin API does not require a connection to a MySQL server, but this structure must be properly initialized. The structure is used to obtain connection-related information.

• plugin: A pointer to the plugin structure.

Return Values

A pointer to the plugin for success. NULL if an error occurred.

Errors

To check for errors, call the mysql_error() or mysql_errno() function. See Section 23.8.7.15, “mysql_error()”, and Section 23.8.7.14, “mysql_errno()”.

23.8.14.3 mysql_load_plugin()

struct st_mysql_client_plugin *mysql_load_plugin(MYSQL *mysql, const char *name, int type, int argc, ...)

Description

Loads a MySQL client plugin, specified by name and type. An error occurs if the type is invalid or the plugin cannot be loaded.

It is not possible to load multiple plugins of the same type. An error occurs if you try to load a plugin of a type already loaded.

Specify the parameters as follows:

• mysql: A pointer to a MYSQL structure. The plugin API does not require a connection to a MySQL server, but this structure must be properly initialized. The structure is used to obtain connection-related information.

• name: The name of the plugin to load.

• type: The type of plugin to load, or −1 to disable type checking. If type is not −1, only plugins matching the type are considered for loading.

• argc: The number of following arguments (0 if there are none). Interpretation of any following arguments depends on the plugin type.

Another way to cause plugins to be loaded is to set the LIBMYSQL_PLUGIN environment variable to a list of semicolon-separated plugin names. For example:
Plugins named by `LIBMYSQL_PLUGINS` are loaded when the client program calls `mysql_library_init()`. No error is reported if problems occur loading these plugins.

The `LIBMYSQL_PLUGIN_DIR` environment variable can be set to the path name of the directory in which to look for client plugins. This variable is used in two ways:

- During client plugin preloading, the value of the `--plugin-dir` option is not available, so client plugin loading fails unless the plugins are located in the hardwired default directory. If the plugins are located elsewhere, `LIBMYSQL_PLUGIN_DIR` environment variable can be set to the proper directory to enable plugin preloading to succeed.

- For explicit client plugin loading, the `mysql_load_plugin()` and `mysql_load_plugin_v()` C API functions use the `LIBMYSQL_PLUGIN_DIR` value if it exists and the `--plugin-dir` option was not given. If `--plugin-dir` is given, `mysql_load_plugin()` and `mysql_load_plugin_v()` ignore `LIBMYSQL_PLUGIN_DIR`.

### Return Values

A pointer to the plugin if it was loaded successfully. `NULL` if an error occurred.

### Errors

To check for errors, call the `mysql_error()` or `mysql_errno()` function. See Section 23.8.7.15, “mysql_error()”, and Section 23.8.7.14, “mysql_errno()”.

### Example

```c
MYSQL mysql;
if(!mysql_load_plugin(&mysql, "myplugin", MYSQL_CLIENT_AUTHENTICATION_PLUGIN, 0))
{
    fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
    exit(-1);
}
```

### See Also

See also Section 23.8.14.3, “mysql_load_plugin()”, Section 23.8.7.15, “mysql_error()”, Section 23.8.7.14, “mysql_errno()”.

### 23.8.14.4 mysql_load_plugin_v()

```c
struct st_mysql_client_plugin *mysql_load_plugin_v(MYSQL *mysql, const char *name, int type, int argc, va_list args)
```

### Description

This function is equivalent to `mysql_load_plugin()`, but it accepts a `va_list` instead of a variable list of parameters.

### See Also

See also Section 23.8.14.3, “mysql_load_plugin()”.

---

```
shell> export LIBMYSQL_PLUGINS="myplugin1;myplugin2"
```
23.8.14.5 mysql_plugin_options()

```c
int mysql_plugin_options(struct st_mysql_client_plugin *plugin, const char *
option, const void *value)
```

**Description**

Passes an option type and value to a plugin. This function can be called multiple times to set several options. If the plugin does not have an option handler, an error occurs.

Specify the parameters as follows:

- **plugin**: A pointer to the plugin structure.
- **option**: The option to be set.
- **value**: A pointer to the option value.

**Return Values**

Zero for success, 1 if an error occurred. If the plugin has an option handler, that handler should also return zero for success and 1 if an error occurred.

23.8.15 C API Encrypted Connection Support

For applications that require control over how encrypted connections are established, the C API provides these capabilities:

- The `mysql_options()` function enables applications to set the appropriate SSL/TLS options before calling `mysql_real_connect()`. For example, to require the use of an encrypted connection, see [Enforcing an Encrypted Connection](#).

- The `mysql_get_ssl_cipher()` function enables applications to determine, after a connection has been established, whether the connection uses encryption. A `NULL` return value indicates that encryption is not being used. A non-`NULL` return value indicates an encrypted connection and names the encryption cipher. See [Section 23.8.7.33, “mysql_get_ssl_cipher()”](#).

- **C API Options for Encrypted Connections**

- **Enforcing an Encrypted Connection**

- **Improving Security of Encrypted Connections**

**C API Options for Encrypted Connections**

`mysql_options()` provides the following options for control over use of encrypted connections. For option details, see [Section 23.8.7.49, “mysql_options()”](#).

- **MYSQL_OPT_SSL_CA**: The path name of the Certificate Authority (CA) certificate file. This option, if used, must specify the same certificate used by the server.

- **MYSQL_OPT_SSL_CAPATH**: The path name of the directory that contains trusted SSL CA certificate files.

- **MYSQL_OPT_SSL_CERT**: The path name of the client public key certificate file.

- **MYSQL_OPT_SSL_CIPHER**: The list of permissible ciphers for SSL encryption.
C API Encrypted Connection Support

- **MYSQL_OPT_SSL_CRL**: The path name of the file containing certificate revocation lists.
- **MYSQL_OPT_SSL_CRLPATH**: The path name of the directory that contains certificate revocation list files.
- **MYSQL_OPT_SSL_KEY**: The path name of the client private key file.
- **MYSQL_OPT_SSL_MODE**: The connection security state.
- **MYSQL_OPT_SSL_VERIFY_SERVER_CERT**: Whether to perform host name identity verification of the server certificate Common Name value.

`mysql_ssl_set()` can be used as a convenience routine that is equivalent to a set of `mysql_options()` calls that specify certificate and key files, encryption ciphers, and so forth. See Section 23.8.7.68, “mysql_ssl_set()”.

**Enforcing an Encrypted Connection**

`mysql_options()` options for information such as SSL certificate and key files are used to establish an encrypted connection if such connections are available, but do not enforce any requirement that the connection obtained be encrypted. To require an encrypted connection, use the following technique:

1. Call `mysql_options()` as necessary supply the appropriate SSL parameters (certificate and key files, encryption ciphers, and so forth).

2. For MySQL 5.6.36 and higher, `MYSQL_OPT_SSL_MODE` is available, so call `mysql_options()` to pass the `MYSQL_OPT_SSL_MODE` option with a value of `SSL_MODE_REQUIRED`.

3. Call `mysql_real_connect()` to connect to the server. As of MySQL 5.6.36, the call fails if an encrypted connection cannot be obtained; exit with an error. Prior to 5.6.36 (before `MYSQL_OPT_SSL_MODE` is available), clients are required to check for themselves, after calling `mysql_real_connect()`, whether the connection is encrypted. To do this if `mysql_real_connect()` succeeds, call `mysql_get_ssl_cipher()` to check whether the resulting connection is encrypted. If not, exit with an error.

MySQL clients implement this technique using a wrapper function named `mysql_connect_ssl_check()` to establish and check the connection, rather than calling `mysql_real_connect()` directly. To see how this works, look in the client directory of a MySQL source distribution at the source for any of the standard MySQL clients, as well as the `client_priv.h` file that contains the `mysql_connect_ssl_check()` wrapper function implementation. A call to `mysql_connect_ssl_check()` takes arguments like the arguments to `mysql_real_connect()`, plus an extra argument indicating whether to require an encrypted connection:

```c
if (!mysql_connect_ssl_check(&mysql, host, user, pass, db, port, sock, flags, opt_ssl_required))
```
/* failure: connection not obtained, or not encrypted if required to be */
else {
/* success: connection obtained, encrypted if required to be */

Version notes:

• In MySQL 5.6.30, the `--ssl-mode=REQUIRED` command-line option was backported from MySQL 5.7 to MySQL 5.6. Clients can check for this option and use it to determine whether to require an encrypted connection. If so, clients must check for themselves, after calling `mysql_real_connect()`, whether the connection is encrypted, and fail if not. To do this, call `mysql_get_ssl_cipher()` and check the return value.

• In MySQL 5.6.36, the `MYSQL_OPT_SSL_MODE` option for `mysql_options()` was backported from MySQL 5.7 to MySQL 5.6. A call to `mysql_options()` to set the `MYSQL_OPT_SSL_MODE` option to value of `SSL_MODE_REQUIRED` suffices to cause `mysql_real_connect()` to fail if the connection is not encrypted. `mysql_get_ssl_cipher()` can still be called after connecting, although it is not necessary to do so.

Improving Security of Encrypted Connections

For additional security relative to that provided by the default encryption, clients can supply a CA certificate matching the one used by the server and enable host name identity verification. In this way, the server and client place their trust in the same CA certificate and the client verifies that the host to which it connected is the one intended:

• To specify the CA certificate, call `mysql_options()` to pass the `MYSQL_OPT_SSL_CA` (or `MYSQL_OPT_SSL_CAPATH`) option.

• To enable host name identity verification, call `mysql_options()` to enable the `MYSQL_OPT_SSL_VERIFY_SERVER_CERT` option.

• To require an encrypted connection, call `mysql_options()` to pass the `MYSQL_OPT_SSL_MODE` option with a value of `SSL_MODE_REQUIRED`. (For details about `SSL_MODE_REQUIRED`, see Enforcing an Encrypted Connection.)

23.8.16 C API Multiple Statement Execution Support

By default, `mysql_query()` and `mysql_real_query()` interpret their statement string argument as a single statement to be executed, and you process the result according to whether the statement produces a result set (a set of rows, as for `SELECT`) or an affected-rows count (as for `INSERT`, `UPDATE`, and so forth).

MySQL also supports the execution of a string containing multiple statements separated by semicolon (`;`) characters. This capability is enabled by special options that are specified either when you connect to the server with `mysql_real_connect()` or after connecting by calling `mysql_set_server_option()`.

Executing a multiple-statement string can produce multiple result sets or row-count indicators. Processing these results involves a different approach than for the single-statement case: After handling the result from the first statement, it is necessary to check whether more results exist and process them in turn if so. To support multiple-result processing, the C API includes the `mysql_more_results()` and `mysql_next_result()` functions. These functions are used at the end of a loop that iterates as long as more results are available. *Failure to process the result this way may result in a dropped connection to the server.*
Multiple-result processing also is required if you execute `CALL` statements for stored procedures. Results from a stored procedure have these characteristics:

- Statements within the procedure may produce result sets (for example, if it executes `SELECT` statements). These result sets are returned in the order that they are produced as the procedure executes.

  In general, the caller cannot know how many result sets a procedure will return. Procedure execution may depend on loops or conditional statements that cause the execution path to differ from one call to the next. Therefore, you must be prepared to retrieve multiple results.

- The final result from the procedure is a status result that includes no result set. The status indicates whether the procedure succeeded or an error occurred.

The multiple statement and result capabilities can be used only with `mysql_query()` or `mysql_real_query()`. They cannot be used with the prepared statement interface. Prepared statement handlers are defined to work only with strings that contain a single statement. See Section 23.8.8, “C API Prepared Statements”.

To enable multiple-statement execution and result processing, the following options may be used:

- The `mysql_real_connect()` function has a `flags` argument for which two option values are relevant:

  - `CLIENT_MULTI_RESULTS` enables the client program to process multiple results. This option must be enabled if you execute `CALL` statements for stored procedures that produce result sets. Otherwise, such procedures result in an error: `Error 1312 (0A000): PROCEDURE proc_name can't return a result set in the given context`. In MySQL 5.6, `CLIENT_MULTI_RESULTS` is enabled by default.

  - `CLIENT_MULTI_STATEMENTS` enables `mysql_query()` and `mysql_real_query()` to execute statement strings containing multiple statements separated by semicolons. This option also enables `CLIENT_MULTI_RESULTS` implicitly, so a `flags` argument of `CLIENT_MULTI_STATEMENTS` to `mysql_real_connect()` is equivalent to an argument of `CLIENT_MULTI_STATEMENTS | CLIENT_MULTI_RESULTS`. That is, `CLIENT_MULTI_STATEMENTS` is sufficient to enable multiple-statement execution and all multiple-result processing.

  - After the connection to the server has been established, you can use the `mysql_set_server_option()` function to enable or disable multiple-statement execution by passing it an argument of `MYSQL_OPTION_MULTI_STATEMENTS_ON` or `MYSQL_OPTION_MULTI_STATEMENTS_OFF`. Enabling multiple-statement execution with this function also enables processing of “simple” results for a multiple-statement string where each statement produces a single result, but is not sufficient to permit processing of stored procedures that produce result sets.

The following procedure outlines a suggested strategy for handling multiple statements:

1. Pass `CLIENT_MULTI_STATEMENTS` to `mysql_real_connect()`, to fully enable multiple-statement execution and multiple-result processing.

2. After calling `mysql_query()` or `mysql_real_query()` and verifying that it succeeds, enter a loop within which you process statement results.

3. For each iteration of the loop, handle the current statement result, retrieving either a result set or an affected-rows count. If an error occurs, exit the loop.

4. At the end of the loop, call `mysql_next_result()` to check whether another result exists and initiate retrieval for it if so. If no more results are available, exit the loop.
One possible implementation of the preceding strategy is shown following. The final part of the loop can be reduced to a simple test of whether `mysql_next_result()` returns nonzero. The code as written distinguishes between no more results and an error, which enables a message to be printed for the latter occurrence.

```c
/* connect to server with the CLIENT_MULTI_STATEMENTS option */
if (mysql_real_connect (mysql, host_name, user_name, password,
    db_name, port_num, socket_name, CLIENT_MULTI_STATEMENTS) == NULL)
{
    printf("mysql_real_connect() failed\n");
    mysql_close(mysql);
    exit(1);
}

/* execute multiple statements */
status = mysql_query(mysql, "DROP TABLE IF EXISTS test_table;
    CREATE TABLE test_table(id INT);
    INSERT INTO test_table VALUES(10);
    UPDATE test_table SET id=20 WHERE id=10;
    SELECT * FROM test_table;
    DROP TABLE test_table");
if (status)
{
    printf("Could not execute statement(s)\n");
    mysql_close(mysql);
    exit(0);
}

/* process each statement result */
do {
    /* did current statement return data? */
    result = mysql_store_result(mysql);
    if (result)
    {
        /* yes; process rows and free the result set */
        process_result_set(mysql, result);
        mysql_free_result(result);
    }
    else          /* no result set or error */
    {
        if (mysql_field_count(mysql) == 0)
        {
            printf("%lld rows affected\n", mysql_affected_rows(mysql));
        }
        else  /* some error occurred */
        {
            printf("Could not retrieve result set\n");
            break;
        }
    }
    /* more results? -1 = no, >0 = error, 0 = yes (keep looping) */
    if ((status = mysql_next_result(mysql)) > 0)
    {
        printf("Could not execute statement\n");
    } while (status == 0);

mysql_close(mysql);
```

**23.8.17 C API Prepared Statement Handling of Date and Time Values**

The binary (prepared statement) protocol enables you to send and receive date and time values (`DATE`, `TIME`, `DATETIME`, and `TIMESTAMP`), using the `MYSQL_TIME` structure. The members of this structure are described in Section 23.8.9, "C API Prepared Statement Data Structures".
To send temporal data values, create a prepared statement using `mysql_stmt_prepare()`. Then, before calling `mysql_stmt_execute()` to execute the statement, use the following procedure to set up each temporal parameter:

1. In the `MYSQL_BIND` structure associated with the data value, set the `buffer_type` member to the type that indicates what kind of temporal value you're sending. For `DATE`, `TIME`, `DATETIME`, or `TIMESTAMP` values, set `buffer_type` to `MYSQL_TYPE_DATE`, `MYSQL_TYPE_TIME`, `MYSQL_TYPE_DATETIME`, or `MYSQL_TYPE_TIMESTAMP`, respectively.

2. Set the `buffer` member of the `MYSQL_BIND` structure to the address of the `MYSQL_TIME` structure in which you pass the temporal value.

3. Fill in the members of the `MYSQL_TIME` structure that are appropriate for the type of temporal value to pass.

Use `mysql_stmt_bind_param()` to bind the parameter data to the statement. Then you can call `mysql_stmt_execute()`.

To retrieve temporal values, the procedure is similar, except that you set the `buffer_type` member to the type of value you expect to receive, and the `buffer` member to the address of a `MYSQL_TIME` structure into which the returned value should be placed. Use `mysql_stmt_bind_result()` to bind the buffers to the statement after calling `mysql_stmt_execute()` and before fetching the results.

Here is a simple example that inserts `DATE`, `TIME`, and `TIMESTAMP` data. The `mysql` variable is assumed to be a valid connection handler.

```c
MYSQL_TIME ts;
MYSQL_BIND bind[3];
MYSQL_STMT *stmt;

strmov(query, "INSERT INTO test_table(date_field, time_field, \
    timestamp_field) VALUES(?,?,?);

stmt = mysql_stmt_init(mysql);
if (!stmt)
    { fprintf(stderr, " mysql_stmt_init(), out of memory\n")
      exit(0);
    }
if (mysql_stmt_prepare(mysql, query, strlen(query)))
    { fprintf(stderr, " \n mysql_stmt_prepare(), INSERT failed"
      fprintf(stderr, " \n %s", mysql_stmt_error(stmt));
      exit(0);
    }

    /* set up input buffers for all 3 parameters */
    bind[0].buffer_type= MYSQL_TYPE_DATE;
    bind[0].buffer= (char *)&ts;
    bind[0].is_null= 0;
    bind[0].length= 0;
    ... 
    bind[1]= bind[2]= bind[0];
    ...
    mysql_stmt_bind_param(stmt, bind);

    /* supply the data to be sent in the ts structure */
    ts.year= 2002;
    ts.month= 02;
```
23.8.18 C API Prepared CALL Statement Support

This section describes prepared-statement support in the C API for stored procedures executed using `CALL` statements:

Stored procedures executed using prepared `CALL` statements can be used in the following ways:

- A stored procedure can produce any number of result sets. The number of columns and the data types of the columns need not be the same for all result sets.

- The final values of `OUT` and `INOUT` parameters are available to the calling application after the procedure returns. These parameters are returned as an extra single-row result set following any result sets produced by the procedure itself. The row contains the values of the `OUT` and `INOUT` parameters in the order in which they are declared in the procedure parameter list.

For information about the effect of unhandled conditions on procedure parameters, see Section 13.6.7.8, “Condition Handling and OUT or INOUT Parameters”.

The following discussion shows how to use these capabilities through the C API for prepared statements. To use prepared `CALL` statements through the `PREPARE` and `EXECUTE` statements, see Section 13.2.1, “CALL Syntax”.

An application that executes a prepared `CALL` statement should use a loop that fetches a result and then invokes `mysql_stmt_next_result()` to determine whether there are more results. The results consist of any result sets produced by the stored procedure followed by a final status value that indicates whether the procedure terminated successfully.

If the procedure has `OUT` or `INOUT` parameters, the result set preceding the final status value contains their values. To determine whether a result set contains parameter values, test whether the `SERVER_PS_OUT_PARAMS` bit is set in the `server_status` member of the `MYSQL` connection handler:

```c
mysql->server_status & SERVER_PS_OUT_PARAMS
```

The following example uses a prepared `CALL` statement to execute a stored procedure that produces multiple result sets and that provides parameter values back to the caller by means of `OUT` and `INOUT` parameters. The procedure takes parameters of all three types (`IN`, `OUT`, `INOUT`), displays their initial values, assigns new values, displays the updated values, and returns. The expected return information from the procedure therefore consists of multiple result sets and a final status:

- One result set from a `SELECT` that displays the initial parameter values: `10`, `NULL`, `30`. (The `OUT` parameter is assigned a value by the caller, but this assignment is expected to be ineffective: `OUT` parameters are seen as `NULL` within a procedure until assigned a value within the procedure.)

- One result set from a `SELECT` that displays the modified parameter values: `100`, `200`, `300`.

- One result set containing the final `OUT` and `INOUT` parameter values: `200`, `300`.

```c
ts.day= 03;
ts.hour= 10;
ts.minute= 45;
ts.second= 20;
mysql_stmt_execute(stmt);
```
C API Prepared CALL Statement Support

- A final status packet.

The code to execute the procedure:

```c
MYSQL_STMT *stmt;
MYSQL_BIND ps_params[3]; /* input parameter buffers */
int int_data[3]; /* input/output values */
my_bool is_null[3]; /* output value nullability */
int status;

/* set up stored procedure */
status = mysql_query(mysql, "DROP PROCEDURE IF EXISTS p1");
test_error(mysql, status);

status = mysql_query(mysql,
  "CREATE PROCEDURE p1("
  "  IN p_in INT, 
  "  OUT p_out INT, 
  "  INOUT p_inout INT) 
  "BEGIN 
  "  SELECT p_in, p_out, p_inout; 
  "  SET p_in = 100, p_out = 200, p_inout = 300; 
  "  SELECT p_in, p_out, p_inout; 
  "END");
test_error(mysql, status);

/* initialize and prepare CALL statement with parameter placeholders */
stmt = mysql_stmt_init(mysql);
if (!stmt)
{
    printf("Could not initialize statement\n");
    exit(1);
}
status = mysql_stmt_prepare(stmt, "CALL p1(?, ?, ?)", 16);
test_stmt_error(stmt, status);

/* initialize parameters: p_in, p_out, p_inout (all INT) */
memset(ps_params, 0, sizeof (ps_params));

ps_params[0].buffer_type = MYSQL_TYPE_LONG;
ps_params[0].buffer = (char *) &int_data[0];
ps_params[0].length = 0;
ps_params[0].is_null = 0;

ps_params[1].buffer_type = MYSQL_TYPE_LONG;
ps_params[1].buffer = (char *) &int_data[1];
ps_params[1].length = 0;
ps_params[1].is_null = 0;

ps_params[2].buffer_type = MYSQL_TYPE_LONG;
ps_params[2].buffer = (char *) &int_data[2];
ps_params[2].length = 0;
ps_params[2].is_null = 0;

/* bind parameters */
status = mysql_stmt_bind_param(stmt, ps_params);
test_stmt_error(stmt, status);

/* assign values to parameters and execute statement */
int_data[0] = 10; /* p_in */
int_data[1] = 20; /* p_out */
int_data[2] = 30; /* p_inout */
status = mysql_stmt_execute(stmt);
test_stmt_error(stmt, status);
```
/* process results until there are no more */
do {
    int num_fields;            /* number of columns in result */
    MYSQL_FIELD *fields;      /* for result set metadata */
    MYSQL_BIND *rs_bind;      /* for output buffers */

    /* the column count is > 0 if there is a result set */
    /* 0 if the result is only the final status packet */
    num_fields = mysql_stmt_field_count(stmt);

    if (num_fields > 0) {
        /* there is a result set to fetch */
        printf("Number of columns in result: %d\n", (int) num_fields);

        /* what kind of result set is this? */
        printf("Data: ");
        if(mysql->server_status & SERVER_PS_OUT_PARAMS)
            printf("this result set contains OUT/INOUT parameters\n");
        else
            printf("this result set is produced by the procedure\n");

        MYSQL_RES *rs_metadata = mysql_stmt_result_metadata(stmt);
        test_stmt_error(stmt, rs_metadata == NULL);
        fields = mysql_fetch_fields(rs_metadata);

        rs_bind = (MYSQL_BIND *) malloc(sizeof (MYSQL_BIND) * num_fields);
        if (!rs_bind)
            printf("Cannot allocate output buffers\n");
        else
            memset(rs_bind, 0, sizeof (MYSQL_BIND) * num_fields);

        /* set up and bind result set output buffers */
        for (i = 0; i < num_fields; ++i)
            rs_bind[i].buffer_type = fields[i].type;
        rs_bind[i].is_null = &is_null[i];

        switch (fields[i].type)
        { 
            case MYSQL_TYPE_LONG:
                rs_bind[i].buffer = (char *) &(int_data[i]);
                rs_bind[i].buffer_length = sizeof (int_data);
                break;
            default:
                fprintf(stderr, "ERROR: unexpected type: %d.\n", fields[i].type);
                exit(1);
        }
    }
    status = mysql_stmt_bind_result(stmt, rs_bind);
    test_stmt_error(stmt, status);

    /* fetch and display result set rows */
    while (1)
    { 
        status = mysql_stmt_fetch(stmt);

        if (status == 1 || status == MYSQL_NO_DATA)
            break;
        for (i = 0; i < num_fields; ++i)
C API Prepared CALL Statement Support

```c
{ switch (rs_bind[i].buffer_type)
{ case MYSQL_TYPE_LONG:
    if (*rs_bind[i].is_null)
        printf(" val[%d] = NULL;", i);
    else
        printf(" val[%d] = %ld;", i, (long) *((int *) rs_bind[i].buffer));
    break;
default:
    printf(" unexpected type (%d)\n", rs_bind[i].buffer_type);
    break;
}
}
printf("\n");

mysql_free_result(rs_metadata); /* free metadata */
free(rs_bind);                  /* free output buffers */
}
else
{ /* no columns = final status packet */
    printf("End of procedure output\n");
}

/* more results? -1 = no, >0 = error, 0 = yes (keep looking) */
status = mysql_stmt_next_result(stmt);
if (status > 0)
    test_stmt_error(stmt, status);
while (status == 0);

mysql_stmt_close(stmt);
```

Execution of the procedure should produce the following output:

```
Number of columns in result: 3
Data: this result set is produced by the procedure
Number of columns in result: 3
Data: this result set is produced by the procedure
  val[0] = 100; val[1] = 200; val[2] = 300;
Number of columns in result: 2
Data: this result set contains OUT/INOUT parameters
  val[0] = 200; val[1] = 300;
End of procedure output
```

The code uses two utility routines, `test_error()` and `test_stmt_error()`, to check for errors and terminate after printing diagnostic information if an error occurred:

```c
static void test_error(MYSQL *mysql, int status)
{
    if (status)
    {
        fprintf(stderr, "Error: %s (errno: %d)\n",
                mysql_error(mysql), mysql_errno(mysql));
        exit(1);
    }
}

static void test_stmt_error(MYSQL_STMT *stmt, int status)
{```
```
if (status)
{
  fprintf(stderr, "Error: %s (errno: %d)\n",
          mysql_stmt_error(stmt), mysql_stmt_errno(stmt));
  exit(1);
}

23.8.19 C API Prepared Statement Problems

Here follows a list of the currently known problems with prepared statements:

- TIME, TIMESTAMP, and DATETIME do not support parts of seconds (for example, from DATE_FORMAT()).

- When converting an integer to string, ZEROFILL is honored with prepared statements in some cases where the MySQL server does not print the leading zeros. (For example, with MIN(number-with-zerofill)).

- When converting a floating-point number to a string in the client, the rightmost digits of the converted value may differ slightly from those of the original value.

- Prepared statements use the query cache under the conditions described in Section 8.10.3.1, “How the Query Cache Operates”.

- Prepared statements do not support multi-statements (that is, multiple statements within a single string separated by ; characters).

- The capabilities of prepared CALL statements are described in Section 23.8.18, “C API Prepared CALL Statement Support”.

23.8.20 C API Automatic Reconnection Control

The MySQL client library can perform an automatic reconnection to the server if it finds that the connection is down when you attempt to send a statement to the server to be executed. If auto-reconnect is enabled, the library tries once to reconnect to the server and send the statement again.

Auto-reconnect is disabled by default.

If it is important for your application to know that the connection has been dropped (so that it can exit or take action to adjust for the loss of state information), be sure that auto-reconnect is disabled. To ensure this, call mysql_options() with the MYSQL_OPT_RECONNECT option:

```c
my_bool reconnect = 0;
mysql_options(&mysql, MYSQL_OPT_RECONNECT, &reconnect);
```

If the connection has gone down, the effect of mysql_ping() depends on the auto-reconnect state. If auto-reconnect is enabled, mysql_ping() performs a reconnect. Otherwise, it returns an error.

Some client programs might provide the capability of controlling automatic reconnection. For example, mysql reconnects by default, but the --skip-reconnect option can be used to suppress this behavior.

If an automatic reconnection does occur (for example, as a result of calling mysql_ping()), there is no explicit indication of it. To check for reconnection, call mysql_thread_id() to get the original connection identifier before calling mysql_ping(), then call mysql_thread_id() again to see whether the identifier changed.
Automatic reconnection can be convenient because you need not implement your own reconnect code, but if a reconnection does occur, several aspects of the connection state are reset on the server side and your application will not be notified.

The connection-related state is affected as follows:

- Any active transactions are rolled back and autocommit mode is reset.
- All table locks are released.
- All temporary tables are closed (and dropped).
- Session system variables are reinitialized to the values of the corresponding global system variables, including system variables that are set implicitly by statements such as `SET NAMES`.
- User variable settings are lost.
- Prepared statements are released.
- `@handler` variables are closed.
- The value of `LAST_INSERT_ID()` is reset to 0.
- Locks acquired with `GET_LOCK()` are released.
- The association of the client with the Performance Schema `threads` table row that determines connection thread instrumentation is lost. If the client reconnects after a disconnect, the session is associated with a new row in the `threads` table and the thread monitoring state may be different. See Section 22.12.10.3, “The threads Table”.

If reconnection occurs, any SQL statement specified by calling `mysql_options()` with the `MYSQL_INIT_COMMAND` option is re-executed.

If the connection drops, it is possible that the session associated with the connection on the server side will still be running if the server has not yet detected that the client is no longer connected. In this case, any locks held by the original connection still belong to that session, so you may want to kill it by calling `mysql_kill()`.

### 23.8.21 C API Common Issues

#### 23.8.21.1 Why `mysql_store_result()` Sometimes Returns NULL After `mysql_query()` Returns Success

It is possible for `mysql_store_result()` to return NULL following a successful call to `mysql_query()`. When this happens, it means one of the following conditions occurred:

- There was a `malloc()` failure (for example, if the result set was too large).
- The data could not be read (an error occurred on the connection).
- The query returned no data (for example, it was an `INSERT`, `UPDATE`, or `DELETE`).

You can always check whether the statement should have produced a nonempty result by calling `mysql_field_count()`. If `mysql_field_count()` returns zero, the result is empty and the last query was a statement that does not return values (for example, an `INSERT` or a `DELETE`). If `mysql_field_count()` returns a nonzero value, the statement should have produced a nonempty result. See the description of the `mysql_field_count()` function for an example.
You can test for an error by calling `mysql_error()` or `mysql_errno()`.

### 23.8.21.2 What Results You Can Get from a Query

In addition to the result set returned by a query, you can also get the following information:

- **mysql_affected_rows()** returns the number of rows affected by the last query when doing an INSERT, UPDATE, or DELETE.

  For a fast re-create, use TRUNCATE TABLE.

- **mysql_num_rows()** returns the number of rows in a result set. With `mysql_store_result()`, `mysql_num_rows()` may be called as soon as `mysql_store_result()` returns. With `mysql_use_result()`, `mysql_num_rows()` may be called only after you have fetched all the rows with `mysql_fetch_row()`.

- **mysql_insert_id()** returns the ID generated by the last query that inserted a row into a table with an AUTO_INCREMENT index. See Section 23.8.7.37, "mysql_insert_id()".

- Some queries (LOAD DATA, INSERT INTO ... SELECT, UPDATE) return additional information. The result is returned by `mysql_info()`. See the description for `mysql_info()` for the format of the string that it returns. `mysql_info()` returns a NULL pointer if there is no additional information.

### 23.8.21.3 How to Get the Unique ID for the Last Inserted Row

If you insert a record into a table that contains an AUTO_INCREMENT column, you can obtain the value stored into that column by calling the `mysql_insert_id()` function.

You can check from your C applications whether a value was stored in an AUTO_INCREMENT column by executing the following code (which assumes that you've checked that the statement succeeded). It determines whether the query was an INSERT with an AUTO_INCREMENT index:

```c
if ((result = mysql_store_result(&mysql)) == 0 &&
    mysql_field_count(&mysql) == 0 &&
    mysql_insert_id(&mysql) != 0) {
    used_id = mysql_insert_id(&mysql);
}
```

When a new AUTO_INCREMENT value has been generated, you can also obtain it by executing a SELECT LAST_INSERT_ID() statement with `mysql_query()` and retrieving the value from the result set returned by the statement.

When inserting multiple values, the last automatically incremented value is returned.

For LAST_INSERT_ID(), the most recently generated ID is maintained in the server on a per-connection basis. It is not changed by another client. It is not even changed if you update another AUTO_INCREMENT column with a nonmagic value (that is, a value that is not NULL and not 0). Using LAST_INSERT_ID() and AUTO_INCREMENT columns simultaneously from multiple clients is perfectly valid. Each client will receive the last inserted ID for the last statement that client executed.

If you want to use the ID that was generated for one table and insert it into a second table, you can use SQL statements like this:

```sql
INSERT INTO foo (auto,text) VALUES(NULL,'text');  # generate ID by inserting NULL
INSERT INTO foo2 (id,text)
```
VALUES(LAST_INSERT_ID(),'text');  # use ID in second table

mysql_insert_id() returns the value stored into an AUTO_INCREMENT column, whether that value is automatically generated by storing NULL or 0 or was specified as an explicit value. LAST_INSERT_ID() returns only automatically generated AUTO_INCREMENT values. If you store an explicit value other than NULL or 0, it does not affect the value returned by LAST_INSERT_ID().

For more information on obtaining the last ID in an AUTO_INCREMENT column:

- For information on LAST_INSERT_ID(), which can be used within an SQL statement, see Section 12.15, “Information Functions”.
- For information on mysql_insert_id(), the function you use from within the C API, see Section 23.8.7.37, “mysql_insert_id()”.
- For information on obtaining the auto-incremented value when using Connector/J, see Retrieving AUTO_INCREMENT Column Values through JDBC.
- For information on obtaining the auto-incremented value when using Connector/ODBC, see Obtaining Auto-Increment Values.

23.9 MySQL PHP API

The MySQL PHP API manual is now published in standalone form, not as part of the MySQL Reference Manual. See MySQL and PHP.

23.10 MySQL Perl API

The Perl DBI module provides a generic interface for database access. You can write a DBI script that works with many different database engines without change. To use DBI with MySQL, install the following:

1. The DBI module.
2. The DBD::mysql module. This is the DataBase Driver (DBD) module for Perl.
3. Optionally, the DBD module for any other type of database server you want to access.

Perl DBI is the recommended Perl interface. It replaces an older interface called mysqlperl, which should be considered obsolete.

These sections contain information about using Perl with MySQL and writing MySQL applications in Perl:

- For installation instructions for Perl DBI support, see Section 2.13, “Perl Installation Notes”.
- For an example of reading options from option files, see Section 5.7.4, “Using Client Programs in a Multiple-Server Environment”.
- For secure coding tips, see Section 6.1.1, “Security Guidelines”.
- For debugging tips, see Section 24.5.1.4, “Debugging mysqld under gdb”.
- For some Perl-specific environment variables, see Section 4.9, “MySQL Environment Variables”.
- For considerations for running on OS X, see Section 2.4, “Installing MySQL on OS X”.
- For ways to quote string literals, see Section 9.1.1, “String Literals”.

DBI information is available at the command line, online, or in printed form:
• Once you have the DBI and DBD::mysql modules installed, you can get information about them at the command line with the perldoc command:

```shell
shell> perldoc DBI
shell> perldoc DBI::FAQ
shell> perldoc DBD::mysql
```

You can also use pod2man, pod2html, and so on to translate this information into other formats.

• For online information about Perl DBI, visit the DBI website, http://dbi.perl.org/. That site hosts a general DBI mailing list.

• For printed information, the official DBI book is Programming the Perl DBI (Alligator Descartes and Tim Bunce, O'Reilly & Associates, 2000). Information about the book is available at the DBI website, http://dbi.perl.org/.

23.11 MySQL Python API

MySQLdb is a third-party driver that provides MySQL support for Python, compliant with the Python DB API version 2.0. It can be found at http://sourceforge.net/projects/mysql-python/.

The new MySQL Connector/Python component provides an interface to the same Python API, and is built into the MySQL Server and supported by Oracle. See MySQL Connector/Python Developer Guide for details on the Connector, as well as coding guidelines for Python applications and sample Python code.

23.12 MySQL Ruby APIs

Two APIs are available for Ruby programmers developing MySQL applications:

• The MySQL/Ruby API is based on the libmysqlclient API library. For information on installing and using the MySQL/Ruby API, see Section 23.12.1, “The MySQL/Ruby API”.

• The Ruby/MySQL API is written to use the native MySQL network protocol (a native driver). For information on installing and using the Ruby/MySQL API, see Section 23.12.2, “The Ruby/MySQL API”.

For background and syntax information about the Ruby language, see Ruby Programming Language.

23.12.1 The MySQL/Ruby API

The MySQL/Ruby module provides access to MySQL databases using Ruby through libmysqlclient.

For information on installing the module, and the functions exposed, see MySQL/Ruby.

23.12.2 The Ruby/MySQL API

The Ruby/MySQL module provides access to MySQL databases using Ruby through a native driver interface using the MySQL network protocol.

For information on installing the module, and the functions exposed, see Ruby/MySQL.

23.13 MySQL Tcl API

MySQLtcl is a simple API for accessing a MySQL database server from the Tcl programming language. It can be found at http://www.xdobry.de/mysqltcl/.
23.14 MySQL Eiffel Wrapper

Eiffel MySQL is an interface to the MySQL database server using the Eiffel programming language, written by Michael Ravits. It can be found at http://efsa.sourceforge.net/archive/ravits/mysql.htm.

24.1 MySQL Internals

This chapter describes what you need to know when working on the MySQL code. To track or contribute to MySQL development, follow the instructions in Section 2.9.5, “Installing MySQL Using a Development Source Tree”. If you are interested in MySQL internals, you should also join the MySQL Community Slack. Feel free to ask questions about the code and to send patches that you would like to contribute to the MySQL project!

24.1.1 MySQL Threads

The MySQL server creates the following threads:

- Connection manager threads handle client connection requests on the network interfaces that the server listens to. On all platforms, one manager thread handles TCP/IP connection requests. On Unix, this manager thread also handles Unix socket file connection requests. On Windows, a manager thread handles shared-memory connection requests, and another handles named-pipe connection requests. The server does not create threads to handle interfaces that it does not listen to. For example, a Windows server that does not have support for named-pipe connections enabled does not create a thread to handle them.

- Connection manager threads associate each client connection with a thread dedicated to it that handles authentication and request processing for that connection. Manager threads create a new thread when necessary but try to avoid doing so by consulting the thread cache first to see whether it contains a thread that can be used for the connection. When a connection ends, its thread is returned to the thread cache if the cache is not full.

For information about tuning the parameters that control thread resources, see Section 8.12.5.1, “How MySQL Handles Client Connections”.

- On a master replication server, connections from slave servers are handled like client connections: There is one thread per connected slave.
The MySQL Test Suite

On a slave replication server, an I/O thread is started to connect to the master server and read updates from it. An SQL thread is started to apply updates read from the master. These two threads run independently and can be started and stopped independently.

A signal thread handles all signals. This thread also normally handles alarms and calls `process_alarm()` to force timeouts on connections that have been idle too long.

If InnoDB is used, there will be additional read and write threads by default. The number of these are controlled by the `innodb_read_io_threads` and `innodb_write_io_threads` parameters. See Section 14.14, “InnoDB Startup Options and System Variables”.

If `mysqld` is compiled with `-DUSE_ALARM_THREAD`, a dedicated thread that handles alarms is created. This is only used on some systems where there are problems with `sigwait()` or if you want to use the `thr_alarm()` code in your application without a dedicated signal handling thread.

If the server is started with the `--flush_time=val` option, a dedicated thread is created to flush all tables every `val` seconds.

Each table for which `INSERT DELAYED` statements are issued gets its own thread. See Section 13.2.5.3, “INSERT DELAYED Syntax”.

If the event scheduler is active, there is one thread for the scheduler, and a thread for each event currently running. See Section 20.4.1, “Event Scheduler Overview”.

`mysqladmin processlist` only shows the connection, `INSERT DELAYED`, replication, and event threads.

24.1.2 The MySQL Test Suite

The test system that is included in Unix source and binary distributions makes it possible for users and developers to perform regression tests on the MySQL code. These tests can be run on Unix.

You can also write your own test cases. For information, including system requirements, see The MySQL Test Framework in the MySQL Server Doxygen documentation, available at https://dev.mysql.com/doc/index-other.html.

The current set of test cases does not test everything in MySQL, but it should catch most obvious bugs in the SQL processing code, operating system or library issues, and is quite thorough in testing replication. Our goal is to have the tests cover 100% of the code. We welcome contributions to our test suite. You may especially want to contribute tests that examine the functionality critical to your system because this ensures that all future MySQL releases work well with your applications.

The test system consists of a test language interpreter (`mysqltest`), a Perl script to run all tests (`mysql-test-run.pl`), the actual test cases written in a special test language, and their expected results. To run the test suite on your system after a build, type `make test` from the source root directory, or change location to the `mysql-test` directory and type `./mysql-test-run.pl`. If you have installed a binary distribution, change location to the `mysql-test` directory under the installation root directory (for example, `/usr/local/mysql/mysql-test`), and run `./mysql-test-run.pl`. All tests should succeed. If any do not, feel free to try to find out why and report the problem if it indicates a bug in MySQL. See Section 1.6, “How to Report Bugs or Problems”.

If one test fails, you should run `mysql-test-run.pl` with the `--force` option to check whether any other tests fail.

If you have a copy of `mysqld` running on the machine where you want to run the test suite, you do not have to stop it, as long as it is not using ports 9306 or 9307. If either of those ports is taken, you should
set the MTR_BUILD_THREAD environment variable to an appropriate value, and the test suite will use a different set of ports for master, slave, and NDB). For example:

```
shell> export MTR_BUILD_THREAD=31
shell> ./mysql-test-run.pl [options] [test_name]
```

In the mysql-test directory, you can run an individual test case with ./mysql-test-run.pl test_name.

If you have a question about the test suite, or have a test case to contribute, join the MySQL Community Slack.

### 24.2 The MySQL Plugin API

MySQL supports a plugin API that enables creation of server components. Plugins can be loaded at server startup, or loaded and unloaded at runtime without restarting the server. The API is generic and does not specify what plugins can do. The components supported by this interface include, but are not limited to, storage engines, full-text parser plugins, and server extensions.

For example, full-text parser plugins can be used to replace or augment the built-in full-text parser. A plugin can parse text into words using rules that differ from those used by the built-in parser. This can be useful if you need to parse text with characteristics different from those expected by the built-in parser.

The plugin interface is more general than the older user-defined function (UDF) interface.

The plugin interface uses the plugin table in the mysql database to record information about plugins that have been installed permanently with the INSTALL PLUGIN statement. This table is created as part of the MySQL installation process. Plugins can also be installed for a single server invocation with the --plugin-load option. Plugins installed this way are not recorded in the plugin table. See Section 5.5.1, “Installing and Uninstalling Plugins”.

MySQL supports an API for client plugins in addition to that for server plugins. This is used, for example, by authentication plugins where a server-side plugin and a client-side plugin cooperate to enable clients to connect to the server through a variety of authentication methods.

### Additional Resources

The book MySQL 5.1 Plugin Development by Sergei Golubchik and Andrew Hutchings provides a wealth of detail about the plugin API. Despite the fact that the book's title refers to MySQL Server 5.1, most of the information in it applies to later versions as well.

### 24.2.1 Types of Plugins

The plugin API enables creation of plugins that implement several capabilities:

- Storage engines
- Full-text parsers
- Daemons
- INFORMATION_SCHEMA tables
- Semisynchronous replication
- Auditing
- Authentication
• Password validation and strength checking

The following sections provide an overview of these plugin types.

• Storage Engine Plugins
• Full-Text Parser Plugins
• Daemon Plugins
• INFORMATION_SCHEMA Plugins
• Semisynchronous Replication Plugins
• Audit Plugins
• Authentication Plugins
• Password-Validation Plugins

Storage Engine Plugins

The pluggable storage engine architecture used by MySQL Server enables storage engines to be written as plugins and loaded into and unloaded from a running server. For a description of this architecture, see Section 15.11, “Overview of MySQL Storage Engine Architecture”.

For information on how to use the plugin API to write storage engines, see MySQL Internals: Writing a Custom Storage Engine.

Full-Text Parser Plugins

MySQL has a built-in parser that it uses by default for full-text operations (parsing text to be indexed, or parsing a query string to determine the terms to be used for a search). For full-text processing, “parsing” means extracting words from text or a query string based on rules that define which character sequences make up a word and where word boundaries lie.

When parsing for indexing purposes, the parser passes each word to the server, which adds it to a full-text index. When parsing a query string, the parser passes each word to the server, which accumulates the words for use in a search.

The parsing properties of the built-in full-text parser are described in Section 12.9, “Full-Text Search Functions”. These properties include rules for determining how to extract words from text. The parser is influenced by certain system variables such as ft_min_word_len and ft_max_word_len that cause words shorter or longer to be excluded, and by the stopword list that identifies common words to be ignored.

The plugin API enables you to provide a full-text parser of your own so that you have control over the basic duties of a parser. A parser plugin can operate in either of two roles:

• The plugin can replace the built-in parser. In this role, the plugin reads the input to be parsed, splits it up into words, and passes the words to the server (either for indexing or for word accumulation).

  One reason to use a parser this way is that you need to use different rules from those of the built-in parser for determining how to split up input into words. For example, the built-in parser considers the text “case-sensitive” to consist of two words “case” and “sensitive,” whereas an application might need to treat the text as a single word.

• The plugin can act in conjunction with the built-in parser by serving as a front end for it. In this role, the plugin extracts text from the input and passes the text to the parser, which splits up the text into words.
using its normal parsing rules. In particular, this parsing will be affected by the `ft_xxx` system variables and the stopword list.

One reason to use a parser this way is that you need to index content such as PDF documents, XML documents, or `.doc` files. The built-in parser is not intended for those types of input but a plugin can pull out the text from these input sources and pass it to the built-in parser.

It is also possible for a parser plugin to operate in both roles. That is, it could extract text from noncleartext input (the front end role), and also parse the text into words (thus replacing the built-in parser).

A full-text plugin is associated with full-text indexes on a per-index basis. That is, when you install a parser plugin initially, that does not cause it to be used for any full-text operations. It simply becomes available. For example, a full-text parser plugin becomes available to be named in a `WITH PARSER` clause when creating individual `FULLTEXT` indexes. To create such an index at table-creation time, do this:

```sql
CREATE TABLE t
(
  doc CHAR(255),
  FULLTEXT INDEX (doc) WITH PARSER my_parser
) ENGINE=MyISAM;
```

Or you can add the index after the table has been created:

```sql
ALTER TABLE t ADD FULLTEXT INDEX (doc) WITH PARSER my_parser;
```

The only SQL change for associating the parser with the index is the `WITH PARSER` clause. Searches are specified as before, with no changes needed for queries.

When you associate a parser plugin with a `FULLTEXT` index, the plugin is required for using the index. If the parser plugin is dropped, any index associated with it becomes unusable. Any attempt to use a table for which a plugin is not available results in an error, although `DROP TABLE` is still possible.

For more information about full-text plugins, see Section 24.2.4.4, “Writing Full-Text Parser Plugins”. MySQL 5.6 only supports full-text plugins with `MyISAM`.

### Daemon Plugins

A daemon plugin is a simple type of plugin used for code that should be run by the server but that does not communicate with it. MySQL distributions include an example daemon plugin that writes periodic heartbeat messages to a file.

For more information about daemon plugins, see Section 24.2.4.5, “Writing Daemon Plugins”.

### INFORMATION_SCHEMA Plugins

`INFORMATION_SCHEMA` plugins enable the creation of tables containing server metadata that are exposed to users through the `INFORMATION_SCHEMA` database. For example, `InnoDB` uses `INFORMATION_SCHEMA` plugins to provide tables that contain information about current transactions and locks.

For more information about `INFORMATION_SCHEMA` plugins, see Section 24.2.4.6, “Writing INFORMATION_SCHEMA Plugins”.

### Semisynchronous Replication Plugins

MySQL replication is asynchronous by default. With semisynchronous replication, a commit performed on the master side blocks before returning to the session that performed the transaction until at least one slave acknowledges that it has received and logged the events for the transaction. Semisynchronous
replication is implemented through complementary master and client plugins. See Section 17.3.9, “Semisynchronous Replication”.

For more information about semisynchronous replication plugins, see Section 24.2.4.7, “Writing Semisynchronous Replication Plugins”.

Audit Plugins

The MySQL server provides a pluggable audit interface that enables information about server operations to be reported to interested parties. Audit notification occurs for these operations (although the interface is general and the server could be modified to report others):

• Write a message to the general query log (if the log is enabled)
• Write a message to the error log
• Send a query result to a client

Audit plugins may register with the audit interface to receive notification about server operations. When an auditable event occurs within the server, the server determines whether notification is needed. For each registered audit plugin, the server checks the event against those event classes in which the plugin is interested and passes the event to the plugin if there is a match.

This interface enables audit plugins to receive notifications only about operations in event classes they consider significant and to ignore others. The interface provides for categorization of operations into event classes and further division into event subclasses within each class.

When an audit plugin is notified of an auditable event, it receives a pointer to the current THD structure and a pointer to a structure that contains information about the event. The plugin can examine the event and perform whatever auditing actions are appropriate. For example, the plugin can see what statement produced a result set or was logged, the number of rows in a result, who the current user was for an operation, or the error code for failed operations.

For more information about audit plugins, see Section 24.2.4.8, “Writing Audit Plugins”.

Authentication Plugins

MySQL supports pluggable authentication. Authentication plugins exist on both the server and client sides. Plugins on the server side implement authentication methods for use by clients when they connect to the server. A plugin on the client side communicates with a server-side plugin to provide the authentication information that it requires. A client-side plugin may interact with the user, performing tasks such as soliciting a password or other authentication credentials to be sent to the server. See Section 6.2.11, “Pluggable Authentication”.

Pluggable authentication also enables proxy user capability, in which one user takes the identity of another user. A server-side authentication plugin can return to the server the name of the user whose identity the connecting user should have. See Section 6.2.12, “Proxy Users”.

For more information about authentication plugins, see Section 24.2.4.9, “Writing Authentication Plugins”.

Password-Validation Plugins

The server provides an interface for writing plugins that test passwords. Such a plugin implements two capabilities:

• Rejection of too-weak passwords in statements that assign passwords (such as CREATE USER, GRANT, and SET PASSWORD statements), and passwords given as arguments to the PASSWORD() and OLD_PASSWORD() functions.
• Assessing the strength of potential passwords for the \texttt{VALIDATE\_PASSWORD\_STRENGTH()} SQL function.

For information about writing this type of plugin, see Section 24.2.4.10, “Writing Password-Validation Plugins”.

### 24.2.2 Plugin API Characteristics

The server plugin API has these characteristics:

- All plugins have several things in common.

  Each plugin has a name that it can be referred to in SQL statements, as well as other metadata such as an author and a description that provide other information. This information can be examined in the \texttt{INFORMATION\_SCHEMA.PLUGINS} table or using the \texttt{SHOW PLUGINS} statement.

- The plugin framework is extendable to accommodate different kinds of plugins.

  Although some aspects of the plugin API are common to all types of plugins, the API also permits type-specific interface elements so that different types of plugins can be created. A plugin with one purpose can have an interface most appropriate to its own requirements and not the requirements of some other plugin type.

  Interfaces for several types of plugins exist, such as storage engines, full-text parser, and \texttt{INFORMATION\_SCHEMA} tables. Others can be added.

- Plugins can expose information to users.

  A plugin can implement system and status variables that are available through the \texttt{SHOW VARIABLES} and \texttt{SHOW STATUS} statements.

- The plugin API includes versioning information.

  The version information included in the plugin API enables a plugin library and each plugin that it contains to be self-identifying with respect to the API version that was used to build the library. If the API changes over time, the version numbers will change, but a server can examine a given plugin library’s version information to determine whether it supports the plugins in the library.

  There are two types of version numbers. The first is the version for the general plugin framework itself. Each plugin library includes this kind of version number. The second type of version applies to individual plugins. Each specific type of plugin has a version for its interface, so each plugin in a library has a type-specific version number. For example, a library containing a full-text parser plugin has a general plugin API version number, and the plugin has a version number specific to the full-text plugin interface.

- The plugin API implements security restrictions.

  A plugin library must be installed in a specific dedicated directory for which the location is controlled by the server and cannot be changed at runtime. Also, the library must contain specific symbols that identify it as a plugin library. The server will not load something as a plugin if it was not built as a plugin.

- Plugins have access to server services.

  The services interface exposes server functionality that plugins can access using ordinary function calls. For details, see Section 24.3, “MySQL Services for Plugins”.

In some respects, the server plugin API is similar to the older user-defined function (UDF) API that it supersedes, but the plugin API has several advantages over the older interface. For example, UDFs had
no versioning information. Also, the newer plugin interface eliminates the security issues of the older UDF interface. The older interface for writing nonplugin UDFs permitted libraries to be loaded from any directory searched by the system's dynamic linker, and the symbols that identified the UDF library were relatively nonspecific.

The client plugin API has similar architectural characteristics, but client plugins have no direct access to the server the way server plugins do.

### 24.2.3 Plugin API Components

The server plugin implementation comprises several components.

**SQL statements:**

- **INSTALL PLUGIN** registers a plugin in the `mysql.plugin` table and loads the plugin code.
- **UNINSTALL PLUGIN** unregisters a plugin from the `mysql.plugin` table and unloads the plugin code.
- The **WITH PARSER** clause for full-text index creation associates a full-text parser plugin with a given **FULLTEXT** index.
- **SHOW PLUGINS** displays information about server plugins.

**Command-line options and system variables:**

- The **--plugin-load** option enables plugins to be loaded at server startup time.
- The **plugin_dir** system variable indicates the location of the directory where all plugins must be installed. The value of this variable can be specified at server startup with a **--plugin_dir=dir_name** option. `mysql_config --plugindir` displays the default plugin directory path name.

For additional information about plugin loading, see Section 5.5.1, “Installing and Uninstalling Plugins”.

**Plugin-related tables:**

- The **INFORMATION_SCHEMA.PLUGINS** table contains plugin information.
- The **mysql.plugin** table lists each plugin that was installed with **INSTALL PLUGIN** and is required for plugin use. For new MySQL installations, this table is created during the installation process.

The client plugin implementation is simpler:

- For the **mysql_options() C API function**, the **MYSQL_DEFAULT_AUTH** and **MYSQL_PLUGIN_DIR** options enable client programs to load authentication plugins.
- There are **C API functions** that enable management of client plugins.

To examine how MySQL implements plugins, consult the following source files in a MySQL source distribution:

- In the **include/mysql** directory, **plugin.h** exposes the public plugin API. This file should be examined by anyone who wants to write a plugin library. **plugin_xxx.h** files provide additional information that pertains to specific types of plugins. **client_plugin.h** contains information specific to client plugins.
- In the **sql** directory, **sql_plugin.h** and **sql_plugin.cc** comprise the internal plugin implementation. **sql_acl.cc** is where the server uses authentication plugins. These files need not be consulted by plugin developers. They may be of interest for those who want to know more about how the server handles plugins.
In the sql-common directory, client_plugin.h implements the C API client plugin functions, and client.c implements client authentication support. These files need not be consulted by plugin developers. They may be of interest for those who want to know more about how the server handles plugins.

### 24.2.4 Writing Plugins

To create a plugin library, you must provide the required descriptor information that indicates what plugins the library file contains, and write the interface functions for each plugin.

Every server plugin must have a general descriptor that provides information to the plugin API, and a type-specific descriptor that provides information about the plugin interface for a given type of plugin. The structure of the general descriptor is the same for all plugin types. The structure of the type-specific descriptor varies among plugin types and is determined by the requirements of what the plugin needs to do. The server plugin interface also enables plugins to expose status and system variables. These variables become visible through the `SHOW STATUS` and `SHOW VARIABLES` statements and the corresponding INFORMATION_SCHEMA tables.

For client-side plugins, the architecture is a bit different. Each plugin must have a descriptor, but there is no division into separate general and type-specific descriptors. Instead, the descriptor begins with a fixed set of members common to all client plugin types, and the common members are followed by any additional members required to implement the specific plugin type.

You can write plugins in C or C++ (or another language that can use C calling conventions). Plugins are loaded and unloaded dynamically, so your operating system must support dynamic loading and you must have compiled the calling application dynamically (not statically). For server plugins, this means that mysqld must be linked dynamically.

A server plugin contains code that becomes part of the running server, so when you write the plugin, you are bound by any and all constraints that otherwise apply to writing server code. For example, you may have problems if you attempt to use functions from the libstdc++ library. These constraints may change in future versions of the server, so it is possible that server upgrades will require revisions to plugins originally written for older servers. For information about these constraints, see Section 2.9.7, “MySQL Source-Configuration Options”, and Section 2.9.8, “Dealing with Problems Compiling MySQL”.

Client plugin writers should avoid dependencies on what symbols the calling application has because you cannot be sure what applications will use the plugin.

#### 24.2.4.1 Overview of Plugin Writing

The following procedure provides an overview of the steps needed to create a plugin library. The next sections provide additional details on setting plugin data structures and writing specific types of plugins.

1. In the plugin source file, include the header files that the plugin library needs. The plugin.h file is required, and the library might require other files as well. For example:

   ```
   #include <stdlib.h>
   #include <ctype.h>
   #include <mysql/plugin.h>
   ```

2. Set up the descriptor information for the plugin library file. For server plugins, write the library descriptor, which must contain the general plugin descriptor for each server plugin in the file. For more information, see Server Plugin Library and Plugin Descriptors. In addition, set up the type-specific descriptor for each server plugin in the library. Each plugin's general descriptor points to its type-specific descriptor.

   For client plugins, write the client descriptor. For more information, see Client Plugin Descriptors.
3. Write the plugin interface functions for each plugin. For example, each plugin's general plugin descriptor points to the initialization and deinitialization functions that the server should invoke when it loads and unloads the plugin. The plugin's type-specific description may also point to interface functions.

4. For server plugins, set up the status and system variables, if there are any.

5. Compile the plugin library as a shared library and install it in the plugin directory. For more information, see Section 24.2.4.3, “Compiling and Installing Plugin Libraries”.

6. For server plugins, register the plugin with the server. For more information, see Section 5.5.1, “Installing and Uninstalling Plugins”.

7. Test the plugin to verify that it works properly.

24.2.4.2 Plugin Data Structures

A plugin library file includes descriptor information to indicate what plugins it contains.

If the plugin library contains any server plugins, it must include the following descriptor information:

- A library descriptor indicates the general server plugin API version number used by the library and contains a general plugin descriptor for each server plugin in the library. To provide the framework for this descriptor, invoke two macros from the plugin.h header file:

```c
mysql_declare_plugin(name)
   ... one or more server plugin descriptors here ...
mysql_declare_plugin_end;
```

The macros expand to provide a declaration for the API version automatically. You must provide the plugin descriptors.

- Within the library descriptor, each general server plugin is described by a st_mysql_plugin structure. This plugin descriptor structure contains information that is common to every type of server plugin: A value that indicates the plugin type; the plugin name, author, description, and license type; pointers to the initialization and deinitialization functions that the server invokes when it loads and unloads the plugin, and pointers to any status or system variables the plugin implements.

- Each general server plugin descriptor within the library descriptor also contains a pointer to a type-specific plugin descriptor. The structure of the type-specific descriptors varies from one plugin type to another because each type of plugin can have its own API. A type-specific plugin descriptor contains a type-specific API version number and pointers to the functions that are needed to implement that plugin type. For example, a full-text parser plugin has initialization and deinitialization functions, and a main parsing function. The server invokes these functions when it uses the plugin to parse text.

The plugin library also contains the interface functions that are referenced by the general and type-specific descriptors for each plugin in the library.

If the plugin library contains a client plugin, it must include a descriptor for the plugin. The descriptor begins with a fixed set of members common to all client plugins, followed by any members specific to the plugin type. To provide the descriptor framework, invoke two macros from the client_plugin.h header file:

```c
mysql_declare_client_plugin(plugin_type)
   ... members common to all client plugins ...
   ... type-specific extra members ...
mysql_end_client_plugin;
```

The plugin library also contains any interface functions referenced by the client descriptor.
The `mysql_declare_plugin()` and `mysql_declare_client_plugin()` macros differ somewhat in how they can be invoked, which has implications for the contents of plugin libraries. The following guidelines summarize the rules:

- `mysql_declare_plugin()` and `mysql_declare_client_plugin()` can both be used in the same source file, which means that a plugin library can contain both server and client plugins. However, each of `mysql_declare_plugin()` and `mysql_declare_client_plugin()` can be used at most once.

- `mysql_declare_plugin()` permits multiple server plugin declarations, so a plugin library can contain multiple server plugins.

- `mysql_declare_client_plugin()` permits only a single client plugin declaration. To create multiple client plugins, separate plugin libraries must be used.

When a client program looks for a client plugin that is in a plugin library and not built into `libmysqlclient`, it looks for a file with a base name that is the same as the plugin name. For example, if a program needs to use a client authentication plugin named `auth_xxx` on a system that uses `.so` as the library suffix, it looks in the file named `auth_xxx.so`. (On OS X, the program looks first for `auth_xxx.dylib`, then for `auth_xxx.so`.) For this reason, if a plugin library contains a client plugin, the library must have the same base name as that plugin.

The same is not true for a library that contains server plugins. The `--plugin-load` option and the `INSTALL PLUGIN` statement provide the library file name explicitly, so there need be no explicit relationship between the library name and the name of any server plugins it contains.

### Server Plugin Library and Plugin Descriptors

Every plugin library that contains server plugins must include a library descriptor that contains the general plugin descriptor for each server plugin in the file. This section discusses how to write the library and general descriptors for server plugins.

The library descriptor must define two symbols:

- `_mysql_plugin_interface_version_` specifies the version number of the general plugin framework. This is given by the `MYSQL_PLUGIN_INTERFACE_VERSION` symbol, which is defined in the `plugin.h` file.

- `_mysql_plugin_declarations_` defines an array of plugin declarations, terminated by a declaration with all members set to 0. Each declaration is an instance of the `st_mysql_plugin` structure (also defined in `plugin.h`). There must be one of these for each server plugin in the library.

If the server does not find those two symbols in a library, it does not accept it as a legal plugin library and rejects it with an error. This prevents use of a library for plugin purposes unless it was built specifically as a plugin library.

The conventional way to define the two required symbols is by using the `mysql_declare_plugin()` and `mysql_declare_plugin_end` macros from the `plugin.h` file:

```c
mysql_declare_plugin(name)
  ... one or more server plugin descriptors here ... 
mysql_declare_plugin_end;
```

Each server plugin must have a general descriptor that provides information to the server plugin API. The general descriptor has the same structure for all plugin types. The `st_mysql_plugin` structure in the `plugin.h` file defines this descriptor:
The `st_mysql_plugin` descriptor structure members are used as follows. `char *` members should be specified as null-terminated strings.

- **type**: The plugin type. This must be one of the plugin-type values from `plugin.h`:

  ```
  /*
   * The allowable types of plugins
   */
  #define MYSQL_UDF_PLUGIN    0 /* User-defined function */
  #define MYSQL_STORAGE_ENGINE_PLUGIN 1 /* Storage Engine */
  #define MYSQL_FTPARSER_PLUGIN 2 /* Full-text parser plugin */
  #define MYSQL_DAEMON_PLUGIN 3 /* The daemon/raw plugin type */
  #define MYSQL_INFORMATION_SCHEMA_PLUGIN 4 /* The I_S plugin type */
  #define MYSQL_AUDIT_PLUGIN 5 /* The Audit plugin type */
  #define MYSQL_REPLICATION_PLUGIN 6 /* The replication plugin type */
  #define MYSQL_AUTHENTICATION_PLUGIN 7 /* The authentication plugin type */
  ...
  ```

  For example, for a full-text parser plugin, the `type` value is `MYSQL_FTPARSER_PLUGIN`.

- **info**: A pointer to the type-specific descriptor for the plugin. This descriptor’s structure depends on the particular type of plugin, unlike that of the general plugin descriptor structure. For version-control purposes, the first member of the type-specific descriptor for every plugin type is expected to be the interface version for the type. This enables the server to check the type-specific version for every plugin no matter its type. Following the version number, the descriptor includes any other members needed, such as callback functions and other information needed by the server to invoke the plugin properly. Later sections on writing particular types of server plugins describe the structure of their type-specific descriptors.

- **name**: A string that gives the plugin name. This is the name that will be listed in the `mysql.plugin` table and by which you refer to the plugin in SQL statements such as `INSTALL PLUGIN` and `UNINSTALL PLUGIN`, or with the `--plugin-load` option. The name is also visible in the `INFORMATION_SCHEMA.PLUGINS` table or the output from `SHOW PLUGINS`.

  The plugin name should not begin with the name of any server option. If it does, the server will fail to initialize it. For example, the server has a `--socket` option, so you should not use a plugin name such as `socket`, `socket_plugin`, and so forth.

- **author**: A string naming the plugin author. This can be whatever you like.

- **desc**: A string that provides a general description of the plugin. This can be whatever you like.

- **license**: The plugin license type. The value can be one of `PLUGIN_LICENSE_PROPRIETARY`, `PLUGIN_LICENSE_GPL`, or `PLUGIN_LICENSE_BSD`. 

```c
struct st_mysql_plugin
{
    int type;             /* the plugin type (a MYSQL_XXX_PLUGIN value) */
    void *info;           /* pointer to type-specific plugin descriptor */
    const char *name;     /* plugin name */
    const char *author;   /* plugin author (for I_S.PLUGINS) */
    const char *descr;    /* general descriptive text (for I_S.PLUGINS) */
    int license;          /* the plugin license (PLUGIN_LICENSE_XXX) */
    int (*init)(void *);  /* the function to invoke when plugin is loaded */
    int (*deinit)(void *);/* the function to invoke when plugin is unloaded */
    unsigned int version; /* plugin version (for I_S.PLUGINS) */
    struct st_mysql_show_var *status_vars;
    struct st_mysql_sys_var **system_vars;
    void *__reserved1;   /* reserved for dependency checking */
    unsigned long flags;  /* flags for plugin */
};
```
Writing Plugins

- **init**: A once-only initialization function, or `NULL` if there is no such function. The server executes this function when it loads the plugin, which happens for `INSTALL PLUGIN` or, for plugins listed in the `mysql.plugin` table, at server startup. The function takes one argument that points to the internal structure used to identify the plugin. It returns zero for success and nonzero for failure.

- **deinit**: A once-only deinitialization function, or `NULL` if there is no such function. The server executes this function when it unloads the plugin, which happens for `UNINSTALL PLUGIN` or, for plugins listed in the `mysql.plugin` table, at server shutdown. The function takes one argument that points to the internal structure used to identify the plugin. It returns zero for success and nonzero for failure.

- **version**: The plugin version number. When the plugin is installed, this value can be retrieved from the `INFORMATION_SCHEMA.PLUGINS` table. The value includes major and minor numbers. If you write the value as a hex constant, the format is `0xMMNN`, where `MM` and `NN` are the major and minor numbers, respectively. For example, `0x0302` represents version 3.2.

- **status_vars**: A pointer to a structure for status variables associated with the plugin, or `NULL` if there are no such variables. When the plugin is installed, these variables are displayed in the output of the `SHOW STATUS` statement.

  The `status_vars` member, if not `NULL`, points to an array of `st_mysql_show_var` structures that describe status variables. See Server Plugin Status and System Variables.

- **system_vars**: A pointer to a structure for system variables associated with the plugin, or `NULL` if there are no such variables. These options and system variables can be used to help initialize variables within the plugin. When the plugin is installed, these variables are displayed in the output of the `SHOW VARIABLES` statement.

  The `system_vars` member, if not `NULL`, points to an array of `st_mysql_sys_var` structures that describe system variables. See Server Plugin Status and System Variables.

- **__reserved1**: A placeholder for the future. It should be set to `NULL`.

- **flags**: Plugin flags. Individual bits correspond to different flags. The value should be set to the OR of the applicable flags. These flags are available:

  ```
  #define PLUGIN_OPT_NO_INSTALL 1UL   /* Not dynamically loadable */
  #define PLUGIN_OPT_NO_UNINSTALL 2UL   /* Not dynamically unloadable */
  ```

  The flags have the following meanings when enabled:

  - **PLUGIN_OPT_NO_INSTALL**: The plugin cannot be loaded at runtime with the `INSTALL PLUGIN` statement. This is appropriate for plugins that must be loaded at server startup with the `--plugin-load` or `--plugin-load-add` option.

  - **PLUGIN_OPT_NO_UNINSTALL**: The plugin cannot be unloaded at runtime with the `UNINSTALL PLUGIN` statement.

  The server invokes the `init` and `deinit` functions in the general plugin descriptor only when loading and unloading the plugin. They have nothing to do with use of the plugin such as happens when an SQL statement causes the plugin to be invoked.

  For example, the descriptor information for a library that contains a single full-text parser plugin named `simple_parser` looks like this:

  ```
  mysql_declare_plugin(ftexample)
  ```
Writing Plugins

For a full-text parser plugin, the type must be `MYSQL_FTPARSER_PLUGIN`. This is the value that identifies the plugin as being legal for use in a `WITH PARSER` clause when creating a `FULLTEXT` index. (No other plugin type is legal for this clause.)

`plugin.h` defines the `mysql_declare_plugin()` and `mysql_declare_plugin_end` macros like this:

```c
#define mysql_declare_plugin(NAME) \
__MYSQL_DECLARE_PLUGIN(NAME, \ 
builtin_ ## NAME _plugin_interface_version, \ 
builtin_ ## NAME _sizeof_struct_st_plugin, \ 
builtin_ ## NAME _plugin)
#define mysql_declare_plugin_end ,{0,0,0,0,0,0,0,0,0,0,0,0,0})
```

### Note

Those declarations define the `__mysql_plugin_interface_version_` symbol only if the `MYSQL_DYNAMIC_PLUGIN` symbol is defined. This means that `-DMYSQL_DYNAMIC_PLUGIN` must be provided as part of the compilation command to build the plugin as a shared library.

When the macros are used as just shown, they expand to the following code, which defines both of the required symbols (`__mysql_plugin_interface_version_` and `__mysql_plugin_declarations_`):

```c
int __mysql_plugin_interface_version_= MYSQL_PLUGIN_INTERFACE_VERSION;
int __mysql_sizeof_struct_st_plugin_= sizeof(struct st_mysql_plugin);
struct st_mysql_plugin __mysql_plugin_declarations_[]= {
    
    MYSQL_FTPARSER_PLUGIN,      /* type                            */
    &simple_parser_descriptor,  /* descriptor                      */
    "simple_parser",            /* name                            */
    "Oracle Corporation",       /* author                          */
    "Simple Full-Text Parser",  /* description                     */
    PLUGIN_LICENSE_GPL,         /* plugin license                  */
    simple_parser_plugin_init,  /* init function (when loaded)    */
    simple_parser_plugin_deinit,/* deinit function (when unloaded)  */
    0x0001,                     /* version                         */
    NULL,
    0
};
```
The preceding example declares a single plugin in the general descriptor, but it is possible to declare multiple plugins. List the declarations one after the other between `mysql_declare_plugin()` and `mysql_declare_plugin_end`, separated by commas.

MySQL server plugins can be written in C or C++ (or another language that can use C calling conventions). If you write a C++ plugin, one C++ feature that you should not use is nonconstant variables to initialize global structures. Members of structures such as the `st_mysql_plugin` structure should be initialized only with constant variables. The `simple_parser` descriptor shown earlier is permissible in a C++ plugin because it satisfies that requirement:

```c

mysql_declare_plugin(ftexample)
{
  MYSQL_FTPARSER_PLUGIN,      /* type                            */
  &simple_parser_descriptor,  /* descriptor                      */
  "simple_parser",            /* name                            */
  "Oracle Corporation",       /* author                          */
  "Simple Full-Text Parser",  /* description                     */
  PLUGIN_LICENSE_GPL,         /* plugin license                  */
  simple_parser_plugin_init,  /* init function (when loaded)     */
  simple_parser_plugin_deinit,/* deinit function (when unloaded) */
  0x0001,                     /* version                         */
  NULL,                      /* status variables                */
  simple_system_variables,    /* system variables                */
  0
}
```

Here is another valid way to write the general descriptor. It uses constant variables to indicate the plugin name, author, and description:

```c

const char *simple_parser_name = "simple_parser";
const char *simple_parser_author = "Oracle Corporation";
const char *simple_parser_description = "Simple Full-Text Parser";

mysql_declare_plugin(ftexample)
{
  MYSQL_FTPARSER_PLUGIN,      /* type                            */
  &simple_parser_descriptor,  /* descriptor                      */
  simple_parser_name,         /* name                            */
  simple_parser_author,       /* author                          */
  simple_parser_description,  /* description                     */
  PLUGIN_LICENSE_GPL,         /* plugin license                  */
  simple_parser_plugin_init,  /* init function (when loaded)     */
  simple_parser_plugin_deinit,/* deinit function (when unloaded) */
  0x0001,                     /* version                         */
  NULL,                      /* status variables                */
  simple_system_variables,    /* system variables                */
  0
}
```
However, the following general descriptor is invalid. It uses structure members to indicate the plugin name, author, and description, but structures are not considered constant initializers in C++:

```c
typedef struct
{
    const char *name;
    const char *author;
    const char *description;
} plugin_info;

plugin_info parser_info = {
    "simple_parser",
    "Oracle Corporation",
    "Simple Full-Text Parser"
};

mysql_declare_plugin(ftexample)
{
    MYSQL_FTPARSER_PLUGIN,     /* type                            */
    &simple_parser_descriptor,  /* descriptor                      */
    parser_info.name,           /* name                            */
    parser_info.author,         /* author                          */
    parser_info.description,    /* description                     */
    PLUGIN_LICENSE_GPL,         /* plugin license                  */
    simple_parser_plugin_init,  /* init function (when loaded)     */
    simple_parser_plugin_deinit,/* deinit function (when unloaded)   */
    0x0001,                      /* version                         */
    simple_status,              /* status variables                */
    simple_system_variables,    /* system variables                */
    NULL,
    0
};
mysql_declare_plugin_end;
```

**Server Plugin Status and System Variables**

The server plugin interface enables plugins to expose status and system variables using the `status_vars` and `system_vars` members of the general plugin descriptor.

The `status_vars` member of the general plugin descriptor, if not 0, points to an array of `st_mysql_show_var` structures, each of which describes one status variable, followed by a structure with all members set to 0. The `st_mysql_show_var` structure has this definition:

```c
struct st_mysql_show_var {
    const char *name;
    char *value;
    enum enum_mysql_show_type type;
};
```

The following table shows the permissible status variable type values and what the corresponding variable should be.

**Table 24.1 Server Plugin Status Variable Types**

<table>
<thead>
<tr>
<th>Variable Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>SHOW_BOOL</td>
<td>Pointer to a boolean variable</td>
</tr>
<tr>
<td>SHOW_INT</td>
<td>Pointer to an integer variable</td>
</tr>
</tbody>
</table>
Variable Type | Meaning
---|---
SHOW_LONG | Pointer to a long integer variable
SHOW_LONGLONG | Pointer to a longlong integer variable
SHOW_CHAR | A string
SHOW_CHAR_PTR | Pointer to a string
SHOW_ARRAY | Pointer to another `st_mysql_show_var` array
SHOW_FUNC | Pointer to a function
SHOW_DOUBLE | Pointer to a double

For the `SHOW_FUNC` type, the function is called and fills in its `out` parameter, which then provides information about the variable to be displayed. The function has this signature:

```c
#define SHOW_VAR_FUNC_BUFF_SIZE 1024
typedef int (*mysql_show_var_func) (void *thd,
                                        struct st_mysql_show_var *out,
                                        char *buf);
```

The `system_vars` member, if not 0, points to an array of `st_mysql_sys_var` structures, each of which describes one system variable (which can also be set from the command-line or configuration file), followed by a structure with all members set to 0. The `st_mysql_sys_var` structure is defined as follows:

```c
struct st_mysql_sys_var {
    int flags;
    const char *name, *comment;
    int (*check)(THD*, struct st_mysql_sys_var *, void*, st_mysql_value*);
    void (*update)(THD*, struct st_mysql_sys_var *, void*, const void*);
};
```

Additional fields are append as required depending upon the flags.

For convenience, a number of macros are defined that make creating new system variables within a plugin much simpler.

Throughout the macros, the following fields are available:

- `name`: An unquoted identifier for the system variable.
- `varname`: The identifier for the static variable. Where not available, it is the same as the `name` field.
- `opt`: Additional use flags for the system variable. The following table shows the permissible flags.

### Table 24.2 Server Plugin System Variable Flags

<table>
<thead>
<tr>
<th>Flag Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PLUGIN_VAR_READONLY</td>
<td>The system variable is read only</td>
</tr>
<tr>
<td>PLUGIN_VAR_NOSYSSVAR</td>
<td>The system variable is not user visible at runtime</td>
</tr>
<tr>
<td>PLUGIN_VAR_NOCMDOPT</td>
<td>The system variable is not configurable from the command line</td>
</tr>
<tr>
<td>PLUGIN_VAR_NOCMDARG</td>
<td>No argument is required at the command line (typically used for boolean variables)</td>
</tr>
<tr>
<td>PLUGIN_VAR_RQMCDARG</td>
<td>An argument is required at the command line (this is the default)</td>
</tr>
<tr>
<td>PLUGIN_VAR_OPCMDARG</td>
<td>An argument is optional at the command line</td>
</tr>
<tr>
<td>Flag Value</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>PLUGIN_VAR_MEMALLOC</td>
<td>Used for string variables; indicates that memory is to be allocated for storage of the string</td>
</tr>
</tbody>
</table>

- **comment**: A descriptive comment to be displayed in the server help message. **NULL** if this variable is to be hidden.

- **check**: The check function, **NULL** for default.

- **update**: The update function, **NULL** for default.

- **default**: The variable default value.

- **minimum**: The variable minimum value.

- **maximum**: The variable maximum value.

- **blocksize**: The variable block size. When the value is set, it is rounded to the nearest multiple of **blocksize**.

A system variable may be accessed either by using the static variable directly or by using the **SYSVAR()** accessor macro. The **SYSVAR()** macro is provided for completeness. Usually it should be used only when the code cannot directly access the underlying variable.

For example:

```c
static int my_foo;
static MYSQL_SYSVAR_INT(foo_var, my_foo,
                        PLUGIN_VAR_RQCMDARG, "foo comment",
                        NULL, NULL, 0, 0, INT_MAX, 0);
...
SYSVAR(foo_var)= value;
value= SYSVAR(foo_var);
my_foo= value;
value= my_foo;
```

Session variables may be accessed only through the **THDVAR()** accessor macro. For example:

```c
static MYSQL_THDVAR_BOOL(some_flag,
                        PLUGIN_VAR_NOCMDARG, "flag comment",
                        NULL, NULL, FALSE);
...
if (THDVAR(thd, some_flag))
{
  do_something();
  THDVAR(thd, some_flag)= FALSE;
}
```

All global and session system variables must be published to **mysql** before use. This is done by constructing a **NULL**-terminated array of the variables and linking to it in the plugin public interface. For example:

```c
static struct st_mysql_sys_var *my_plugin_vars[]= {
  MYSQL_SYSVAR(foo_var),
  MYSQL_SYSVAR(some_flag),
  NULL
};
mysql_declare_plugin(fooplug)
```
MYSQL_.PLUGIN,
4plugin_data,
"fooplugin",
"foo author",
"This does foo!",
PLUGIN_LICENSE_GPL,
foo_init,
foo_fini,
0x0001,
NULL,
my_plugin_vars,
NULL,
0
}mysql_declare_plugin_end;

The following convenience macros enable you to declare different types of system variables:

- **Boolean system variables** of type `my_bool`, which is a 1-byte boolean. (0 = FALSE, 1 = TRUE)

```c
MYSQL_THDVAR_BOOL(name, opt, comment, check, update, default)
MYSQL_SYSVAR_BOOL(name, varname, opt, comment, check, update, default)
```

- **String system variables** of type `char*`, which is a pointer to a null-terminated string.

```c
MYSQL_THDVAR_STR(name, opt, comment, check, update, default)
MYSQL_SYSVAR_STR(name, varname, opt, comment, check, update, default)
```

- **Integer system variables**, of which there are several varieties.

  - **An int** system variable, which is typically a 4-byte signed word.

```c
MYSQL_THDVAR_INT(name, opt, comment, check, update, default, min, max, blk)
MYSQL_SYSVAR_INT(name, varname, opt, comment, check, update, default,
minimum, maximum, blocksize)
```

  - **An unsigned int** system variable, which is typically a 4-byte unsigned word.

```c
MYSQL_THDVAR_UINT(name, opt, comment, check, update, default, min, max, blk)
MYSQL_SYSVAR_UINT(name, varname, opt, comment, check, update, default,
minimum, maximum, blocksize)
```

  - **A long** system variable, which is typically either a 4- or 8-byte signed word.

```c
MYSQL_THDVAR_LONG(name, opt, comment, check, update, default, min, max, blk)
MYSQL_SYSVAR_LONG(name, varname, opt, comment, check, update, default,
minimum, maximum, blocksize)
```

  - **An unsigned long** system variable, which is typically either a 4- or 8-byte unsigned word.

```c
MYSQL_THDVAR_ULONG(name, opt, comment, check, update, default, min, max, blk)
MYSQL_SYSVAR_ULONG(name, varname, opt, comment, check, update, default,
minimum, maximum, blocksize)
```

  - **A long long** system variable, which is typically an 8-byte signed word.

```c
MYSQL_THDVAR_LONGLONG(name, opt, comment, check, update,
default, minimum, maximum, blocksize)
```
Writing Plugins

- **An unsigned long long** system variable, which is typically an 8-byte unsigned word.

| MYSQL_SYSVAR_LONGLONG(name, varname, opt, comment, check, update, default, minimum, maximum, blocksize) |

- **An unsigned long** system variable, which is typically either a 4- or 8-byte unsigned word. The range of possible values is an ordinal of the number of elements in the typelib, starting from 0.

| MYSQL_THDVAR_ULONGLONG(name, opt, comment, check, update, default, minimum, maximum, blocksize) |
| MYSQL_SYSVAR_ULONGLONG(name, varname, opt, comment, check, update, default, minimum, maximum, blocksize) |

- **An unsigned long long** system variable, which is typically an 8-byte unsigned word. Each bit represents an element in the typelib.

| MYSQL_THDVAR_ENUM(name, opt, comment, check, update, default, typelib) |
| MYSQL_SYSVAR_ENUM(name, varname, opt, comment, check, update, default, typelib) |

| MYSQL_THDVAR_SET(name, opt, comment, check, update, default, typelib) |
| MYSQL_SYSVAR_SET(name, varname, opt, comment, check, update, default, typelib) |

Internally, all mutable and plugin system variables are stored in a HASH structure.

Display of the server command-line help text is handled by compiling a DYNAMIC_ARRAY of all variables relevant to command-line options, sorting them, and then iterating through them to display each option.

When a command-line option has been handled, it is then removed from the argv by the handle_option() function (my_getopt.c); in effect, it is consumed.

The server processes command-line options during the plugin installation process, immediately after the plugin has been successfully loaded but before the plugin initialization function has been called.

Plugins loaded at runtime do not benefit from any configuration options and must have usable defaults. Once they are installed, they are loaded at mysqld initialization time and configuration options can be set at the command line or within my.cnf.

Plugins should consider the thd parameter to be read only.

**Client Plugin Descriptors**

Each client plugin must have a descriptor that provides information to the client plugin API. The descriptor structure begins with a fixed set of members common to all client plugins, followed by any members specific to the plugin type.

The st_mysql_client_plugin structure in the client_plugin.h file defines a “generic” descriptor that contains the common members:

```c
struct st_mysql_client_plugin
{
  int type;
  unsigned int interface_version;
  const char *name;
  const char *author;
  const char *desc;
  unsigned int version[3];
};
```
The common `st_mysql_client_plugin` descriptor structure members are used as follows. `char *` members should be specified as null-terminated strings.

- **type**: The plugin type. This must be one of the plugin-type values from `client_plugin.h`, such as `MYSQL_CLIENT_AUTHENTICATION_PLUGIN`.

- **interface_version**: The plugin interface version. For example, this is `MYSQL_CLIENT_AUTHENTICATION_PLUGIN_INTERFACE_VERSION` for an authentication plugin.

- **name**: A string that gives the plugin name. This is the name by which you refer to the plugin when you call `mysql_options()` with the `MYSQL_DEFAULT_AUTH` option or specify the `--default-auth` option to a MySQL client program.

- **author**: A string naming the plugin author. This can be whatever you like.

- **desc**: A string that provides a general description of the plugin. This can be whatever you like.

- **version**: The plugin version as an array of three integers indicating the major, minor, and teeny versions. For example, `{1,2,3}` indicates version 1.2.3.

- **license**: A string that specifies the license type.

- **mysql_api**: For internal use. Specify it as `NULL` in the plugin descriptor.

- **init**: A once-only initialization function, or `NULL` if there is no such function. The client library executes this function when it loads the plugin. The function returns zero for success and nonzero for failure.

  The `init` function uses its first two arguments to return an error message if an error occurs. The first argument is a pointer to a `char` buffer, and the second argument indicates the buffer length. Any message returned by the `init` function must be null-terminated, so the maximum message length is the buffer length minus one. The next arguments are passed to `mysql_load_plugin()`. The first indicates how many more arguments there are (0 if none), followed by any remaining arguments.

- **deinit**: A once-only deinitialization function, or `NULL` if there is no such function. The client library executes this function when it unloads the plugin. The function takes no arguments. It returns zero for success and nonzero for failure.

- **options**: A function for handling options passed to the plugin, or `NULL` if there is no such function. The function takes two arguments representing the option name and a pointer to its value. The function returns zero for success and nonzero for failure.

For a given client plugin type, the common descriptor members may be followed by additional members necessary to implement plugins of that type. For example, the `st_mysql_client_plugin_AUTHENTICATION` structure for authentication plugins has a function at the end that the client library calls to perform authentication.

To declare a plugin, use the `mysql_declare_client_plugin()` and `mysql_end_client_plugin` macros:
Do not specify the *type* or *interface_version* member explicitly. The `mysql_declare_client_plugin()` macro uses the *plugin_type* argument to generate their values automatically. For example, declare an authentication client plugin like this:

```c
mysql_declare_client_plugin(AUTHENTICATION)
    "my_auth_plugin",
    "Author Name",
    "My Client Authentication Plugin",
    {1,0,0},
    "GPL",
    NULL,
    my_auth_init,
    my_auth_deinit,
    my_auth_options,
    my_auth_main
mysql_end_client_plugin;
```

This declaration uses the **AUTHENTICATION** argument to set the *type* and *interface_version* members to **MYSQL_CLIENT_AUTHENTICATION_PLUGIN** and **MYSQL_CLIENT_AUTHENTICATION_PLUGIN_INTERFACE_VERSION**.

Depending on the plugin type, the descriptor may have other members following the common members. For example, for an authentication plugin, there is a function (*my_auth_main()* in the descriptor just shown) that handles communication with the server. See Section 24.2.4.9, “Writing Authentication Plugins”.

Normally, a client program that supports the use of authentication plugins causes a plugin to be loaded by calling `mysql_options()` to set the **MYSQL_DEFAULT_AUTH** and **MYSQL_PLUGIN_DIR** options:

```c
char *plugin_dir = "path_to_plugin_dir";
char *default_auth = "plugin_name";
/* ... process command-line options ... */
mysql_options(&mysql, MYSQL_PLUGIN_DIR, plugin_dir);
mysql_options(&mysql, MYSQL_DEFAULT_AUTH, default_auth);
```

Typically, the program will also accept **--plugin-dir** and **--default-auth** options that enable users to override the default values.

Should a client program require lower-level plugin management, the client library contains functions that take an `st_mysql_client_plugin` argument. See Section 23.8.14, “C API Client Plugin Functions”.

### 24.2.4.3 Compiling and Installing Plugin Libraries

After your plugin is written, you must compile it and install it. The procedure for compiling shared objects varies from system to system. If you build your library using **CMake**, it should be able to generate the correct compilation commands for your system. If the library is named **somepluglib**, you should end up with a shared library file that has a name something like **somepluglib.so**. (The `.so` file name suffix might differ on your system.)

To use **CMake**, you’ll need to set up the configuration files to enable the plugin to be compiled and installed. Use the plugin examples under the **plugin** directory of a MySQL source distribution as a guide.

Create **CMakeLists.txt**, which should look something like this:
When \texttt{CMake} generates the \texttt{Makefile}, it should take care of passing to the compilation command the \texttt{-DMYSQL\_DYNAMIC\_PLUGIN} flag, and passing to the linker the \texttt{-lmysqlservices} flag, which is needed to link in any functions from services provided through the plugin services interface. See Section 24.3, “MySQL Services for Plugins”.

Run \texttt{CMake}, then run \texttt{make}:

\begin{verbatim}
shell> cmake .
shell> make
\end{verbatim}

If you need to specify configuration options to \texttt{CMake}, see Section 2.9.7, “MySQL Source-Configuration Options”, for a list. For example, you might want to specify \texttt{CMAKE\_INSTALL\_PREFIX} to indicate the MySQL base directory under which the plugin should be installed. You can see what value to use for this option with \texttt{SHOW VARIABLES}:

\begin{verbatim}
mysql> SHOW VARIABLES LIKE 'basedir';
+---------------+------------------+
| Variable_name | Value            |
+---------------+------------------+
| base          | /usr/local/mysql |
+---------------+------------------+
\end{verbatim}

The location of the plugin directory where you should install the library is given by the \texttt{plugin\_dir} system variable. For example:

\begin{verbatim}
mysql> SHOW VARIABLES LIKE 'plugin\_dir';
+---------------+-----------------------------------+
| Variable_name | Value                             |
+---------------+-----------------------------------+
| plugin\_dir   | /usr/local/mysql/lib/mysql/plugin |
+---------------+-----------------------------------+
\end{verbatim}

To install the plugin library, use \texttt{make}:

\begin{verbatim}
shell> make install
\end{verbatim}

Verify that \texttt{make install} installed the plugin library in the proper directory. After installing it, make sure that the library permissions permit it to be executed by the server.

### 24.2.4.4 Writing Full-Text Parser Plugins

MySQL supports server-side full-text parser plugins only with \texttt{MyISAM}. For introductory information about full-text parser plugins, see Full-Text Parser Plugins.

A full-text parser plugin can be used to replace or modify the built-in full-text parser. This section describes how to write a full-text parser plugin named \texttt{simple\_parser}. This plugin performs parsing based on simpler rules than those used by the MySQL built-in full-text parser: Words are nonempty runs of whitespace characters.

The instructions use the source code in the \texttt{plugin/fulltext} directory of MySQL source distributions, so change location into that directory. The following procedure describes how the plugin library is created:

1. To write a full-text parser plugin, include the following header file in the plugin source file. Other MySQL or general header files might also be needed, depending on the plugin capabilities and requirements.
Writing Plugins

```
#include <mysql/plugin.h>

plugin.h defines the MYSQL_FTPARSER_PLUGIN server plugin type and the data structures needed to declare the plugin.

2. Set up the library descriptor for the plugin library file.

This descriptor contains the general plugin descriptor for the server plugin. For a full-text parser plugin, the type must be MYSQL_FTPARSER_PLUGIN. This is the value that identifies the plugin as being legal for use in a WITH PARSER clause when creating a FULLTEXT index. (No other plugin type is legal for this clause.)

For example, the library descriptor for a library that contains a single full-text parser plugin named simple_parser looks like this:

```c
mysql_declare_plugin(ftexample)
{
  MYSQL_FTPARSER_PLUGIN,      /* type                            */
  &simple_parser_descriptor,  /* descriptor                      */
  "simple_parser",            /* name                            */
  "Oracle Corporation",       /* author                          */
  "Simple Full-Text Parser",  /* description                     */
  PLUGIN_LICENSE_GPL,         /* plugin license                  */
  simple_parser_plugin_init,  /* init function (when loaded)     */
  simple_parser_plugin_deinit,/* deinit function (when unloaded) */
  0x0001,                     /* version                         */
  NULL,
  0
}
mysql_declare_plugin_end;
```

The name member (simple_parser) indicates the name to use for references to the plugin in statements such as INSTALL PLUGIN or UNINSTALL PLUGIN. This is also the name displayed by SHOW PLUGINS or INFORMATION_SCHEMA.PLUGINS.

For more information, see Server Plugin Library and Plugin Descriptors.

3. Set up the type-specific plugin descriptor.

Each general plugin descriptor in the library descriptor points to a type-specific descriptor. For a full-text parser plugin, the type-specific descriptor is an instance of the st_mysql_ftparser structure in the plugin.h file:

```c
struct st_mysql_ftparser
{
  int interface_version;
  int (*parse)(MYSQL_FTPARSER_PARAM *param);
  int (*init)(MYSQL_FTPARSER_PARAM *param);
  int (*deinit)(MYSQL_FTPARSER_PARAM *param);
};
```

As shown by the structure definition, the descriptor has an interface version number and contains pointers to three functions.

The interface version number is specified using a symbol, which is in the form: MYSQL_xxx_INTERFACE_VERSION. For full-text parser plugins, the symbol is
Writing Plugins

MYSQL_FTPARSER_INTERFACE_VERSION. In the source code, you will find the actual interface version number for the full-text parser plugin defined in `include/mysql/plugin_ftparser.h`.

The `init` and `deinit` members should point to a function or be set to 0 if the function is not needed. The `parse` member must point to the function that performs the parsing.

In the `simple_parser` declaration, that descriptor is indicated by `&simple_parser_descriptor`. The descriptor specifies the version number for the full-text plugin interface (as given by `MYSQL_FTPARSER_INTERFACE_VERSION`), and the plugin's parsing, initialization, and deinitialization functions:

```c
static struct st_mysql_ftparser simple_parser_descriptor =
{
    MYSQL_FTPARSER_INTERFACE_VERSION, /* interface version */
    simple_parser_parse,              /* parsing function */
    simple_parser_init,               /* parser init function */
    simple_parser_deinit              /* parser deinit function */
};
```

A full-text parser plugin is used in two different contexts, indexing and searching. In both contexts, the server calls the initialization and deinitialization functions at the beginning and end of processing each SQL statement that causes the plugin to be invoked. However, during statement processing, the server calls the main parsing function in context-specific fashion:

- For indexing, the server calls the parser for each column value to be indexed.
- For searching, the server calls the parser to parse the search string. The parser might also be called for rows processed by the statement. In natural language mode, there is no need for the server to call the parser. For boolean mode phrase searches or natural language searches with query expansion, the parser is used to parse column values for information that is not in the index. Also, if a boolean mode search is done for a column that has no `FULLTEXT` index, the built-in parser will be called. (Plugins are associated with specific indexes. If there is no index, no plugin is used.)

The plugin declaration in the general plugin descriptor has `init` and `deinit` members that point initialization and deinitialization functions, and so does the type-specific plugin descriptor to which it points. However, these pairs of functions have different purposes and are invoked for different reasons:

- For the plugin declaration in the general plugin descriptor, the initialization and deinitialization functions are invoked when the plugin is loaded and unloaded.
- For the type-specific plugin descriptor, the initialization and deinitialization functions are invoked per SQL statement for which the plugin is used.

Each interface function named in the plugin descriptor should return zero for success or nonzero for failure, and each of them receives an argument that points to a `MYSQL_FTPARSER_PARAM` structure containing the parsing context. The structure has this definition:

```c
typedef struct st_mysql_ftparser_param
{
    int (*mysql_parse)(struct st_mysql_ftparser_param *,
                       char *doc, int doc_len);
    int (*mysql_add_word)(struct st_mysql_ftparser_param *,
                          char *word, int word_len,
                          MYSQL_FTPARSER_BOOLEAN_INFO *boolean_info);
    void *ftparser_state;
    void *mysql_ftparam;
    struct charset_info_st *cs;
};
```
char *doc;
int length;
int flags;
enum enum_ftparser_mode mode;
} MYSQL_FTPARSER_PARAM;

The structure members are used as follows:

• `mysql_parse`: A pointer to a callback function that invokes the server’s built-in parser. Use this callback when the plugin acts as a front end to the built-in parser. That is, when the plugin parsing function is called, it should process the input to extract the text and pass the text to the `mysql_parse` callback.

The first parameter for this callback function should be the `param` value itself:

```c
param->mysql_parse(param, ...);
```

A front end plugin can extract text and pass it all at once to the built-in parser, or it can extract and pass text to the built-in parser a piece at a time. However, in this case, the built-in parser treats the pieces of text as though there are implicit word breaks between them.

• `mysql_add_word`: A pointer to a callback function that adds a word to a full-text index or to the list of search terms. Use this callback when the parser plugin replaces the built-in parser. That is, when the plugin parsing function is called, it should parse the input into words and invoke the `mysql_add_word` callback for each word.

The first parameter for this callback function should be the `param` value itself:

```c
param->mysql_add_word(param, ...);
```

• `ftparser_state`: This is a generic pointer. The plugin can set it to point to information to be used internally for its own purposes.

• `mysql_ftparam`: This is set by the server. It is passed as the first argument to the `mysql_parse` or `mysql_add_word` callback.

• `cs`: A pointer to information about the character set of the text, or 0 if no information is available.

• `doc`: A pointer to the text to be parsed.

• `length`: The length of the text to be parsed, in bytes.

• `flags`: Parser flags. This is zero if there are no special flags. The only nonzero flag is `MYSQL_FTPFLAGS_NEED_COPY`, which means that `mysql_add_word()` must save a copy of the word (that is, it cannot use a pointer to the word because the word is in a buffer that will be overwritten.)

This flag might be set or reset by MySQL before calling the parser plugin, by the parser plugin itself, or by the `mysql_parse()` function.

• `mode`: The parsing mode. This value will be one of the following constants:

  • `MYSQL_FTPARSER_SIMPLE_MODE`: Parse in fast and simple mode, which is used for indexing and for natural language queries. The parser should pass to the server only those words that should be indexed. If the parser uses length limits or a stopword list to determine which words to ignore, it should not pass such words to the server.
Writing Plugins

- **MYSQL_FTPARSER_WITH_STOPWORDS**: Parse in stopword mode. This is used in boolean searches for phrase matching. The parser should pass all words to the server, even stopwords or words that are outside any normal length limits.

- **MYSQL_FTPARSER_FULL_BOOLEAN_INFO**: Parse in boolean mode. This is used for parsing boolean query strings. The parser should recognize not only words but also boolean-mode operators and pass them to the server as tokens using the `mysql_add_word` callback. To tell the server what kind of token is being passed, the plugin needs to fill in a **MYSQL_FTPARSER_BOOLEAN_INFO** structure and pass a pointer to it.

If the parser is called in boolean mode, the param->mode value will be **MYSQL_FTPARSER_FULL_BOOLEAN_INFO**. The **MYSQL_FTPARSER_BOOLEAN_INFO** structure that the parser uses for passing token information to the server looks like this:

```c
typedef struct st_mysql_ftparser_boolean_info {
    enum enum_ft_token_type type;
    int yesno;
    int weight_adjust;
    char wasign;
    char trunc;
    /* These are parser state and must be removed. */
    char prev;
    char *quot;
} MYSQL_FTPARSER_BOOLEAN_INFO;
```

The parser should fill in the structure members as follows:

- **type**: The token type. The following table shows the permissible types.

```
<table>
<thead>
<tr>
<th>Token Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>FT_TOKEN_EOF</td>
<td>End of data</td>
</tr>
<tr>
<td>FT_TOKEN_WORD</td>
<td>A regular word</td>
</tr>
<tr>
<td>FT_TOKEN_LEFT_PAREN</td>
<td>The beginning of a group or subexpression</td>
</tr>
<tr>
<td>FT_TOKEN_RIGHT_PAREN</td>
<td>The end of a group or subexpression</td>
</tr>
<tr>
<td>FT_TOKEN_STOPWORD</td>
<td>A stopword</td>
</tr>
</tbody>
</table>
```

- **yesno**: Whether the word must be present for a match to occur. 0 means that the word is optional but increases the match relevance if it is present. Values larger than 0 mean that the word must be present. Values smaller than 0 mean that the word must not be present.

- **weight_adjust**: A weighting factor that determines how much a match for the word counts. It can be used to increase or decrease the word's importance in relevance calculations. A value of zero indicates no weight adjustment. Values greater than or less than zero mean higher or lower weight, respectively. The examples at Section 12.9.2, “Boolean Full-Text Searches”, that use the `<` and `>` operators illustrate how weighting works.

- **wasign**: The sign of the weighting factor. A negative value acts like the ~ boolean-search operator, which causes the word's contribution to the relevance to be negative.

- **trunc**: Whether matching should be done as if the boolean-mode * truncation operator had been given.
Plugins should not use the `prev` and `quot` members of the `MYSQL_FTPARSER_BOOLEAN_INFO` structure.

**Note**

The plugin parser framework does not support:

- The `@distance` boolean operator.
- A leading plus sign (+) or minus sign (−) boolean operator followed by a space and then a word (`'+ apple'` or `'- apple'`). The leading plus or minus sign must be directly adjacent to the word, for example: `'+apple'` or `'-apple'`.

For information about boolean full-text search operators, see Section 12.9.2, “Boolean Full-Text Searches”.

4. Set up the plugin interface functions.

The general plugin descriptor in the library descriptor names the initialization and deinitialization functions that the server should invoke when it loads and unloads the plugin. For `simple_parser`, these functions do nothing but return zero to indicate that they succeeded:

```c
static int simple_parser_plugin_init(void *arg __attribute__((unused)))
{
    return(0);
}

static int simple_parser_plugin_deinit(void *arg __attribute__((unused)))
{
    return(0);
}
```

Because those functions do not actually do anything, you could omit them and specify 0 for each of them in the plugin declaration.

The type-specific plugin descriptor for `simple_parser` names the initialization, deinitialization, and parsing functions that the server invokes when the plugin is used. For `simple_parser`, the initialization and deinitialization functions do nothing:

```c
static int simple_parser_init(MYSQL_FTPARSER_PARAM *param __attribute__((unused)))
{
    return(0);
}

static int simple_parser_deinit(MYSQL_FTPARSER_PARAM *param __attribute__((unused)))
{
    return(0);
}
```

Here too, because those functions do nothing, you could omit them and specify 0 for each of them in the plugin descriptor.

The main parsing function, `simple_parser_parse()`, acts as a replacement for the built-in full-text parser, so it needs to split text into words and pass each word to the server. The parsing function's first
argument is a pointer to a structure that contains the parsing context. This structure has a doc member that points to the text to be parsed, and a length member that indicates how long the text is. The simple parsing done by the plugin considers nonempty runs of whitespace characters to be words, so it identifies words like this:

```c
static int simple_parser_parse(MYSQL_FTPARSER_PARAM *param)
{
    char *end, *start, *docend= param->doc + param->length;
    for (end= start= param->doc;; end++)
    {
        if (end == docend)
        {
            if (end > start)
                add_word(param, start, end - start);
            break;
        }
        else if (isspace(*end))
        {
            if (end > start)
                add_word(param, start, end - start);
            start= end + 1;
        }
    }
    return(0);
}
```

As the parser finds each word, it invokes a function add_word() to pass the word to the server. add_word() is a helper function only; it is not part of the plugin interface. The parser passes the parsing context pointer to add_word(), as well as a pointer to the word and a length value:

```c
static void add_word(MYSQL_FTPARSER_PARAM *param, char *word, size_t len)
{
    MYSQL_FTPARSER_BOOLEAN_INFO bool_info=
    { FT_TOKEN_WORD, 0, 0, 0, 0, ' ', 0 };
    param->mysql_add_word(param, word, len, &bool_info);
}
```

For boolean-mode parsing, add_word() fills in the members of the bool_info structure as described earlier in the discussion of the st_mysql_ftparser_boolean_info structure.

5. Set up the status variables. For the simple_parser plugin, the following status variable array sets up one status variable with a value that is static text, and another with a value that is stored in a long integer variable:

```c
long number_of_calls= 0;
struct st_mysql_show_var simple_status[]= {
    {"simple_parser_static", (char *)"just a static text", SHOW_CHAR},
    {"simple_parser_called", (char *)&number_of_calls, SHOW_LONG},
    {0,0,0}
};
```

By using status variable names that begin with the plugin name, you can easily display the variables for a plugin with SHOW STATUS:

```
mysql> SHOW STATUS LIKE 'simple_parser';
```
6. To compile and install a plugin library file, use the instructions in Section 24.2.4.3, “Compiling and Installing Plugin Libraries”. To make the library file available for use, install it in the plugin directory (the directory named by the `plugin_dir` system variable). For the `simple_parser` plugin, it is compiled and installed when you build MySQL from source. It is also included in binary distributions. The build process produces a shared object library with a name of `mypluglib.so` (the `.so` suffix might differ depending on your platform).

7. To use the plugin, register it with the server. For example, to register the plugin at runtime, use this statement (adjust the `.so` suffix for your platform as necessary):

```sql
INSTALL PLUGIN simple_parser SONAME 'mypluglib.so';
```

For additional information about plugin loading, see Section 5.5.1, “Installing and Uninstalling Plugins”.

8. To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement. See Section 5.5.2, “Obtaining Server Plugin Information”.

9. Test the plugin to verify that it works properly.

Create a table that contains a string column and associate the parser plugin with a `FULLTEXT` index on the column:

```sql
mysql> CREATE TABLE t (c VARCHAR(255),
    ->  FULLTEXT (c) WITH PARSER simple_parser
    -> ) ENGINE=MyISAM;
Query OK, 0 rows affected (0.01 sec)
```

Insert some text into the table and try some searches. These should verify that the parser plugin treats all nonwhitespace characters as word characters:

```sql
mysql> INSERT INTO t VALUES
    -> ('latin1_general_cs is a case-sensitive collation'),
    -> ('I\'d like a case of oranges'),
    -> ('this is sensitive information'),
    -> ('another row'),
    -> ('yet another row');
Query OK, 5 rows affected (0.02 sec)
Records: 5  Duplicates: 0  Warnings: 0
mysql> SELECT c FROM t;
+-------------------------------------------------+
| c                                               |
+-------------------------------------------------+
| latin1_general_cs is a case-sensitive collation |
| I'd like a case of oranges                      |
| this is sensitive information                   |
| another row                                     |
| yet another row                                 |
+-------------------------------------------------+
5 rows in set (0.00 sec)
```

```sql
mysql> SELECT MATCH(c) AGAINST('case') FROM t;
+--------------------------+
<table>
<thead>
<tr>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>--------------------------</td>
</tr>
<tr>
<td>--------------------------</td>
</tr>
<tr>
<td>--------------------------</td>
</tr>
<tr>
<td>--------------------------</td>
</tr>
<tr>
<td>--------------------------</td>
</tr>
</tbody>
</table>
```

3598
Neither “case” nor “insensitive” match “case-insensitive” the way that they would for the built-in parser.

### 24.2.4.5 Writing Daemon Plugins

A daemon plugin is a simple type of plugin used for code that should be run by the server but that does not communicate with it. This section describes how to write a daemon server plugin, using the example plugin found in the `plugin/daemon_example` directory of MySQL source distributions. That directory contains the `daemon_example.cc` source file for a daemon plugin named `daemon_example` that writes a heartbeat string at regular intervals to a file named `mysql-heartbeat.log` in the data directory.

To write a daemon plugin, include the following header file in the plugin source file. Other MySQL or general header files might also be needed, depending on the plugin capabilities and requirements.

```c
#include <mysql/plugin.h>
```

`plugin.h` defines the `MYSQL_DAEMON_PLUGIN` server plugin type and the data structures needed to declare the plugin.
The `daemon_example.cc` file sets up the library descriptor as follows. The library descriptor includes a single general server plugin descriptor.

```c
mysql_declare_plugin(daemon_example)
{
    MYSQL_DAEMON_PLUGIN,
    idaemon_example_plugin,
    "daemon_example",
    "Brian Aker",
    "Daemon example, creates a heartbeat beat file in mysql-heartbeat.log",
    PLUGIN_LICENSE_GPL,
    daemon_example_plugin_init, /* Plugin Init */
    daemon_example_plugin_deinit, /* Plugin Deinit */
    0x0100 /* 1.0 */,
    NULL, /* status variables */
    NULL, /* system variables */
    NULL, /* config options */
    0, /* flags */
}
mysql_declare_plugin_end;
```

The `name` member (`daemon_example`) indicates the name to use for references to the plugin in statements such as `INSTALL PLUGIN` or `UNINSTALL PLUGIN`. This is also the name displayed by `SHOW PLUGINS` or `INFORMATION_SCHEMA.PLUGINS`.

The second member of the plugin descriptor, `daemon_example_plugin`, points to the type-specific daemon plugin descriptor. This structure consists only of the type-specific API version number:

```c
struct st_mysql_daemon daemon_example_plugin=
{ MYSQL_DAEMON_INTERFACE_VERSION };```

The type-specific structure has no interface functions. There is no communication between the server and the plugin, except that the server calls the initialization and deinitialization functions from the general plugin descriptor to start and stop the plugin:

- `daemon_example_plugin_init()` opens the heartbeat file and spawns a thread that wakes up periodically and writes the next message to the file.
- `daemon_example_plugin_deinit()` closes the file and performs other cleanup.

To compile and install a plugin library file, use the instructions in Section 24.2.4.3, “Compiling and Installing Plugin Libraries”. To make the library file available for use, install it in the plugin directory (the directory named by the `plugin_dir` system variable). For the `daemon_example` plugin, it is compiled and installed when you build MySQL from source. It is also included in binary distributions. The build process produces a shared object library with a name of `libdaemon_example.so` (the `.so` suffix might differ depending on your platform).

To use the plugin, register it with the server. For example, to register the plugin at runtime, use this statement (adjust the `.so` suffix for your platform as necessary):

```
INSTALL PLUGIN daemon_example SONAME 'libdaemon_example.so';
```

For additional information about plugin loading, see Section 5.5.1, “Installing and Uninstalling Plugins”.

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement. See Section 5.5.2, “Obtaining Server Plugin Information”.
While the plugin is loaded, it writes a heartbeat string at regular intervals to a file named `mysql-heartbeat.log` in the data directory. This file grows without limit, so after you have satisfied yourself that the plugin operates correctly, unload it:

```
UNINSTALL PLUGIN daemon_example;
```

### 24.2.4.6 Writing INFORMATION_SCHEMA Plugins

This section describes how to write a server-side INFORMATION_SCHEMA table plugin. For example code that implements such plugins, see the `sql/sql_show.cc` file of a MySQL source distribution. You can also look at the example plugins found in the InnoDB source. See the `handler/i_s.cc` and `handler/ha_innodb.cc` files within the InnoDB source tree (in the `storage/innobase` directory).

To write an INFORMATION_SCHEMA table plugin, include the following header files in the plugin source file. Other MySQL or general header files might also be needed, depending on the plugin capabilities and requirements.

```c
#include <sql_class.h>
#include <table.h>
```

These header files are located in the `sql` directory of MySQL source distributions. They contain C++ structures, so the source file for an INFORMATION_SCHEMA plugin must be compiled as C++ (not C) code.

The source file for the example plugin developed here is named `simple_i_s_table.cc`. It creates a simple INFORMATION_SCHEMA table named `SIMPLE_I_S_TABLE` that has two columns named `NAME` and `VALUE`. The general descriptor for a plugin library that implements the table looks like this:

```c
mysql_declare_plugin(simple_i_s_library)
{
    MYSQL_INFORMATION_SCHEMA_PLUGIN,
    &simple_table_info,  /* type-specific descriptor */
    "SIMPLE_I_S_TABLE",  /* table name */
    "Author Name",       /* author */
    "Simple INFORMATION_SCHEMA", /* description */
    PLUGIN_LICENSE_GPL,  /* license type */
    simple_table_init,   /* init function */
    NULL,                /* version = 1.0 */
    NULL,                /* no status variables */
    NULL,                /* no system variables */
    NULL,                /* no reserved information */
    0                    /* no flags */
}
mysql_declare_plugin_end;
```

The `name` member (`SIMPLE_I_S_TABLE`) indicates the name to use for references to the plugin in statements such as `INSTALL PLUGIN` or `UNINSTALL PLUGIN`. This is also the name displayed by `SHOW PLUGINS` or `INFORMATION_SCHEMA.PLUGINS`.

The `simple_table_info` member of the general descriptor points to the type-specific descriptor, which consists only of the type-specific API version number:

```c
static struct st_mysql_information_schema simple_table_info =
{ MYSQL_INFORMATION_SCHEMA_INTERFACE_VERSION };
```

The general descriptor points to the initialization and deinitialization functions:
• The initialization function provides information about the table structure and a function that populates the table.

• The deinitialization function performs any required cleanup. If no cleanup is needed, this descriptor member can be NULL (as in the example shown).

The initialization function should return 0 for success, 1 if an error occurs. The function receives a generic pointer, which it should interpret as a pointer to the table structure:

```c
static int table_init(void *ptr)
{
    ST_SCHEMA_TABLE *schema_table= (ST_SCHEMA_TABLE*)ptr;
    schema_table->fields_info= simple_table_fields;
    schema_table->fill_table= simple_fill_table;
    return 0;
}
```

The function should set these two members of the table structure:

• fields_info: An array of ST_FIELD_INFO structures that contain information about each column.

• fill_table: A function that populates the table.

The array pointed to by fields_info should contain one element per column of the INFORMATION_SCHEMA plus a terminating element. The following simple_table_fields array for the example plugin indicates that SIMPLE_I_S_TABLE has two columns. NAME is string-valued with a length of 10 and VALUE is integer-valued with a display width of 20. The last structure marks the end of the array.

```c
static ST_FIELD_INFO simple_table_fields[]=
{
    {"NAME", 10, MYSQL_TYPE_STRING, 0, 0, 0},
    {"VALUE", 6, MYSQL_TYPE_LONG, 0, MY_I_S_UNSIGNED, 0, 0},
    {0, 0, MYSQL_TYPE_NULL, 0, 0, 0, 0}
};
```

For more information about the column information structure, see the definition of ST_FIELD_INFO in the table.h header file. The permissible MYSQL_TYPE_xxx type values are those used in the C API; see Section 23.8.5, “C API Data Structures”.

The fill_table member should be set to a function that populates the table and returns 0 for success, 1 if an error occurs. For the example plugin, the simple_fill_table() function looks like this:

```c
static int simple_fill_table(THD *thd, TABLE_LIST *tables, Item *cond)
{
    TABLE *table= tables->table;
    table->field[0] ->store("Name 1", 6, system_charset_info);
    table->field[1] ->store(1);
    if (schema_table_store_record(thd, table))
        return 1;
    table->field[0] ->store("Name 2", 6, system_charset_info);
    table->field[1] ->store(2);
    if (schema_table_store_record(thd, table))
        return 1;
    return 0;
}
```

For each row of the INFORMATION_SCHEMA table, this function initializes each column, then calls schema_table_store_record() to install the row. The store() method arguments depend on the
type of value to be stored. For column 0 (\texttt{NAME}, a string), \texttt{store()} takes a pointer to a string, its length, and information about the character set of the string:

\begin{verbatim}
store(const char *to, uint length, CHARSET_INFO *cs);
\end{verbatim}

For column 1 (\texttt{VALUE}, an integer), \texttt{store()} takes the value and a flag indicating whether it is unsigned:

\begin{verbatim}
store(longlong nr, bool unsigned_value);
\end{verbatim}

For other examples of how to populate \texttt{INFORMATION_SCHEMA} tables, search for instances of \texttt{schema_table_store_record()} in \texttt{sql_show.cc}.

To compile and install a plugin library file, use the instructions in Section 24.2.4.3, “Compiling and Installing Plugin Libraries”. To make the library file available for use, install it in the plugin directory (the directory named by the \texttt{plugin_dir} system variable).

To test the plugin, install it:

\begin{verbatim}
mysql> INSTALL PLUGIN SIMPLE_I_S_TABLE SONAME 'simple_i_s_table.so';
\end{verbatim}

Verify that the table is present:

\begin{verbatim}
mysql> SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
    >> WHERE TABLE_NAME = 'SIMPLE_I_S_TABLE';
+------------------+
<table>
<thead>
<tr>
<th>TABLE_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>SIMPLE_I_S_TABLE</td>
</tr>
</tbody>
</table>
+------------------+
\end{verbatim}

Try to select from it:

\begin{verbatim}
mysql> SELECT * FROM INFORMATION_SCHEMA.SIMPLE_I_S_TABLE;
+--------+-------+
<table>
<thead>
<tr>
<th>NAME</th>
<th>VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name 1</td>
<td>1</td>
</tr>
<tr>
<td>Name 2</td>
<td>2</td>
</tr>
</tbody>
</table>
+--------+-------+
\end{verbatim}

Uninstall it:

\begin{verbatim}
mysql> UNINSTALL PLUGIN SIMPLE_I_S_TABLE;
\end{verbatim}

24.2.4.7 Writing Semisynchronous Replication Plugins

This section describes how to write server-side semisynchronous replication plugins, using the example plugins found in the \texttt{plugin/semisync} directory of MySQL source distributions. That directory contains the source files for master and slave plugins named \texttt{rpl_semi_sync_master} and \texttt{rpl_semi_sync_slave}. The information here covers only how to set up the plugin framework. For details about how the plugins implement replication functions, see the source.

To write a semisynchronous replication plugin, include the following header file in the plugin source file. Other MySQL or general header files might also be needed, depending on the plugin capabilities and requirements.
Writing Plugins

#include <mysql/plugin.h>

`plugin.h` defines the `MYSQL_REPLICATION_PLUGIN` server plugin type and the data structures needed to declare the plugin.

For the master side, `semisync_master_plugin.cc` contains this general descriptor for a plugin named `rpl_semi_sync_master`:

```c
mysql_declare_plugin(semi_sync_master)
{
    MYSQL_REPLICATION_PLUGIN,
    &semi_sync_master_plugin,
    "rpl_semi_sync_master",
    "He Zhenxing",
    "Semi-synchronous replication master",
    PLUGIN_LICENSE_GPL,
    semi_sync_master_plugin_init, /* Plugin Init */
    semi_sync_master_plugin_deinit, /* Plugin Deinit */
    0x0100 /* 1.0 */,
    semi_sync_master_status_vars, /* status variables */
    semi_sync_master_system_vars, /* system variables */
    NULL, /* config options */
    0, /* flags */
}
mysql_declare_plugin_end;
```

For the slave side, `semisync_slave_plugin.cc` contains this general descriptor for a plugin named `rpl_semi_sync_slave`:

```c
mysql_declare_plugin(semi_sync_slave)
{
    MYSQL_REPLICATION_PLUGIN,
    &semi_sync_slave_plugin,
    "rpl_semi_sync_slave",
    "He Zhenxing",
    "Semi-synchronous replication slave",
    PLUGIN_LICENSE_GPL,
    semi_sync_slave_plugin_init, /* Plugin Init */
    semi_sync_slave_plugin_deinit, /* Plugin Deinit */
    0x0100 /* 1.0 */,
    semi_sync_slave_status_vars, /* status variables */
    semi_sync_slave_system_vars, /* system variables */
    NULL, /* config options */
    0, /* flags */
}
mysql_declare_plugin_end;
```

For both the master and slave plugins, the general descriptor has pointers to the type-specific descriptor, the initialization and deinitialization functions, and to the status and system variables implemented by the plugin. For information about variable setup, see `Server Plugin Status and System Variables`. The following remarks discuss the type-specific descriptor and the initialization and deinitialization functions for the master plugin but apply similarly to the slave plugin.

The `semi_sync_master_plugin` member of the master general descriptor points to the type-specific descriptor, which consists only of the type-specific API version number:

```c
struct Mysql_replication semi_sync_master_plugin= {
    MYSQL_REPLICATION_INTERFACE_VERSION
};
```
The initialization and deinitialization function declarations look like this:

```c
static int semi_sync_master_plugin_init(void *p);
static int semi_sync_master_plugin_deinit(void *p);
```

The initialization function uses the pointer to register transaction and binary logging “observers” with the server. After successful initialization, the server takes care of invoking the observers at the appropriate times. (For details on the observers, see the source files.) The deinitialization function cleans up by deregistering the observers. Each function returns 0 for success or 1 if an error occurs.

To compile and install a plugin library file, use the instructions in Section 24.2.4.3, “Compiling and Installing Plugin Libraries”. To make the library file available for use, install it in the plugin directory (the directory named by the `plugin_dir` system variable). For the `rpl_semi_sync_master` and `rpl_semi_sync_slave` plugins, they are compiled and installed when you build MySQL from source. They are also included in binary distributions. The build process produces shared object libraries with names of `semisync_master.so` and `semisync_slave.so` (the `.so` suffix might differ depending on your platform).

### 24.2.4.8 Writing Audit Plugins

This section describes how to write a server-side audit plugin, using the example plugin found in the `plugin/audit_null` directory of MySQL source distributions. The `audit_null.c` source file in that directory implements a simple example audit plugin named `NULL_AUDIT`.

Within the server, the pluggable audit interface is implemented in the `sql_audit.h` and `sql_audit.cc` files in the `sql` directory of MySQL source distributions. Additionally, several places in the server call the audit interface when an auditable event occurs, so that registered audit plugins can be notified about the event if necessary. To see where such calls occur, search the server source files for invocations of functions with names of the form `mysql_audit_xxx()`. Audit notification occurs for server operations such as these:

- Client connect and disconnect events
- Writing a message to the general query log (if the log is enabled)
- Writing a message to the error log
- Sending a query result to a client

To write an audit plugin, include the following header file in the plugin source file. Other MySQL or general header files might also be needed, depending on the plugin capabilities and requirements.

```c
#include <mysql/plugin_audit.h>
```

`plugin_audit.h` includes `plugin.h`, so you need not include the latter file explicitly. `plugin.h` defines the `MYSQL_AUDIT_PLUGIN` server plugin type and the data structures needed to declare the plugin.

`plugin_audit.h` defines data structures specific to audit plugins.

An audit plugin, like any MySQL server plugin, has a general plugin descriptor (see Server Plugin Library and Plugin Descriptors) and a type-specific plugin descriptor. In `audit_null.c`, the general descriptor for `audit_null` looks like this:

```c
mysql_declare_plugin(audit_null)
{
  MYSQL_AUDIT_PLUGIN,    /* type */
```
Writing Plugins

```c
&audit_null_descriptor,     /* descriptor */
"NULL_AUDIT",              /* name */
"Oracle Corp",             /* author */
"Simple NULL Audit",       /* description */
PLUGIN_LICENSE_GPL,
audit_null_plugin_init,     /* init function (when loaded) */
audit_null_plugin_deinit,   /* deinit function (when unloaded) */
0x0003,                     /* version */
simple_status,              /* status variables */
NULL,                       /* system variables */
0,
}
mysql_declare_plugin_end;
```

The first member, **MYSQL_AUDIT_PLUGIN**, identifies this plugin as an audit plugin.

**audit_null_descriptor** points to the type-specific plugin descriptor, described later.

The **name** member (**NULL_AUDIT**) indicates the name to use for references to the plugin in statements such as **INSTALL PLUGIN** or **UNINSTALL PLUGIN**. This is also the name displayed by **INFORMATION_SCHEMA.PLUGINS** or **SHOW PLUGINS**.

The general plugin descriptor also refers to **simple_status**, a structure that exposes several status variables to the **SHOW STATUS** statement:

```c
static struct st_mysql_show_var simple_status[] =
{
    { "Audit_null_called",       (char *) &number_of_calls, SHOW_INT },
    { "Audit_null_general_log",  (char *) &number_of Calls_general_log, SHOW_INT },
    { "Audit_null_general_error", (char *) &number_of Calls_general_error, SHOW_INT },
    { "Audit_null_general_result", (char *) &number_of Calls_general_result, SHOW_INT },
    { "Audit_null_general_status", (char *) &number_of Calls_general_status, SHOW_INT },
    { "Audit_null_connection_connect", (char *) &number_of Calls_connection_connect, SHOW_INT },
    { "Audit_null_connection_disconnect", (char *) &number_of Calls_connection_disconnect, SHOW_INT },
    { "Audit_null_connection_change_user", (char *) &number_of Calls_connection_change_user, SHOW_INT },
    { 0, 0, 0 }
};
```

The **audit_null_plugin_init** initialization function sets the status variables to zero when the plugin is loaded. The **audit_null_plugin_deinit** function performs cleanup when the plugin is unloaded. During operation, the plugin increments the first status variable for each notification it receives. It also increments the others according to the event class and subclass. In effect, the first variable is the aggregate of the counts for the event subclasses.

The **audit_null_descriptor** value in the general plugin descriptor points to the type-specific plugin descriptor. For audit plugins, this descriptor has the following structure:
struct st_mysql_audit
{
  int interface_version;
  void (*release_thd)(MYSQL_THD);
  void (*event_notify)(MYSQL_THD, unsigned int, const void *);
  unsigned long class_mask[MYSQL_AUDIT_CLASS_MASK_SIZE];
};

The type-specific plugin descriptor for audit plugins has these members:

• \textit{interface} \textit{version}: By convention, type-specific plugin descriptors begin with the interface version for the given plugin type. The server checks \textit{interface} \textit{version} when it loads the plugin to see whether the plugin is compatible with it. For audit plugins, the value of the \textit{interface} \textit{version} member is \texttt{MYSQL_AUDIT_INTERFACE_VERSION} (defined in \texttt{plugin_audit.h}).

• \textit{release} \textit{thd}: A function that the server calls to inform the plugin that it is being dissociated from its thread context. This should be \texttt{NULL} if there is no such function.

• \textit{event} \textit{notify}: A function that the server calls to notify the plugin that an auditable event has occurred. This function should not be \texttt{NULL}; that would not make sense because no auditing would occur.

• \textit{class} \textit{mask}: A bitmask that indicates the event classes for which the plugin wants to receive notification. If this value is 0, the server passes no events to the plugin.

The server uses the \textit{event} \textit{notify} and \textit{release} \textit{thd} functions together. They are called within the context of a specific thread, and a thread might perform an activity that produces several event notifications. The first time the server calls \textit{event} \textit{notify} for a thread, it creates a binding of the plugin to the thread. The plugin cannot be uninstalled while this binding exists. When no more events for the thread will occur, the server informs the plugin of this by calling the \textit{release} \textit{thd} function, and then destroys the binding. For example, when a client issues a statement, the thread processing the statement might notify audit plugins about the result set produced by the statement and about the statement being logged. After these notifications occur, the server releases the plugin before putting the thread to sleep until the client issues another statement.

This design enables the plugin to allocate resources needed for a given thread in the first call to the \textit{event} \textit{notify} function and release them in the \textit{release} \textit{thd} function:

\begin{verbatim}
event_notify function:
  if memory is needed to service the thread
    allocate memory
  ... rest of notification processing ...

release_thd function:
  if memory was allocated
    release memory
  ... rest of release processing ...
\end{verbatim}

That is more efficient than allocating and releasing memory repeatedly in the notification function.

For the \texttt{NULL_AUDIT} audit plugin, the type-specific plugin descriptor looks like this:

\begin{verbatim}
static struct st_mysql_audit audit_null_descriptor=
{
  MYSQL_AUDIT_INTERFACE_VERSION, /* interface version */
  NULL, /* release_thd function */
  audit_null_notify, /* notify function */
  { (unsigned long) MYSQL_AUDIT_GENERAL_CLASSMASK |
    MYSQL_AUDIT_CONNECTION_CLASSMASK } /* class mask */
};
\end{verbatim}
Writing Plugins

The server calls `audit_null_notify()` to pass audit event information to the plugin. There is no `release_thd` function.

The event class mask indicates an interest in all events of the “general” and “connection” classes. `plugin_audit.h` defines symbols for these classes and their corresponding class masks:

```c
#define MYSQL_AUDIT_GENERAL_CLASS 0
#define MYSQL_AUDIT_GENERAL_CLASSMASK (1 << MYSQL_AUDIT_GENERAL_CLASS)
#define MYSQL_AUDIT_CONNECTION_CLASS 1
#define MYSQL_AUDIT_CONNECTION_CLASSMASK (1 << MYSQL_AUDIT_CONNECTION_CLASS)
```

In the type-specific plugin descriptor, the second and third parameters of the `event_notify` function prototype represent the event class and a generic pointer to an event structure:

```c
void (*event_notify)(MYSQL_THD, unsigned int, const void *);
```

Events in different classes may have different structures, so the notification function should use the event class value to determine how to interpret the pointer to the event structure.

If the server calls the notification function with an event class of `MYSQL_AUDIT_GENERAL_CLASS`, it passes the event structure as a pointer to a `mysql_event_general` structure:

```c
struct mysql_event_general
{
    unsigned int event_subclass;
    int general_error_code;
    unsigned long general_thread_id;
    const char *general_user;
    unsigned int general_user_length;
    const char *general_command;
    unsigned int general_command_length;
    const char *general_query;
    unsigned int general_query_length;
    struct charset_info_st *general_charset;
    unsigned long long general_time;
    unsigned long long general_rows;
};
```

Audit plugins can interpret `mysql_event_general` members as follows:

- **event_subclass**: The event subclass, one of the following values:

  ```c
  #define MYSQL_AUDIT_GENERAL_LOG 0
  #define MYSQL_AUDIT_GENERAL_ERROR 1
  #define MYSQL_AUDIT_GENERAL_RESULT 2
  #define MYSQL_AUDIT_GENERAL_STATUS 3
  ```

- **general_error_code**: The error code. This is a value like that returned by the `mysql_errno()` C API function; 0 means “no error.”

- **general_thread_id**: The ID of the thread for which the event occurred.

- **general_user**: The current user for the event.

- **general_user_length**: The length of `general_user`, in bytes.
• **general_command**: For general query log events, the type of operation. Examples: Connect, Query, Shutdown. For error log events, the error message. This is a value like that returned by the mysql_error() C API function; an empty string means “no error.” For result events, this is empty.

• **general_command_length**: The length of general_command, in bytes.

• **general_query**: The SQL statement that was logged or produced a result.

• **general_query_length**: The length of general_query, in bytes.

• **general_charset**: Character set information for the event.

• **general_time**: A TIMESTAMP value indicating the time just before the notification function was called.

• **general_rows**: For general query log events, zero. For error log events, the row number at which an error occurred. For result events, the number of rows in the result plus one. For statements that produce no result set, the value is 0. This encoding enables statements that produce no result set to be distinguished from those that produce an empty result set. For example, for a DELETE statement, this value is 0. For a SELECT, the result is always 1 or more, where 1 represents an empty result set.

• **general_host**: For general query log events, a string representing the client host name.

• **general_sql_command**: For general query log events, a string that indicates the type of action performed, such as connect or drop_table.

• **general_external_user**: For general query log events, a string representing the external user (empty if none).

• **general_ip**: For general query log events, a string representing the client IP address.

The **general_host**, **general_sql_command**, **general_external_user**, and **general_ip** members are new in MySQL 5.6.14. These are MYSQL_LEX_STRING structures that pair a string and its length. For example, if event_general is a pointer to a general event, you can access the members of the general_host value as follows:

```
event_general->general_host.length
event_general->general_host.str
```

If the server calls the notification function with an event class of MYSQL_AUDIT_CONNECTION_CLASS, it passes the event structure as a pointer to a mysql_event_connection structure, which is similar to and interpreted much the same way as the mysql_event_general structure.

The **NULL_AUDIT** plugin notification function is quite simple. It increments a global event counter, determines the event class, then looks at the event subclass to determine which subclass counter to increment:

```
static void audit_null_notify(MYSQL_THD thd __attribute__((unused)),
                              unsigned int event_class,
                              const void *event)
{
  /* prone to races, oh well */
  number_of_calls++;
  if (event_class == MYSQL_AUDITGENERAL_CLASS)
  {
    const struct mysql_event_general *event_general=
      (const struct mysql_event_general *) event;
    switch (event_general->event_subclass)
    {
```
case MYSQL_AUDIT_GENERAL_LOG:
    number_of_calls_general_log++;
    break;
case MYSQL_AUDIT_GENERAL_ERROR:
    number_of_calls_general_error++;
    break;
case MYSQL_AUDIT_GENERAL_RESULT:
    number_of_calls_general_result++;
    break;
case MYSQL_AUDIT_GENERAL_STATUS:
    number_of_calls_general_status++;
    break;
default:
    break;
}
}
else if (event_class == MYSQL_AUDIT_CONNECTION_CLASS)
{
    const struct mysql_event_connection *event_connection=
    (const struct mysql_event_connection *) event;
    switch (event_connection->event_subclass)
    {
    case MYSQL_AUDIT_CONNECTION_CONNECT:
        number_of_calls_connection_connect++;
        break;
    case MYSQL_AUDIT_CONNECTION_DISCONNECT:
        number_of_calls_connection_disconnect++;
        break;
    case MYSQL_AUDIT_CONNECTION_CHANGE_USER:
        number_of_calls_connection_change_user++;
        break;
default:
    break;
    }
}
}

To compile and install a plugin library file, use the instructions in Section 24.2.4.3, “Compiling and Installing Plugin Libraries”. To make the library file available for use, install it in the plugin directory (the directory named by the `plugin_dir` system variable). For the NULL_AUDIT plugin, it is compiled and installed when you build MySQL from source. It is also included in binary distributions. The build process produces a shared object library with a name of `adt_null.so` (the `.so` suffix might differ depending on your platform).

To register the plugin at runtime, use this statement (adjust the `.so` suffix for your platform as necessary):

```
INSTALL PLUGIN NULL_AUDIT SONAME 'adt_null.so';
```

For additional information about plugin loading, see Section 5.5.1, “Installing and Uninstalling Plugins”.

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement. See Section 5.5.2, “Obtaining Server Plugin Information”.

While the audit plugin is installed, it exposes status variables that indicate the events for which the plugin has been called:

```
mysql> SHOW STATUS LIKE 'Audit_null%';
+-------------------------------+-------+
| Variable_name                  | Value |
|-------------------------------+-------|
| Audit_null_called             | 1388  |
| Audit_null_connection_change_user | 0     |
+-------------------------------+-------+
```
Audience_null_connection_connect | 22 |
Audience_null_connection_disconnect | 21 |
Audience_null_general_error | 1 |
Audience_null_general_log | 513 |
Audience_null_general_result | 415 |
Audience_null_general_status | 416 |

Audit_null_called counts all events, and the other variables count instances of event subclasses.
For example, the preceding SHOW STATUS statement causes the server to send a result to the client and
to write a message to the general query log if that log is enabled. Thus, a client that issues the statement
repeatedly causes Audit_null_called and Audit_null_general_result to be incremented each
time, and Audit_null_general_log to be incremented. (Before MySQL 5.6.24, notification of events
for the general query log are received only if the general query log is enabled. As of 5.6.24, notifications
are received regardless of whether that log is enabled.)

To disable the plugin after testing it, use this statement to unload it:

UNINSTALL PLUGIN NULL_AUDIT;

24.2.4.9 Writing Authentication Plugins

MySQL supports pluggable authentication, in which plugins are invoked to authenticate client connections.
Authentication plugins enable the use of authentication methods other than the built-in method of
passwords stored in the mysql.user system table. For example, plugins can be written to access
external authentication methods. Also, authentication plugins can support the proxy user capability,
such that the connecting user is a proxy for another user and is treated, for purposes of access control,
as having the privileges of a different user. For more information, see Section 6.2.11, “Pluggable
Authentication”, and Section 6.2.12, “Proxy Users”.

An authentication plugin can be written for the server side or the client side. Server-side plugins use the
same plugin API that is used for the other server plugin types such as full-text parser or audit plugins
(although with a different type-specific descriptor). Client-side plugins use the client plugin API.

Several header files contain information relevant to authentication plugins:

- **plugin.h**: Defines the MYSQL_AUTHENTICATION_PLUGIN server plugin type.
- **client_plugin.h**: Defines the API for client plugins. This includes the client plugin descriptor and
  function prototypes for client plugin C API calls (see Section 23.8.14, “C API Client Plugin Functions”).
- **plugin_auth.h**: Defines the part of the server plugin API specific to authentication plugins.
  This includes the type-specific descriptor for server-side authentication plugins and the
  MYSQL_SERVER_AUTH_INFO structure.
- **plugin_auth_common.h**: Contains common elements of client and server authentication plugins. This
  includes return value definitions and the MYSQL_PLUGIN_VIO structure.

To write an authentication plugin, include the following header files in the plugin source file. Other MySQL
or general header files might also be needed, depending on the plugin capabilities and requirements.

- For a source file that implements a server authentication plugin, include this file:

```c
#include <mysql/plugin_auth.h>
```

- For a source file that implements a client authentication plugin, or both client and server plugins, include
  these files:
Writing Plugins

```c
#include <mysql/plugin_auth.h>
#include <mysql/client_plugin.h>
#include <mysql.h>
```

`plugin_auth.h` includes `plugin.h` and `plugin_auth_common.h`, so you need not include the latter files explicitly.

This section describes how to write a pair of simple server and client authentication plugins that work together.

---

**Warning**

These plugins accept any non-empty password and the password is sent as cleartext. This is insecure, so the plugins should not be used in production environments.

---

The server-side and client-side plugins developed here both are named `auth_simple`. As described in Section 24.2.4.2, “Plugin Data Structures”, the plugin library file must have the same base name as the client plugin, so the source file name is `auth_simple.c` and produces a library named `auth_simple.so` (assuming that your system uses `.so` as the suffix for library files).

In MySQL source distributions, authentication plugin source is located in the `plugin/auth` directory and can be examined as a guide to writing other authentication plugins. Also, to see how the built-in authentication plugins are implemented, see `sql/sql_acl.cc` for plugins that are built in to the MySQL server and `sql-common/client.c` for plugins that are built in to the `libmysqlclient` client library. (For the built-in client plugins, note that the `auth_plugin_t` structures used there differ from the structures used with the usual client plugin declaration macros. In particular, the first two members are provided explicitly, not by declaration macros.)

### Writing the Server-Side Authentication Plugin

Declare the server-side plugin with the usual general descriptor format that is used for all server plugin types (see Server Plugin Library and Plugin Descriptors). For the `auth_simple` plugin, the descriptor looks like this:

```c
mysql_declare_plugin(auth_simple)
{
    MYSQL_AUTHENTICATION_PLUGIN,
    &auth_simple_handler,       /* type-specific descriptor */
    "auth_simple",              /* plugin name */
    "Author Name",              /* author */
    "Any-password authentication plugin", /* description */
    PLUGIN_LICENSE_GPL,         /* license type */
    NULL,                       /* no init function */
    NULL,                       /* no deinit function */
    0x0100,                     /* version = 1.0 */
    NULL,                       /* no status variables */
    NULL,                       /* no system variables */
    NULL,                       /* no reserved information */
    0,                          /* no flags */
}
mysql_declare_plugin_end;
```

The `name` member (`auth_simple`) indicates the name to use for references to the plugin in statements such as `INSTALL PLUGIN` or `UNINSTALL PLUGIN`. This is also the name displayed by `SHOW PLUGINS` or `INFORMATION_SCHEMA.PLUGINS`. 

---

3612
The `auth_simple_handler` member of the general descriptor points to the type-specific descriptor. For an authentication plugin, the type-specific descriptor is an instance of the `st_mysql_auth` structure (defined in `plugin_auth.h`):

```c
struct st_mysql_auth
{
    int interface_version;
    const char *client_auth_plugin;
    int (*authenticate_user)(MYSQL_PLUGIN_VIO *vio, MYSQL_SERVER_AUTH_INFO *info);
};
```

The `st_mysql_auth` structure has these members:

- **interface_version**: The type-specific API version number, always `MYSQL_AUTHENTICATION_INTERFACE_VERSION`
- **client_auth_plugin**: The client plugin name
- **authenticate_user**: A pointer to the main plugin function that communicates with the client

The `client_auth_plugin` member should indicate the name of the client plugin if a specific plugin is required. A value of `NULL` means “any plugin.” In the latter case, whatever plugin the client uses will do. This is useful if the server plugin does not care about the client plugin or what user name or password it sends. For example, this might be true if the server plugin authenticates only local clients and uses some property of the operating system rather than the information sent by the client plugin.

For `auth_simple`, the type-specific descriptor looks like this:

```c
static struct st_mysql_auth auth_simple_handler =
{
    MYSQL_AUTHENTICATION_INTERFACE_VERSION,
    "auth_simple", /* required client-side plugin name */
    auth_simple_server /* server-side plugin main function */
};
```

The main function, `auth_simple_server()`, takes two arguments representing an I/O structure and a `MYSQL_SERVER_AUTH_INFO` structure. The structure definition, found in `plugin_auth.h`, looks like this:

```c
typedef struct st_mysql_server_auth_info
{
    char *user_name;
    unsigned int user_name_length;
    const char *auth_string;
    unsigned long auth_string_length;
    char authenticated_as[MYSQL_USERNAME_LENGTH+1];
    char external_user[512];
    int password_used;
    const char *host_or_ip;
    unsigned int host_or_ip_length;
} MYSQL_SERVER_AUTH_INFO;
```

The character set for string members is UTF-8. If there is a `_length` member associated with a string, it indicates the string length in bytes. Strings are also null-terminated.

When an authentication plugin is invoked by the server, it should interpret the `MYSQL_SERVER_AUTH_INFO` structure members as follows. Some of these are used to set the value of SQL functions or system variables within the client session, as indicated:

- **user_name**: The user name sent by the client. The value becomes the `USER()` function value.
Writing Plugins

- **user_name_length**: The length of *user_name* in bytes.

- **auth_string**: The value of the *authentication_string* column of the row in the *mysql.user* system table for the matching account name (that is, the row that matches the client user name and host name and that the server uses to determine how to authenticate the client).

Suppose that you create an account using the following statement:

```sql
CREATE USER 'my_user'@'localhost'
    IDENTIFIED WITH my_plugin AS 'my_auth_string';
```

When *my_user* connects from the local host, the server invokes *my_plugin* and passes *'my_auth_string'* to it as the *auth_string* value.

- **auth_string_length**: The length of *auth_string* in bytes.

- **authenticated_as**: The server sets this to the user name (the value of *user_name*). The plugin can alter it to indicate that the client should have the privileges of a different user. For example, if the plugin supports proxy users, the initial value is the name of the connecting (proxy) user, and the plugin can change this member to the proxied user name. The server then treats the proxy user as having the privileges of the proxied user (assuming that the other conditions for proxy user support are satisfied; see Implementing Proxy User Support in Authentication Plugins). The value is represented as a string at most 51 bytes long, plus a terminating null. The value becomes the *

- **external_user**: The server sets this to the empty string (null terminated). Its value becomes the *

- **password_used**: This member applies when authentication fails. The plugin can set it or ignore it. The value is used to construct the failure error message of *Authentication fails. Password used: %s*. The value of *password_used* determines how %s is handled, as shown in the following table.

<table>
<thead>
<tr>
<th>password_used</th>
<th>%s Handling</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>NO</td>
</tr>
<tr>
<td>1</td>
<td>YES</td>
</tr>
<tr>
<td>2</td>
<td>There will be no %s</td>
</tr>
</tbody>
</table>

- **host_or_ip**: The name of the client host if it can be resolved, or the IP address otherwise.

- **host_or_ip_length**: The length of *host_or_ip* in bytes.

The *auth_simple* main function, *auth_simple_server()*, reads the password (a null-terminated string) from the client and succeeds if the password is nonempty (first byte not null):

```c
static int auth_simple_server (MYSQL_PLUGIN_VIO *vio,
       MYSQL_SERVER_AUTH_INFO *info)
{
    unsigned char *pkt;
    int pkt_len;

    /* read the password as null-terminated string, fail on error */
    if ((pkt_len= vio->read_packet(vio, &pkt)) < 0)
        return CR_ERROR;
```
Writing Plugins

```c
/* fail on empty password */
if (!pkt_len || *pkt == '\0')
{
    info->password_used = PASSWORD_USED_NO;
    return CR_ERROR;
}
/* accept any nonempty password */
info->password_used = PASSWORD_USED_YES;
return CR_OK;
```

The main function should return one of the error codes shown in the following table.

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>CR_OK</td>
<td>Success</td>
</tr>
<tr>
<td>CR_OK_HANDSHAKE_COMPLETE</td>
<td>Do not send a status packet back to client</td>
</tr>
<tr>
<td>CR_ERROR</td>
<td>Error</td>
</tr>
<tr>
<td>CR_AUTH_USER_CREDENTIALS</td>
<td>Authentication failure</td>
</tr>
<tr>
<td>CR_AUTH_HANDSHAKE</td>
<td>Authentication handshake failure</td>
</tr>
<tr>
<td>CR_AUTH_PLUGIN_ERROR</td>
<td>Internal plugin error</td>
</tr>
</tbody>
</table>

For an example of how the handshake works, see the `plugin/auth/dialog.c` source file.

The server counts plugin errors in the Performance Schema `host_cache` table.

The server counts plugin errors in the Performance Schema `host_cache` table.

auth_simple() is so basic that it does not use the authentication information structure except to set the member that indicates whether a password was received.

A plugin that supports proxy users must return to the server the name of the proxied user (the MySQL user whose privileges the client user should get). To do this, the plugin must set the `info->authenticated_as` member to the proxied user name. For information about proxying, see Section 6.2.12, "Proxy Users", and Implementing Proxy User Support in Authentication Plugins.

Writing the Client-Side Authentication Plugin

Declare the client-side plugin descriptor with the `mysql_declare_client_plugin()` and `mysql_end_client_plugin` macros (see Client Plugin Descriptors). For the `auth_simple` plugin, the descriptor looks like this:

```c
mysql_declare_client_plugin(AUTHENTICATION)
 "auth_simple", /* plugin name */
 "Author Name", /* author */
 "Any-password authentication plugin", /* description */
 {1,0,0}, /* version = 1.0.0 */
 "GPL", /* license type */
 NULL, /* for internal use */
 NULL, /* no init function */
 NULL, /* no deinit function */
 NULL, /* no option-handling function */
 auth_simple_client /* main function */
mysql_end_client_plugin;
```

The descriptor members from the plugin name through the option-handling function are common to all client plugin types. (For descriptions, see Client Plugin Descriptors.) Following the common members, the descriptor has an additional member specific to authentication plugins. This is the “main” function, which
Writing Plugins

handles communication with the server. The function takes two arguments representing an I/O structure and a connection handler. For our simple any-password plugin, the main function does nothing but write to the server the password provided by the user:

```c
static int auth_simple_client (MYSQL_PLUGIN_VIO *vio, MYSQL *mysql)
{
    int res;

    /* send password as null-terminated string as cleartext */
    res= vio->write_packet(vio, (const unsigned char *) mysql->passwd,
                        strlen(mysql->passwd) + 1);

    return res ? CR_ERROR : CR_OK;
}
```

The main function should return one of the error codes shown in the following table.

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>CR_OK</td>
<td>Success</td>
</tr>
<tr>
<td>CR_OK_HANDSHAKE_COMPLETE</td>
<td>Success, client done</td>
</tr>
<tr>
<td>CR_ERROR</td>
<td>Error</td>
</tr>
</tbody>
</table>

CR_OK_HANDSHAKE_COMPLETE indicates that the client has done its part successfully and has read the last packet. A client plugin may return CR_OK_HANDSHAKE_COMPLETE if the number of round trips in the authentication protocol is not known in advance and the plugin must read another packet to determine whether authentication is finished.

Using the Authentication Plugins

To compile and install a plugin library file, use the instructions in Section 24.2.4.3, “Compiling and Installing Plugin Libraries”. To make the library file available for use, install it in the plugin directory (the directory named by the plugin_dir system variable).

Register the server-side plugin with the server. For example, to load the plugin at server startup, use a --plugin-load=auth_simple.so option (adjust the .so suffix for your platform as necessary).

Create a user for whom the server will use the auth_simple plugin for authentication:

```sql
mysql> CREATE USER 'x'@'localhost'
-> IDENTIFIED WITH auth_simple;
```

Use a client program to connect to the server as user x. The server-side auth_simple plugin communicates with the client program that it should use the client-side auth_simple plugin, and the latter sends the password to the server. The server plugin should reject connections that send an empty password and accept connections that send a nonempty password. Invoke the client program each way to verify this:

```shell
tshell> mysql --user=x --skip-password
ERROR 1045 (28000): Access denied for user 'x'@'localhost' (using password: NO)
tshell> mysql --user=x --password
Enter password: abc
mysql>
```

Because the server plugin accepts any nonempty password, it should be considered insecure. After testing the plugin to verify that it works, restart the server without the --plugin-load option so as not to
Writing Plugins

indadvertently leave the server running with an insecure authentication plugin loaded. Also, drop the user with DROP USER 'x'@'localhost'.

For additional information about loading and using authentication plugins, see Section 5.5.1, "Installing and Uninstalling Plugins", and Section 6.2.11, "Pluggable Authentication".

If you are writing a client program that supports the use of authentication plugins, normally such a program causes a plugin to be loaded by calling mysql_options() to set the MYSQL_DEFAULT_AUTH and MYSQL_PLUGIN_DIR options:

```c
char *plugin_dir = "path_to_plugin_dir";
char *default_auth = "plugin_name";
/* ... process command-line options ... */
mysql_options(&mysql, MYSQL_PLUGIN_DIR, plugin_dir);
mysql_options(&mysql, MYSQL_DEFAULT_AUTH, default_auth);
```

Typically, the program will also accept --plugin-dir and --default-auth options that enable users to override the default values.

Should a client program require lower-level plugin management, the client library contains functions that take an st_mysql_client_plugin argument. See Section 23.8.14, "C API Client Plugin Functions".

Implementing Proxy User Support in Authentication Plugins

One of the capabilities that pluggable authentication makes possible is proxy users (see Section 6.2.12, "Proxy Users"). For a server-side authentication plugin to participate in proxy user support, these conditions must be satisfied:

• When a connecting client should be treated as a proxy user, the plugin must return a different name in the authenticated_as member of the MYSQL_SERVER_AUTH_INFO structure, to indicate the proxied user name. It may also optionally set the external_user member, to set the value of the external_user system variable.

• Proxy user accounts must be set up to be authenticated by the plugin. Use the CREATE USER or GRANT statement to associate accounts with plugins.

• Proxy user accounts must have the PROXY privilege for the proxied accounts. Use the GRANT statement to grant this privilege.

In other words, the only aspect of proxy user support required of the plugin is that it set authenticated_as to the proxied user name. The rest is optional (setting external_user) or done by the DBA using SQL statements.

How does an authentication plugin determine which proxied user to return when the proxy user connects? That depends on the plugin. Typically, the plugin maps clients to proxied users based on the authentication string passed to it by the server. This string comes from the AS part of the IDENTIFIED WITH clause of the CREATE USER statement that specifies use of the plugin for authentication.

The plugin developer determines the syntax rules for the authentication string and implements the plugin according to those rules. Suppose that a plugin takes a comma-separated list of pairs that map external users to MySQL users. For example:

```sql
CREATE USER ''@'.example.com'
 IDENTIFIED WITH my_plugin AS 'extuser1=mysqlusera, extuser2=mysqluserb'
CREATE USER ''@'.example.org'
```
IDENTIFIED WITH my_plugin AS 'extuser1=mysqluserc, extuser2=mysqluserd'

When the server invokes a plugin to authenticate a client, it passes the appropriate authentication string to the plugin. The plugin is responsible to:

1. Parse the string into its components to determine the mapping to use
2. Compare the client user name to the mapping
3. Return the proper MySQL user name

For example, if extuser2 connects from an example.com host, the server passes 'extuser1=mysqlusera, extuser2=mysqluserb' to the plugin, and the plugin should copy mysqluserb into authenticated_as, with a terminating null byte. If extuser2 connects from an example.org host, the server passes 'extuser1=mysqluserc, extuser2=mysqluserd', and the plugin should copy mysqluserd instead.

If there is no match in the mapping, the action depends on the plugin. If a match is required, the plugin likely will return an error. Or the plugin might simply return the client name; in this case, it should not change authenticated_as, and the server will not treat the client as a proxy.

The following example demonstrates how to handle proxy users using a plugin named auth_simple_proxy. Like the auth_simple plugin described earlier, auth_simple_proxy accepts any nonempty password as valid (and thus should not be used in production environments). In addition, it examines the auth_string authentication string member and uses these very simple rules for interpreting it:

- If the string is empty, the plugin returns the user name as given and no proxying occurs. That is, the plugin leaves the value of authenticated_as unchanged.
- If the string is nonempty, the plugin treats it as the name of the proxied user and copies it to authenticated_as so that proxying occurs.

For testing, set up one account that is not proxied according to the preceding rules, and one that is. This means that one account has no AS clause, and one includes an AS clause that names the proxied user:

```
CREATE USER 'plugin_user1'@'localhost'
    IDENTIFIED WITH auth_simple_proxy;
CREATE USER 'plugin_user2'@'localhost'
    IDENTIFIED WITH auth_simple_proxy AS 'proxied_user';
```

In addition, create an account for the proxied user and grant plugin_user2 the PROXY privilege for it:

```
CREATE USER 'proxied_user'@'localhost'
    IDENTIFIED BY 'proxied_user_pass';
GRANT PROXY
    ON 'proxied_user'@'localhost'
    TO 'plugin_user2'@'localhost';
```

Before the server invokes an authentication plugin, it sets authenticated_as to the client user name. To indicate that the user is a proxy, the plugin should set authenticated_as to the proxied user name. For auth_simple_proxy, this means that it must examine the auth_string value, and, if the value is nonempty, copy it to the authenticated_as member to return it as the name of the proxied user. In addition, when proxying occurs, the plugin sets the external_user member to the client user name; this becomes the value of the external_user system variable.
Writing Plugins

static int auth_simple_proxy_server (MYSQL_PLUGIN_VIO *vio,
    MYSQL_SERVER_AUTH_INFO *info)
{
    unsigned char *pkt;
    int pkt_len;

    /* read the password as null-terminated string, fail on error */
    if ((pkt_len= vio->read_packet(vio, &pkt)) < 0)
        return CR_ERROR;

    /* fail on empty password */
    if (!pkt_len || *pkt == '\0')
    {
        info->password_used= PASSWORD_USED_NO;
        return CR_ERROR;
    }

    /* accept any nonempty password */
    info->password_used= PASSWORD_USED_YES;

    /* if authentication string is nonempty, use as proxied user name */
    /* and use client name as external_user value */
    if (info->auth_string_length > 0)
    {
        strcpy (info->authenticated_as, info->auth_string);
        strcpy (info->external_user, info->user_name);
    }

    return CR_OK;
}

After a successful connection, the USER() function should indicate the connecting client user and host name, and CURRENT_USER() should indicate the account whose privileges apply during the session. The latter value should be the connecting user account if no proxying occurs or the proxied account if proxying does occur.

Compile and install the plugin, then test it. First, connect as plugin_user1:

shell> mysql --user=plugin_user1 --password
Enter password: x

In this case, there should be no proxying:

mysql> SELECT USER(), CURRENT_USER(), @@proxy_user, @@external_user\G
*************************** 1. row ***************************
USER(): plugin_user1@localhost
CURRENT_USER(): plugin_user1@localhost
@@proxy_user: NULL
@@external_user: NULL

Then connect as plugin_user2:

shell> mysql --user=plugin_user2 --password
Enter password: x

In this case, plugin_user2 should be proxied to proxied_user:

mysql> SELECT USER(), CURRENT_USER(), @@proxy_user, @@external_user\G
*************************** 1. row ***************************
USER(): plugin_user2@localhost
CURRENT_USER(): proxied_user@localhost
24.2.4.10 Writing Password-Validation Plugins

This section describes how to write a server-side password-validation plugin. The instructions are based on the source code in the `plugin/password_validation` directory of MySQL source distributions. The `validate_password.cc` source file in that directory implements the plugin named `validate_password`.

To write a password-validation plugin, include the following header file in the plugin source file. Other MySQL or general header files might also be needed, depending on the plugin capabilities and requirements.

```c
#include <mysql/plugin_validate_password.h>
```

`plugin_validate_password.h` includes `plugin.h`, so you need not include the latter file explicitly. `plugin.h` defines the `MYSQL_VALIDATE_PASSWORD_PLUGIN` server plugin type and the data structures needed to declare the plugin. `plugin_validate_password.h` defines data structures specific to password-validation plugins.

A password-validation plugin, like any MySQL server plugin, has a general plugin descriptor (see Server Plugin Library and Plugin Descriptors). In `validate_password.cc`, the general descriptor for `validate_password` looks like this:

```c
mysql_declare_plugin(validate_password)
{
  MYSQL_VALIDATE_PASSWORD_PLUGIN,     /*   type                            */
  &validate_password_descriptor,      /*   descriptor                      */
  "validate_password",                /*   name                            */
  "Oracle Corporation",               /*   author                          */
  "check password strength",          /*   description                     */
  PLUGIN_LICENSE_GPL,
  validate_password_init,             /*   init function (when loaded)     */
  validate_password_deinit,           /*   deinit function (when unloaded) */
  0x0100,                             /*   version                         */
  NULL,
  validate_password_system_variables, /*   system variables                */
  NULL,
  0,
}
mysql_declare_plugin_end;
```

The `name` member (`validate_password`) indicates the name to use for references to the plugin in statements such as `INSTALL PLUGIN` or `UNINSTALL PLUGIN`. This is also the name displayed by `INFORMATION_SCHEMA.PLUGINS` or `SHOW PLUGINS`.

The general descriptor also refers to `validate_password_system_variables`, a structure that exposes several system variables to the `SHOW VARIABLES` statement:

```c
static struct st_mysql_sys_var* validate_password_system_variables[]= {
  MYSQL_SYSVAR(length),
  MYSQL_SYSVAR(number_count),
  MYSQL_SYSVAR(mixed_case_count),
  MYSQL_SYSVAR(special_char_count),
  MYSQL_SYSVAR(policy),
  MYSQL_SYSVAR(dictionary_file),
  NULL
};
```
The `validate_password_init` initialization function reads the dictionary file if one was specified, and the `validate_password_deinit` function frees data structures associated with the file.

The `validate_password_descriptor` value in the general descriptor points to the type-specific descriptor. For password-validation plugins, this descriptor has the following structure:

```c
struct st_mysql_validate_password
{
    int interface_version;
    /*
     * This function returns TRUE for passwords which satisfy the password
     * policy (as chosen by plugin variable) and FALSE for all other
     * password
     */
    int (*validate_password)(mysql_string_handle password);
    /*
     * This function returns the password strength (0-100) depending
     * upon the policies
     */
    int (*get_password_strength)(mysql_string_handle password);
};
```

The type-specific descriptor has these members:

- **interface_version**: By convention, type-specific plugin descriptors begin with the interface version for the given plugin type. The server checks `interface_version` when it loads the plugin to see whether the plugin is compatible with it. For password-validation plugins, the value of the `interface_version` member is `MYSQL_VALIDATE_PASSWORD_INTERFACE_VERSION` (defined in `plugin_validate_password.h`).

- **validate_password**: A function that the server calls to test whether a password satisfies the current password policy. It returns 1 if the password is okay and 0 otherwise. The argument is the password, passed as a `mysql_string_handle` value. This data type is implemented by the `mysql_string` server service. For details, see the `string_service.h` and `string_service.cc` source files in the `sql` directory.

- **get_password_strength**: A function that the server calls to assess the strength of a password. It returns a value from 0 (weak) to 100 (strong). The argument is the password, passed as a `mysql_string_handle` value.

For the `validate_password` plugin, the type-specific descriptor looks like this:

```c
static struct st_mysql_validate_password validate_password_descriptor=
{   MYSQL_VALIDATE_PASSWORD_INTERFACE_VERSION,
    validate_password, /* validate function */
    get_password_strength /* validate strength function */
};
```

To compile and install a plugin library file, use the instructions in Section 24.2.4.3, “Compiling and Installing Plugin Libraries”. To make the library file available for use, install it in the plugin directory (the directory named by the `plugin_dir` system variable). For the `validate_password` plugin, it is compiled and installed when you build MySQL from source. It is also included in binary distributions. The build process produces a shared object library with a name of `validate_password.so` (the `.so` suffix might differ depending on your platform).

To register the plugin at runtime, use this statement (adjust the `.so` suffix for your platform as necessary):
 INSTALL PLUGIN validate_password SONAME 'validate_password.so';

For additional information about plugin loading, see Section 5.5.1, “Installing and Uninstalling Plugins”.

To verify plugin installation, examine the INFORMATION_SCHEMA.PLUGINS table or use the SHOW PLUGINS statement. See Section 5.5.2, “Obtaining Server Plugin Information”.

While the validate_password plugin is installed, it exposes system variables that indicate the password-checking parameters:

```
mysql> SHOW VARIABLES LIKE 'validate_password%';
+--------------------------------------+--------+
<table>
<thead>
<tr>
<th>Variable_name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>validate_password_dictionary_file</td>
<td></td>
</tr>
<tr>
<td>validate_password_length</td>
<td>8</td>
</tr>
<tr>
<td>validate_password_mixed_case_count</td>
<td>1</td>
</tr>
<tr>
<td>validate_password_number_count</td>
<td>1</td>
</tr>
<tr>
<td>validate_password_policy</td>
<td>MEDIUM</td>
</tr>
<tr>
<td>validate_password_special_char_count</td>
<td>1</td>
</tr>
</tbody>
</table>
+--------------------------------------|--------+
```

For descriptions of these variables, see Section 6.4.3.2, “Password Validation Plugin Options and Variables”.

To disable the plugin after testing it, use this statement to unload it:

UNINSTALL PLUGIN validate_password;

### 24.3 MySQL Services for Plugins

MySQL server plugins have access to server “plugin services.” The plugin services interface exposes server functionality that plugins can call. It complements the plugin API and has these characteristics:

- Services enable plugins to access code inside the server using ordinary function calls. Services are also available to user-defined functions (UDFs).
- Services are portable and work on multiple platforms.
- The interface includes a versioning mechanism so that service versions supported by the server can be checked at load time against plugin versions. Versioning protects against incompatibilities between the version of a service that the server provides and the version of the service expected or required by a plugin.

The plugin services interface differs from the plugin API as follows:

- The plugin API enables plugins to be used by the server. The calling initiative lies with the server to invoke plugins. This enables plugins to extend server functionality or register to receive notifications about server processing.
- The plugin services interface enables plugins to call code inside the server. The calling initiative lies with plugins to invoke service functions. This enables functionality already implemented in the server to be used by many plugins; they need not individually implement it themselves.

To determine what services exist and what functions they provide, look in the `include/mysql` directory of a MySQL source distribution. The relevant files are:
MySQL Services for Plugins

• **plugin.h** includes **services.h**, which is the “umbrella” header that includes all available service-specific header files.

• Service-specific headers have names of the form **service_xxx.h**.

Each service-specific header should contain comments that provide full usage documentation for a given service, including what service functions are available, their calling sequences, and return values.

For developers who wish to modify the server to add a new service, see MySQL Internals: MySQL Services for Plugins.

Available services include the following:

• **my_plugin_log_service**: A service that enables plugins to report errors and specify error messages. The server writes the messages to its error log.

• **my_snprintf**: A string-formatting service that produces consistent results across platforms.

• **my_thd_scheduler**: A service for plugins to select a thread scheduler.

• **mysql_string**: A service for string manipulation.

• **thd_alloc**: A memory-allocation service.

• **thd_wait**: A service for plugins to report when they are going to sleep or stall.

The remainder of this section describes how a plugin uses server functionality that is available as a service. See also the source for the “daemon” example plugin, which uses the **my_snprintf** service. Within a MySQL source distribution, that plugin is located in the **plugin/daemon_example** directory.

To use a service or services from within a plugin, the plugin source file must include the **plugin.h** header file to access service-related information:

```
#include <mysql/plugin.h>
```

This does not represent any additional setup cost. A plugin must include that file anyway because it contains definitions and structures that every plugin needs.

To access a service, a plugin calls service functions like any other function. For example, to format a string into a buffer for printing, call the **my_snprintf()** function provided by the service of the same name:

```
char buffer[BUFFER_SIZE];
my_snprintf(buffer, sizeof(buffer), format_string, argument_to_format, ...);
```

To report an error that the server will write to its error log, first choose an error level. **mysql/service_my_plugin_log.h** defines these levels:

```
enum plugin_log_level
{
    MY_ERROR_LEVEL,
    MY_WARNING_LEVEL,
    MY_INFORMATION_LEVEL
};
```

Then invoke **my_plugin_log_message()**:

```
```
Adding Functions to MySQL

```c
int my_plugin_log_message(MYSQL_PLUGIN *plugin, enum plugin_log_level level,
const char *format, ...);
```

For example:

```c
my_plugin_log_message(plugin_ptr, MY_ERROR_LEVEL, "Cannot initialize plugin");
```

When you build your plugin, use the `-lmysqlservices` flag at link time to link in the `libmysqlservices` library. For example, for CMake, put this in the top-level CMakeLists.txt file:

```cmake
FIND_LIBRARY(MYSQLSERVICES_LIB mysqlservices
PATHS "${MYSQL_SRCDIR}/libservices" NO_DEFAULT_PATH)
```

Put this in the CMakeLists.txt file in the directory containing the plugin source:

```cmake
# the plugin needs the mysql services library for error logging
TARGET_LINK_LIBRARIES (your_plugin_library_name ${MYSQLSERVICES_LIB})
```

### 24.4 Adding Functions to MySQL

There are three ways to add functions to MySQL:

- Through the user-defined function (UDF) interface. User-defined functions are compiled as library files and then added to and removed from the server dynamically using the `CREATE FUNCTION` and `DROP FUNCTION` statements. See Section 13.7.3.1, “CREATE FUNCTION Syntax for User-Defined Functions”.

- By creating native (built-in) MySQL functions. Native functions are compiled into the `mysqld` server and become available on a permanent basis.

- By creating stored functions. These are written using SQL statements rather than by compiling object code. The syntax for writing stored functions is not covered here. See Section 20.2, “Using Stored Routines”.

Each method of creating compiled functions has advantages and disadvantages:

- If you write user-defined functions, you must install object files in addition to the server itself. If you compile your function into the server, you need not do that.

- Native functions require you to modify a source distribution. UDFs do not. You can add UDFs to a binary MySQL distribution. No access to MySQL source is necessary.

- If you upgrade your MySQL distribution, you can continue to use your previously installed UDFs, unless you upgrade to a newer version for which the UDF interface changes. For native functions, you must repeat your modifications each time you upgrade.

Whichever method you use to add functions, they can be invoked in SQL statements just like native functions such as `ABS()` or `SOUNDEX()`.

For the rules describing how the server interprets references to different kinds of functions see Section 9.2.5, “Function Name Parsing and Resolution”.

The following sections describe features of the UDF interface, provide instructions for writing UDFs, discuss security precautions that MySQL takes to prevent UDF misuse, and describe how to add native MySQL functions.
For example source code that illustrates how to write UDFs, take a look at the sql/udf_example.cc file that is provided in MySQL source distributions.

### 24.4.1 Features of the User-Defined Function Interface

The MySQL interface for user-defined functions provides the following features and capabilities:

- Functions can return string, integer, or real values and can accept arguments of those same types.
- You can define simple functions that operate on a single row at a time, or aggregate functions that operate on groups of rows.
- Information is provided to functions that enables them to check the number, types, and names of the arguments passed to them.
- You can tell MySQL to coerce arguments to a given type before passing them to a function.
- You can indicate that a function returns NULL or that an error occurred.

### 24.4.2 Adding a User-Defined Function

For the UDF mechanism to work, functions must be written in C or C++ and your operating system must support dynamic loading. MySQL source distributions include a file sql/udf_example.cc that defines five UDF functions. Consult this file to see how UDF calling conventions work. The include/mysql_com.h header file defines UDF-related symbols and data structures, although you need not include this header file directly; it is included by mysql.h.

A UDF contains code that becomes part of the running server, so when you write a UDF, you are bound by any and all constraints that apply to writing server code. For example, you may have problems if you attempt to use functions from the libstdc++ library. These constraints may change in future versions of the server, so it is possible that server upgrades will require revisions to UDFs that were originally written for older servers. For information about these constraints, see Section 2.9.7, “MySQL Source-Configuration Options”, and Section 2.9.8, “Dealing with Problems Compiling MySQL”.

To be able to use UDFs, you must link mysqld dynamically. If you want to use a UDF that needs to access symbols from mysqld (for example, the metaphone function in sql/udf_example.cc uses default_charset_info), you must link the program with -rdynamic (see man dlopen).

For each function that you want to use in SQL statements, you should define corresponding C (or C++) functions. In the following discussion, the name “xxx” is used for an example function name. To distinguish between SQL and C/C++ usage, XXX() (uppercase) indicates an SQL function call, and xxx() (lowercase) indicates a C/C++ function call.

---

**Note**

When using C++, encapsulate your C functions within this construct:

```c
extern "C" {
  ...
}
```

This ensures that your C++ function names remain readable in the completed UDF.

- UDF Calling Sequences for Aggregate Functions
Adding a User-Defined Function

- UDF Argument Processing
- UDF Return Values and Error Handling
- UDF Compiling and Installing
- UDF Security Precautions

User-Defined Function Interface Functions

The following list describes the C/C++ functions that you write to implement the interface for a function named `xxx()`. The main function, `xxx()`, is required. In addition, a UDF requires at least one of the other functions described here, for reasons discussed in UDF Security Precautions.

- `xxx()`
  
The main function. This is where the function result is computed. The correspondence between the SQL function data type and the return type of your C/C++ function is shown here.

<table>
<thead>
<tr>
<th>SQL Type</th>
<th>C/C++ Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>STRING</td>
<td>char *</td>
</tr>
<tr>
<td>INTEGER</td>
<td>long long</td>
</tr>
<tr>
<td>REAL</td>
<td>double</td>
</tr>
</tbody>
</table>

It is also possible to declare a DECIMAL function, but the value is returned as a string, so you should write the UDF as though it were a STRING function. ROW functions are not implemented.

- `xxx_init()`
  
The initialization function for `xxx()`. If present, it can be used for the following purposes:

  - To check the number of arguments to `xxx()`.
  - To verify that the arguments are of a required type or, alternatively, to tell MySQL to coerce arguments to the required types when the main function is called.
  - To allocate any memory required by the main function.
  - To specify the maximum length of the result.
  - To specify (for REAL functions) the maximum number of decimal places in the result.
  - To specify whether the result can be NULL.

- `xxx_deinit()`
  
The deinitialization function for `xxx()`. If present, it should deallocate any memory allocated by the initialization function.

When an SQL statement invokes `xxx()`, MySQL calls the initialization function `xxx_init()` to let it perform any required setup, such as argument checking or memory allocation. If `xxx_init()` returns an error, MySQL aborts the SQL statement with an error message and does not call the main or deinitialization functions. Otherwise, MySQL calls the main function `xxx()` once for each row. After all rows have been processed, MySQL calls the deinitialization function `xxx_deinit()` so that it can perform any required cleanup.

For aggregate functions that work like `SUM()`, you must also provide the following functions:
Adding a User-Defined Function

- **xxx_clear()**
  
  Reset the current aggregate value but do not insert the argument as the initial aggregate value for a new group.

- **xxx_add()**
  
  Add the argument to the current aggregate value.

MySQL handles aggregate UDFs as follows:

1. Call **xxx_init()** to let the aggregate function allocate any memory it needs for storing results.
2. Sort the table according to the **GROUP BY** expression.
3. Call **xxx_clear()** for the first row in each new group.
4. Call **xxx_add()** for each row that belongs in the same group.
5. Call **xxx()** to get the result for the aggregate when the group changes or after the last row has been processed.
6. Repeat steps 3 to 5 until all rows has been processed
7. Call **xxx_deinit()** to let the UDF free any memory it has allocated.

All functions must be thread-safe. This includes not just the main function, but the initialization and deinitialization functions as well, and also the additional functions required by aggregate functions. A consequence of this requirement is that you are not permitted to allocate any global or static variables that change! If you need memory, you must it in **xxx_init()** and free it in **xxx_deinit()**.

**UDF Calling Sequences for Simple Functions**

This section describes the different functions that you must define to create a simple UDF. For information about the order in which MySQL calls these functions, see User-Defined Function Interface Functions.

The main **xxx()** function should be declared as shown in this section. Note that the return type and parameters differ, depending on whether you declare the SQL function **XXX()** to return **STRING**, **INTEGER**, or **REAL** in the CREATE FUNCTION statement:

For **STRING** functions:

```c
char *xxx(UDF_INIT *initid, UDF_ARGS *args, 
          char *result, unsigned long *length, 
          char *is_null, char *error);
```

For **INTEGER** functions:

```c
long long xxx(UDF_INIT *initid, UDF_ARGS *args, 
              char *is_null, char *error);
```

For **REAL** functions:

```c
double xxx(UDF_INIT *initid, UDF_ARGS *args, 
           char *is_null, char *error);
```
**DECIMAL** functions return string values and are declared the same way as **STRING** functions. **ROW** functions are not implemented.

Declare the initialization and deinitialization functions like this:

```c
my_bool xxx_init(UDF_INIT *initid, UDF_ARGS *args, char *message);
void xxx_deinit(UDF_INIT *initid);
```

The `initid` parameter is passed to all three functions. It points to a **UDF_INIT** structure that is used to communicate information between functions. The **UDF_INIT** structure members follow. The initialization function should fill in any members that it wishes to change. (To use the default for a member, leave it unchanged.)

- **my_bool maybe_null**
  
  `xxx_init()` should set `maybe_null` to 1 if `xxx()` can return **NULL**. The default value is 1 if any of the arguments are declared `maybe_null`.

- **unsigned int decimals**
  
  The number of decimal digits to the right of the decimal point. The default value is the maximum number of decimal digits in the arguments passed to the main function. For example, if the function is passed `1.34`, `1.345`, and `1.3`, the default would be 3, because `1.345` has 3 decimal digits.

  For arguments that have no fixed number of decimals, the `decimals` value is set to 31, which is 1 more than the maximum number of decimals permitted for the **DECIMAL**, **FLOAT**, and **DOUBLE** data types. This value is available as the constant `NOT_FIXED_DEC` in the `mysql_com.h` header file.

  A `decimals` value of 31 is used for arguments in cases such as a **FLOAT** or **DOUBLE** column declared without an explicit number of decimals (for example, **FLOAT** rather than **FLOAT(10,3)**) and for floating-point constants such as `1345E-3`. It is also used for string and other nonnumber arguments that might be converted within the function to numeric form.

  The value to which the `decimals` member is initialized is only a default. It can be changed within the function to reflect the actual calculation performed. The default is determined such that the largest number of decimals of the arguments is used. If the number of decimals is `NOT_FIXED_DEC` for even one of the arguments, that is the value used for `decimals`.

- **unsigned int max_length**
  
  The maximum length of the result. The default `max_length` value differs depending on the result type of the function. For string functions, the default is the length of the longest argument. For integer functions, the default is 21 digits. For real functions, the default is 13 plus the number of decimal digits indicated by `initid->decimals`. (For numeric functions, the length includes any sign or decimal point characters.)

  If you want to return a blob value, you can set `max_length` to 65KB or 16MB. This memory is not allocated, but the value is used to decide which data type to use if there is a need to temporarily store the data.

- **char *ptr**
  
  A pointer that the function can use for its own purposes. For example, functions can use `initid->ptr` to communicate allocated memory among themselves. `xxx_init()` should allocate the memory and assign it to this pointer:

  ```c
  initid->ptr = allocated_memory;
  ```
In `xxx()` and `xxx_deinit()`, refer to `initid->ptr` to use or deallocate the memory.

- **my_bool const_item**

  `xxx_init()` should set `const_item` to 1 if `xxx()` always returns the same value and to 0 otherwise.

### UDF Calling Sequences for Aggregate Functions

This section describes the different functions that you need to define when you create an aggregate UDF. For information about the order in which MySQL calls these functions, see [User-Defined Function Interface Functions](#).

- **xxx_reset()**

  This function is called when MySQL finds the first row in a new group. It should reset any internal summary variables and then use the given `UDF_ARGS` argument as the first value in your internal summary value for the group. Declare `xxx_reset()` as follows:

  ```c
  void xxx_reset(UDF_INIT *initid, UDF_ARGS *args, char *is_null, char *error);
  ```

  `xxx_reset()` is not needed or used in MySQL 5.6, in which the UDF interface uses `xxx_clear()` instead. However, you can define both `xxx_reset()` and `xxx_clear()` if you want to have your UDF work with older versions of the server. (If you do include both functions, the `xxx_reset()` function in many cases can be implemented internally by calling `xxx_clear()` to reset all variables, and then calling `xxx_add()` to add the `UDF_ARGS` argument as the first value in the group.)

- **xxx_clear()**

  This function is called when MySQL needs to reset the summary results. It is called at the beginning for each new group but can also be called to reset the values for a query where there were no matching rows. Declare `xxx_clear()` as follows:

  ```c
  void xxx_clear(UDF_INIT *initid, char *is_null, char *error);
  ```

  `is_null` is set to point to `CHAR(0)` before calling `xxx_clear()`.

  If something went wrong, you can store a value in the variable to which the `error` argument points. `error` points to a single-byte variable, not to a string buffer.

  `xxx_clear()` is required by MySQL 5.6.

- **xxx_add()**

  This function is called for all rows that belong to the same group. You should use it to add the value in the `UDF_ARGS` argument to your internal summary variable.

  ```c
  void xxx_add(UDF_INIT *initid, UDF_ARGS *args, char *is_null, char *error);
  ```

  The `xxx()` function for an aggregate UDF should be declared the same way as for a nonaggregate UDF. See [UDF Calling Sequences for Simple Functions](#).

  For an aggregate UDF, MySQL calls the `xxx()` function after all rows in the group have been processed. You should normally never access its `UDF_ARGS` argument here but instead return a value based on your internal summary variables.
Return value handling in \texttt{xxx()} should be done the same way as for a nonaggregate UDF. See UDF Return Values and Error Handling.

The \texttt{xxx_reset()} and \texttt{xxx_add()} functions handle their \texttt{UDF_ARGS} argument the same way as functions for nonaggregate UDFs. See UDF Argument Processing.

The pointer arguments to \texttt{is\_null} and \texttt{error} are the same for all calls to \texttt{xxx\_reset()}, \texttt{xxx\_clear()}, \texttt{xxx\_add()} and \texttt{xxx()}. You can use this to remember that you got an error or whether the \texttt{xxx()} function should return \texttt{NULL}. You should not store a string into \*\texttt{error}; \texttt{error} points to a single-byte variable, not to a string buffer.

\*\texttt{is\_null} is reset for each group (before calling \texttt{xxx\_clear()}). \*\texttt{error} is never reset.

If \*\texttt{is\_null} or \*\texttt{error} are set when \texttt{xxx()} returns, MySQL returns \texttt{NULL} as the result for the group function.

**UDF Argument Processing**

The \texttt{args} parameter points to a \texttt{UDF\_ARGS} structure that has the members listed here:

- \texttt{unsigned int \_arg\_count}

  The number of arguments. Check this value in the initialization function if you require your function to be called with a particular number of arguments. For example:

  ```
  if (args->arg_count != 2) {
    strcpy(message,"XXX() requires two arguments");
    return 1;
  }
  ```

  For other \texttt{UDF\_ARGS} member values that are arrays, array references are zero-based. That is, refer to array members using index values from 0 to \texttt{args->arg\_count} − 1.

- \texttt{enum Item\_result \*arg\_type}

  A pointer to an array containing the types for each argument. The possible type values are \texttt{STRING\_RESULT}, \texttt{INT\_RESULT}, \texttt{REAL\_RESULT}, and \texttt{DECIMAL\_RESULT}.

  To make sure that arguments are of a given type and return an error if they are not, check the \texttt{arg\_type} array in the initialization function. For example:

  ```
  if (args->arg_type[0] != STRING\_RESULT ||
      args->arg_type[1] != INT\_RESULT) {
    strcpy(message,"XXX() requires a string and an integer");
    return 1;
  }
  ```

  Arguments of type \texttt{DECIMAL\_RESULT} are passed as strings, so you handle them the same way as \texttt{STRING\_RESULT} values.

  As an alternative to requiring your function's arguments to be of particular types, you can use the initialization function to set the \texttt{arg\_type} elements to the types you want. This causes MySQL to coerce arguments to those types for each call to \texttt{xxx()}. For example, to specify that the first two arguments should be coerced to string and integer, respectively, do this in \texttt{xxx\_init()}:

  ```
  args->arg_type[0] = STRING\_RESULT;
  ```
Adding a User-Defined Function

```c
args->arg_type[1] = INT_RESULT;
```

Exact-value decimal arguments such as `1.3` or `DECIMAL` column values are passed with a type of `DECIMAL_RESULT`. However, the values are passed as strings. To receive a number, use the initialization function to specify that the argument should be coerced to a `REAL_RESULT` value:

```c
args->arg_type[2] = REAL_RESULT;
```

- `char **args`

  `args->args` communicates information to the initialization function about the general nature of the arguments passed to your function. For a constant argument `i`, `args->args[i]` points to the argument value. (See later for instructions on how to access the value properly.) For a nonconstant argument, `args->args[i]` is `0`. A constant argument is an expression that uses only constants, such as `3` or `4*7-2` or `SIN(3.14)`). A nonconstant argument is an expression that refers to values that may change from row to row, such as column names or functions that are called with nonconstant arguments.

  For each invocation of the main function, `args->args` contains the actual arguments that are passed for the row currently being processed.

  If argument `i` represents `NULL`, `args->args[i]` is a null pointer (0). If the argument is not `NULL`, functions can refer to it as follows:

  - An argument of type `STRING_RESULT` is given as a string pointer plus a length, to enable handling of binary data or data of arbitrary length. The string contents are available as `args->args[i]` and the string length is `args->lengths[i]`. Do not assume that the string is null-terminated.

  - For an argument of type `INT_RESULT`, you must cast `args->args[i]` to a `long long` value:

    ```c
    long long int_val;
    int_val = *((long long*) args->args[i]);
    ```

  - For an argument of type `REAL_RESULT`, you must cast `args->args[i]` to a `double` value:

    ```c
    double    real_val;
    real_val = *((double*) args->args[i]);
    ```

  - For an argument of type `DECIMAL_RESULT`, the value is passed as a string and should be handled like a `STRING_RESULT` value.

  - `ROW_RESULT` arguments are not implemented.

- `unsigned long *lengths`

  For the initialization function, the `lengths` array indicates the maximum string length for each argument. You should not change these. For each invocation of the main function, `lengths` contains the actual lengths of any string arguments that are passed for the row currently being processed. For arguments of types `INT_RESULT` or `REAL_RESULT`, `lengths` still contains the maximum length of the argument (as for the initialization function).

- `char *maybe_null`

  For the initialization function, the `maybe_null` array indicates for each argument whether the argument value might be null (0 if no, 1 if yes).

- `char **attributes`
Adding a User-Defined Function

`args->attributes` communicates information about the names of the UDF arguments. For argument `i`, the attribute name is available as a string in `args->attributes[i]` and the attribute length is `args->attribute_lengths[i]`. Do not assume that the string is null-terminated.

By default, the name of a UDF argument is the text of the expression used to specify the argument. For UDFs, an argument may also have an optional `[AS] alias_name` clause, in which case the argument name is `alias_name`. The `attributes` value for each argument thus depends on whether an alias was given.

Suppose that a UDF `my_udf()` is invoked as follows:

```sql
SELECT my_udf(expr1, expr2 AS alias1, expr3 alias2);
```

In this case, the `attributes` and `attribute_lengths` arrays will have these values:

- `args->attributes[0] = "expr1"
- `args->attribute_lengths[0] = 5`
- `args->attributes[1] = "alias1"
- `args->attribute_lengths[1] = 6`
- `args->attributes[2] = "alias2"
- `args->attribute_lengths[2] = 6`

- `unsigned long *attribute_lengths`

The `attribute_lengths` array indicates the length of each argument name.

UDF Return Values and Error Handling

The initialization function should return `0` if no error occurred and `1` otherwise. If an error occurs, `xxx_init()` should store a null-terminated error message in the `message` parameter. The message is returned to the client. The message buffer is `MYSQL_ERRMSG_SIZE` characters long. Try to keep the message to less than 80 characters so that it fits the width of a standard terminal screen.

The return value of the main function `xxx()` is the function value, for `long long` and `double` functions. A string function should return a pointer to the result and set `*length` to the length (in bytes) of the return value. For example:

```c
memcpy(result, "result string", 13);
*length = 13;
```

MySQL passes a buffer to the `xxx()` function using the `result` parameter. This buffer is sufficiently long to hold 255 characters, which can be multibyte characters. The `xxx()` function can store the result in this buffer if it fits, in which case the return value should be a pointer to the buffer. If the function stores the result in a different buffer, it should return a pointer to that buffer.

If your string function does not use the supplied buffer (for example, if it needs to return a string longer than 255 characters), you must allocate the space for your own buffer with `malloc()` in the `xxx_init()` function or the `xxx()` function and free it in your `xxx_deinit()` function. You can store the allocated memory in the `ptr` slot in the `UDF_INIT` structure for reuse by future `xxx()` calls. See UDF Calling Sequences for Simple Functions.

To indicate a return value of `NULL` in the main function, set `*is_null` to `1`:
Adding a User-Defined Function

*is_null = 1;

To indicate an error return in the main function, set *error to 1:

*error = 1;

If xxx() sets *error to 1 for any row, the function value is NULL for the current row and for any subsequent rows processed by the statement in which xxx() was invoked. (xxx() is not even called for subsequent rows.)

UDF Compiling and Installing

Files implementing UDFs must be compiled and installed on the host where the server runs. The process is described here for the example UDF file sql/udf_example.cc that is included in MySQL source distributions. For additional information about UDF installation, see Section 5.6.1, “Installing and Uninstalling User-Defined Functions”.

If a UDF will be referred to in statements that will be replicated to slave servers, you must ensure that every slave also has the function available. Otherwise, replication fails on the slaves when they attempt to invoke the function.

The udf_example.cc file contains the following functions:

• metaphor() returns a metaphon string of the string argument. This is something like a soundex string, but it is more tuned for English.

• myfunc_double() returns the sum of the ASCII values of the characters in its arguments, divided by the sum of the length of its arguments.

• myfunc_int() returns the sum of the length of its arguments.

• sequence(const int) returns a sequence starting from the given number or 1 if no number has been given.

• lookup() returns the IP address for a host name.

• reverse_lookup() returns the host name for an IP address. The function may be called either with a single string argument of the form 'xxx.xxx.xxx.xxx' or with four numbers.

• avgcost() returns an average cost. This is an aggregate function.

On Unix and Unix-like systems, compile user-defined functions using the following procedure:

A dynamically loadable file should be compiled as a sharable library file, using a command something like this:

gcc -shared -o udf_example.so udf_example.cc

If you are using gcc with CMake (which is how MySQL itself is configured), you should be able to create udf_example.so with a simpler command:

make udf_example

After compiling a shared object containing UDFs, you must install it and tell MySQL about it. Compiling a shared object from udf_example.cc using gcc directly produces a file named udf_example.so. Copy
the shared object to the server’s plugin directory and name it `udf_example.so`. This directory is given by the value of the `plugin_dir` system variable.

On some systems, the `ldconfig` program that configures the dynamic linker does not recognize a shared object unless its name begins with `lib`. In this case you should rename a file such as `udf_example.so` to `libudf_example.so`.

On Windows, compile user-defined functions using the following procedure:

1. Obtain a MySQL source distribution. See Section 2.1.2, “How to Get MySQL”.

2. Obtain the `CMake` build utility, if necessary, from http://www.cmake.org. (Version 2.6 or later is required).

3. In the source tree, look in the `sql` directory for files named `udf_example.def` and `udf_example.cc`. Copy both files from this directory to your working directory.

4. Create a `CMake` makefile (`CMakeLists.txt`) with these contents:

```cpp
PROJECT(udf_example)
# Path for MySQL include directory
INCLUDE_DIRECTORIES("c:/mysql/include")
ADD_DEFINITIONS("-DHAVE_DLOPEN")
ADD_LIBRARY(udf_example MODULE udf_example.cc udf_example.def)
TARGET_LINK_LIBRARIES(udf_example wsock32)
```

5. Create the VC project and solution files, substituting an appropriate `generator` value:

```
cmake -G "generator"
```

Invoking `cmake --help` shows you a list of valid generators.

6. Create `udf_example.dll`:

```
devenv udf_example.sln /build Release
```

On all platforms, after the shared library file has been copied to the `plugin_dir` directory, notify `mysqld` about the new functions with the following statements. If library files have a suffix different from `.so` on your system, substitute the correct suffix throughout (for example, `.dll` on Windows).

```sql
CREATE FUNCTION metaphon RETURNS STRING SONAME 'udf_example.so';
CREATE FUNCTION myfunc_double RETURNS REAL SONAME 'udf_example.so';
CREATE FUNCTION myfunc_int RETURNS INTEGER SONAME 'udf_example.so';
CREATE FUNCTION sequence RETURNS INTEGER SONAME 'udf_example.so';
CREATE FUNCTION lookup RETURNS STRING SONAME 'udf_example.so';
CREATE FUNCTION reverse_lookup RETURNS STRING SONAME 'udf_example.so';
CREATE AGGREGATE FUNCTION avgcost RETURNS REAL SONAME 'udf_example.so';
```

Once installed, a function remains installed until it is uninstalled.
Adding a Native Function

To remove functions, use `DROP FUNCTION`:

```
DROP FUNCTION metaphon;
DROP FUNCTION myfunc_double;
DROP FUNCTION myfunc_int;
DROP FUNCTION sequence;
DROP FUNCTION lookup;
DROP FUNCTION reverse_lookup;
DROP FUNCTION avgcost;
```

The `CREATE FUNCTION` and `DROP FUNCTION` statements update the `func` table in the `mysql` system database that serves as a UDF registry. The function's name, type and shared library name are saved in the `mysql.func` table. To create functions, you must have the `INSERT` privilege for the `mysql` database. To drop functions, you must have the `DELETE` privilege for the `mysql` database.

You cannot use `CREATE FUNCTION` to reinstall a function that has previously been installed. To reinstall a function, first remove it with `DROP FUNCTION`, then install it with `CREATE FUNCTION`. You would need to do this, for example, if you upgrade to a new version of MySQL that provides an updated implementation of the function, or you recompile a new version of a function that you have written. Otherwise, the server continues to use the old version.

An active function is one that has been loaded with `CREATE FUNCTION` and not removed with `DROP FUNCTION`. All active functions are reloaded each time the server starts, unless you start `mysqld` with the `--skip-grant-tables` option. In this case, the server does not load UDFs during startup and UDFs are unavailable.

**UDF Security Precautions**

MySQL takes several measures to prevent misuse of user-defined functions.

UDF library files cannot be placed in arbitrary directories. They must be located in the server's plugin directory. This directory is given by the value of the `plugin_dir` system variable.

To use `CREATE FUNCTION` or `DROP FUNCTION`, you must have the `INSERT` or `DELETE` privilege, respectively, for the `mysql` database. This is necessary because those statements add and delete rows from the `mysql.func` table.

UDFs should have at least one symbol defined in addition to the `xxx` symbol that corresponds to the main `xxx()` function. These auxiliary symbols correspond to the `xxx_init()`, `xxx_deinit()`, `xxx_reset()`, `xxx_clear()`, and `xxx_add()` functions. `mysqld` also supports an `--allow-suspicious-udfs` option that controls whether UDFs that have only an `xxx` symbol can be loaded. By default, the option is off, to prevent attempts at loading functions from shared library files other than those containing legitimate UDFs. If you have older UDFs that contain only the `xxx` symbol and that cannot be recompiled to include an auxiliary symbol, it may be necessary to specify the `--allow-suspicious-udfs` option. Otherwise, you should avoid enabling this capability.

24.4.3 Adding a Native Function

To add a new native MySQL function, use the procedure described here, which requires that you use a source distribution. You cannot add native functions to a binary distribution because it is necessary to modify MySQL source code and compile MySQL from the modified source. If you migrate to another version of MySQL (for example, when a new version is released), you must repeat the procedure with the new version.

If the new native function will be referred to in statements that will be replicated to slave servers, you must ensure that every slave server also has the function available. Otherwise, replication will fail on the slaves when they attempt to invoke the function.
Adding a Native Function

To add a new native function, follow these steps to modify source files in the sql directory:

1. Create a subclass for the function in item_create.cc:
   - If the function takes a fixed number of arguments, create a subclass of Create_func_arg0, Create_func_arg1, Create_func_arg2, or Create_func_arg3, respectively, depending on whether the function takes zero, one, two, or three arguments. For examples, see the Create_func_uuid, Create_func_abs, Create_func_pow, and Create_func_lpad classes.
   - If the function takes a variable number of arguments, create a subclass of Create_native_func. For an example, see Create_func_concat.

2. To provide a name by which the function can be referred to in SQL statements, register the name in item_create.cc by adding a line to this array:

   static Native_func_registry func_array[]

   You can register several names for the same function. For example, see the lines for "LCASE" and "LOWER", which are aliases for Create_func_lcase.

3. In item_func.h, declare a class inheriting from Item_num_func or Item_str_func, depending on whether your function returns a number or a string.

4. In item_func.cc, add one of the following declarations, depending on whether you are defining a numeric or string function:

   double   Item_func_newname::val()
   longlong Item_func_newname::val_int()
   String  *Item_func_newname::Str(String *str)

   If you inherit your object from any of the standard items (like Item_num_func), you probably only have to define one of these functions and let the parent object take care of the other functions. For example, the Item_str_func class defines a val() function that executes atof() on the value returned by ::str().

5. If the function is nondeterministic, include the following statement in the item constructor to indicate that function results should not be cached:

   current_thd->lex->safe_to_cache_query=0;

   A function is nondeterministic if, given fixed values for its arguments, it can return different results for different invocations.

6. You should probably also define the following object function:

   void Item_func_newname::fix_length_and_dec()

   This function should at least calculate max_length based on the given arguments. max_length is the maximum number of characters the function may return. This function should also set maybe_null = 0 if the main function cannot return a NULL value. The function can check whether any of the function arguments can return NULL by checking the arguments' maybe_null variable. Look at Item_func_mod::fix_length_and_dec for a typical example of how to do this.

   All functions must be thread-safe. In other words, do not use any global or static variables in the functions without protecting them with mutexes.
If you want to return `NULL` from `::val()`, `::val_int()`, or `::str()`, you should set `null_value` to 1 and return 0.

For `::str()` object functions, there are additional considerations to be aware of:

- The `String *str` argument provides a string buffer that may be used to hold the result. (For more information about the `String` type, take a look at the `sql_string.h` file.)
- The `::str()` function should return the string that holds the result, or `(char*) 0` if the result is `NULL`.
- All current string functions try to avoid allocating any memory unless absolutely necessary!

## 24.5 Debugging and Porting MySQL

This section helps you port MySQL to other operating systems. Do check the list of currently supported operating systems first. See [https://www.mysql.com/support/supportedplatforms/database.html](https://www.mysql.com/support/supportedplatforms/database.html). If you have created a new port of MySQL, please let us know so that we can list it here and on our website ([http://www.mysql.com/](http://www.mysql.com/)), recommending it to other users.

**Note**

If you create a new port of MySQL, you are free to copy and distribute it under the GPL license, but it does not make you a copyright holder of MySQL.

A working POSIX thread library is needed for the server.

To build MySQL from source, your system must satisfy the tool requirements listed at [Section 2.9, “Installing MySQL from Source”](#).

**Important**

If you are trying to build MySQL 5.6 with `icc` on the IA64 platform, and need support for NDB Cluster, you should first ensure that you are using `icc` version 9.1.043 or later. (For details, see Bug #21875.)

If you run into problems with a new port, you may have to do some debugging of MySQL! See [Section 24.5.1, “Debugging a MySQL Server”](#).

**Note**

Before you start debugging `mysqld`, first get the test programs `mysys/thr_alarm` and `mysys/thr_lock` to work. This ensures that your thread installation has even a remote chance to work!

### 24.5.1 Debugging a MySQL Server

If you are using some functionality that is very new in MySQL, you can try to run `mysqld` with the `--skip-new` (which disables all new, potentially unsafe functionality). See [Section B.4.3.3, “What to Do If MySQL Keeps Crashing”](#).

If `mysqld` does not want to start, verify that you have no `my.cnf` files that interfere with your setup! You can check your `my.cnf` arguments with `mysqld --print-defaults` and avoid using them by starting with `mysqld --no-defaults` ....

If `mysqld` starts to eat up CPU or memory or if it “hangs,” you can use `mysqladmin processlist status` to find out if someone is executing a query that takes a long time. It may be a good idea to run
mysqladmin -i10 processlist status in some window if you are experiencing performance problems or problems when new clients cannot connect.

The command mysqladmin debug dumps some information about locks in use, used memory and query usage to the MySQL log file. This may help solve some problems. This command also provides some useful information even if you have not compiled MySQL for debugging!

If the problem is that some tables are getting slower and slower you should try to optimize the table with OPTIMIZE TABLE or myisamchk. See Chapter 5, MySQL Server Administration. You should also check the slow queries with EXPLAIN.

You should also read the OS-specific section in this manual for problems that may be unique to your environment. See Section 2.1, “General Installation Guidance”.

### 24.5.1.1 Compiling MySQL for Debugging

If you have some very specific problem, you can always try to debug MySQL. To do this you must configure MySQL with the --WITH_DEBUG=1 option. You can check whether MySQL was compiled with debugging by doing: mysqld --help. If the --debug flag is listed with the options then you have debugging enabled. mysqladmin ver also lists the mysqld version as mysql ... --debug in this case.

If mysqld stops crashing when you configure it with the --WITH_DEBUG=1 CMake option, you probably have found a compiler bug or a timing bug within MySQL. In this case, you can try to add -g using the CMAKE_C_FLAGS and CMAKE_CXX_FLAGS CMake options and not use --WITH_DEBUG=1. If mysqld dies, you can at least attach to it with gdb or use gdb on the core file to find out what happened.

When you configure MySQL for debugging you automatically enable a lot of extra safety check functions that monitor the health of mysqld. If they find something “unexpected,” an entry is written to stderr, which mysqld_safe directs to the error log! This also means that if you are having some unexpected problems with MySQL and are using a source distribution, the first thing you should do is to configure MySQL for debugging. If you believe that you have found a bug, please use the instructions at Section 1.6, “How to Report Bugs or Problems”.

In the Windows MySQL distribution, mysql.exe is by default compiled with support for trace files.

### 24.5.1.2 Creating Trace Files

If the mysqld server does not start or it crashes easily, you can try to create a trace file to find the problem.

To do this, you must have a mysqld that has been compiled with debugging support. You can check this by executing mysqld -V. If the version number ends with -debug, it is compiled with support for trace files. (On Windows, the debugging server is named mysqld-debug rather than mysqld.)

Start the mysqld server with a trace log in /tmp/mysqld.trace on Unix or \mysqld.trace on Windows:

```
shell> mysqld --debug
```

On Windows, you should also use the --standalone flag to not start mysqld as a service. In a console window, use this command:

```
C:\> mysqld-debug --debug --standalone
```

After this, you can use the mysql.exe command-line tool in a second console window to reproduce the problem. You can stop the mysqld server with mysqladmin shutdown.
The trace file can become very large! To generate a smaller trace file, you can use debugging options something like this:

```
mysqld --debug=d,info,error,query,general,where:O,/tmp/mysqld.trace
```

This only prints information with the most interesting tags to the trace file.

If you file a bug, please add only those lines from the trace file to the bug report that indicate where something seems to go wrong. If you cannot locate the wrong place, open a bug report and upload the whole trace file to the report, so that a MySQL developer can take a look at it. For instructions, see Section 1.6, “How to Report Bugs or Problems”.

The trace file is made with the DBUG package by Fred Fish. See Section 24.5.3, “The DBUG Package”.

### 24.5.1.3 Using WER with PDB to create a Windows crashdump

Program Database (PDB) files (with file name suffix `pdb`) are included in ZIP Archive distributions (but not MSI distributions) of MySQL. These files provide information for debugging your MySQL installation in the event of a problem.

The PDB file contains more detailed information about `mysqld` and other tools that enables more detailed trace and dump files to be created. You can use these with WinDbg or Visual Studio to debug `mysqld`.

For more information on PDB files, see Microsoft Knowledge Base Article 121366. For more information on the debugging options available, see Debugging Tools for Windows.

To use WinDbg, either install the full Windows Driver Kit (WDK) or install the standalone version.

**Important**

The `.exe` and `.pdb` files must be an exact match (both version number and MySQL server edition) or WinDBG will complain while attempting to load the symbols.

1. To generate a minidump `mysqld.dmp`, enable the `core-file` option under the `[mysqld]` section in `my.ini`. Restart the MySQL server after making these changes.

2. Create a directory to store the generated files, such as `c:\symbols`

3. Determine the path to your `windbg.exe` executable using the Find GUI or from the command line, for example: `dir /s /b windbg.exe` -- a common default is `C:\Program Files\Debugging Tools for Windows (x64)\windbg.exe`

4. Launch `windbg.exe` giving it the paths to `mysqld-debug.exe`, `mysqld.pdb`, `mysqld.dmp`, and the source code. Alternatively, pass in each path from the WinDbg GUI. For example:

   ```
   windbg.exe -i "C:\mysql-5.6.47-winx64\bin\"^ 
   -z "C:\mysql-5.6.47-winx64\data\mysqld.dmp"^ 
   -srcpath "E:\ade\mysql_archives\5.6\5.6.47\mysql-5.6.47"^ 
   -y "C:\mysql-5.6.47-winx64\bin;SRV*c:\symbols*http://msdl.microsoft.com/download/symbols"^ 
   -v -n -c "!analyze -vvvvv"
   ```

**Note**

The `^` character and newline are removed by the Windows command line processor, so be sure the spaces remain intact.

### 24.5.1.4 Debugging mysqld under gdb

Debugging a MySQL Server

On most systems you can also start `mysql` from `gdb` to get more information if `mysql` crashes.

With some older `gdb` versions on Linux you must use `run --one-thread` if you want to be able to debug `mysql` threads. In this case, you can only have one thread active at a time. It is best to upgrade to `gdb` 5.1 because thread debugging works much better with this version!

NPTL threads (the new thread library on Linux) may cause problems while running `mysql` under `gdb`. Some symptoms are:

- `mysql` hangs during startup (before it writes `ready for connections`).
- `mysql` crashes during a `pthread_mutex_lock()` or `pthread_mutex_unlock()` call.

In this case, you should set the following environment variable in the shell before starting `gdb`:

```bash
LD_ASSUME_KERNEL=2.4.1
export LD_ASSUME_KERNEL
```

When running `mysql` under `gdb`, you should disable the stack trace with `--skip-stack-trace` to be able to catch segfaults within `gdb`.

Use the `--gdb` option to `mysql` to install an interrupt handler for `SIGINT` (needed to stop `mysql` with `^C` to set breakpoints) and disable stack tracing and core file handling.

It is very hard to debug MySQL under `gdb` if you do a lot of new connections the whole time as `gdb` does not free the memory for old threads. You can avoid this problem by starting `mysql` with `thread_cache_size` set to a value equal to `max_connections` + 1. In most cases just using `--thread_cache_size=5` helps a lot!

If you want to get a core dump on Linux if `mysql` dies with a SIGSEGV signal, you can start `mysql` with the `--core-file` option. This core file can be used to make a backtrace that may help you find out why `mysql` died:

```bash
shell> gdb mysql core
gdb> backtrace full
gdb> quit
```

See Section B.4.3.3, “What to Do If MySQL Keeps Crashing”.

If you are using `gdb` 4.17.x or above on Linux, you should install a `.gdb` file, with the following information, in your current directory:

```bash
set print sevenbit off
handle SIGUSR1 nostop noprof
handle SIGUSR2 nostop noprof
handle SIGTSTP nostop noprof
handle SIGTTOU nostop noprof
handle SIGTTOU nostop noprof
handle SIGWINCH nostop
handle SIGPIPE nostop
handle SIGALRM nostop
handle SIGHUP nostop
handle SIGTERM nostop noprof
```

If you have problems debugging threads with `gdb`, you should download `gdb` 5.x and try this instead. The new `gdb` version has very improved thread handling!

Here is an example how to debug `mysql`: 
shell> gdb /usr/local/libexec/mysqld
    gdb> run
    ...
    backtrace full # Do this when mysqld crashes

Include the preceding output in a bug report, which you can file using the instructions in Section 1.6, “How to Report Bugs or Problems”.

If mysqld hangs, you can try to use some system tools like strace or /usr/proc/bin/pstack to examine where mysqld has hung.

strace /tmp/log libexec/mysqld

If you are using the Perl DBI interface, you can turn on debugging information by using the trace method or by setting the DBI_TRACE environment variable.

### 24.5.1.5 Using a Stack Trace

On some operating systems, the error log contains a stack trace if mysqld dies unexpectedly. You can use this to find out where (and maybe why) mysqld died. See Section 5.4.2, “The Error Log”. To get a stack trace, you must not compile mysqld with the -fomit-frame-pointer option to gcc. See Section 24.5.1.1, “Compiling MySQL for Debugging”.

A stack trace in the error log looks something like this:

```plaintext
mysqld got signal 11;
Attempting backtrace. You can use the following information to find out where mysqld died. If you see no messages after this, something went terribly wrong...

stack_bottom = 0x41fd0110 thread_stack 0x40000
mysqld(my_print_stacktrace+0x32)[0x9da402]
mysqld(handle_segfault+0x28a)[0x6648e9]
/lib/libpthread.so.0[0x7f1a5af000f0]
/mylib.so.6(strcmp+0x2)[0x7f1a5a10f0f2]
mysqld(_Z21check_change_passwordP3THDPCcj+0x7c)[0x7412cb]
mysqld(_ZN16set_var_password5checkEP3THD+0xd0)[0x688354]
mysqld(_Z17sql_set_variablesP3THDPCListI12set_var_baseE+0x68)[0x688494]
mysqld(_Z11mysql_execute_commandP3THD+0x41a0)[0x67a170]
mysqld(_Z11mysql_parse3THDPCrj+0x282)[0x67f0ad]
mysqld(_Z16dispatch_command19enum_server_commandP3THD+0x24d)[0x67f01d]
mysqld(handle_one_connection+0x11c)[0x66e05e]
```

If resolution of function names for the trace fails, the trace contains less information:

```plaintext
mysqld got signal 11;
Attempting backtrace. You can use the following information to find out where mysqld died. If you see no messages after this, something went terribly wrong...

stack_bottom = 0x41fd0110 thread_stack 0x40000
[0x9da402]
[0x6648e9]
[0x7f1a5af000f0]
[0x7f1a5a10f0f2]
[0x7412cb]
[0x66e05e]
```
In the latter case, you can use the `resolve_stack_dump` utility to determine where `mysqld` died by using the following procedure:

1. Copy the numbers from the stack trace to a file, for example `mysqld.stack`. The numbers should not include the surrounding square brackets:

   0x9da402
   0x6648e9
   0x7f1a5af000f0
   0x7f1a5a10f0f2
   0x7412cb
   0x688354
   0x688494
   0x67a170
   0x67f0ad
   0x6811b6
   0x66e05e

2. Make a symbol file for the `mysqld` server:

   ```
   shell> nm -n libexec/mysqld > /tmp/mysqld.sym
   ```

   If `mysqld` is not linked statically, use the following command instead:

   ```
   shell> nm -D -n libexec/mysqld > /tmp/mysqld.sym
   ```

   If you want to decode C++ symbols, use the `--demangle` option, if available, to `nm`. If your version of `nm` does not have this option, you will need to use the `c++filt` command after the stack dump has been produced to demangle the C++ names.

3. Execute the following command:

   ```
   shell> resolve_stack_dump -s /tmp/mysqld.sym -n mysqld.stack
   ```

   If you were not able to include demangled C++ names in your symbol file, process the `resolve_stack_dump` output using `c++filt`:

   ```
   shell> resolve_stack_dump -s /tmp/mysqld.sym -n mysqld.stack | c++filt
   ```

   This prints out where `mysqld` died. If that does not help you find out why `mysqld` died, you should create a bug report and include the output from the preceding command with the bug report.

   However, in most cases it does not help us to have just a stack trace to find the reason for the problem. To be able to locate the bug or provide a workaround, in most cases we need to know the statement that killed `mysqld` and preferably a test case so that we can repeat the problem! See Section 1.6, “How to Report Bugs or Problems”.

   Newer versions of `glibc` stack trace functions also print the address as relative to the object. On `glibc`-based systems (Linux), the trace for a crash within a plugin looks something like:
Debugging a MySQL Server

To translate the relative address (+0x9a6) into a file name and line number, use this command:

```
shell> addr2line -fie auth_test_plugin.so 0x9a6
auth_test_plugin
mysql-trunk/plugin/auth/test_plugin.c:65
```

The `addr2line` utility is part of the `binutils` package on Linux.

On Solaris, the procedure is similar. The Solaris `printstack()` already prints relative addresses:

```
plugin/auth/auth_test_plugin.so:0x1510
```

To translate, use this command:

```
shell> gaddr2line -fie auth_test_plugin.so 0x1510
mysql-trunk/plugin/auth/test_plugin.c:88
```

Windows already prints the address, function name and line:

```
000007FEF07E10A4 auth_test_plugin.dll!auth_test_plugin() [test_plugin.c:72]
```

### 24.5.1.6 Using Server Logs to Find Causes of Errors in mysqld

Before starting `mysqld` with the general query log enabled, you should check all your tables with `myisamchk`. See Chapter 5, *MySQL Server Administration*.

If `mysqld` dies or hangs, you should start `mysqld` with the general query log enabled. See Section 5.4.3, “The General Query Log”. When `mysqld` dies again, you can examine the end of the log file for the query that killed `mysqld`.

If you use the default general query log file, the log is stored in the database directory as `host_name.log`. In most cases it is the last query in the log file that killed `mysqld`, but if possible you should verify this by restarting `mysqld` and executing the found query from the `mysql` command-line tools. If this works, you should also test all complicated queries that did not complete.

You can also try the command `EXPLAIN` on all `SELECT` statements that takes a long time to ensure that `mysqld` is using indexes properly. See Section 13.8.2, “EXPLAIN Syntax”.

You can find the queries that take a long time to execute by starting `mysqld` with the slow query log enabled. See Section 5.4.5, “The Slow Query Log”.

If you find the text `mysqld restarted` in the error log (normally a file named `host_name.err`) you probably have found a query that causes `mysqld` to fail. If this happens, you should check all your tables with `myisamchk` (see Chapter 5, *MySQL Server Administration*), and test the queries in the MySQL log files to see whether one fails. If you find such a query, try first upgrading to the newest MySQL version. If this does not help, report a bug, see Section 1.6, “How to Report Bugs or Problems”.

If you have started `mysqld` with the `myisam_recover_options` system variable set, MySQL automatically checks and tries to repair MyISAM tables if they are marked as ‘not closed properly’ or ‘crashed’. If this happens, MySQL writes an entry in the `hostname.err` file ‘Warning: Checking table ...’ which is followed by Warning: Repairing table if the table needs to be repaired. If you
get a lot of these errors, without mysqld having died unexpectedly just before, then something is wrong and needs to be investigated further. See Section 5.1.6, “Server Command Options”.

When the server detects MyISAM table corruption, it writes additional information to the error log, such as the name and line number of the source file, and the list of threads accessing the table. Example: Got an error from thread_id=1, mi_dynrec.c:368. This is useful information to include in bug reports.

It is not a good sign if mysqld did die unexpectedly, but in this case, you should not investigate the Checking table... messages, but instead try to find out why mysqld died.

### 24.5.1.7 Making a Test Case If You Experience Table Corruption

The following procedure applies to MyISAM tables. For information about steps to take when encountering InnoDB table corruption, see Section 1.6, “How to Report Bugs or Problems”.

If you encounter corrupted MyISAM tables or if mysqld always fails after some update statements, you can test whether the issue is reproducible by doing the following:

1. Stop the MySQL daemon with mysqladmin shutdown.
2. Make a backup of the tables to guard against the very unlikely case that the repair does something bad.
3. Check all tables with myisamchk -s database/*.MYI. Repair any corrupted tables with myisamchk -r database/table.MYI.
4. Make a second backup of the tables.
5. Remove (or move away) any old log files from the MySQL data directory if you need more space.
6. Start mysqld with the binary log enabled. If you want to find a statement that crashes mysqld, you should start the server with the general query log enabled as well. See Section 5.4.3, “The General Query Log”, and Section 5.4.4, “The Binary Log”.
7. When you have gotten a crashed table, stop the mysqld server.
8. Restore the backup.
9. Restart the mysqld server without the binary log enabled.
10. Re-execute the statements with mysqlbinlog binary-log-file | mysql. The binary log is saved in the MySQL database directory with the name hostname-bin.NNNNNN.
11. If the tables are corrupted again or you can get mysqld to die with the above command, you have found a reproducible bug. FTP the tables and the binary log to our bugs database using the instructions given in Section 1.6, “How to Report Bugs or Problems”. If you are a support customer, you can use the MySQL Customer Support Center (https://www.mysql.com/support/) to alert the MySQL team about the problem and have it fixed as soon as possible.

### 24.5.2 Debugging a MySQL Client

To be able to debug a MySQL client with the integrated debug package, you should configure MySQL with -DWITH_DEBUG=1. See Section 2.9.7, “MySQL Source-Configuration Options”.

Before running a client, you should set the MYSQL_DEBUG environment variable:

```shell
shell> MYSQL_DEBUG=d:t:O,/tmp/client.trace
shell> export MYSQL_DEBUG
```
This causes clients to generate a trace file in \texttt{/tmp/client.trace}.

If you have problems with your own client code, you should attempt to connect to the server and run your query using a client that is known to work. Do this by running \texttt{mysql} in debugging mode (assuming that you have compiled MySQL with debugging on):

\begin{verbatim}
shell> mysql --debug=d:t:O,/tmp/client.trace
\end{verbatim}

This provides useful information in case you mail a bug report. See Section 1.6, “How to Report Bugs or Problems”.

If your client crashes at some 'legal' looking code, you should check that your \texttt{mysql.h} include file matches your MySQL library file. A very common mistake is to use an old \texttt{mysql.h} file from an old MySQL installation with new MySQL library.

### 24.5.3 The DBUG Package

The MySQL server and most MySQL clients are compiled with the DBUG package originally created by Fred Fish. When you have configured MySQL for debugging, this package makes it possible to get a trace file of what the program is doing. See Section 24.5.1.2, “Creating Trace Files”.

This section summarizes the argument values that you can specify in debug options on the command line for MySQL programs that have been built with debugging support.

The DBUG package can be used by invoking a program with the \texttt{--debug=[debug_options]} or \texttt{-# [debug_options]} option. If you specify the \texttt{--debug} or \texttt{-#} option without a \texttt{debug_options} value, most MySQL programs use a default value. The server default is \texttt{d:t:i:o,/tmp/mysqld.trace} on Unix and \texttt{d:t:i:O,\mysqld.trace} on Windows. The effect of this default is:

- \texttt{d}: Enable output for all debug macros
- \texttt{t}: Trace function calls and exits
- \texttt{i}: Add PID to output lines
- \texttt{o,/tmp/mysqld.trace,O,\mysqld.trace}: Set the debug output file.

Most client programs use a default \texttt{debug_options} value of \texttt{d:t:o,/tmp/program_name.trace}, regardless of platform.

Here are some example debug control strings as they might be specified on a shell command line:

\begin{verbatim}
--debug=d:t
--debug=d:f,main,subr1:F:L:t,20
--debug=d,input,output,files:n
--debug=d:t:i:O,\mysqld.trace
\end{verbatim}

For \texttt{mysqld}, it is also possible to change DBUG settings at runtime by setting the \texttt{debug} system variable. This variable has global and session values:

\begin{verbatim}
mysql> SET GLOBAL debug = '\texttt{debug_options}';
mysql> SET SESSION debug = '\texttt{debug_options}';
\end{verbatim}

Changing the global \texttt{debug} value requires privileges sufficient to set global system variables. Changing the session \texttt{debug} value requires privileges sufficient to set restricted session system variables. See Section 5.1.8.1, “System Variable Privileges”.
The `debug_options` value is a sequence of colon-separated fields:

```
field_1:field_2:...:field_N
```

Each field within the value consists of a mandatory flag character, optionally preceded by a `+` or `−` character, and optionally followed by a comma-delimited list of modifiers:

```
[+−]flag[,modifier,modifier,...,modifier]
```

The following table describes the permitted flag characters. Unrecognized flag characters are silently ignored.

<table>
<thead>
<tr>
<th>Flag</th>
<th>Description</th>
</tr>
</thead>
</table>
| `d`  | Enable output from `DBUG_XXX` macros for the current state. May be followed by a list of keywords, which enables output only for the `DBUG` macros with that keyword. An empty list of keywords enables output for all macros.  
  In MySQL, common debug macro keywords to enable are `enter`, `exit`, `error`, `warning`, `info`, and `loop`. |
| `D`  | Delay after each debugger output line. The argument is the delay, in tenths of seconds, subject to machine capabilities. For example, `D, 20` specifies a delay of two seconds. |
| `f`  | Limit debugging, tracing, and profiling to the list of named functions. An empty list enables all functions. The appropriate `d` or `t` flags must still be given; this flag only limits their actions if they are enabled. |
| `F`  | Identify the source file name for each line of debug or trace output. |
| `i`  | Identify the process with the PID or thread ID for each line of debug or trace output. |
| `L`  | Identify the source file line number for each line of debug or trace output. |
| `n`  | Print the current function nesting depth for each line of debug or trace output. |
| `N`  | Number each line of debug output. |
| `o`  | Redirect the debugger output stream to the specified file. The default output is `stderr`. |
| `O`  | Like `o`, but the file is really flushed between each write. When needed, the file is closed and reopened between each write. |
| `p`  | Limit debugger actions to specified processes. A process must be identified with the `DBUG_PROCESS` macro and match one in the list for debugger actions to occur. |
| `P`  | Print the current process name for each line of debug or trace output. |
| `r`  | When pushing a new state, do not inherit the previous state’s function nesting level. Useful when the output is to start at the left margin. |
| `S`  | Do function `_sanity(_file_, _line_)` at each debugged function until `_sanity()` returns something that differs from 0. |
| `t`  | Enable function call/exit trace lines. May be followed by a list (containing only one modifier) giving a numeric maximum trace level, beyond which no output occurs for either debugging or tracing macros. The default is a compile time option. |

The leading `+` or `−` character and trailing list of modifiers are used for flag characters such as `d` or `f` that can enable a debug operation for all applicable modifiers or just some of them:

- With no leading `+` or `−`, the flag value is set to exactly the modifier list as given.
- With a leading `+` or `−`, the modifiers in the list are added to or subtracted from the current modifier list.
The DBUG Package

The following examples show how this works for the \texttt{d} flag. An empty \texttt{d} list enabled output for all debug macros. A nonempty list enables output only for the macro keywords in the list.

These statements set the \texttt{d} value to the modifier list as given:

```sql
mysql> SET debug = 'd';
mysql> SELECT @@debug;
| @@debug |
| d       |

mysql> SET debug = 'd,error,warning';
mysql> SELECT @@debug;
| @@debug         |
| d,error,warning |
```

A leading \texttt{+} or \texttt{-} adds to or subtracts from the current \texttt{d} value:

```sql
mysql> SET debug = '+d,loop';
mysql> SELECT @@debug;
| @debug         |
| d,loop         |

mysql> SET debug = '-d,error,loop';
mysql> SELECT @@debug;
| @debug         |
| d,error,loop   |
```

Adding to “all macros enabled” results in no change:

```sql
mysql> SET debug = 'd';
mysql> SELECT @@debug;
| @debug         |
| d              |

mysql> SET debug = '+d,loop';
mysql> SELECT @@debug;
| @debug         |
| d              |
```

Disabling all enabled macros disables the \texttt{d} flag entirely:

```sql
mysql> SET debug = 'd,error,loop';
mysql> SELECT @@debug;
| @debug         |
| d,error,loop   |
```
mysql> SET debug = '-d, error, loop';
mysql> SELECT @@debug;

+---------+
| @@debug |
+---------+

Note

Prior to MySQL 5.6.12, the + and - modifiers were not always handled correctly and could leave a flag value in an incorrect state. Verify your debug-setting sequence in advance or set it without using + or -.
Chapter 25 MySQL Enterprise Edition

25.8 MySQL Enterprise Data Masking and De-Identification Overview ..................... 3652

MySQL Enterprise Edition is a commercial product. Like MySQL Community Edition, MySQL Enterprise Edition includes MySQL Server, a fully integrated transaction-safe, ACID-compliant database with full commit, rollback, crash-recovery, and row-level locking capabilities. In addition, MySQL Enterprise Edition includes the following components designed to provide monitoring and online backup, as well as improved security and scalability:

The following sections briefly discuss each of these components and indicate where to find more detailed information. To learn more about commercial products, see https://www.mysql.com/products/.

- MySQL Enterprise Monitor
- MySQL Enterprise Backup
- MySQL Enterprise Security
- MySQL Enterprise Encryption
- MySQL Enterprise Audit
- MySQL Enterprise Firewall
- MySQL Enterprise Thread Pool
- MySQL Enterprise Data Masking and De-Identification

25.1 MySQL Enterprise Monitor Overview

MySQL Enterprise Monitor is an enterprise monitoring system for MySQL that keeps an eye on your MySQL servers, notifies you of potential issues and problems, and advises you how to fix the issues. MySQL Enterprise Monitor can monitor all kinds of configurations, from a single MySQL server that is important to your business, all the way up to a huge farm of MySQL servers powering a busy website.

The following discussion briefly summarizes the basic components that make up the MySQL Enterprise Monitor product. For more information, see the MySQL Enterprise Monitor manual, available at https://dev.mysql.com/doc/mysql-monitor/en/.

MySQL Enterprise Monitor components can be installed in various configurations depending on your database and network topology, to give you the best combination of reliable and responsive monitoring data, with minimal overhead on the database server machines. A typical MySQL Enterprise Monitor installation consists of:
MySQL Enterprise Backup Overview

MySQL Enterprise Monitor is designed to monitor one or more MySQL servers. The monitoring information is collected by using an agent, **MySQL Enterprise Monitor Agent**. The agent communicates with the hosts and MySQL servers that it monitors, collecting variables, status and health information, and sending this information to the MySQL Enterprise Service Manager.

The information collected by the agent about each MySQL server and host you are monitoring is sent to the **MySQL Enterprise Service Manager**. This server collates all of the information from the agents. As it collates the information sent by the agents, the MySQL Enterprise Service Manager continually tests the collected data, comparing the status of the server to reasonable values. When thresholds are reached, the server can trigger an event (including an alarm and notification) to highlight a potential issue, such as low memory, high CPU usage, or more complex conditions such insufficient buffer sizes and status information. We call each test, with its associated threshold value, a **rule**.

These rules, and the alarms and notifications, are each known as a **MySQL Enterprise Advisors**. Advisors form a critical part of the MySQL Enterprise Service Manager, as they provide warning information and troubleshooting advice about potential problems.

The MySQL Enterprise Service Manager includes a web server, and you interact with it through any web browser. This interface, the MySQL Enterprise Monitor User Interface, displays all of the information collected by the agents, and lets you view all of your servers and their current status as a group or individually. You control and configure all aspects of the service using the MySQL Enterprise Monitor User Interface.

The information supplied by the MySQL Enterprise Monitor Agent processes also includes statistical and query information, which you can view in the form of graphs. For example, you can view aspects such as server load, query numbers, or index usage information as a graph over time. The graph lets you pinpoint problems or potential issues on your server, and can help diagnose the impact from database or external problems (such as external system or network failure) by examining the data from a specific time interval.

The MySQL Enterprise Monitor Agent can also be configured to collect detailed information about the queries executed on your server, including the row counts and performance times for executing each query. You can correlate the detailed query data with the graphical information to identify which queries were executing when you experienced a particularly high load, index or other issue. The query data is supported by a system called Query Analyzer, and the data can be presented in different ways depending on your needs.

### 25.2 MySQL Enterprise Backup Overview

MySQL Enterprise Backup performs hot backup operations for MySQL databases. The product is architected for efficient and reliable backups of tables created by the InnoDB storage engine. For completeness, it can also back up tables from MyISAM and other storage engines.

Hot backups are performed while the database is running and applications are reading and writing to it. This type of backup does not block normal database operations, and it captures even changes that occur while the backup is happening. For these reasons, hot backups are desirable when your database
“grows up” -- when the data is large enough that the backup takes significant time, and when your data is important enough to your business that you must capture every last change, without taking your application, website, or web service offline.

MySQL Enterprise Backup does a hot backup of all tables that use the InnoDB storage engine. For tables using MyISAM or other non-InnoDB storage engines, it does a “warm” backup, where the database continues to run, but those tables cannot be modified while being backed up. For efficient backup operations, you can designate InnoDB as the default storage engine for new tables, or convert existing tables to use the InnoDB storage engine.

### 25.3 MySQL Enterprise Security Overview

MySQL Enterprise Edition provides plugins that implement security features using external services:

- MySQL Enterprise Edition includes an authentication plugin that enables MySQL Server to use PAM (Pluggable Authentication Modules) to authenticate MySQL users. PAM enables a system to use a standard interface to access various kinds of authentication methods, such as Unix passwords or an LDAP directory. For more information, see Section 6.4.1.6, “PAM Pluggable Authentication”.

- MySQL Enterprise Edition includes an authentication plugin that performs external authentication on Windows, enabling MySQL Server to use native Windows services to authenticate client connections. Users who have logged in to Windows can connect from MySQL client programs to the server based on the information in their environment without specifying an additional password. For more information, see Section 6.4.1.7, “Windows Pluggable Authentication”.

- MySQL Enterprise Edition 5.6 and higher includes a set of encryption functions based on the OpenSSL library that expose OpenSSL capabilities at the SQL level. These functions enable masking existing data using several methods such as obfuscation (removing identifying characteristics), generation of formatted random data, and data replacement or substitution. For more information, see Section 25.4, “MySQL Enterprise Encryption Overview”.

- MySQL Enterprise Edition 5.7 and higher includes a keyring plugin that uses Oracle Key Vault as a back end for keyring storage. For more information, see The MySQL Keyring.

For other related Enterprise security features, see Section 25.4, “MySQL Enterprise Encryption Overview”.

### 25.4 MySQL Enterprise Encryption Overview

MySQL Enterprise Edition 5.6 and higher includes a set of encryption functions based on the OpenSSL library that expose OpenSSL capabilities at the SQL level. These functions enable Enterprise applications to perform the following operations:

- Implement added data protection using public-key asymmetric cryptography
- Create public and private keys and digital signatures
- Perform asymmetric encryption and decryption
- Use cryptographic hashing for digital signing and data verification and validation

For more information, see Section 12.18, “MySQL Enterprise Encryption Functions”.

For other related Enterprise security features, see Section 25.3, “MySQL Enterprise Security Overview”.

### 25.5 MySQL Enterprise Audit Overview
MySQL Enterprise Edition includes MySQL Enterprise Audit, implemented using a server plugin. MySQL Enterprise Audit uses the open MySQL Audit API to enable standard, policy-based monitoring and logging of connection and query activity executed on specific MySQL servers. Designed to meet the Oracle audit specification, MySQL Enterprise Audit provides an out of box, easy to use auditing and compliance solution for applications that are governed by both internal and external regulatory guidelines.

When installed, the audit plugin enables MySQL Server to produce a log file containing an audit record of server activity. The log contents include when clients connect and disconnect, and what actions they perform while connected, such as which databases and tables they access.

For more information, see Section 6.4.4, “MySQL Enterprise Audit”.

25.6 MySQL Enterprise Firewall Overview

MySQL Enterprise Edition 5.6 and higher includes MySQL Enterprise Firewall, an application-level firewall that enables database administrators to permit or deny SQL statement execution based on matching against whitelists of accepted statement patterns. This helps harden MySQL Server against attacks such as SQL injection or attempts to exploit applications by using them outside of their legitimate query workload characteristics.

Each MySQL account registered with the firewall has its own statement whitelist, enabling protection to be tailored per account. For a given account, the firewall can operate in recording or protecting mode, for training in the accepted statement patterns or protection against unacceptable statements.

For more information, see Section 6.4.5, “MySQL Enterprise Firewall”.

25.7 MySQL Enterprise Thread Pool Overview

MySQL Enterprise Edition includes MySQL Enterprise Thread Pool, implemented using a server plugin. The default thread-handling model in MySQL Server executes statements using one thread per client connection. As more clients connect to the server and execute statements, overall performance degrades. In MySQL Enterprise Edition, a thread pool plugin provides an alternative thread-handling model designed to reduce overhead and improve performance. The plugin implements a thread pool that increases server performance by efficiently managing statement execution threads for large numbers of client connections.

For more information, see Section 5.5.3, “MySQL Enterprise Thread Pool”.

25.8 MySQL Enterprise Data Masking and De-Identification Overview

MySQL Enterprise Edition 5.7 and higher includes MySQL Enterprise Data Masking and De-Identification, implemented as a plugin library containing a plugin and a set of user-defined functions. Data masking hides sensitive information by replacing real values with substitutes. MySQL Enterprise Data Masking and De-Identification functions enable masking existing data using several methods such as obfuscation (removing identifying characteristics), generation of formatted random data, and data replacement or substitution.

For more information, see MySQL Enterprise Data Masking and De-Identification.
Chapter 26 MySQL Workbench

MySQL Workbench provides a graphical tool for working with MySQL servers and databases. MySQL Workbench fully supports MySQL versions 5.5 and higher.

The following discussion briefly describes MySQL Workbench capabilities. For more information, see the MySQL Workbench manual, available at https://docs.oracle.com/cd/E17952_01/workbench-en/.

MySQL Workbench provides five main areas of functionality:

- **SQL Development**: Enables you to create and manage connections to database servers. As well as enabling you to configure connection parameters. MySQL Workbench provides the capability to execute SQL queries on the database connections using the built-in SQL Editor. This functionality replaces that previously provided by the Query Browser standalone application.

- **Data Modeling**: Enables you to create models of your database schema graphically, reverse and forward engineer between a schema and a live database, and edit all aspects of your database using the comprehensive Table Editor. The Table Editor provides easy-to-use facilities for editing Tables, Columns, Indexes, Triggers, Partitioning, Options, Inserts and Privileges, Routines and Views.

- **Server Administration**: Enables you to create and administer server instances.

- **Data Migration**: Allows you to migrate from Microsoft SQL Server, Sybase ASE, SQLite, SQL Anywhere, PostreSQL, and other RDBMS tables, objects and data to MySQL. Migration also supports migrating from earlier versions of MySQL to the latest releases.

- **MySQL Enterprise Support**: Support for Enterprise products such as MySQL Enterprise Backup and MySQL Audit.

MySQL Workbench is available in two editions, the Community Edition and the Commercial Edition. The Community Edition is available free of charge. The Commercial Edition provides additional Enterprise features, such as database documentation generation, at low cost.

A.1 MySQL 5.6 FAQ: General

A.1.1 Which version of MySQL is production-ready (GA)? .......................... 3655
A.1.2 Can MySQL 5.6 do subqueries? ..................................................... 3656
A.1.3 Can MySQL 5.6 perform multiple-table inserts, updates, and deletes? .......... 3656
A.1.4 Does MySQL 5.6 have a Query Cache? Does it work on Server, Instance or Database? ........... 3656
A.1.5 Does MySQL 5.6 have Sequences? ............................................... 3656
A.1.6 Does MySQL 5.6 have a NOW() function with fractions of seconds? .............. 3656
A.1.7 Does MySQL 5.6 work with multi-core processors? ............................ 3656
A.1.8 Why do I see multiple processes for mysqld? ................................ 3656
A.1.9 Can MySQL 5.6 perform ACID transactions? .................................. 3656

A.1.1. Which version of MySQL is production-ready (GA)?

MySQL 8.0, 5.7, and MySQL 5.6 are supported for production use.

MySQL 8.0 achieved General Availability (GA) status with MySQL 8.0.11, which was released for production use on 19 April 2018.

MySQL 5.7 achieved General Availability (GA) status with MySQL 5.7.9, which was released for production use on 21 October 2015.

MySQL 5.6 achieved General Availability (GA) status with MySQL 5.6.10, which was released for production use on 5 February 2013.

MySQL 5.5 achieved General Availability (GA) status with MySQL 5.5.8, which was released for production use on 3 December 2010. The MySQL 5.5 series is no longer current, but still supported in production.

MySQL 5.1 achieved General Availability (GA) status with MySQL 5.1.30, which was released for production use on 14 November 2008. Active development for MySQL 5.1 has ended.
MySQL 5.0 achieved General Availability (GA) status with MySQL 5.0.15, which was released for production use on 19 October 2005. Active development for MySQL 5.0 has ended.

A.1.2. Can MySQL 5.6 do subqueries?

Yes. See Section 13.2.10, “Subquery Syntax”.

A.1.3. Can MySQL 5.6 perform multiple-table inserts, updates, and deletes?

Yes. For the syntax required to perform multiple-table updates, see Section 13.2.11, “UPDATE Syntax”; for that required to perform multiple-table deletes, see Section 13.2.2, “DELETE Syntax”.

A multiple-table insert can be accomplished using a trigger whose `FOR EACH ROW` clause contains multiple `INSERT` statements within a `BEGIN ... END` block. See Section 20.3, “Using Triggers”.

A.1.4. Does MySQL 5.6 have a Query Cache? Does it work on Server, Instance or Database?

Yes. The query cache operates on the server level, caching complete result sets matched with the original query string. If an exactly identical query is made (which often happens, particularly in web applications), no parsing or execution is necessary; the result is sent directly from the cache. Various tuning options are available. See Section 8.10.3, “The MySQL Query Cache”.

A.1.5. Does MySQL 5.6 have Sequences?

No. However, MySQL has an `AUTO_INCREMENT` system, which in MySQL 5.6 can also handle inserts in a multi-master replication setup. With the `auto_increment_increment` and `auto_increment_offset` system variables, you can set each server to generate auto-increment values that don't conflict with other servers. The `auto_increment_increment` value should be greater than the number of servers, and each server should have a unique offset.

A.1.6. Does MySQL 5.6 have a `NOW()` function with fractions of seconds?

Yes, see Section 11.3.6, “Fractional Seconds in Time Values”.

A.1.7. Does MySQL 5.6 work with multi-core processors?

Yes. MySQL is fully multithreaded, and will make use of multiple CPUs, provided that the operating system supports them.

A.1.8. Why do I see multiple processes for `mysqld`?

When using LinuxThreads, you should see a minimum of three `mysqld` processes running. These are in fact threads. There is one thread for the LinuxThreads manager, one thread to handle connections, and one thread to handle alarms and signals.

A.1.9. Can MySQL 5.6 perform ACID transactions?

Yes. All current MySQL versions support transactions. The InnoDB storage engine offers full ACID transactions with row-level locking, multi-versioning, nonlocking repeatable reads, and all four SQL standard isolation levels.

The NDB storage engine supports the `READ COMMITTED` transaction isolation level only.

A.2 MySQL 5.6 FAQ: Storage Engines

A.2.1 Where can I obtain complete documentation for MySQL storage engines? ................................. 3657
A.2.2 Are there any new storage engines in MySQL 5.6? ................................................................. 3657
A.2.3 Have any storage engines been removed in MySQL 5.6? ............................................................. 3657
A.2.4 What are the unique benefits of the ARCHIVE storage engine? .............................................. 3657

A.2.1. Where can I obtain complete documentation for MySQL storage engines?

See Chapter 15, Alternative Storage Engines. That chapter contains information about all MySQL storage engines except for the InnoDB storage engine and the NDB storage engine (used for MySQL Cluster). InnoDB is covered in Chapter 14, The InnoDB Storage Engine. NDB is covered in Chapter 18, MySQL NDB Cluster 7.3 and NDB Cluster 7.4.

A.2.2. Are there any new storage engines in MySQL 5.6?

The features from the optional InnoDB Plugin from MySQL 5.1 are folded into the built-in InnoDB storage engine, so you can take advantage of features such as the Barracuda file format, InnoDB table compression, and the new configuration options for performance. See Chapter 14, The InnoDB Storage Engine for details. InnoDB also becomes the default storage engine for new tables. See Section 14.1, “Introduction to InnoDB” for details.

A.2.3. Have any storage engines been removed in MySQL 5.6?

No.

A.2.4. What are the unique benefits of the ARCHIVE storage engine?

The ARCHIVE storage engine stores large amounts of data without indexes; it has a small footprint, and performs selects using table scans. See Section 15.5, “The ARCHIVE Storage Engine”, for details.

A.3 MySQL 5.6 FAQ: Server SQL Mode

A.3.1 What are server SQL modes? ........................................................................................................ 3657
A.3.2 How many server SQL modes are there? ..................................................................................... 3657
A.3.3 How do you determine the server SQL mode? ............................................................................ 3657
A.3.4 Is the mode dependent on the database or connection? ............................................................... 3658
A.3.5 Can the rules for strict mode be extended? ............................................................................... 3658
A.3.6 Does strict mode impact performance? ....................................................................................... 3658
A.3.7 What is the default server SQL mode when MySQL 5.6 is installed? ........................................ 3658

A.3.1. What are server SQL modes?

Server SQL modes define what SQL syntax MySQL should support and what kind of data validation checks it should perform. This makes it easier to use MySQL in different environments and to use MySQL together with other database servers. The MySQL Server apply these modes individually to different clients. For more information, see Section 5.1.10, “Server SQL Modes”.

A.3.2. How many server SQL modes are there?

Each mode can be independently switched on and off. See Section 5.1.10, “Server SQL Modes”, for a complete list of available modes.

A.3.3. How do you determine the server SQL mode?

You can set the default SQL mode (for mysqld startup) with the --sql-mode option. Using the statement SET [GLOBAL|SESSION] sql_mode='modes', you can change the settings from within a connection, either locally to the connection, or to take effect globally. You can retrieve the current mode by issuing a SELECT @@sql_mode statement.
A.3.4. Is the mode dependent on the database or connection?

A mode is not linked to a particular database. Modes can be set locally to the session (connection), or globally for the server. You can change these settings using `SET [GLOBAL|SESSION] sql_mode='modes'`.

A.3.5. Can the rules for strict mode be extended?

When we refer to strict mode, we mean a mode where at least one of the modes TRADITIONAL, STRICT_TRANS_TABLES, or STRICT_ALL_TABLES is enabled. Options can be combined, so you can add restrictions to a mode. See Section 5.1.10, “Server SQL Modes”, for more information.

A.3.6. Does strict mode impact performance?

The intensive validation of input data that some settings require more time than if the validation is not done. While the performance impact is not that great, if you do not require such validation (perhaps your application already handles all of this), then MySQL gives you the option of leaving strict mode disabled. However, if you do require it, strict mode can provide such validation.

A.3.7. What is the default server SQL mode when MySQL 5.6 is installed?

The default SQL mode is NO_ENGINE_SUBSTITUTION. For information about all available modes and default MySQL behavior, see Section 5.1.10, “Server SQL Modes”.

A.4 MySQL 5.6 FAQ: Stored Procedures and Functions

A.4.1 Does MySQL 5.6 support stored procedures and functions? .................................................. 3659
A.4.2 Where can I find documentation for MySQL stored procedures and stored functions? .......... 3659
A.4.3 Is there a discussion forum for MySQL stored procedures? ..................................................... 3659
A.4.4 Where can I find the ANSI SQL 2003 specification for stored procedures? ............................ 3659
A.4.5 How do you manage stored routines? ......................................................................................... 3659
A.4.6 Is there a way to view all stored procedures and stored functions in a given database? ............ 3659
A.4.7 Where are stored procedures stored? ......................................................................................... 3659
A.4.8 Is it possible to group stored procedures or stored functions into packages? .......................... 3659
A.4.9 Can a stored procedure call another stored procedure? ............................................................ 3660
A.4.10 Can a stored procedure call a trigger? ......................................................................................... 3660
A.4.11 Can a stored procedure access tables? ......................................................................................... 3660
A.4.12 Do stored procedures have a statement for raising application errors? ................................. 3660
A.4.13 Do stored procedures provide exception handling? ............................................................... 3660
A.4.14 Can MySQL 5.6 stored routines return result sets? ................................................................. 3660
A.4.15 Is WITH RECOMPILE supported for stored procedures? ....................................................... 3660
A.4.16 Is there a MySQL equivalent to using mod_plsql as a gateway on Apache to talk directly to a stored procedure in the database? ................................................................. 3660
A.4.17 Can I pass an array as input to a stored procedure? ................................................................. 3660
A.4.18 Can I pass a cursor as an IN parameter to a stored procedure? ............................................. 3660
A.4.19 Can I return a cursor as an OUT parameter from a stored procedure? .................................... 3660
A.4.20 Can I print out a variable's value within a stored routine for debugging purposes? ................. 3660
A.4.21 Can I commit or roll back transactions inside a stored procedure? .......................................... 3661
A.4.22 Do MySQL 5.6 stored procedures and functions work with replication? .............................. 3661
A.4.23 Are stored procedures and functions created on a master server replicated to a slave? ............ 3661
A.4.24 How are actions that take place inside stored procedures and functions replicated? ............... 3661
A.4.25 Are there special security requirements for using stored procedures and functions together with replication? .............................................................................................................. 3661
A.4.26 What limitations exist for replicating stored procedure and function actions? .................. 3661
A.4.27 Do the preceding limitations affect the ability of MySQL to do point-in-time recovery? ........ 3661
A.4.28 What is being done to correct the aforementioned limitations? .......................................... 3662
A.4.1. Does MySQL 5.6 support stored procedures and functions?
Yes. MySQL 5.6 supports two types of stored routines, stored procedures and stored functions.

A.4.2. Where can I find documentation for MySQL stored procedures and stored functions?
See Section 20.2, “Using Stored Routines”.

A.4.3. Is there a discussion forum for MySQL stored procedures?

A.4.4. Where can I find the ANSI SQL 2003 specification for stored procedures?
Unfortunately, the official specifications are not freely available (ANSI makes them available for purchase). However, there are books, such as SQL-99 Complete, Really by Peter Gulutzan and Trudy Pelzer, that provide a comprehensive overview of the standard, including coverage of stored procedures.

A.4.5. How do you manage stored routines?
It is always good practice to use a clear naming scheme for your stored routines. You can manage stored procedures with CREATE [FUNCTION|PROCEDURE], ALTER [FUNCTION|PROCEDURE], DROP [FUNCTION|PROCEDURE], and SHOW CREATE [FUNCTION|PROCEDURE]. You can obtain information about existing stored procedures using the ROUTINES table in the INFORMATION_SCHEMA database (see Section 21.19, “The INFORMATION_SCHEMA ROUTINES Table”).

A.4.6. Is there a way to view all stored procedures and stored functions in a given database?
Yes. For a database named `dbname`, use this query on the INFORMATION_SCHEMA table:

```sql
SELECT ROUTINE_TYPE, ROUTINE_NAME
FROM INFORMATION_SCHEMA.ROUTINES
WHERE ROUTINE_SCHEMA='dbname';
```

For more information, see Section 21.19, “The INFORMATION_SCHEMA ROUTINES Table”.

The body of a stored routine can be viewed using SHOW CREATE FUNCTION (for a stored function) or SHOW CREATE PROCEDURE (for a stored procedure). See Section 13.7.5.11, “SHOW CREATE PROCEDURE Syntax”, for more information.

A.4.7. Where are stored procedures stored?
In the `proc` table of the mysql system database. However, you should not access the tables in the system database directly. Instead, query the INFORMATION_SCHEMA ROUTINES and PARAMETERS tables. See Section 21.19, “The INFORMATION_SCHEMA ROUTINES Table”, and Section 21.13, “The INFORMATION_SCHEMA PARAMETERS Table”.

You can also use SHOW CREATE FUNCTION to obtain information about stored functions, and SHOW CREATE PROCEDURE to obtain information about stored procedures. See Section 13.7.5.11, “SHOW CREATE PROCEDURE Syntax”.

A.4.8. Is it possible to group stored procedures or stored functions into packages?
No. This is not supported in MySQL 5.6.
A.4.9. Can a stored procedure call another stored procedure?
  Yes.

A.4.10. Can a stored procedure call a trigger?
  A stored procedure can execute an SQL statement, such as an UPDATE, that causes a trigger to activate.

A.4.11. Can a stored procedure access tables?
  Yes. A stored procedure can access one or more tables as required.

A.4.12. Do stored procedures have a statement for raising application errors?
  Yes. MySQL 5.6 implements the SQL standard SIGNAL and RESIGNAL statements. See Section 13.6.7, “Condition Handling”.

A.4.13. Do stored procedures provide exception handling?
  MySQL implements HANDLER definitions according to the SQL standard. See Section 13.6.7.2, “DECLARE ... HANDLER Syntax”, for details.

A.4.14. Can MySQL 5.6 stored routines return result sets?
  Stored procedures can, but stored functions cannot. If you perform an ordinary SELECT inside a stored procedure, the result set is returned directly to the client. You need to use the MySQL 4.1 (or higher) client/server protocol for this to work. This means that, for example, in PHP, you need to use the mysqli extension rather than the old mysql extension.

A.4.15. Is WITH RECOMPILE supported for stored procedures?
  Not in MySQL 5.6.

A.4.16. Is there a MySQL equivalent to using mod_plsql as a gateway on Apache to talk directly to a stored procedure in the database?
  There is no equivalent in MySQL 5.6.

A.4.17. Can I pass an array as input to a stored procedure?
  Not in MySQL 5.6.

A.4.18. Can I pass a cursor as an IN parameter to a stored procedure?
  In MySQL 5.6, cursors are available inside stored procedures only.

A.4.19. Can I return a cursor as an OUT parameter from a stored procedure?
  In MySQL 5.6, cursors are available inside stored procedures only. However, if you do not open a cursor on a SELECT, the result will be sent directly to the client. You can also SELECT INTO variables. See Section 13.2.9, “SELECT Syntax”.

A.4.20. Can I print out a variable’s value within a stored routine for debugging purposes?
  Yes, you can do this in a stored procedure, but not in a stored function. If you perform an ordinary SELECT inside a stored procedure, the result set is returned directly to the client. You will need to use the MySQL 4.1 (or above) client/server protocol for this to work. This means that, for example, in PHP, you need to use the mysqli extension rather than the old mysql extension.
A.4.21 Can I commit or roll back transactions inside a stored procedure?

Yes. However, you cannot perform transactional operations within a stored function.

A.4.22 Do MySQL 5.6 stored procedures and functions work with replication?

Yes, standard actions carried out in stored procedures and functions are replicated from a master MySQL server to a slave server. There are a few limitations that are described in detail in Section 20.7, “Stored Program Binary Logging”.

A.4.23 Are stored procedures and functions created on a master server replicated to a slave?

Yes, creation of stored procedures and functions carried out through normal DDL statements on a master server are replicated to a slave, so the objects will exist on both servers. ALTER and DROP statements for stored procedures and functions are also replicated.

A.4.24 How are actions that take place inside stored procedures and functions replicated?

MySQL records each DML event that occurs in a stored procedure and replicates those individual actions to a slave server. The actual calls made to execute stored procedures are not replicated. Stored functions that change data are logged as function invocations, not as the DML events that occur inside each function.

A.4.25 Are there special security requirements for using stored procedures and functions together with replication?

Yes. Because a slave server has authority to execute any statement read from a master's binary log, special security constraints exist for using stored functions with replication. If replication or binary logging in general (for the purpose of point-in-time recovery) is active, then MySQL DBAs have two security options open to them:

1. Any user wishing to create stored functions must be granted the SUPER privilege.
2. Alternatively, a DBA can set the log_bin_trust_function_creators system variable to 1, which enables anyone with the standard CREATE ROUTINE privilege to create stored functions.

A.4.26 What limitations exist for replicating stored procedure and function actions?

Nondeterministic (random) or time-based actions embedded in stored procedures may not replicate properly. By their very nature, randomly produced results are not predictable and cannot be exactly reproduced, and therefore, random actions replicated to a slave will not mirror those performed on a master. Declaring stored functions to be DETERMINISTIC or setting the log_bin_trust_function_creators system variable to 0 will not allow random-valued operations to be invoked.

In addition, time-based actions cannot be reproduced on a slave because the timing of such actions in a stored procedure is not reproducible through the binary log used for replication. It records only DML events and does not factor in timing constraints.

Finally, nontransactional tables for which errors occur during large DML actions (such as bulk inserts) may experience replication issues in that a master may be partially updated from DML activity, but no updates are done to the slave because of the errors that occurred. A workaround is for a function's DML actions to be carried out with the IGNORE keyword so that updates on the master that cause errors are ignored and updates that do not cause errors are replicated to the slave.

A.4.27 Do the preceding limitations affect the ability of MySQL to do point-in-time recovery?
The same limitations that affect replication do affect point-in-time recovery.

A.4.28 What is being done to correct the aforementioned limitations?

You can choose either statement-based replication or row-based replication. The original replication implementation is based on statement-based binary logging. Row-based binary logging resolves the limitations mentioned earlier.

**Mixed** replication is also available (by starting the server with `--binlog-format=mixed`). This hybrid form of replication "knows" whether statement-level replication can safely be used, or row-level replication is required.

For additional information, see Section 17.1.2, "Replication Formats".

A.5 MySQL 5.6 FAQ: Triggers

A.5.1 Where can I find the documentation for MySQL 5.6 triggers? ................................. 3662
A.5.2 Is there a discussion forum for MySQL Triggers? ...................................................... 3662
A.5.3 Does MySQL 5.6 have statement-level or row-level triggers? ............................... 3662
A.5.4 Are there any default triggers? ................................................................. 3662
A.5.5 How are triggers managed in MySQL? ....................................................................... 3662
A.5.6 Is there a way to view all triggers in a given database? .............................................. 3663
A.5.7 Where are triggers stored? ...................................................................................... 3663
A.5.8 Can a trigger call a stored procedure? ................................................................. 3663
A.5.9 Can triggers access tables? ...................................................................................... 3663
A.5.10 Can a table have multiple triggers with the same trigger event and action time? ........ 3663
A.5.11 Can triggers call an external application through a UDF? .................................... 3663
A.5.12 Is it possible for a trigger to update tables on a remote server? .............................. 3663
A.5.13 Do triggers work with replication? ........................................................................... 3663
A.5.14 How are actions carried out through triggers on a master replicated to a slave? ........ 3663

A.5.1. Where can I find the documentation for MySQL 5.6 triggers?

See Section 20.3, “Using Triggers”.

A.5.2. Is there a discussion forum for MySQL Triggers?

A.5.3. Does MySQL 5.6 have statement-level or row-level triggers?

In MySQL 5.6, all triggers are **FOR EACH ROW**; that is, the trigger is activated for each row that is inserted, updated, or deleted. MySQL 5.6 does not support triggers using **FOR EACH STATEMENT**.

A.5.4. Are there any default triggers?

Not explicitly. MySQL does have specific special behavior for some **TIMESTAMP** columns, as well as for columns which are defined using **AUTO_INCREMENT**.

A.5.5. How are triggers managed in MySQL?

In MySQL 5.6, triggers can be created using the **CREATE TRIGGER** statement, and dropped using **DROP TRIGGER**. See Section 13.1.19, “CREATE TRIGGER Syntax”, and Section 13.1.30, “DROP TRIGGER Syntax”, for more about these statements.

Information about triggers can be obtained by querying the **INFORMATION_SCHEMA.TRIGGERS** table. See Section 21.27, “The INFORMATION_SCHEMA TRIGGERS Table”.

A.5.6. Is there a way to view all triggers in a given database?

Yes. You can obtain a listing of all triggers defined on database `dbname` using a query on the `INFORMATION_SCHEMA.TRIGGERS` table such as the one shown here:

```sql
SELECT TRIGGER_NAME, EVENT_MANIPULATION, EVENT_OBJECT_TABLE, ACTION_STATEMENT
FROM INFORMATION_SCHEMA.TRIGGERS
WHERE TRIGGER_SCHEMA='dbname';
```

For more information about this table, see Section 21.27, “The INFORMATION_SCHEMA TRIGGERS Table”.

You can also use the `SHOW TRIGGERS` statement, which is specific to MySQL. See Section 13.7.5.39, “SHOW TRIGGERS Syntax”.

A.5.7. Where are triggers stored?

Triggers are stored in `.TRG` files, with one such file one per table.

A.5.8. Can a trigger call a stored procedure?

Yes.

A.5.9. Can triggers access tables?

A trigger can access both old and new data in its own table. A trigger can also affect other tables, but it is not permitted to modify a table that is already being used (for reading or writing) by the statement that invoked the function or trigger.

A.5.10. Can a table have multiple triggers with the same trigger event and action time?

In MySQL 5.6, there cannot be multiple triggers for a given table that have the same trigger event and action time. For example, you cannot have two `BEFORE UPDATE` triggers for a table. This limitation is lifted in MySQL 5.7.

A.5.11. Can triggers call an external application through a UDF?

Yes. For example, a trigger could invoke the `sys_exec()` UDF.

A.5.12. Is it possible for a trigger to update tables on a remote server?

Yes. A table on a remote server could be updated using the `FEDERATED` storage engine. (See Section 15.8, “The FEDERATED Storage Engine”).

A.5.13. Do triggers work with replication?

Yes. However, the way in which they work depends whether you are using MySQL’s “classic” statement-based or row-based replication format.

When using statement-based replication, triggers on the slave are executed by statements that are executed on the master (and replicated to the slave).

When using row-based replication, triggers are not executed on the slave due to statements that were run on the master and then replicated to the slave. Instead, when using row-based replication, the changes caused by executing the trigger on the master are applied on the slave.

For more information, see Section 17.4.1.33, “Replication and Triggers”.

A.5.14. How are actions carried out through triggers on a master replicated to a slave?
Again, this depends on whether you are using statement-based or row-based replication.

**Statement-based replication.** First, the triggers that exist on a master must be re-created on the slave server. Once this is done, the replication flow works as any other standard DML statement that participates in replication. For example, consider a table `EMP` that has an `AFTER` insert trigger, which exists on a master MySQL server. The same `EMP` table and `AFTER` insert trigger exist on the slave server as well. The replication flow would be:

1. An **INSERT** statement is made to **EMP**.
2. The **AFTER** trigger on **EMP** activates.
3. The **INSERT** statement is written to the binary log.
4. The replication slave picks up the **INSERT** statement to **EMP** and executes it.
5. The **AFTER** trigger on **EMP** that exists on the slave activates.

**Row-based replication.** When you use row-based replication, the changes caused by executing the trigger on the master are applied on the slave. However, the triggers themselves are not actually executed on the slave under row-based replication. This is because, if both the master and the slave applied the changes from the master and, in addition, the trigger causing these changes were applied on the slave, the changes would in effect be applied twice on the slave, leading to different data on the master and the slave.

In most cases, the outcome is the same for both row-based and statement-based replication. However, if you use different triggers on the master and slave, you cannot use row-based replication. (This is because the row-based format replicates the changes made by triggers executing on the master to the slaves, rather than the statements that caused the triggers to execute, and the corresponding triggers on the slave are not executed.) Instead, any statements causing such triggers to be executed must be replicated using statement-based replication.

For more information, see Section 17.4.1.33, “Replication and Triggers”.

### A.6 MySQL 5.6 FAQ: Views

**A.6.1** Where can I find documentation covering MySQL Views?

See Section 20.5, “Using Views”.

**A.6.2** Is there a discussion forum for MySQL Views?

Yes. See [https://forums.mysql.com/list.php?100](https://forums.mysql.com/list.php?100)

**A.6.3** What happens to a view if an underlying table is dropped or renamed?

After a view has been created, it is possible to drop or alter a table or view to which the definition refers. To check a view definition for problems of this kind, use the **CHECK TABLE** statement. (See Section 13.7.2.2, “CHECK TABLE Syntax”.)
A.6.4. Does MySQL 5.6 have table snapshots?

No.

A.6.5. Does MySQL 5.6 have materialized views?

No.

A.6.6. Can you insert into views that are based on joins?

It is possible, provided that your `INSERT` statement has a column list that makes it clear there is only one table involved.

You cannot insert into multiple tables with a single insert on a view.

A.7 MySQL 5.6 FAQ: INFORMATION_SCHEMA

A.7.1. Where can I find documentation for the MySQL `INFORMATION_SCHEMA` database?

See Chapter 21, `INFORMATION_SCHEMA Tables`.

A.7.2. Is there a discussion forum for `INFORMATION_SCHEMA`?

A.7.3. Where can I find the ANSI SQL 2003 specification for `INFORMATION_SCHEMA`?

Unfortunately, the official specifications are not freely available. (ANSI makes them available for purchase.) However, there are books available, such as `SQL-99 Complete, Really` by Peter Gulutzan and Trudy Pelzer, that provide a comprehensive overview of the standard, including `INFORMATION_SCHEMA`.

A.7.4. What is the difference between the Oracle Data Dictionary and MySQL `INFORMATION_SCHEMA`?

Both Oracle and MySQL provide metadata in tables. However, Oracle and MySQL use different table names and column names. The MySQL implementation is more similar to those found in DB2 and SQL Server, which also support `INFORMATION_SCHEMA` as defined in the SQL standard.

A.7.5. Can I add to or otherwise modify the tables found in the `INFORMATION_SCHEMA` database?

No. Since applications may rely on a certain standard structure, this should not be modified. For this reason, we cannot support bugs or other issues which result from modifying `INFORMATION_SCHEMA` tables or data.

A.8 MySQL 5.6 FAQ: Migration

A.8.1. Where can I find information on how to migrate from MySQL 5.5 to MySQL 5.6?

A.8.2. How has storage engine (table type) support changed in MySQL 5.6 from previous versions?
MySQL 5.6 FAQ: Security

A.8.1. Where can I find information on how to migrate from MySQL 5.5 to MySQL 5.6?

For detailed upgrade information, see Section 2.11, “Upgrading MySQL”. Do not skip a major version when upgrading, but rather complete the process in steps, upgrading from one major version to the next in each step. This may seem more complicated, but it will you save time and trouble. If you encounter problems during the upgrade, their origin will be easier to identify, either by you or, if you have a MySQL Enterprise subscription, by MySQL support.

A.8.2. How has storage engine (table type) support changed in MySQL 5.6 from previous versions?

Storage engine support has changed as follows:

• Support for ISAM tables was removed in MySQL 5.0 and you should now use the MyISAM storage engine in place of ISAM. To convert a table tblname from ISAM to MyISAM, simply issue a statement such as this one:

  ALTER TABLE tblname ENGINE=MYISAM;

• Internal RAID for MyISAM tables was also removed in MySQL 5.0. This was formerly used to allow large tables in file systems that did not support file sizes greater than 2GB. All modern file systems allow for larger tables; in addition, there are now other solutions such as MERGE tables and views.

• The VARCHAR column type now retains trailing spaces in all storage engines.

• MEMORY tables (formerly known as HEAP tables) can also contain VARCHAR columns.

A.9 MySQL 5.6 FAQ: Security

A.9.1 Where can I find documentation that addresses security issues for MySQL? .......................... 3666
A.9.2 What is the default authentication plugin in MySQL 5.6? ...................................................... 3667
A.9.3 Does MySQL 5.6 have native support for SSL? ................................................................. 3667
A.9.4 Is SSL support built into MySQL binaries, or must I recompile the binary myself to enable it? ... 3667
A.9.5 Does MySQL 5.6 have built-in authentication against LDAP directories? .............................. 3667
A.9.6 Does MySQL 5.6 include support for Roles Based Access Control (RBAC)? .......................... 3667

A.9.1. Where can I find documentation that addresses security issues for MySQL?

The best place to start is Chapter 6, Security.

Other portions of the MySQL Documentation which you may find useful with regard to specific security concerns include the following:

• Section 6.1.1, “Security Guidelines”.
• Section 6.1.3, “Making MySQL Secure Against Attackers”.

A.9.2. What is the default authentication plugin in MySQL 5.6?

The default authentication plugin in MySQL 5.6 is `mysql_native_password`. For information about this plugin, see Section 6.4.1.1, “Native Pluggable Authentication”. For general information about pluggable authentication and other available authentication plugins, see Section 6.2.11, “Pluggable Authentication”, and Section 6.4.1, “Authentication Plugins”.

A.9.3. Does MySQL 5.6 have native support for SSL?

Most 5.6 binaries have support for SSL connections between the client and server. See Section 6.3, “Using Encrypted Connections”.

You can also tunnel a connection using SSH, if (for example) the client application does not support SSL connections. For an example, see Section 6.3.5, “Connecting to MySQL Remotely from Windows with SSH”.

A.9.4. Is SSL support built into MySQL binaries, or must I recompile the binary myself to enable it?

Most 5.6 binaries have SSL enabled for client/server connections that are secured, authenticated, or both. See Section 6.3, “Using Encrypted Connections”.

A.9.5. Does MySQL 5.6 have built-in authentication against LDAP directories?

The Enterprise edition includes a PAM Authentication Plugin that supports authentication against an LDAP directory.

A.9.6. Does MySQL 5.6 include support for Roles Based Access Control (RBAC)?

Not at this time.

A.10 MySQL 5.6 FAQ: NDB Cluster

In the following section, we answer questions that are frequently asked about NDB Cluster and the NDB storage engine.

A.10.1 Which versions of the MySQL software support NDB Cluster? Do I have to compile from source? ................................................................. 3668
A.10.2 What do “NDB” and “NDBCluster” mean? ................................................................. 3669

A.10.41 What is an “angel process”? ......................................................................................... 3680

A.10.1 Which versions of the MySQL software support NDB Cluster? Do I have to compile from source?

NDB Cluster is not supported in standard MySQL Server 5.6 releases. Instead, MySQL NDB Cluster is provided as a separate product. Available NDB Cluster release series include the following:

- **NDB Cluster 7.2.** This series is a previous General Availability (GA) version of NDB Cluster, still supported for existing deployments, although we recommend that new deployments use the latest NDB Cluster 7.6 release. The most recent NDB Cluster 7.2 release can be obtained from https://dev.mysql.com/downloads/cluster/.

- **NDB Cluster 7.3.** This series is a previous General Availability (GA) version of NDB Cluster, still available for production, although we recommend that new deployments use the latest NDB Cluster 7.6 release. The most recent NDB Cluster 7.3 release can be obtained from https://dev.mysql.com/downloads/cluster/.

- **NDB Cluster 7.4.** This series is a previous General Availability (GA) version of NDB Cluster, still available for production, although we recommend that new deployments use the latest NDB Cluster 7.6 release. The most recent NDB Cluster 7.4 release can be obtained from https://dev.mysql.com/downloads/cluster/.

- **NDB Cluster 7.5.** This series is a previous General Availability (GA) version of NDB Cluster, still available for production, although we recommend that new deployments use the latest NDB Cluster 7.6 release. The latest NDB Cluster 7.5 releases can be obtained from https://dev.mysql.com/downloads/cluster/.
• **NDB Cluster 7.6.** This series is the most recent General Availability (GA) version of NDB Cluster, based on version 7.6 of the NDB storage engine and MySQL Server 5.7. NDB Cluster 7.6 is available for production use; new deployments intended for production should use the latest GA release in this series, which is currently NDB Cluster 7.6.12. You can obtain the most recent NDB Cluster 7.6 release from [https://dev.mysql.com/downloads/cluster/](https://dev.mysql.com/downloads/cluster/). For information about new features and other important changes in this series, see What is New in NDB Cluster 7.6.

• **NDB Cluster 8.0.** This series is now available as a Developer Preview release for evaluation and testing of new features in the NDBCLUSTER storage engine; for more information, see MySQL NDB Cluster 8.0.

You should use NDB Cluster 7.6 for any new deployments; if you are using an older version of NDB Cluster, you should upgrade to this version soon as possible. For an overview of improvements made in NDB Cluster 7.6, see What is New in NDB Cluster 7.6. For an overview of improvements made in NDB Cluster 7.5, see What is New in NDB Cluster 7.5.

You can determine whether your MySQL Server has NDB support using one of the statements `SHOW VARIABLES LIKE 'have_%'`, `SHOW ENGINES`, or `SHOW PLUGINS`.

**A.10.2 What do “NDB” and “NDBCLUSTER” mean?**

“NDB” stands for “Network Database”. NDB and NDBCLUSTER are both names for the storage engine that enables clustering support with MySQL. NDB is preferred, but either name is correct.

**A.10.3 What is the difference between using NDB Cluster versus using MySQL Replication?**

In traditional MySQL replication, a master MySQL server updates one or more slaves. Transactions are committed sequentially, and a slow transaction can cause the slave to lag behind the master. This means that if the master fails, it is possible that the slave might not have recorded the last few transactions. If a transaction-safe engine such as InnoDB is being used, a transaction will either be complete on the slave or not applied at all, but replication does not guarantee that all data on the master and the slave will be consistent at all times. In NDB Cluster, all data nodes are kept in synchrony, and a transaction committed by any one data node is committed for all data nodes. In the event of a data node failure, all remaining data nodes remain in a consistent state.

In short, whereas standard MySQL replication is asynchronous, NDB Cluster is synchronous.

Asynchronous replication is also available in NDB Cluster. NDB Cluster Replication (also sometimes known as “geo-replication”) includes the capability to replicate both between two NDB Clusters, and from an NDB Cluster to a non-Cluster MySQL server. See Section 18.6, “NDB Cluster Replication”.

**A.10.4 Do I need any special networking to run NDB Cluster? How do computers in a cluster communicate?**

NDB Cluster is intended to be used in a high-bandwidth environment, with computers connecting using TCP/IP. Its performance depends directly upon the connection speed between the cluster's computers. The minimum connectivity requirements for NDB Cluster include a typical 100-megabit Ethernet network or the equivalent. We recommend you use gigabit Ethernet whenever available.

**A.10.5 How many computers do I need to run an NDB Cluster, and why?**

A minimum of three computers is required to run a viable cluster. However, the minimum recommended number of computers in an NDB Cluster is four: one each to run the management and SQL nodes, and two computers to serve as data nodes. The purpose of the two data nodes is to provide redundancy; the management node must run on a separate machine to guarantee continued arbitration services in the event that one of the data nodes fails.
To provide increased throughput and high availability, you should use multiple SQL nodes (MySQL Servers connected to the cluster). It is also possible (although not strictly necessary) to run multiple management servers.

**A.10.6 What do the different computers do in an NDB Cluster?**

An NDB Cluster has both a physical and logical organization, with computers being the physical elements. The logical or functional elements of a cluster are referred to as *nodes*, and a computer housing a cluster node is sometimes referred to as a *cluster host*. There are three types of nodes, each corresponding to a specific role within the cluster. These are:

- **Management node.** This node provides management services for the cluster as a whole, including startup, shutdown, backups, and configuration data for the other nodes. The management node server is implemented as the application `ndb_mgmd`; the management client used to control NDB Cluster is `ndb_mgm`. See Section 18.4.4, "ndb_mgmd — The NDB Cluster Management Server Daemon", and Section 18.4.5, "ndb_mgm — The NDB Cluster Management Client", for information about these programs.

- **Data node.** This type of node stores and replicates data. Data node functionality is handled by instances of the NDB data node process `ndbd`. For more information, see Section 18.4.1, "ndbd — The NDB Cluster Data Node Daemon".

- **SQL node.** This is simply an instance of MySQL Server (`mysqld`) that is built with support for the NDBCLUSTER storage engine and started with the `--ndb-cluster` option to enable the engine and the `--ndb-connectstring` option to enable it to connect to an NDB Cluster management server. For more about these options, see MySQL Server Options for NDB Cluster.

**Note**

An API node is any application that makes direct use of Cluster data nodes for data storage and retrieval. An SQL node can thus be considered a type of API node that uses a MySQL Server to provide an SQL interface to the Cluster. You can write such applications (that do not depend on a MySQL Server) using the NDB API, which supplies a direct, object-oriented transaction and scanning interface to NDB Cluster data; see NDB Cluster API Overview: The NDB API, for more information.

**A.10.7 When I run the `SHOW` command in the NDB Cluster management client, I see a line of output that looks like this:**

```
  id=2  010.100.10.32  (Version: 5.6.46-ndb-7.4.26 Nodegroup: 0, *)
```

What does the * mean? How is this node different from the others?

The simplest answer is, “It’s not something you can control, and it’s nothing that you need to worry about in any case, unless you’re a software engineer writing or analyzing the NDB Cluster source code”.

If you don’t find that answer satisfactory, here’s a longer and more technical version:

A number of mechanisms in NDB Cluster require distributed coordination among the data nodes. These distributed algorithms and protocols include global checkpointing, DDL (schema) changes, and node restart handling. To make this coordination simpler, the data nodes “elect” one of their number to act as leader. (This node was once referred to as a “master”, but this terminology was dropped to avoid confusion with master server in MySQL Replication.) There is no user-facing
mechanism for influencing this selection, which is completely automatic; the fact that it is automatic is a key part of NDB Cluster's internal architecture.

When a node acts as the "leader" for any of these mechanisms, it is usually the point of coordination for the activity, and the other nodes act as "followers", carrying out their parts of the activity as directed by the leader. If the node acting as leader fails, then the remaining nodes elect a new leader. Tasks in progress that were being coordinated by the old leader may either fail or be continued by the new leader, depending on the actual mechanism involved.

It is possible for some of these different mechanisms and protocols to have different leader nodes, but in general the same leader is chosen for all of them. The node indicated as the leader in the output of `SHOW` in the management client is known internally as the `DICT` manager (see The `DBDICT Block`, in the `NDB Cluster API Developer Guide`, for more information), responsible for coordinating DDL and metadata activity.

NDB Cluster is designed in such a way that the choice of leader has no discernible effect outside the cluster itself. For example, the current leader does not have significantly higher CPU or resource usage than the other data nodes, and failure of the leader should not have a significantly different impact on the cluster than the failure of any other data node.

**A.10.8** With which operating systems can I use NDB Cluster?

NDB Cluster is supported on most Unix-like operating systems. NDB Cluster is also supported in production settings on Microsoft Windows operating systems.

For more detailed information concerning the level of support which is offered for NDB Cluster on various operating system versions, operating system distributions, and hardware platforms, please refer to [https://www.mysql.com/support/supportedplatforms/cluster.html](https://www.mysql.com/support/supportedplatforms/cluster.html).

**A.10.9** What are the hardware requirements for running NDB Cluster?

NDB Cluster should run on any platform for which NDB-enabled binaries are available. For data nodes and API nodes, faster CPUs and more memory are likely to improve performance, and 64-bit CPUs are likely to be more effective than 32-bit processors. There must be sufficient memory on machines used for data nodes to hold each node’s share of the database (see *How much RAM do I Need?* for more information). For a computer which is used only for running the NDB Cluster management server, the requirements are minimal; a common desktop PC (or the equivalent) is generally sufficient for this task. Nodes can communicate through the standard TCP/IP network and hardware. They can also use the high-speed SCI protocol; however, special networking hardware and software are required to use SCI (see *Section 18.3.4, “Using High-Speed Interconnects with NDB Cluster”*).

**A.10.10** How much RAM do I need to use NDB Cluster? Is it possible to use disk memory at all?

NDB Cluster was originally implemented as in-memory only, but all versions currently available also provide the ability to store NDB Cluster on disk. See *Section 18.5.12, “NDB Cluster Disk Data Tables”*, for more information.

For in-memory NDB tables, you can use the following formula for obtaining a rough estimate of how much RAM is needed for each data node in the cluster:

\[
\text{(Size of Database} \times \text{Number of Replicas} \times 1.1) / \text{Number of Data Nodes}
\]

To calculate the memory requirements more exactly requires determining, for each table in the cluster database, the storage space required per row (see *Section 11.7, “Data Type Storage*...
Requirements”, for details), and multiplying this by the number of rows. You must also remember to account for any column indexes as follows:

- Each primary key or hash index created for an NDBCLUSTER table requires 21–25 bytes per record. These indexes use IndexMemory.

- Each ordered index requires 10 bytes storage per record, using DataMemory.

- Creating a primary key or unique index also creates an ordered index, unless this index is created with USING HASH. In other words:
  
  - A primary key or unique index on a Cluster table normally takes up 31 to 35 bytes per record.
  
  - However, if the primary key or unique index is created with USING HASH, then it requires only 21 to 25 bytes per record.

Creating NDB Cluster tables with USING HASH for all primary keys and unique indexes will generally cause table updates to run more quickly—in some cases by a much as 20 to 30 percent faster than updates on tables where USING HASH was not used in creating primary and unique keys. This is due to the fact that less memory is required (because no ordered indexes are created), and that less CPU must be utilized (because fewer indexes must be read and possibly updated). However, it also means that queries that could otherwise use range scans must be satisfied by other means, which can result in slower selects.

When calculating Cluster memory requirements, you may find useful the ndb_size.pl utility which is available in recent MySQL 5.6 releases. This Perl script connects to a current (non-Cluster) MySQL database and creates a report on how much space that database would require if it used the NDBCLUSTER storage engine. For more information, see Section 18.4.27, “ndb_size.pl — NDBCLUSTER Size Requirement Estimator”.

It is especially important to keep in mind that every NDB Cluster table must have a primary key. The NDB storage engine creates a primary key automatically if none is defined; this primary key is created without USING HASH.

You can determine how much memory is being used for storage of NDB Cluster data and indexes at any given time using the REPORT MEMORYUSAGE command in the ndb_mgm client; see Section 18.5.2, “Commands in the NDB Cluster Management Client”, for more information. In addition, warnings are written to the cluster log when 80% of available DataMemory or IndexMemory is in use, and again when usage reaches 85%, 90%, and so on.

A.10.1 What file systems can I use with NDB Cluster? What about network file systems or network shares?

Generally, any file system that is native to the host operating system should work well with NDB Cluster. If you find that a given file system works particularly well (or not so especially well) with NDB Cluster, we invite you to discuss your findings in the NDB Cluster Forums.

For Windows, we recommend that you use NTFS file systems for NDB Cluster, just as we do for standard MySQL. We do not test NDB Cluster with FAT or VFAT file systems. Because of this, we do not recommend their use with MySQL or NDB Cluster.

NDB Cluster is implemented as a shared-nothing solution; the idea behind this is that the failure of a single piece of hardware should not cause the failure of multiple cluster nodes, or possibly even the failure of the cluster as a whole. For this reason, the use of network shares or network file systems is not supported for NDB Cluster. This also applies to shared storage devices such as SANs.
A.10.12. Can I run NDB Cluster nodes inside virtual machines (such as those created by VMWare, Parallels, or Xen)?

NDB Cluster is supported for use in virtual machines. We currently support and test using Oracle VM.

Some NDB Cluster users have successfully deployed NDB Cluster using other virtualization products; in such cases, Oracle can provide NDB Cluster support, but issues specific to the virtual environment must be referred to that product's vendor.

A.10.13. I am trying to populate an NDB Cluster database. The loading process terminates prematurely and I get an error message like this one:

```
ERROR 1114: The table 'my_cluster_table' is full
```

Why is this happening?

The cause is very likely to be that your setup does not provide sufficient RAM for all table data and all indexes, including the primary key required by the NDB storage engine and automatically created in the event that the table definition does not include the definition of a primary key.

It is also worth noting that all data nodes should have the same amount of RAM, since no data node in a cluster can use more memory than the least amount available to any individual data node. For example, if there are four computers hosting Cluster data nodes, and three of these have 3GB of RAM available to store Cluster data while the remaining data node has only 1GB RAM, then each data node can devote at most 1GB to NDB Cluster data and indexes.

In some cases it is possible to get Table is full errors in MySQL client applications even when `ndb_mgm -e "ALL REPORT MEMORYUSAGE"` shows significant free DataMemory. You can force NDB to create extra partitions for NDB Cluster tables and thus have more memory available for hash indexes by using the `MAX_ROWS` option for `CREATE TABLE`. In general, setting `MAX_ROWS` to twice the number of rows that you expect to store in the table should be sufficient.

For similar reasons, you can also sometimes encounter problems with data node restarts on nodes that are heavily loaded with data. The `MinFreePct` parameter can help with this issue by reserving a portion (5% by default) of DataMemory and IndexMemory for use in restarts. This reserved memory is not available for storing NDB tables or data.

A.10.14. NDB Cluster uses TCP/IP. Does this mean that I can run it over the Internet, with one or more nodes in remote locations?

It is very unlikely that a cluster would perform reliably under such conditions, as NDB Cluster was designed and implemented with the assumption that it would be run under conditions guaranteeing dedicated high-speed connectivity such as that found in a LAN setting using 100 Mbps or gigabit Ethernet—preferably the latter. We neither test nor warrant its performance using anything slower than this.

Also, it is extremely important to keep in mind that communications between the nodes in an NDB Cluster are not secure; they are neither encrypted nor safeguarded by any other protective mechanism. The most secure configuration for a cluster is in a private network behind a firewall, with no direct access to any Cluster data or management nodes from outside. (For SQL nodes, you should take the same precautions as you would with any other instance of the MySQL server.) For more information, see Section 18.5.11, “NDB Cluster Security Issues”.

A.10.15. Do I have to learn a new programming or query language to use NDB Cluster?
No. Although some specialized commands are used to manage and configure the cluster itself, only standard (My)SQL statements are required for the following operations:

- Creating, altering, and dropping tables
- Inserting, updating, and deleting table data
- Creating, changing, and dropping primary and unique indexes

Some specialized configuration parameters and files are required to set up an NDB Cluster—see Section 18.3.3, “NDB Cluster Configuration Files”, for information about these.

A few simple commands are used in the NDB Cluster management client (ndb_mgm) for tasks such as starting and stopping cluster nodes. See Section 18.5.2, “Commands in the NDB Cluster Management Client”.

A.10.16 What programming languages and APIs are supported by NDB Cluster?

NDB Cluster supports the same programming APIs and languages as the standard MySQL Server, including ODBC, .Net, the MySQL C API, and numerous drivers for popular scripting languages such as PHP, Perl, and Python. NDB Cluster applications written using these APIs behave similarly to other MySQL applications; they transmit SQL statements to a MySQL Server (in the case of NDB Cluster, an SQL node), and receive responses containing rows of data. For more information about these APIs, see Chapter 23, Connectors and APIs.

NDB Cluster also supports application programming using the NDB API, which provides a low-level C++ interface to NDB Cluster data without needing to go through a MySQL Server. See The NDB API. In addition, many NDBCLUSTER management functions are exposed by the C-language MGM API; see The MGM API, for more information.

NDB Cluster also supports Java application programming using ClusterJ, which supports a domain object model of data using sessions and transactions. See Java and NDB Cluster, for more information.

In addition, NDB Cluster provides support for memcached, allowing developers to access data stored in NDB Cluster using the memcached interface; for more information, see ndbmemcache—Memcache API for NDB Cluster.

NDB Cluster 7.3 and later include adapters supporting NoSQL applications written against Node.js, with NDB Cluster as the data store. See MySQL NoSQL Connector for JavaScript, for more information.

A.10.17 Does NDB Cluster include any management tools?

NDB Cluster includes a command line client for performing basic management functions. See Section 18.4.5, “ndb_mgm — The NDB Cluster Management Client”, and Section 18.5.2, “Commands in the NDB Cluster Management Client”.

NDB Cluster is also supported by MySQL Cluster Manager, a separate product providing an advanced command line interface that can automate many NDB Cluster management tasks such as rolling restarts and configuration changes. For more information about MySQL Cluster Manager, see MySQL™ Cluster Manager 1.4.7 User Manual.

NDB Cluster 7.3 introduces a graphical, browser-based Auto-Installer for setting up and deploying NDB Cluster, as part of the NDB Cluster software distribution. For more information, see Section 18.2.1, “The NDB Cluster Auto-Installer”.
A.10.18 How do I find out what an error or warning message means when using NDB Cluster?

There are two ways in which this can be done:

- From within the `mysql` client, use `SHOW ERRORS` or `SHOW WARNINGS` immediately upon being notified of the error or warning condition.
- From a system shell prompt, use `perror --ndb error_code`.

A.10.19 Is NDB Cluster transaction-safe? What isolation levels are supported?

Yes. For tables created with the NDB storage engine, transactions are supported. Currently, NDB Cluster supports only the `READ COMMITTED` transaction isolation level.

A.10.20 What storage engines are supported by NDB Cluster?

Clustering with MySQL is supported only by the NDB storage engine. That is, in order for a table to be shared between nodes in an NDB Cluster, the table must be created using `ENGINE=NDB` (or the equivalent option `ENGINE=NDDBCUMTNER`).

It is possible to create tables using other storage engines (such as InnoDB or MyISAM) on a MySQL server being used with an NDB Cluster, but since these tables do not use NDB, they do not participate in clustering; each such table is strictly local to the individual MySQL server instance on which it is created.

A.10.21 In the event of a catastrophic failure— for example, the whole city loses power and my UPS fails—would I lose all my data?

All committed transactions are logged. Therefore, although it is possible that some data could be lost in the event of a catastrophe, this should be quite limited. Data loss can be further reduced by minimizing the number of operations per transaction. (It is not a good idea to perform large numbers of operations per transaction in any case.)

A.10.22 Is it possible to use FULLTEXT indexes with NDB Cluster?

FULLTEXT indexing is currently supported only by the InnoDB (MySQL 5.6.4 and later) and MyISAM storage engines. See Section 12.9, “Full-Text Search Functions”, for more information.

A.10.23 Can I run multiple nodes on a single computer?

It is possible but not always advisable. One of the chief reasons to run a cluster is to provide redundancy. To obtain the full benefits of this redundancy, each node should reside on a separate machine. If you place multiple nodes on a single machine and that machine fails, you lose all of those nodes. For this reason, if you do run multiple data nodes on a single machine, it is extremely important that they be set up in such a way that the failure of this machine does not cause the loss of all the data nodes in a given node group.

Given that NDB Cluster can be run on commodity hardware loaded with a low-cost (or even no-cost) operating system, the expense of an extra machine or two is well worth it to safeguard mission-critical data. It also worth noting that the requirements for a cluster host running a management node are minimal. This task can be accomplished with a 300 MHz Pentium or equivalent CPU and sufficient RAM for the operating system, plus a small amount of overhead for the `ndb_mgm` and `ndb_mgmd` processes.

It is acceptable to run multiple cluster data nodes on a single host that has multiple CPUs, cores, or both. The NDB Cluster distribution also provides a multithreaded version of the data node binary intended for use on such systems. For more information, see Section 18.4.3, “ndbmt.d — The NDB Cluster Data Node Daemon (Multi-Threaded)”. 
It is also possible in some cases to run data nodes and SQL nodes concurrently on the same machine; how well such an arrangement performs is dependent on a number of factors such as number of cores and CPUs as well as the amount of disk and memory available to the data node and SQL node processes, and you must take these factors into account when planning such a configuration.

A.10.24 Can I add data nodes to an NDB Cluster without restarting it?

It is possible to add new data nodes to a running NDB Cluster without taking the cluster offline. For more information, see Section 18.5.14, “Adding NDB Cluster Data Nodes Online”.

For other types of NDB Cluster nodes, a rolling restart is all that is required (see Section 18.5.5, “Performing a Rolling Restart of an NDB Cluster”).

A.10.25 Are there any limitations that I should be aware of when using NDB Cluster?

Limitations on NDB tables in MySQL NDB Cluster 7.3 and later include the following:

- Temporary tables are not supported; a CREATE TEMPORARY TABLE statement using ENGINE=NDB or ENGINE=NDBCLUSTER fails with an error.

- The only types of user-defined partitioning supported for NDBCLUSTER tables are KEY and LINEAR KEY. Trying to create an NDB table using any other partitioning type fails with an error.

- FULLTEXT indexes are not supported.

- Index prefixes are not supported. Only complete columns may be indexed.

- Spatial indexes are not supported (although spatial columns can be used). See Section 11.5, “Spatial Data Types”.

- Support for partial transactions and partial rollbacks is comparable to that of other transactional storage engines such as InnoDB that can roll back individual statements.

- The maximum number of attributes allowed per table is 512. Attribute names cannot be any longer than 31 characters. For each table, the maximum combined length of the table and database names is 122 characters.

- The maximum size for a table row is 14 kilobytes, not counting BLOB values.

  There is no set limit for the number of rows per NDB table. Limits on table size depend on a number of factors, in particular on the amount of RAM available to each data node.

For a complete listing of limitations in NDB Cluster, see Section 18.1.7, “Known Limitations of NDB Cluster”. See also Section 18.1.7.11, “Previous NDB Cluster Issues Resolved in NDB Cluster 7.3”.

A.10.26 Does NDB Cluster support foreign keys?

NDB Cluster 7.3 and later provide support for foreign key constraints, comparable to that found in the InnoDB storage engine; see Section 1.7.3.2, “FOREIGN KEY Constraints”, for more detailed information, as well as Section 13.1.17.6, “Using FOREIGN KEY Constraints”. Applications requiring foreign key support should use NDB Cluster 7.3, 7.4, 7.5, or later.

A.10.27 How do I import an existing MySQL database into an NDB Cluster?

You can import databases into NDB Cluster much as you would with any other version of MySQL. Other than the limitations mentioned elsewhere in this FAQ, the only other special requirement is
that any tables to be included in the cluster must use the NDB storage engine. This means that the tables must be created with ENGINE=NDB or ENGINE=NDBCLUSTER.

It is also possible to convert existing tables that use other storage engines to NDBCLUSTER using one or more ALTER TABLE statement. However, the definition of the table must be compatible with the NDBCLUSTER storage engine prior to making the conversion. In MySQL 5.6, an additional workaround is also required; see Section 18.1.7, “Known Limitations of NDB Cluster”, for details.

A.10.28 How do NDB Cluster nodes communicate with one another?

Cluster nodes can communicate through any of three different transport mechanisms: TCP/IP, SHM (shared memory), and SCI (Scalable Coherent Interface). Where available, SHM is used by default between nodes residing on the same cluster host; however, this is considered experimental. SCI is a high-speed (1 gigabit per second and higher), high-availability protocol used in building scalable multi-processor systems; it requires special hardware and drivers. See Section 18.3.4, “Using High-Speed Interconnects with NDB Cluster”, for more about using SCI as a transport mechanism for NDB Cluster.

A.10.29 What is an arbitrator?

If one or more data nodes in a cluster fail, it is possible that not all cluster data nodes will be able to “see” one another. In fact, it is possible that two sets of data nodes might become isolated from one another in a network partitioning, also known as a “split-brain” scenario. This type of situation is undesirable because each set of data nodes tries to behave as though it is the entire cluster. An arbitrator is required to decide between the competing sets of data nodes.

When all data nodes in at least one node group are alive, network partitioning is not an issue, because no single subset of the cluster can form a functional cluster on its own. The real problem arises when no single node group has all its nodes alive, in which case network partitioning (the “split-brain” scenario) becomes possible. Then an arbitrator is required. All cluster nodes recognize the same node as the arbitrator, which is normally the management server; however, it is possible to configure any of the MySQL Servers in the cluster to act as the arbitrator instead. The arbitrator accepts the first set of cluster nodes to contact it, and tells the remaining set to shut down. Arbitrator selection is controlled by the ArbitrationRank configuration parameter for MySQL Server and management server nodes. You can also use the ArbitrationRank configuration parameter to control the arbitrator selection process. For more information about these parameters, see Section 18.3.3.5, “Defining an NDB Cluster Management Server”.

The role of arbitrator does not in and of itself impose any heavy demands upon the host so designated, and thus the arbitrator host does not need to be particularly fast or to have extra memory especially for this purpose.

A.10.30 What data types are supported by NDB Cluster?

NDB Cluster supports all of the usual MySQL data types, including those associated with MySQL’s spatial extensions; however, the NDB storage engine does not support spatial indexes. (Spatial indexes are supported only by MyISAM; see Section 11.5, “Spatial Data Types”, for more information.) In addition, there are some differences with regard to indexes when used with NDB tables.

Note

NDB Cluster Disk Data tables (that is, tables created with TABLESPACE ... STORAGE DISK ENGINE=NDB or TABLESPACE ... STORAGE DISK ENGINE=NDBCLUSTER) have only fixed-width rows. This means that (for example) each Disk Data table record containing a VARCHAR(255) column
requires space for 255 characters (as required for the character set and
collation being used for the table), regardless of the actual number of
characters stored therein.

See Section 18.1.7, “Known Limitations of NDB Cluster”, for more information about these issues.

A.10.31. How do I start and stop NDB Cluster?

It is necessary to start each node in the cluster separately, in the following order:

1. Start the management node, using the \texttt{ndb\_mgmd} command.
   
   You must include the \texttt{-f} or \texttt{--config-file} option to tell the management node where its
   configuration file can be found.

2. Start each data node with the \texttt{ndbd} command.
   
   Each data node must be started with the \texttt{-c} or \texttt{--ndb\-connectstring} option so that the data
   node knows how to connect to the management server.

3. Start each MySQL Server (SQL node) using your preferred startup script, such as \texttt{mysqld\_safe}.
   
   Each MySQL Server must be started with the \texttt{--ndb\_cluster} and \texttt{--ndb\-connectstring}
   options. These options cause \texttt{mysqld} to enable \texttt{NDB\_CLUSTER} storage engine support and how to
   connect to the management server.

Each of these commands must be run from a system shell on the machine housing the affected
node. (You do not have to be physically present at the machine—a remote login shell can be used
for this purpose.) You can verify that the cluster is running by starting the \texttt{NDB} management client
\texttt{ndb\_mgm} on the machine housing the management node and issuing the \texttt{SHOW} or \texttt{ALL STATUS}
command.

To shut down a running cluster, issue the command \texttt{SHUTDOWN} in the management client.
Alternatively, you may enter the following command in a system shell:

\begin{verbatim}
shell> ndb\_mgm -e "SHUTDOWN"
\end{verbatim}

(The quotation marks in this example are optional, since there are no spaces in the command
string following the \texttt{-e} option; in addition, the \texttt{SHUTDOWN} command, like other management client
commands, is not case-sensitive.)

Either of these commands causes the \texttt{ndb\_mgm}, \texttt{ndb\_mgm}, and any \texttt{ndbd} processes to terminate
gracefully. MySQL servers running as SQL nodes can be stopped using \texttt{mysql\_admin shutdown}.

For more information, see Section 18.5.2, “Commands in the NDB Cluster Management Client”, and
Section 18.2.7, “Safe Shutdown and Restart of NDB Cluster”.

A.10.32. What happens to NDB Cluster data when the NDB Cluster is shut down?

The data that was held in memory by the cluster’s data nodes is written to disk, and is reloaded into
memory the next time that the cluster is started.

A.10.33. Is it a good idea to have more than one management node for an NDB Cluster?
It can be helpful as a fail-safe. Only one management node controls the cluster at any given time, but it is possible to configure one management node as primary, and one or more additional management nodes to take over in the event that the primary management node fails.

See Section 18.3.3, “NDB Cluster Configuration Files”, for information on how to configure NDB Cluster management nodes.

A.10.34. Can I mix different kinds of hardware and operating systems in one NDB Cluster?

Yes, as long as all machines and operating systems have the same “endianness” (all big-endian or all little-endian).

It is also possible to use software from different NDB Cluster releases on different nodes. However, we support this only as part of a rolling upgrade procedure (see Section 18.5.5, “Performing a Rolling Restart of an NDB Cluster”).

A.10.35. Can I run two data nodes on a single host? Two SQL nodes?

Yes, it is possible to do this. In the case of multiple data nodes, it is advisable (but not required) for each node to use a different data directory. If you want to run multiple SQL nodes on one machine, each instance of `mysqld` must use a different TCP/IP port.

Running data nodes and SQL nodes together on the same host is possible, but you should be aware that the `ndbd` (or `ndbmtd`) and `mysqld` processes may compete for memory.

A.10.36. Can I use host names with NDB Cluster?

Yes, it is possible to use DNS and DHCP for cluster hosts. However, if your application requires “five nines” availability, you should use fixed (numeric) IP addresses, since making communication between Cluster hosts dependent on services such as DNS and DHCP introduces additional potential points of failure.

A.10.37. Does NDB Cluster support IPv6?

IPv6 is supported for connections between SQL nodes (MySQL servers), but connections between all other types of NDB Cluster nodes must use IPv4.

In practical terms, this means that you can use IPv6 for replication between NDB Clusters, but connections between nodes in the same NDB Cluster must use IPv4. For more information, see Section 18.6.3, “Known Issues in NDB Cluster Replication”.

A.10.38. How do I handle MySQL users in an NDB Cluster having multiple MySQL servers?

MySQL user accounts and privileges are normally not automatically propagated between different MySQL servers accessing the same NDB Cluster. MySQL NDB Cluster provides support for distributed privileges, which you can enable by following a procedure provided in the documentation; see Section 18.5.15, “Distributed Privileges Using Shared Grant Tables”, for more information.

A.10.39. How do I continue to send queries in the event that one of the SQL nodes fails?

MySQL NDB Cluster does not provide any sort of automatic failover between SQL nodes. Your application must be prepared to handle the loss of SQL nodes and to fail over between them.

A.10.40. How do I back up and restore an NDB Cluster?

You can use the NDB Cluster native backup and restore functionality in the NDB management client and the `ndb_restore` program. See Section 18.5.3, “Online Backup of NDB Cluster”, and Section 18.4.22, “`ndb_restore` — Restore an NDB Cluster Backup”.
You can also use the traditional functionality provided for this purpose in `mysqldump` and the MySQL server. See Section 4.5.4, "mysqldump — A Database Backup Program", for more information.

A.10.4 What is an “angel process”?

This process monitors and, if necessary, attempts to restart the data node process. If you check the list of active processes on your system after starting `ndbd`, you can see that there are actually 2 processes running by that name, as shown here (we omit the output from `ndb_mgmd` and `ndbd` for brevity):

```bash
shell> ./ndb_mgmd
shell> ps aux | grep ndb
me  23002  0.0  0.0  122948  3104 ?        Ssl  14:14   0:00 ./ndb_mgmd
me  23025  0.0  0.0   5284   820 pts/2    S+  14:14   0:00 grep ndb

shell> ./ndbd -c 127.0.0.1 --initial
shell> ps aux | grep ndb
me  23002  0.0  0.0  123080  3356 ?        Ssl  14:14   0:00 ./ndb_mgmd
me  23096  0.0  0.0   35876   2036 ?        Ss  14:14   0:00 ./ndbd -c 127.0.0.1 --initial
me  23097  1.0  2.4  524116 91096 ?        Sl  14:14   0:00 ./ndbd -c 127.0.0.1 --initial
me  23168  0.0  0.0   5284   812 pts/2    R+  14:15   0:00 grep ndb
```

The `ndbd` process showing 0 memory and CPU usage is the angel process. It actually does use a very small amount of each, of course. It simply checks to see if the main `ndbd` process (the primary data node process that actually handles the data) is running. If permitted to do so (for example, if the `StopOnError` configuration parameter is set to false—see Section 18.3.2.1, "NDB Cluster Data Node Configuration Parameters"), the angel process tries to restart the primary data node process.

A.11 MySQL 5.6 FAQ: MySQL Chinese, Japanese, and Korean Character Sets

This set of Frequently Asked Questions derives from the experience of MySQL's Support and Development groups in handling many inquiries about CJK (Chinese-Japanese-Korean) issues.

A.11.1 What CJK character sets are available in MySQL? .......................................................... 3681
A.11.2 I have inserted CJK characters into my table. Why does `SELECT` display them as “?” characters? .......................................................... 3682
A.11.3 What problems should I be aware of when working with the Big5 Chinese character set? .... 3684
A.11.4 Why do Japanese character set conversions fail? .......................................................... 3684
A.11.5 What should I do if I want to convert SJIS 81CA to `cp932`? ........................................ 3685
A.11.6 How does MySQL represent the Yen (¥) sign? .............................................................. 3685
A.11.7 Of what issues should I be aware when working with Korean character sets in MySQL? .... 3685
A.11.8 Why do I get `Incorrect string value` error messages? ................................................ 3685
A.11.9 Why does my GUI front end or browser display CJK characters incorrectly in my application using Access, PHP, or another API? ......................................................... 3686
A.11.10 I've upgraded to MySQL 5.6. How can I revert to behavior like that in MySQL 4.0 with regard to character sets? .......................................................... 3687
A.11.11 Why do some `LIKE` and `FULLTEXT` searches with CJK characters fail? .................... 3688
A.11.12 How do I know whether character `x` is available in all character sets? ....................... 3689
A.11.13 Why do CJK strings sort incorrectly in Unicode? (I) ................................................ 3690
A.11.14 Why do CJK strings sort incorrectly in Unicode? (II) .............................................. 3691
A.11.15 Why are my supplementary characters rejected by MySQL? ........................................ 3692
A.11.16 Should “CJK” be “CJKV”? ................................................................. 3692
A.11.17 Does MySQL permit CJK characters to be used in database and table names? ........ 3693
A.11.18 Where can I find translations of the MySQL Manual into Chinese, Japanese, and Korean? ... 3693
A.11.19 Where can I get help with CJK and related issues in MySQL? .................. 3693

A.11.1 What CJK character sets are available in MySQL?

The list of CJK character sets may vary depending on your MySQL version. For example, the gb18030 character set is not supported prior to MySQL 5.7.4. However, since the name of the applicable language appears in the DESCRIPTION column for every entry in the INFORMATION_SCHEMA.CHARACTER_SETS table, you can obtain a current list of all the non-Unicode CJK character sets using this query:

```sql
mysql> SELECT CHARACTER_SET_NAME, DESCRIPTION
FROM INFORMATION_SCHEMA.CHARACTER_SETS
WHERE DESCRIPTION LIKE '%Chin%'
OR DESCRIPTION LIKE '%Japanese%'
OR DESCRIPTION LIKE '%Korean%'
ORDER BY CHARACTER_SET_NAME;
```

+-------------------+---------------------------------+
| CHARACTER_SET_NAME | DESCRIPTION                     |
|--------------------+---------------------------------|
| big5               | Big5 Traditional Chinese        |
| cp932              | SJIS for Windows Japanese       |
| eucjpms            | UJIS for Windows Japanese       |
| euckr              | EUC-KR Korean                   |
| gb18030            | China National Standard GB18030 |
| gb2312             | GB2312 Simplified Chinese       |
| gbk                | GBK Simplified Chinese          |
| sjis               | Shift-JIS Japanese              |
| ujis               | EUC-JP Japanese                 |

(For more information, see Section 21.2, “The INFORMATION_SCHEMA CHARACTER_SETS Table”.)

MySQL supports three variants of the GB (Guojia Biaozhun, or National Standard, or Simplified Chinese) character sets which are official in the People’s Republic of China: gb2312, gbk, and (as of MySQL 5.7.4) gb18030.

Sometimes people try to insert gbk characters into gb2312, and it works most of the time because gbk is a superset of gb2312. But eventually they try to insert a rarer Chinese character and it does not work. (For an example, see Bug #16072).

Here, we try to clarify exactly what characters are legitimate in gb2312 or gbk, with reference to the official documents. Please check these references before reporting gb2312 or gbk bugs:

- The MySQL gbk character set is in reality “Microsoft code page 936”. This differs from the official gbk for characters A1A4 (middle dot), A1AA (em dash), A6E0–A6F5, and A8BB–A8C0.

- For a listing of gbk/Unicode mappings, see http://www.unicode.org/Public/MAPPINGS/VENDORS/MICSFT/WINDOWS/CP936.TXT.

It is also possible to store CJK characters in Unicode character sets, although the available collations may not sort characters quite as you expect:

- The utf8 and ucs2 character sets support the characters from Unicode Basic Multilingual Plane (BMP). These characters have code point values between U+0000 and U+FFFF.
MySQL 5.6 FAQ: MySQL Chinese, Japanese, and Korean Character Sets

- The **utf8mb4**, **utf16**, **utf16le**, and **utf32** character sets support BMP characters, as well as supplementary characters that lie outside the BMP. Supplementary characters have code point values between $U+10000$ and $U+10FFFF$.

The collation used for a Unicode character set determines the ability to sort (that is, distinguish) characters in the set:

- Collations based on Unicode Collation Algorithm (UCA) 4.0.0 distinguish only BMP characters.
- Collations based on UCA 5.2.0 or 9.0.0 distinguish BMP and supplementary characters.
- Non-UCA collations may not distinguish all Unicode characters. For example, the **utf8mb4** default collation is **utf8mb4_general_ci**, which distinguishes only BMP characters.

Moreover, distinguishing characters is not the same as ordering them per the conventions of a given CJK language. Currently, MySQL has only one CJK-specific UCA collation, **gb18030_unicode_520_ci** (which requires use of the non-Unicode **gb18030** character set).

For information about Unicode collations and their differentiating properties, including collation properties for supplementary characters, see Section 10.10.1, “Unicode Character Sets”.

**A.11.2** I have inserted CJK characters into my table. Why does **SELECT** display them as “?” characters?

This problem is usually due to a setting in MySQL that does not match the settings for the application program or the operating system. Here are some common steps for correcting these types of issues:

- **Be certain of what MySQL version you are using.**
  
  Use the statement **SELECT VERSION();** to determine this.

- **Make sure that the database is actually using the desired character set.**

  People often think that the client character set is always the same as either the server character set or the character set used for display purposes. However, both of these are false assumptions. You can make sure by checking the result of **SHOW CREATE TABLE tablename** or, better yet, by using this statement:

  ```sql
  SELECT character_set_name, collation_name
  FROM information_schema.columns
  WHERE table_schema = your_database_name
  AND table_name = your_table_name
  AND column_name = your_column_name;
  ```

- **Determine the hexadecimal value of the character or characters that are not being displayed correctly.**

  You can obtain this information for a column **column_name** in the table **table_name** using the following query:

  ```sql
  SELECT HEX(column_name)
  FROM table_name;
  ```

  $3F$ is the encoding for the “?” character; this means that “?” is the character actually stored in the column. This most often happens because of a problem converting a particular character from your client character set to the target character set.
MySQL 5.6 FAQ: MySQL Chinese, Japanese, and Korean Character Sets

- **Make sure that a round trip is possible. When you select literal (or _introducer hexadecimal-value), do you obtain literal as a result?**

  For example, the Japanese Katakana character Pe (ぺ) exists in all CJK character sets, and has the code point value (hexadecimal coding) 0x30da. To test a round trip for this character, use this query:

  ```sql
  SELECT 'ぺ' AS 'ぺ';         /* or SELECT _ucs2 0x30da; */
  ```

  If the result is not also ぺ, the round trip failed.

  For bug reports regarding such failures, we might ask you to follow up with `SELECT HEX('ぺ');`. Then we can determine whether the client encoding is correct.

- **Make sure that the problem is not with the browser or other application, rather than with MySQL.**

  Use the `mysql` client program to accomplish this task. If `mysql` displays characters correctly but your application does not, your problem is probably due to system settings.

  To determine your settings, use the `SHOW VARIABLES` statement, whose output should resemble what is shown here:

  ```
  mysql> SHOW VARIABLES LIKE 'char%';
  +--------------------------+----------------------------------------+
  | Variable_name            | Value                                  |
  +--------------------------+----------------------------------------+
  | character_set_client     | utf8                                   |
  | character_set_connection | utf8                                   |
  | character_set_database   | latin1                                 |
  | character_set_filesystem | binary                                 |
  | character_set_results    | utf8                                   |
  | character_set_server     | latin1                                 |
  | character_set_system     | utf8                                   |
  | character_sets_dir       | /usr/local/mysql/share/mysql/charsets/  |
  +--------------------------+----------------------------------------+
  ```

  These are typical character-set settings for an international-oriented client (notice the use of `utf8` Unicode) connected to a server in the West (`latin1` is a West Europe character set).

  Although Unicode (usually the `utf8` variant on Unix, and the `ucs2` variant on Windows) is preferable to Latin, it is often not what your operating system utilities support best. Many Windows users find that a Microsoft character set, such as `cp932` for Japanese Windows, is suitable.

  If you cannot control the server settings, and you have no idea what setting your underlying computer uses, try changing to a common character set for the country that you're in (`euckr` = Korea; `gb18030, gb2312` or `gbk` = People's Republic of China; `big5` = Taiwan; `sjis, ujis, cp932, or eucjpms` = Japan; `ucs2` or `utf8` = anywhere). Usually it is necessary to change only the client and connection and results settings. The `SET NAMES` statement changes all three at once. For example:

  ```
  SET NAMES 'big5';
  ```

  Once the setting is correct, you can make it permanent by editing `my.cnf` or `my.ini`. For example you might add lines looking like these:
A.11.3 What problems should I be aware of when working with the Big5 Chinese character set?

MySQL supports the Big5 character set which is common in Hong Kong and Taiwan (Republic of China). The MySQL big5 character set is in reality Microsoft code page 950, which is very similar to the original big5 character set.

A feature request for adding HKSCS extensions has been filed. People who need this extension may find the suggested patch for Bug #13577 to be of interest.

A.11.4 Why do Japanese character set conversions fail?

MySQL supports the sjis, ujis, cp932, and eucjpms character sets, as well as Unicode. A common need is to convert between character sets. For example, there might be a Unix server (typically with sjis or ujis) and a Windows client (typically with cp932).

In the following conversion table, the ucs2 column represents the source, and the sjis, cp932, ujis, and eucjpms columns represent the destinations; that is, the last 4 columns provide the hexadecimal result when we use CONVERT(ucs2) or we assign a ucs2 column containing the value to an sjis, cp932, ujis, or eucjpms column.

MySQL 5.6 FAQ: MySQL Chinese, Japanese, and Korean Character Sets

<table>
<thead>
<tr>
<th>Character Name</th>
<th>ucs2</th>
<th>sjis</th>
<th>cp932</th>
<th>ujis</th>
<th>eucjpms</th>
</tr>
</thead>
<tbody>
<tr>
<td>FULLWIDTH POUND SIGN</td>
<td>FFE1</td>
<td>3F</td>
<td>8192</td>
<td>3F</td>
<td>A1F2</td>
</tr>
<tr>
<td>NOT SIGN</td>
<td>00AC</td>
<td>81CA</td>
<td>3F</td>
<td>A2CC</td>
<td>3F</td>
</tr>
<tr>
<td>FULLWIDTH NOT SIGN</td>
<td>FFE2</td>
<td>3F</td>
<td>81CA</td>
<td>3F</td>
<td>A2CC</td>
</tr>
</tbody>
</table>

Now consider the following portion of the table.

<table>
<thead>
<tr>
<th></th>
<th>ucs2</th>
<th>sjis</th>
<th>cp932</th>
</tr>
</thead>
<tbody>
<tr>
<td>NOT SIGN</td>
<td>00AC</td>
<td>81CA</td>
<td>3F</td>
</tr>
<tr>
<td>FULLWIDTH NOT SIGN</td>
<td>FFE2</td>
<td>3F</td>
<td>81CA</td>
</tr>
</tbody>
</table>

This means that MySQL converts the NOT SIGN (Unicode U+00AC) to sjis code point 0x81CA and to cp932 code point 3F. (3F is the question mark (“?”). This is what is always used when the conversion cannot be performed.)

A.11.5 What should I do if I want to convert SJIS 81CA to cp932?

Our answer is: “?”. There are disadvantages to this, and many people would prefer a “loose” conversion, so that 81CA (NOT SIGN) in sjis becomes 81CA (FULLWIDTH NOT SIGN) in cp932.

A.11.6 How does MySQL represent the Yen (¥) sign?

A problem arises because some versions of Japanese character sets (both sjis and euc) treat 5C as a reverse solidus (\, also known as a backslash), whereas others treat it as a yen sign (¥).

MySQL follows only one version of the JIS (Japanese Industrial Standards) standard description. In MySQL, 5C is always the reverse solidus (\).

A.11.7 Of what issues should I be aware when working with Korean character sets in MySQL?

In theory, while there have been several versions of the euckr (Extended Unix Code Korea) character set, only one problem has been noted. We use the “ASCII” variant of EUC-KR, in which the code point 0x5C is REVERSE SOLIDUS, that is \, instead of the “KS-Roman” variant of EUC-KR, in which the code point 0x5C is WON SIGN (₩). This means that you cannot convert Unicode U+20A9 to euckr:

```sql
mysql> SELECT
CONVERT('₩' USING euckr) AS euckr,
HEX(CONVERT('₩' USING euckr)) AS hexeuckr;
+----------+----------+
| euckr    | hexeuckr |
| ?        | 3F       |
+----------+----------+
```

A.11.8 Why do I get Incorrect string value error messages?

To see the problem, create a table with one Unicode (ucs2) column and one Chinese (gb2312) column.

```sql
mysql> CREATE TABLE ch
(ucs2 CHAR(3) CHARACTER SET ucs2,
 gb2312 CHAR(3) CHARACTER SET gb2312);
```
In nonstrict SQL mode, try to place the rare character 浴 in both columns.

```sql
mysql> SET sql_mode = '';
mysql> INSERT INTO ch VALUES ('A海B','A海B');
Query OK, 1 row affected, 1 warning (0.00 sec)
```

The `INSERT` produces a warning. Use the following statement to see what it is:

```sql
mysql> SHOW WARNINGS\G
```

```plaintext
*************************** 1. row ***************************
Level: Warning
Code: 1366
Message: Incorrect string value: '\xE6\xB1\x8CB' for column 'gb2312' at row 1
```

So it is a warning about the `gb2312` column only.

```sql
mysql> SELECT ucs2,HEX(ucs2),gb2312,HEX(gb2312) FROM ch;
```

| ucs2  | HEX(ucs2)    | gb2312 | HEX(gb2312) |
|-------+--------------+--------+-------------|
| A海B | 00416C4C0042 | A海B   | 413F42      |

Several things need explanation here:

1. The 浴 character is not in the `gb2312` character set, as described earlier.
2. If you are using an old version of MySQL, you may see a different message.
3. A warning occurs rather than an error because MySQL is not set to use strict SQL mode. In nonstrict mode, MySQL tries to do what it can, to get the best fit, rather than give up. With strict SQL mode, the `Incorrect string value` message occurs as an error rather than a warning, and the `INSERT` fails.

**A.11.9 Why does my GUI front end or browser display CJK characters incorrectly in my application using Access, PHP, or another API?**

Obtain a direct connection to the server using the `mysql` client, and try the same query there. If `mysql` responds correctly, the trouble may be that your application interface requires initialization. Use `mysql` to tell you what character set or sets it uses with the statement `SHOW VARIABLES LIKE 'char%';`. If you are using Access, you are most likely connecting with Connector/ODBC. In this case, you should check Configuring Connector/ODBC. If, for example, you use `big5`, you would enter `SET NAMES 'big5';`. (In this case, no ; character is required.) If you are using ASP, you might need to add `SET NAMES` in the code. Here is an example that has worked in the past:

```html
<%
Session.CodePage=0
Dim strConnection
Dim Conn
strConnection="driver={MySQL ODBC 3.51 Driver};server=server;uid=username;" & 
"pwd=;database=database;stmt=SET NAMES 'big5';"
Set Conn = Server.CreateObject("ADODB.Connection")
Conn.Open strConnection
%>
```
In much the same way, if you are using any character set other than **latin1** with Connector/NET, you must specify the character set in the connection string. See [Connecting to MySQL Using Connector/NET](#), for more information.

If you are using PHP, try this:

```php
<?php
    $link = new mysqli($host, $usr, $pwd, $db);
    if( mysqli_connect_errno() )
    {
        printf("Connect failed: %s\n", mysqli_connect_error());
        exit();
    }
    $link->query("SET NAMES 'utf8'");
?>
```

In this case, we used **SET NAMES** to change **character_set_client**, **character_set_connection**, and **character_set_results**.

Another issue often encountered in PHP applications has to do with assumptions made by the browser. Sometimes adding or changing a `<meta>` tag suffices to correct the problem: for example, to insure that the user agent interprets page content as **UTF-8**, include `<meta http-equiv="Content-Type" content="text/html; charset=utf-8">` in the `<head>` section of the HTML page.

If you are using Connector/J, see Using Character Sets and Unicode.

### A.11.10 I've upgraded to MySQL 5.6. How can I revert to behavior like that in MySQL 4.0 with regard to character sets?

In MySQL Version 4.0, there was a single “global” character set for both server and client, and the decision as to which character to use was made by the server administrator. This changed starting with MySQL Version 4.1. What happens now is a “handshake”, as described in Section 10.4, “Connection Character Sets and Collations”:

When a client connects, it sends to the server the name of the character set that it wants to use. The server uses the name to set the **character_set_client**, **character_set_results**, and **character_set_connection** system variables. In effect, the server performs a **SET NAMES** operation using the character set name.

The effect of this is that you cannot control the client character set by starting `mysqld` with `--character-set-server=utf8`. However, some Asian customers prefer the MySQL 4.0 behavior. To make it possible to retain this behavior, we added a `mysqld` switch, `--character-set-client-handshake`, which can be turned off with `--skip-character-set-client-handshake`. If you start `mysqld` with `--skip-character-set-client-handshake`, then, when a client connects, it sends to the server the name of the character set that it wants to use. However, *the server ignores this request from the client*.

By way of example, suppose that your favorite server character set is **latin1**. Suppose further that the client uses **utf8** because this is what the client's operating system supports. Start the server with **latin1** as its default character set:

```bash
mysqld --character-set-server=latin1
```
And then start the client with the default character set $\texttt{utf8}$:

```
mysql --default-character-set=utf8
```

The resulting settings can be seen by viewing the output of `SHOW VARIABLES`:

```
mysql> SHOW VARIABLES LIKE 'char%';
+--------------------------+----------------------------------------+
| Variable_name            | Value                                  |
+--------------------------+----------------------------------------+
| character_set_client     | utf8                                   |
| character_set_connection | utf8                                   |
| character_set_database   | latin1                                 |
| character_set_filesystem | binary                                 |
| character_set_results    | utf8                                   |
| character_set_server     | latin1                                 |
| character_set_system     | utf8                                   |
| character_sets_dir       | /usr/local/mysql/share/mysql/charsets/  |
+--------------------------+----------------------------------------+
```

Now stop the client, and stop the server using `mysqladmin`. Then start the server again, but this time tell it to skip the handshake like so:

```
mysqld --character-set-server=utf8 --skip-character-set-client-handshake
```

Start the client with $\texttt{utf8}$ once again as the default character set, then display the resulting settings:

```
mysql> SHOW VARIABLES LIKE 'char%';
+--------------------------+----------------------------------------+
| Variable_name            | Value                                  |
+--------------------------+----------------------------------------+
| character_set_client     | latin1                                 |
| character_set_connection | latin1                                 |
| character_set_database   | latin1                                 |
| character_set_filesystem | binary                                 |
| character_set_results    | latin1                                 |
| character_set_server     | latin1                                 |
| character_set_system     | utf8                                   |
| character_sets_dir       | /usr/local/mysql/share/mysql/charsets/  |
+--------------------------+----------------------------------------+
```

As you can see by comparing the differing results from `SHOW VARIABLES`, the server ignores the client's initial settings if the `--skip-character-set-client-handshake` option is used.

### A.11.1 Why do some LIKE and FULLTEXT searches with CJK characters fail?

For `LIKE` searches, there is a very simple problem with binary string column types such as `BINARY` and `BLOB`: we must know where characters end. With multibyte character sets, different characters might have different octet lengths. For example, in $\texttt{utf8}$, `A` requires one byte but `忾` requires three bytes, as shown here:

```
+-------------------------+---------------------------+-------------------------+---------------------------+
| OCTET_LENGTH(_utf8 'A') | OCTET_LENGTH(_utf8 '忾') | OCTET_LENGTH(_utf8 ' tuyến') | OCTET_LENGTH(_utf8 'tolower') |
|-------------------------|---------------------------+-------------------------+---------------------------+
| 1                       | 3                         | 8                       | 6                         |
```
If we do not know where the first character in a string ends, we do not know where the second character begins, in which case even very simple searches such as `LIKE '_A%'` fail. The solution is to use a nonbinary string column type defined to have the proper CJK character set. For example: `mycol TEXT CHARACTER SET sjis`. Alternatively, convert to a CJK character set before comparing.

This is one reason why MySQL cannot permit encodings of nonexistent characters. If it is not strict about rejecting bad input, it has no way of knowing where characters end.

For `FULLTEXT` searches, we must know where words begin and end. With Western languages, this is rarely a problem because most (if not all) of these use an easy-to-identify word boundary: the space character. However, this is not usually the case with Asian writing. We could use arbitrary halfway measures, like assuming that all Han characters represent words, or (for Japanese) depending on changes from Katakana to Hiragana due to grammatical endings. However, the only sure solution requires a comprehensive word list, which means that we would have to include a dictionary in the server for each Asian language supported. This is simply not feasible.

**A.11.12.** How do I know whether character X is available in all character sets?

The majority of simplified Chinese and basic nonhalfwidth Japanese Kana characters appear in all CJK character sets. The following stored procedure accepts a `UCS-2` Unicode character, converts it to other character sets, and displays the results in hexadecimal.

```sql
DELIMITER //

CREATE PROCEDURE p_convert(ucs2_char CHAR(1) CHARACTER SET ucs2)
BEGIN
    CREATE TABLE tj
    (ucs2 CHAR(1) character set ucs2,
    utf8 CHAR(1) character set utf8,
    big5 CHAR(1) character set big5,
    cp932 CHAR(1) character set cp932,
    eucjpms CHAR(1) character set eucjpms,
    euckr CHAR(1) character set euckr,
    gb2312 CHAR(1) character set gb2312,
    gbk CHAR(1) character set gbk,
    sjis CHAR(1) character set sjis,
    ujis CHAR(1) character set ujis);

    INSERT INTO tj (ucs2) VALUES (ucs2_char);
    UPDATE tj SET utf8=ucs2,
    big5=ucs2,
    cp932=ucs2,
    eucjpms=ucs2,
    euckr=ucs2,
    gb2312=ucs2,
    gbk=ucs2,
    sjis=ucs2,
    ujis=ucs2;

    /* If there are conversion problems, UPDATE produces warnings. */

    SELECT hex(ucs2) AS ucs2,
    hex(utf8) AS utf8,
    hex(big5) AS big5,
    hex(cp932) AS cp932,
    hex(eucjpms) AS eucjpms,
    hex(euckr) AS euckr,
    hex(gb2312) AS gb2312;

END;
DELIMITER //
```
The input can be any single ucs2 character, or it can be the code value (hexadecimal representation) of that character. For example, from Unicode's list of ucs2 encodings and names (http://www.unicode.org/Public/UNIDATA/UnicodeData.txt), we know that the Katakana character Pe appears in all CJK character sets, and that its code value is X'30DA'. If we use this value as the argument to p_convert(), the result is as shown here:

```sql
mysql> CALL p_convert(X'30DA');
+------+--------+------+-------+---------+-------+--------+------+------+------+
| ucs2 | utf8   | big5 | cp932 | eucjpms | euckr | gb2312 | gbk  | sjis | ujis |
|------|--------+------+-------+---------+-------+--------+------+------+------+
| 30DA | E3839A | C772 | 8379  | A5DA    | ABDA  | A5DA   | A5DA | 8379 | A5DA |
+------+--------+------+-------+---------+-------+--------+------+------+------+
```

Since none of the column values is 3F (that is, the question mark character, ?), we know that every conversion worked.

Note

The CJK sorting problems described here can occur for MySQL versions prior to MySQL 8.0. As of MySQL 8.0, they can be solved by using the utf8mb4 character set and the utf8mb4_ja_0900_as_cs collation.

Sometimes people observe that the result of a utf8_unicode_ci or ucs2_unicode_ci search, or of an ORDER BY sort is not what they think a native would expect. Although we never rule out the possibility that there is a bug, we have found in the past that many people do not correctly read the standard table of weights for the Unicode Collation Algorithm. MySQL uses the tables found under http://www.unicode.org/Public/UCA/:

- UCA 4.0.0 table: http://www.unicode.org/Public/UCA/4.0.0/allkeys-4.0.0.txt
  - This includes xxx_unicode_ci collations with no version number in the collation name.
- UCA 5.2.0 table: http://www.unicode.org/Public/UCA/5.2.0/allkeys.txt
  - This includes collations with _520_ in the collation name.
- UCA 9.0.0 table: http://www.unicode.org/Public/UCA/9.0.0/allkeys.txt
  - This includes collations with _0900_ in the collation name.

To handle newer UCA versions, we create new collations. We are very wary about changing ordering of existing collations because that affects indexes, which can bring about situations such as that reported in Bug #16526, illustrated as follows:

```sql
mysql> CREATE TABLE tj (s1 CHAR(1) CHARACTER SET utf8 COLLATE utf8_unicode_ci);
```
The character in the first result row is not the one that we searched for. Why did MySQL retrieve it? First we look for the Unicode code point value, which is possible by reading the hexadecimal number for the ucs2 version of the characters:

```
mysql> SELECT s1, HEX(CONVERT(s1 USING ucs2)) FROM tj;
+------+-----------------------------+
<table>
<thead>
<tr>
<th>s1</th>
<th>HEX(CONVERT(s1 USING ucs2))</th>
</tr>
</thead>
<tbody>
<tr>
<td>が</td>
<td>304C</td>
</tr>
<tr>
<td>か</td>
<td>304B</td>
</tr>
</tbody>
</table>
+------+-----------------------------+
```

Now we search for 304B and 304C in the 4.0.0 allkeys table, and find these lines:

```
304B ; [.1E57.0020.000E.304B] # HIRAGANA LETTER KA
304C ; [.1E57.0020.000E.304B][.0000.0140.0002.3099] # HIRAGANA LETTER GA; QQCM
```

The official Unicode names (following the “#” mark) tell us the Japanese syllabary (Hiragana), the informal classification (letter, digit, or punctuation mark), and the Western identifier (KA or GA, which happen to be voiced and unvoiced components of the same letter pair). More importantly, the primary weight (the first hexadecimal number inside the square brackets) is 1E57 on both lines. For comparisons in both searching and sorting, MySQL pays attention to the primary weight only, ignoring all the other numbers. This means that we are sorting が and か correctly according to the Unicode specification. If we wanted to distinguish them, we'd have to use a non-UCA (Unicode Collation Algorithm) collation (utf8_bin or utf8_general_ci), or to compare the HEX() values, or use ORDER BY CONVERT(s1 USING sjis). Being correct “according to Unicode” is not enough, of course: the person who submitted the bug was equally correct. To solve this, we need another collation for Japanese according to the JIS X 4061 standard, in which voiced/unvoiced letter pairs like KA/GA are distinguishable for ordering purposes.

**Note**

The CJK sorting problems described here can occur for MySQL versions prior to MySQL 8.0. As of MySQL 8.0, they can be solved by using the utf8mb4 character set and the utf8mb4_ja_0900_as_cs collation.

If you are using Unicode (ucs2 or utf8), and you know what the Unicode sort order is (see Section A.11, “MySQL 5.6 FAQ: MySQL Chinese, Japanese, and Korean Character Sets”), but MySQL still seems to sort your table incorrectly, first verify the character set in the table definition:

```
mysql> SHOW CREATE TABLE t
```
Since the character set for the column `s1` appears to be correct (`ucs2`), check what information the INFORMATION_SCHEMA.COLUMNS table can provide about this column:

```
mysql> SELECT COLUMN_NAME, CHARACTER_SET_NAME, COLLATION_NAME
    > FROM INFORMATION_SCHEMA.COLUMNS
    > WHERE COLUMN_NAME = 's1'
    > AND TABLE_NAME = 't';
```

(See Section 21.5, “The INFORMATION_SCHEMA COLUMNS Table”, for more information.)

You can see that the collation is `ucs2_general_ci` instead of `ucs2_unicode_ci`. The reason why this is so can be found using SHOW CHARACTER SET, as shown here:

```
mysql> SHOW CHARSET LIKE 'ucs2%';
```

For `ucs2` and `utf8`, the default collation is “general”. To specify a Unicode UCA collation, use `COLLATE ucs2_unicode_ci`, as shown in the preceding item.

A.11.15 Why are my supplementary characters rejected by MySQL?

Supplementary characters lie outside the Unicode Basic Multilingual Plane / Plane 0. BMP characters have code point values between \texttt{U+0000} and \texttt{U+FFFF}. Supplementary characters have code point values between \texttt{U+10000} and \texttt{U+10FFFF}.

To store supplementary characters, you must use a character set that permits them:

- The `utf8` and `ucs2` character sets support BMP characters only.

  The `utf8` character set permits only UTF-8 characters that take up to three bytes. This has led to reports such as that found in Bug #12600, which we rejected as “not a bug”. With `utf8`, MySQL must truncate an input string when it encounters bytes that it does no understand. Otherwise, it is unknown how long the bad multibyte character is.

  One possible workaround is to use `ucs2` instead of `utf8`, in which case the “bad” characters are changed to question marks. However, no truncation takes place. You can also change the data type to `BLOB` or `BINARY`, which perform no validity checking.

- The `utf8mb4`, `utf16`, `utf16le`, and `utf32` character sets support BMP characters, as well as supplementary characters outside the BMP.

A.11.16 Should “CJK” be “CJKV”?
No. The term “CJKV” (Chinese Japanese Korean Vietnamese) refers to Vietnamese character sets which contain Han (originally Chinese) characters. MySQL supports the modern Vietnamese script with Western characters, but does not support the old Vietnamese script using Han characters.

As of MySQL 5.6, there are Vietnamese collations for Unicode character sets, as described in Section 10.10.1, “Unicode Character Sets”.

A.11.17. Does MySQL permit CJK characters to be used in database and table names?
Yes.

The Japanese translation of the MySQL 5.6 manual can be downloaded from https://dev.mysql.com/doc/.

A.11.19. Where can I get help with CJK and related issues in MySQL?
The following resources are available:
• A listing of MySQL user groups can be found at https://wikis.oracle.com/display/mysql/List+of+MySQL+User+Groups.
• View feature requests relating to character set issues at http://tinyurl.com/y6xcuf.

A.12 MySQL 5.6 FAQ: Connectors & APIs
For common questions, issues, and answers relating to the MySQL Connectors and other APIs, see the following areas of the Manual:
• Section 23.8.21, “C API Common Issues”
• Common Problems with MySQL and PHP
• Connector/ODBC Notes and Tips
• Connector/NET Programming
• MySQL Connector/J 5.1 Developer Guide

A.13 MySQL 5.6 FAQ: C API, Connector/C, libmysql
Frequently asked questions about MySQL C API, Connector/C, and libmysql.
A.13.1 What is “MySQL Native C API”? What are typical benefits and use cases? 3693
A.13.2 What is “Connector/C”? ............................................................... 3694
A.13.3 Which version of libmysql should I use? ........................................ 3694
A.13.4 What if I want to use the “NoSQL” X DevAPI? ............................. 3694
A.13.5 How to I download libmysql? .................................................... 3694
A.13.6 Where is the documentation? ..................................................... 3694
A.13.7 How do I report bugs? .............................................................. 3694
A.13.8 Is it possible to compile the library myself? .................................... 3694
A.13.1 What is “MySQL Native C API”? What are typical benefits and use cases?
libmysql is a C-based API that you can use in C applications to connect with the MySQL database server. It is also itself used as the foundation for drivers for standard database APIs like ODBC, Perl's DBI, and Python's DB API.

A.13.2 What is “Connector/C”?

libmysql and Connector/C are synonyms these days. In the past there were separate packages for installing; now we default to the libmysql packaging alone.

A.13.3 Which version of libmysql should I use?

For MySQL 8.0, 5.7, 5.6, and 5.5, we recommend libmysql 8.0, also known as MySQL Connector/C 8.0.

A.13.4 What if I want to use the “NoSQL” X DevAPI?

For C-language and X DevAPI Document Store for MySQL 8.0, we recommend MySQL Connector/C++. Connector/C++ 8.0 has compatible C headers. (This is not applicable to MySQL 5.7 or before.)

A.13.5 How do I download libmysql?

Download Connector/C 8.0 (libmysqlclient 8.0).

- Linux: The Client Utilities Package is available from the MySQL Community Server download page.
- Repos: The Client Utilities Package is available from the Yum, APT, SuSE repositories.
- Windows: The Client Utilities Package is available from Windows Installer.

A.13.6 Where is the documentation?

Online documentation:

- MySQL Connector/C Installation Instructions
- Documentation
- Change History

A.13.7 How do I report bugs?

Please report any bugs or inconsistencies you observe to our Bugs Database. Select the C API Client as shown.

A.13.8 Is it possible to compile the library myself?

Yes, you can download the libmysqlclient source code and compile it on our own. Here's an example:

```
$ git clone --depth 1 https://github.com/mysql/mysql-server
$ cd mysql-server
$ mkdir build
$ cd build
$ cmake .. -GNinja -DDOWNLOAD_BOOST=1
   -DWITH_BOOST=/tmp -DCMAKE_BUILD_TYPE=Release -DWITHOUT_SERVER=ON
   -DWITH_SSL=system $ ninja libmysqlclient.a
$ ls -la archive_output_directory/libmysqlclient.a
-rw-rw-r-- 1 kg kg 8,5M wrz 5 04:57 archive_output_directory/libmysqlclient.a
```
Note
This example uses https://ninja-build.org/ as a build system instead of make.

A.14 MySQL 5.6 FAQ: Replication

In the following section, we provide answers to questions that are most frequently asked about MySQL Replication.

A.14.1 Must the slave be connected to the master all the time? ................................................................. 3695
A.14.2 Must I enable networking on my master and slave to enable replication? ............................ 3695
A.14.3 How do I know how late a slave is compared to the master? In other words, how do I know the date of the last statement replicated by the slave? ................................................................. 3695
A.14.4 How do I force the master to block updates until the slave catches up? ............................ 3696
A.14.5 What issues should I be aware of when setting up two-way replication? ............................ 3696
A.14.6 How can I use replication to improve performance of my system? ............................ 3696
A.14.7 What should I do to prepare client code in my own applications to use performance-enhancing replication? .......................................................................................................................... 3697
A.14.8 When and how much can MySQL replication improve the performance of my system? .......... 3697
A.14.9 How can I use replication to provide redundancy or high availability? ............................ 3698
A.14.10 How do I tell whether a master server is using statement-based or row-based binary logging format? .......................................................................................................................... 3698
A.14.11 How do I tell a slave to use row-based replication? ................................................................. 3698
A.14.12 How do I prevent GRANT and REVOKE statements from replicating to slave machines? ........ 3698
A.14.13 Does replication work on mixed operating systems (for example, the master runs on Linux while slaves run on OS X and Windows)? ........................................................................ 3698
A.14.14 Does replication work on mixed hardware architectures (for example, the master runs on a 64-bit machine while slaves run on 32-bit machines)? ..................................................... 3698

A.14.1 Must the slave be connected to the master all the time?

No, it does not. The slave can go down or stay disconnected for hours or even days, and then reconect and catch up on updates. For example, you can set up a master/slave relationship over a dial-up link where the link is up only sporadically and for short periods of time. The implication of this is that, at any given time, the slave is not guaranteed to be in synchrony with the master unless you take some special measures.

To ensure that catchup can occur for a slave that has been disconnected, you must not remove binary log files from the master that contain information that has not yet been replicated to the slaves. Asynchronous replication can work only if the slave is able to continue reading the binary log from the point where it last read events.

A.14.2 Must I enable networking on my master and slave to enable replication?

Yes, networking must be enabled on the master and slave. If networking is not enabled, the slave cannot connect to the master and transfer the binary log. Check that the skip-networking option has not been enabled in the configuration file for either server.

A.14.3 How do I know how late a slave is compared to the master? In other words, how do I know the date of the last statement replicated by the slave?

Check the Seconds_Behind_Master column in the output from SHOW SLAVE STATUS. See Section 17.1.5.1, “Checking Replication Status”.
When the slave SQL thread executes an event read from the master, it modifies its own time to the event timestamp. (This is why `TIMESTAMP` is well replicated.) In the `Time` column in the output of `SHOW PROCESSLIST`, the number of seconds displayed for the slave SQL thread is the number of seconds between the timestamp of the last replicated event and the real time of the slave machine. You can use this to determine the date of the last replicated event. Note that if your slave has been disconnected from the master for one hour, and then reconnects, you may immediately see large `Time` values such as 3600 for the slave SQL thread in `SHOW PROCESSLIST`. This is because the slave is executing statements that are one hour old. See Section 17.2.1, “Replication Implementation Details”.

**A.14.4** How do I force the master to block updates until the slave catches up?

Use the following procedure:

1. On the master, execute these statements:

```
mysql> FLUSH TABLES WITH READ LOCK;
mysql> SHOW MASTER STATUS;
```

Record the replication coordinates (the current binary log file name and position) from the output of the `SHOW` statement.

2. On the slave, issue the following statement, where the arguments to the `MASTER_POS_WAIT()` function are the replication coordinate values obtained in the previous step:

```
mysql> SELECT MASTER_POS_WAIT('log_name', log_pos);
```

The `SELECT` statement blocks until the slave reaches the specified log file and position. At that point, the slave is in synchrony with the master and the statement returns.

3. On the master, issue the following statement to enable the master to begin processing updates again:

```
mysql> UNLOCK TABLES;
```

**A.14.5** What issues should I be aware of when setting up two-way replication?

MySQL replication currently does not support any locking protocol between master and slave to guarantee the atomicity of a distributed (cross-server) update. In other words, it is possible for client A to make an update to co-master 1, and in the meantime, before it propagates to co-master 2, client B could make an update to co-master 2 that makes the update of client A work differently than it did on co-master 1. Thus, when the update of client A makes it to co-master 2, it produces tables that are different from what you have on co-master 1, even after all the updates from co-master 2 have also propagated. This means that you should not chain two servers together in a two-way replication relationship unless you are sure that your updates can safely happen in any order, or unless you take care of mis-ordered updates somehow in the client code.

You should also realize that two-way replication actually does not improve performance very much (if at all) as far as updates are concerned. Each server must do the same number of updates, just as you would have a single server do. The only difference is that there is a little less lock contention because the updates originating on another server are serialized in one slave thread. Even this benefit might be offset by network delays.

**A.14.6** How can I use replication to improve performance of my system?
Set up one server as the master and direct all writes to it. Then configure as many slaves as you have the budget and rackspace for, and distribute the reads among the master and the slaves. You can also start the slaves with the `--skip-innodb` option, enable the `low_priority_updates` system variable, and set the `delay_key_write` system variable to `ALL` to get speed improvements on the slave end. In this case, the slave uses nontransactional MyISAM tables instead of InnoDB tables to get more speed by eliminating transactional overhead.

**A.14.7** What should I do to prepare client code in my own applications to use performance-enhancing replication?

See the guide to using replication as a scale-out solution, Section 17.3.4, “Using Replication for Scale-Out”.

**A.14.8** When and how much can MySQL replication improve the performance of my system?

MySQL replication is most beneficial for a system that processes frequent reads and infrequent writes. In theory, by using a single-master/multiple-slave setup, you can scale the system by adding more slaves until you either run out of network bandwidth, or your update load grows to the point that the master cannot handle it.

To determine how many slaves you can use before the added benefits begin to level out, and how much you can improve performance of your site, you must know your query patterns, and determine empirically by benchmarking the relationship between the throughput for reads and writes on a typical master and a typical slave. The example here shows a rather simplified calculation of what you can get with replication for a hypothetical system. Let `reads` and `writes` denote the number of reads and writes per second, respectively.

Let's say that system load consists of 10% writes and 90% reads, and we have determined by benchmarking that

\[ \text{reads} = 1200 - 2 \times \text{writes} \]

In other words, the system can do 1,200 reads per second with no writes, the average write is twice as slow as the average read, and the relationship is linear. Suppose that the master and each slave have the same capacity, and that we have one master and \( N \) slaves. Then we have for each server (master or slave):

\[
\begin{align*}
\text{reads} &= 1200 - 2 \times \text{writes} \\
\text{reads} &= \frac{9 \times \text{writes}}{N + 1} \quad \text{(reads are split, but writes replicated to all slaves)} \\
9 \times \text{writes} / (N + 1) + 2 \times \text{writes} &= 1200 \\
\text{writes} &= \frac{1200}{2 + 9/(N + 1)}
\end{align*}
\]

The last equation indicates the maximum number of writes for \( N \) slaves, given a maximum possible read rate of 1,200 per second and a ratio of nine reads per write.

This analysis yields the following conclusions:

- If \( N = 0 \) (which means we have no replication), our system can handle about \( 1200/11 = 109 \) writes per second.
- If \( N = 1 \), we get up to 184 writes per second.
- If \( N = 8 \), we get up to 400 writes per second.
- If \( N = 17 \), we get up to 480 writes per second.
• Eventually, as $N$ approaches infinity (and our budget negative infinity), we can get very close to 600 writes per second, increasing system throughput about 5.5 times. However, with only eight servers, we increase it nearly four times.

These computations assume infinite network bandwidth and neglect several other factors that could be significant on your system. In many cases, you may not be able to perform a computation similar to the one just shown that accurately predicts what will happen on your system if you add $N$ replication slaves. However, answering the following questions should help you decide whether and by how much replication will improve the performance of your system:

• What is the read/write ratio on your system?

• How much more write load can one server handle if you reduce the reads?

• For how many slaves do you have bandwidth available on your network?

How can I use replication to provide redundancy or high availability?

How you implement redundancy is entirely dependent on your application and circumstances. High-availability solutions (with automatic failover) require active monitoring and either custom scripts or third party tools to provide the failover support from the original MySQL server to the slave.

To handle the process manually, you should be able to switch from a failed master to a pre-configured slave by altering your application to talk to the new server or by adjusting the DNS for the MySQL server from the failed server to the new server.

For more information and some example solutions, see Section 17.3.7, “Switching Masters During Failover”.

How do I tell whether a master server is using statement-based or row-based binary logging format?

Check the value of the `binlog_format` system variable:

```
mysql> SHOW VARIABLES LIKE 'binlog_format';
```

The value shown will be one of `STATEMENT`, `ROW`, or `MIXED`. For `MIXED` mode, statement-based logging is used by default but replication switches automatically to row-based logging under certain conditions, such as unsafe statements. For information about when this may occur, see Section 5.4.4.3, “Mixed Binary Logging Format”.

How do I tell a slave to use row-based replication?

Slaves automatically know which format to use.

How do I prevent `GRANT` and `REVOKE` statements from replicating to slave machines?

Start the server with the `--replicate-wild-ignore-table=mysql.%` option to ignore replication for tables in the `mysql` database.

Does replication work on mixed operating systems (for example, the master runs on Linux while slaves run on OS X and Windows)?

Yes.

Does replication work on mixed hardware architectures (for example, the master runs on a 64-bit machine while slaves run on 32-bit machines)?
A.15 MySQL 5.6 FAQ: MySQL Enterprise Thread Pool

A.15.1 What is the Thread Pool and what problem does it solve?

The MySQL Thread Pool is a MySQL server plugin that extends the default connection-handling capabilities of the MySQL server to limit the number of concurrently executing statements/queries and transactions to ensure that each has sufficient CPU and memory resources to fulfill its task. For MySQL 5.6, the Thread Pool plugin is included in MySQL Enterprise Edition, a commercial product.

The default thread-handling model in MySQL Server executes statements using one thread per client connection. As more clients connect to the server and execute statements, overall performance degrades. The Thread Pool plugin provides an alternative thread-handling model designed to reduce overhead and improve performance. The Thread Pool plugin increases server performance by efficiently managing statement execution threads for large numbers of client connections, especially on modern multi-CPU/Core systems.

For more information, see Section 5.5.3, “MySQL Enterprise Thread Pool”.

A.15.2 How does the Thread Pool limit and manage concurrent sessions and transactions for optimal performance and throughput?

The Thread Pool uses a “divide and conquer” approach to limiting and balancing concurrency. Unlike the default connection handling of the MySQL Server, the Thread Pool separates connections and threads, so there is no fixed relationship between connections and the threads that execute statements received from those connections. The Thread Pool then manages client connections within configurable thread groups, where they are prioritized and queued based on the nature of the work they were submitted to accomplish.

For more information, see Section 5.5.3.3, “Thread Pool Operation”.

A.15.3 How is the Thread Pool different from the client side Connection Pool?

The MySQL Connection Pool operates on the client side to ensure that a MySQL client does not constantly connect to and disconnect from the MySQL server. It is designed to cache idle connections in the MySQL client for use by other users as they are needed. This minimizes the overhead and expense of establishing and tearing down connections as queries are submitted to the MySQL server. The MySQL Connection Pool has no visibility as to the query handling capabilities or load of the back-end MySQL server. By contrast, the Thread Pool operates on the MySQL server side and is designed to manage the execution of inbound concurrent connections and queries as they are received from the client connections accessing the back-end MySQL database. Because of the separation of duties, the MySQL Connection Pool and Thread Pool are orthogonal and can be used independent of each other.

MySQL Connection Pooling via the MySQL Connectors is covered in Chapter 23, Connectors and APIs.

A.15.4 When should I use the Thread Pool?
There are a few rules of thumb to consider for optimal Thread Pool use cases:

The MySQL `Threads_running` variable keeps track of the number of concurrent statements currently executing in the MySQL Server. If this variable consistently exceeds a region where the server won’t operate optimally (usually going beyond 40 for InnoDB workloads), the Thread Pool will be beneficial, especially in extreme parallel overload situations.

If you are using the `innodb_thread_concurrency` to limit the number of concurrently executing statements, you will find the Thread Pool solves the same problem, only better, by assigning connections to thread groups, then queuing executions based on transactional content, user defined designations, and so forth.

Lastly, if your workload comprises mainly short queries, the Thread Pool will be beneficial.

To learn more, see Section 5.5.3.4, “Thread Pool Tuning”.

A.16 MySQL 5.6 FAQ: InnoDB Change Buffer

A.16.1 What types of operations modify secondary indexes and result in change buffering? 

**INSERT**, **UPDATE**, and **DELETE** operations can modify secondary indexes. If an affected index page is not in the buffer pool, the changes can be buffered in the change buffer.

A.16.2 What is the benefit of the **InnoDB** change buffer?

Buffering secondary index changes when secondary index pages are not in the buffer pool avoids expensive random access I/O operations that would be required to immediately read in affected index pages from disk. Buffered changes can be applied later, in batches, as pages are read into the buffer pool by other read operations.

A.16.3 Does the change buffer support other types of indexes?

No. The change buffer only supports secondary indexes. Clustered indexes, full-text indexes, and spatial indexes are not supported. Full-text indexes have their own caching mechanism.

A.16.4 How much space does **InnoDB** use for the change buffer?

Prior to the introduction of the `innodb_change_buffer_max_size` configuration option in MySQL 5.6, the maximum size of the on-disk change buffer in the system tablespace was 1/3 of the **InnoDB** buffer pool size.
In MySQL 5.6 and later, the `innodb_change_buffer_max_size` configuration option defines the maximum size of the change buffer as a percentage of the total buffer pool size. By default, `innodb_change_buffer_max_size` is set to 25. The maximum setting is 50.

**InnoDB** does not buffer an operation if it would cause the on-disk change buffer to exceed the defined limit.

Change buffer pages are not required to persist in the buffer pool and may be evicted by LRU operations.

**A.16.5 How do I determine the current size of the change buffer?**

The current size of the change buffer is reported by `SHOW ENGINE INNODB STATUS \G`, under the `INSERT BUFFER AND ADAPTIVE HASH INDEX` heading. For example:

```
-------------------------------------
INSERT BUFFER AND ADAPTIVE HASH INDEX
-------------------------------------
Ibuf: size 1, free list len 0, seg size 2, 0 merges
```

Relevant data points include:

- **size**: The number of pages used within the change buffer. Change buffer size is equal to `seg size - (1 + free list len)`. The `1 +` value represents the change buffer header page.
- **seg size**: The size of the change buffer, in pages.

For information about monitoring change buffer status, see Section 14.5.2, "Change Buffer".

**A.16.6 When does change buffer merging occur?**

- When a page is read into the buffer pool, buffered changes are merged upon completion of the read, before the page is made available.
- Change buffer merging is performed as a background task. The `innodb_io_capacity` parameter sets an upper limit on the I/O activity performed by InnoDB background tasks such as merging data from the change buffer.
- A change buffer merge is performed during crash recovery. Changes are applied from the change buffer (in the system tablespace) to leaf pages of secondary indexes as index pages are read into the buffer pool.
- The change buffer is fully durable and will survive a system crash. Upon restart, change buffer merge operations resume as part of normal operations.
- A full merge of the change buffer can be forced as part of a slow server shutdown using `--innodb-fast-shutdown=0`.

**A.16.7 When is the change buffer flushed?**

Updated pages are flushed by the same flushing mechanism that flushes the other pages that occupy the buffer pool.

**A.16.8 When should the change buffer be used?**

The change buffer is a feature designed to reduce random I/O to secondary indexes as indexes grow larger and no longer fit in the InnoDB buffer pool. Generally, the change buffer should be used when the entire data set does not fit into the buffer pool, when there is substantial DML activity that
modifies secondary index pages, or when there are lots of secondary indexes that are regularly changed by DML activity.

A.16.9 When should the change buffer not be used?

You might consider disabling the change buffer if the entire data set fits within the InnoDB buffer pool, if you have relatively few secondary indexes, or if you are using solid-state storage, where random reads are about as fast as sequential reads. Before making configuration changes, it is recommended that you run tests using a representative workload to determine if disabling the change buffer provides any benefit.

A.16.10 Where can I find additional information about the change buffer?

See Section 14.5.2, “Change Buffer”.

A.17 MySQL 5.6 FAQ: Virtualization Support

A.17.1 Is MySQL supported on virtualized environments such as Oracle VM, VMWare, Docker, Microsoft Hyper-V, or others?

MySQL is supported on virtualized environments, but is certified only for Oracle VM. Contact Oracle Support for more information.

Be aware of potential problems when using virtualization software. The usual ones are related to performance, performance degradations, slowness, or unpredictability of disk, I/O, network, and memory.

This appendix describes the types of error information MySQL provides and how to obtain information about them. It also lists the error messages that the MySQL server and MySQL client programs generate. The final section is for troubleshooting. It describes common problems and errors that may occur and potential resolutions.

Additional Resources

Other sections that discuss error-related topics include:

- Information about configuring where and how the server writes the error log: Section 5.4.2, “The Error Log”
- Information about the character set used for error messages: Section 10.6, “Error Message Character Set”
- Information about the language used for error messages: Section 10.12, “Setting the Error Message Language”
- Information about errors related to InnoDB: Section 14.21.4, “InnoDB Error Handling”

B.1 Error Message Sources and Components

This section discusses how error messages originate within MySQL and the components they contain.

- Error Message Sources
- Error Message Components

Error Message Sources

Error messages can originate on the server side or the client side:

- On the server side, error messages may occur during the startup and shutdown processes, as a result of issues that occur during SQL statement execution, and so forth.
• The MySQL server writes some error messages to its error log. These indicate issues of interest to database administrators or that require DBA action.

• The server sends other error messages to client programs. These indicate issues pertaining only to a particular client. The MySQL client library takes errors received from the server and makes them available to the host client program.

• Client-side error messages are generated from within the MySQL client library, usually involving problems communicating with the server.

Example server-side error messages written to the error log:

• This message produced during the startup process provides a status or progress indicator:

```
2018-08-29 08:27:31 16664 [Note] Event Scheduler: scheduler thread started with id 1
```

• This message indicates an issue that requires DBA action:

```
2018-10-02 03:20:39 0 [ERROR] Can't open the mysql.plugin table. Please run mysql_upgrade to create it.
```

Example server-side error message sent to client programs, as displayed by the mysql client:

```
mysql> SELECT * FROM no_such_table;
ERROR 1146 (42S02): Table 'test.no_such_table' doesn't exist
```

Example client-side error message originating from within the client library, as displayed by the mysql client:

```
shell> mysql -h no-such-host
ERROR 2005 (HY000): Unknown MySQL server host 'no-such-host' (0)
```

Whether an error originates from within the client library or is received from the server, a MySQL client program may respond in varying ways. As just illustrated, the client may display the error message so the user can take corrective measures. The client may instead internally attempt to resolve or retry a failed operation, or take other action.

**Error Message Components**

When an error occurs, error information includes several components: an error code, SQLSTATE value, and message string. These components have the following characteristics:

• Error code: This value is numeric. It is MySQL-specific and is not portable to other database systems.

  Each error number has a corresponding symbolic value. Examples:

  • The symbol for server error number **1146** is `ER_NO_SUCH_TABLE`.
  
  • The symbol for client error number **2005** is `CR_UNKNOWN_HOST`.

  Error codes are stable across General Availability (GA) releases of a given MySQL series. Before a series reaches GA status, new codes may still be under development and are subject to change.
• SQLSTATE value: This value is a five-character string (for example, '42S02'). SQLSTATE values are taken from ANSI SQL and ODBC and are more standardized than the numeric error codes. The first two characters of an SQLSTATE value indicate the error class:

  - Class = '00' indicates success.
  - Class = '01' indicates a warning.
  - Class = '02' indicates "not found." This is relevant within the context of cursors and is used to control what happens when a cursor reaches the end of a data set. This condition also occurs for SELECT ... INTO var_list statements that retrieve no rows.
  - Class > '02' indicates an exception.

For server-side errors, not all MySQL error numbers have corresponding SQLSTATE values. In these cases, 'HY000' (general error) is used.

For client-side errors, the SQLSTATE value is always 'HY000' (general error), so it is not meaningful for distinguishing one client error from another.

• Message string: This string provides a textual description of the error.

B.2 Error Information Interfaces

Error messages can originate on the server side or the client side, and each error message includes an error code, SQLSTATE value, and message string, as described in Section B.1, “Error Message Sources and Components”. For lists of server-side, client-side, and global (shared between server and clients) errors, see Section B.3, “Error Message Reference”.

For error checking from within programs, use error code numbers or symbols, not error message strings. Message strings do not change often, but it is possible. Also, if the database administrator changes the language setting, that affects the language of message strings; see Section 10.12, “Setting the Error Message Language”.

Error information in MySQL is available in the server error log, at the SQL level, from within client programs, and at the command line.

• Error Log
• SQL Error Message Interface
• Client Error Message Interface
• Command-Line Error Message Interface

Error Log

On the server side, some messages are intended for the error log. For information about configuring where and how the server writes the log, see Section 5.4.2, “The Error Log”.

Other server error messages are intended to be sent to client programs and are available as described in Client Error Message Interface.

SQL Error Message Interface

At the SQL level, there are several sources of error information in MySQL:
• SQL statement warning and error information is available through the `SHOW WARNINGS` and `SHOW ERRORS` statements. The `warning_count` system variable indicates the number of errors, warnings, and notes (with notes excluded if the `sql_notes` system variable is disabled). The `error_count` system variable indicates the number of errors. Its value excludes warnings and notes.

• The `GET DIAGNOSTICS` statement may be used to inspect the diagnostic information in the diagnostics area. See Section 13.6.7.3, “GET DIAGNOSTICS Syntax”.

• `SHOW SLAVE STATUS` statement output includes information about replication errors occurring on replication slave servers.

• `SHOW ENGINE INNODB STATUS` statement output includes information about the most recent foreign key error if a `CREATE TABLE` statement for an InnoDB table fails.

**Client Error Message Interface**

Client programs receive errors from two sources:

• Errors that originate on the client side from within the MySQL client library.

• Errors that originate on the server side and are sent to the client by the server. These are received within the client library, which makes them available to the host client program.

Regardless of whether an error originates from within the client library or is received from the server, a MySQL client program obtains the error code, SQLSTATE value, message string, and other related information by calling C API functions in the client library:

• `mysql_errno()` returns the MySQL error code.

• `mysql_sqlstate()` returns the SQLSTATE value.

• `mysql_error()` returns the message string.

• `mysql_stmt_errno()`, `mysql_stmt_sqlstate()`, and `mysql_stmt_error()` are the corresponding error functions for prepared statements.

• `mysql_warning_count()` returns the number of errors, warnings, and notes for the most recent statement.

For descriptions of the client library error functions, see Section 23.8, “MySQL C API”.

A MySQL client program may respond to an error in varying ways. The client may display the error message so the user can take corrective measures, internally attempt to resolve or retry a failed operation, or take other action. For example, (using the `mysql` client), a failure to connect to the server might result in this message:

```
shell> mysql -h no-such-host
ERROR 2005 (HY000): Unknown MySQL server host 'no-such-host' (0)
```

**Command-Line Error Message Interface**

The `perror` program provides information from the command line about error numbers. See Section 4.8.1, “`perror` — Display MySQL Error Message Information”.

```
shell> perror 1231
MySQL error code 1231 (ER_WRONG_VALUE_FOR_VAR): Variable '%-.64s' can't be set to the value of '%-.200s'
```
B.3 Error Message Reference

This section provides a reference for the various types of error messages in MySQL:

- Error messages produced only by the server: Section B.3.1, “Server Error Message Reference”
- Error messages that originate only from within the MySQL client library: Section B.3.2, “Client Error Message Reference”
- Error messages that are shared between the server and the client library: Section B.3.3, “Global Error Message Reference”

B.3.1 Server Error Message Reference

The MySQL server writes some error messages to its error log, and sends others to client programs.

Example server-side error messages written to the error log:

```
2018-08-29 08:27:31 16664 [Note] Event Scheduler: scheduler thread started with id 1

2018-10-02 03:20:39 0 [ERROR] Can't open the mysql.plugin table. Please run mysql_upgrade to create it.
```

Example server-side error message sent to client programs, as displayed by the `mysql` client:

```
mysql> SELECT * FROM no_such_table;
ERROR 1146 (42S02): Table 'test.no_such_table' doesn't exist
```

Each server error message includes an error code, SQLSTATE value, and message string, as described in Section B.1, “Error Message Sources and Components”. These components are available as described in Section B.2, “Error Information Interfaces”.

In addition to the errors in the following list, the server can also produce error messages that have error codes in the range from 1 to 999. See Section B.3.3, “Global Error Message Reference”

- Error number: 1000; Symbol: ER_HASHCHK; SQLSTATE: HY000
  Message: hashchk
  Unused.

- Error number: 1001; Symbol: ER_NISAMCHK; SQLSTATE: HY000
  Message: isamchk
  Unused.

- Error number: 1002; Symbol: ER_NO; SQLSTATE: HY000
  Message: NO
  Used in the construction of other messages.

- Error number: 1003; Symbol: ER_YES; SQLSTATE: HY000
  Message: YES
Extended EXPLAIN format generates Note messages. ER_YES is used in the Code column for these messages in subsequent SHOW WARNINGS output.

- **Error number:** 1004; **Symbol:** ER_CANT_CREATE_FILE; **SQLSTATE:** HY000
  
  **Message:** Can't create file '%s' (errno: %d - %s)
  
  Occurs for failure to create or copy a file needed for some operation.

  **Possible causes:** Permissions problem for source file; destination file already exists but is not writeable.

- **Error number:** 1005; **Symbol:** ER_CANT_CREATE_TABLE; **SQLSTATE:** HY000
  
  **Message:** Can't create table '%s' (errno: %d)
  
  InnoDB reports this error when a table cannot be created. If the error message refers to error 150, table creation failed because a foreign key constraint was not correctly formed. If the error message refers to error -1, table creation probably failed because the table includes a column name that matched the name of an internal InnoDB table.

- **Error number:** 1006; **Symbol:** ER_CANT_CREATE_DB; **SQLSTATE:** HY000
  
  **Message:** Can't create database '%s' (errno: %d)

- **Error number:** 1007; **Symbol:** ER_DB_CREATE_EXISTS; **SQLSTATE:** HY000
  
  **Message:** Can't create database '%s'; database exists
  
  An attempt to create a database failed because the database already exists.

  Drop the database first if you really want to replace an existing database, or add an IF NOT EXISTS clause to the CREATE DATABASE statement if to retain an existing database without having the statement produce an error.

- **Error number:** 1008; **Symbol:** ER_DB_DROP_EXISTS; **SQLSTATE:** HY000
  
  **Message:** Can't drop database '%s'; database doesn't exist

- **Error number:** 1009; **Symbol:** ER_DB_DROP_DELETE; **SQLSTATE:** HY000
  
  **Message:** Error dropping database (can't delete '%s', errno: %d)

- **Error number:** 1010; **Symbol:** ER_DB_DROP_RMDIR; **SQLSTATE:** HY000
  
  **Message:** Error dropping database (can't rmdir '%s', errno: %d)

- **Error number:** 1011; **Symbol:** ER_CANT_DELETE_FILE; **SQLSTATE:** HY000
  
  **Message:** Error on delete of '%s' (errno: %d - %s)

- **Error number:** 1012; **Symbol:** ER_CANT_FIND_SYSTEM_REC; **SQLSTATE:** HY000
  
  **Message:** Can't read record in system table
  
  Returned by InnoDB for attempts to access InnoDB INFORMATION_SCHEMA tables when InnoDB is unavailable.
• Error number: **1013**; Symbol: `ER_CANT_GET_STAT`; SQLSTATE: `HY000`
  Message: Can't get status of '%s' (errno: %d - %s)

• Error number: **1014**; Symbol: `ER_CANT_GET_WD`; SQLSTATE: `HY000`
  Message: Can't get working directory (errno: %d - %s)

• Error number: **1015**; Symbol: `ER_CANT_LOCK`; SQLSTATE: `HY000`
  Message: Can't lock file (errno: %d - %s)

• Error number: **1016**; Symbol: `ER_CANT_OPEN_FILE`; SQLSTATE: `HY000`
  Message: Can't open file: '%s' (errno: %d - %s)

  *InnoDB* reports this error when the table from the InnoDB data files cannot be found, even though the .frm file for the table exists. See Section 14.21.3, “Troubleshooting InnoDB Data Dictionary Operations”.

• Error number: **1017**; Symbol: `ER_FILE_NOT_FOUND`; SQLSTATE: `HY000`
  Message: Can't find file: '%s' (errno: %d - %s)

• Error number: **1018**; Symbol: `ER_CANT_READ_DIR`; SQLSTATE: `HY000`
  Message: Can't read dir of '%s' (errno: %d - %s)

• Error number: **1019**; Symbol: `ER_CANT_SET_WD`; SQLSTATE: `HY000`
  Message: Can't change dir to '%s' (errno: %d - %s)

• Error number: **1020**; Symbol: `ER_CHECKREAD`; SQLSTATE: `HY000`
  Message: Record has changed since last read in table '%s'

• Error number: **1021**; Symbol: `ER_DISK_FULL`; SQLSTATE: `HY000`
  Message: Disk full (%s); waiting for someone to free some space... (errno: %d - %s)

• Error number: **1022**; Symbol: `ER_DUP_KEY`; SQLSTATE: `23000`
  Message: Can't write; duplicate key in table '%s'

• Error number: **1023**; Symbol: `ER_ERROR_ON_CLOSE`; SQLSTATE: `HY000`
  Message: Error on close of '%s' (errno: %d - %s)

• Error number: **1024**; Symbol: `ER_ERROR_ON_READ`; SQLSTATE: `HY000`
  Message: Error reading file '%s' (errno: %d - %s)

• Error number: **1025**; Symbol: `ER_ERROR_ON_RENAME`; SQLSTATE: `HY000`
  Message: Error on rename of '%s' to '%s' (errno: %d - %s)

• Error number: **1026**; Symbol: `ER_ERROR_ON_WRITE`; SQLSTATE: `HY000`
  Message: Error writing file '%s' (errno: %d - %s)
Server Error Message Reference

- Error number: 1027; Symbol: ER_FILE_USED; SQLSTATE: HY000
  Message: '%s' is locked against change

- Error number: 1028; Symbol: ER_FILSORT_ABORT; SQLSTATE: HY000
  Message: Sort aborted

- Error number: 1029; Symbol: ER_FORM_NOT_FOUND; SQLSTATE: HY000
  Message: View '%s' doesn't exist for '%s'

- Error number: 1030; Symbol: ER_GET_ERRNO; SQLSTATE: HY000
  Message: Got error %d from storage engine
  Check the %d value to see what the OS error means. For example, 28 indicates that you have run out of disk space.

- Error number: 1031; Symbol: ER_ILLEGAL_HA; SQLSTATE: HY000
  Message: Table storage engine for '%s' doesn't have this option

- Error number: 1032; Symbol: ER_KEY_NOT_FOUND; SQLSTATE: HY000
  Message: Can't find record in '%s'

- Error number: 1033; Symbol: ER_NOT_FORM_FILE; SQLSTATE: HY000
  Message: Incorrect information in file: '%s'

- Error number: 1034; Symbol: ER_NOT_KEYFILE; SQLSTATE: HY000
  Message: Incorrect key file for table '%s'; try to repair it

- Error number: 1035; Symbol: ER_OLD_KEYFILE; SQLSTATE: HY000
  Message: Old key file for table '%s'; repair it!

- Error number: 1036; Symbol: ER_OPEN_AS_READONLY; SQLSTATE: HY000
  Message: Table '%s' is read only

- Error number: 1037; Symbol: ER_OUTOFMEMORY; SQLSTATE: HY001
  Message: Out of memory; restart server and try again (needed %d bytes)

- Error number: 1038; Symbol: ER_OUT_OF_SORTMEMORY; SQLSTATE: HY001
  Message: Out of sort memory, consider increasing server sort buffer size

- Error number: 1039; Symbol: ER_UNEXPECTED_EOF; SQLSTATE: HY000
  Message: Unexpected EOF found when reading file '%s' (errno: %d - %s)

- Error number: 1040; Symbol: ER_CON_COUNT_ERROR; SQLSTATE: 08004
  Message: Too many connections

- Error number: 1041; Symbol: ER_OUT_OF_RESOURCES; SQLSTATE: HY000
Message: Out of memory; check if mysqld or some other process uses all available memory; if not, you may have to use 'ulimit' to allow mysqld to use more memory or you can add more swap space

- Error number: 1042; Symbol: ER_BAD_HOST_ERROR; SQLSTATE: 08S01
  Message: Can't get hostname for your address

- Error number: 1043; Symbol: ER_HANDSHAKE_ERROR; SQLSTATE: 08S01
  Message: Bad handshake

- Error number: 1044; Symbol: ER_DBACCESS_DENIED_ERROR; SQLSTATE: 42000
  Message: Access denied for user '%s'@'%s' to database '%s'

- Error number: 1045; Symbol: ER_ACCESS_DENIED_ERROR; SQLSTATE: 28000
  Message: Access denied for user '%s'@'%s' (using password: %s)

- Error number: 1046; Symbol: ER_NO_DB_ERROR; SQLSTATE: 3D000
  Message: No database selected

- Error number: 1047; Symbol: ER_UNKNOWN_COM_ERROR; SQLSTATE: 08S01
  Message: Unknown command

- Error number: 1048; Symbol: ER_BAD_NULL_ERROR; SQLSTATE: 23000
  Message: Column '%s' cannot be null

- Error number: 1049; Symbol: ER_BAD_DB_ERROR; SQLSTATE: 42000
  Message: Unknown database '%s'

- Error number: 1050; Symbol: ER_TABLE_EXISTS_ERROR; SQLSTATE: 42S01
  Message: Table '%s' already exists

- Error number: 1051; Symbol: ER_BAD_TABLE_ERROR; SQLSTATE: 42S02
  Message: Unknown table '%s'

- Error number: 1052; Symbol: ER_NON_UNIQ_ERROR; SQLSTATE: 23000
  Message: Column '%s' in %s is ambiguous

  %s = column name
  %s = location of column (for example, "field list")

  Likely cause: A column appears in a query without appropriate qualification, such as in a select list or ON clause.

  Examples:

  mysql> SELECT i FROM t INNER JOIN t AS t2;
  ERROR 1052 (23000): Column 'i' in field list is ambiguous
Resolution:

- Qualify the column with the appropriate table name:

  ```sql
  mysql> SELECT t2.i FROM t INNER JOIN t AS t2;
  ```

- Modify the query to avoid the need for qualification:

  ```sql
  mysql> SELECT * FROM t LEFT JOIN t AS t2 USING (i);
  ```

- Error number: 1053; Symbol: ER_SERVER_SHUTDOWN; SQLSTATE: 08S01
  Message: Server shutdown in progress

- Error number: 1054; Symbol: ER_BAD_FIELD_ERROR; SQLSTATE: 42S22
  Message: Unknown column '%s' in '%s'

- Error number: 1055; Symbol: ER_WRONG_FIELD_WITH_GROUP; SQLSTATE: 42000
  Message: '%s' isn't in GROUP BY

- Error number: 1056; Symbol: ER_WRONG_GROUP_FIELD; SQLSTATE: 42000
  Message: Can't group on '%s'

- Error number: 1057; Symbol: ER_WRONG_SUM_SELECT; SQLSTATE: 42000
  Message: Statement has sum functions and columns in same statement

- Error number: 1058; Symbol: ER_WRONG_VALUE_COUNT; SQLSTATE: 21S01
  Message: Column count doesn't match value count

- Error number: 1059; Symbol: ER_TOO_LONG_IDENT; SQLSTATE: 42000
  Message: Identifier name '%s' is too long

- Error number: 1060; Symbol: ER_DUP_FIELDNAME; SQLSTATE: 42S21
  Message: Duplicate column name '%s'

- Error number: 1061; Symbol: ER_DUP_KEYNAME; SQLSTATE: 42000
  Message: Duplicate key name '%s'

- Error number: 1062; Symbol: ER_DUP_ENTRY; SQLSTATE: 23000
  Message: Duplicate entry '%s' for key %d

  The message returned with this error uses the format string for ER_DUP_ENTRY_WITH_KEY_NAME.

- Error number: 1063; Symbol: ER_WRONG_FIELD_SPEC; SQLSTATE: 42000
  Message: Incorrect column specifier for column '%s'
Server Error Message Reference

- Error number: 1064; Symbol: ER_PARSE_ERROR; SQLSTATE: 42000
  Message: %s near '%%s' at line %d

- Error number: 1065; Symbol: ER_EMPTY_QUERY; SQLSTATE: 42000
  Message: Query was empty

- Error number: 1066; Symbol: ER_NONUNIQ_TABLE; SQLSTATE: 42000
  Message: Not unique table/alias: '%s'

- Error number: 1067; Symbol: ER_INVALID_DEFAULT; SQLSTATE: 42000
  Message: Invalid default value for '%s'

- Error number: 1068; Symbol: ER_MULTIPLE_PRI_KEY; SQLSTATE: 42000
  Message: Multiple primary key defined

- Error number: 1069; Symbol: ER_TOO_MANY_KEYS; SQLSTATE: 42000
  Message: Too many keys specified; max %d keys allowed

- Error number: 1070; Symbol: ER_TOO_MANY_KEY_PARTS; SQLSTATE: 42000
  Message: Too many key parts specified; max %d parts allowed

- Error number: 1071; Symbol: ER_TOO_LONG_KEY; SQLSTATE: 42000
  Message: Specified key was too long; max key length is %d bytes

- Error number: 1072; Symbol: ER_KEY_COLUMN_DOES_NOT_EXITS; SQLSTATE: 42000
  Message: Key column '%s' doesn't exist in table

- Error number: 1073; Symbol: ER_BLOB_USED_AS_KEY; SQLSTATE: 42000
  Message: BLOB column '%s' can't be used in key specification with the used table type

- Error number: 1074; Symbol: ER_TOO_BIG_FIELDLENGTH; SQLSTATE: 42000
  Message: Column length too big for column '%s' (max = %lu); use BLOB or TEXT instead

- Error number: 1075; Symbol: ER_WRONG_AUTO_KEY; SQLSTATE: 42000
  Message: Incorrect table definition; there can be only one auto column and it must be defined as a key

- Error number: 1076; Symbol: ER_READY; SQLSTATE: HY000
  Message: %s: ready for connections. Version: '%s' socket: '%s' port: %d

- Error number: 1077; Symbol: ER_NORMAL_SHUTDOWN; SQLSTATE: HY000
  Message: %s: Normal shutdown

- Error number: 1078; Symbol: ER_GOT_SIGNAL; SQLSTATE: HY000
  Message: %s: Got signal %d. Aborting!
• Error number: 1079; Symbol: ER_SHUTDOWN_COMPLETE; SQLSTATE: HY000
  Message: %s: Shutdown complete
• Error number: 1080; Symbol: ER_FORCING_CLOSE; SQLSTATE: 08S01
  Message: %s: Forcing close of thread %ld user: '%s'
• Error number: 1081; Symbol: ER_IPSOCK_ERROR; SQLSTATE: 08S01
  Message: Can't create IP socket
• Error number: 1082; Symbol: ER_NO_SUCH_INDEX; SQLSTATE: 42S12
  Message: Table '%s' has no index like the one used in CREATE INDEX; recreate the table
• Error number: 1083; Symbol: ER_WRONG_FIELD_TERMINATORS; SQLSTATE: 42000
  Message: Field separator argument is not what is expected; check the manual
• Error number: 1084; Symbol: ER_BLOBS_AND_NO_TERMINATED; SQLSTATE: 42000
  Message: You can't use fixed rowlength with BLOBs; please use 'fields terminated by'
• Error number: 1085; Symbol: ER_TEXTFILE_NOT_READABLE; SQLSTATE: HY000
  Message: The file '%s' must be in the database directory or be readable by all
• Error number: 1086; Symbol: ER_FILE_EXISTS_ERROR; SQLSTATE: HY000
  Message: File '%s' already exists
• Error number: 1087; Symbol: ER_LOAD_INFO; SQLSTATE: HY000
  Message: Records: %ld Deleted: %ld Skipped: %ld Warnings: %ld
• Error number: 1088; Symbol: ER_ALTER_INFO; SQLSTATE: HY000
  Message: Records: %ld Duplicates: %ld
• Error number: 1089; Symbol: ER_WRONG_SUB_KEY; SQLSTATE: HY000
  Message: Incorrect prefix key; the used key part isn't a string, the used length is longer than the key part, or the storage engine doesn't support unique prefix keys
• Error number: 1090; Symbol: ER_CANT_REMOVE_ALL_FIELDS; SQLSTATE: 42000
  Message: You can't delete all columns with ALTER TABLE; use DROP TABLE instead
• Error number: 1091; Symbol: ER_CANT_DROP_FIELD_OR_KEY; SQLSTATE: 42000
  Message: Can't DROP '%s'; check that column/key exists
• Error number: 1092; Symbol: ER_INSERT_INFO; SQLSTATE: HY000
  Message: Records: %ld Duplicates: %ld Warnings: %ld
• Error number: 1093; Symbol: ER_UPDATE_TABLE_USED; SQLSTATE: HY000
  Message: You can't specify target table '%s' for update in FROM clause
This error occurs for attempts to select from and modify the same table within a single statement. See Section 13.2.10.12, “Restrictions on Subqueries”.

- Error number: 1094; Symbol: ER_NO_SUCH_THREAD; SQLSTATE: HY000
  Message: Unknown thread id: %lu

- Error number: 1095; Symbol: ER_KILL_DENIED_ERROR; SQLSTATE: HY000
  Message: You are not owner of thread %lu

- Error number: 1096; Symbol: ER_NO_TABLES_USED; SQLSTATE: HY000
  Message: No tables used

- Error number: 1097; Symbol: ER_TOO_BIG_SET; SQLSTATE: HY000
  Message: Too many strings for column %s and SET

- Error number: 1098; Symbol: ER_NO_UNIQUE_LOGFILE; SQLSTATE: HY000
  Message: Can't generate a unique log-filename %s.(1-999)

- Error number: 1099; Symbol: ER_TABLE_NOT_LOCKED_FOR_WRITE; SQLSTATE: HY000
  Message: Table %s was locked with a READ lock and can't be updated

- Error number: 1100; Symbol: ER_TABLE_NOT_LOCKED; SQLSTATE: HY000
  Message: Table %s was not locked with LOCK TABLES

- Error number: 1101; Symbol: ER_BLOB_CANT_HAVE_DEFAULT; SQLSTATE: 42000
  Message: BLOB/TEXT column %s' can't have a default value

- Error number: 1102; Symbol: ER_WRONG_DB_NAME; SQLSTATE: 42000
  Message: Incorrect database name %s'

- Error number: 1103; Symbol: ER_WRONG_TABLE_NAME; SQLSTATE: 42000
  Message: Incorrect table name %s'

- Error number: 1104; Symbol: ER_TOO_BIG_SELECT; SQLSTATE: 42000
  Message: The SELECT would examine more than MAX_JOIN_SIZE rows; check your WHERE and use SET SQL_BIG_SELECTS=# if the SELECT is okay

- Error number: 1105; Symbol: ER_UNKNOWN_ERROR; SQLSTATE: HY000
  Message: Unknown error

- Error number: 1106; Symbol: ER_UNKNOWN_PROCEDURE; SQLSTATE: 42000
  Message: Unknown procedure %s'

- Error number: 1107; Symbol: ER_WRONG_PARAMCOUNT_TO_PROCEDURE; SQLSTATE: 42000
  Message: Incorrect parameter count to procedure %s'
• Error number: **1108**; Symbol: **ER_WRONG_PARAMETERS_TO_PROCEDURE**; SQLSTATE: **HY000**
  Message: Incorrect parameters to procedure '%s'

• Error number: **1109**; Symbol: **ER_UNKNOWN_TABLE**; SQLSTATE: **42S02**
  Message: Unknown table '%s' in %s

• Error number: **1110**; Symbol: **ER_FIELD_SPECIFIED_TWICE**; SQLSTATE: **42000**
  Message: Column '%s' specified twice

• Error number: **1111**; Symbol: **ER_INVALID_GROUP_FUNC_USE**; SQLSTATE: **HY000**
  Message: Invalid use of group function

• Error number: **1112**; Symbol: **ER_UNSUPPORTED_EXTENSION**; SQLSTATE: **42000**
  Message: Table '%s' uses an extension that doesn't exist in this MySQL version

• Error number: **1113**; Symbol: **ER_TABLE_MUST_HAVE_COLUMNS**; SQLSTATE: **42000**
  Message: A table must have at least 1 column

• Error number: **1114**; Symbol: **ER_RECORD_FILE_FULL**; SQLSTATE: **HY000**
  Message: The table '%s' is full
  InnoDB reports this error when the system tablespace runs out of free space. Reconfigure the system tablespace to add a new data file.

• Error number: **1115**; Symbol: **ER_UNKNOWN_CHARACTER_SET**; SQLSTATE: **42000**
  Message: Unknown character set: '%s'

• Error number: **1116**; Symbol: **ER_TOO_MANY_TABLES**; SQLSTATE: **HY000**
  Message: Too many tables; MySQL can only use %d tables in a join

• Error number: **1117**; Symbol: **ER_TOO_MANY_FIELDS**; SQLSTATE: **HY000**
  Message: Too many columns

• Error number: **1118**; Symbol: **ER_TOO_BIG_ROWSIZE**; SQLSTATE: **42000**
  Message: Row size too large. The maximum row size for the used table type, not counting BLOBs, is %ld. This includes storage overhead, check the manual. You have to change some columns to TEXT or BLOBs

• Error number: **1119**; Symbol: **ER_STACK_OVERRUN**; SQLSTATE: **HY000**
  Message: Thread stack overrun: Used: %ld of a %ld stack. Use 'mysqld --thread_stack=#' to specify a bigger stack if needed

• Error number: **1120**; Symbol: **ER_WRONG_OUTER_JOIN**; SQLSTATE: **42000**
  Message: Cross dependency found in OUTER JOIN; examine your ON conditions

• Error number: **1121**; Symbol: **ER_NULL_COLUMN_IN_INDEX**; SQLSTATE: **42000**
Server Error Message Reference

Message: Table handler doesn't support NULL in given index. Please change column '%s' to be NOT NULL or use another handler

•   Error number: 1122; Symbol: ER_CANT_FIND_UDF; SQLSTATE: HY000
Message: Can't load function '%s'

•   Error number: 1123; Symbol: ER_CANT_INITIALIZE_UDF; SQLSTATE: HY000
Message: Can't initialize function '%s'; %s

•   Error number: 1124; Symbol: ER_UDF_NO_PATHS; SQLSTATE: HY000
Message: No paths allowed for shared library

•   Error number: 1125; Symbol: ER_UDF_EXISTS; SQLSTATE: HY000
Message: Function '%s' already exists

•   Error number: 1126; Symbol: ER_CANT_OPEN_LIBRARY; SQLSTATE: HY000
Message: Can't open shared library '%s' (errno: %d %s)

•   Error number: 1127; Symbol: ER_CANT_FIND_DL_ENTRY; SQLSTATE: HY000
Message: Can't find symbol '%s' in library

•   Error number: 1128; Symbol: ER_FUNCTION_NOT_DEFINED; SQLSTATE: HY000
Message: Function '%s' is not defined

•   Error number: 1129; Symbol: ER_HOST_IS_BLOCKED; SQLSTATE: HY000
Message: Host '%s' is blocked because of many connection errors; unblock with 'mysqladmin flush-hosts'

•   Error number: 1130; Symbol: ER_HOST_NOT_PRIVILEGED; SQLSTATE: HY000
Message: Host '%s' is not allowed to connect to this MySQL server

•   Error number: 1131; Symbol: ER_PASSWORD_ANONYMOUS_USER; SQLSTATE: 42000
Message: You are using MySQL as an anonymous user and anonymous users are not allowed to change passwords

•   Error number: 1132; Symbol: ER_PASSWORD_NOT_ALLOWED; SQLSTATE: 42000
Message: You must have privileges to update tables in the mysql database to be able to change passwords for others

•   Error number: 1133; Symbol: ER_PASSWORD_NO_MATCH; SQLSTATE: 42000
Message: Can't find any matching row in the user table

•   Error number: 1134; Symbol: ER_UPDATE_INFO; SQLSTATE: HY000
Message: Rows matched: %ld Changed: %ld Warnings: %ld

•   Error number: 1135; Symbol: ER_CANT_CREATE_THREAD; SQLSTATE: HY000
Message: Can't create a new thread (errno %d); if you are not out of available memory, you can consult the manual for a possible OS-dependent bug

- Error number: 1136; Symbol: ER_WRONG_VALUE_COUNT_ON_ROW; SQLSTATE: 21S01

Message: Column count doesn't match value count at row %ld

- Error number: 1137; Symbol: ER_CANT_REOPEN_TABLE; SQLSTATE: HY000

Message: Can't reopen table: '%%s'

- Error number: 1138; Symbol: ER_INVALID_USE_OF_NULL; SQLSTATE: 22004

Message: Invalid use of NULL value

- Error number: 1139; Symbol: ER_REGEXP_ERROR; SQLSTATE: 42000

Message: Got error '%%s' from regexp

- Error number: 1140; Symbol: ER_MIX_OF_GROUP_FUNC_AND_FIELDS; SQLSTATE: 42000

Message: Mixing of GROUP columns (MIN(),MAX(),COUNT(),...) with no GROUP columns is illegal if there is no GROUP BY clause

- Error number: 1141; Symbol: ER_NONEXISTING_GRANT; SQLSTATE: 42000

Message: There is no such grant defined for user '%%s' on host '%%s'

- Error number: 1142; Symbol: ER_TABLEACCESS_DENIED_ERROR; SQLSTATE: 42000

Message: %s command denied to user '%%s'@'%%s' for table '%%s'

- Error number: 1143; Symbol: ER_COLUMNACCESS_DENIED_ERROR; SQLSTATE: 42000

Message: %s command denied to user '%%s'@'%%s' for column '%%s' in table '%%s'

- Error number: 1144; Symbol: ER_ILLEGAL_GRANT_FOR_TABLE; SQLSTATE: 42000

Message: Illegal GRANT/REVOKE command; please consult the manual to see which privileges can be used

- Error number: 1145; Symbol: ER_GRANT_WRONG_HOST_OR_USER; SQLSTATE: 42000

Message: The host or user argument to GRANT is too long

- Error number: 1146; Symbol: ER_NO_SUCH_TABLE; SQLSTATE: 42S02

Message: Table '%%s.%%s' doesn't exist

- Error number: 1147; Symbol: ER_NONEXISTING_TABLE_GRANT; SQLSTATE: 42000

Message: There is no such grant defined for user '%%s' on host '%%s' on table '%%s'

- Error number: 1148; Symbol: ER_NOT_ALLOWED_COMMAND; SQLSTATE: 42000

Message: The used command is not allowed with this MySQL version

- Error number: 1149; Symbol: ER_SYNTAX_ERROR; SQLSTATE: 42000
Server Error Message Reference

Message: You have an error in your SQL syntax; check the manual that corresponds to your MySQL server version for the right syntax to use

- Error number: 1150; Symbol: ER_DELAYED_CANT_CHANGE_LOCK; SQLSTATE: HY000
  Message: Delayed insert thread couldn't get requested lock for table %s

- Error number: 1151; Symbol: ER_TOO_MANY_DELAYED_THREADS; SQLSTATE: HY000
  Message: Too many delayed threads in use

- Error number: 1152; Symbol: ER_ABORTING_CONNECTION; SQLSTATE: 08S01
  Message: Aborted connection %ld to db: '%s' user: '%s' (%s)

- Error number: 1153; Symbol: ER_NET_PACKET_TOO_LARGE; SQLSTATE: 08S01
  Message: Got a packet bigger than 'max_allowed_packet' bytes

- Error number: 1154; Symbol: ER_NET_READ_ERROR_FROM_PIPE; SQLSTATE: 08S01
  Message: Got a read error from the connection pipe

- Error number: 1155; Symbol: ER_NET_FCNTL_ERROR; SQLSTATE: 08S01
  Message: Got an error from fcntl()

- Error number: 1156; Symbol: ER_NET_PACKETS_OUT_OF_ORDER; SQLSTATE: 08S01
  Message: Got packets out of order

- **Error number:** 1204; **Symbol:** ER_SET_CONSTANTS_ONLY; **SQLSTATE:** HY000
  Message: You may only use constant expressions with SET

- **Error number:** 1205; **Symbol:** ER_LOCK_WAIT_TIMEOUT; **SQLSTATE:** HY000
  Message: Lock wait timeout exceeded; try restarting transaction

  *InnoDB* reports this error when lock wait timeout expires. The statement that waited too long was rolled back (not the entire transaction). You can increase the value of the `innodb_lock_wait_timeout` configuration option if SQL statements should wait longer for other transactions to complete, or decrease it if too many long-running transactions are causing locking problems and reducing concurrency on a busy system.

- **Error number:** 1206; **Symbol:** ER_LOCK_TABLE_FULL; **SQLSTATE:** HY000
  Message: The total number of locks exceeds the lock table size
InnoDB reports this error when the total number of locks exceeds the amount of memory devoted to managing locks. To avoid this error, increase the value of `innodb_buffer_pool_size`. Within an individual application, a workaround may be to break a large operation into smaller pieces. For example, if the error occurs for a large `INSERT`, perform several smaller `INSERT` operations.

- **Error number:** 1212; **Symbol:** `ER_UNION_TABLES_IN_DIFFERENT_DIR`; **SQLSTATE:** HY000
  Message: Incorrect table definition; all MERGE tables must be in the same database

- **Error number:** 1213; **Symbol:** `ER_LOCK_DEADLOCK`; **SQLSTATE:** 40001
  Message: Deadlock found when trying to get lock; try restarting transaction

  InnoDB reports this error when a transaction encounters a deadlock and is automatically rolled back so that your application can take corrective action. To recover from this error, run all the operations in this transaction again. A deadlock occurs when requests for locks arrive in inconsistent order between transactions. The transaction that was rolled back released all its locks, and the other transaction can now get all the locks it requested. Thus, when you re-run the transaction that was rolled back, it might have to wait for other transactions to complete, but typically the deadlock does not recur. If you encounter frequent deadlocks, make the sequence of locking operations (`LOCK TABLES`, `SELECT ... FOR UPDATE`, and so on) consistent between the different transactions or applications that experience the issue. See Section 14.7.5, “Deadlocks in InnoDB” for details.

- **Error number:** 1214; **Symbol:** `ER_TABLE_CANT_HANDLE_FT`; **SQLSTATE:** HY000
  Message: The used table type doesn't support FULLTEXT indexes

- **Error number:** 1215; **Symbol:** `ER_CANNOT_ADD_FOREIGN`; **SQLSTATE:** HY000
  Message: Cannot add foreign key constraint

- **Error number:** 1216; **Symbol:** `ER_NO_REFERENCED_ROW`; **SQLSTATE:** 23000
  Message: Cannot add or update a child row: a foreign key constraint fails

  InnoDB reports this error when you try to add a row but there is no parent row, and a foreign key constraint fails. Add the parent row first.
Server Error Message Reference

- Error number: 1217; Symbol: ER_ROW_IS_REFERENCED; SQLSTATE: 23000
  Message: Cannot delete or update a parent row: a foreign key constraint fails

  *InnoDB* reports this error when you try to delete a parent row that has children, and a foreign key constraint fails. Delete the children first.

• Error number: 1358; Symbol: ER_SP_GOTO_IN_HNDLR; SQLSTATE: HY000
  Message: GOTO is not allowed in a stored procedure handler
• Error number: 1359; Symbol: ER_TRG_ALREADY_EXISTS; SQLSTATE: HY000
  Message: Trigger already exists
• Error number: 1360; Symbol: ER_TRG_DOES_NOT_EXIST; SQLSTATE: HY000
  Message: Trigger does not exist
• Error number: 1361; Symbol: ER_TRG_ON_VIEW_OR_TEMP_TABLE; SQLSTATE: HY000
  Message: Trigger's '%s' is view or temporary table
• Error number: 1362; Symbol: ER_TRG_CANT_CHANGE_ROW; SQLSTATE: HY000
  Message: Updating of %s row is not allowed in %strigger
• Error number: 1363; Symbol: ER_TRG_NO_SUCH_ROW_IN_TRG; SQLSTATE: HY000
  Message: There is no %s row in %s trigger
• Error number: 1364; Symbol: ER_NO_DEFAULT_FOR_FIELD; SQLSTATE: HY000
  Message: Field '%s' doesn't have a default value
Server Error Message Reference

- Error number: 1365; Symbol: ER_DIVISION_BY_ZERO; SQLSTATE: 22012
  Message: Division by 0

- Error number: 1366; Symbol: ER_TRUNCATED_WRONG_VALUE_FOR_FIELD; SQLSTATE: HY000
  Message: Incorrect %s value: '%s' for column '%s' at row %ld

- Error number: 1367; Symbol: ER_ILLEGAL_VALUE_FOR_TYPE; SQLSTATE: 22007
  Message: Illegal %s '%s' value found during parsing

- Error number: 1368; Symbol: ER_VIEW_NONUPD_CHECK; SQLSTATE: HY000
  Message: CHECK OPTION on non-updatable view '%s.%s'

- Error number: 1369; Symbol: ER_VIEW_CHECK_FAILED; SQLSTATE: HY000
  Message: CHECK OPTION failed '%s.%s'

- Error number: 1370; Symbol: ER_PROCACCESS_DENIED_ERROR; SQLSTATE: 42000
  Message: %s command denied to user '%s'@'%s' for routine '%s'

- Error number: 1371; Symbol: ER_RELAY_LOG_FAIL; SQLSTATE: HY000
  Message: Failed purging old relay logs: %s

- Error number: 1372; Symbol: ER_PASSWD_LENGTH; SQLSTATE: HY000
  Message: Password hash should be a %d-digit hexadecimal number

- Error number: 1373; Symbol: ER_UNKNOWN_TARGET_BINLOG; SQLSTATE: HY000
  Message: Target log not found in binlog index

- Error number: 1374; Symbol: ER_IO_ERR_LOG_INDEX_READ; SQLSTATE: HY000
  Message: I/O error reading log index file

- Error number: 1375; Symbol: ER_BINLOG_PURGE_PROHIBITED; SQLSTATE: HY000
  Message: Server configuration does not permit binlog purge

- Error number: 1376; Symbol: ER_FSEEK_FAIL; SQLSTATE: HY000
  Message: Failed on fseek()

- Error number: 1377; Symbol: ER_BINLOG_PURGE_FATAL_ERR; SQLSTATE: HY000
  Message: Fatal error during log purge

- Error number: 1378; Symbol: ER_LOG_IN_USE; SQLSTATE: HY000
  Message: A purgeable log is in use, will not purge

- Error number: 1379; Symbol: ER_LOG_PURGE_UNKNOWN_ERR; SQLSTATE: HY000
  Message: Unknown error during log purge
• Error number: 1380; Symbol: ER_RELAY_LOG_INIT; SQLSTATE: HY000
  Message: Failed initializing relay log position: %s
• Error number: 1381; Symbol: ER_NO_BINARY_LOGGING; SQLSTATE: HY000
  Message: You are not using binary logging
• Error number: 1382; Symbol: ER_RESERVED_SYNTAX; SQLSTATE: HY000
  Message: The '%s' syntax is reserved for purposes internal to the MySQL server
• Error number: 1383; Symbol: ER_WSAS_FAILED; SQLSTATE: HY000
  Message: WSASStartup Failed
• Error number: 1384; Symbol: ER_DIFF_GROUPS_PROC; SQLSTATE: HY000
  Message: Can't handle procedures with different groups yet
• Error number: 1385; Symbol: ER_NO_GROUP_FOR_PROC; SQLSTATE: HY000
  Message: Select must have a group with this procedure
• Error number: 1386; Symbol: ER_ORDER_WITH_PROC; SQLSTATE: HY000
  Message: Can't use ORDER clause with this procedure
• Error number: 1387; Symbol: ER_LOGGING_PROHIBIT_CHANGING_OF; SQLSTATE: HY000
  Message: Binary logging and replication forbid changing the global server %s
• Error number: 1388; Symbol: ER_NO_FILE_MAPPING; SQLSTATE: HY000
  Message: Can't map file: %s, errno: %d
• Error number: 1389; Symbol: ER_WRONG_MAGIC; SQLSTATE: HY000
  Message: Wrong magic in %s
• Error number: 1390; Symbol: ER_PS_MANY_PARAM; SQLSTATE: HY000
  Message: Prepared statement contains too many placeholders
• Error number: 1391; Symbol: ER_KEY_PART_0; SQLSTATE: HY000
  Message: Key part '%s' length cannot be 0
• Error number: 1392; Symbol: ER_VIEW_CHECKSUM; SQLSTATE: HY000
  Message: View text checksum failed
• Error number: 1393; Symbol: ER_VIEW_MULTIUPDATE; SQLSTATE: HY000
  Message: Can not modify more than one base table through a join view '%s.%s'
• Error number: 1394; Symbol: ER_VIEW_NO_INSERT_FIELD_LIST; SQLSTATE: HY000
  Message: Can not insert into join view '%s.%s' without fields list
• Error number: 1395; Symbol: ER_VIEW_DELETE_MERGE_VIEW; SQLSTATE: HY000
Message: Can not delete from join view '%s.%s'
• Error number: 1396; Symbol: ER_CANNOT_USER; SQLSTATE: HY000
Message: Operation %s failed for %s
• Error number: 1397; Symbol: ER_XAER_NOTA; SQLSTATE: XAE04
Message: XAER_NOTA: Unknown XID
• Error number: 1398; Symbol: ER_XAER_INVAL; SQLSTATE: XAE05
Message: XAER_INVAL: Invalid arguments (or unsupported command)
• Error number: 1399; Symbol: ER_XAER_RMFAIL; SQLSTATE: XAE07
Message: XAER_RMFAIL: The command cannot be executed when global transaction is in the %s state
• Error number: 1400; Symbol: ER_XAER_OUTSIDE; SQLSTATE: XAE09
Message: XAER_OUTSIDE: Some work is done outside global transaction
• Error number: 1401; Symbol: ER_XAER_RMERR; SQLSTATE: XAE03
Message: XAER_RMERR: Fatal error occurred in the transaction branch - check your data for consistency
• Error number: 1402; Symbol: ER_XA_RBROLLBACK; SQLSTATE: XA100
Message: XA_RBROLLBACK: Transaction branch was rolled back
• Error number: 1403; Symbol: ER_NONEXISTING_PROC_GRANT; SQLSTATE: 42000
Message: There is no such grant defined for user '%s' on host '%s' on routine '%s'
• Error number: 1404; Symbol: ER_PROC_AUTO_GRANT_FAIL; SQLSTATE: HY000
Message: Failed to grant EXECUTE and ALTER ROUTINE privileges
• Error number: 1405; Symbol: ER_PROC_AUTO_REVOKE_FAIL; SQLSTATE: HY000
Message: Failed to revoke all privileges to dropped routine
• Error number: 1406; Symbol: ER_DATA_TOO_LONG; SQLSTATE: 22001
Message: Data too long for column '%s' at row %ld
• Error number: 1407; Symbol: ER_SP_BAD_SQLSTATE; SQLSTATE: 42000
Message: Bad SQLSTATE: '%s'
• Error number: 1408; Symbol: ER_STARTUP; SQLSTATE: HY000
Message: '%s': ready for connections. Version: '%s' socket: '%s' port: %d %s
• Error number: 1409; Symbol: ER_LOAD_FROM_FIXED_SIZE_ROWS_TO_VAR; SQLSTATE: HY000
Message: Can't load value from file with fixed size rows to variable
• Error number: 1410; Symbol: ER_CANT_CREATE_USER_WITH_GRANT; SQLSTATE: 42000
Message: You are not allowed to create a user with GRANT

- **Error number:** 1411; **Symbol:** ER_WRONG_VALUE_FOR_TYPE; **SQLSTATE:** HY000
  
  Message: Incorrect %s value: '%s' for function %s

- **Error number:** 1412; **Symbol:** ER_TABLE_DEF_CHANGED; **SQLSTATE:** HY000
  
  Message: Table definition has changed, please retry transaction

- **Error number:** 1413; **Symbol:** ER_SP_DUPLICATE_HANDLER; **SQLSTATE:** 42000
  
  Message: Duplicate handler declared in the same block

- **Error number:** 1414; **Symbol:** ER_SP_NOT_VAR_ARG; **SQLSTATE:** 42000
  
  Message: OUT or INOUT argument %d for routine %s is not a variable or NEW pseudo-variable in BEFORE trigger

- **Error number:** 1415; **Symbol:** ER_SP_NO_RETSET; **SQLSTATE:** 0A000
  
  Message: Not allowed to return a result set from a %s

- **Error number:** 1416; **Symbol:** ER_CANT_CREATE_GEOMETRY_OBJECT; **SQLSTATE:** 22003
  
  Message: Cannot get geometry object from data you send to the GEOMETRY field

- **Error number:** 1417; **Symbol:** ER_FAILED_ROUTINE_BREAK_BINLOG; **SQLSTATE:** HY000
  
  Message: A routine failed and has neither NO SQL nor READS SQL DATA in its declaration and binary logging is enabled; if non-transactional tables were updated, the binary log will miss their changes

- **Error number:** 1418; **Symbol:** ER_BINLOG_UNSAFE_ROUTINE; **SQLSTATE:** HY000
  
  Message: This function has none of DETERMINISTIC, NO SQL, or READS SQL DATA in its declaration and binary logging is enabled (you *might* want to use the less safe log_bin_trust_function_creators variable)

- **Error number:** 1419; **Symbol:** ER_BINLOG_CREATE_ROUTINE_NEED_SUPER; **SQLSTATE:** HY000
  
  Message: You do not have the SUPER privilege and binary logging is enabled (you *might* want to use the less safe log_bin_trust_function_creators variable)

- **Error number:** 1420; **Symbol:** ER_EXEC_STMT_WITH_OPEN_CURSOR; **SQLSTATE:** HY000
  
  Message: You can't execute a prepared statement which has an open cursor associated with it. Reset the statement to re-execute it.

- **Error number:** 1421; **Symbol:** ER_STMT_HAS_NO_OPEN_CURSOR; **SQLSTATE:** HY000
  
  Message: The statement (%lu) has no open cursor.

- **Error number:** 1422; **Symbol:** ER_COMMIT_NOT_ALLOWED_IN_SF_OR_TRG; **SQLSTATE:** HY000
  
  Message: Explicit or implicit commit is not allowed in stored function or trigger.

- **Error number:** 1423; **Symbol:** ER_NO_DEFAULT_FOR_VIEW_FIELD; **SQLSTATE:** HY000
  
  Message: Field of view '%s.%s' underlying table doesn't have a default value
• Error number: 1424; Symbol: ER_SP_NO_RECURSION; SQLSTATE: HY000
Message: Recursive stored functions and triggers are not allowed.

• Error number: 1425; Symbol: ER_TOO_BIG_SCALE; SQLSTATE: 42000
Message: Too big scale %d specified for column '%s'. Maximum is %lu.

• Error number: 1426; Symbol: ER_TOO_BIG_PRECISION; SQLSTATE: 42000
Message: Too big precision %d specified for column '%s'. Maximum is %lu.

• Error number: 1427; Symbol: ER_M_BIGGER_THAN_D; SQLSTATE: 42000
Message: For float(M,D), double(M,D) or decimal(M,D), M must be >= D (column '%s').

• Error number: 1428; Symbol: ER_WRONG_LOCK_OF_SYSTEM_TABLE; SQLSTATE: HY000
Message: You can't combine write-locking of system tables with other tables or lock types.

• Error number: 1429; Symbol: ER_CONNECT_TO_FOREIGN_DATA_SOURCE; SQLSTATE: HY000
Message: Unable to connect to foreign data source: %s

• Error number: 1430; Symbol: ER_QUERY_ON_FOREIGN_DATA_SOURCE; SQLSTATE: HY000
Message: There was a problem processing the query on the foreign data source. Data source error: %s

• Error number: 1431; Symbol: ER_FOREIGN_DATA_SOURCE_DOESNT_EXIST; SQLSTATE: HY000
Message: The foreign data source you are trying to reference does not exist. Data source error: %s

• Error number: 1432; Symbol: ER_FOREIGN_DATA_STRING_INVALID_CANT_CREATE; SQLSTATE: HY000
Message: Can't create federated table. The data source connection string '%s' is not in the correct format

• Error number: 1433; Symbol: ER_FOREIGN_DATA_STRING_INVALID; SQLSTATE: HY000
Message: The data source connection string '%s' is not in the correct format

• Error number: 1434; Symbol: ER_CANT_CREATE_FEDERATED_TABLE; SQLSTATE: HY000
Message: Can't create federated table. Foreign data src error: %s

• Error number: 1435; Symbol: ER_TRG_IN_WRONG_SCHEMA; SQLSTATE: HY000
Message: Trigger in wrong schema

• Error number: 1436; Symbol: ER_STACK_OVERRUN_NEED_MORE; SQLSTATE: HY000
Message: Thread stack overrun: %ld bytes used of a %ld byte stack, and %ld bytes needed. Use 'mysqld --thread_stack=#' to specify a bigger stack.

• Error number: 1437; Symbol: ER_TOO_LONG_BODY; SQLSTATE: 42000
Message: Routine body for '%s' is too long

• Error number: 1438; Symbol: ER_WARN_CANT_DROP_DEFAULT_KEYCACHE; SQLSTATE: HY000
Message: Cannot drop default keycache
- Error number: 1439; Symbol: ER_TOO_BIG_DISPLAYWIDTH; SQLSTATE: 42000
  Message: Display width out of range for column '%s' (max = %lu)
- Error number: 1440; Symbol: ER_XAER_DUPLICATED; SQLSTATE: XAE08
  Message: XAER_DUPLICATED: The XID already exists
- Error number: 1441; Symbol: ER_DATETIME_FUNCTION_OVERFLOW; SQLSTATE: 22008
  Message: Datetime function: %s field overflow
- Error number: 1442; Symbol: ER_CANT_UPDATE_USED_TABLE_IN_SF_OR_TRG; SQLSTATE: HY000
  Message: Can't update table '%s' in stored function/trigger because it is already used by statement which invoked this stored function/trigger.
- Error number: 1443; Symbol: ER_VIEW_PREVENT_UPDATE; SQLSTATE: HY000
  Message: The definition of table '%s' prevents operation %s on table '%s'.
- Error number: 1444; Symbol: ER_PS_NO_RECURSION; SQLSTATE: HY000
  Message: The prepared statement contains a stored routine call that refers to that same statement. It's not allowed to execute a prepared statement in such a recursive manner
- Error number: 1445; Symbol: ER_SP_CANT_SET_AUTOCOMMIT; SQLSTATE: HY000
  Message: Not allowed to set autocommit from a stored function or trigger
- Error number: 1446; Symbol: ER_MALFORMED_DEFINER; SQLSTATE: HY000
  Message: Definer is not fully qualified
- Error number: 1447; Symbol: ER_VIEW_FRM_NO_USER; SQLSTATE: HY000
  Message: View '%s'.'%s' has no definer information (old table format). Current user is used as definer. Please recreate the view!
- Error number: 1448; Symbol: ER_VIEW_OTHER_USER; SQLSTATE: HY000
  Message: You need the SUPER privilege for creation view with '%s'@'%s' definer
- Error number: 1449; Symbol: ER_NO_SUCH_USER; SQLSTATE: HY000
  Message: The user specified as a definer ('%s'@'%s') does not exist
- Error number: 1450; Symbol: ER_FORBID_SCHEMA_CHANGE; SQLSTATE: HY000
  Message: Changing schema from '%s' to '%s' is not allowed.
- Error number: 1451; Symbol: ER_ROW_IS_REFERENCED_2; SQLSTATE: 23000
  Message: Cannot delete or update a parent row: a foreign key constraint fails (%s)

*InnoDB* reports this error when you try to delete a parent row that has children, and a foreign key constraint fails. Delete the children first.
• Error number: 1452; Symbol: ER_NO_REFERENCED_ROW_2; SQLSTATE: 23000
Message: Cannot add or update a child row: a foreign key constraint fails (%s)
InnoDB reports this error when you try to add a row but there is no parent row, and a foreign key constraint fails. Add the parent row first.

• Error number: 1453; Symbol: ER_SP_BAD_VAR_SHADOW; SQLSTATE: 42000
Message: Variable '%s' must be quoted with `...`, or renamed

• Error number: 1454; Symbol: ER_TRG_NO_DEFINER; SQLSTATE: HY000
Message: No definer attribute for trigger '%s'.'%s'. The trigger will be activated under the authorization of the invoker, which may have insufficient privileges. Please recreate the trigger.

• Error number: 1455; Symbol: ER_OLD_FILE_FORMAT; SQLSTATE: HY000
Message: '%s' has an old format, you should re-create the '%s' object(s)

• Error number: 1456; Symbol: ER_SP_RECURSION_LIMIT; SQLSTATE: HY000
Message: Recursive limit %d (as set by the max_sp_recursion_depth variable) was exceeded for routine %s

• Error number: 1457; Symbol: ER_SP_PROC_TABLE_CORRUPT; SQLSTATE: HY000
Message: Failed to load routine %s. The table mysql.proc is missing, corrupt, or contains bad data (internal code %d)

• Error number: 1458; Symbol: ER_SP_WRONG_NAME; SQLSTATE: 42000
Message: Incorrect routine name '%s'

• Error number: 1459; Symbol: ER_TABLE_NEEDS_UPGRADE; SQLSTATE: HY000
Message: Table upgrade required. Please do "REPAIR TABLE `%s`" or dump/reload to fix it!

• Error number: 1460; Symbol: ER_SP_NO_AGGREGATE; SQLSTATE: 42000
Message: AGGREGATE is not supported for stored functions

• Error number: 1461; Symbol: ER_MAX_PREPARED_STMT_COUNT_REACHED; SQLSTATE: 42000
Message: Can’t create more than max_prepared_stmt_count statements (current value: %lu)

• Error number: 1462; Symbol: ER_VIEW_RECURSIVE; SQLSTATE: HY000
Message: `%s`.'%s` contains view recursion

• Error number: 1463; Symbol: ER_NON_GROUPING_FIELD_USED; SQLSTATE: 42000
Message: Non-grouping field '%s' is used in %s clause

• Error number: 1464; Symbol: ER_TABLE_CANT_HANDLE_SPKEYS; SQLSTATE: HY000
Message: The used table type doesn't support SPATIAL indexes

• Error number: 1465; Symbol: ER_NO_TRIGGERS_ON_SYSTEM_SCHEMA; SQLSTATE: HY000
Message: Triggers can not be created on system tables
• Error number: 1466; Symbol: ER_REMOVED_SPACES; SQLSTATE: HY000
  Message: Leading spaces are removed from name '%s'
• Error number: 1467; Symbol: ER_AUTOINC_READ FAILED; SQLSTATE: HY000
  Message: Failed to read auto-increment value from storage engine
• Error number: 1468; Symbol: ER_USERNAME; SQLSTATE: HY000
  Message: user name
• Error number: 1469; Symbol: ER_HOSTNAME; SQLSTATE: HY000
  Message: host name
• Error number: 1470; Symbol: ER_WRONG_STRING_LENGTH; SQLSTATE: HY000
  Message: String '%s' is too long for %s (should be no longer than %d)
• Error number: 1471; Symbol: ER_NON_INSERTABLE_TABLE; SQLSTATE: HY000
  Message: The target table %s of the %s is not insertable-into
• Error number: 1472; Symbol: ER_ADMIN_WRONG_MRG_TABLE; SQLSTATE: HY000
  Message: Table '%s' is differently defined or of non-MyISAM type or doesn't exist
• Error number: 1473; Symbol: ER_TOO_HIGH_LEVEL_OF_NESTING_FOR_SELECT; SQLSTATE: HY000
  Message: Too high level of nesting for select
• Error number: 1474; Symbol: ER_NAME_BECOMES_EMPTY; SQLSTATE: HY000
  Message: Name '%s' has become "
• Error number: 1475; Symbol: ER_AMBIGUOUS_FIELD_TERM; SQLSTATE: HY000

Message: Same old and new event name

Error number: 1552; Symbol: ER_EVENT_DATA_TOO_LONG; SQLSTATE: HY000
Message: Data for column '%s' too long

•   Error number: 1553; Symbol: ER_DROP_INDEX_FK; SQLSTATE: HY000
Message: Cannot drop index '%s': needed in a foreign key constraint

InnoDB reports this error when you attempt to drop the last index that can enforce a particular referential constraint.

For optimal performance with DML statements, InnoDB requires an index to exist on foreign key columns, so that UPDATE and DELETE operations on a parent table can easily check whether corresponding rows exist in the child table. MySQL creates or drops such indexes automatically when needed, as a side-effect of CREATE_TABLE, CREATE_INDEX, and ALTER_TABLE statements.

When you drop an index, InnoDB checks if the index is used for checking a foreign key constraint. It is still OK to drop the index if there is another index that can be used to enforce the same constraint. InnoDB prevents you from dropping the last index that can enforce a particular referential constraint.

•   Error number: 1554; Symbol: ER_WARN_DEPRECATED_SYNTAX_WITH_VER; SQLSTATE: HY000
Message: The syntax '%s' is deprecated and will be removed in MySQL %. Please use %s instead

•   Error number: 1555; Symbol: ER_CANT_WRITE_LOCK_LOG_TABLE; SQLSTATE: HY000
Message: You can't write-lock a log table. Only read access is possible

•   Error number: 1556; Symbol: ER_CANT_LOCK_LOG_TABLE; SQLSTATE: HY000
Message: You can’t use locks with log tables.

•   Error number: 1557; Symbol: ER_FOREIGN_DUPLICATE_KEY; SQLSTATE: 23000
Message: Upholding foreign key constraints for table '%s', entry '%s', key %d would lead to a duplicate entry

In 5.6.4: ER_FOREIGN_DUPLICATE_KEY was renamed to ER_FOREIGN_DUPLICATE_KEY_OLD_UNUSED.

ER_FOREIGN_DUPLICATE_KEY was removed after 5.6.3.

•   Error number: 1557; Symbol: ER_FOREIGN_DUPLICATE_KEY_OLD_UNUSED; SQLSTATE: 23000
Message: Upholding foreign key constraints for table '%s', entry '%s', key %d would lead to a duplicate entry

In 5.6.4: ER_FOREIGN_DUPLICATE_KEY was renamed to ER_FOREIGN_DUPLICATE_KEY_OLD_UNUSED.

ER_FOREIGN_DUPLICATE_KEY_OLD_UNUSED was added in 5.6.4.

•   Error number: 1558; Symbol: ER_COL_COUNT_DOESNT_MATCH_PLEASE_UPDATE; SQLSTATE: HY000
Message: Column count of mysql.%s is wrong. Expected %d, found %d. Created with MySQL %d, now running %d. Please use mysql_upgrade to fix this error.

- Error number: 1657; Symbol: ER_TOO_MANY_VALUES_ERROR; SQLSTATE: HY000
  Message: Cannot have more than one value for this type of %s partitioning
Server Error Message Reference

- Error number: 1658; Symbol: ER_ROW_SINGLE_PARTITION_FIELD_ERROR; SQLSTATE: HY000
  Message: Row expressions in VALUES IN only allowed for multi-field column partitioning

- Error number: 1659; Symbol: ER_FIELD_TYPE_NOT_ALLOWED_AS_PARTITION_FIELD; SQLSTATE: HY000
  Message: Field '%s' is of a not allowed type for this type of partitioning

- Error number: 1660; Symbol: ER_PARTITION_FIELDS_TOO_LONG; SQLSTATE: HY000
  Message: The total length of the partitioning fields is too large

- Error number: 1661; Symbol: ER_BINLOG_ROW_ENGINE_AND_STMT_ENGINE; SQLSTATE: HY000
  Message: Cannot execute statement: impossible to write to binary log since both row-incapable engines and statement-incapable engines are involved.

- Error number: 1662; Symbol: ER_BINLOG_ROW_MODE_AND_STMT_ENGINE; SQLSTATE: HY000
  Message: Cannot execute statement: impossible to write to binary log since BINLOG_FORMAT = ROW and at least one table uses a storage engine limited to statement-based logging.

- Error number: 1663; Symbol: ER_BINLOG_UNSAFE_AND_STMT_ENGINE; SQLSTATE: HY000
  Message: Cannot execute statement: impossible to write to binary log since statement is unsafe, storage engine is limited to statement-based logging, and BINLOG_FORMAT = MIXED. %s

- Error number: 1664; Symbol: ER_BINLOG_ROW_INJECTION_AND_STMT_ENGINE; SQLSTATE: HY000
  Message: Cannot execute statement: impossible to write to binary log since statement is in row format and at least one table uses a storage engine limited to statement-based logging.

- Error number: 1665; Symbol: ER_BINLOG_STMT_MODE_AND_ROW_ENGINE; SQLSTATE: HY000
  Message: Cannot execute statement: impossible to write to binary log since BINLOG_FORMAT = STATEMENT and at least one table uses a storage engine limited to row-based logging.%s

- Error number: 1666; Symbol: ER_BINLOG_ROW_INJECTION_AND_STMT_MODE; SQLSTATE: HY000
  Message: Cannot execute statement: impossible to write to binary log since statement is in row format and BINLOG_FORMAT = STATEMENT.

- Error number: 1667; Symbol: ER_BINLOG_MULTIPLE_ENGINES_AND_SELF_LOGGING_ENGINE; SQLSTATE: HY000
  Message: Cannot execute statement: impossible to write to binary log since more than one engine is involved and at least one engine is self-logging.

- Error number: 1668; Symbol: ER_BINLOG_UNSAFE_LIMIT; SQLSTATE: HY000
  Message: The statement is unsafe because it uses a LIMIT clause. This is unsafe because the set of rows included cannot be predicted.

- Error number: 1669; Symbol: ER_BINLOG_UNSAFE_INSERT_DELAYED; SQLSTATE: HY000
  Message: The statement is unsafe because it uses INSERT DELAYED. This is unsafe because the times when rows are inserted cannot be predicted.
• Error number: 1670; Symbol: `ER_BINLOG_UNSAFE_SYSTEM_TABLE`; SQLSTATE: HY000
Message: The statement is unsafe because it uses the general log, slow query log, or performance_schema table(s). This is unsafe because system tables may differ on slaves.

• Error number: 1671; Symbol: `ER_BINLOG_UNSAFE_AUTOINC_COLUMNS`; SQLSTATE: HY000
Message: Statement is unsafe because it invokes a trigger or a stored function that inserts into an AUTO_INCREMENT column. Inserted values cannot be logged correctly.

• Error number: 1672; Symbol: `ER_BINLOG_UNSAFE_UDF`; SQLSTATE: HY000
Message: Statement is unsafe because it uses a UDF which may not return the same value on the slave.

• Error number: 1673; Symbol: `ER_BINLOG_UNSAFE_SYSTEM_VARIABLE`; SQLSTATE: HY000
Message: Statement is unsafe because it uses a system variable that may have a different value on the slave.

• Error number: 1674; Symbol: `ER_BINLOG_UNSAFE_SYSTEM_FUNCTION`; SQLSTATE: HY000
Message: Statement is unsafe because it uses a system function that may return a different value on the slave.

• Error number: 1675; Symbol: `ER_BINLOG_UNSAFE_NONTRANS_AFTER_TRANS`; SQLSTATE: HY000
Message: Statement is unsafe because it accesses a non-transactional table after accessing a transactional table within the same transaction.

• Error number: 1676; Symbol: `ER_MESSAGE_AND_STATEMENT`; SQLSTATE: HY000
Message: %s Statement: %s

• Error number: 1677; Symbol: `ER_SLAVE_CONVERSION_FAILED`; SQLSTATE: HY000
Message: Column %d of table '%s.%s' cannot be converted from type '%s' to type '%s'

• Error number: 1678; Symbol: `ER_SLAVE_CANT_CREATE_CONVERSION`; SQLSTATE: HY000
Message: Can't create conversion table for table '%s.%s'

• Error number: 1679; Symbol: `ER_INSIDE_TRANSACTION_PREVENTS_SWITCH_BINLOG_FORMAT`; SQLSTATE: HY000
Message: Cannot modify @@session.binlog_format inside a transaction

• Error number: 1680; Symbol: `ER_PATH_LENGTH`; SQLSTATE: HY000
Message: The path specified for %s is too long.

• Error number: 1681; Symbol: `ER_WARN_DEPRECATED_SYNTAX_NO_REPLACEMENT`; SQLSTATE: HY000
Message: '%s' is deprecated and will be removed in a future release.

• Error number: 1682; Symbol: `ER_WRONG_NATIVE_TABLE_STRUCTURE`; SQLSTATE: HY000
Message: Native table '%s.%s' has the wrong structure
Server Error Message Reference

- **Error number:** 1683; **Symbol:** ER_WRONG_PERFSHEMA_USAGE; **SQLSTATE:** HY000
  Message: Invalid performance_schema usage.

- **Error number: 1697; Symbol: ER_VALUES_IS_NOT_INT_TYPE_ERROR; SQLSTATE: HY000**
  Message: VALUES value for partition '%s' must have type INT

  
  **ER_VALUES_IS_NOT_INT_TYPE_ERROR** was added in 5.6.1.

- **Error number: 1698; Symbol: ER_ACCESS_DENIED_NO_PASSWORD_ERROR; SQLSTATE: 28000**
  Message: Access denied for user '%s'@'%s'

  
  **ER_ACCESS_DENIED_NO_PASSWORD_ERROR** was added in 5.6.1.

- **Error number: 1699; Symbol: ER_SET_PASSWORD_AUTH_PLUGIN; SQLSTATE: HY000**
  Message: SET PASSWORD has no significance for users authenticating via plugins

  
  **ER_SET_PASSWORD_AUTH_PLUGIN** was added in 5.6.1.

- **Error number: 1700; Symbol: ER_GRANT_PLUGIN_USER_EXISTS; SQLSTATE: HY000**
  Message: GRANT with IDENTIFIED WITH is illegal because the user %s already exists

  
  **ER_GRANT_PLUGIN_USER_EXISTS** was added in 5.6.1.

- **Error number: 1701; Symbol: ER_TRUNCATE_ILLEGAL_FK; SQLSTATE: 42000**
  Message: Cannot truncate a table referenced in a foreign key constraint (%s)

  
  **ER_TRUNCATE_ILLEGAL_FK** was added in 5.6.1.

- **Error number: 1702; Symbol: ER_PLUGIN_IS_PERMANENT; SQLSTATE: HY000**
  Message: Plugin '%s' is force_plus_permanent and can not be unloaded

  
  **ER_PLUGIN_IS_PERMANENT** was added in 5.6.1.

- **Error number: 1703; Symbol: ER_SLAVE_HEARTBEAT_VALUE_OUT_OF_RANGE_MIN; SQLSTATE: HY000**
  Message: The requested value for the heartbeat period is less than 1 millisecond. The value is reset to 0, meaning that heartbeating will effectively be disabled.

  
  **ER_SLAVE_HEARTBEAT_VALUE_OUT_OF_RANGE_MIN** was added in 5.6.1.

- **Error number: 1704; Symbol: ER_SLAVE_HEARTBEAT_VALUE_OUT_OF_RANGE_MAX; SQLSTATE: HY000**
  Message: The requested value for the heartbeat period exceeds the value of `slave_net_timeout` seconds. A sensible value for the period should be less than the timeout.

  
  **ER_SLAVE_HEARTBEAT_VALUE_OUT_OF_RANGE_MAX** was added in 5.6.1.

- **Error number: 1705; Symbol: ER_STMT_CACHE_FULL; SQLSTATE: HY000**
  Message: Multi-row statements required more than `max_binlog_stmt_cache_size` bytes of storage; increase this mysqld variable and try again
**ER_STMT_CACHE_FULL** was added in 5.6.1.

- Error number: 1706; Symbol: **ER_MULTI_UPDATE_KEY_CONFLICT**; SQLSTATE: HY000
  
  Message: Primary key/partition key update is not allowed since the table is updated both as ‘%s’ and ‘%s’.

  **ER_MULTI_UPDATE_KEY_CONFLICT** was added in 5.6.2.

- Error number: 1707; Symbol: **ER_TABLE_NEEDS_REBUILD**; SQLSTATE: HY000
  
  Message: Table rebuild required. Please do "ALTER TABLE `%s` FORCE" or dump/reload to fix it!

  **ER_TABLE_NEEDS_REBUILD** was added in 5.6.3.

- Error number: 1708; Symbol: **WARN_OPTION_BELOW_LIMIT**; SQLSTATE: HY000
  
  Message: The value of ‘%s’ should be no less than the value of ‘%s’

  **WARN_OPTION_BELOW_LIMIT** was added in 5.6.3.

- Error number: 1709; Symbol: **ER_INDEX_COLUMN_TOO_LONG**; SQLSTATE: HY000
  
  Message: Index column size too large. The maximum column size is %lu bytes.

  **ER_INDEX_COLUMN_TOO_LONG** was added in 5.6.3.

- Error number: 1710; Symbol: **ER_ERROR_IN_TRIGGER_BODY**; SQLSTATE: HY000
  
  Message: Trigger ‘%s’ has an error in its body: ‘%s’

  **ER_ERROR_IN_TRIGGER_BODY** was added in 5.6.3.

- Error number: 1711; Symbol: **ER_ERROR_IN_UNKNOWN_TRIGGER_BODY**; SQLSTATE: HY000
  
  Message: Unknown trigger has an error in its body: ‘%s’

  **ER_ERROR_IN_UNKNOWN_TRIGGER_BODY** was added in 5.6.3.

- Error number: 1712; Symbol: **ER_INDEX_CORRUPT**; SQLSTATE: HY000
  
  Message: Index ‘%s’ is corrupted

  **ER_INDEX_CORRUPT** was added in 5.6.3.

- Error number: 1713; Symbol: **ER_UNDO_RECORD_TOO_BIG**; SQLSTATE: HY000
  
  Message: Undo log record is too big.

  **ER_UNDO_RECORD_TOO_BIG** was added in 5.6.4.

- Error number: 1714; Symbol: **ER_BINLOG_UNSAFE_INSERT_IGNORE_SELECT**; SQLSTATE: HY000
  
  Message: INSERT IGNORE... SELECT is unsafe because the order in which rows are retrieved by the SELECT determines which (if any) rows are ignored. This order cannot be predicted and may differ on master and the slave.

  **ER_BINLOG_UNSAFE_INSERT_IGNORE_SELECT** was added in 5.6.4.
• Error number: 1715; Symbol: ER_BINLOG_UNSAFE_INSERT_SELECT_UPDATE; SQLSTATE: HY000
Message: INSERT... SELECT... ON DUPLICATE KEY UPDATE is unsafe because the order in which rows are retrieved by the SELECT determines which (if any) rows are updated. This order cannot be predicted and may differ on master and the slave.
ER_BINLOG_UNSAFE_INSERT_SELECT_UPDATE was added in 5.6.4.

• Error number: 1716; Symbol: ER_BINLOG_UNSAFE_REPLACE_SELECT; SQLSTATE: HY000
Message: REPLACE... SELECT is unsafe because the order in which rows are retrieved by the SELECT determines which (if any) rows are replaced. This order cannot be predicted and may differ on master and the slave.
ER_BINLOG_UNSAFE_REPLACE_SELECT was added in 5.6.4.

• Error number: 1717; Symbol: ER_BINLOG_UNSAFE_CREATE_IGNORE_SELECT; SQLSTATE: HY000
Message: CREATE... IGNORE SELECT is unsafe because the order in which rows are retrieved by the SELECT determines which (if any) rows are ignored. This order cannot be predicted and may differ on master and the slave.
ER_BINLOG_UNSAFE_CREATE_IGNORE_SELECT was added in 5.6.4.

• Error number: 1718; Symbol: ER_BINLOG_UNSAFE_CREATE_REPLACE_SELECT; SQLSTATE: HY000
Message: CREATE... REPLACE SELECT is unsafe because the order in which rows are retrieved by the SELECT determines which (if any) rows are replaced. This order cannot be predicted and may differ on master and the slave.
ER_BINLOG_UNSAFE_CREATE_REPLACE_SELECT was added in 5.6.4.

• Error number: 1719; Symbol: ER_BINLOG_UNSAFE_UPDATE_IGNORE; SQLSTATE: HY000
Message: UPDATE IGNORE is unsafe because the order in which rows are updated determines which (if any) rows are ignored. This order cannot be predicted and may differ on master and the slave.
ER_BINLOG_UNSAFE_UPDATE_IGNORE was added in 5.6.4.

• Error number: 1720; Symbol: ER_PLUGIN_NO_UNINSTALL; SQLSTATE: HY000
Message: Plugin ‘%s’ is marked as not dynamically uninstallable. You have to stop the server to uninstall it.
ER_PLUGIN_NO_UNINSTALL was added in 5.6.4.

• Error number: 1721; Symbol: ER_CANT_LOCK_RPL_INFO_TABLE; SQLSTATE: HY000
Message: You can't use locks with rpl info tables.
ER_CANT_LOCK_RPL_INFO_TABLE was added in 5.6.1, removed after 5.6.3.

• Error number: 1721; Symbol: ER_PLUGIN_NO_INSTALL; SQLSTATE: HY000
Message: Plugin ‘%s’ is marked as not dynamically installable. You have to stop the server to install it.
ER_PLUGIN_NO_INSTALL was added in 5.6.4.

• Error number: 1722; Symbol: ER_BINLOG_UNSAFE_WRITE_AUTOINC_SELECT; SQLSTATE: HY000
Message: Statements writing to a table with an auto-increment column after selecting from another table are unsafe because the order in which rows are retrieved determines what (if any) rows will be written. This order cannot be predicted and may differ on master and the slave.

`ER_BINLOG_UNSAFE_WRITE_AUTOINC_SELECT` was added in 5.6.5.

- Error number: 1723; Symbol: `ER_BINLOG_UNSAFE_CREATE_SELECT_AUTOINC`; SQLSTATE: HY000

Message: CREATE TABLE... SELECT... on a table with an auto-increment column is unsafe because the order in which rows are retrieved by the SELECT determines which (if any) rows are inserted. This order cannot be predicted and may differ on master and the slave.

`ER_BINLOG_UNSAFE_CREATE_SELECT_AUTOINC` was added in 5.6.5.

- Error number: 1724; Symbol: `ER_BINLOG_UNSAFE_INSERT_TWO_KEYS`; SQLSTATE: HY000

Message: INSERT... ON DUPLICATE KEY UPDATE on a table with more than one UNIQUE KEY is unsafe

`ER_BINLOG_UNSAFE_INSERT_TWO_KEYS` was added in 5.6.6.

- Error number: 1725; Symbol: `ER_TABLE_IN_FK_CHECK`; SQLSTATE: HY000

Message: Table is being used in foreign key check.

`ER_TABLE_IN_FK_CHECK` was added in 5.6.6.

- Error number: 1726; Symbol: `ER_UNSUPPORTED_ENGINE`; SQLSTATE: HY000

Message: Storage engine '%s' does not support system tables. [%s.%s]

`ER_UNSUPPORTED_ENGINE` was added in 5.6.6.

- Error number: 1727; Symbol: `ER_BINLOG_UNSAFE_AUTOINC_NOT_FIRST`; SQLSTATE: HY000

Message: INSERT into autoincrement field which is not the first part in the composed primary key is unsafe.

`ER_BINLOG_UNSAFE_AUTOINC_NOT_FIRST` was added in 5.6.6.

- Error number: 1728; Symbol: `ER_CANNOT_LOAD_FROM_TABLE_V2`; SQLSTATE: HY000

Message: Cannot load from %s.%s. The table is probably corrupted

- Error number: 1729; Symbol: `ER_MASTER_DELAY_VALUE_OUT_OF_RANGE`; SQLSTATE: HY000

Message: The requested value %s for the master delay exceeds the maximum %u

- Error number: 1730; Symbol: `ER_ONLY_FD_AND_RBR_EVENTS_ALLOWED_IN_BINLOG_STATEMENT`; SQLSTATE: HY000

Message: Only Format_description_log_event and row events are allowed in BINLOG statements (but %s was provided)

- Error number: 1731; Symbol: `ER_PARTITION_EXCHANGE_DIFFERENT_OPTION`; SQLSTATE: HY000

Message: Non matching attribute '%s' between partition and table

- Error number: 1732; Symbol: `ER_PARTITION_EXCHANGE_PART_TABLE`; SQLSTATE: HY000
Message: Table to exchange with partition is partitioned: '%s'
•   Error number: 1733; Symbol: ER_PARTITION_EXCHANGE_TEMP_TABLE; SQLSTATE: HY000
Message: Table to exchange with partition is temporary: '%s'
•   Error number: 1734; Symbol: ER_PARTITION_INSTEAD_OF_SUBPARTITION; SQLSTATE: HY000
Message: Subpartitioned table, use subpartition instead of partition
•   Error number: 1735; Symbol: ER_UNKNOWN_PARTITION; SQLSTATE: HY000
Message: Unknown partition '%s' in table '%s'
•   Error number: 1736; Symbol: ER_TABLES_DIFFERENT_METADATA; SQLSTATE: HY000
Message: Tables have different definitions
•   Error number: 1737; Symbol: ER_ROW_DOES_NOT_MATCH_PARTITION; SQLSTATE: HY000
Message: Found a row that does not match the partition
•   Error number: 1738; Symbol: ER_BINLOG_CACHE_SIZE_GREATER_THAN_MAX; SQLSTATE: HY000
Message: Option binlog_cache_size (%lu) is greater than max_binlog_cache_size (%lu); setting binlog_cache_size equal to max_binlog_cache_size.
   ER_BINLOG_CACHE_SIZE_GREATER_THAN_MAX was added in 5.6.1.
•   Error number: 1739; Symbol: ER_WARN_INDEX_NOT_APPLICABLE; SQLSTATE: HY000
Message: Cannot use %s access on index '%s' due to type or collation conversion on field '%s'
   ER_WARN_INDEX_NOT_APPLICABLE was added in 5.6.1.
•   Error number: 1740; Symbol: ER_PARTITION_EXCHANGE_FOREIGN_KEY; SQLSTATE: HY000
Message: Table to exchange with partition has foreign key references: '%s'
   ER_PARTITION_EXCHANGE_FOREIGN_KEY was added in 5.6.1.
•   Error number: 1741; Symbol: ER_NO_SUCH_KEY_VALUE; SQLSTATE: HY000
Message: Key value '%s' was not found in table '%s.%s'
   ER_NO_SUCH_KEY_VALUE was added in 5.6.1.
•   Error number: 1742; Symbol: ER_RPL_INFO_DATA_TOO_LONG; SQLSTATE: HY000
Message: Data for column '%s' too long
   ER_RPL_INFO_DATA_TOO_LONG was added in 5.6.1.
•   Error number: 1743; Symbol: ER_NETWORK_READ_EVENT_CHECKSUM_FAILURE; SQLSTATE: HY000
Message: Replication event checksum verification failed while reading from network.
   ERNETWORK_READ_EVENT_CHECKSUM_FAILURE was added in 5.6.1.
•   Error number: 1744; Symbol: ER_BINLOG_READ_EVENT_CHECKSUM_FAILURE; SQLSTATE: HY000
Message: Replication event checksum verification failed while reading from a log file.

ER_BINLOG_READ_EVENT_CHECKSUM_FAILURE was added in 5.6.1.

- Error number: 1745; Symbol: ER_BINLOG_STMT_CACHE_SIZE_GREATER_THAN_MAX; SQLSTATE: HY000

Message: Option binlog_stmt_cache_size (%lu) is greater than max_binlog_stmt_cache_size (%lu); setting binlog_stmt_cache_size equal to max_binlog_stmt_cache_size.

ER_BINLOG_STMT_CACHE_SIZE_GREATER_THAN_MAX was added in 5.6.1.

- Error number: 1746; Symbol: ER_NO_SUCH_PARTITION; SQLSTATE: HY000

Message: partition '%s' doesn't exist

ER_NO_SUCH_PARTITION was added in 5.6.2, removed after 5.6.5.

- Error number: 1746; Symbol: ER_CANT_UPDATE_TABLE_IN_CREATE_TABLE_SELECT; SQLSTATE: HY000

Message: Can't update table '%s' while '%s' is being created.

ER_CANT_UPDATE_TABLE_IN_CREATE_TABLE_SELECT was added in 5.6.2.

- Error number: 1747; Symbol: ER_PARTITION_CLAUSE_ON_NONPARTITIONED; SQLSTATE: HY000

Message: PARTITION () clause on non partitioned table

ER_PARTITION_CLAUSE_ON_NONPARTITIONED was added in 5.6.2.

- Error number: 1748; Symbol: ER_ROW_DOES_NOT_MATCH_GIVEN_PARTITION_SET; SQLSTATE: HY000

Message: Found a row not matching the given partition set

ER_ROW_DOES_NOT_MATCH_GIVEN_PARTITION_SET was added in 5.6.2.

- Error number: 1749; Symbol: ER_NO_SUCH_PARTITIONUNUSED; SQLSTATE: HY000

Message: partition '%s' doesn't exist

ER_NO_SUCH_PARTITIONUNUSED was added in 5.6.6.

- Error number: 1750; Symbol: ER_CHANGE_RPL_INFO_REPOSITORY_FAILURE; SQLSTATE: HY000

Message: Failure while changing the type of replication repository: %s.

ERCHANGE_RPL_INFO_REPOSITORY_FAILURE was added in 5.6.3.

- Error number: 1751; Symbol:

ER_WARNING_NOT_COMPLETE_ROLLBACK_WITH_CREATED_TEMP_TABLE; SQLSTATE: HY000

Message: The creation of some temporary tables could not be rolled back.

ER_WARNING_NOT_COMPLETE_ROLLBACK_WITH_CREATED_TEMP_TABLE was added in 5.6.3.

- Error number: 1752; Symbol:

ER_WARNING_NOT_COMPLETE_ROLLBACK_WITH_DROPPED_TEMP_TABLE; SQLSTATE: HY000
Message: Some temporary tables were dropped, but these operations could not be rolled back.

ER_WARNING_NOT_COMPLETE_ROLLBACK_WITH_DROPPED_TEMP_TABLE was added in 5.6.3.

- Error number: 1753; Symbol: ER_MTS_FEATURE_IS_NOT_SUPPORTED; SQLSTATE: HY000
  Message: %s is not supported in multi-threaded slave mode. %s
  ER_MTS_FEATURE_IS_NOT_SUPPORTED was added in 5.6.3.

- Error number: 1754; Symbol: ER_MTS_UPDATED_DBS_GREATER_MAX; SQLSTATE: HY000
  Message: The number of modified databases exceeds the maximum %d; the database names will not be included in the replication event metadata.
  ER_MTS_UPDATED_DBS_GREATER_MAX was added in 5.6.3.

- Error number: 1755; Symbol: ER_MTS_CANT_PARALLEL; SQLSTATE: HY000
  Message: Cannot execute the current event group in the parallel mode. Encountered event %s, relay-log name %s, position %s which prevents execution of this event group in parallel mode. Reason: %s.
  ER_MTS_CANT_PARALLEL was added in 5.6.3.

- Error number: 1756; Symbol: ER_MTS_INCONSISTENT_DATA; SQLSTATE: HY000
  Message: %s
  ER_MTS_INCONSISTENT_DATA was added in 5.6.3.

- Error number: 1757; Symbol: ER_FULLTEXT_NOT_SUPPORTED_WITH_PARTITIONING; SQLSTATE: HY000
  Message: FULLTEXT index is not supported for partitioned tables.
  ER_FULLTEXT_NOT_SUPPORTED_WITH_PARTITIONING was added in 5.6.4.

- Error number: 1758; Symbol: ER_DA_INVALID_CONDITION_NUMBER; SQLSTATE: 35000
  Message: Invalid condition number
  ER_DA_INVALID_CONDITION_NUMBER was added in 5.6.4.

- Error number: 1759; Symbol: ER_INSECUREPLAINTEXT; SQLSTATE: HY000
  Message: Sending passwords in plain text without SSL/TLS is extremely insecure.
  ER_INSECUREPLAINTEXT was added in 5.6.4.

- Error number: 1760; Symbol: ER_INSECURECHANGE_MASTER; SQLSTATE: HY000
  Message: Storing MySQL user name or password information in the master info repository is not secure and is therefore not recommended. Please consider using the USER and PASSWORD connection options for START SLAVE; see the 'START SLAVE Syntax' in the MySQL Manual for more information.
  ER_INSECURECHANGE_MASTER was added in 5.6.4.

- Error number: 1761; Symbol: ER_FOREIGN_DUPLICATE_KEY_WITH_CHILD_INFO; SQLSTATE: 23000
Server Error Message Reference

Message: Foreign key constraint for table '%s', record '%s' would lead to a duplicate entry in table '%s', key '%s'

ER_FOREIGN_DUPLICATE_KEY_WITH_CHILD_INFO was added in 5.6.4.

- Error number: 1762; Symbol: ER_FOREIGN_DUPLICATE_KEY_WITHOUT_CHILD_INFO; SQLSTATE: 23000

Message: Foreign key constraint for table '%s', record '%s' would lead to a duplicate entry in a child table

ER_FOREIGN_DUPLICATE_KEY_WITHOUT_CHILD_INFO was added in 5.6.4.

- Error number: 1763; Symbol: ER_SQLTHREAD_WITH_SECURE_SLAVE; SQLSTATE: HY000

Message: Setting authentication options is not possible when only the Slave SQL Thread is being started.

ER_SQLTHREAD_WITH_SECURE_SLAVE was added in 5.6.4.

- Error number: 1764; Symbol: ER_TABLE_HAS_NO_FT; SQLSTATE: HY000

Message: The table does not have FULLTEXT index to support this query

ER_TABLE_HAS_NO_FT was added in 5.6.4.

- Error number: 1765; Symbol: ER_VARIABLE_NOT_SETTABLE_IN_SF_OR_TRIGGER; SQLSTATE: HY000

Message: The system variable %s cannot be set in stored functions or triggers.

ER_VARIABLE_NOT_SETTABLE_IN_SF_OR_TRIGGER was added in 5.6.5.

- Error number: 1766; Symbol: ER_VARIABLE_NOT_SETTABLE_IN_TRANSACTION; SQLSTATE: HY000

Message: The system variable %s cannot be set when there is an ongoing transaction.

ER_VARIABLE_NOT_SETTABLE_IN_TRANSACTION was added in 5.6.5.

- Error number: 1767; Symbol: ER_GTID_NEXT_IS_NOT_IN_GTID_NEXT_LIST; SQLSTATE: HY000

Message: The system variable @@SESSION.GTID_NEXT has the value %s, which is not listed in @@SESSION.GTID_NEXT_LIST.

ER_GTID_NEXT_IS_NOT_IN_GTID_NEXT_LIST was added in 5.6.5.

- Error number: 1768; Symbol:

  ER_CANT_CHANGE_GTID_NEXT_IN_TRANSACTION_WHEN_GTID_NEXT_LIST_IS_NULL; SQLSTATE: HY000

Message: The system variable @@SESSION.GTID_NEXT cannot change inside a transaction.

ER_CANT_CHANGE_GTID_NEXT_IN_TRANSACTION_WHEN_GTID_NEXT_LIST_IS_NULL was added in 5.6.5.

- Error number: 1769; Symbol: ER_SET_STATEMENT_CANNOT_INVOKE_FUNCTION; SQLSTATE: HY000
Message: The statement 'SET %s' cannot invoke a stored function.  
ER_SET_STATEMENT_CANT_INVOKE_FUNCTION was added in 5.6.5.

- Error number: 1770; Symbol: ER_GTID_NEXT_CANT_BE_AUTOMATIC_IF_GTID_NEXT_LIST_IS_NON_NULL; SQLSTATE: HY000  
Message: The system variable @@SESSION.GTID_NEXT cannot be 'AUTOMATIC' when @@SESSION.GTID_NEXT_LIST is non-NULL.  
ER_GTID_NEXT_CANT_BE_AUTOMATIC_IF_GTID_NEXT_LIST_IS_NON_NULL was added in 5.6.5.

- Error number: 1771; Symbol: ER_SKIPPING_LOGGED_TRANSACTION; SQLSTATE: HY000  
Message: Skipping transaction %s because it has already been executed and logged.  
ER_SKIPPING_LOGGED_TRANSACTION was added in 5.6.5.

- Error number: 1772; Symbol: ER_MALFORMED_GTID_SET_SPECIFICATION; SQLSTATE: HY000  
Message: Malformed GTID set specification '%s'.  
ER_MALFORMED_GTID_SET_SPECIFICATION was added in 5.6.5.

- Error number: 1773; Symbol: ER_MALFORMED_GTID_SET_ENCODING; SQLSTATE: HY000  
Message: Malformed GTID set encoding.  
ER_MALFORMED_GTID_SET_ENCODING was added in 5.6.5.

- Error number: 1774; Symbol: ER_MALFORMED_GTID_SPECIFICATION; SQLSTATE: HY000  
Message: Malformed GTID specification '%s'.  
ER_MALFORMED_GTID_SPECIFICATION was added in 5.6.5.

- Error number: 1775; Symbol: ER_GNO_EXHAUSTED; SQLSTATE: HY000  
Message: Impossible to generate Global Transaction Identifier: the integer component reached the maximal value. Restart the server with a new server_uuid.  
ER_GNO_EXHAUSTED was added in 5.6.5.

- Error number: 1776; Symbol: ER_BAD_SLAVE_AUTO_POSITION; SQLSTATE: HY000  
Message: Parameters MASTER_LOG_FILE, MASTER_LOG_POS, RELAY_LOG_FILE and RELAY_LOG_POS cannot be set when MASTER_AUTO_POSITION is active.  
ER_BAD_SLAVE_AUTO_POSITION was added in 5.6.5.

- Error number: 1777; Symbol: ER_AUTO_POSITION_REQUIRES_GTID_MODE_ON; SQLSTATE: HY000  
Message: CHANGE MASTER TO MASTER_AUTO_POSITION = 1 can only be executed when @@GLOBAL.GTID_MODE = ON.  
ER_AUTO_POSITION_REQUIRES_GTID_MODE_ON was added in 5.6.5.

- Error number: 1778; Symbol: ER_CANT_DO_IMPLICIT_COMMIT_IN_TRX_WHEN_GTID_NEXT_IS_SET; SQLSTATE: HY000
Message: Cannot execute statements with implicit commit inside a transaction when @@SESSION.GTID_NEXT != AUTOMATIC.

ER_CANT_DO_IMPLICIT_COMMIT_IN_TRX_WHEN_GTID_NEXT_IS_SET was added in 5.6.5.

- Error number: 1779; Symbol: ER_GTID_MODE_2_OR_3_REQUIRES_DISABLE_GTID_UNSAFE_STATEMENTS_ON; SQLSTATE: HY000

Message: GTID_MODE = ON or GTID_MODE = UPGRADE_STEP_2 requires DISABLE_GTID_UNSAFE_STATEMENTS = 1.

In 5.6.9: ER_GTID_MODE_2_OR_3_REQUIRES_DISABLE_GTID_UNSAFE_STATEMENTS_ON was renamed to ER_GTID_MODE_2_OR_3_REQUIRES_ENFORCE_GTID_CONSISTENCY_ON.

ER_GTID_MODE_2_OR_3_REQUIRES_DISABLE_GTID_UNSAFE_STATEMENTS_ON was added in 5.6.5, removed after 5.6.8.

- Error number: 1779; Symbol: ER_GTID_MODE_2_OR_3_REQUIRES_ENFORCE_GTID_CONSISTENCY_ON; SQLSTATE: HY000

Message: @@GLOBAL.GTID_MODE = ON or UPGRADING_STEP_1 requires DISABLE_GTID_UNSAFE_STATEMENTS = 1.

In 5.6.9: ER_GTID_MODE_2_OR_3_REQUIRES_DISABLE_GTID_UNSAFE_STATEMENTS_ON was renamed to ER_GTID_MODE_2_OR_3_REQUIRES_ENFORCE_GTID_CONSISTENCY_ON.

ER_GTID_MODE_2_OR_3_REQUIRES_ENFORCE_GTID_CONSISTENCY_ON was added in 5.6.9.

- Error number: 1780; Symbol: ER_GTID_MODE_REQUIRES_BINLOG; SQLSTATE: HY000

Message: @@GLOBAL.GTID_MODE = ON or UPGRADE_STEP_2 requires --log-bin and --log-slave-updates.

ER_GTID_MODE_REQUIRES_BINLOG was added in 5.6.5.

- Error number: 1781; Symbol: ER_CANT_SET_GTID_NEXT_TO_GTID_WHEN_GTID_MODE_IS_OFF; SQLSTATE: HY000

Message: @@SESSION.GTID_NEXT cannot be set to UUID:NUMBER when @@GLOBAL.GTID_MODE = OFF.

ER_CANT_SET_GTID_NEXT_TO_GTID_WHEN_GTID_MODE_IS_OFF was added in 5.6.5.

- Error number: 1782; Symbol: ER_CANT_SET_GTID_NEXT_TO_ANONYMOUS_WHEN_GTID_MODE_IS_ON; SQLSTATE: HY000

Message: @@SESSION.GTID_NEXT cannot be set to ANONYMOUS when @@GLOBAL.GTID_MODE = ON.

ER_CANT_SET_GTID_NEXT_TO_ANONYMOUS_WHEN_GTID_MODE_IS_ON was added in 5.6.5.

- Error number: 1783; Symbol: ER_CANT_SET_GTID_NEXT_LIST_TO_NON_NULL_WHEN_GTID_MODE_IS_OFF; SQLSTATE: HY000

Message: @@SESSION.GTID_NEXT_LIST cannot be set to a non-NULL value when @@GLOBAL.GTID_MODE = OFF.
**ER_CANT_SET_GTID_NEXT_LIST_TO_NON_NULL_WHEN_GTID_MODE_IS_OFF** was added in 5.6.5.

- **Error number:** 1784; Symbol: `ER_FOUND_GTID_EVENT_WHEN_GTID_MODE_IS_OFF`; SQLSTATE: HY000
  
  Message: Found a Gtid_log_event or Previous_gtid_event when @@GLOBAL.GTID_MODE = OFF.

**ER_FOUND_GTID_EVENT_WHEN_GTID_MODE_IS_OFF** was added in 5.6.5.

- **Error number:** 1785; Symbol: `ER_GTID_UNSAFE_NON_TRANSACTIONAL_TABLE`; SQLSTATE: HY000
  
  Message: When @@GLOBAL.ENFORCE_GTID_CONSISTENCY = 1, updates to non-transactional tables can only be done in either autocommitted statements or single-statement transactions, and never in the same statement as updates to transactional tables.

**ER_GTID_UNSAFE_NON_TRANSACTIONAL_TABLE** was added in 5.6.5.

- **Error number:** 1786; Symbol: `ER_GTID_UNSAFE_CREATE_SELECT`; SQLSTATE: HY000
  
  Message: CREATE TABLE ... SELECT is forbidden when @@GLOBAL.ENFORCE_GTID_CONSISTENCY = 1.

**ER_GTID_UNSAFE_CREATE_SELECT** was added in 5.6.5.

- **Error number:** 1787; Symbol: `ER_GTID_UNSAFE_CREATE_DROP_TEMPORARY_TABLE_IN_TRANSACTION`; SQLSTATE: HY000
  
  Message: When @@GLOBAL.ENFORCE_GTID_CONSISTENCY = 1, the statements CREATE TEMPORARY TABLE and DROP TEMPORARY TABLE can be executed in a non-transactional context only, and require that AUTOCOMMIT = 1. These statements are also not allowed in a function or trigger because functions and triggers are also considered to be multi-statement transactions.

**ER_GTID_UNSAFE_CREATE_DROP_TEMPORARY_TABLE_IN_TRANSACTION** was added in 5.6.5.

- **Error number:** 1788; Symbol: `ER_GTID_MODE_CAN_ONLY_CHANGE_ONE_STEP_AT_A_TIME`; SQLSTATE: HY000
  
  Message: The value of @@GLOBAL.GTID_MODE can only change one step at a time: OFF <-> UPGRADE_STEP_1 <-> UPGRADE_STEP_2 <-> ON. Also note that this value must be stepped up or down simultaneously on all servers; see the Manual for instructions.

**ER_GTID_MODE_CAN_ONLY_CHANGE_ONE_STEP_AT_A_TIME** was added in 5.6.5.

- **Error number:** 1789; Symbol: `ER_MASTER_HAS_PURGED_REQUIRED_GTIDS`; SQLSTATE: HY000
  
  Message: The slave is connecting using CHANGE MASTER TO MASTER_AUTO_POSITION = 1, but the master has purged binary logs containing GTIDs that the slave requires.

**ER_MASTER_HAS_PURGED_REQUIRED_GTIDS** was added in 5.6.5.

- **Error number:** 1790; Symbol: `ER_CANT_SET_GTID_NEXT_WHEN_OWNING_GTID`; SQLSTATE: HY000
  
  Message: @@SESSION.GTID_NEXT cannot be changed by a client that owns a GTID. The client owns %s. Ownership is released on COMMIT or ROLLBACK.

**ER_CANT_SET_GTID_NEXT_WHEN_OWNING_GTID** was added in 5.6.5.
• Error number: 1791; Symbol: ER_UNKNOWN_EXPLAIN_FORMAT; SQLSTATE: HY000
  Message: Unknown EXPLAIN format name: '%s'
  ER_UNKNOWN_EXPLAIN_FORMAT was added in 5.6.5.

• Error number: 1792; Symbol: ER_CANT_EXECUTE_IN_READ_ONLY_TRANSACTION; SQLSTATE: 25006
  Message: Cannot execute statement in a READ ONLY transaction.
  ER_CANT_EXECUTE_IN_READ_ONLY_TRANSACTION was added in 5.6.5.

• Error number: 1793; Symbol: ER_TOO_LONG_TABLE_PARTITION_COMMENT; SQLSTATE: HY000
  Message: Comment for table partition '%s' is too long (max = %lu)
  ER_TOO_LONG_TABLE_PARTITION_COMMENT was added in 5.6.6.

• Error number: 1794; Symbol: ER_SLAVE_CONFIGURATION; SQLSTATE: HY000
  Message: Slave is not configured or failed to initialize properly. You must at least set --server-id to enable either a master or a slave. Additional error messages can be found in the MySQL error log.
  ER_SLAVE_CONFIGURATION was added in 5.6.6.

• Error number: 1795; Symbol: ER_INNODB_FT_LIMIT; SQLSTATE: HY000
  Message: InnoDB presently supports one FULLTEXT index creation at a time
  ER_INNODB_FT_LIMIT was added in 5.6.4.

• Error number: 1796; Symbol: ER_INNODB_NO_FT_TEMP_TABLE; SQLSTATE: HY000
  Message: Cannot create FULLTEXT index on temporary InnoDB table
  ER_INNODB_NO_FT_TEMP_TABLE was added in 5.6.4.

• Error number: 1797; Symbol: ER_INNODB_FT_WRONG_DOCID_COLUMN; SQLSTATE: HY000
  Message: Column '%s' is of wrong type for an InnoDB FULLTEXT index
  ER_INNODB_FT_WRONG_DOCID_COLUMN was added in 5.6.6.

• Error number: 1798; Symbol: ER_INNODB_FT_WRONG_DOCID_INDEX; SQLSTATE: HY000
  Message: Index '%s' is of wrong type for an InnoDB FULLTEXT index
  ER_INNODB_FT_WRONG_DOCID_INDEX was added in 5.6.6.

• Error number: 1799; Symbol: ER_INNODB_ONLINE_LOG_TOO_BIG; SQLSTATE: HY000
  Message: Creating index '%s' required more than 'innodb_online_alter_log_max_size' bytes of modification log. Please try again.
  ER_INNODB_ONLINE_LOG_TOO_BIG was added in 5.6.6.

• Error number: 1800; Symbol: ER_UNKNOWN_ALTER_ALGORITHM; SQLSTATE: HY000
  Message: Unknown ALGORITHM '%s'
**ER_UNKNOWN_ALTER_ALGORITHM** was added in 5.6.6.

- **Error number:** 1801; **Symbol:** ER_UNKNOWN_ALTER_LOCK; **SQLSTATE:** HY000
  
  Message: Unknown LOCK type '%s'

**ER_UNKNOWN_ALTER_LOCK** was added in 5.6.6.

- **Error number:** 1802; **Symbol:** ER_MTS_CHANGE_MASTER_CANT_RUN_WITH_GAPS; **SQLSTATE:** HY000
  
  Message: CHANGE MASTER cannot be executed when the slave was stopped with an error or killed in MTS mode. Consider using RESET SLAVE or START SLAVE UNTIL.

**ER_MTS_CHANGE_MASTER_CANT_RUN_WITH_GAPS** was added in 5.6.6.

- **Error number:** 1803; **Symbol:** ER_MTS_RECOVERY_FAILURE; **SQLSTATE:** HY000
  
  Message: Cannot recover after SLAVE errored out in parallel execution mode. Additional error messages can be found in the MySQL error log.

**ER_MTS_RECOVERY_FAILURE** was added in 5.6.6.

- **Error number:** 1804; **Symbol:** ER_MTS_RESET_WORKERS; **SQLSTATE:** HY000
  
  Message: Cannot clean up worker info tables. Additional error messages can be found in the MySQL error log.

**ER_MTS_RESET_WORKERS** was added in 5.6.6.

- **Error number:** 1805; **Symbol:** ER_COL_COUNT_DOESNT_MATCH_CORRUPTED_V2; **SQLSTATE:** HY000
  
  Message: Column count of %s.%s is wrong. Expected %d, found %d. The table is probably corrupted

- **Error number:** 1806; **Symbol:** ER_SLAVE_SILENT_RETRY_TRANSACTION; **SQLSTATE:** HY000
  
  Message: Slave must silently retry current transaction

**ER_SLAVE_SILENT_RETRY_TRANSACTION** was added in 5.6.6.

- **Error number:** 1807; **Symbol:** ER_DISCARD_FK_CHECKS_RUNNING; **SQLSTATE:** HY000
  
  Message: There is a foreign key check running on table '%s'. Cannot discard the table.

**ER_DISCARD_FK_CHECKS_RUNNING** was added in 5.6.6.

- **Error number:** 1808; **Symbol:** ER_TABLE_SCHEMA_MISMATCH; **SQLSTATE:** HY000
  
  Message: Schema mismatch (%s)

**ER_TABLE_SCHEMA_MISMATCH** was added in 5.6.6.

- **Error number:** 1809; **Symbol:** ER_TABLE_IN_SYSTEM_TABLESPACE; **SQLSTATE:** HY000
  
  Message: Table '%s' in system tablespace

**ER_TABLE_IN_SYSTEM_TABLESPACE** was added in 5.6.6.

- **Error number:** 1810; **Symbol:** ER_IO_READ_ERROR; **SQLSTATE:** HY000
Message: IO Read error: (%lu, %s) %s

ER_IO_READ_ERROR was added in 5.6.6.

- Error number: 1811; Symbol: ER_IO_WRITE_ERROR; SQLSTATE: HY000
  Message: IO Write error: (%lu, %s) %s

ER_IO_WRITE_ERROR was added in 5.6.6.

- Error number: 1812; Symbol: ER_TABLESPACE_MISSING; SQLSTATE: HY000
  Message: Tablespace is missing for table '%s'

ER_TABLESPACE_MISSING was added in 5.6.6.

- Error number: 1813; Symbol: ER_TABLESPACE_EXISTS; SQLSTATE: HY000
  Message: Tablespace for table '%s' exists. Please DISCARD the tablespace before IMPORT.

ER_TABLESPACE_EXISTS was added in 5.6.6.

- Error number: 1814; Symbol: ER_TABLESPACE_DISCARDED; SQLSTATE: HY000
  Message: Tablespace has been discarded for table '%s'

ER_TABLESPACE_DISCARDED was added in 5.6.6.

- Error number: 1815; Symbol: ER_INTERNAL_ERROR; SQLSTATE: HY000
  Message: Internal error: %s

ER_INTERNAL_ERROR was added in 5.6.6.

- Error number: 1816; Symbol: ER_INNODB_IMPORT_ERROR; SQLSTATE: HY000
  Message: ALTER TABLE '%s' IMPORT TABLESPACE failed with error %lu : '%s'

ER_INNODB_IMPORT_ERROR was added in 5.6.6.

- Error number: 1817; Symbol: ER_INNODB_INDEX_CORRUPT; SQLSTATE: HY000
  Message: Index corrupt: %s

ER_INNODB_INDEX_CORRUPT was added in 5.6.6.

- Error number: 1818; Symbol: ER_INVALID_YEAR_COLUMN_LENGTH; SQLSTATE: HY000
  Message: YEAR(%lu) column type is deprecated. Creating YEAR(4) column instead.

ER_INVALID_YEAR_COLUMN_LENGTH was added in 5.6.6.

- Error number: 1819; Symbol: ER_NOT_VALID_PASSWORD; SQLSTATE: HY000
  Message: Your password does not satisfy the current policy requirements

ER_NOT_VALID_PASSWORD was added in 5.6.6.

- Error number: 1820; Symbol: ER_MUST_CHANGE_PASSWORD; SQLSTATE: HY000
Message: You must SET PASSWORD before executing this statement

`ER_MUST_CHANGE_PASSWORD` was added in 5.6.6.

- Error number: 1821; Symbol: `ER_FK_NO_INDEX_CHILD`; SQLSTATE: HY000
  Message: Failed to add the foreign key constraint. Missing index for constraint '%s' in the foreign table '%s'
  `ER_FK_NO_INDEX_CHILD` was added in 5.6.6.

- Error number: 1822; Symbol: `ER_FK_NO_INDEX_PARENT`; SQLSTATE: HY000
  Message: Failed to add the foreign key constraint. Missing index for constraint '%s' in the referenced table '%s'
  `ER_FK_NO_INDEX_PARENT` was added in 5.6.6.

- Error number: 1823; Symbol: `ER_FK_FAIL_ADD_SYSTEM`; SQLSTATE: HY000
  Message: Failed to add the foreign key constraint '%s' to system tables
  `ER_FK_FAIL_ADD_SYSTEM` was added in 5.6.6.

- Error number: 1824; Symbol: `ER_FK_CANNOT_OPEN_PARENT`; SQLSTATE: HY000
  Message: Failed to open the referenced table '%s'
  `ER_FK_CANNOT_OPEN_PARENT` was added in 5.6.6.

- Error number: 1825; Symbol: `ER_FK_INCORRECT_OPTION`; SQLSTATE: HY000
  Message: Failed to add the foreign key constraint on table '%s'. Incorrect options in FOREIGN KEY constraint '%s'
  `ER_FK_INCORRECT_OPTION` was added in 5.6.6.

- Error number: 1826; Symbol: `ER_FK_DUP_NAME`; SQLSTATE: HY000
  Message: Duplicate foreign key constraint name '%s'
  `ER_FK_DUP_NAME` was added in 5.6.6.

- Error number: 1827; Symbol: `ER_PASSWORD_FORMAT`; SQLSTATE: HY000
  Message: The password hash doesn't have the expected format. Check if the correct password algorithm is being used with the PASSWORD() function.
  `ER_PASSWORD_FORMAT` was added in 5.6.6.

- Error number: 1828; Symbol: `ER_FK_COLUMN_CANNOT_DROP`; SQLSTATE: HY000
  Message: Cannot drop column '%s': needed in a foreign key constraint '%s'
  `ER_FK_COLUMN_CANNOT_DROP` was added in 5.6.6.

- Error number: 1829; Symbol: `ER_FK_COLUMN_CANNOT_DROP_CHILD`; SQLSTATE: HY000
  Message: Cannot drop column '%s': needed in a foreign key constraint '%s' of table '%s'
Server Error Message Reference

**ER_FK_COLUMN_CANNOT_DROP_CHILD** was added in 5.6.6.

- **Error number:** 1830; **Symbol:** ER_FK_COLUMN_NOT_NULL; **SQLSTATE:** HY000
  Message: Column '%s' cannot be NOT NULL: needed in a foreign key constraint '%s' SET NULL
  **ER_FK_COLUMN_NOT_NULL** was added in 5.6.6.

- **Error number:** 1831; **Symbol:** ER_DUP_INDEX; **SQLSTATE:** HY000
  Message: Duplicate index '%s' defined on the table '%s.%s'. This is deprecated and will be disallowed in a future release.
  **ER_DUP_INDEX** was added in 5.6.7.

- **Error number:** 1832; **Symbol:** ER_FK_COLUMN_CANNOT_CHANGE; **SQLSTATE:** HY000
  Message: Cannot change column '%s': used in a foreign key constraint '%s'
  **ER_FK_COLUMN_CANNOT_CHANGE** was added in 5.6.7.

- **Error number:** 1833; **Symbol:** ER_FK_COLUMN_CANNOT_CHANGE_CHILD; **SQLSTATE:** HY000
  Message: Cannot change column '%s': used in a foreign key constraint '%s' of table '%s'
  **ER_FK_COLUMN_CANNOT_CHANGE_CHILD** was added in 5.6.7.

- **Error number:** 1834; **Symbol:** ER_FK_CANNOT_DELETE_PARENT; **SQLSTATE:** HY000
  Message: Cannot delete rows from table which is parent in a foreign key constraint '%s' of table '%s'
  **ER_FK_CANNOT_DELETE_PARENT** was added in 5.6.7.

- **Error number:** 1835; **Symbol:** ER_MALFORMED_PACKET; **SQLSTATE:** HY000
  Message: Malformed communication packet.
  **ER_MALFORMED_PACKET** was added in 5.6.7.

- **Error number:** 1836; **Symbol:** ER_READ_ONLY_MODE; **SQLSTATE:** HY000
  Message: Running in read-only mode
  **ER_READ_ONLY_MODE** was added in 5.6.8.

- **Error number:** 1837; **Symbol:** ER_GTID_NEXT_TYPE_UNDEFINED_GROUP; **SQLSTATE:** HY000
  Message: When @@SESSION.GTID_NEXT is set to a GTID, you must explicitly set it to a different value after a COMMIT or ROLLBACK. Please check GTID_NEXT variable manual page for detailed explanation. Current @@SESSION.GTID_NEXT is '%s'.
  **ER_GTID_NEXT_TYPE_UNDEFINED_GROUP** was added in 5.6.9.

- **Error number:** 1838; **Symbol:** ER_VARIABLE_NOT_SETTABLE_IN_SP; **SQLSTATE:** HY000
  Message: The system variable %s cannot be set in stored procedures.
  **ER_VARIABLE_NOT_SETTABLE_IN_SP** was added in 5.6.9.
• Error number: **1839**; Symbol: \texttt{ER\_CANT\_SET\_GTID\_PURGED\_WHEN\_GTID\_MODE\_IS\_OFF}; SQLSTATE: \texttt{HY000}

Message: `@@GLOBAL.GTID\_PURGED` can only be set when `@@GLOBAL.GTID\_MODE = ON`.

\texttt{ER\_CANT\_SET\_GTID\_PURGED\_WHEN\_GTID\_MODE\_IS\_OFF} was added in 5.6.9.

• Error number: **1840**; Symbol: \texttt{ER\_CANT\_SET\_GTID\_PURGED\_WHEN\_GTID\_EXECUTED\_IS\_NOT\_EMPTY}; SQLSTATE: \texttt{HY000}

Message: `@@GLOBAL.GTID\_PURGED` can only be set when there are no ongoing transactions (not even in other clients).

\texttt{ER\_CANT\_SET\_GTID\_PURGED\_WHEN\_OWNED\_GTIDS\_IS\_NOT\_EMPTY} was added in 5.6.9.

• Error number: **1842**; Symbol: \texttt{ER\_GTID\_PURGED\_WAS\_CHANGED}; SQLSTATE: \texttt{HY000}

Message: `@@GLOBAL.GTID\_PURGED` was changed from `\%s` to `\%s`.

\texttt{ER\_GTID\_PURGED\_WAS\_CHANGED} was added in 5.6.9.

• Error number: **1843**; Symbol: \texttt{ER\_GTID\_EXECUTED\_WAS\_CHANGED}; SQLSTATE: \texttt{HY000}

Message: `@@GLOBAL.GTID\_EXECUTED` was changed from `\%s` to `\%s`.

\texttt{ER\_GTID\_EXECUTED\_WAS\_CHANGED} was added in 5.6.9.

• Error number: **1844**; Symbol: \texttt{ER\_BINLOG\_STMT\_MODE\_AND\_NO\_REPL\_TABLES}; SQLSTATE: \texttt{HY000}

Message: Cannot execute statement: impossible to write to binary log since \texttt{BINLOG\_FORMAT = STATEMENT}, and both replicated and non replicated tables are written to.

\texttt{ER\_BINLOG\_STMT\_MODE\_AND\_NO\_REPL\_TABLES} was added in 5.6.9.

• Error number: **1845**; Symbol: \texttt{ER\_ALTER\_OPERATION\_NOT\_SUPPORTED}; SQLSTATE: \texttt{0A000}

Message: `\%s` is not supported for this operation. Try `%s`.

\texttt{ER\_ALTER\_OPERATION\_NOT\_SUPPORTED} was added in 5.6.10.

• Error number: **1846**; Symbol: \texttt{ER\_ALTER\_OPERATION\_NOT\_SUPPORTED\_REASON}; SQLSTATE: \texttt{0A000}

Message: `\%s` is not supported. Reason: `%s`. Try `%s`.

\texttt{ER\_ALTER\_OPERATION\_NOT\_SUPPORTED\_REASON} was added in 5.6.10.

• Error number: **1847**; Symbol: \texttt{ER\_ALTER\_OPERATION\_NOT\_SUPPORTED\_REASON\_COPY}; SQLSTATE: \texttt{HY000}

Message: COPY algorithm requires a lock
ER_ALTER_OPERATION_NOT_SUPPORTED_REASON_COPY was added in 5.6.10.

- Error number: 1848; Symbol: ER_ALTER_OPERATION_NOT_SUPPORTED_REASON_PARTITION; SQLSTATE: HY000
  
  Message: Partition specific operations do not yet support LOCK/ALGORITHM

ER_ALTER_OPERATION_NOT_SUPPORTED_REASON_PARTITION was added in 5.6.10.

- Error number: 1849; Symbol: ER_ALTER_OPERATION_NOT_SUPPORTED_REASON_FK_RENAME; SQLSTATE: HY000
  
  Message: Columns participating in a foreign key are renamed

ER_ALTER_OPERATION_NOT_SUPPORTED_REASON_FK_RENAME was added in 5.6.10.

- Error number: 1850; Symbol: ER_ALTER_OPERATION_NOT_SUPPORTED_REASON_COLUMN_TYPE; SQLSTATE: HY000
  
  Message: Cannot change column type INPLACE

ER_ALTER_OPERATION_NOT_SUPPORTED_REASON_COLUMN_TYPE was added in 5.6.10.

- Error number: 1851; Symbol: ER_ALTER_OPERATION_NOT_SUPPORTED_REASON_FK_CHECK; SQLSTATE: HY000
  
  Message: Adding foreign keys needs foreign_key_checks=OFF

ER_ALTER_OPERATION_NOT_SUPPORTED_REASON_FK_CHECK was added in 5.6.10.

- Error number: 1852; Symbol: ER_ALTER_OPERATION_NOT_SUPPORTED_REASON_IGNORE; SQLSTATE: HY000
  
  Message: Creating unique indexes with IGNORE requires COPY algorithm to remove duplicate rows

ER_ALTER_OPERATION_NOT_SUPPORTED_REASON_IGNORE was added in 5.6.10.

- Error number: 1853; Symbol: ER_ALTER_OPERATION_NOT_SUPPORTED_REASON_NOPK; SQLSTATE: HY000
  
  Message: Dropping a primary key is not allowed without also adding a new primary key

ER_ALTER_OPERATION_NOT_SUPPORTED_REASON_NOPK was added in 5.6.10.

- Error number: 1854; Symbol: ER_ALTER_OPERATION_NOT_SUPPORTED_REASON_AUTOINC; SQLSTATE: HY000
  
  Message: Adding an auto-increment column requires a lock

ER_ALTER_OPERATION_NOT_SUPPORTED_REASON_AUTOINC was added in 5.6.10.

- Error number: 1855; Symbol: ER_ALTER_OPERATION_NOT_SUPPORTED_REASON_HIDDEN_FTS; SQLSTATE: HY000
  
  Message: Cannot replace hidden FTS_DOC_ID with a user-visible one

ER_ALTER_OPERATION_NOT_SUPPORTED_REASON_HIDDEN_FTS was added in 5.6.10.
• Error number: 1856; Symbol: ER_ALTER_OPERATION_NOT_SUPPORTED_REASON_CHANGE_FTS; SQLSTATE: HY000
  
  Message: Cannot drop or rename FTS_DOC_ID

  ER_ALTER_OPERATION_NOT_SUPPORTED_REASON_CHANGE_FTS was added in 5.6.10.

• Error number: 1857; Symbol: ER_ALTER_OPERATION_NOT_SUPPORTED_REASON_FTS; SQLSTATE: HY000
  
  Message: Fulltext index creation requires a lock

  ER_ALTER_OPERATION_NOT_SUPPORTED_REASON_FTS was added in 5.6.10.

• Error number: 1858; Symbol: ER_SQL_SLAVE_SKIP_COUNTER_NOT_SETTABLE_IN_GTID_MODE; SQLSTATE: HY000
  
  Message: sql_slave_skip_counter can not be set when the server is running with @@GLOBAL.GTID_MODE = ON. Instead, for each transaction that you want to skip, generate an empty transaction with the same GTID as the transaction

  ER_SQL_SLAVE_SKIP_COUNTER_NOT_SETTABLE_IN_GTID_MODE was added in 5.6.10.

• Error number: 1859; Symbol: ER_DUP_UNKNOWN_IN_INDEX; SQLSTATE: 23000
  
  Message: Duplicate entry for key '%%s'

  ER_DUP_UNKNOWN_IN_INDEX was added in 5.6.10.

• Error number: 1860; Symbol: ER_IDENT_CAUSES_TOO_LONG_PATH; SQLSTATE: HY000
  
  Message: Long database name and identifier for object resulted in path length exceeding %d characters. Path: '%%s'.

  ER_IDENT_CAUSES_TOO_LONG_PATH was added in 5.6.10.

• Error number: 1861; Symbol: ER_ALTER_OPERATION_NOT_SUPPORTED_REASON_NOT_NULL; SQLSTATE: HY000
  
  Message: cannot silently convert NULL values, as required in this SQL_MODE

  ER_ALTER_OPERATION_NOT_SUPPORTED_REASON_NOT_NULL was added in 5.6.10.

• Error number: 1862; Symbol: ER_MUST_CHANGE_PASSWORD_LOGIN; SQLSTATE: HY000
  
  Message: Your password has expired. To log in you must change it using a client that supports expired passwords.

  ER_MUST_CHANGE_PASSWORD_LOGIN was added in 5.6.11.

• Error number: 1863; Symbol: ER_ROW_IN_WRONG_PARTITION; SQLSTATE: HY000
  
  Message: Found a row in wrong partition %s

  ER_ROW_IN_WRONG_PARTITION was added in 5.6.11.

• Error number: 1864; Symbol: ER_MTS_EVENT_BIGGER_PENDING_JOBS_SIZE_MAX; SQLSTATE: HY000
Message: Cannot schedule event %s, relay-log name %s, position %s to Worker thread because its size %lu exceeds %lu of slave_pending_jobs_size_max.

ER_MTS_EVENT_BIGGER_PENDING_JOBS_SIZE_MAX was added in 5.6.12.

•   Error number: 1865; Symbol: ER_INNODB_NO_FT_USES_PARSER; SQLSTATE: HY000

Message: Cannot CREATE FULLTEXT INDEX WITH PARSER on InnoDB table

ER_INNODB_NO_FT_USES_PARSER was added in 5.6.12.

•   Error number: 1866; Symbol: ER_BINLOG_LOGICAL_CORRUPTION; SQLSTATE: HY000

Message: The binary log file '%s' is logically corrupted: %s

ER_BINLOG_LOGICAL_CORRUPTION was added in 5.6.12.

•   Error number: 1867; Symbol: ER_WARN_PURGE_LOG_IN_USE; SQLSTATE: HY000

Message: file %s was not purged because it was being read by %d thread(s), purged only %d out of %d files.

ER_WARN_PURGE_LOG_IN_USE was added in 5.6.12.

•   Error number: 1868; Symbol: ER_WARN_PURGE_LOG_IS_ACTIVE; SQLSTATE: HY000

Message: file %s was not purged because it is the active log file.

ER_WARN_PURGE_LOG_IS_ACTIVE was added in 5.6.12.

•   Error number: 1869; Symbol: ER_AUTO_INCREMENT_CONFLICT; SQLSTATE: HY000

Message: Auto-increment value in UPDATE conflicts with internally generated values

ER_AUTO_INCREMENT_CONFLICT was added in 5.6.12.

•   Error number: 1870; Symbol: WARN_ON_BLOCKHOLE_IN_RBR; SQLSTATE: HY000

Message: Row events are not logged for %s statements that modify BLACKHOLE tables in row format. Table(s): '%s'

WARN_ON_BLOCKHOLE_IN_RBR was added in 5.6.12.

•   Error number: 1871; Symbol: ER_SLAVE_MI_INIT_REPOSITORY; SQLSTATE: HY000

Message: Slave failed to initialize master info structure from the repository

ER_SLAVE_MI_INIT_REPOSITORY was added in 5.6.12.

•   Error number: 1872; Symbol: ER_SLAVE_RLI_INIT_REPOSITORY; SQLSTATE: HY000

Message: Slave failed to initialize relay log info structure from the repository

ER_SLAVE_RLI_INIT_REPOSITORY was added in 5.6.12.

•   Error number: 1873; Symbol: ER_ACCESS_DENIED_CHANGE_USER_ERROR; SQLSTATE: 28000

Message: Access denied trying to change to user '%s'@'%s' (using password: %s). Disconnecting.
**ER_ACCESS_DENIED_CHANGE_USER_ERROR** was added in 5.6.13.

- Error number: **1874**; Symbol: **ER_INNODB_READ_ONLY**; SQLSTATE: **HY000**
  Message: InnoDB is in read only mode.

**ER_INNODB_READ_ONLY** was added in 5.6.13.

- Error number: **1875**; Symbol: **ER_STOP_SLAVE_SQL_THREAD_TIMEOUT**; SQLSTATE: **HY000**
  Message: STOP SLAVE command execution is incomplete: Slave SQL thread got the stop signal, thread is busy, SQL thread will stop once the current task is complete.

**ER_STOP_SLAVE_SQL_THREAD_TIMEOUT** was added in 5.6.13.

- Error number: **1876**; Symbol: **ER_STOP_SLAVE_IO_THREAD_TIMEOUT**; SQLSTATE: **HY000**
  Message: STOP SLAVE command execution is incomplete: Slave IO thread got the stop signal, thread is busy, IO thread will stop once the current task is complete.

**ER_STOP_SLAVE_IO_THREAD_TIMEOUT** was added in 5.6.13.

- Error number: **1877**; Symbol: **ER_TABLE_CORRUPT**; SQLSTATE: **HY000**
  Message: Operation cannot be performed. The table '%s.%s' is missing, corrupt or contains bad data.

**ER_TABLE_CORRUPT** was added in 5.6.14.

- Error number: **1878**; Symbol: **ER_TEMP_FILE_WRITE_FAILURE**; SQLSTATE: **HY000**
  Message: Temporary file write failure.

**ER_TEMP_FILE_WRITE_FAILURE** was added in 5.6.15.

- Error number: **1879**; Symbol: **ER_INNODB_FT_AUX_NOT_HEX_ID**; SQLSTATE: **HY000**
  Message: Upgrade index name failed, please use create index(alter table) algorithm copy to rebuild index.

**ER_INNODB_FT_AUX_NOT_HEX_ID** was added in 5.6.16.

- Error number: **1880**; Symbol: **ER_OLD_TEMPORALS_UPGRADED**; SQLSTATE: **HY000**
  Message: TIME/TIMESTAMP/DATETIME columns of old format have been upgraded to the new format.

**ER_OLD_TEMPORALS_UPGRADED** was added in 5.6.16.

- Error number: **1881**; Symbol: **ER_INNODB_FORCED_RECOVERY**; SQLSTATE: **HY000**
  Message: Operation not allowed when innodb_forced_recovery > 0.

**ER_INNODB_FORCED_RECOVERY** was added in 5.6.16.

- Error number: **1882**; Symbol: **ER_AES_INVALID_IV**; SQLSTATE: **HY000**
  Message: The initialization vector supplied to %s is too short. Must be at least %d bytes long

**ER_AES_INVALID_IV** was added in 5.6.17.
• Error number: **1883**; Symbol: `ER_PLUGIN_CANNOT_BE_UNINSTALLED`; SQLSTATE: **HY000**
  
  Message: Plugin '%s' cannot be uninstalled now. %s

  `ER_PLUGIN_CANNOT_BE_UNINSTALLED` was added in 5.6.20.

• Error number: **1884**; Symbol: `ER_GTID_UNSAFE_BINLOG_SPLITTABLE_STATEMENT_AND_GTID_GROUP`; SQLSTATE: **HY000**
  
  Message: Cannot execute statement because it needs to be written to the binary log as multiple statements, and this is not allowed when `@@SESSION.GTID_NEXT == 'UUID:NUMBER'`.

  `ER_GTID_UNSAFE_BINLOG_SPLITTABLE_STATEMENT_AND_GTID_GROUP` was added in 5.6.20.

• Error number: **1885**; Symbol: `ER_SLAVE_HAS_MORE_GTIDS_THAN_MASTER`; SQLSTATE: **HY000**
  
  Message: Slave has more GTIDs than the master has, using the master's SERVER_UUID. This may indicate that the end of the binary log was truncated or that the last binary log file was lost, e.g., after a power or disk failure when `sync_binlog != 1`. The master may or may not have rolled back transactions that were already replicated to the slave. Suggest to replicate any transactions that master has rolled back from slave to master, and/or commit empty transactions on master to account for transactions that have been committed on master but are not included in GTID_EXECUTED.

  `ER_SLAVE_HAS_MORE_GTIDS_THAN_MASTER` was added in 5.6.23.

• Error number: **1886**; Symbol: `ER_MISSING_KEY`; SQLSTATE: **HY000**
  
  Message: The table '%s.%s' does not have the necessary key(s) defined on it. Please check the table definition and create index(s) accordingly.

  `ER_MISSING_KEY` was added in 5.6.40.

• Error number: **1887**; Symbol: `WARN_NAMED_PIPE_ACCESS_EVERYONE`; SQLSTATE: **HY000**
  
  Message: Setting named_pipe_full_access_group='%s' is insecure. Consider using a Windows group with fewer members.

  `WARN_NAMED_PIPE_ACCESS_EVERYONE` was added in 5.6.45.

### B.3.2 Client Error Message Reference

Client error messages originate from within the MySQL client library. Here is an example client error message, as displayed by the `mysql` client:

```
shell> mysql -h no-such-host
ERROR 2005 (HY000): Unknown MySQL server host 'no-such-host' (0)
```

Each client error message includes an error code, SQLSTATE value, and message string, as described in Section B.1, “Error Message Sources and Components”. These components are available as described in Section B.2, “Error Information Interfaces”. For client errors, the SQLSTATE value is always ‘HY000’ (general error), so it is not meaningful for distinguishing one client error from another.

The client library also makes available to host client programs any errors that originate on the server side and are received by the client from the server. For a list of server-side errors, see Section B.3.1, “Server Error Message Reference”.

In addition to the errors in the following list, the client library can also produce error messages that have error codes in the range from 1 to 999. See Section B.3.3, “Global Error Message Reference”
Client Error Message Reference

- **Error number:** 2000; Symbol: `CR_UNKNOWN_ERROR`;
  
  Message: Unknown MySQL error

- **Error number:** 2001; Symbol: `CR_SOCKET_CREATE_ERROR`;
  
  Message: Can't create UNIX socket (%d)

- **Error number:** 2002; Symbol: `CR_CONNECTION_ERROR`;
  
  Message: Can't connect to local MySQL server through socket '%s' (%d)

- **Error number:** 2003; Symbol: `CR_CONN_HOST_ERROR`;
  
  Message: Can't connect to MySQL server on '%s' (%d)

- **Error number:** 2004; Symbol: `CR_IPSOCK_ERROR`;
  
  Message: Can't create TCP/IP socket (%d)

- **Error number:** 2005; Symbol: `CR_UNKNOWN_HOST`;
  
  Message: Unknown MySQL server host '%s' (%d)

- **Error number:** 2006; Symbol: `CR_SERVER_GONE_ERROR`;
  
  Message: MySQL server has gone away

- **Error number:** 2007; Symbol: `CR_VERSION_ERROR`;
  
  Message: Protocol mismatch; server version = %d, client version = %d

- **Error number:** 2008; Symbol: `CR_OUT_OF_MEMORY`;
  
  Message: MySQL client ran out of memory

- **Error number:** 2009; Symbol: `CR_WRONG_HOST_INFO`;
  
  Message: Wrong host info

- **Error number:** 2010; Symbol: `CR_LOCALHOST_CONNECTION`;
  
  Message: Localhost via UNIX socket

- **Error number:** 2011; Symbol: `CR_TCP_CONNECTION`;
  
  Message: %s via TCP/IP

- **Error number:** 2012; Symbol: `CR_SERVER_HANDSHAKE_ERR`;
  
  Message: Error in server handshake

- **Error number:** 2013; Symbol: `CR_SERVER_LOST`;
  
  Message: Lost connection to MySQL server during query

- **Error number:** 2014; Symbol: `CR_COMMANDS_OUT_OF_SYNC`;
  
  Message: Commands out of sync; you can't run this command now
Commands were executed in an improper order. This error occurs when a function is called that is not appropriate for the current state of the connection. For example, if `mysql_stmt_fetch()` is not called enough times to read an entire result set (that is, enough times to return `MYSQL_NO_DATA`), this error may occur for the following C API call.

- Error number: 2015; Symbol: `CR_NAMEDPIPE_CONNECTION`;
  Message: Named pipe: %s

- Error number: 2016; Symbol: `CR_NAMEDPIPEWAIT_ERROR`;
  Message: Can't wait for named pipe to host: %s pipe: %s (%lu)

- Error number: 2017; Symbol: `CR_NAMEDPIPEOPEN_ERROR`;
  Message: Can't open named pipe to host: %s pipe: %s (%lu)

- Error number: 2018; Symbol: `CR_NAMEDPIPESETSTATE_ERROR`;
  Message: Can't set state of named pipe to host: %s pipe: %s (%lu)

- Error number: 2019; Symbol: `CR_CANT_READ_CHARSET`;
  Message: Can't initialize character set %s (path: %s)

- Error number: 2020; Symbol: `CR_NET_PACKET_TOO_LARGE`;
  Message: Got packet bigger than 'max_allowed_packet' bytes

- Error number: 2021; Symbol: `CR_EMBEDDED_CONNECTION`;
  Message: Embedded server

- Error number: 2022; Symbol: `CR_PROBE_SLAVE_STATUS`;
  Message: Error on SHOW SLAVE STATUS:

- Error number: 2023; Symbol: `CR_PROBE_SLAVE_HOSTS`;
  Message: Error on SHOW SLAVE HOSTS:

- Error number: 2024; Symbol: `CR_PROBE_SLAVE_CONNECT`;
  Message: Error connecting to slave:

- Error number: 2025; Symbol: `CR_PROBE_MASTER_CONNECT`;
  Message: Error connecting to master:

- Error number: 2026; Symbol: `CR_SSL_CONNECTION_ERROR`;
  Message: SSL connection error: %s

- Error number: 2027; Symbol: `CR_MALFORMED_PACKET`;
  Message: Malformed packet

- Error number: 2028; Symbol: `CR_WRONG_LICENSE`;
Message: This client library is licensed only for use with MySQL servers having '%s' license
•   Error number: 2029; Symbol: CR_NULL_POINTER;
Message: Invalid use of null pointer
•   Error number: 2030; Symbol: CR_NO_PREPARE_STMT;
Message: Statement not prepared
•   Error number: 2031; Symbol: CR_PARAMS_NOT_BOUND;
Message: No data supplied for parameters in prepared statement
•   Error number: 2032; Symbol: CR_DATA_TRUNCATED;
Message: Data truncated
•   Error number: 2033; Symbol: CR_NO_PARAMETERS_EXISTS;
Message: No parameters exist in the statement
•   Error number: 2034; Symbol: CR_INVALID_PARAMETER_NO;
Message: Invalid parameter number
The column number for `mysql_stmt_fetch_column()` was invalid.
The parameter number for `mysql_stmt_send_long_data()` was invalid.
From 5.6.6: A key name was empty or the amount of connection attribute data for `mysql_options4()` exceeds the 64KB limit.
•   Error number: 2035; Symbol: CR_INVALID_BUFFER_USE;
Message: Can't send long data for non-string/non-binary data types (parameter: %d)
•   Error number: 2036; Symbol: CR_UNSUPPORTED_PARAM_TYPE;
Message: Using unsupported buffer type: %d (parameter: %d)
•   Error number: 2037; Symbol: CR_SHARED_MEMORY_CONNECTION;
Message: Shared memory: %s
•   Error number: 2038; Symbol: CR_SHARED_MEMORY_CONNECT_REQUEST_ERROR;
Message: Can't open shared memory; client could not create request event (%lu)
•   Error number: 2039; Symbol: CR_SHARED_MEMORY_CONNECT_ANSWER_ERROR;
Message: Can't open shared memory; no answer event received from server (%lu)
•   Error number: 2040; Symbol: CR_SHARED_MEMORY_CONNECT_FILE_MAP_ERROR;
Message: Can't open shared memory; server could not allocate file mapping (%lu)
•   Error number: 2041; Symbol: CR_SHARED_MEMORY_CONNECT_MAP_ERROR;
Message: Can't open shared memory; server could not get pointer to file mapping (%lu)
• Error number: 2042; Symbol: CR_SHARED_MEMORY_FILE_MAP_ERROR;
  Message: Can't open shared memory; client could not allocate file mapping (%lu)
• Error number: 2043; Symbol: CR_SHARED_MEMORY_MAP_ERROR;
  Message: Can't open shared memory; client could not get pointer to file mapping (%lu)
• Error number: 2044; Symbol: CR_SHARED_MEMORY_EVENT_ERROR;
  Message: Can't open shared memory; client could not create %s event (%lu)
• Error number: 2045; Symbol: CR_SHARED_MEMORY_CONNECT_ABANDONED_ERROR;
  Message: Can't open shared memory; no answer from server (%lu)
• Error number: 2046; Symbol: CR_SHARED_MEMORY_CONNECT_SET_ERROR;
  Message: Can't open shared memory; cannot send request event to server (%lu)
• Error number: 2047; Symbol: CR_CONN_UNKNOW_PROTOCOL;
  Message: Wrong or unknown protocol
• Error number: 2048; Symbol: CR_INVALID_CONN_HANDLE;
  Message: Invalid connection handle
• Error number: 2049; Symbol: CR_SECURE_AUTH;
  Message: Connection using old (pre-4.1.1) authentication protocol refused (client option 'secure_auth' enabled)
• Error number: 2050; Symbol: CR_FETCH_CANCELED;
  Message: Row retrieval was canceled by mysql_stmt_close() call
• Error number: 2051; Symbol: CR_NO_DATA;
  Message: Attempt to read column without prior row fetch
• Error number: 2052; Symbol: CR_NO_STMT_METADATA;
  Message: Prepared statement contains no metadata
• Error number: 2053; Symbol: CR_NO_RESULT_SET;
  Message: Attempt to read a row while there is no result set associated with the statement
• Error number: 2054; Symbol: CR_NOT_IMPLEMENTED;
  Message: This feature is not implemented yet
• Error number: 2055; Symbol: CR_SERVER_LOST_EXTENDED;
  Message: Lost connection to MySQL server at '%s', system error: %d
• Error number: 2056; Symbol: CR_STMT_CLOSED;
  Message: Statement closed indirectly because of a preceeding %s() call
Global Error Message Reference

- Error number: 2057; Symbol: CR_NEW_STMT_METADATA;
  Message: The number of columns in the result set differs from the number of bound buffers. You must
  reset the statement, rebind the result set columns, and execute the statement again

- Error number: 2058; Symbol: CR_ALREADY_CONNECTED;
  Message: This handle is already connected. Use a separate handle for each connection.

- Error number: 2059; Symbol: CR_AUTH_PLUGIN_CANNOT_LOAD;
  Message: Authentication plugin '%s' cannot be loaded: %s
  CR_AUTH_PLUGIN_CANNOT_LOAD was added in 5.6.1.

- Error number: 2060; Symbol: CR_DUPLICATE_CONNECTION_ATTR;
  Message: There is an attribute with the same name already
  From 5.6.6: A duplicate connection attribute name was specified for mysql_options4().
  CR_DUPLICATE_CONNECTION_ATTR was added in 5.6.6.

- Error number: 2061; Symbol: CR_AUTH_PLUGIN_ERR;
  Message: Authentication plugin '%s' reported error: %s
  CR_AUTH_PLUGIN_ERR was added in 5.6.10.

B.3.3 Global Error Message Reference

This section lists global error messages that are shared in the sense that they can be produced by the
MySQL server or by MySQL client programs. These errors have error codes in the range from 1 to 999.

Each global error message includes an error code, SQLSTATE value, and message string, as described
in Section B.1, "Error Message Sources and Components". These components are available as described
in Section B.2, "Error Information Interfaces". For global errors, the SQLSTATE value is always 'HY000'
general error), so it is not meaningful for distinguishing one client error from another.

- Error number: 1; Symbol: EE_CANTCREATEFILE;
  Message: Can't create/write to file '%s' (Errcode: %d - %s)

- Error number: 2; Symbol: EE_READ;
  Message: Error reading file '%s' (Errcode: %d - %s)

- Error number: 3; Symbol: EE_WRITE;
  Message: Error writing file '%s' (Errcode: %d - %s)

- Error number: 4; Symbol: EE_BADCLOSE;
  Message: Error on close of '%s' (Errcode: %d - %s)

- Error number: 5; Symbol: EE_OUTOFMEMORY;
  Message: Out of memory (Needed %u bytes)
• Error number: 6; Symbol: EE_DELETE;
  Message: Error on delete of '%s' (Errcode: %d - %s)
• Error number: 7; Symbol: EE_LINK;
  Message: Error on rename of '%s' to '%s' (Errcode: %d - %s)
• Error number: 9; Symbol: EE_EOFERR;
  Message: Unexpected EOF found when reading file '%s' (Errcode: %d - %s)
• Error number: 10; Symbol: EE_CANTLOCK;
  Message: Can't lock file (Errcode: %d - %s)
• Error number: 11; Symbol: EE_CANTUNLOCK;
  Message: Can't unlock file (Errcode: %d - %s)
• Error number: 12; Symbol: EE_DIR;
  Message: Can't read dir of '%s' (Errcode: %d - %s)
• Error number: 13; Symbol: EE_STAT;
  Message: Can't get stat of '%s' (Errcode: %d - %s)
• Error number: 14; Symbol: EE_CANT_CHSIZE;
  Message: Can't change size of file (Errcode: %d - %s)
• Error number: 15; Symbol: EE_CANT_OPEN_STREAM;
  Message: Can't open stream from handle (Errcode: %d - %s)
• Error number: 16; Symbol: EE_GETWD;
  Message: Can't get working directory (Errcode: %d - %s)
• Error number: 17; Symbol: EE_SETWD;
  Message: Can't change dir to '%s' (Errcode: %d - %s)
• Error number: 18; Symbol: EE_LINK_WARNING;
  Message: Warning: '%s' had %d links
• Error number: 19; Symbol: EE_OPEN_WARNING;
  Message: Warning: %d files and %d streams is left open
• Error number: 20; Symbol: EE_DISK_FULL;
  Message: Disk is full writing '%s' (Errcode: %d - %s). Waiting for someone to free space...
• Error number: 21; Symbol: EE_CANT_MKDIR;
  Message: Can't create directory '%s' (Errcode: %d - %s)
B.4 Problems and Common Errors

This section lists some common problems and error messages that you may encounter. It describes how to determine the causes of the problems and what to do to solve them.

B.4.1 How to Determine What Is Causing a Problem

When you run into a problem, the first thing you should do is to find out which program or piece of equipment is causing it:
• If you have one of the following symptoms, then it is probably a hardware problem (such as memory, motherboard, CPU, or hard disk) or kernel problem:

• The keyboard does not work. This can normally be checked by pressing the Caps Lock key. If the Caps Lock light does not change, you have to replace your keyboard. (Before doing this, you should try to restart your computer and check all cables to the keyboard.)

• The mouse pointer does not move.

• The machine does not answer to a remote machine's pings.

• Other programs that are not related to MySQL do not behave correctly.

• Your system restarted unexpectedly. (A faulty user-level program should never be able to take down your system.)

In this case, you should start by checking all your cables and run some diagnostic tool to check your hardware! You should also check whether there are any patches, updates, or service packs for your operating system that could likely solve your problem. Check also that all your libraries (such as glibc) are up to date.

It is always good to use a machine with ECC memory to discover memory problems early.

• If your keyboard is locked up, you may be able to recover by logging in to your machine from another machine and executing kbd_mode -a.

• Please examine your system log file (/var/log/messages or similar) for reasons for your problem. If you think the problem is in MySQL, you should also examine MySQL's log files. See Section 5.4, "MySQL Server Logs".

• If you do not think you have hardware problems, you should try to find out which program is causing problems. Try using top, ps, Task Manager, or some similar program, to check which program is taking all CPU or is locking the machine.

• Use top, df, or a similar program to check whether you are out of memory, disk space, file descriptors, or some other critical resource.

• If the problem is some runaway process, you can always try to kill it. If it does not want to die, there is probably a bug in the operating system.

If you have examined all other possibilities and concluded that the MySQL server or a MySQL client is causing the problem, it is time to create a bug report, see Section 1.6, “How to Report Bugs or Problems”. In the bug report, try to give a complete description of how the system is behaving and what you think is happening. Also state why you think that MySQL is causing the problem. Take into consideration all the situations described in this chapter. State any problems exactly how they appear when you examine your system. Use the “copy and paste” method for any output and error messages from programs and log files.

Try to describe in detail which program is not working and all symptoms you see. We have in the past received many bug reports that state only “the system does not work.” This provides us with no information about what could be the problem.

If a program fails, it is always useful to know the following information:

• Has the program in question made a segmentation fault (did it dump core)?

• Is the program taking up all available CPU time? Check with top. Let the program run for a while, it may simply be evaluating something computationally intensive.
Common Errors When Using MySQL Programs

- If the `mysqld` server is causing problems, can you get any response from it with `mysqladmin -u root ping` or `mysqladmin -u root processlist`?

- What does a client program say when you try to connect to the MySQL server? (Try with `mysql`, for example.) Does the client jam? Do you get any output from the program?

When sending a bug report, you should follow the outline described in Section 1.6, “How to Report Bugs or Problems”.

B.4.2 Common Errors When Using MySQL Programs

This section lists some errors that users frequently encounter when running MySQL programs. Although the problems show up when you try to run client programs, the solutions to many of the problems involves changing the configuration of the MySQL server.

B.4.2.1 Access denied

An **Access denied** error can have many causes. Often the problem is related to the MySQL accounts that the server permits client programs to use when connecting. See Section 6.2, “Access Control and Account Management”, and Section 6.2.14, “Troubleshooting Problems Connecting to MySQL”.

B.4.2.2 Can't connect to [local] MySQL server

A MySQL client on Unix can connect to the `mysqld` server in two different ways: By using a Unix socket file to connect through a file in the file system (default `/tmp/mysql.sock`), or by using TCP/IP, which connects through a port number. A Unix socket file connection is faster than TCP/IP, but can be used only when connecting to a server on the same computer. A Unix socket file is used if you do not specify a host name or if you specify the special host name `localhost`.

If the MySQL server is running on Windows, you can connect using TCP/IP. If the server is started with the `named_pipe` system variable enabled, you can also connect with named pipes if you run the client on the host where the server is running. The name of the named pipe is `MySQL` by default. If you do not give a host name when connecting to `mysqld`, a MySQL client first tries to connect to the named pipe. If that does not work, it connects to the TCP/IP port. You can force the use of named pipes on Windows by using `.` as the host name.

The error (2002) **Can't connect to ...** normally means that there is no MySQL server running on the system or that you are using an incorrect Unix socket file name or TCP/IP port number when trying to connect to the server. You should also check that the TCP/IP port you are using has not been blocked by a firewall or port blocking service.

The error (2003) **Can't connect to MySQL server on 'server' (10061)** indicates that the network connection has been refused. You should check that there is a MySQL server running, that it has network connections enabled, and that the network port you specified is the one configured on the server.

Start by checking whether there is a process named `mysqld` running on your server host. (Use `ps xa | grep mysqld` on Unix or the Task Manager on Windows.) If there is no such process, you should start the server. See Section 2.10.2, “Starting the Server”.

If a `mysqld` process is running, you can check it by trying the following commands. The port number or Unix socket file name might be different in your setup. `host_ip` represents the IP address of the machine where the server is running.

```
shell> mysqladmin version
shell> mysqladmin variables
shell> mysqladmin -h `hostname` version variables
```
Regarding the use of backticks rather than forward quotation marks with the `hostname` command; these cause the output of `hostname` (that is, the current host name) to be substituted into the `mysqladmin` command. If you have no `hostname` command or are running on Windows, you can manually type the host name of your machine (without backticks) following the `-h` option. You can also try `-h 127.0.0.1` to connect with TCP/IP to the local host.

Make sure that the server has not been configured to ignore network connections or (if you are attempting to connect remotely) that it has not been configured to listen only locally on its network interfaces. If the server was started with `--skip-networking`, it will not accept TCP/IP connections at all. If the server was started with the `bind_address` system variable set to `127.0.0.1`, it will listen for TCP/IP connections only locally on the loopback interface and will not accept remote connections.

Check to make sure that there is no firewall blocking access to MySQL. Your firewall may be configured on the basis of the application being executed, or the port number used by MySQL for communication (3306 by default). Under Linux or Unix, check your IP tables (or similar) configuration to ensure that the port has not been blocked. Under Windows, applications such as ZoneAlarm or Windows Firewall may need to be configured not to block the MySQL port.

Here are some reasons the `Can't connect to local MySQL server` error might occur:

- **mysqld** is not running on the local host. Check your operating system's process list to ensure the `mysqld` process is present.

- You’re running a MySQL server on Windows with many TCP/IP connections to it. If you’re experiencing that quite often your clients get that error, you can find a workaround here: [Connection to MySQL Server Failing on Windows](#).

- Someone has removed the Unix socket file that `mysqld` uses (`/tmp/mysql.sock` by default). For example, you might have a cron job that removes old files from the `/tmp` directory. You can always run `mysqladmin version` to check whether the Unix socket file that `mysqladmin` is trying to use really exists. The fix in this case is to change the cron job to not remove `mysql.sock` or to place the socket file somewhere else. See Section B.4.3.6, “How to Protect or Change the MySQL Unix Socket File”.

- You have started the `mysqld` server with the `--socket=/path/to/socket` option, but forgotten to tell client programs the new name of the socket file. If you change the socket path name for the server, you must also notify the MySQL clients. You can do this by providing the same `--socket` option when you run client programs. You also need to ensure that clients have permission to access the `mysql.sock` file. To find out where the socket file is, you can do:

```
shell> netstat -ln | grep mysql
```

See Section B.4.3.6, “How to Protect or Change the MySQL Unix Socket File”.

- You are using Linux and one server thread has died (dumped core). In this case, you must kill the other `mysqld` threads (for example, with `kill`) before you can restart the MySQL server. See Section B.4.3.3, “What to Do If MySQL Keeps Crashing”.

- The server or client program might not have the proper access privileges for the directory that holds the Unix socket file or the socket file itself. In this case, you must either change the access privileges for the directory or socket file so that the server and clients can access them, or restart `mysqld` with a `--socket` option that specifies a socket file name in a directory where the server can create it and where client programs can access it.
If you get the error message `Can't connect to MySQL server on some_host`, you can try the following things to find out what the problem is:

- Check whether the server is running on that host by executing `telnet some_host 3306` and pressing the Enter key a couple of times. (3306 is the default MySQL port number. Change the value if your server is listening to a different port.) If there is a MySQL server running and listening to the port, you should get a response that includes the server’s version number. If you get an error such as `telnet: Unable to connect to remote host: Connection refused`, then there is no server running on the given port.

- If the server is running on the local host, try using `mysqladmin -h localhost variables` to connect using the Unix socket file. Verify the TCP/IP port number that the server is configured to listen to (it is the value of the `port` variable.)

- If you are running under Linux and Security-Enhanced Linux (SELinux) is enabled, make sure you have disabled SELinux protection for the `mysqld` process.

### Connection to MySQL Server Failing on Windows

When you’re running a MySQL server on Windows with many TCP/IP connections to it, and you’re experiencing that quite often your clients get a `Can't connect to MySQL server` error, the reason might be that Windows does not allow for enough ephemeral (short-lived) ports to serve those connections.

The purpose of `TIME_WAIT` is to keep a connection accepting packets even after the connection has been closed. This is because Internet routing can cause a packet to take a slow route to its destination and it may arrive after both sides have agreed to close. If the port is in use for a new connection, that packet from the old connection could break the protocol or compromise personal information from the original connection. The `TIME_WAIT` delay prevents this by ensuring that the port cannot be reused until after some time has been permitted for those delayed packets to arrive.

It is safe to reduce `TIME_WAIT` greatly on LAN connections because there is little chance of packets arriving at very long delays, as they could through the Internet with its comparatively large distances and latencies.

Windows permits ephemeral (short-lived) TCP ports to the user. After any port is closed it will remain in a `TIME_WAIT` status for 120 seconds. The port will not be available again until this time expires. The default range of port numbers depends on the version of Windows, with a more limited number of ports in older versions:

- Windows through Server 2003: Ports in range 1025–5000

With a small stack of available TCP ports (5000) and a high number of TCP ports being open and closed over a short period of time along with the `TIME_WAIT` status you have a good chance for running out of ports. There are two ways to address this problem:

- Reduce the number of TCP ports consumed quickly by investigating connection pooling or persistent connections where possible
- Tune some settings in the Windows registry (see below)

**Important**

The following procedure involves modifying the Windows registry. Before you modify the registry, make sure to back it up and make sure that you understand how to restore it if a problem occurs. For information about how to back up, restore,
Common Errors When Using MySQL Programs

and edit the registry, view the following article in the Microsoft Knowledge Base:

1. Start Registry Editor (Regedt32.exe).

2. Locate the following key in the registry:

   HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters

3. On the Edit menu, click Add Value, and then add the following registry value:

   Value Name: MaxUserPort
   Data Type: REG_DWORD
   Value: 65534

   This sets the number of ephemeral ports available to any user. The valid range is between 5000 and 65534 (decimal). The default value is 0x1388 (5000 decimal).

4. On the Edit menu, click Add Value, and then add the following registry value:

   Value Name: TcpTimedWaitDelay
   Data Type: REG_DWORD
   Value: 30

   This sets the number of seconds to hold a TCP port connection in TIME_WAIT state before closing. The valid range is between 30 and 300 decimal, although you may wish to check with Microsoft for the latest permitted values. The default value is 0x78 (120 decimal).

5. Quit Registry Editor.

6. Reboot the machine.

Note

Undoing the above should be as simple as deleting the registry entries you've created.

B.4.2.3 Lost connection to MySQL server

There are three likely causes for this error message.

Usually it indicates network connectivity trouble and you should check the condition of your network if this error occurs frequently. If the error message includes "during query," this is probably the case you are experiencing.

Sometimes the “during query” form happens when millions of rows are being sent as part of one or more queries. If you know that this is happening, you should try increasing net_read_timeout from its default of 30 seconds to 60 seconds or longer, sufficient for the data transfer to complete.

More rarely, it can happen when the client is attempting the initial connection to the server. In this case, if your connect_timeout value is set to only a few seconds, you may be able to resolve the problem by increasing it to ten seconds, perhaps more if you have a very long distance or slow connection. You can determine whether you are experiencing this more uncommon cause by using SHOW GLOBAL STATUS LIKE 'Aborted_connects'. It will increase by one for each initial connection attempt that the server aborts. You may see “reading authorization packet” as part of the error message; if so, that also suggests that this is the solution that you need.
If the cause is none of those just described, you may be experiencing a problem with BLOB values that are larger than \texttt{max\_allowed\_packet}, which can cause this error with some clients. Sometime you may see an \texttt{ER\_NET\_PACKET\_TOO\_LARGE} error, and that confirms that you need to increase \texttt{max\_allowed\_packet}.

**B.4.2.4 Client does not support authentication protocol**

The current implementation of the authentication protocol uses a password hashing algorithm that is incompatible with that used by older (pre-4.1) clients. Attempts to connect to a 4.1 or higher server with an older client may fail with the following message:

```
shell> mysql
Client does not support authentication protocol requested by server; consider upgrading MySQL client
```

To deal with this problem, the preferred solution is to upgrade all client programs to use a 4.1.1 or higher client library. If that is not possible, use one of the following approaches:

- To connect to the server with a pre-4.1 client program, use an account that still has a pre-4.1-style password.

- Reset the password to pre-4.1 style for each user that needs to use a pre-4.1 client program. This can be done using the \texttt{SET PASSWORD} statement and the \texttt{OLD\_PASSWORD()} function. As of MySQL 5.6.6, it is also necessary to first ensure that the authentication plugin for the account is \texttt{mysql\_old\_password}:

  ```
  mysql> UPDATE mysql.user SET plugin = 'mysql\_old\_password'
  mysql> WHERE User = 'some\_user' AND Host = 'some\_host';
  mysql> SET PASSWORD FOR 'some\_user'@'some\_host' = OLD\_PASSWORD('new\_password');
  mysql> FLUSH PRIVILEGES;
  mysql> SET PASSWORD FOR ->
  -> 'some\_user'@'some\_host' = OLD\_PASSWORD('new\_password');
  ```

Substitute the password you want to use for "new\_password" in the preceding example. MySQL cannot tell you what the original password was, so you'll need to pick a new one.

- Tell the server to use the older password hashing algorithm by default:

  1. Start \texttt{mysqld} with the \texttt{old\_passwords} system variable set to 1.

  2. Assign an old-format password to each account that has had its password updated to the longer 4.1 format. You can identify these accounts with the following query:

    ```
    mysql> SELECT Host, User, Password FROM mysql.user
    -> WHERE LENGTH(Password) > 16;
    ```

    For each account record displayed by the query, use the \texttt{Host} and \texttt{User} values and assign a password using one of the methods described previously.

The \texttt{Client does not support authentication protocol} error also can occur if multiple versions of MySQL are installed but client programs are dynamically linked and link to an older library. Make sure that clients use the most recent library version with which they are compatible. The procedure to do this will depend on your system.

\begin{itemize}
  \item \textbf{Note} The PHP \texttt{mysql} extension does not support the authentication protocol in MySQL 4.1.1 and higher. This is true regardless of the PHP version being used. If you wish
to use the `mysql` extension with MySQL 4.1 or higher, you may need to follow one of the options discussed above for configuring MySQL to work with old clients. The `mysqli` extension (stands for "MySQL, Improved"; added in PHP 5) is compatible with the improved password hashing employed in MySQL 4.1 and higher, and no special configuration of MySQL need be done to use this MySQL client library. For more information about the `mysqli` extension, see [http://php.net/mysqli](http://php.net/mysqli).

For additional background on password hashing and authentication, see Section 6.1.2.4, "Password Hashing in MySQL".

### B.4.2.5 Password Fails When Entered Interactively

MySQL client programs prompt for a password when invoked with a ```--password``` or ```-p``` option that has no following password value:

```
shell> mysql -u user_name -p
Enter password:
```

On some systems, you may find that your password works when specified in an option file or on the command line, but not when you enter it interactively at the ```Enter password:``` prompt. This occurs when the library provided by the system to read passwords limits password values to a small number of characters (typically eight). That is a problem with the system library, not with MySQL. To work around it, change your MySQL password to a value that is eight or fewer characters long, or put your password in an option file.

### B.4.2.6 Host 'host_name' is blocked

If the following error occurs, it means that `mysqld` has received many connection requests from the given host that were interrupted in the middle:

```
Host 'host_name' is blocked because of many connection errors.
Unblock with 'mysqladmin flush-hosts'
```

The value of the `max_connect_errors` system variable determines how many successive interrupted connection requests are permitted. After `max_connect_errors` failed requests without a successful connection, `mysqld` assumes that something is wrong (for example, that someone is trying to break in), and blocks the host from further connections until you flush the host cache by executing a `FLUSH HOSTS` statement, a `TRUNCATE TABLE` statement that truncates the Performance Schema `host_cache` table, or a `mysqladmin flush-hosts` command.

To adjust the permitted number of successive connection errors, set `max_connect_errors` at server startup. For example, put these lines in the server `my.cnf` file:

```
[mysqld]
max_connect_errors=10000
```

The value can also be set at runtime:

```
SET GLOBAL max_connect_errors=10000;
```

If you get the ```Host 'host_name' is blocked``` error message for a given host, you should first verify that there is nothing wrong with TCP/IP connections from that host. If you are having network problems, it does no good to increase the value of `max_connect_errors`.  

3793
For more information about how the host cache works, see Section 8.12.5.2, “DNS Lookup Optimization and the Host Cache”.

**B.4.2.7 Too many connections**

If clients encounter Too many connections errors when attempting to connect to the **mysqld** server, all available connections are in use by other clients.

The permitted number of connections is controlled by the **max_connections** system variable. The default value is 151 to improve performance when MySQL is used with the Apache Web server. To support more connections, set **max_connections** to a larger value.

**mysqld** actually permits **max_connections** + 1 client connections. The extra connection is reserved for use by accounts that have the **SUPER** privilege. By granting the privilege to administrators and not to normal users (who should not need it), an administrator who also has the **PROCESS** privilege can connect to the server and use **SHOW PROCESSLIST** to diagnose problems even if the maximum number of unprivileged clients are connected. See Section 13.7.5.30, “SHOW PROCESSLIST Syntax”.

For more information about how the server handles client connections, see Section 8.12.5.1, “How MySQL Handles Client Connections”.

**B.4.2.8 Out of memory**

If you issue a query using the **mysql** client program and receive an error like the following one, it means that **mysql** does not have enough memory to store the entire query result:

```
mysql: Out of memory at line 42, 'malloc.c'
mysql: needed 8136 byte (8k), memory in use: 12481367 bytes (12189k)
ERROR 2008: MySQL client ran out of memory
```

To remedy the problem, first check whether your query is correct. Is it reasonable that it should return so many rows? If not, correct the query and try again. Otherwise, you can invoke **mysql** with the **--quick** option. This causes it to use the **mysql_use_result()** C API function to retrieve the result set, which places less of a load on the client (but more on the server).

**B.4.2.9 MySQL server has gone away**

This section also covers the related Lost connection to server during query error.

The most common reason for the **MySQL server has gone away** error is that the server timed out and closed the connection. In this case, you normally get one of the following error codes (which one you get is operating system-dependent).

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CR_SERVER_GONE_ERROR</td>
<td>The client couldn't send a question to the server.</td>
</tr>
<tr>
<td>CR_SERVER_LOST</td>
<td>The client didn't get an error when writing to the server, but it didn't get a full answer (or any answer) to the question.</td>
</tr>
</tbody>
</table>

By default, the server closes the connection after eight hours if nothing has happened. You can change the time limit by setting the **wait_timeout** variable when you start **mysqld**. See Section 5.1.7, “Server System Variables”.

If you have a script, you just have to issue the query again for the client to do an automatic reconnection. This assumes that you have automatic reconnection in the client enabled (which is the default for the **mysql** command-line client).
Some other common reasons for the MySQL server has gone away error are:

- You (or the db administrator) has killed the running thread with a KILL statement or a mysqladmin kill command.

- You tried to run a query after closing the connection to the server. This indicates a logic error in the application that should be corrected.

- A client application running on a different host does not have the necessary privileges to connect to the MySQL server from that host.

- You got a timeout from the TCP/IP connection on the client side. This may happen if you have been using the commands: mysql_options(..., MYSQL_OPT_READ_TIMEOUT,...) or mysql_options(..., MYSQL_OPT_WRITE_TIMEOUT,...). In this case increasing the timeout may help solve the problem.

- You have encountered a timeout on the server side and the automatic reconnection in the client is disabled (the reconnect flag in the MYSQL structure is equal to 0).

- You are using a Windows client and the server had dropped the connection (probably because wait_timeout expired) before the command was issued.

  The problem on Windows is that in some cases MySQL does not get an error from the OS when writing to the TCP/IP connection to the server, but instead gets the error when trying to read the answer from the connection.

  The solution to this is to either do a mysql_ping() on the connection if there has been a long time since the last query (this is what Connector/ODBC does) or set wait_timeout on the mysqld server so high that it in practice never times out.

- You can also get these errors if you send a query to the server that is incorrect or too large. If mysqld receives a packet that is too large or out of order, it assumes that something has gone wrong with the client and closes the connection. If you need big queries (for example, if you are working with big BLOB columns), you can increase the query limit by setting the server’s max_allowed_packet variable, which has a default value of 4MB (1MB before MySQL 5.6.6). You may also need to increase the maximum packet size on the client end. More information on setting the packet size is given in Section B.4.2.10, “Packet Too Large”.

  An INSERT or REPLACE statement that inserts a great many rows can also cause these sorts of errors. Either one of these statements sends a single request to the server irrespective of the number of rows to be inserted; thus, you can often avoid the error by reducing the number of rows sent per INSERT or REPLACE.

- It is also possible to see this error if host name lookups fail (for example, if the DNS server on which your server or network relies goes down). This is because MySQL is dependent on the host system for name resolution, but has no way of knowing whether it is working—from MySQL’s point of view the problem is indistinguishable from any other network timeout.

  You may also see the MySQL server has gone away error if MySQL is started with the --skip-networking option.

  Another networking issue that can cause this error occurs if the MySQL port (default 3306) is blocked by your firewall, thus preventing any connections at all to the MySQL server.

- You can also encounter this error with applications that fork child processes, all of which try to use the same connection to the MySQL server. This can be avoided by using a separate connection for each child process.
• You have encountered a bug where the server died while executing the query.

You can check whether the MySQL server died and restarted by executing `mysqladmin version` and examining the server's uptime. If the client connection was broken because `mysqld` crashed and restarted, you should concentrate on finding the reason for the crash. Start by checking whether issuing the query again kills the server again. See Section B.4.3.3, “What to Do If MySQL Keeps Crashing”.

You can obtain more information about lost connections by starting `mysqld` with the `--log-warnings=2` option. This logs some of the disconnected errors in the `hostname.err` file. See Section 5.4.2, “The Error Log”.

If you want to create a bug report regarding this problem, be sure that you include the following information:

• Indicate whether the MySQL server died. You can find information about this in the server error log. See Section B.4.3.3, “What to Do If MySQL Keeps Crashing”.

• If a specific query kills `mysqld` and the tables involved were checked with `CHECK TABLE` before you ran the query, can you provide a reproducible test case? See Section 24.5, “Debugging and Porting MySQL”.

• What is the value of the `wait_timeout` system variable in the MySQL server? (`mysqladmin variables` gives you the value of this variable.)

• Have you tried to run `mysqld` with the general query log enabled to determine whether the problem query appears in the log? (See Section 5.4.3, “The General Query Log”.)

See also Section B.4.2.11, “Communication Errors and Aborted Connections”, and Section 1.6, “How to Report Bugs or Problems”.

### B.4.2.10 Packet Too Large

A communication packet is a single SQL statement sent to the MySQL server, a single row that is sent to the client, or a binary log event sent from a master replication server to a slave.

The largest possible packet that can be transmitted to or from a MySQL 5.6 server or client is 1GB.

When a MySQL client or the `mysqld` server receives a packet bigger than `max_allowed_packet` bytes, it issues an `ER_NET_PACKET_TOO_LARGE` error and closes the connection. With some clients, you may also get a `Lost connection to MySQL server during query` error if the communication packet is too large.

Both the client and the server have their own `max_allowed_packet` variable, so if you want to handle big packets, you must increase this variable both in the client and in the server.

If you are using the `mysql` client program, its default `max_allowed_packet` variable is 16MB. To set a larger value, start `mysql` like this:

```shell
shell> mysql --max_allowed_packet=32M
```

That sets the packet size to 32MB.

The server's default `max_allowed_packet` value is 4MB (1MB before MySQL 5.6.6). You can increase this if the server needs to handle big queries (for example, if you are working with big `BLOB` columns). For example, to set the variable to 16MB, start the server like this:

```shell
shell> mysqld --max_allowed_packet=16M
```
You can also use an option file to set `max_allowed_packet`. For example, to set the size for the server to 16MB, add the following lines in an option file:

```
[mysqld]
max_allowed_packet=16M
```

It is safe to increase the value of this variable because the extra memory is allocated only when needed. For example, `mysqld` allocates more memory only when you issue a long query or when `mysqld` must return a large result row. The small default value of the variable is a precaution to catch incorrect packets between the client and server and also to ensure that you do not run out of memory by using large packets accidentally.

You can also get strange problems with large packets if you are using large `BLOB` values but have not given `mysqld` access to enough memory to handle the query. If you suspect this is the case, try adding `ulimit -d 256000` to the beginning of the `mysqld_safe` script and restarting `mysqld`.

### B.4.2.11 Communication Errors and Aborted Connections

If connection problems occur such as communication errors or aborted connections, use these sources of information to diagnose problems:

- The error log. See Section 5.4.2, “The Error Log”.
- The general query log. See Section 5.4.3, “The General Query Log”.
- The `Aborted_`xxx and `Connection_errors_`xxx status variables. See Section 5.1.9, “Server Status Variables”.
- The host cache, which is accessible using the Performance Schema `host_cache` table. See Section 8.12.5.2, “DNS Lookup Optimization and the Host Cache”, and Section 22.12.10.1, “The host_cache Table”.

If you start the server with the `--log-warnings` option, you might find messages like this in your error log:

```
Aborted connection 854 to db: 'employees' user: 'josh'
```

If a client is unable even to connect, the server increments the `Aborted_connects` status variable. Unsuccessful connection attempts can occur for the following reasons:

- A client attempts to access a database but has no privileges for it.
- A client uses an incorrect password.
- A connection packet does not contain the right information.
- It takes more than `connect_timeout` seconds to obtain a connect packet. See Section 5.1.7, “Server System Variables”.

If these kinds of things happen, it might indicate that someone is trying to break into your server! If the general query log is enabled, messages for these types of problems are logged to it.

If a client successfully connects but later disconnects improperly or is terminated, the server increments the `Aborted_clients` status variable, and logs an `Aborted connection` message to the error log. The cause can be any of the following:

- The client program did not call `mysql_close()` before exiting.
Common Errors When Using MySQL Programs

• The client had been sleeping more than `wait_timeout` or `interactive_timeout` seconds without issuing any requests to the server. See Section 5.1.7, “Server System Variables”.

• The client program ended abruptly in the middle of a data transfer.

Other reasons for problems with aborted connections or aborted clients:

• The `max_allowed_packet` variable value is too small or queries require more memory than you have allocated for `mysqld`. See Section B.4.2.10, “Packet Too Large”.

• Use of Ethernet protocol with Linux, both half and full duplex. Some Linux Ethernet drivers have this bug. You should test for this bug by transferring a huge file using FTP between the client and server machines. If a transfer goes in burst-pause-burst-pause mode, you are experiencing a Linux duplex syndrome. Switch the duplex mode for both your network card and hub/switch to either full duplex or to half duplex and test the results to determine the best setting.

• A problem with the thread library that causes interrupts on reads.

• Badly configured TCP/IP.

• Faulty Ethernets, hubs, switches, cables, and so forth. This can be diagnosed properly only by replacing hardware.

See also Section B.4.2.9, “MySQL server has gone away”.

B.4.2.12 The table is full

If a table-full error occurs, it may be that the disk is full or that the table has reached its maximum size. The effective maximum table size for MySQL databases is usually determined by operating system constraints on file sizes, not by MySQL internal limits. See Section 8.4.6, “Limits on Table Size”.

B.4.2.13 Can’t create/write to file

If you get an error of the following type for some queries, it means that MySQL cannot create a temporary file for the result set in the temporary directory:

```
Can't create/write to file '\sqla3fe_0.ism'.
```

The preceding error is a typical message for Windows; the Unix message is similar.

One fix is to start `mysqld` with the `--tmpdir` option or to add the option to the `[mysqld]` section of your option file. For example, to specify a directory of `C:\temp`, use these lines:

```
[mysqld]
tmpdir=C:/temp
```

The `C:\temp` directory must exist and have sufficient space for the MySQL server to write to. See Section 4.2.2.2, “Using Option Files”.

Another cause of this error can be permissions issues. Make sure that the MySQL server can write to the `tmpdir` directory.

Check also the error code that you get with `perror`. One reason the server cannot write to a table is that the file system is full:

```
shell> perror 28
OS error code  28:  No space left on device
```
If you get an error of the following type during startup, it indicates that the file system or directory used for storing data files is write protected. Provided that the write error is to a test file, the error is not serious and can be safely ignored.

| Can't create test file /usr/local/mysql/data/master.lower-test |

**B.4.2.14 Commands out of sync**

If you get *Commands out of sync; you can't run this command now* in your client code, you are calling client functions in the wrong order.

This can happen, for example, if you are using `mysql_use_result()` and try to execute a new query before you have called `mysql_free_result()`. It can also happen if you try to execute two queries that return data without calling `mysql_use_result()` or `mysql_store_result()` in between.

**B.4.2.15 Ignoring user**

If you get the following error, it means that when `mysqld` was started or when it reloaded the grant tables, it found an account in the `user` table that had an invalid password.

**Found wrong password for user 'some_user'@'some_host'; ignoring user**

As a result, the account is simply ignored by the permission system.

The following list indicates possible causes of and fixes for this problem:

- You may be running a new version of `mysqld` with an old `user` table. Check whether the `Password` column of that table is shorter than 16 characters. If so, correct this condition by running `mysql_upgrade`.
- The account has an old password (eight characters long). Update the account in the `user` table to have a new password.
- You have specified a password in the `user` table without using the `PASSWORD()` function. Use `mysql` to update the account in the `user` table with a new password, making sure to use the `PASSWORD()` function:

```sql
mysql> UPDATE user SET Password=PASSWORD('new_password')
    --> WHERE User='some_user' AND Host='some_host';
```

**B.4.2.16 Table 'tbl_name' doesn't exist**

If you get either of the following errors, it usually means that no table exists in the default database with the given name:

| Table 'tbl_name' doesn't exist |
| Can't find file: 'tbl_name' (errno: 2) |

In some cases, it may be that the table does exist but that you are referring to it incorrectly:

- Because MySQL uses directories and files to store databases and tables, database and table names are case sensitive if they are located on a file system that has case-sensitive file names.

- Even for file systems that are not case-sensitive, such as on Windows, all references to a given table within a query must use the same lettercase.

You can check which tables are in the default database with `SHOW TABLES`. See Section 13.7.5, "SHOW Syntax".
B.4.2.17 Can't initialize character set

You might see an error like this if you have character set problems:

MySQL Connection Failed: Can't initialize character set \textit{charset-name}

This error can have any of the following causes:

- The character set is a multibyte character set and you have no support for the character set in the client. In this case, you need to recompile the client by running \texttt{CMake} with the \texttt{-DDEFAULT_CHARSET=charset-name} or \texttt{-DWITH_EXTRA_CHARSETS=charset-name} option. See Section 2.9.7, “MySQL Source-Configuration Options”.

  All standard MySQL binaries are compiled with \texttt{-DWITH_EXTRA_CHARSETS=complex}, which enables support for all multibyte character sets. See Section 2.9.7, “MySQL Source-Configuration Options”.

- The character set is a simple character set that is not compiled into \texttt{mysqld}, and the character set definition files are not in the place where the client expects to find them.

  In this case, you need to use one of the following methods to solve the problem:

  - Recompile the client with support for the character set. See Section 2.9.7, “MySQL Source-Configuration Options”.
  
  - Specify to the client the directory where the character set definition files are located. For many clients, you can do this with the \texttt{--character-sets-dir} option.

  - Copy the character definition files to the path where the client expects them to be.

B.4.2.18 File Not Found and Similar Errors

If you get \texttt{ERROR \textbackslash'file-name' not found (errno: 23)}, \texttt{Can't open file: file-name (errno: 24)}, or any other error with \texttt{errno 23} or \texttt{errno 24} from MySQL, it means that you have not allocated enough file descriptors for the MySQL server. You can use the \texttt{perror} utility to get a description of what the error number means:

\begin{verbatim}
shell> perror 23
OS error code 23: File table overflow
shell> perror 24
OS error code 24: Too many open files
shell> perror 11
OS error code 11: Resource temporarily unavailable
\end{verbatim}

The problem here is that \texttt{mysqld} is trying to keep open too many files simultaneously. You can either tell \texttt{mysqld} not to open so many files at once or increase the number of file descriptors available to \texttt{mysqld}.

To tell \texttt{mysqld} to keep open fewer files at a time, you can make the table cache smaller by reducing the value of the \texttt{table_open_cache} system variable (the default value is 64). This may not entirely prevent running out of file descriptors because in some circumstances the server may attempt to extend the cache size temporarily, as described in Section 8.4.3.1, “How MySQL Opens and Closes Tables”. Reducing the value of \texttt{max_connections} also reduces the number of open files (the default value is 100).

To change the number of file descriptors available to \texttt{mysqld}, you can use the \texttt{--open-files-limit} option to \texttt{mysqld_safe} or set the \texttt{open_files_limit} system variable. See Section 5.1.7, “Server System Variables”. The easiest way to set these values is to add an option to your option file. See Section 4.2.2.2, “Using Option Files”. If you have an old version of \texttt{mysqld} that does not support setting the open files limit, you can edit the \texttt{mysqld_safe} script. There is a commented-out line \texttt{ulimit -n 256}
in the script. You can remove the `#` character to uncomment this line, and change the number 256 to set
the number of file descriptors to be made available to `mysqld`.

`--open-files-limit` and `ulimit` can increase the number of file descriptors, but only up to the
limit imposed by the operating system. There is also a “hard” limit that can be overridden only if you
start `mysqld_safe` or `mysqld` as `root` (just remember that you also need to start the server with the
`--user` option in this case so that it does not continue to run as `root` after it starts up). If you need to
increase the operating system limit on the number of file descriptors available to each process, consult the
documentation for your system.

**Note**
If you run the `tcsh` shell, `ulimit` does not work! `tcsh` also reports incorrect
values when you ask for the current limits. In this case, you should start
`mysqld_safe` using `sh`.

### B.4.2.19 Table-Corruption Issues

If you have started `mysqld` with the `myisam_recover_options` system variable set, MySQL
automatically checks and tries to repair MyISAM tables if they are marked as 'not closed properly' or
'crashed'. If this happens, MySQL writes an entry in the `hostname.err` file 'Warning: Checking
table ...' which is followed by `Warning: Repairing table` if the table needs to be repaired. If you
get a lot of these errors, without `mysqld` having died unexpectedly just before, then something is wrong
and needs to be investigated further.

When the server detects MyISAM table corruption, it writes additional information to the error log, such as
the name and line number of the source file, and the list of threads accessing the table. Example: `Got an
error from thread_id=1, mi_dynrec.c:368`. This is useful information to include in bug reports.

See also [Section 5.1.6, “Server Command Options”](#), and [Section 24.5.1.7, “Making a Test Case If You
Experience Table Corruption”](#).

### B.4.3 Administration-Related Issues

#### B.4.3.1 Problems with File Permissions

If you have problems with file permissions, the `UMASK` or `UMASK_DIR` environment variable might be set
incorrectly when `mysqld` starts. For example, `mysqld` might issue the following error message when you
create a table:

```
ERROR: Can't find file: 'path/with/filename.frm' (Errcode: 13)
```

The default `UMASK` and `UMASK_DIR` values are 0660 and 0700, respectively. `mysqld` assumes that the
value for `UMASK` or `UMASK_DIR` is in octal if it starts with a zero. For example, setting `UMASK=0600` is
equivalent to `UMASK=384` because 0600 octal is 384 decimal.

Assuming that you start `mysqld` using `mysqld_safe`, change the default `UMASK` value as follows:

```
UMASK=384  # = 600 in octal
export UMASK
mysqld_safe &
```

**Note**
An exception applies for the error log file if you start `mysqld` using `mysqld_safe`,
which does not respect `UMASK`. `mysqld_safe` may create the error log file if it does
Administration-Related Issues

not exist prior to starting `mysqld`, and `mysqld_safe` uses a umask set to a strict value of 0137. If this is unsuitable, create the error file manually with the desired access mode prior to executing `mysqld_safe`.

By default, `mysqld` creates database directories with an access permission value of 0700. To modify this behavior, set the `UMASK_DIR` variable. If you set its value, new directories are created with the combined `UMASK` and `UMASK_DIR` values. For example, to give group access to all new directories, start `mysqld_safe` as follows:

```
UMASK_DIR=504  # = 770 in octal
export UMASK_DIR
mysqld_safe &
```

For additional details, see Section 4.9, “MySQL Environment Variables”.

B.4.3.2 How to Reset the Root Password

If you have never assigned a root password for MySQL, the server does not require a password at all for connecting as root. However, this is insecure. For instructions on assigning passwords, see Section 2.10.4, “Securing the Initial MySQL Accounts”.

If you know the root password and want to change it, see Section 13.7.1.7, “SET PASSWORD Syntax”.

If you assigned a root password previously but have forgotten it, you can assign a new password. The following sections provide instructions for Windows and Unix and Unix-like systems, as well as generic instructions that apply to any system.

Resetting the Root Password: Windows Systems

On Windows, use the following procedure to reset the password for the MySQL `root'@'localhost` account. To change the password for a root account with a different host name part, modify the instructions to use that host name.

1. Log on to your system as Administrator.
2. Stop the MySQL server if it is running. For a server that is running as a Windows service, go to the Services manager: From the Start menu, select Control Panel, then Administrative Tools, then Services. Find the MySQL service in the list and stop it.
   
   If your server is not running as a service, you may need to use the Task Manager to force it to stop.
3. Create a text file containing the following statement on a single line. Replace the password with the password that you want to use.
   ```
   SET PASSWORD FOR 'root'@'localhost' = PASSWORD('MyNewPass');
   ```
4. Save the file. This example assumes that you name the file `C:\mysql-init.txt`.
5. Open a console window to get to the command prompt: From the Start menu, select Run, then enter cmd as the command to be run.
6. Start the MySQL server with the `init_file` system variable set to name the file (notice that the backslash in the option value is doubled):
   ```
   C:\> cd "C:\Program Files\MySQL\MySQL Server 5.6\bin"
   C:\> mysqld --init-file=C:\mysql-init.txt
   ```
If you installed MySQL to a different location, adjust the `cd` command accordingly.

The server executes the contents of the file named by the `init_file` system variable at startup, changing the 'root'@'localhost' account password.

To have server output to appear in the console window rather than in a log file, add the `--console` option to the `mysqld` command.

If you installed MySQL using the MySQL Installation Wizard, you may need to specify a `--defaults-file` option. For example:

```
C:\> mysqld --defaults-file="C:\ProgramData\MySQL\MySQL Server 5.6\my.ini"
 --init-file=C:\mysql-init.txt
```

The appropriate `--defaults-file` setting can be found using the Services Manager: From the Start menu, select Control Panel, then Administrative Tools, then Services. Find the MySQL service in the list, right-click it, and choose the Properties option. The Path to executable field contains the `--defaults-file` setting.

7. After the server has started successfully, delete `C:\mysql-init.txt`.

You should now be able to connect to the MySQL server as root using the new password. Stop the MySQL server and restart it normally. If you run the server as a service, start it from the Windows Services window. If you start the server manually, use whatever command you normally use.

**Resetting the Root Password: Unix and Unix-Like Systems**

On Unix, use the following procedure to reset the password for the MySQL 'root'@'localhost' account. To change the password for a root account with a different host name part, modify the instructions to use that host name.

The instructions assume that you will start the MySQL server from the Unix login account that you normally use for running it. For example, if you run the server using the mysql login account, you should log in as mysql before using the instructions. Alternatively, you can log in as root, but in this case you must start `mysqld` with the `--user=mysql` option. If you start the server as root without using `--user=mysql`, the server may create root-owned files in the data directory, such as log files, and these may cause permission-related problems for future server startups. If that happens, you will need to either change the ownership of the files to mysql or remove them.

1. Log on to your system as the Unix user that the MySQL server runs as (for example, mysql).

2. Stop the MySQL server if it is running. Locate the .pid file that contains the server's process ID. The exact location and name of this file depend on your distribution, host name, and configuration. Common locations are /var/lib/mysql/, /var/run/mysqld/, and /usr/local/mysql/data/. Generally, the file name has an extension of .pid and begins with either mysqld or your system's host name.

   Stop the MySQL server by sending a normal `kill` (not `kill -9`) to the mysqld process. Use the actual path name of the .pid file in the following command:

   ```shell>
   kill `cat /mysql-data-directory/host_name.pid`
   ```

   Use backticks (not forward quotation marks) with the `cat` command. These cause the output of `cat` to be substituted into the `kill` command.
3. Create a text file containing the following statement on a single line. Replace the password with the password that you want to use.

```sql
SET PASSWORD FOR 'root'@'localhost' = PASSWORD('MyNewPass');
```

4. Save the file. This example assumes that you name the file `/home/me/mysql-init`. The file contains the password, so do not save it where it can be read by other users. If you are not logged in as mysql (the user the server runs as), make sure that the file has permissions that permit mysql to read it.

5. Start the MySQL server with the `init_file` system variable set to name the file:

```shell
shell> mysqld --init-file=/home/me/mysql-init &
```

The server executes the contents of the file named by the `init_file` system variable at startup, changing the 'root'@'localhost' account password.

Other options may be necessary as well, depending on how you normally start your server. For example, `--defaults-file` may be needed before the `init_file` argument.

6. After the server has started successfully, delete `/home/me/mysql-init`.

You should now be able to connect to the MySQL server as root using the new password. Stop the server and restart it normally.

### Resetting the Root Password: Generic Instructions

The preceding sections provide password-resetting instructions specifically for Windows and Unix and Unix-like systems. Alternatively, on any platform, you can reset the password using the `mysql` client (but this approach is less secure):

1. Stop the MySQL server if necessary, then restart it with the `--skip-grant-tables` option. This enables anyone to connect without a password and with all privileges, and disables account-management statements such as `SET PASSWORD`. Because this is insecure, you might want to use `--skip-grant-tables` in conjunction with `--skip-networking` to prevent remote clients from connecting.

2. Connect to the MySQL server using the `mysql` client; no password is necessary because the server was started with `--skip-grant-tables`:

```shell
shell> mysql
```

3. In the `mysql` client, tell the server to reload the grant tables so that account-management statements work:

```mysql
mysql> FLUSH PRIVILEGES;
```

Then change the 'root'@'localhost' account password. Replace the password with the password that you want to use. To change the password for a root account with a different host name part, modify the instructions to use that host name.

```mysql
mysql> SET PASSWORD FOR 'root'@'localhost' = PASSWORD('MyNewPass');
```

You should now be able to connect to the MySQL server as root using the new password. Stop the server and restart it normally (without the `--skip-grant-tables` and `--skip-networking` options).
B.4.3.3 What to Do If MySQL Keeps Crashing

Each MySQL version is tested on many platforms before it is released. This does not mean that there are no bugs in MySQL, but if there are bugs, they should be very few and can be hard to find. If you have a problem, it always helps if you try to find out exactly what crashes your system, because you have a much better chance of getting the problem fixed quickly.

First, you should try to find out whether the problem is that the mysqld server dies or whether your problem has to do with your client. You can check how long your mysqld server has been up by executing mysqladmin version. If mysqld has died and restarted, you may find the reason by looking in the server's error log. See Section 5.4.2, “The Error Log”.

On some systems, you can find in the error log a stack trace of where mysqld died that you can resolve with the resolve_stack_dump program. See Section 24.5, “Debugging and Porting MySQL”. Note that the variable values written in the error log may not always be 100% correct.

Many server crashes are caused by corrupted data files or index files. MySQL updates the files on disk with the write() system call after every SQL statement and before the client is notified about the result. (This is not true if you are running with the delay_key_write system variable enabled, in which case data files are written but not index files.) This means that data file contents are safe even if mysqld crashes, because the operating system ensures that the unflushed data is written to disk. You can force MySQL to flush everything to disk after every SQL statement by starting mysqld with the --flush option.

The preceding means that normally you should not get corrupted tables unless one of the following happens:

- The MySQL server or the server host was killed in the middle of an update.
- You have found a bug in mysqld that caused it to die in the middle of an update.
- Some external program is manipulating data files or index files at the same time as mysqld without locking the table properly.
- You are running many mysqld servers using the same data directory on a system that does not support good file system locks (normally handled by the lockd lock manager), or you are running multiple servers with external locking disabled.
- You have a crashed data file or index file that contains very corrupt data that confused mysqld.
- You have found a bug in the data storage code. This isn't likely, but it is at least possible. In this case, you can try to change the storage engine to another engine by using ALTER TABLE on a repaired copy of the table.

Because it is very difficult to know why something is crashing, first try to check whether things that work for others crash for you. Try the following things:

- Stop the mysqld server with mysqladmin shutdown, run myisamchk --silent --force */*.MYI from the data directory to check all MyISAM tables, and restart mysqld. This ensures that you are running from a clean state. See Chapter 5, MySQL Server Administration.

- Start mysqld with the general query log enabled (see Section 5.4.3, “The General Query Log”). Then try to determine from the information written to the log whether some specific query kills the server. About 95% of all bugs are related to a particular query. Normally, this is one of the last queries in the log file just before the server restarts. See Section 5.4.3, “The General Query Log”. If you can repeatedly kill MySQL with a specific query, even when you have checked all tables just before issuing it, then you have isolated the bug and should submit a bug report for it. See Section 1.6, “How to Report Bugs or Problems”.
• Try to make a test case that we can use to repeat the problem. See Section 24.5, “Debugging and Porting MySQL”.

• Try the fork_big.pl script. (It is located in the tests directory of source distributions.)

• Configuring MySQL for debugging makes it much easier to gather information about possible errors if something goes wrong. Reconfigure MySQL with the –DWITH_DEBUG=1 option to CMake and then recompile. See Section 24.5, “Debugging and Porting MySQL”.

• Make sure that you have applied the latest patches for your operating system.

• Use the --skip-external-locking option to mysqld. On some systems, the lockd lock manager does not work properly; the --skip-external-locking option tells mysqld not to use external locking. (This means that you cannot run two mysqld servers on the same data directory and that you must be careful if you use myisamchk. Nevertheless, it may be instructive to try the option as a test.)

• If mysqld appears to be running but not responding, try mysqladmin –u root processlist. Sometimes mysqld is not hung even though it seems unresponsive. The problem may be that all connections are in use, or there may be some internal lock problem. mysqladmin –u root processlist usually is able to make a connection even in these cases, and can provide useful information about the current number of connections and their status.

• Run the command mysqladmin –i 5 status or mysqladmin –i 5 –r status in a separate window to produce statistics while running other queries.

• Try the following:
  1. Start mysqld from gdb (or another debugger). See Section 24.5, “Debugging and Porting MySQL”.
  2. Run your test scripts.
  3. Print the backtrace and the local variables at the three lowest levels. In gdb, you can do this with the following commands when mysqld has crashed inside gdb:

```
backtrace
info local
up
info local
up
info local
```

With gdb, you can also examine which threads exist with info threads and switch to a specific thread with thread N, where N is the thread ID.

• Try to simulate your application with a Perl script to force MySQL to crash or misbehave.

• Send a normal bug report. See Section 1.6, “How to Report Bugs or Problems”. Be even more detailed than usual. Because MySQL works for many people, the crash might result from something that exists only on your computer (for example, an error that is related to your particular system libraries).

• If you have a problem with tables containing dynamic-length rows and you are using only VARCHAR columns (not BLOB or TEXT columns), you can try to change all VARCHAR to CHAR with ALTER TABLE. This forces MySQL to use fixed-size rows. Fixed-size rows take a little extra space, but are much more tolerant to corruption.

The current dynamic row code has been in use for several years with very few problems, but dynamic-length rows are by nature more prone to errors, so it may be a good idea to try this strategy to see whether it helps.
• Consider the possibility of hardware faults when diagnosing problems. Defective hardware can be the cause of data corruption. Pay particular attention to your memory and disk subsystems when troubleshooting hardware.

B.4.3.4 How MySQL Handles a Full Disk

This section describes how MySQL responds to disk-full errors (such as “no space left on device”), and to quota-exceeded errors (such as “write failed” or “user block limit reached”).

This section is relevant for writes to MyISAM tables. It also applies for writes to binary log files and binary log index file, except that references to “row” and “record” should be understood to mean “event.”

When a disk-full condition occurs, MySQL does the following:

• It checks once every minute to see whether there is enough space to write the current row. If there is enough space, it continues as if nothing had happened.

• Every 10 minutes it writes an entry to the log file, warning about the disk-full condition.

To alleviate the problem, take the following actions:

• To continue, you only have to free enough disk space to insert all records.

• Alternatively, to abort the thread, use `mysqladmin kill`. The thread is aborted the next time it checks the disk (in one minute).

• Other threads might be waiting for the table that caused the disk-full condition. If you have several “locked” threads, killing the one thread that is waiting on the disk-full condition enables the other threads to continue.

Exceptions to the preceding behavior are when you use `REPAIR TABLE` or `OPTIMIZE TABLE` or when the indexes are created in a batch after `LOAD DATA` or after an `ALTER TABLE` statement. All of these statements may create large temporary files that, if left to themselves, would cause big problems for the rest of the system. If the disk becomes full while MySQL is doing any of these operations, it removes the big temporary files and mark the table as crashed. The exception is that for `ALTER TABLE`, the old table is left unchanged.

B.4.3.5 Where MySQL Stores Temporary Files

On Unix, MySQL uses the value of the `TMPDIR` environment variable as the path name of the directory in which to store temporary files. If `TMPDIR` is not set, MySQL uses the system default, which is usually `/tmp, /var/tmp, or /usr/tmp`.

On Windows, MySQL checks in order the values of the `TMPDIR`, `TEMP`, and `TMP` environment variables. For the first one found to be set, MySQL uses it and does not check those remaining. If none of `TMPDIR`, `TEMP`, or `TMP` are set, MySQL uses the Windows system default, which is usually `C:\windows\temp\`.

If the file system containing your temporary file directory is too small, you can use the `mysqld --tmpdir` option to specify a directory in a file system where you have enough space.

The `--tmpdir` option can be set to a list of several paths that are used in round-robin fashion. Paths should be separated by colon characters (:) on Unix and semicolon characters (;) on Windows.

Note

To spread the load effectively, these paths should be located on different physical disks, not different partitions of the same disk.
If the MySQL server is acting as a replication slave, you can use the `--slave-load-tmpdir` option to specify a separate directory for holding temporary files when replicating `LOAD DATA` statements. This directory should be in a disk-based file system (not a memory-based file system) so that the temporary files used to replicate `LOAD DATA` can survive machine restarts. The directory also should not be one that is cleared by the operating system during the system startup process. However, replication can now continue after a restart if the temporary files have been removed.

MySQL arranges that temporary files are removed if `mysqld` is terminated. On platforms that support it (such as Unix), this is done by unlinking the file after opening it. The disadvantage of this is that the name does not appear in directory listings and you do not see a big temporary file that fills up the file system in which the temporary file directory is located. (In such cases, `lsof +L1` may be helpful in identifying large files associated with `mysqld`.)

When sorting (`ORDER BY` or `GROUP BY`), MySQL normally uses one or two temporary files. The maximum disk space required is determined by the following expression:

\[
\text{(length of what is sorted + sizeof(row pointer))} \\
\times \text{number of matched rows} \\
\times 2
\]

The row pointer size is usually four bytes, but may grow in the future for really big tables.

For some statements, MySQL creates temporary SQL tables that are not hidden and have names that begin with `#sql`.

Some `SELECT` queries creates temporary SQL tables to hold intermediate results.

DDL operations that rebuild the table and are not performed online using the `ALGORITHM=INPLACE` technique create a temporary copy of the original table in the same directory as the original table.

Online DDL operations may use temporary log files for recording concurrent DML, temporary sort files when creating an index, and temporary intermediate tables files when rebuilding the table. For more information, see Section 14.13.3, “Online DDL Space Requirements”.

See also Orphan Temporary Tables.

### B.4.3.6 How to Protect or Change the MySQL Unix Socket File

The default location for the Unix socket file that the server uses for communication with local clients is `/tmp/mysql.sock`. (For some distribution formats, the directory might be different, such as `/var/lib/mysql` for RPMs.)

On some versions of Unix, anyone can delete files in the `/tmp` directory or other similar directories used for temporary files. If the socket file is located in such a directory on your system, this might cause problems.

On most versions of Unix, you can protect your `/tmp` directory so that files can be deleted only by their owners or the superuser (`root`). To do this, set the `sticky` bit on the `/tmp` directory by logging in as `root` and using the following command:

```
shell> chmod +t /tmp
```

You can check whether the `sticky` bit is set by executing `ls -ld /tmp`. If the last permission character is `t`, the bit is set.
Another approach is to change the place where the server creates the Unix socket file. If you do this, you should also let client programs know the new location of the file. You can specify the file location in several ways:

- Specify the path in a global or local option file. For example, put the following lines in /etc/my.cnf:

```
[mysqld]
socket=/path/to/socket

[client]
socket=/path/to/socket
```

See Section 4.2.2.2, “Using Option Files”.

- Specify a --socket option on the command line to mysqld_safe and when you run client programs.

- Set the MYSQL_UNIX_PORT environment variable to the path of the Unix socket file.

- Recompile MySQL from source to use a different default Unix socket file location. Define the path to the file with the MYSQL_UNIX_ADDR option when you run CMake. See Section 2.9.7, “MySQL Source-Configuration Options”.

You can test whether the new socket location works by attempting to connect to the server with this command:

```
shell> mysqladmin --socket=/path/to/socket version
```

### B.4.3.7 Time Zone Problems

If you have a problem with SELECT NOW() returning values in UTC and not your local time, you have to tell the server your current time zone. The same applies if UNIX_TIMESTAMP() returns the wrong value. This should be done for the environment in which the server runs (for example, in mysqld_safe or mysql.server). See Section 4.9, “MySQL Environment Variables”.

You can set the time zone for the server with the --timezone=timezone_name option to mysqld_safe. You can also set it by setting the TZ environment variable before you start mysqld.

The permissible values for --timezone or TZ are system dependent. Consult your operating system documentation to see what values are acceptable.

### B.4.4 Query-Related Issues

#### B.4.4.1 Case Sensitivity in String Searches

For nonbinary strings (CHAR, VARCHAR, TEXT), string searches use the collation of the comparison operands. For binary strings (BINARY, VARBINARY, BLOB), comparisons use the numeric values of the bytes in the operands; this means that for alphabetic characters, comparisons will be case-sensitive.

A comparison between a nonbinary string and binary string is treated as a comparison of binary strings.

Simple comparison operations (>=, >, =, <, <=, sorting, and grouping) are based on each character's “sort value.” Characters with the same sort value are treated as the same character. For example, if è and é have the same sort value in a given collation, they compare as equal.

The default character set and collation are latin1 and latin1_swedish_ci, so nonbinary string comparisons are case insensitive by default. This means that if you search with col_name LIKE 'a
Query-Related Issues

\%', you get all column values that start with A or a. To make this search case-sensitive, make sure that one of the operands has a case-sensitive or binary collation. For example, if you are comparing a column and a string that both have the latin1 character set, you can use the COLLATE operator to cause either operand to have the latin1_general_cs or latin1_bin collation:

\[
\begin{align*}
\text{col_name COLLATE latin1_general_cs LIKE 'a\%'} \\
\text{col_name LIKE 'a\%' COLLATE latin1_general_cs} \\
\text{col_name COLLATE latin1_bin LIKE 'a\%'} \\
\text{col_name LIKE 'a\%' COLLATE latin1_bin}
\end{align*}
\]

If you want a column always to be treated in case-sensitive fashion, declare it with a case-sensitive or binary collation. See Section 13.1.17, “CREATE TABLE Syntax”.

To cause a case-sensitive comparison of nonbinary strings to be case insensitive, use COLLATE to name a case-insensitive collation. The strings in the following example normally are case-sensitive, but COLLATE changes the comparison to be case insensitive:

mysql> SET @s1 = 'MySQL' COLLATE latin1_bin,
>            @s2 = 'mysql' COLLATE latin1_bin;
mysql> SELECT @s1 = @s2;
+-----------+
| @s1 = @s2 |
+-----------+
|         0  |
+-----------+
mysql> SELECT @s1 COLLATE latin1_swedish_ci = @s2;
+-------------------------------------+
| @s1 COLLATE latin1_swedish_ci = @s2 |
+-------------------------------------+
|                                   1 |
+-------------------------------------+

A binary string is case-sensitive in comparisons. To compare the string as case insensitive, convert it to a nonbinary string and use COLLATE to name a case-insensitive collation:

mysql> SET @s = BINARY 'MySQL';
mysql> SELECT @s = 'mysql';
+--------------+
| @s = 'mysql' |
+--------------+
|            0  |
+--------------+
mysql> SELECT CONVERT(@s USING latin1) COLLATE latin1_swedish_ci = 'mysql';
+--------------------------------------------------------------+
| CONVERT(@s USING latin1) COLLATE latin1_swedish_ci = 'mysql' |
+--------------------------------------------------------------+
|                                                            1 |
+--------------------------------------------------------------+

To determine whether a value will compare as a nonbinary or binary string, use the COLLATION() function. This example shows that VERSION() returns a string that has a case-insensitive collation, so comparisons are case insensitive:

mysql> SELECT COLLATION(VERSION());
+----------------------+
| COLLATION(VERSION()) |
| utf8_general_ci      |
+----------------------+
Query-Related Issues

For binary strings, the collation value is \texttt{binary}, so comparisons will be case sensitive. One context in which you will see \texttt{binary} is for compression functions, which return binary strings as a general rule:

\begin{verbatim}
mysql> SELECT COLLATION(COMPRESS('x'));
+--------------------------+
| COLLATION(COMPRESS('x')) |
+--------------------------+
| binary                   |
+--------------------------+
\end{verbatim}

To check the sort value of a string, the \texttt{WEIGHT\_STRING()} may be helpful. See Section 12.5, “String Functions and Operators”.

B.4.4.2 Problems Using DATE Columns

The format of a \texttt{DATE} value is 'YYYY-MM-DD'. According to standard SQL, no other format is permitted. You should use this format in \texttt{UPDATE} expressions and in the \texttt{WHERE} clause of \texttt{SELECT} statements. For example:

\begin{verbatim}
SELECT * FROM t1 WHERE date >= '2003-05-05';
\end{verbatim}

As a convenience, MySQL automatically converts a date to a number if the date is used in a numeric context and vice versa. MySQL also permits a “relaxed” string format when updating and in a \texttt{WHERE} clause that compares a date to a \texttt{DATE}, \texttt{DATETIME}, or \texttt{TIMESTAMP} column. “Relaxed” format means that any punctuation character may be used as the separator between parts. For example, '2004-08-15' and '2004#08#15' are equivalent. MySQL can also convert a string containing no separators (such as '20040815'), provided it makes sense as a date.

When you compare a \texttt{DATE}, \texttt{TIME}, \texttt{DATETIME}, or \texttt{TIMESTAMP} to a constant string with the \texttt{<}, \texttt{<=}, \texttt{=}, \texttt{>=}, \texttt{>}, or \texttt{BETWEEN} operators, MySQL normally converts the string to an internal long integer for faster comparison (and also for a bit more “relaxed” string checking). However, this conversion is subject to the following exceptions:

- When you compare two columns
- When you compare a \texttt{DATE}, \texttt{TIME}, \texttt{DATETIME}, or \texttt{TIMESTAMP} column to an expression
- When you use any comparison method other than those just listed, such as \texttt{IN} or \texttt{STRCMP ()}.

For those exceptions, the comparison is done by converting the objects to strings and performing a string comparison.

To be on the safe side, assume that strings are compared as strings and use the appropriate string functions if you want to compare a temporal value to a string.

The special “zero” date '0000-00-00' can be stored and retrieved as '0000-00-00'. When a '0000-00-00' date is used through Connector/ODBC, it is automatically converted to \texttt{NULL} because ODBC cannot handle that kind of date.

Because MySQL performs the conversions just described, the following statements work (assume that \texttt{idate} is a \texttt{DATE} column):

\begin{verbatim}
INSERT INTO t1 (idate) VALUES (19970505);
INSERT INTO t1 (idate) VALUES ('19970505');
INSERT INTO t1 (idate) VALUES ('97-05-05');
INSERT INTO t1 (idate) VALUES ('1997.05.05');
\end{verbatim}
### Query-Related Issues

<table>
<thead>
<tr>
<th>SQL Query</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>INSERT INTO t1 (idate) VALUES ('1997 05 05');</code></td>
<td>Insert date '1997-05-05' into t1.</td>
</tr>
<tr>
<td><code>INSERT INTO t1 (idate) VALUES ('0000-00-00');</code></td>
<td>Insert date '0000-00-00' into t1.</td>
</tr>
<tr>
<td><code>SELECT idate FROM t1 WHERE idate &gt;= '1997-05-05';</code></td>
<td>Select dates greater than or equal to '1997-05-05'.</td>
</tr>
<tr>
<td><code>SELECT idate FROM t1 WHERE idate &gt;= 19970505;</code></td>
<td>Select dates greater than or equal to 19970505.</td>
</tr>
<tr>
<td><code>SELECT MOD(idate,100) FROM t1 WHERE idate &gt;= 19970505;</code></td>
<td>Select the last two digits of dates greater than or equal to 19970505.</td>
</tr>
<tr>
<td><code>SELECT idate FROM t1 WHERE idate &gt;= '19970505';</code></td>
<td>Select dates greater than or equal to '19970505'.</td>
</tr>
</tbody>
</table>

However, the following statement does not work:

<table>
<thead>
<tr>
<th>SQL Query</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>SELECT idate FROM t1 WHERE STRCMP(idate,'20030505')=0;</code></td>
<td>String comparison function.</td>
</tr>
</tbody>
</table>

**STRCMP()** is a string function, so it converts *idate* to a string in 'YYYY-MM-DD' format and performs a string comparison. It does not convert '20030505' to the date '2003-05-05' and perform a date comparison.

If you enable the **ALLOW_INVALID_DATES** SQL mode, MySQL permits you to store dates that are given only limited checking: MySQL requires only that the day is in the range from 1 to 31 and the month is in the range from 1 to 12. This makes MySQL very convenient for Web applications where you obtain year, month, and day in three different fields and you want to store exactly what the user inserted (without date validation).

MySQL permits you to store dates where the day or month and day are zero. This is convenient if you want to store a birthdate in a **DATE** column and you know only part of the date. To disallow zero month or day parts in dates, enable the **NO_ZERO_IN_DATE** SQL mode.

MySQL permits you to store a “zero” value of '0000-00-00' as a “dummy date.” This is in some cases more convenient than using **NULL** values. If a date to be stored in a **DATE** column cannot be converted to any reasonable value, MySQL stores '0000-00-00'. To disallow '0000-00-00', enable the **NO_ZERO_DATE** SQL mode.

To have MySQL check all dates and accept only legal dates (unless overridden by **IGNORE**), set the **sql_mode** system variable to "NO_ZERO_IN_DATE,NO_ZERO_DATE".

### B.4.4.3 Problems with NULL Values

The concept of the NULL value is a common source of confusion for newcomers to SQL, who often think that NULL is the same thing as an empty string ''. This is not the case. For example, the following statements are completely different:

```sql
mysql> INSERT INTO my_table (phone) VALUES (NULL);
mysql> INSERT INTO my_table (phone) VALUES ('');
```

Both statements insert a value into the **phone** column, but the first inserts a **NULL** value and the second inserts an empty string. The meaning of the first can be regarded as “phone number is not known” and the meaning of the second can be regarded as “the person is known to have no phone, and thus no phone number.”

To help with NULL handling, you can use the **IS NULL** and **IS NOT NULL** operators and the **IFNULL()** function.

In SQL, the **NULL** value is never true in comparison to any other value, even **NULL**. An expression that contains **NULL** always produces a **NULL** value unless otherwise indicated in the documentation for the operators and functions involved in the expression. All columns in the following example return **NULL**:

```sql
mysql> SELECT NULL, 1+NULL, CONCAT('Invisible',NULL);
```
To search for column values that are `NULL`, you cannot use an `expr = NULL` test. The following statement returns no rows, because `expr = NULL` is never true for any expression:

```sql
mysql> SELECT * FROM my_table WHERE phone = NULL;
```

To look for `NULL` values, you must use the `IS NULL` test. The following statements show how to find the `NULL` phone number and the empty phone number:

```sql
mysql> SELECT * FROM my_table WHERE phone IS NULL;
mysql> SELECT * FROM my_table WHERE phone = '';
```

See Section 3.3.4.6, "Working with NULL Values", for additional information and examples.

You can add an index on a column that can have `NULL` values if you are using the `MyISAM`, `InnoDB`, or `MEMORY` storage engine. Otherwise, you must declare an indexed column `NOT NULL`, and you cannot insert `NULL` into the column.

When reading data with `LOAD DATA`, empty or missing columns are updated with `' '`.

To load a `NULL` value into a column, use `\N` in the data file. The literal word `NULL` may also be used under some circumstances. See Section 13.2.6, "LOAD DATA Syntax".

When using `DISTINCT`, `GROUP BY`, or `ORDER BY`, all `NULL` values are regarded as equal.

When using `ORDER BY`, `NULL` values are presented first, or last if you specify `DESC` to sort in descending order.

Aggregate (summary) functions such as `COUNT()`, `MIN()`, and `SUM()` ignore `NULL` values. The exception to this is `COUNT(*)`, which counts rows and not individual column values. For example, the following statement produces two counts. The first is a count of the number of rows in the table, and the second is a count of the number of non-`NULL` values in the `age` column:

```sql
mysql> SELECT COUNT(*), COUNT(age) FROM person;
```

For some data types, MySQL handles `NULL` values specially. If you insert `NULL` into a `TIMESTAMP` column, the current date and time is inserted. If you insert `NULL` into an integer or floating-point column that has the `AUTO_INCREMENT` attribute, the next number in the sequence is inserted.

### B.4.4.4 Problems with Column Aliases

An alias can be used in a query select list to give a column a different name. You can use the alias in `GROUP BY`, `ORDER BY`, or `HAVING` clauses to refer to the column:

```sql
SELECT SQRT(a*b) AS root FROM tbl_name
GROUP BY root HAVING root > 0;
SELECT id, COUNT(*) AS cnt FROM tbl_name
GROUP BY id HAVING cnt > 0;
SELECT id AS 'Customer identity' FROM tbl_name;
```

Standard SQL disallows references to column aliases in a `WHERE` clause. This restriction is imposed because when the `WHERE` clause is evaluated, the column value may not yet have been determined. For example, the following query is illegal:

```sql
SELECT id, COUNT(*) AS cnt FROM tbl_name WHERE cnt > 0 GROUP BY id;
```
The `WHERE` clause determines which rows should be included in the `GROUP BY` clause, but it refers to the alias of a column value that is not known until after the rows have been selected, and grouped by the `GROUP BY`.

In the select list of a query, a quoted column alias can be specified using identifier or string quoting characters:

```sql
SELECT 1 AS 'one', 2 AS 'two';
```

Elsewhere in the statement, quoted references to the alias must use identifier quoting or the reference is treated as a string literal. For example, this statement groups by the values in column `id`, referenced using the alias `a`:

```sql
SELECT id AS 'a', COUNT(*) AS cnt FROM tbl_name
GROUP BY 'a';
```

But this statement groups by the literal string `'a'` and will not work as expected:

```sql
SELECT id AS 'a', COUNT(*) AS cnt FROM tbl_name
GROUP BY 'a';
```

### B.4.4.5 Rollback Failure for Nontransactional Tables

If you receive the following message when trying to perform a `ROLLBACK`, it means that one or more of the tables you used in the transaction do not support transactions:

```
Warning: Some non-transactional changed tables couldn't be rolled back
```

These nontransactional tables are not affected by the `ROLLBACK` statement.

If you were not deliberately mixing transactional and nontransactional tables within the transaction, the most likely cause for this message is that a table you thought was transactional actually is not. This can happen if you try to create a table using a transactional storage engine that is not supported by your `mysqld` server (or that was disabled with a startup option). If `mysqld` does not support a storage engine, it instead creates the table as a `MyISAM` table, which is nontransactional.

You can check the storage engine for a table by using either of these statements:

```sql
SHOW TABLE STATUS LIKE 'tbl_name';
SHOW CREATE TABLE tbl_name;
```

See Section 13.7.5.37, “SHOW TABLE STATUS Syntax”, and Section 13.7.5.12, “SHOW CREATE TABLE Syntax”.

To check which storage engines your `mysqld` server supports, use this statement:

```sql
SHOW ENGINES;
```

See Section 13.7.5.17, “SHOW ENGINES Syntax” for full details.

### B.4.4.6 Deleting Rows from Related Tables

If the total length of the `DELETE` statement for `related_table` is more than 1MB (the default value of the `max_allowed_packet` system variable), you should split it into smaller parts and execute
multiple DELETE statements. You probably get the fastest DELETE by specifying only 100 to 1,000 related_column values per statement if the related_column is indexed. If the related_column isn’t indexed, the speed is independent of the number of arguments in the IN clause.

B.4.4.7 Solving Problems with No Matching Rows

If you have a complicated query that uses many tables but that returns no rows, you should use the following procedure to find out what is wrong:

1. Test the query with EXPLAIN to check whether you can find something that is obviously wrong. See Section 13.8.2, “EXPLAIN Syntax”.
2. Select only those columns that are used in the WHERE clause.
3. Remove one table at a time from the query until it returns some rows. If the tables are large, it is a good idea to use LIMIT 10 with the query.
4. Issue a SELECT for the column that should have matched a row against the table that was last removed from the query.
5. If you are comparing FLOAT or DOUBLE columns with numbers that have decimals, you cannot use equality (=) comparisons. This problem is common in most computer languages because not all floating-point values can be stored with exact precision. In some cases, changing the FLOAT to a DOUBLE fixes this. See Section B.4.4.8, “Problems with Floating-Point Values”.
6. If you still cannot figure out what is wrong, create a minimal test that can be run with mysql test < query.sql that shows your problems. You can create a test file by dumping the tables with mysqldump --quick db_name tbl_name_1 ... tbl_name_n > query.sql. Open the file in an editor, remove some insert lines (if there are more than needed to demonstrate the problem), and add your SELECT statement at the end of the file.

Verify that the test file demonstrates the problem by executing these commands:

```
shell> mysqladmin create test2
shell> mysql test2 < query.sql
```

Attach the test file to a bug report, which you can file using the instructions in Section 1.6, “How to Report Bugs or Problems”.

B.4.4.8 Problems with Floating-Point Values

Floating-point numbers sometimes cause confusion because they are approximate and not stored as exact values. A floating-point value as written in an SQL statement may not be the same as the value represented internally. Attempts to treat floating-point values as exact in comparisons may lead to problems. They are also subject to platform or implementation dependencies. The FLOAT and DOUBLE data types are subject to these issues. For DECIMAL columns, MySQL performs operations with a precision of 65 decimal digits, which should solve most common inaccuracy problems.

The following example uses DOUBLE to demonstrate how calculations that are done using floating-point operations are subject to floating-point error.

```
mysql> CREATE TABLE t1 (i INT, d1 DOUBLE, d2 DOUBLE);
mysql> INSERT INTO t1 VALUES (1, 101.40, 21.40), (1, -80.00, 0.00),
-> (2, 0.00, 0.00), (2, -29.60, 0.00), (2, 59.60, 46.40),
-> (2, 30.40, 30.40), (3, 37.00, 7.40), (3, -29.60, 0.00),
-> (4, 60.00, 15.40), (4, -10.60, 0.00), (4, -34.00, 0.00),
```
The result is correct. Although the first five records look like they should not satisfy the comparison (the values of \( a \) and \( b \) do not appear to be different), they may do so because the difference between the numbers shows up around the tenth decimal or so, depending on factors such as computer architecture or the compiler version or optimization level. For example, different CPUs may evaluate floating-point numbers differently.

If columns \texttt{d1} and \texttt{d2} had been defined as \texttt{DECIMAL} rather than \texttt{DOUBLE}, the result of the \texttt{SELECT} query would have contained only one row—the last one shown above.

The correct way to do floating-point number comparison is to first decide on an acceptable tolerance for differences between the numbers and then do the comparison against the tolerance value. For example, if we agree that floating-point numbers should be regarded the same if they are same within a precision of one in ten thousand (0.0001), the comparison should be written to find differences larger than the tolerance value:

```sql
mysql> SELECT i, SUM(d1) AS a, SUM(d2) AS b FROM t1
    -> GROUP BY i HAVING ABS(a - b) > 0.0001;
```

The test should find differences within the tolerance value:

```sql
mysql> SELECT i, SUM(d1) AS a, SUM(d2) AS b FROM t1
    -> GROUP BY i HAVING ABS(a - b) <= 0.0001;
```

Floating-point values are subject to platform or implementation dependencies. Suppose that you execute the following statements:

```sql
mysql> SELECT i, SUM(d1) AS a, SUM(d2) AS b FROM t1
    -> (5, 33.00, 0.00), (5, -25.80, 0.00), (5, 0.00, 7.20),
    -> (6, 0.00, 0.00), (6, -51.40, 0.00);
```

The correct way to do floating-point number comparison is to first decide on an acceptable tolerance for differences between the numbers and then do the comparison against the tolerance value. For example, if we agree that floating-point numbers should be regarded the same if they are same within a precision of one in ten thousand (0.0001), the comparison should be written to find differences larger than the tolerance value:
CREATE TABLE t1(c1 FLOAT(53,0), c2 FLOAT(53,0));
INSERT INTO t1 VALUES('1e+52','-1e+52');
SELECT * FROM t1;

On some platforms, the `SELECT` statement returns `inf` and `−inf`. On others, it returns `0` and `−0`.

An implication of the preceding issues is that if you attempt to create a replication slave by dumping table contents with `mysqldump` on the master and reloading the dump file into the slave, tables containing floating-point columns might differ between the two hosts.

**B.4.5 Optimizer-Related Issues**

MySQL uses a cost-based optimizer to determine the best way to resolve a query. In many cases, MySQL can calculate the best possible query plan, but sometimes MySQL does not have enough information about the data at hand and has to make “educated” guesses about the data.

For the cases when MySQL does not do the "right" thing, tools that you have available to help MySQL are:

- Use the `EXPLAIN` statement to get information about how MySQL processes a query. To use it, just add the keyword `EXPLAIN` to the front of your `SELECT` statement:

```
mysql> EXPLAIN SELECT * FROM t1, t2 WHERE t1.i = t2.i;
```

`EXPLAIN` is discussed in more detail in Section 13.8.2, “EXPLAIN Syntax”.

- Use `ANALYZE TABLE tbl_name` to update the key distributions for the scanned table. See Section 13.7.2.1, “ANALYZE TABLE Syntax”.

- Use `FORCE INDEX` for the scanned table to tell MySQL that table scans are very expensive compared to using the given index:

```
SELECT * FROM t1, t2 FORCE INDEX (index_for_column)
WHERE t1.col_name=t2.col_name;
```

`USE INDEX` and `IGNORE INDEX` may also be useful. See Section 8.9.3, “Index Hints”.

- Global and table-level `STRAIGHT_JOIN`. See Section 13.2.9, “SELECT Syntax”.

- You can tune global or thread-specific system variables. For example, start `mysqld` with the `--max-seeks-for-key=1000` option or use `SET max_seeks_for_key=1000` to tell the optimizer to assume that no key scan causes more than 1,000 key seeks. See Section 5.1.7, “Server System Variables”.

**B.4.6 Table Definition-Related Issues**

**B.4.6.1 Problems with ALTER TABLE**

If you get a duplicate-key error when using `ALTER TABLE` to change the character set or collation of a character column, the cause is either that the new column collation maps two keys to the same value or that the table is corrupted. In the latter case, you should run `REPAIR TABLE` on the table. `REPAIR TABLE` works for `MyISAM`, `ARCHIVE`, and `CSV` tables.

If `ALTER TABLE` dies with the following error, the problem may be that MySQL crashed during an earlier `ALTER TABLE` operation and there is an old table named `A-xxx` or `B-xxx` lying around:

```
Error on rename of './database/name.frm'
to './database/B-xxx.frm' (Errcode: 17)
```
In this case, go to the MySQL data directory and delete all files that have names starting with `A-` or `B-`. (You may want to move them elsewhere instead of deleting them.)

**ALTER TABLE** works in the following way:

- Create a new table named `A-xxx` with the requested structural changes.
- Copy all rows from the original table to `A-xxx`.
- Rename the original table to `B-xxx`.
- Rename `A-xxx` to your original table name.
- Delete `B-xxx`.

If something goes wrong with the renaming operation, MySQL tries to undo the changes. If something goes seriously wrong (although this shouldn't happen), MySQL may leave the old table as `B-xxx`. A simple rename of the table files at the system level should get your data back.

If you use **ALTER TABLE** on a transactional table or if you are using Windows, **ALTER TABLE** unlocks the table if you had done a **LOCK TABLE** on it. This is done because InnoDB and these operating systems cannot drop a table that is in use.

### B.4.6.2 TEMPORARY Table Problems

Temporary tables created with **CREATE TEMPORARY TABLE** have the following limitations:

- **TEMPORARY** tables are supported only by the InnoDB, MEMORY, MyISAM, and MERGE storage engines.
- Temporary tables are not supported for NDB Cluster.
- The **SHOW TABLES** statement does not list **TEMPORARY** tables.
- To rename **TEMPORARY** tables, **RENAME TABLE** does not work. Use **ALTER TABLE** instead:

  ```sql
  ALTER TABLE old_name RENAME new_name;
  ```

- You cannot refer to a **TEMPORARY** table more than once in the same query. For example, the following does not work:

  ```sql
  SELECT * FROM temp_table JOIN temp_table AS t2;
  ```

  The statement produces this error:

  ```sql
  ERROR 1137: Can't reopen table: 'temp_table'
  ```

- The **Can't reopen table** error also occurs if you refer to a temporary table multiple times in a stored function under different aliases, even if the references occur in different statements within the function. It may occur for temporary tables created outside stored functions and referred to across multiple calling and callee functions.

- If a **TEMPORARY** is created with the same name as an existing non-**TEMPORARY** table, the non-**TEMPORARY** table is hidden until the **TEMPORARY** table is dropped, even if the tables use different storage engines.

- There are known issues in using temporary tables with replication. See Section 17.4.1.29, “Replication and Temporary Tables”, for more information.
B.4.7 Known Issues in MySQL

This section lists known issues in recent versions of MySQL.

For information about platform-specific issues, see the installation and porting instructions in Section 2.1, “General Installation Guidance”, and Section 24.5, “Debugging and Porting MySQL”.

The following problems are known:

- Subquery optimization for `IN` is not as effective as for `=`.

- Even if you use `lower_case_table_names=2` (which enables MySQL to remember the case used for databases and table names), MySQL does not remember the case used for database names for the function `DATABASE()` or within the various logs (on case-insensitive systems).

- Dropping a `FOREIGN KEY` constraint does not work in replication because the constraint may have another name on the slave.

- `REPLACE` (and `LOAD DATA` with the `REPLACE` option) does not trigger `ON DELETE CASCADE`.

- `DISTINCT` with `ORDER BY` does not work inside `GROUP_CONCAT()` if you do not use all and only those columns that are in the `DISTINCT` list.

- When inserting a big integer value (between $2^{63}$ and $2^{64}-1$) into a decimal or string column, it is inserted as a negative value because the number is evaluated in a signed integer context.

- `ANALYZE TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` may cause problems on nontransactional tables for which you are using `INSERT DELAYED`.

- With statement-based binary logging, the master writes the executed queries to the binary log. This is a very fast, compact, and efficient logging method that works perfectly in most cases. However, it is possible for the data on the master and slave to become different if a query is designed in such a way that the data modification is nondeterministic (generally not a recommended practice, even outside of replication).

For example:

- `CREATE TABLE ... SELECT` or `INSERT ... SELECT` statements that insert zero or `NULL` values into an `AUTO_INCREMENT` column.

- `DELETE` if you are deleting rows from a table that has foreign keys with `ON DELETE CASCADE` properties.

- `REPLACE ... SELECT, INSERT IGNORE ... SELECT` if you have duplicate key values in the inserted data.

If and only if the preceding queries have no `ORDER BY` clause guaranteeing a deterministic order.

For example, for `INSERT ... SELECT` with no `ORDER BY`, the `SELECT` may return rows in a different order (which results in a row having different ranks, hence getting a different number in the `AUTO_INCREMENT` column), depending on the choices made by the optimizers on the master and slave.

A query is optimized differently on the master and slave only if:

- The table is stored using a different storage engine on the master than on the slave. (It is possible to use different storage engines on the master and slave. For example, you can use `InnoDB` on the master, but `MyISAM` on the slave if the slave has less available disk space.)
Known Issues in MySQL

• MySQL buffer sizes (key_buffer_size, and so on) are different on the master and slave.

• The master and slave run different MySQL versions, and the optimizer code differs between these versions.

This problem may also affect database restoration using `mysqlbinlog`|`mysql`.

The easiest way to avoid this problem is to add an ORDER BY clause to the aforementioned nondeterministic queries to ensure that the rows are always stored or modified in the same order. Using row-based or mixed logging format also avoids the problem.

• Log file names are based on the server host name if you do not specify a file name with the startup option. To retain the same log file names if you change your host name to something else, you must explicitly use options such as `--log-bin=old_host_name-bin`. See Section 5.1.6, “Server Command Options”. Alternatively, rename the old files to reflect your host name change. If these are binary logs, you must edit the binary log index file and fix the binary log file names there as well. (The same is true for the relay logs on a slave server.)

• `mysqlbinlog` does not delete temporary files left after a LOAD DATA statement. See Section 4.6.8, “mysqlbinlog — Utility for Processing Binary Log Files”.

• `RENAME` does not work with `TEMPORARY` tables or tables used in a `MERGE` table.

• When using `SET CHARACTER SET`, you cannot use translated characters in database, table, and column names.

• You cannot use _ or % with `ESCAPE` in LIKE ... ESCAPE.

• The server uses only the first `max_sort_length` bytes when comparing data values. This means that values cannot reliably be used in `GROUP BY`, ORDER BY, or DISTINCT if they differ only after the first `max_sort_length` bytes. To work around this, increase the variable value. The default value of `max_sort_length` is 1024 and can be changed at server startup time or at runtime.

• Numeric calculations are done with `BIGINT` or `DOUBLE` (both are normally 64 bits long). Which precision you get depends on the function. The general rule is that bit functions are performed with `BIGINT` precision, IF() and ELT() with `BIGINT` or `DOUBLE` precision, and the rest with `DOUBLE` precision. You should try to avoid using unsigned long long values if they resolve to be larger than 63 bits (9223372036854775807) for anything other than bit fields.

• You can have up to 255 `ENUM` and `SET` columns in one table.

• In `MIN()`, `MAX()`, and other aggregate functions, MySQL currently compares `ENUM` and `SET` columns by their string value rather than by the string's relative position in the set.

• In an `UPDATE` statement, columns are updated from left to right. If you refer to an updated column, you get the updated value instead of the original value. For example, the following statement increments `KEY` by 2, not 1:

```sql
mysql> UPDATE tbl_name SET KEY=KEY+1,KEY=KEY+1;
```

• You can refer to multiple temporary tables in the same query, but you cannot refer to any given temporary table more than once. For example, the following does not work:

```sql
mysql> SELECT * FROM temp_table, temp_table AS t2;
ERROR 1137: Can't reopen table: 'temp_table'
```
• The optimizer may handle `DISTINCT` differently when you are using “hidden” columns in a join than when you are not. In a join, hidden columns are counted as part of the result (even if they are not shown), whereas in normal queries, hidden columns do not participate in the `DISTINCT` comparison.

An example of this is:

```sql
SELECT DISTINCT mp3id FROM band_downloads
WHERE userid = 9 ORDER BY id DESC;
```

and

```sql
SELECT DISTINCT band_downloads.mp3id
FROM band_downloads,band_mp3
WHERE band_downloads.userid = 9
AND band_mp3.id = band_downloads.mp3id
ORDER BY band_downloads.id DESC;
```

In the second case, you may get two identical rows in the result set (because the values in the hidden `id` column may differ).

This happens only for queries that do not have the `ORDER BY` columns in the result.

• If you execute a `PROCEDURE` on a query that returns an empty set, in some cases the `PROCEDURE` does not transform the columns.

• Creation of a table of type `MERGE` does not check whether the underlying tables are compatible types.

• If you use `ALTER TABLE` to add a `UNIQUE` index to a table used in a `MERGE` table and then add a normal index on the `MERGE` table, the key order is different for the tables if there was an old, non-`UNIQUE` key in the table. This is because `ALTER TABLE` puts `UNIQUE` indexes before normal indexes to be able to detect duplicate keys as early as possible.

MySQL Glossary

These terms are commonly used in information about the MySQL database server. This glossary originated as a reference for terminology about the InnoDB storage engine, and the majority of definitions are InnoDB-related.

A

.ARZ file
Metadata for ARCHIVE tables. Contrast with .ARM file. Files with this extension are always included in backups produced by the mysqlbackup command of the MySQL Enterprise Backup product. See Also .ARM file, MySQL Enterprise Backup, mysqlbackup command.

.ARM file
Data for ARCHIVE tables. Contrast with .ARZ file. Files with this extension are always included in backups produced by the mysqlbackup command of the MySQL Enterprise Backup product. See Also .ARZ file, MySQL Enterprise Backup, mysqlbackup command.

ACID
An acronym standing for atomicity, consistency, isolation, and durability. These properties are all desirable in a database system, and are all closely tied to the notion of a transaction. The transactional features of InnoDB adhere to the ACID principles.

Transactions are atomic units of work that can be committed or rolled back. When a transaction makes multiple changes to the database, either all the changes succeed when the transaction is committed, or all the changes are undone when the transaction is rolled back.

The database remains in a consistent state at all times — after each commit or rollback, and while transactions are in progress. If related data is being updated across multiple tables, queries see either all old values or all new values, not a mix of old and new values.

Transactions are protected (isolated) from each other while they are in progress; they cannot interfere with each other or see each other’s uncommitted data. This isolation is achieved through the locking mechanism. Experienced users can adjust the isolation level, trading off less protection in favor of increased performance and concurrency, when they can be sure that the transactions really do not interfere with each other.

The results of transactions are durable: once a commit operation succeeds, the changes made by that transaction are safe from power failures, system crashes, race conditions, or other potential dangers that many non-database applications are vulnerable to. Durability typically involves writing to disk storage, with a certain amount of redundancy to protect against power failures or software crashes during write operations. (In InnoDB, the doublewrite buffer assists with durability.) See Also atomic, commit, concurrency, doublewrite buffer, isolation level, locking, rollback, transaction.

adaptive flushing
An algorithm for InnoDB tables that smoothes out the I/O overhead introduced by checkpoints. Instead of flushing all modified pages from the buffer pool to the data files at once, MySQL periodically flushes small sets of modified pages. The adaptive flushing algorithm extends this process by estimating the optimal rate to perform these periodic flushes, based on the rate of flushing and how fast redo information is generated. See Also buffer pool, checkpoint, data files, flush, InnoDB, page, redo log.

adaptive hash index
An optimization for InnoDB tables that can speed up lookups using = and IN operators, by constructing a hash index in memory. MySQL monitors index searches for InnoDB tables, and if queries could benefit from a hash index, it builds one automatically for index pages that are frequently accessed. In a sense, the adaptive hash index configures MySQL at runtime to take advantage of ample main memory, coming closer to the architecture
of main-memory databases. This feature is controlled by the `innodb_adaptive_hash_index` configuration option. Because this feature benefits some workloads and not others, and the memory used for the hash index is reserved in the buffer pool, typically you should benchmark with this feature both enabled and disabled.

The hash index is always built based on an existing B-tree index on the table. MySQL can build a hash index on a prefix of any length of the key defined for the B-tree, depending on the pattern of searches against the index. A hash index can be partial; the whole B-tree index does not need to be cached in the buffer pool.

In MySQL 5.6 and higher, another way to take advantage of fast single-value lookups with InnoDB tables is to use the InnoDB memcached plugin. See Section 14.20, “InnoDB memcached Plugin” for details. See Also B-tree, buffer pool, hash index, memcached, page, secondary index.

AIO
Acronym for asynchronous I/O. You might see this acronym in InnoDB messages or keywords. See Also asynchronous I/O.

Antelope
The code name for the original InnoDB file format. It supports the REDUNDANT and COMPACT row formats, but not the newer DYNAMIC and COMPRESSED row formats available in the Barracuda file format. See Also Barracuda, compact row format, compressed row format, dynamic row format, file format, innodb_file_format, redundant row format.

Application programming interface (API)
A set of functions or procedures. An API provides a stable set of names and types for functions, procedures, parameters, and return values.

apply
When a backup produced by the MySQL Enterprise Backup product does not include the most recent changes that occurred while the backup was underway, the process of updating the backup files to include those changes is known as the apply step. It is specified by the apply-log option of the mysqlbackup command.

Before the changes are applied, we refer to the files as a raw backup. After the changes are applied, we refer to the files as a prepared backup. The changes are recorded in the ibbackup_logfile file; once the apply step is finished, this file is no longer necessary.
See Also hot backup, ibbackup_logfile, MySQL Enterprise Backup, prepared backup, raw backup.

Asynchronous I/O
A type of I/O operation that allows other processing to proceed before the I/O is completed. Also known as nonblocking I/O and abbreviated as AIO. InnoDB uses this type of I/O for certain operations that can run in parallel without affecting the reliability of the database, such as reading pages into the buffer pool that have not actually been requested, but might be needed soon.

Historically, InnoDB used asynchronous I/O on Windows systems only. Starting with the InnoDB Plugin 1.1 and MySQL 5.5, InnoDB uses asynchronous I/O on Linux systems. This change introduces a dependency on libaio. Asynchronous I/O on Linux systems is configured using the innodb_use_native_aio option, which is enabled by default. On other Unix-like systems, InnoDB uses synchronous I/O only.
See Also buffer pool, nonblocking I/O.

Atomic
In the SQL context, transactions are units of work that either succeed entirely (when committed) or have no effect at all (when rolled back). The indivisible (“atomic”) property of transactions is the “A” in the acronym ACID. See Also ACID, commit, rollback, transaction.

Atomic DDL
An atomic DDL statement is one that combines the data dictionary updates, storage engine operations, and binary log writes associated with a DDL operation into a single, atomic transaction. The transaction is either fully
committed or rolled back, even if the server halts during the operation. Atomic DDL support was added in MySQL 8.0. For more information, see Atomic Data Definition Statement Support.
See Also binary log, data dictionary, DDL, storage engine.

atomic instruction
Special instructions provided by the CPU, to ensure that critical low-level operations cannot be interrupted.

auto-increment
A property of a table column (specified by the AUTO_INCREMENT keyword) that automatically adds an ascending sequence of values in the column.

It saves work for the developer, not to have to produce new unique values when inserting new rows. It provides useful information for the query optimizer, because the column is known to be not null and with unique values. The values from such a column can be used as lookup keys in various contexts, and because they are auto-generated there is no reason to ever change them; for this reason, primary key columns are often specified as auto-incrementing.

Auto-increment columns can be problematic with statement-based replication, because replaying the statements on a slave might not produce the same set of column values as on the master, due to timing issues. When you have an auto-incrementing primary key, you can use statement-based replication only with the setting innodb_autoinc_lock_mode=1. If you have innodb_autoinc_lock_mode=2, which allows higher concurrency for insert operations, use row-based replication rather than statement-based replication. The setting innodb_autoinc_lock_mode=0 should not be used except for compatibility purposes.

Consecutive lock mode (innodb_autoinc_lock_mode=1) is the default setting prior to MySQL 8.0.3. As of MySQL 8.0.3, interleaved lock mode (innodb_autoinc_lock_mode=2) is the default, which reflects the change from statement-based to row-based replication as the default replication type.
See Also auto-increment locking, innodb_autoinc_lock_mode, primary key, row-based replication, statement-based replication.

auto-increment locking
The convenience of an auto-increment primary key involves some tradeoff with concurrency. In the simplest case, if one transaction is inserting values into the table, any other transactions must wait to do their own inserts into that table, so that rows inserted by the first transaction receive consecutive primary key values. InnoDB includes optimizations and the innodb_autoinc_lock_mode option so that you can configure and optimal balance between predictable sequences of auto-increment values and maximum concurrency for insert operations.
See Also auto-increment, concurrency, innodb_autoinc_lock_mode.

autocommit
A setting that causes a commit operation after each SQL statement. This mode is not recommended for working with InnoDB tables with transactions that span several statements. It can help performance for read-only transactions on InnoDB tables, where it minimizes overhead from locking and generation of undo data, especially in MySQL 5.6.4 and up. It is also appropriate for working with MyISAM tables, where transactions are not applicable.
See Also commit, locking, read-only transaction, SQL, transaction, undo.

availability
The ability to cope with, and if necessary recover from, failures on the host, including failures of MySQL, the operating system, or the hardware and maintenance activity that may otherwise cause downtime. Often paired with scalability as critical aspects of a large-scale deployment.
See Also scalability.
B-tree

A tree data structure that is popular for use in database indexes. The structure is kept sorted at all times, enabling fast lookup for exact matches (equals operator) and ranges (for example, greater than, less than, and BETWEEN operators). This type of index is available for most storage engines, such as InnoDB and MyISAM.

Because B-tree nodes can have many children, a B-tree is not the same as a binary tree, which is limited to 2 children per node.

Contrast with hash index, which is only available in the MEMORY storage engine. The MEMORY storage engine can also use B-tree indexes, and you should choose B-tree indexes for MEMORY tables if some queries use range operators.

The use of the term B-tree is intended as a reference to the general class of index design. B-tree structures used by MySQL storage engines may be regarded as variants due to sophistications not present in a classic B-tree design. For related information, refer to the InnoDB Page Structure Fill Header section of the MySQL Internals Manual.
See Also hash index.

backticks

Identifiers within MySQL SQL statements must be quoted using the backtick character (``) if they contain special characters or reserved words. For example, to refer to a table named `FOO#BAR` or a column named `SELECT`, you would specify the identifiers as ``FOO#BAR` and `SELECT`. Since the backticks provide an extra level of safety, they are used extensively in program-generated SQL statements, where the identifier names might not be known in advance.

Many other database systems use double quotation marks ("" around such special names. For portability, you can enable ANSI_QUOTES mode in MySQL and use double quotation marks instead of backticks to qualify identifier names.
See Also SQL.

backup

The process of copying some or all table data and metadata from a MySQL instance, for safekeeping. Can also refer to the set of copied files. This is a crucial task for DBAs. The reverse of this process is the restore operation.

With MySQL, physical backups are performed by the MySQL Enterprise Backup product, and logical backups are performed by the mysqldump command. These techniques have different characteristics in terms of size and representation of the backup data, and speed (especially speed of the restore operation).

Backups are further classified as hot, warm, or cold depending on how much they interfere with normal database operation. (Hot backups have the least interference, cold backups the most.)
See Also cold backup, hot backup, logical backup, MySQL Enterprise Backup, mysqldump, physical backup, warm backup.

Barracuda

The code name for an InnoDB file format that supports the COMPRESSED row format that enables InnoDB table compression, and the DYNAMIC row format that improves the storage layout for long variable-length columns.

The MySQL Enterprise Backup product version 3.5 and above supports backing up tablespaces that use the Barracuda file format.
See Also Antelope, compact row format, compressed row format, dynamic row format, file format, file-per-table, general tablespace, innodb_file_format, MySQL Enterprise Backup, row format, system tablespace.
beta
An early stage in the life of a software product, when it is available only for evaluation, typically without a definite release number or a number less than 1. InnoDB does not use the beta designation, preferring an early adopter phase that can extend over several point releases, leading to a GA release.
See Also early adopter, GA.

binary log
A file containing a record of all statements that attempt to change table data. These statements can be replayed to bring slave servers up to date in a replication scenario, or to bring a database up to date after restoring table data from a backup. The binary logging feature can be turned on and off, although Oracle recommends always enabling it if you use replication or perform backups.

You can examine the contents of the binary log, or replay those statements during replication or recovery, by using the mysqlbinlog command. For full information about the binary log, see Section 5.4.4, “The Binary Log”. For MySQL configuration options related to the binary log, see Section 17.1.4.4, “Binary Log Options and Variables”.

For the MySQL Enterprise Backup product, the file name of the binary log and the current position within the file are important details. To record this information for the master server when taking a backup in a replication context, you can specify the --slave-info option.

Prior to MySQL 5.0, a similar capability was available, known as the update log. In MySQL 5.0 and higher, the binary log replaces the update log.
See Also binlog, MySQL Enterprise Backup, replication.

binlog
An informal name for the binary log file. For example, you might see this abbreviation used in e-mail messages or forum discussions.
See Also binary log.

blind query expansion
A special mode of full-text search enabled by the WITH QUERY EXPANSION clause. It performs the search twice, where the search phrase for the second search is the original search phrase concatenated with the few most highly relevant documents from the first search. This technique is mainly applicable for short search phrases, perhaps only a single word. It can uncover relevant matches where the precise search term does not occur in the document.
See Also full-text search.

bottleneck
A portion of a system that is constrained in size or capacity, that has the effect of limiting overall throughput. For example, a memory area might be smaller than necessary; access to a single required resource might prevent multiple CPU cores from running simultaneously; or waiting for disk I/O to complete might prevent the CPU from running at full capacity. Removing bottlenecks tends to improve concurrency. For example, the ability to have multiple InnoDB buffer pool instances reduces contention when multiple sessions read from and write to the buffer pool simultaneously.
See Also buffer pool, concurrency.

bounce
A shutdown operation immediately followed by a restart. Ideally with a relatively short warmup period so that performance and throughput quickly return to a high level.
See Also shutdown.

buddy allocator
A mechanism for managing different-sized pages in the InnoDB buffer pool.
See Also buffer pool, page, page size.
buffer
A memory or disk area used for temporary storage. Data is buffered in memory so that it can be written to disk efficiently, with a few large I/O operations rather than many small ones. Data is buffered on disk for greater reliability, so that it can be recovered even when a crash or other failure occurs at the worst possible time. The main types of buffers used by InnoDB are the buffer pool, the doublewrite buffer, and the change buffer.
See Also buffer pool, change buffer, crash, doublewrite buffer.

buffer pool
The memory area that holds cached InnoDB data for both tables and indexes. For efficiency of high-volume read operations, the buffer pool is divided into pages that can potentially hold multiple rows. For efficiency of cache management, the buffer pool is implemented as a linked list of pages; data that is rarely used is aged out of the cache, using a variation of the LRU algorithm. On systems with large memory, you can improve concurrency by dividing the buffer pool into multiple buffer pool instances.
Several InnoDB status variables, INFORMATION_SCHEMA tables, and performance_schema tables help to monitor the internal workings of the buffer pool. Starting in MySQL 5.6, you can avoid a lengthy warmup period after restarting the server, particularly for instances with large buffer pools, by saving the buffer pool state at server shutdown and restoring the buffer pool to the same state at server startup. See Section 14.8.3.5, “Saving and Restoring the Buffer Pool State”.
See Also buffer pool instance, LRU, page, warm up.

buffer pool instance
Any of the multiple regions into which the buffer pool can be divided, controlled by the innodb_buffer_pool_instances configuration option. The total memory size specified by innodb_buffer_pool_size is divided among all buffer pool instances. Typically, having multiple buffer pool instances is appropriate for systems that allocate multiple gigabytes to the InnoDB buffer pool, with each instance being one gigabyte or larger. On systems loading or looking up large amounts of data in the buffer pool from many concurrent sessions, having multiple buffer pool instances reduces contention for exclusive access to data structures that manage the buffer pool.
See Also buffer pool.

built-in
The built-in InnoDB storage engine within MySQL is the original form of distribution for the storage engine. Contrast with the InnoDB Plugin. Starting with MySQL 5.5, the InnoDB Plugin is merged back into the MySQL code base as the built-in InnoDB storage engine (known as InnoDB 1.1).

This distinction is important mainly in MySQL 5.1, where a feature or bug fix might apply to the InnoDB Plugin but not the built-in InnoDB, or vice versa.
See Also InnoDB.

business rules
The relationships and sequences of actions that form the basis of business software, used to run a commercial company. Sometimes these rules are dictated by law, other times by company policy. Careful planning ensures that the relationships encoded and enforced by the database, and the actions performed through application logic, accurately reflect the real policies of the company and can handle real-life situations.
For example, an employee leaving a company might trigger a sequence of actions from the human resources department. The human resources database might also need the flexibility to represent data about a person who has been hired, but not yet started work. Closing an account at an online service might result in data being removed from a database, or the data might be moved or flagged so that it could be recovered if the account is re-opened. A company might establish policies regarding salary maximums, minimums, and adjustments, in addition to basic sanity checks such as the salary not being a negative number. A retail database might not allow a purchase with the same serial number to be returned more than once, or might not allow credit card purchases above a certain value, while a database used to detect fraud might allow these kinds of things.
See Also relational.
.cfg file
A metadata file used with the InnoDB transportable tablespace feature. It is produced by the command FLUSH TABLES ... FOR EXPORT, puts one or more tables in a consistent state that can be copied to another server. The .cfg file is copied along with the corresponding .ibd file, and used to adjust the internal values of the .ibd file, such as the space ID, during the ALTER TABLE ... IMPORT TABLESPACE step.
See Also .ibd file, space ID, transportable tablespace.

cache
The general term for any memory area that stores copies of data for frequent or high-speed retrieval. In InnoDB, the primary kind of cache structure is the buffer pool.
See Also buffer, buffer pool.

cardinality
The number of different values in a table column. When queries refer to columns that have an associated index, the cardinality of each column influences which access method is most efficient. For example, for a column with a unique constraint, the number of different values is equal to the number of rows in the table. If a table has a million rows but only 10 different values for a particular column, each value occurs (on average) 100,000 times. A query such as SELECT c1 FROM t1 WHERE c1 = 50; thus might return 1 row or a huge number of rows, and the database server might process the query differently depending on the cardinality of c1.

If the values in a column have a very uneven distribution, the cardinality might not be a good way to determine the best query plan. For example, SELECT c1 FROM t1 WHERE c1 = x; might return 1 row when x=50 and a million rows when x=30. In such a case, you might need to use index hints to pass along advice about which lookup method is more efficient for a particular query.

Cardinality can also apply to the number of distinct values present in multiple columns, as in a composite index.
See Also column, composite index, index, index hint, persistent statistics, random dive, selectivity, unique constraint.

change buffer
A special data structure that records changes to pages in secondary indexes. These values could result from SQL INSERT, UPDATE, or DELETE statements (DML). The set of features involving the change buffer is known collectively as change buffering, consisting of insert buffering, delete buffering, and purge buffering.

Changes are only recorded in the change buffer when the relevant page from the secondary index is not in the buffer pool. When the relevant index page is brought into the buffer pool while associated changes are still in the change buffer, the changes for that page are applied in the buffer pool (merged) using the data from the change buffer. Periodically, the purge operation that runs during times when the system is mostly idle, or during a slow shutdown, writes the new index pages to disk. The purge operation can write the disk blocks for a series of index values more efficiently than if each value were written to disk immediately.

Physically, the change buffer is part of the system tablespace, so that the index changes remain buffered across database restarts. The changes are only applied (merged) when the pages are brought into the buffer pool due to some other read operation.

The kinds and amount of data stored in the change buffer are governed by the innodb_change_buffering and innodb_change_buffer_max_size configuration options. To see information about the current data in the change buffer, issue the SHOW ENGINE INNODB STATUS command.

Formerly known as the insert buffer.
See Also buffer pool, change buffering, delete buffering, DML, insert buffer, insert buffering, merge, page, purge, purge buffering, secondary index, system tablespace.
change buffering
The general term for the features involving the change buffer, consisting of insert buffering, delete buffering, and purge buffering. Index changes resulting from SQL statements, which could normally involve random I/O operations, are held back and performed periodically by a background thread. This sequence of operations can write the disk blocks for a series of index values more efficiently than if each value were written to disk immediately. Controlled by the innodb_change_buffering and innodb_change_buffer_max_size configuration options.
See Also change buffer, delete buffering, insert buffering, purge buffering.

checkpoint
As changes are made to data pages that are cached in the buffer pool, those changes are written to the data files sometime later, a process known as flushing. The checkpoint is a record of the latest changes (represented by an LSN value) that have been successfully written to the data files.
See Also buffer pool, data files, flush, fuzzy checkpointing, LSN.

checksum
In InnoDB, a validation mechanism to detect corruption when a page in a tablespace is read from disk into the InnoDB buffer pool. This feature is controlled by the innodb_checksums configuration option in MySQL 5.5. innodb_checksums is deprecated in MySQL 5.6.3, replaced by innodb_checksum_algorithm.
The innochecksum command helps diagnose corruption problems by testing the checksum values for a specified tablespace file while the MySQL server is shut down.
MySQL also uses checksums for replication purposes. For details, see the configuration options binlog_checksum, master_verify_checksum, and slave_sql_verify_checksum.
See Also buffer pool, page, checksum, tablespace.

child table
In a foreign key relationship, a child table is one whose rows refer (or point) to rows in another table with an identical value for a specific column. This is the table that contains the FOREIGN KEY ... REFERENCES clause and optionally ON UPDATE and ON DELETE clauses. The corresponding row in the parent table must exist before the row can be created in the child table. The values in the child table can prevent delete or update operations on the parent table, or can cause automatic deletion or updates in the child table, based on the ON CASCADE option used when creating the foreign key.
See Also foreign key, parent table.

clean page
A page in the InnoDB buffer pool where all changes made in memory have also been written (flushed) to the data files. The opposite of a dirty page.
See Also buffer pool, data files, dirty page, flush, page.

clean shutdown
A shutdown that completes without errors and applies all changes to InnoDB tables before finishing, as opposed to a crash or a fast shutdown. Synonym for slow shutdown.
See Also crash, fast shutdown, shutdown, slow shutdown.

client
A type of program that sends requests to a server, and interprets or processes the results. The client software might run only some of the time (such as a mail or chat program), and might run interactively (such as the mysql command processor).
See Also mysql, server.

clustered index
The InnoDB term for a primary key index. InnoDB table storage is organized based on the values of the primary key columns, to speed up queries and sorts involving the primary key columns. For best performance, choose the primary key columns carefully based on the most performance-critical queries. Because modifying
the columns of the clustered index is an expensive operation, choose primary columns that are rarely or never updated.

In the Oracle Database product, this type of table is known as an **index-organized table**.

See Also index, primary key, secondary index.

cold backup

A backup taken while the database is shut down. For busy applications and websites, this might not be practical, and you might prefer a **warm backup** or a **hot backup**.

See Also backup, hot backup, warm backup.

column

A data item within a row, whose storage and semantics are defined by a data type. Each table and index is largely defined by the set of columns it contains.

Each column has a **cardinality** value. A column can be the primary key for its table, or part of the primary key. A column can be subject to a unique constraint, a NOT NULL constraint, or both. Values in different columns, even across different tables, can be linked by a foreign key relationship.

In discussions of MySQL internal operations, sometimes field is used as a synonym.

See Also cardinality, foreign key, index, NOT NULL constraint, primary key, row, table, unique constraint.

column index

An index on a single column.

See Also composite index, index.

column prefix

When an index is created with a length specification, such as CREATE INDEX idx ON t1 (c1(N)), only the first N characters of the column value are stored in the index. Keeping the index prefix small makes the index compact, and the memory and disk I/O savings help performance. (Although making the index prefix too small can hinder query optimization by making rows with different values appear to the query optimizer to be duplicates.)

For columns containing binary values or long text strings, where sorting is not a major consideration and storing the entire value in the index would waste space, the index automatically uses the first N (typically 768) characters of the value to do lookups and sorts.

See Also index.

commit

A SQL statement that ends a transaction, making permanent any changes made by the transaction. It is the opposite of rollback, which undoes any changes made in the transaction.

**InnoDB** uses an optimistic mechanism for commits, so that changes can be written to the data files before the commit actually occurs. This technique makes the commit itself faster, with the tradeoff that more work is required in case of a rollback.

By default, MySQL uses the **autocommit** setting, which automatically issues a commit following each SQL statement.

See Also autocommit, optimistic, rollback, SQL, transaction.

compact row format

The default **InnoDB row format** for InnoDB tables since MySQL 5.0.3. The **COMPACT** row format provides a more compact representation for nulls and variable-length columns than the prior default (**REDUNDANT** row format).

For additional information about **InnoDB COMPACT** row format, see Section 14.11, "InnoDB Row Formats".

See Also Antelope, dynamic row format, file format, redundant row format, row format.
composite index
   An index that includes multiple columns.
   See Also index.

compressed backup
   The compression feature of the MySQL Enterprise Backup product makes a compressed copy of each
   tablespace, changing the extension from .ibd to .ibz. Compressing backup data allows you to keep more
   backups on hand, and reduces the time to transfer backups to a different server. The data is uncompressed
   during the restore operation. When a compressed backup operation processes a table that is already
   compressed, it skips the compression step for that table, because compressing again would result in little or no
   space savings.

   A set of files produced by the MySQL Enterprise Backup product, where each tablespace is compressed. The
   compressed files are renamed with a .ibz file extension.

   Applying compression at the start of the backup process helps to avoid storage overhead during the
   compression process, and to avoid network overhead when transferring the backup files to another server. The
   process of applying the binary log takes longer, and requires uncompressing the backup files.
   See Also apply, binary log, compression, hot backup, MySQL Enterprise Backup, tablespace.

compressed row format
   A row format that enables data and index compression for InnoDB tables. It was introduced in the InnoDB
   Plugin, available as part of the Barracuda file format. Large fields are stored away from the page that holds the
   rest of the row data, as in dynamic row format. Both index pages and large fields are compressed, yielding
   memory and disk savings. Depending on the structure of the data, the decrease in memory and disk usage might
   or might not outweigh the performance overhead of uncompressing the data as it is used. See Section 14.9,
   “InnoDB Table Compression” for usage details.

   For additional information about InnoDB COMPRESSED row format, see DYNAMIC Row Format.
   See Also Barracuda, compression, dynamic row format, row format.

compressed table
   A table for which the data is stored in compressed form. For InnoDB, it is a table created with
   ROW_FORMAT=COMPRESSED. See Section 14.9, “InnoDB Table Compression” for more information.
   See Also compressed row format, compression.

compression
   A feature with wide-ranging benefits from using less disk space, performing less I/O, and using less memory for
   caching. InnoDB table and index data can be kept in a compressed format during database operation.

   The data is uncompressed when needed for queries, and re-compressed when changes are made by DML
   operations. After you enable compression for a table, this processing is transparent to users and application
   developers. DBAs can consult InnoDB INFORMATION_SCHEMA tables to monitor how efficiently the compression
   parameters work for the MySQL instance and for particular compressed tables.

   When InnoDB table data is compressed, the compression applies to the table itself, any associated index data,
   and the pages loaded into the buffer pool. Compression does not apply to pages in the undo buffer.

   The table compression feature requires using MySQL 5.5 or higher, or the InnoDB Plugin in MySQL 5.1
   or earlier, and creating the table using the Barracuda file format and compressed row format, with the
   innodb_file_per_table setting enabled.

   Compression for each table is influenced by the KEY_BLOCK_SIZE clause of the CREATE TABLE and ALTER
   TABLE statements. In MySQL 5.6 and higher, compression is also affected by the server-wide configuration
   options innodb_compression_failure_threshold_pct, innodb_compression_level, and
   innodb_compression_pad_pct_max. See Section 14.9, “InnoDB Table Compression” for usage details.

   Another type of compression is the compressed backup feature of the MySQL Enterprise Backup product.
comprehension failure
Not actually an error, rather an expensive operation that can occur when using compression in combination with DML operations. It occurs when: updates to a compressed page overflow the area on the page reserved for recording modifications; the page is compressed again, with all changes applied to the table data; the re-compressed data does not fit on the original page, requiring MySQL to split the data into two new pages and compress each one separately. To check the frequency of this condition, query the INFORMATION_SCHEMA.INNODB_CMP table and check how much the value of the COMPRESS_OPS column exceeds the value of the COMPRESS_OPS_OK column. Ideally, compression failures do not occur often; when they do, you can adjust the innodb_compression_level, innodb_compression_failure_threshold_pct, and innodb_compression_pad_pct_max configuration options.

See Also compression, DML, page.

concatenated index
See composite index.

concurrency
The ability of multiple operations (in database terminology, transactions) to run simultaneously, without interfering with each other. Concurrency is also involved with performance, because ideally the protection for multiple simultaneous transactions works with a minimum of performance overhead, using efficient mechanisms for locking.

See Also ACID, locking, transaction.

configuration file
The file that holds the option values used by MySQL at startup. Traditionally, on Linux and Unix this file is named my.cnf, and on Windows it is named my.ini. You can set a number of options related to InnoDB under the [mysqld] section of the file.

See Section 4.2.2.2, “Using Option Files” for information about where MySQL searches for configuration files.

When you use the MySQL Enterprise Backup product, you typically use two configuration files: one that specifies where the data comes from and how it is structured (which could be the original configuration file for your server), and a stripped-down one containing only a small set of options that specify where the backup data goes and how it is structured. The configuration files used with the MySQL Enterprise Backup product must contain certain options that are typically left out of regular configuration files, so you might need to add options to your existing configuration file for use with MySQL Enterprise Backup.

See Also my.cnf, MySQL Enterprise Backup, option, option file.

consistent read
A read operation that uses snapshot information to present query results based on a point in time, regardless of changes performed by other transactions running at the same time. If queried data has been changed by another transaction, the original data is reconstructed based on the contents of the undo log. This technique avoids some of the locking issues that can reduce concurrency by forcing transactions to wait for other transactions to finish.

With REPEATABLE READ isolation level, the snapshot is based on the time when the first read operation is performed. With READ COMMITTED isolation level, the snapshot is reset to the time of each consistent read operation.

Consistent read is the default mode in which InnoDB processes SELECT statements in READ COMMITTED and REPEATABLE READ isolation levels. Because a consistent read does not set any locks on the tables it accesses, other sessions are free to modify those tables while a consistent read is being performed on the table.

For technical details about the applicable isolation levels, see Section 14.7.2.3, “Consistent Nonlocking Reads”. See Also concurrency, isolation level, locking, READ COMMITTED, REPEATABLE READ, snapshot, transaction, undo log.
constraint
   An automatic test that can block database changes to prevent data from becoming inconsistent. (In computer science terms, a kind of assertion related to an invariant condition.) Constraints are a crucial component of the ACID philosophy, to maintain data consistency. Constraints supported by MySQL include FOREIGN KEY constraints and unique constraints.
   See Also ACID, foreign key, unique constraint.

counter
   A value that is incremented by a particular kind of InnoDB operation. Useful for measuring how busy a server is, troubleshooting the sources of performance issues, and testing whether changes (for example, to configuration settings or indexes used by queries) have the desired low-level effects. Different kinds of counters are available through Performance Schema tables and INFORMATION_SCHEMA tables, particularly INFORMATION_SCHEMA.INNODB_METRICS.
   See Also INFORMATION_SCHEMA, metrics counter, Performance Schema.

covering index
   An index that includes all the columns retrieved by a query. Instead of using the index values as pointers to find the full table rows, the query returns values from the index structure, saving disk I/O. InnoDB can apply this optimization technique to more indexes than MyISAM can, because InnoDB secondary indexes also include the primary key columns. InnoDB cannot apply this technique for queries against tables modified by a transaction, until that transaction ends.

   Any column index or composite index could act as a covering index, given the right query. Design your indexes and queries to take advantage of this optimization technique wherever possible.
   See Also column index, composite index, index, primary key, secondary index.

CPU-bound
   A type of workload where the primary bottleneck is CPU operations in memory. Typically involves read-intensive operations where the results can all be cached in the buffer pool.
   See Also bottleneck, buffer pool, workload.

crash
   MySQL uses the term “crash” to refer generally to any unexpected shutdown operation where the server cannot do its normal cleanup. For example, a crash could happen due to a hardware fault on the database server machine or storage device; a power failure; a potential data mismatch that causes the MySQL server to halt; a fast shutdown initiated by the DBA; or many other reasons. The robust, automatic crash recovery for InnoDB tables ensures that data is made consistent when the server is restarted, without any extra work for the DBA.
   See Also crash recovery, fast shutdown, InnoDB, shutdown.

crash recovery
   The cleanup activities that occur when MySQL is started again after a crash. For InnoDB tables, changes from incomplete transactions are replayed using data from the redo log. Changes that were committed before the crash, but not yet written into the data files, are reconstructed from the doublewrite buffer. When the database is shut down normally, this type of activity is performed during shutdown by the purge operation.

   During normal operation, committed data can be stored in the change buffer for a period of time before being written to the data files. There is always a tradeoff between keeping the data files up-to-date, which introduces performance overhead during normal operation, and buffering the data, which can make shutdown and crash recovery take longer.
   See Also change buffer, commit, crash, data files, doublewrite buffer, InnoDB, purge, redo log.

CRUD
   Acronym for “create, read, update, delete”, a common sequence of operations in database applications. Often denotes a class of applications with relatively simple database usage (basic DDL, DML and query statements in SQL) that can be implemented quickly in any language.
cursor
An internal data structure that is used to represent the result set of a query, or other operation that performs a search using an SQL WHERE clause. It works like an iterator in other high-level languages, producing each value from the result set as requested.

Although SQL usually handles the processing of cursors for you, you might delve into the inner workings when dealing with performance-critical code.
See Also query.

data definition language
See DDL.

data dictionary
Metadata that keeps track of InnoDB-related objects such as tables, indexes, and table columns. This metadata is physically located in the InnoDB system tablespace. For historical reasons, it overlaps to some degree with information stored in the .frm files.

Because the MySQL Enterprise Backup product always backs up the system tablespace, all backups include the contents of the data dictionary.
See Also column, file-per-table, .frm file, index, MySQL Enterprise Backup, system tablespace, table.

data directory
The directory under which each MySQL instance keeps the data files for InnoDB and the directories representing individual databases. Controlled by the datadir configuration option.
See Also data files, instance.

data files
The files that physically contain table and index data.

The InnoDB system tablespace, which holds the InnoDB data dictionary and is capable of holding data for multiple InnoDB tables, is represented by one or more .ibdata data files.

File-per-table tablespaces, which hold data for a single InnoDB table, are represented by a .ibd data file.

General tablespaces (introduced in MySQL 5.7.6), which can hold data for multiple InnoDB tables, are also represented by a .ibd data file.
See Also data dictionary, file-per-table, general tablespace, .ibd file, ibdata file, index, system tablespace, table, tablesapce.

data manipulation language
See DML.

data warehouse
A database system or application that primarily runs large queries. The read-only or read-mostly data might be organized in denormalized form for query efficiency. Can benefit from the optimizations for read-only transactions in MySQL 5.6 and higher. Contrast with OLTP.
See Also denormalized, OLTP, query, read-only transaction.

database
Within the MySQL data directory, each database is represented by a separate directory. The InnoDB system tablespace, which can hold table data from multiple databases within a MySQL instance, is kept in data files.
that reside outside of individual database directories. When **file-per-table** mode is enabled, the **.ibd files** representing individual InnoDB tables are stored inside the database directories unless created elsewhere using the **DATA DIRECTORY** clause. General tablespaces, introduced in MySQL 5.7.6, also hold table data in **.ibd files**. Unlike file-per-table **.ibd files**, general tablespace **.ibd files** can hold table data from multiple databases within a MySQL **instance**, and can be assigned to directories relative to or independent of the MySQL data directory.

For long-time MySQL users, a database is a familiar notion. Users coming from an Oracle Database background will find that the MySQL meaning of a database is closer to what Oracle Database calls a **schema**. See Also **data files**, **file-per-table**, **.ibd file**, **instance**, **schema**, **system tablespace**.

**DCL**
- Data control language, a set of **SQL** statements for managing privileges. In MySQL, consists of the **GRANT** and **REVOKE** statements. Contrast with **DDL** and **DML**.
  - See Also **DDL**, **DML**, **SQL**.

**DDL**
- Data definition language, a set of **SQL** statements for manipulating the database itself rather than individual table rows. Includes all forms of the **CREATE**, **ALTER**, and **DROP** statements. Also includes the **TRUNCATE** statement, because it works differently than a **DELETE FROM table_name** statement, even though the ultimate effect is similar.

- DDL statements automatically commit the current transaction; they cannot be rolled back.

- The **InnoDB online DDL** feature enhances performance for **CREATE INDEX**, **DROP INDEX**, and many types of **ALTER TABLE** operations. See Section 14.13, "InnoDB and Online DDL" for more information. Also, the **InnoDB file-per-table** setting can affect the behavior of **DROP TABLE** and **TRUNCATE TABLE** operations.

- Contrast with **DML** and **DCL**.
  - See Also **commit**, **DCL**, **DML**, **file-per-table**, **rollback**, **SQL**, **transaction**.

**deadlock**
- A situation where different **transactions** are unable to proceed, because each holds a **lock** that the other needs. Because both transactions are waiting for a resource to become available, neither will ever release the locks it holds.

- A deadlock can occur when the transactions lock rows in multiple tables (through statements such as **UPDATE** or **SELECT ... FOR UPDATE**), but in the opposite order. A deadlock can also occur when such statements lock ranges of index records and **gaps**, with each transaction acquiring some locks but not others due to a timing issue.

- For background information on how deadlocks are automatically detected and handled, see Section 14.7.5.2, “Deadlock Detection and Rollback”. For tips on avoiding and recovering from deadlock conditions, see Section 14.7.5.3, “How to Minimize and Handle Deadlocks”.
  - See Also **gap**, **lock**, **transaction**.

**deadlock detection**
- A mechanism that automatically detects when a **deadlock** occurs, and automatically **rolls back** one of the **transactions** involved (the **victim**).
  - See Also **deadlock**, **rollback**, **transaction**, **victim**.

**delete**
- When **InnoDB** processes a **DELETE** statement, the rows are immediately marked for deletion and no longer are returned by queries. The storage is reclaimed sometime later, during the periodic garbage collection known as the **purge** operation. For removing large quantities of data, related operations with their own performance characteristics are **TRUNCATE** and **DROP**.
delete buffering
The technique of storing changes to secondary index pages, resulting from DELETE operations, in the change buffer rather than writing the changes immediately, so that the physical writes can be performed to minimize random I/O. (Because delete operations are a two-step process, this operation buffers the write that normally marks an index record for deletion.) It is one of the types of change buffering; the others are insert buffering and purge buffering.
See Also change buffer, change buffering, insert buffer, insert buffering, purge buffering.

denormalized
A data storage strategy that duplicates data across different tables, rather than linking the tables with foreign keys and join queries. Typically used in data warehouse applications, where the data is not updated after loading. In such applications, query performance is more important than making it simple to maintain consistent data during updates. Contrast with normalized.
See Also data warehouse, foreign key, join, normalized.

descending index
A type of index available with some database systems, where index storage is optimized to process ORDER BY column DESC clauses. Currently, although MySQL allows the DESC keyword in the CREATE TABLE statement, it does not use any special storage layout for the resulting index.
See Also index.

dirty page
A page in the InnoDB buffer pool that has been updated in memory, where the changes are not yet written (flushed) to the data files. The opposite of a clean page.
See Also buffer pool, clean page, data files, flush, page.

dirty read
An operation that retrieves unreliable data, data that was updated by another transaction but not yet committed. It is only possible with the isolation level known as read uncommitted.
This kind of operation does not adhere to the ACID principle of database design. It is considered very risky, because the data could be rolled back, or updated further before being committed; then, the transaction doing the dirty read would be using data that was never confirmed as accurate.
Its opposite is consistent read, where InnoDB ensures that a transaction does not read information updated by another transaction, even if the other transaction commits in the meantime.
See Also ACID, commit, consistent read, isolation level, READ UNCOMMITTED, rollback.

disk-based
A kind of database that primarily organizes data on disk storage (hard drives or equivalent). Data is brought back and forth between disk and memory to be operated upon. It is the opposite of an in-memory database. Although InnoDB is disk-based, it also contains features such as he buffer pool, multiple buffer pool instances, and the adaptive hash index that allow certain kinds of workloads to work primarily from memory.
See Also adaptive hash index, buffer pool, in-memory database.

disk-bound
A type of workload where the primary bottleneck is disk I/O. (Also known as I/O-bound.) Typically involves frequent writes to disk, or random reads of more data than can fit into the buffer pool.
See Also bottleneck, buffer pool, workload.

DML
Data manipulation language, a set of SQL statements for performing INSERT, UPDATE, and DELETE operations. The SELECT statement is sometimes considered as a DML statement, because the SELECT ... FOR UPDATE form is subject to the same considerations for locking as INSERT, UPDATE, and DELETE.
DML statements for an InnoDB table operate in the context of a transaction, so their effects can be committed or rolled back as a single unit.

Contrast with DDL and DCL.
See Also commit, DCL, DDL, locking, rollback, SQL, transaction.

document id
In the InnoDB full-text search feature, a special column in the table containing the FULLTEXT index, to uniquely identify the document associated with each ilist value. Its name is FTS_DOC_ID (uppercase required). The column itself must be of BIGINT UNSIGNED NOT NULL type, with a unique index named FTS_DOC_ID_INDEX. Preferably, you define this column when creating the table. If InnoDB must add the column to the table while creating a FULLTEXT index, the indexing operation is considerably more expensive.
See Also full-text search, FULLTEXT index, ilist.

doublewrite buffer
InnoDB uses a file flush technique called doublewrite. Before writing pages to the data files, InnoDB first writes them to a contiguous area called the doublewrite buffer. Only after the write and the flush to the doublewrite buffer have completed, does InnoDB write the pages to their proper positions in the data file. If there is an operating system, storage subsystem, or mysqld process crash in the middle of a page write, InnoDB can later find a good copy of the page from the doublewrite buffer during crash recovery.

Although data is always written twice, the doublewrite buffer does not require twice as much I/O overhead or twice as many I/O operations. Data is written to the buffer itself as a large sequential chunk, with a single fsync() call to the operating system.

To turn off the doublewrite buffer, specify the option innodb_doublewrite=0.
See Also crash recovery, data files, page, purge.

drop
A kind of DDL operation that removes a schema object, through a statement such as DROP TABLE or DROP INDEX. It maps internally to an ALTER TABLE statement. From an InnoDB perspective, the performance considerations of such operations involve the time that the data dictionary is locked to ensure that interrelated objects are all updated, and the time to update memory structures such as the buffer pool. For a table, the drop operation has somewhat different characteristics than a truncate operation (TRUNCATE TABLE statement).
See Also buffer pool, data dictionary, DDL, table, truncate.

dynamic row format
A row format introduced in the InnoDB Plugin, available as part of the Barracuda file format. Because long variable-length column values are stored outside of the page that holds the row data, it is very efficient for rows that include large objects. Since the large fields are typically not accessed to evaluate query conditions, they are not brought into the buffer pool as often, resulting in fewer I/O operations and better utilization of cache memory.

As of MySQL 5.7.9, the default row format is defined by innodb_default_row_format, which has a default value of DYNAMIC.

For additional information about InnoDB DYNAMIC row format, see DYNAMIC Row Format.
See Also Barracuda, buffer pool, file format, row format.

E

early adopter
A stage similar to beta, when a software product is typically evaluated for performance, functionality, and compatibility in a non-mission-critical setting.
See Also beta.
error log

A type of log showing information about MySQL startup and critical runtime errors and crash information. For details, see Section 5.4.2, “The Error Log”.

See Also crash, log.

eviction

The process of removing an item from a cache or other temporary storage area, such as the InnoDB buffer pool. Often, but not always, uses the LRU algorithm to determine which item to remove. When a dirty page is evicted, its contents are flushed to disk, and any dirty neighbor pages might be flushed also.

See Also buffer pool, dirty page, flush, LRU, neighbor page.

exclusive lock

A kind of lock that prevents any other transaction from locking the same row. Depending on the transaction isolation level, this kind of lock might block other transactions from writing to the same row, or might also block other transactions from reading the same row. The default InnoDB isolation level, REPEATABLE READ, enables higher concurrency by allowing transactions to read rows that have exclusive locks, a technique known as consistent read.

See Also concurrency, consistent read, isolation level, lock, REPEATABLE READ, shared lock, transaction.

extent

A group of pages within a tablespace. For the default page size of 16KB, an extent contains 64 pages. In MySQL 5.6, the page size for an InnoDB instance can be 4KB, 8KB, or 16KB, controlled by the innodb_page_size configuration option. For 4KB, 8KB, and 16KB pages sizes, the extent size is always 1MB (or 1048576 bytes).

Support for 32KB and 64KB InnoDB page sizes was added in MySQL 5.7.6. For a 32KB page size, the extent size is 2MB. For a 64KB page size, the extent size is 4MB.

InnoDB features such as segments, read-ahead requests and the doublewrite buffer use I/O operations that read, write, allocate, or free data one extent at a time.

See Also doublewrite buffer, page, page size, read-ahead, segment, tablespace.

F

.frm file

A file containing the metadata, such as the table definition, of a MySQL table.

For backups, you must always keep the full set of .frm files along with the backup data to be able to restore tables that are altered or dropped after the backup.

Although each InnoDB table has a .frm file, InnoDB maintains its own table metadata in the system tablespace; the .frm files are not needed for InnoDB to operate on InnoDB tables.

.frm files are backed up by the MySQL Enterprise Backup product. These files must not be modified by an ALTER TABLE operation while the backup is taking place, which is why backups that include non-InnoDB tables perform a FLUSH TABLES WITH READ LOCK operation to freeze such activity while backing up .frm files. Restoring a backup can result in .frm files being created, changed, or removed to match the state of the database at the time of the backup.

See Also data dictionary, MySQL Enterprise Backup, system tablespace.

Fast Index Creation

A capability first introduced in the InnoDB Plugin, now part of MySQL in 5.5 and higher, that speeds up creation of InnoDB secondary indexes by avoiding the need to completely rewrite the associated table. The speedup applies to dropping secondary indexes also.
Because index maintenance can add performance overhead to many data transfer operations, consider doing operations such as `ALTER TABLE ... ENGINE=INNODB` or `INSERT INTO ... SELECT * FROM ...` without any secondary indexes in place, and creating the indexes afterward.

In MySQL 5.6, this feature becomes more general. You can read and write to tables while an index is being created, and many more kinds of `ALTER TABLE` operations can be performed without copying the table, without blocking DML operations, or both. Thus in MySQL 5.6 and higher, this set of features is referred to as online DDL rather than Fast Index Creation.

For related information, see InnoDB Fast Index Creation, and Section 14.13, “InnoDB and Online DDL”.

See Also DML, index, online DDL, secondary index.

fast shutdown

The default `shutdown` procedure for InnoDB, based on the configuration setting `innodb_fast_shutdown=1`. To save time, certain `flush` operations are skipped. This type of shutdown is safe during normal usage, because the flush operations are performed during the next startup, using the same mechanism as in crash recovery. In cases where the database is being shut down for an upgrade or downgrade, do a slow shutdown instead to ensure that all relevant changes are applied to the data files during the shutdown.

See Also crash recovery, data files, flush, shutdown, slow shutdown.

file format

The file format for InnoDB tables, enabled using the `innodb_file_format` configuration option. Supported file formats are Antelope and Barracuda. Antelope is the original InnoDB file format and supports the REDUNDANT and COMPACT row formats. Barracuda is the newer InnoDB file format and supports the COMPRESSED and DYNAMIC row formats.

See Also Antelope, Barracuda, file-per-table, .ibd file, ibdata file, row format.

file-per-table

A general name for the setting controlled by the `innodb_file_per_table` option, which is an important configuration option that affects aspects of InnoDB file storage, availability of features, and I/O characteristics. As of MySQL 5.6.7, `innodb_file_per_table` is enabled by default.

With the `innodb_file_per_table` option enabled, you can create a table in its own .ibd file rather than in the shared ibdata files of the system tablespace. When table data is stored in an individual .ibd file, you have more flexibility to choose row formats required for features such as data compression. The TRUNCATE TABLE operation is also faster, and reclaimed space can be used by the operating system rather than remaining reserved for InnoDB.

The MySQL Enterprise Backup product is more flexible for tables that are in their own files. For example, tables can be excluded from a backup, but only if they are in separate files. Thus, this setting is suitable for tables that are backed up less frequently or on a different schedule.

See Also compressed row format, compression, file format, .ibd file, ibdata file, innodb_file_per_table, MySQL Enterprise Backup, row format, system tablespace.

fill factor

In an InnoDB index, the proportion of a page that is taken up by index data before the page is split. The unused space when index data is first divided between pages allows for rows to be updated with longer string values without requiring expensive index maintenance operations. If the fill factor is too low, the index consumes more space than needed, causing extra I/O overhead when reading the index. If the fill factor is too high, any update that increases the length of column values can cause extra I/O overhead for index maintenance. See Section 14.6.2.2, “The Physical Structure of an InnoDB Index” for more information.

See Also index, page.

fixed row format

This row format is used by the MyISAM storage engine, not by InnoDB. If you create an InnoDB table with the option `ROW_FORMAT=FIXED` in MySQL 5.7.6 or earlier, InnoDB uses the compact row format instead,
although the \texttt{FIXED} value might still show up in output such as \texttt{SHOW TABLE STATUS} reports. As of MySQL 5.7.7, InnoDB returns an error if \texttt{ROW\_FORMAT=FIXED} is specified.
See Also compact row format, row format.

flush
To write changes to the database files, that had been buffered in a memory area or a temporary disk storage area. The InnoDB storage structures that are periodically flushed include the redo log, the undo log, and the buffer pool.
Flushing can happen because a memory area becomes full and the system needs to free some space, because a commit operation means the changes from a transaction can be finalized, or because a slow shutdown operation means that all outstanding work should be finalized. When it is not critical to flush all the buffered data at once, InnoDB can use a technique called fuzzy checkpointing to flush small batches of pages to spread out the I/O overhead.
See Also buffer pool, commit, fuzzy checkpointing, redo log, slow shutdown, undo log.

flush list
An internal InnoDB data structure that tracks dirty pages in the buffer pool: that is, pages that have been changed and need to be written back out to disk. This data structure is updated frequently by InnoDB internal mini-transactions, and so is protected by its own mutex to allow concurrent access to the buffer pool.
See Also buffer pool, dirty page, LRU, mini-transaction, mutex, page, page cleaner.

foreign key
A type of pointer relationship, between rows in separate InnoDB tables. The foreign key relationship is defined on one column in both the parent table and the child table.
In addition to enabling fast lookup of related information, foreign keys help to enforce referential integrity, by preventing any of these pointers from becoming invalid as data is inserted, updated, and deleted. This enforcement mechanism is a type of constraint. A row that points to another table cannot be inserted if the associated foreign key value does not exist in the other table. If a row is deleted or its foreign key value changed, and rows in another table point to that foreign key value, the foreign key can be set up to prevent the deletion, cause the corresponding column values in the other table to become null, or automatically delete the corresponding rows in the other table.
One of the stages in designing a normalized database is to identify data that is duplicated, separate that data into a new table, and set up a foreign key relationship so that the multiple tables can be queried like a single table, using a join operation.
See Also child table, FOREIGN KEY constraint, join, normalized, NULL, parent table, referential integrity, relational.

FOREIGN KEY constraint
The type of constraint that maintains database consistency through a foreign key relationship. Like other kinds of constraints, it can prevent data from being inserted or updated if data would become inconsistent; in this case, the inconsistency being prevented is between data in multiple tables. Alternatively, when a DML operation is performed, FOREIGN KEY constraints can cause data in child rows to be deleted, changed to different values, or set to null, based on the \texttt{ON CASCADE} option specified when creating the foreign key.
See Also child table, constraint, DML, foreign key, NULL.

FTS
In most contexts, an acronym for full-text search. Sometimes in performance discussions, an acronym for full table scan.
See Also full table scan, full-text search.

full backup
A backup that includes all the tables in each MySQL database, and all the databases in a MySQL instance. Contrast with partial backup.
See Also backup, database, instance, partial backup, table.

full table scan
An operation that requires reading the entire contents of a table, rather than just selected portions using an index. Typically performed either with small lookup tables, or in data warehousing situations with large tables where all available data is aggregated and analyzed. How frequently these operations occur, and the sizes of the tables relative to available memory, have implications for the algorithms used in query optimization and managing the buffer pool.

The purpose of indexes is to allow lookups for specific values or ranges of values within a large table, thus avoiding full table scans when practical.
See Also buffer pool, index.

full-text search
The MySQL feature for finding words, phrases, Boolean combinations of words, and so on within table data, in a faster, more convenient, and more flexible way than using the SQL LIKE operator or writing your own application-level search algorithm. It uses the SQL function MATCH() and FULLTEXT indexes.
See Also FULLTEXT index.

FULLTEXT index
The special kind of index that holds the search index in the MySQL full-text search mechanism. Represents the words from values of a column, omitting any that are specified as stopwords. Originally, only available for MyISAM tables. Starting in MySQL 5.6.4, it is also available for InnoDB tables.
See Also full-text search, index, InnoDB, search index, stopword.

fuzzy checkpointing
A technique that flushes small batches of dirty pages from the buffer pool, rather than flushing all dirty pages at once which would disrupt database processing.
See Also buffer pool, dirty page, flush.

G

GA
“Generally available”, the stage when a software product leaves beta and is available for sale, official support, and production use.
See Also beta.

gap
A place in an InnoDB index data structure where new values could be inserted. When you lock a set of rows with a statement such as SELECT ... FOR UPDATE, InnoDB can create locks that apply to the gaps as well as the actual values in the index. For example, if you select all values greater than 10 for update, a gap lock prevents another transaction from inserting a new value that is greater than 10. The supremum record and infimum record represent the gaps containing all values greater than or less than all the current index values.
See Also concurrency, gap lock, index, infimum record, isolation level, supremum record.

gap lock
A lock on a gap between index records, or a lock on the gap before the first or after the last index record. For example, SELECT c1 FROM t WHERE c1 BETWEEN 10 and 20 FOR UPDATE; prevents other transactions from inserting a value of 15 into the column t.c1, whether or not there was already any such value in the column, because the gaps between all existing values in the range are locked. Contrast with record lock and next-key lock.

Gap locks are part of the tradeoff between performance and concurrency, and are used in some transaction isolation levels and not others.
See Also gap, infimum record, lock, next-key lock, record lock, supremum record.

general log
   See general query log.

general query log
   A type of log used for diagnosis and troubleshooting of SQL statements processed by the MySQL server. Can be stored in a file or in a database table. You must enable this feature through the `general_log` configuration option to use it. You can disable it for a specific connection through the `sql_log_off` configuration option.

   Records a broader range of queries than the slow query log. Unlike the binary log, which is used for replication, the general query log contains SELECT statements and does not maintain strict ordering. For more information, see Section 5.4.3, “The General Query Log”.
   See Also binary log, log, slow query log.

general tablespace
   A shared InnoDB tablespace created using `CREATE TABLESPACE` syntax. General tablespaces can be created outside of the MySQL data directory, are capable of holding multiple tables, and support tables of all row formats. General tablespaces were introduced in MySQL 5.7.6.

   Tables are added to a general tablespace using `CREATE TABLE tbl_name ... TABLESPACE [=] tablespace_name` or `ALTER TABLE tbl_name TABLESPACE [=] tablespace_name` syntax.

   Contrast with system tablespace and file-per-table tablespace.

   For more information, see General Tablespaces.
   See Also file-per-table, system tablespace, table, tablespace.

global transaction
   A type of transaction involved in XA operations. It consists of several actions that are transactional in themselves, but that all must either complete successfully as a group, or all be rolled back as a group. In essence, this extends ACID properties “up a level” so that multiple ACID transactions can be executed in concert as components of a global operation that also has ACID properties.
   See Also ACID, transaction, XA.

group commit
   An InnoDB optimization that performs some low-level I/O operations (log write) once for a set of commit operations, rather than flushing and syncing separately for each commit.
   See Also binary log, commit.

H

hash index
   A type of index intended for queries that use equality operators, rather than range operators such as greater-than or BETWEEN. It is available for MEMORY tables. Although hash indexes are the default for MEMORY tables for historic reasons, that storage engine also supports B-tree indexes, which are often a better choice for general-purpose queries.

   MySQL includes a variant of this index type, the adaptive hash index, that is constructed automatically for InnoDB tables if needed based on runtime conditions.
   See Also adaptive hash index, B-tree, index, InnoDB.

HDD
   Acronym for “hard disk drive”. Refers to storage media using spinning platters, usually when comparing and contrasting with SSD. Its performance characteristics can influence the throughput of a disk-based workload.
heartbeat
   A periodic message that is sent to indicate that a system is functioning properly. In a replication context, if the master stops sending such messages, one of the slaves can take its place. Similar techniques can be used between the servers in a cluster environment, to confirm that all of them are operating properly.
See Also master server, replication.

high-water mark
   A value representing an upper limit, either a hard limit that should not be exceeded at runtime, or a record of the maximum value that was actually reached. Contrast with low-water mark.
See Also low-water mark.

history list
   A list of transactions with delete-marked records scheduled to be processed by the InnoDB purge operation. Recorded in the undo log. The length of the history list is reported by the command SHOW ENGINE INNODB STATUS. If the history list grows longer than the value of the innodb_max_purge_lag configuration option, each DML operation is delayed slightly to allow the purge operation to finish flushing the deleted records.
   Also known as purge lag.
See Also DML, flush, purge, purge lag, rollback segment, transaction, undo log.

hole punching
   Releasing empty blocks from a page. The InnoDB transparent page compression feature relies on hole punching support. For more information, see InnoDB Page Compression.
See Also sparse file, transparent page compression.

hot
   A condition where a row, table, or internal data structure is accessed so frequently, requiring some form of locking or mutual exclusion, that it results in a performance or scalability issue.
   Although “hot” typically indicates an undesirable condition, a hot backup is the preferred type of backup.
See Also hot backup.

hot backup
   A backup taken while the database is running and applications are reading and writing to it. The backup involves more than simply copying data files: it must include any data that was inserted or updated while the backup was in process; it must exclude any data that was deleted while the backup was in process; and it must ignore any changes that were not committed.
   The Oracle product that performs hot backups, of InnoDB tables especially but also tables from MyISAM and other storage engines, is known as MySQL Enterprise Backup.

   The hot backup process consists of two stages. The initial copying of the data files produces a raw backup. The apply step incorporates any changes to the database that happened while the backup was running. Applying the changes produces a prepared backup; these files are ready to be restored whenever necessary.
See Also apply, MySQL Enterprise Backup, prepared backup, raw backup.

.ibd file
   The data file for file-per-table tablespaces and general tablespaces. File-per-table tablespace .ibd files contain a single table and associated index data. General tablespace .ibd files may contain table and index data for multiple tables. General tablespaces were introduced in MySQL 5.7.6.

See Also disk-based, SSD.
The `.ibd` file extension does not apply to the **system tablespace**, which consists of one or more ibdata files.

If a file-per-table tablespace or general tablespace is created with the `DATA DIRECTORY =` clause, the `.ibd` file is located at the specified path, outside the normal data directory, and is pointed to by a `.isl` file.

When a `.ibd` file is included in a compressed backup by the **MySQL Enterprise Backup** product, the compressed equivalent is a `.ibz` file.

See Also database, file-per-table, general tablespace, ibdata file, .ibz file, innodb_file_per_table, .isl file, MySQL Enterprise Backup, system tablespace.

**.ibz file**

When the **MySQL Enterprise Backup** product performs a **compressed backup**, it transforms each tablespace file that is created using the **file-per-table** setting from a `.ibd` extension to a `.ibz` extension.

The compression applied during backup is distinct from the **compressed row format** that keeps table data compressed during normal operation. A compressed backup operation skips the compression step for a tablespace that is already in compressed row format, as compressing a second time would slow down the backup but produce little or no space savings.

See Also compressed backup, compressed row format, file-per-table, .ibd file, MySQL Enterprise Backup, tablespace.

**.isl file**

A file that specifies the location of an `.ibd` file for an InnoDB table created with the `DATA DIRECTORY =` clause in MySQL 5.6 and higher, or with the `CREATE TABLESPACE ... ADD DATAFILE` clause in MySQL 5.7.8 and higher. It functions like a symbolic link, without the platform restrictions of the actual symbolic link mechanism.

You can store InnoDB tablespaces outside the database directory, for example, on an especially large or fast storage device depending on the usage of the table. For details, see Section 14.6.3.4, “Creating a Tablespace Outside of the Data Directory”, and General Tablespaces.

See Also database, .ibd file, table, tablespace.

I/O-bound

See disk-bound.

**ib-file set**

The set of files managed by InnoDB within a MySQL database: the **system tablespace**, **file-per-table** tablespace files, and **redo log** files. Depending on MySQL version and InnoDB configuration, may also include general tablespace, temporary tablespace, and undo tablespace files. This term is sometimes used in detailed discussions of InnoDB file structures and formats to refer to the set of files managed by InnoDB within a MySQL database.

See Also database, file-per-table, general tablespace, redo log, system tablespace, temporary tablespace, undo tablespace.

**ibbackup_logfile**

A supplemental backup file created by the **MySQL Enterprise Backup** product during a **hot backup** operation. It contains information about any data changes that occurred while the backup was running. The initial backup files, including `ibbackup_logfile`, are known as a **raw backup**, because the changes that occurred during the backup operation are not yet incorporated. After you perform the `apply` step to the raw backup files, the resulting files do include those final data changes, and are known as a **prepared backup**. At this stage, the `ibbackup_logfile` file is no longer necessary.

See Also apply, hot backup, MySQL Enterprise Backup, prepared backup, raw backup.

**ibdata file**

A set of files with names such as `ibdata1`, `ibdata2`, and so on, that make up the InnoDB **system tablespace**. These files contain metadata about InnoDB tables, (the InnoDB data dictionary), and the storage areas for one or more undo logs, the change buffer, and the doublewrite buffer. They also can contain some or all of the
table data also (depending on whether the **file-per-table** mode is in effect when each table is created). When the `innodb_file_per_table` option is enabled, data and indexes for newly created tables are stored in separate `.ibd` files rather than in the system tablespace.

The growth of the `ibdata` files is influenced by the `innodb_autoextend_increment` configuration option. See Also change buffer, data dictionary, doublewrite buffer, file-per-table, .ibd file, innodb_file_per_table, system tablespace, undo log.

**ibtmp file**

The **InnoDB temporary tablespace data file** for non-compressed **InnoDB temporary tables** and related objects. The configuration file option, `innodb_temp_data_file_path`, allows users to define a relative path for the temporary tablespace data file. If `innodb_temp_data_file_path` is not specified, the default behavior is to create a single auto-extending 12MB data file named `ibtmp1` in the data directory, alongside `ibdata1`. See Also data files, temporary table, temporary tablespace.

**ib_logfile**

A set of files, typically named `ib_logfile0` and `ib_logfile1`, that form the **redo log**. Also sometimes referred to as the **log group**. These files record statements that attempt to change data in **InnoDB** tables. These statements are replayed automatically to correct data written by incomplete transactions, on startup following a crash.

This data cannot be used for manual recovery; for that type of operation, use the **binary log**. See Also binary log, log group, redo log.

**ilist**

Within an **InnoDB FULLTEXT index**, the data structure consisting of a document ID and positional information for a token (that is, a particular word). See Also FULLTEXT index.

**implicit row lock**

A row lock that **InnoDB** acquires to ensure consistency, without you specifically requesting it. See Also row lock.

**in-memory database**

A type of database system that maintains data in memory, to avoid overhead due to disk I/O and translation between disk blocks and memory areas. Some in-memory databases sacrifice durability (the “D” in the **ACID** design philosophy) and are vulnerable to hardware, power, and other types of failures, making them more suitable for read-only operations. Other in-memory databases do use durability mechanisms such as logging changes to disk or using non-volatile memory.

MySQL features that address the same kinds of memory-intensive processing include the **InnoDB buffer pool**, adaptive hash index, and read-only transaction optimization, the **MEMORY** storage engine, the **MyISAM** key cache, and the MySQL query cache. See Also ACID, adaptive hash index, buffer pool, disk-based, read-only transaction.

**incremental backup**

A type of **hot backup**, performed by the **MySQL Enterprise Backup** product, that only saves data changed since some point in time. Having a full backup and a succession of incremental backups lets you reconstruct backup data over a long period, without the storage overhead of keeping several full backups on hand. You can restore the full backup and then apply each of the incremental backups in succession, or you can keep the full backup up-to-date by applying each incremental backup to it, then perform a single restore operation.

The granularity of changed data is at the **page** level. A page might actually cover more than one row. Each changed page is included in the backup. See Also hot backup, MySQL Enterprise Backup, page.
index

A data structure that provides a fast lookup capability for rows of a table, typically by forming a tree structure (B-tree) representing all the values of a particular column or set of columns.

**InnoDB** tables always have a **clustered index** representing the primary key. They can also have one or more **secondary indexes** defined on one or more columns. Depending on their structure, secondary indexes can be classified as partial, column, or composite indexes.

Indexes are a crucial aspect of query performance. Database architects design tables, queries, and indexes to allow fast lookups for data needed by applications. The ideal database design uses a **covering index** where practical; the query results are computed entirely from the index, without reading the actual table data. Each **foreign key** constraint also requires an index, to efficiently check whether values exist in both the **parent** and **child** tables.

Although a B-tree index is the most common, a different kind of data structure is used for **hash indexes**, as in the **MEMORY** storage engine and the **InnoDB adaptive hash index**. R-tree indexes are used for spatial indexing of multi-dimensional information.

See Also adaptive hash index, B-tree, child table, clustered index, column index, composite index, covering index, foreign key, hash index, parent table, partial index, primary key, query, R-tree, row, secondary index, table.

**index cache**

A memory area that holds the token data for **InnoDB** full-text search. It buffers the data to minimize disk I/O when data is inserted or updated in columns that are part of a **FULLTEXT index**. The token data is written to disk when the index cache becomes full. Each **InnoDB** FULLTEXT index has its own separate index cache, whose size is controlled by the configuration option `innodb_ft_cache_size`.

See Also full-text search, FULLTEXT index.

**index condition pushdown**

Index condition pushdown (ICP) is an optimization that pushes part of a **WHERE** condition down to the storage engine if parts of the condition can be evaluated using fields from the index. ICP can reduce the number of times the storage engine must access the base table and the number of times the MySQL server must access the storage engine. For more information, see Section 8.2.1.5, “Index Condition Pushdown Optimization”.

See Also index, storage engine.

**index hint**

Extended SQL syntax for overriding the **indexes** recommended by the optimizer. For example, the **FORCE INDEX**, **USE INDEX**, and **IGNORE INDEX** clauses. Typically used when indexed columns have unevenly distributed values, resulting in inaccurate **cardinality** estimates.

See Also cardinality, index.

**index prefix**

In an index that applies to multiple columns (known as a **composite index**), the initial or leading columns of the index. A query that references the first 1, 2, 3, and so on columns of a composite index can use the index, even if the query does not reference all the columns in the index.

See Also composite index, index.

**index statistics**

See statistics.

**infimum record**

A pseudo-record in an index, representing the gap below the smallest value in that index. If a transaction has a statement such as `SELECT ... FROM ... WHERE col < 10 FOR UPDATE;`, and the smallest value in the column is 5, it is a lock on the infimum record that prevents other transactions from inserting even smaller values such as 0, -10, and so on.

See Also gap, index, pseudo-record, supremum record.
The name of the **database** that provides a query interface to the MySQL **data dictionary**. (This name is defined by the ANSI SQL standard.) To examine information (metadata) about the database, you can query tables such as `INFORMATION_SCHEMA.TABLES` and `INFORMATION_SCHEMA.COLUMNS`, rather than using **SHOW** commands that produce unstructured output.

The **INFORMATION_SCHEMA** database also contains tables specific to **InnoDB** that provide a query interface to the **InnoDB** data dictionary. You use these tables not to see how the database is structured, but to get real-time information about the workings of **InnoDB** tables to help with performance monitoring, tuning, and troubleshooting.

**See Also** [data dictionary](#), database, **InnoDB**.

**InnoDB**

A MySQL component that combines high performance with **transactional** capability for reliability, robustness, and concurrent access. It embodies the **ACID** design philosophy. Represented as a **storage engine**; it handles tables created or altered with the **ENGINE=INNODB** clause. See Chapter 14, *The InnoDB Storage Engine* for architectural details and administration procedures, and Section 8.5, “Optimizing for InnoDB Tables” for performance advice.

In MySQL 5.5 and higher, **InnoDB** is the default storage engine for new tables and the **ENGINE=INNODB** clause is not required.

**InnoDB** tables are ideally suited for **hot backups**. See Section 25.2, “MySQL Enterprise Backup Overview” for information about the MySQL Enterprise Backup product for backing up MySQL servers without interrupting normal processing.

**See Also** [ACID](#), hot backup, MySQL Enterprise Backup, storage engine, transaction.

**innodb_autoinc_lock_mode**

The **innodb_autoinc_lock_mode** option controls the algorithm used for **auto-increment locking**. When you have an auto-incrementing **primary key**, you can use statement-based replication only with the setting `innodb_autoinc_lock_mode=1`. This setting is known as **consecutive** lock mode, because multi-row inserts within a transaction receive consecutive auto-increment values. If you have `innodb_autoinc_lock_mode=2`, which allows higher concurrency for insert operations, use row-based replication rather than statement-based replication. This setting is known as **interleaved** lock mode, because multiple multi-row insert statements running at the same time can receive **auto-increment** values that are interleaved. The setting `innodb_autoinc_lock_mode=0` should not be used except for compatibility purposes.

Consecutive lock mode (`innodb_autoinc_lock_mode=1`) is the default setting prior to MySQL 8.0.3. As of MySQL 8.0.3, interleaved lock mode (`innodb_autoinc_lock_mode=2`) is the default, which reflects the change from statement-based to row-based replication as the default replication type.

**See Also** auto-increment, auto-increment locking, mixed-mode insert, primary key.

**innodb_file_format**

The **innodb_file_format** option defines the **file format** to use for new **InnoDB** file-per-table **tablespaces**. Currently, you can specify the **Antelope** and **Barracuda** file formats.

**See Also** [Antelope](#), [Barracuda](#), file format, file-per-table, general tablespace, innodb_file_per_table, system tablespace, tablesapce.

**innodb_file_per_table**

An important configuration option that affects many aspects of **InnoDB** file storage, availability of features, and I/O characteristics. In MySQL 5.6.7 and higher, it is enabled by default. The **innodb_file_per_table** option turns on **file-per-table** mode. With this mode enabled, a newly created **InnoDB** table and associated indexes can be stored in a file-per-table **.ibd file**, outside the **system tablespace**.

This option affects the performance and storage considerations for a number of SQL statements, such as **DROP TABLE** and **TRUNCATE TABLE**.
Enabling the `innodb_file_per_table` option allows you to take advantage of features such as table **compression** and named-table backups in MySQL Enterprise Backup.

For more information, see `innodb_file_per_table`, and Section 14.6.3.2, “File-Per-Table Tablespaces”.

**innodb_lock_wait_timeout**

The `innodb_lock_wait_timeout` option sets the balance between *waiting* for shared resources to become available, or giving up and handling the error, retrying, or doing alternative processing in your application. Rolls back any InnoDB transaction that waits more than a specified time to acquire a **lock**. Especially useful if **deadlocks** are caused by updates to multiple tables controlled by different storage engines; such deadlocks are not detected automatically. See Also deadlock, deadlock detection, lock, wait.

**innodb_strict_mode**

The `innodb_strict_mode` option controls whether InnoDB operates in strict mode, where conditions that are normally treated as warnings, cause errors instead (and the underlying statements fail). See Also strict mode.

**insert**

One of the primary DML operations in SQL. The performance of inserts is a key factor in data warehouse systems that load millions of rows into tables, and OLTP systems where many concurrent connections might insert rows into the same table, in arbitrary order. If insert performance is important to you, you should learn about InnoDB features such as the **insert buffer** used in change buffering, and auto-increment columns. See Also auto-increment, change buffering, data warehouse, DML, InnoDB, insert buffer, OLTP, SQL.

**insert buffer**

The former name of the change buffer. In MySQL 5.5, support was added for buffering changes to secondary index pages for DELETE and UPDATE operations. Previously, only changes resulting from INSERT operations were buffered. The preferred term is now change buffer. See Also change buffer, change buffering.

**insert buffering**

The technique of storing changes to secondary index pages, resulting from INSERT operations, in the change buffer rather than writing the changes immediately, so that the physical writes can be performed to minimize random I/O. It is one of the types of change buffering; the others are delete buffering and purge buffering. Insert buffering is not used if the secondary index is unique, because the uniqueness of new values cannot be verified before the new entries are written out. Other kinds of change buffering do work for unique indexes. See Also change buffer, change buffering, delete buffering, insert buffer, purge buffering, unique index.

**insert intention lock**

A type of gap lock that is set by INSERT operations prior to row insertion. This type of lock signals the intent to insert in such a way that multiple transactions inserting into the same index gap need not wait for each other if they are not inserting at the same position within the gap. For more information, see Section 14.7.1, “InnoDB Locking”.

See Also gap lock, lock, next-key lock.

**instance**

A single mysqld daemon managing a data directory representing one or more databases with a set of tables. It is common in development, testing, and some replication scenarios to have multiple instances on the same server machine, each managing its own data directory and listening on its own port or socket. With one instance running a disk-bound workload, the server might still have extra CPU and memory capacity to run additional instances. See Also data directory, database, disk-bound, mysqld, replication, server, table.
instrumentation
  Modifications at the source code level to collect performance data for tuning and debugging. In MySQL, data
collected by instrumentation is exposed through an SQL interface using the INFORMATION_SCHEMA and
PERFORMANCE_SCHEMA databases.
  See Also INFORMATION_SCHEMA, Performance Schema.

intention exclusive lock
  See intention lock.

intention lock
  A kind of lock that applies to the table, used to indicate the kind of lock the transaction intends to acquire on
rows in the table. Different transactions can acquire different kinds of intention locks on the same table, but the
first transaction to acquire an intention exclusive (IX) lock on a table prevents other transactions from acquiring
any S or X locks on the table. Conversely, the first transaction to acquire an intention shared (IS) lock on a table
prevents other transactions from acquiring any X locks on the table. The two-phase process allows the lock
requests to be resolved in order, without blocking locks and corresponding operations that are compatible. For
more information about this locking mechanism, see Section 14.7.1, “InnoDB Locking”.
  See Also lock, lock mode, locking, transaction.

intention shared lock
  See intention lock.

inverted index
  A data structure optimized for document retrieval systems, used in the implementation of InnoDB full-text
search. The InnoDB FULLTEXT index, implemented as an inverted index, records the position of each word
within a document, rather than the location of a table row. A single column value (a document stored as a text
string) is represented by many entries in the inverted index.
  See Also full-text search, FULLTEXT index, ilist.

IOPS
  Acronym for I/O operations per second. A common measurement for busy systems, particularly OLTP
applications. If this value is near the maximum that the storage devices can handle, the application can become
disk-bound, limiting scalability.
  See Also disk-bound, OLTP, scalability.

isolation level
  One of the foundations of database processing. Isolation is the I in the acronym ACID; the isolation level is the
setting that fine-tunes the balance between performance and reliability, consistency, and reproducibility of results
when multiple transactions are making changes and performing queries at the same time.

  From highest amount of consistency and protection to the least, the isolation levels supported by InnoDB are:
SERIALIZABLE, REPEATABLE READ, READ COMMITTED, and READ UNCOMMITTED.

  With InnoDB tables, many users can keep the default isolation level (REPEATABLE READ) for all operations.
Expert users might choose the READ COMMITTED level as they push the boundaries of scalability with OLTP
processing, or during data warehousing operations where minor inconsistencies do not affect the aggregate
results of large amounts of data. The levels on the edges (SERIALIZABLE and READ UNCOMMITTED) change
the processing behavior to such an extent that they are rarely used.
  See Also ACID, OLTP, READ COMMITTED, READ UNCOMMITTED, REPEATABLE READ, SERIALIZABLE,
transaction.

j

join
  A query that retrieves data from more than one table, by referencing columns in the tables that hold identical
values. Ideally, these columns are part of an InnoDB foreign key relationship, which ensures referential
**integrity** and that the join columns are **indexed**. Often used to save space and improve query performance by replacing repeated strings with numeric IDs, in a **normalized** data design.

See Also **foreign key**, **index**, **normalized**, **query**, **referential integrity**.

### K

**KEY_BLOCK_SIZE**

An option to specify the size of data pages within an **InnoDB** table that uses **compressed row format**. The default is 8 kilobytes. Lower values risk hitting internal limits that depend on the combination of row size and compression percentage.

For **MyISAM** tables, **KEY_BLOCK_SIZE** optionally specifies the size in bytes to use for index key blocks. The value is treated as a hint; a different size could be used if necessary. A **KEY_BLOCK_SIZE** value specified for an individual index definition overrides a table-level **KEY_BLOCK_SIZE** value.

See Also **compressed row format**.

### L

**latch**

A lightweight structure used by **InnoDB** to implement a **lock** for its own internal memory structures, typically held for a brief time measured in milliseconds or microseconds. A general term that includes both **mutexes** (for exclusive access) and **rw-locks** (for shared access). Certain latches are the focus of **InnoDB** performance tuning. Statistics about latch use and contention are available through the **Performance Schema** interface.

See Also **lock**, **locking**, **mutex**, **Performance Schema**, **rw-lock**.

**list**

The **InnoDB** buffer pool is represented as a list of memory **pages**. The list is reordered as new pages are accessed and enter the buffer pool, as pages within the buffer pool are accessed again and are considered newer, and as pages that are not accessed for a long time are **evicted** from the buffer pool. The buffer pool is divided into **sublists**, and the replacement policy is a variation of the familiar **LRU** technique.

See Also **buffer pool**, **eviction**, **LRU**, **page**, **sublist**.

**lock**

The high-level notion of an object that controls access to a resource, such as a table, row, or internal data structure, as part of a **locking** strategy. For intensive performance tuning, you might delve into the actual structures that implement locks, such as **mutexes** and **latches**.

See Also **latch**, **lock mode**, **locking**, **mutex**.

**lock escalation**

An operation used in some database systems that converts many **row locks** into a single **table lock**, saving memory space but reducing concurrent access to the table. **InnoDB** uses a space-efficient representation for row locks, so that **lock** escalation is not needed.

See Also **locking**, **row lock**, **table lock**.

**lock mode**

A shared (S) **lock** allows a **transaction** to read a row. Multiple transactions can acquire an S lock on that same row at the same time.

An exclusive (X) lock allows a transaction to update or delete a row. No other transaction can acquire any kind of lock on that same row at the same time.

**Intention locks** apply to the table, and are used to indicate what kind of lock the transaction intends to acquire on rows in the table. Different transactions can acquire different kinds of intention locks on the same table, but the first transaction to acquire an intention exclusive (IX) lock on a table prevents other transactions from acquiring...
any S or X locks on the table. Conversely, the first transaction to acquire an intention shared (IS) lock on a table prevents other transactions from acquiring any X locks on the table. The two-phase process allows the lock requests to be resolved in order, without blocking locks and corresponding operations that are compatible.

See Also intention lock, lock, locking, transaction.

locking

The system of protecting a transaction from seeing or changing data that is being queried or changed by other transactions. The locking strategy must balance reliability and consistency of database operations (the principles of the ACID philosophy) against the performance needed for good concurrency. Fine-tuning the locking strategy often involves choosing an isolation level and ensuring all your database operations are safe and reliable for that isolation level.

See Also ACID, concurrency, isolation level, locking, transaction.

locking read

A SELECT statement that also performs a locking operation on an InnoDB table. Either SELECT ... FOR UPDATE or SELECT ... LOCK IN SHARE MODE. It has the potential to produce a deadlock, depending on the isolation level of the transaction. The opposite of a non-locking read. Not allowed for global tables in a read-only transaction.

SELECT ... FOR SHARE replaces SELECT ... LOCK IN SHARE MODE in MySQL 8.0.1, but LOCK IN SHARE MODE remains available for backward compatibility.

See Section 14.7.2.4, "Locking Reads".

See Also deadlock, isolation level, locking, non-locking read, read-only transaction.

log

In the InnoDB context, "log" or "log files" typically refers to the redo log represented by the ib_logfileN files. Another type of InnoDB log is the undo log, which is a storage area that holds copies of data modified by active transactions.

Other kinds of logs that are important in MySQL are the error log (for diagnosing startup and runtime problems), binary log (for working with replication and performing point-in-time restores), the general query log (for diagnosing application problems), and the slow query log (for diagnosing performance problems).

See Also binary log, error log, general query log, ib_logfile, redo log, slow query log, undo log.

log buffer

The memory area that holds data to be written to the log files that make up the redo log. It is controlled by the innodb_log_buffer_size configuration option.

See Also log file, redo log.

log file

One of the ib_logfileN files that make up the redo log. Data is written to these files from the log buffer memory area.

See Also ib_logfile, log buffer, redo log.

log group

The set of files that make up the redo log, typically named ib_logfile0 and ib_logfile1. (For that reason, sometimes referred to collectively as ib_logfile.)

See Also ib_logfile, redo log.

logical

A type of operation that involves high-level, abstract aspects such as tables, queries, indexes, and other SQL concepts. Typically, logical aspects are important to make database administration and application development convenient and usable. Contrast with physical.

See Also logical backup, physical.
logical backup

A backup that reproduces table structure and data, without copying the actual data files. For example, the `mysqldump` command produces a logical backup, because its output contains statements such as `CREATE TABLE` and `INSERT` that can re-create the data. Contrast with physical backup. A logical backup offers flexibility (for example, you could edit table definitions or insert statements before restoring), but can take substantially longer to restore than a physical backup.

See Also backup, mysqldump, physical backup, restore.

loose

A prefix added to InnoDB configuration options after server startup, so any new configuration options not recognized by the current level of MySQL do not cause a startup failure. MySQL processes configuration options that start with this prefix, but gives a warning rather than a failure if the part after the prefix is not a recognized option.

See Also startup.

low-water mark

A value representing a lower limit, typically a threshold value at which some corrective action begins or becomes more aggressive. Contrast with high-water mark.

See Also high-water mark.

LRU

An acronym for “least recently used”, a common method for managing storage areas. The items that have not been used recently are evicted when space is needed to cache newer items. InnoDB uses the LRU mechanism by default to manage the pages within the buffer pool, but makes exceptions in cases where a page might be read only a single time, such as during a full table scan. This variation of the LRU algorithm is called the midpoint insertion strategy. For more information, see Section 14.5.1, “Buffer Pool”.

See Also buffer pool, eviction, full table scan, midpoint insertion strategy, page.

LSN

Acronym for “log sequence number”. This arbitrary, ever-increasing value represents a point in time corresponding to operations recorded in the redo log. (This point in time is regardless of transaction boundaries; it can fall in the middle of one or more transactions.) It is used internally by InnoDB during crash recovery and for managing the buffer pool.

Prior to MySQL 5.6.3, the LSN was a 4-byte unsigned integer. The LSN became an 8-byte unsigned integer in MySQL 5.6.3 when the redo log file size limit increased from 4GB to 512GB, as additional bytes were required to store extra size information. Applications built on MySQL 5.6.3 or later that use LSN values should use 64-bit rather than 32-bit variables to store and compare LSN values.

In the MySQL Enterprise Backup product, you can specify an LSN to represent the point in time from which to take an incremental backup. The relevant LSN is displayed by the output of the `mysqlbackup` command. Once you have the LSN corresponding to the time of a full backup, you can specify that value to take a subsequent incremental backup, whose output contains another LSN for the next incremental backup.

See Also buffer pool, crash recovery, incremental backup, MySQL Enterprise Backup, redo log, transaction.

M

.MRG file

A file containing references to other tables, used by the MERGE storage engine. Files with this extension are always included in backups produced by the `mysqlbackup` command of the MySQL Enterprise Backup product.

See Also MySQL Enterprise Backup, mysqlbackup command.

.MYD file

A file that MySQL uses to store data for a MyISAM table.
See Also `.MYI` file, MySQL Enterprise Backup, `mysqlbackup` command.

`MYI` file
A file that MySQL uses to store indexes for a `MyISAM` table.
See Also `.MYD` file, MySQL Enterprise Backup, `mysqlbackup` command.

master server
Frequently shortened to “master”. A database server machine in a `replication` scenario that processes the initial insert, update, and delete requests for data. These changes are propagated to, and repeated on, other servers known as `slave servers`.
See Also replication, slave server.

master thread
A `InnoDB` thread that performs various tasks in the background. Most of these tasks are I/O related, such as writing changes from the `change buffer` to the appropriate secondary indexes.

To improve `concurrency`, sometimes actions are moved from the master thread to separate background threads. For example, in MySQL 5.6 and higher, `dirty pages` are `flushed` from the `buffer pool` by the `page cleaner` thread rather than the master thread.
See Also buffer pool, change buffer, concurrency, dirty page, flush, page cleaner, thread.

MDL
Acronym for “metadata lock”.
See Also metadata lock.

memcached
A popular component of many MySQL and NoSQL software stacks, allowing fast reads and writes for single values and caching the results entirely in memory. Traditionally, applications required extra logic to write the same data to a MySQL database for permanent storage, or to read data from a MySQL database when it was not cached yet in memory. Now, applications can use the simple `memcached` protocol, supported by client libraries for many languages, to communicate directly with MySQL servers using `InnoDB` or `NDB` tables. These NoSQL interfaces to MySQL tables allow applications to achieve higher read and write performance than by issuing SQL statements directly, and can simplify application logic and deployment configurations for systems that already incorporate `memcached` for in-memory caching.

The `memcached` interface to `InnoDB` tables is available in MySQL 5.6 and higher; see Section 14.20, “InnoDB memcached Plugin” for details. The `memcached` interface to `NDB` tables is available in NDB Cluster 7.2 and later; see [http://dev.mysql.com/doc/ndbapi/en/ndbmemcache.html](http://dev.mysql.com/doc/ndbapi/en/ndbmemcache.html) for details.
See Also `InnoDB`, NoSQL.

merge
To apply changes to data cached in memory, such as when a page is brought into the `buffer pool`, and any applicable changes recorded in the `change buffer` are incorporated into the page in the buffer pool. The updated data is eventually written to the `tablespace` by the `flush` mechanism.
See Also buffer pool, change buffer, flush, tablespace.

metadata lock
A type of `lock` that prevents DDL operations on a table that is being used at the same time by another transaction. For details, see Section 8.11.4, “Metadata Locking”.

Enhancements to online operations, particularly in MySQL 5.6 and higher, are focused on reducing the amount of metadata locking. The objective is for DDL operations that do not change the table structure (such as `CREATE INDEX` and `DROP INDEX` for `InnoDB` tables) to proceed while the table is being queried, updated, and so on by other transactions.
See Also DDL, lock, online, transaction.
metrics counter

A feature implemented by the `INNODB_METRICS` table in the `INFORMATION_SCHEMA`, in MySQL 5.6 and higher. You can query counts and totals for low-level InnoDB operations, and use the results for performance tuning in combination with data from the Performance Schema.

See Also `counter`, `INFORMATION_SCHEMA`, Performance Schema.

midpoint insertion strategy

The technique of initially bringing pages into the InnoDB buffer pool not at the “newest” end of the list, but instead somewhere in the middle. The exact location of this point can vary, based on the setting of the `innodb_old_blocks_pct` option. The intent is that pages that are only read once, such as during a full table scan, can be aged out of the buffer pool sooner than with a strict LRU algorithm. For more information, see Section 14.5.1, “Buffer Pool”.

See Also `buffer pool`, full table scan, LRU, page.

mini-transaction

An internal phase of InnoDB processing, when making changes at the physical level to internal data structures during DML operations. A mini-transaction (mtr) has no notion of rollback; multiple mini-transactions can occur within a single transaction. Mini-transactions write information to the redo log that is used during crash recovery. A mini-transaction can also happen outside the context of a regular transaction, for example during purge processing by background threads.

See Also `commit`, crash recovery, DML, physical, purge, redo log, rollback, transaction.

mixed-mode insert

An INSERT statement where auto-increment values are specified for some but not all of the new rows. For example, a multi-value INSERT could specify a value for the auto-increment column in some cases and NULL in other cases. InnoDB generates auto-increment values for the rows where the column value was specified as NULL. Another example is an INSERT ... ON DUPLICATE KEY UPDATE statement, where auto-increment values might be generated but not used, for any duplicate rows that are processed as UPDATE rather than INSERT statements.

Can cause consistency issues between master and slave servers in a replication configuration. Can require adjusting the value of the `innodb_autoinc_lock_mode` configuration option.

See Also `auto-increment`, `innodb_autoinc_lock_mode`, `master server`, replication, `slave server`.

mtr

See mini-transaction.

multi-core

A type of processor that can take advantage of multithreaded programs, such as the MySQL server.

multiversion concurrency control

See MVCC.

mutex

Informal abbreviation for “mutex variable”. (Mutex itself is short for “mutual exclusion”.) The low-level object that InnoDB uses to represent and enforce exclusive-access locks to internal in-memory data structures. Once the lock is acquired, any other process, thread, and so on is prevented from acquiring the same lock. Contrast with rw-locks, which InnoDB uses to represent and enforce shared-access locks to internal in-memory data structures. Mutexes and rw-locks are known collectively as latches.

See Also latch, lock, Performance Schema, Pthreads, rw-lock.

MVCC

Acronym for “multiversion concurrency control”. This technique lets InnoDB transactions with certain isolation levels perform consistent read operations; that is, to query rows that are being updated by other transactions, and see the values from before those updates occurred. This is a powerful technique to increase concurrency, by allowing queries to proceed without waiting due to locks held by the other transactions.
This technique is not universal in the database world. Some other database products, and some other MySQL storage engines, do not support it. See Also ACID, concurrency, consistent read, isolation level, lock, transaction.

my.cnf
The name, on Unix or Linux systems, of the MySQL option file. See Also my.ini, option file.

my.ini
The name, on Windows systems, of the MySQL option file. See Also my.cnf, option file.

mysql
The mysql program is the command-line interpreter for the MySQL database. It processes SQL statements, and also MySQL-specific commands such as SHOW TABLES, by passing requests to the mysqld daemon. See Also mysqld, SQL.

MySQL Enterprise Backup
A licensed product that performs hot backups of MySQL databases. It offers the most efficiency and flexibility when backing up InnoDB tables, but can also back up MyISAM and other kinds of tables. See Also hot backup, InnoDB.

mysqlbackup command
A command-line tool of the MySQL Enterprise Backup product. It performs a hot backup operation for InnoDB tables, and a warm backup for MyISAM and other kinds of tables. See Section 25.2, “MySQL Enterprise Backup Overview” for more information about this command. See Also hot backup, MySQL Enterprise Backup, warm backup.

gsql
The mysqld program is the database engine for the MySQL database. It runs as a Unix daemon or Windows service, constantly waiting for requests and performing maintenance work in the background. See Also mysql.

gsqlump
A command that performs a logical backup of some combination of databases, tables, and table data. The results are SQL statements that reproduce the original schema objects, data, or both. For substantial amounts of data, a physical backup solution such as MySQL Enterprise Backup is faster, particularly for the restore operation. See Also logical backup, MySQL Enterprise Backup, physical backup, restore.

N

natural key
An indexed column, typically a primary key, where the values have some real-world significance. Usually advised against because:

- If the value should ever change, there is potentially a lot of index maintenance to re-sort the clustered index and update the copies of the primary key value that are repeated in each secondary index.

- Even seemingly stable values can change in unpredictable ways that are difficult to represent correctly in the database. For example, one country can change into two or several, making the original country code obsolete. Or, rules about unique values might have exceptions. For example, even if taxpayer IDs are intended to be unique to a single person, a database might have to handle records that violate that rule, such as in cases of identity theft. Taxpayer IDs and other sensitive ID numbers also make poor primary keys, because they may need to be secured, encrypted, and otherwise treated differently than other columns.
Thus, it is typically better to use arbitrary numeric values to form a **synthetic key**, for example using an **auto-increment** column.

See Also **auto-increment**, **clustered index**, **primary key**, **secondary index**, **synthetic key**.

**neighbor page**

Any **page** in the same **extent** as a particular page. When a page is selected to be **flushed**, any neighbor pages that are **dirty** are typically flushed as well, as an I/O optimization for traditional hard disks. In MySQL 5.6 and up, this behavior can be controlled by the configuration variable **innodb_flush_neighbors**; you might turn that setting off for SSD drives, which do not have the same overhead for writing smaller batches of data at random locations.

See Also **dirty page**, **extent**, **flush**, **page**.

**next-key lock**

A combination of a **record lock** on the index record and a **gap lock** on the gap before the index record.

See Also **gap lock**, **locking**, **record lock**.

**non-locking read**

A **query** that does not use the **SELECT ... FOR UPDATE** or **SELECT ... LOCK IN SHARE MODE** clauses. The only kind of query allowed for global tables in a **read-only transaction**. The opposite of a **locking read**. See Section 14.7.2.3, “Consistent Nonlocking Reads”.

**SELECT ... FOR SHARE** replaces **SELECT ... LOCK IN SHARE MODE** in MySQL 8.0.1, but **LOCK IN SHARE MODE** remains available for backward compatibility.

See Also **locking read**, **query**, **read-only transaction**.

**non-repeatable read**

The situation when a query retrieves data, and a later query within the same **transaction** retrieves what should be the same data, but the queries return different results (changed by another transaction committing in the meantime).

This kind of operation goes against the **ACID** principle of database design. Within a transaction, data should be consistent, with predictable and stable relationships.

Among different **isolation levels**, non-repeatable reads are prevented by the **serializable read** and **repeatable read** levels, and allowed by the **consistent read**, and **read uncommitted** levels.

See Also **ACID**, **consistent read**, **isolation level**, **READ UNCOMMITTED**, **REPEATABLE READ**, **SERIALIZABLE**, **transaction**.

**nonblocking I/O**

An industry term that means the same as **asynchronous I/O**.

See Also **asynchronous I/O**.

**normalized**

A database design strategy where data is split into multiple tables, and duplicate values condensed into single rows represented by an ID, to avoid storing, querying, and updating redundant or lengthy values. It is typically used in **OLTP** applications.

For example, an address might be given a unique ID, so that a census database could represent the relationship **lives at this address** by associating that ID with each member of a family, rather than storing multiple copies of a complex value such as **123 Main Street, Anytown, USA**.

For another example, although a simple address book application might store each phone number in the same table as a person’s name and address, a phone company database might give each phone number a special ID, and store the numbers and IDs in a separate table. This normalized representation could simplify large-scale updates when area codes split apart.
Normalization is not always recommended. Data that is primarily queried, and only updated by deleting entirely and reloading, is often kept in fewer, larger tables with redundant copies of duplicate values. This data representation is referred to as **denormalized**, and is frequently found in data warehousing applications. See Also **denormalized**, **foreign key**, **OLTP**, **relational**.

**NoSQL**

A broad term for a set of data access technologies that do not use the **SQL** language as their primary mechanism for reading and writing data. Some NoSQL technologies act as key-value stores, only accepting single-value reads and writes; some relax the restrictions of the **ACID** methodology; still others do not require a pre-planned **schema**. MySQL users can combine NoSQL-style processing for speed and simplicity with SQL operations for flexibility and convenience, by using the **memcached** API to directly access some kinds of MySQL tables. The **memcached** interface to **InnoDB** tables is available in MySQL 5.6 and higher; see Section 14.20, “**InnoDB memcached Plugin**” for details. The **memcached** interface to **NDB** tables is available in NDB Cluster 7.2 and later; see **ndbmemcache—Memcache API for NDB Cluster**. See Also **ACID**, **InnoDB**, **memcached**, **schema**, **SQL**.

**NOT NULL constraint**

A type of **constraint** that specifies that a **column** cannot contain any **NULL** values. It helps to preserve **referential integrity**, as the database server can identify data with erroneous missing values. It also helps in the arithmetic involved in query optimization, allowing the optimizer to predict the number of entries in an index on that column. See Also **column**, **constraint**, **NULL**, **primary key**, **referential integrity**.

**NULL**

A special value in **SQL**, indicating the absence of data. Any arithmetic operation or equality test involving a **NULL** value, in turn produces a **NULL** result. (Thus it is similar to the IEEE floating-point concept of NaN, “not a number”.) Any aggregate calculation such as **AVG()** ignores rows with **NULL** values, when determining how many rows to divide by. The only test that works with **NULL** values uses the SQL idioms **IS NULL** or **IS NOT NULL**.

**NULL** values play a part in **index** operations, because for performance a database must minimize the overhead of keeping track of missing data values. Typically, **NULL** values are not stored in an index, because a query that tests an indexed column using a standard comparison operator could never match a row with a **NULL** value for that column. For the same reason, unique indexes do not prevent **NULL** values; those values simply are not represented in the index. Declaring a **NOT NULL** constraint on a column provides reassurance that there are no rows left out of the index, allowing for better query optimization (accurate counting of rows and estimation of whether to use the index).

Because the **primary key** must be able to uniquely identify every row in the table, a single-column primary key cannot contain any **NULL** values, and a multi-column primary key cannot contain any rows with **NULL** values in all columns.

Although the Oracle database allows a **NULL** value to be concatenated with a string, **InnoDB** treats the result of such an operation as **NULL**. See Also **index**, **primary key**, **SQL**.

**.OPT file**

A file containing database configuration information. Files with this extension are included in backups produced by the **mysqlbackup** command of the **MySQL Enterprise Backup** product. See Also **MySQL Enterprise Backup**, **mysqlbackup command**.

**off-page column**

A column containing variable-length data (such as **BLOB** and **VARCHAR**) that is too long to fit on a **B-tree** page. The data is stored in **overflow pages**. The **DYNAMIC** row format is more efficient for such storage than the older **COMPACT** row format.
See Also B-tree, compact row format, dynamic row format, overflow page.

OLTP
Acronym for “Online Transaction Processing”. A database system, or a database application, that runs a workload with many transactions, with frequent writes as well as reads, typically affecting small amounts of data at a time. For example, an airline reservation system or an application that processes bank deposits. The data might be organized in normalized form for a balance between DML (insert/update/delete) efficiency and query efficiency. Contrast with data warehouse.

With its row-level locking and transactional capability, InnoDB is the ideal storage engine for MySQL tables used in OLTP applications.
See Also data warehouse, DML, InnoDB, query, row lock, transaction.

online
A type of operation that involves no downtime, blocking, or restricted operation for the database. Typically applied to DDL. Operations that shorten the periods of restricted operation, such as fast index creation, have evolved into a wider set of online DDL operations in MySQL 5.6.

In the context of backups, a hot backup is an online operation and a warm backup is partially an online operation.
See Also DDL, Fast Index Creation, hot backup, online DDL, warm backup.

online DDL
A feature that improves the performance, concurrency, and availability of InnoDB tables during DDL (primarily ALTER TABLE) operations. See Section 14.13, “InnoDB and Online DDL” for details.

The details vary according to the type of operation. In some cases, the table can be modified concurrently while the ALTER TABLE is in progress. The operation might be able to be performed without a table copy, or using a specially optimized type of table copy. DML log space usage for in-place operations is controlled by the innodb_online_alter_log_max_size configuration option.

This feature is an enhancement of the Fast Index Creation feature in MySQL 5.5.
See Also DDL, Fast Index Creation, online.

optimistic
A methodology that guides low-level implementation decisions for a relational database system. The requirements of performance and concurrency in a relational database mean that operations must be started or dispatched quickly. The requirements of consistency and referential integrity mean that any operation could fail: a transaction might be rolled back, a DML operation could violate a constraint, a request for a lock could cause a deadlock, a network error could cause a timeout. An optimistic strategy is one that assumes most requests or attempts will succeed, so that relatively little work is done to prepare for the failure case. When this assumption is true, the database does little unnecessary work; when requests do fail, extra work must be done to clean up and undo changes.

InnoDB uses optimistic strategies for operations such as locking and commits. For example, data changed by a transaction can be written to the data files before the commit occurs, making the commit itself very fast, but requiring more work to undo the changes if the transaction is rolled back.

The opposite of an optimistic strategy is a pessimistic one, where a system is optimized to deal with operations that are unreliable and frequently unsuccessful. This methodology is rare in a database system, because so much care goes into choosing reliable hardware, networks, and algorithms.
See Also commit, concurrency, DML, locking, pessimistic, referential integrity.

optimizer
The MySQL component that determines the best indexes and join order to use for a query, based on characteristics and data distribution of the relevant tables.
See Also index, join, query, table.
option
A configuration parameter for MySQL, either stored in the option file or passed on the command line.

For the options that apply to InnoDB tables, each option name starts with the prefix innodb_.
See Also InnoDB, option, option file.

option file
The file that holds the configuration options for the MySQL instance. Traditionally, on Linux and Unix this file is named my.cnf, and on Windows it is named my.ini.
See Also configuration file, my.cnf, my.ini, option.

overflow page
Separately allocated disk pages that hold variable-length columns (such as BLOB and VARCHAR) that are too long to fit on a B-tree page. The associated columns are known as off-page columns.
See Also B-tree, off-page column, page.

.P
.par file
A file containing partition definitions. Files with this extension are included in backups produced by the mysqlbackup command of the MySQL Enterprise Backup product.

With the introduction of native partitioning support for InnoDB tables in MySQL 5.7.6, .par files are no longer created for partitioned InnoDB tables. Partitioned MyISAM tables continue to use .par files in MySQL 5.7. In MySQL 8.0, partitioning support is only provided by the InnoDB storage engine. As such, .par files are no longer used as of MySQL 8.0.
See Also MySQL Enterprise Backup, mysqlbackup command.

page
A unit representing how much data InnoDB transfers at any one time between disk (the data files) and memory (the buffer pool). A page can contain one or more rows, depending on how much data is in each row. If a row does not fit entirely into a single page, InnoDB sets up additional pointer-style data structures so that the information about the row can be stored in one page.

One way to fit more data in each page is to use compressed row format. For tables that use BLOBs or large text fields, compact row format allows those large columns to be stored separately from the rest of the row, reducing I/O overhead and memory usage for queries that do not reference those columns.

When InnoDB reads or writes sets of pages as a batch to increase I/O throughput, it reads or writes an extent at a time.

All the InnoDB disk data structures within a MySQL instance share the same page size.
See Also buffer pool, compact row format, compressed row format, data files, extent, page size, row.

page cleaner
An InnoDB background thread that flushes dirty pages from the buffer pool. Prior to MySQL 5.6, this activity was performed by the master thread. The number of page cleaner threads is controlled by the innodb_page_cleaners configuration option, introduced in MySQL 5.7.4.
See Also buffer pool, dirty page, flush, master thread, thread.

page size
For releases up to and including MySQL 5.5, the size of each InnoDB page is fixed at 16 kilobytes. This value represents a balance: large enough to hold the data for most rows, yet small enough to minimize the performance overhead of transferring unneeded data to memory. Other values are not tested or supported.

Starting in MySQL 5.6, the page size for an InnoDB instance can be either 4KB, 8KB, or 16KB, controlled by the innodb_page_size configuration option. As of MySQL 5.7.6, InnoDB also supports 32KB and 64KB page sizes.
sizes. For 32KB and 64KB page sizes, ROW_FORMAT=COMPRESSED is not supported and the maximum record size is 16KB.

Page size is set when creating the MySQL instance, and it remains constant afterward. The same page size applies to all InnoDB tablespaces, including the system tablespace, file-per-table tablespaces, and general tablespaces.

Smaller page sizes can help performance with storage devices that use small block sizes, particularly for SSD devices in disk-bound workloads, such as for OLTP applications. As individual rows are updated, less data is copied into memory, written to disk, reorganized, locked, and so on. See Also disk-bound, file-per-table, general tablespace, instance, OLTP, page, SSD, system tablespace, tablespace.

parent table
The table in a foreign key relationship that holds the initial column values pointed to from the child table. The consequences of deleting, or updating rows in the parent table depend on the ON UPDATE and ON DELETE clauses in the foreign key definition. Rows with corresponding values in the child table could be automatically deleted or updated in turn, or those columns could be set to NULL, or the operation could be prevented. See Also child table, foreign key.

partial backup
A backup that contains some of the tables in a MySQL database, or some of the databases in a MySQL instance. Contrast with full backup. See Also backup, full backup, table.

partial index
An index that represents only part of a column value, typically the first N characters (the prefix) of a long VARCHAR value. See Also index, index prefix.

Performance Schema
The performance_schema schema, in MySQL 5.5 and up, presents a set of tables that you can query to get detailed information about the performance characteristics of many internal parts of the MySQL server. See Chapter 22, MySQL Performance Schema. See Also INFORMATION_SCHEMA, latch, mutex, rw-lock.

persistent statistics
A feature that stores index statistics for InnoDB tables on disk, providing better plan stability for queries. For more information, see Section 14.8.11.1, “Configuring Persistent Optimizer Statistics Parameters”. See Also index, optimizer, plan stability, query, table.

pessimistic
A methodology that sacrifices performance or concurrency in favor of safety. It is appropriate if a high proportion of requests or attempts might fail, or if the consequences of a failed request are severe. InnoDB uses what is known as a pessimistic locking strategy, to minimize the chance of deadlocks. At the application level, you might avoid deadlocks by using a pessimistic strategy of acquiring all locks needed by a transaction at the very beginning.

Many built-in database mechanisms use the opposite optimistic methodology. See Also deadlock, locking, optimistic.

phantom
A row that appears in the result set of a query, but not in the result set of an earlier query. For example, if a query is run twice within a transaction, and in the meantime, another transaction commits after inserting a new row or updating a row so that it matches the WHERE clause of the query.
This occurrence is known as a phantom read. It is harder to guard against than a **non-repeatable read**, because locking all the rows from the first query result set does not prevent the changes that cause the phantom to appear.

Among different **isolation levels**, phantom reads are prevented by the **serializable read** level, and allowed by the **repeatable read**, **consistent read**, and **read uncommitted** levels.  
See Also consistent read, isolation level, non-repeatable read, READ UNCOMMITTED, REPEATABLE READ, SERIALIZABLE, transaction.

**physical**

A type of operation that involves hardware-related aspects such as disk blocks, memory pages, files, bits, disk reads, and so on. Typically, physical aspects are important during expert-level performance tuning and problem diagnosis. Contrast with **logical**.
See Also logical, physical backup.

**physical backup**

A **backup** that copies the actual data files. For example, the `mysqlbackup` command of the MySQL Enterprise Backup product produces a physical backup, because its output contains data files that can be used directly by the `mysqld` server, resulting in a faster **restore** operation. Contrast with **logical backup**.
See Also backup, logical backup, MySQL Enterprise Backup, restore.

**PITR**

Acronym for **point-in-time recovery**.
See Also point-in-time recovery.

**plan stability**

A property of a **query execution plan**, where the optimizer makes the same choices each time for a given **query**, so that performance is consistent and predictable.
See Also query, query execution plan.

**point-in-time recovery**

The process of restoring a **backup** to recreate the state of the database at a specific date and time. Commonly abbreviated “PITR”.
Because it is unlikely that the specified time corresponds exactly to the time of a backup, this technique usually requires a combination of a **physical backup** and a **logical backup**. For example, with the MySQL Enterprise Backup product, you restore the last backup that you took before the specified point in time, then replay changes from the **binary log** between the time of the backup and the PITR time.
See Also backup, binary log, logical backup, MySQL Enterprise Backup, physical backup.

**prefix**

See index prefix.

**prepared backup**

A set of backup files, produced by the MySQL Enterprise Backup product, after all the stages of applying **binary logs** and **incremental backups** are finished. The resulting files are ready to be **restored**. Prior to the apply steps, the files are known as a **raw backup**.
See Also binary log, hot backup, incremental backup, MySQL Enterprise Backup, raw backup, restore.

**primary key**

A set of columns—and by implication, the index based on this set of columns—that can uniquely identify every row in a table. As such, it must be a unique index that does not contain any **NULL** values.

InnoDB requires that every table has such an index (also called the **clustered index** or **cluster index**), and organizes the table storage based on the column values of the primary key.

When choosing primary key values, consider using arbitrary values (**a synthetic key**) rather than relying on values derived from some other source (**a natural key**).
See Also clustered index, index, natural key, synthetic key.
process
An instance of an executing program. The operating system switches between multiple running processes, allowing for a certain degree of concurrency. On most operating systems, processes can contain multiple threads of execution that share resources. Context-switching between threads is faster than the equivalent switching between processes.
See Also concurrency, thread.

pseudo-record
An artificial record in an index, used for locking key values or ranges that do not currently exist.
See Also infimum record, locking, supremum record.

Pthreads
The POSIX threads standard, which defines an API for threading and locking operations on Unix and Linux systems. On Unix and Linux systems, InnoDB uses this implementation for mutexes.
See Also mutex.

purge
A type of garbage collection performed by one or more separate background threads (controlled by innodb_purge_threads) that runs on a periodic schedule. Purge parses and processes undo log pages from the history list for the purpose of removing clustered and secondary index records that were marked for deletion (by previous DELETE statements) and are no longer required for MVCC or rollback. Purge frees undo log pages from the history list after processing them.
See Also history list, MVCC, rollback, undo log.

purge buffering
The technique of storing changes to secondary index pages, resulting from DELETE operations, in the change buffer rather than writing the changes immediately, so that the physical writes can be performed to minimize random I/O. (Because delete operations are a two-step process, this operation buffers the write that normally purges an index record that was previously marked for deletion.) It is one of the types of change buffering; the others are insert buffering and delete buffering.
See Also change buffer, change buffering, delete buffering, insert buffer, insert buffering.

purge lag
Another name for the InnoDB history list. Related to the innodb_max_purge_lag configuration option.
See Also history list, purge.

purge thread
A thread within the InnoDB process that is dedicated to performing the periodic purge operation. In MySQL 5.6 and higher, multiple purge threads are enabled by the innodb_purge_threads configuration option.
See Also purge, thread.

query
In SQL, an operation that reads information from one or more tables. Depending on the organization of data and the parameters of the query, the lookup might be optimized by consulting an index. If multiple tables are involved, the query is known as a join.

For historical reasons, sometimes discussions of internal processing for statements use “query” in a broader sense, including other types of MySQL statements such as DDL and DML statements.
See Also DDL, DML, index, join, SQL, table.

query execution plan
The set of decisions made by the optimizer about how to perform a query most efficiently, including which index or indexes to use, and the order in which to join tables. Plan stability involves the same choices being made consistently for a given query.
See Also index, join, plan stability, query.

query log
See general query log.

quiesce
To reduce the amount of database activity, often in preparation for an operation such as an ALTER TABLE, a backup, or a shutdown. Might or might not involve doing as much flushing as possible, so that InnoDB does not continue doing background I/O.

In MySQL 5.6 and higher, the syntax FLUSH TABLES ... FOR EXPORT writes some data to disk for InnoDB tables that make it simpler to back up those tables by copying the data files.
See Also backup, flush, InnoDB, shutdown.

R

R-tree
A tree data structure used for spatial indexing of multi-dimensional data such as geographical coordinates, rectangles or polygons.
See Also B-tree.

RAID
Acronym for “Redundant Array of Inexpensive Drives”. Spreading I/O operations across multiple drives enables greater concurrency at the hardware level, and improves the efficiency of low-level write operations that otherwise would be performed in sequence.
See Also concurrency.

random dive
A technique for quickly estimating the number of different values in a column (the column's cardinality). InnoDB samples pages at random from the index and uses that data to estimate the number of different values.
See Also cardinality.

raw backup
The initial set of backup files produced by the MySQL Enterprise Backup product, before the changes reflected in the binary log and any incremental backups are applied. At this stage, the files are not ready to restore. After these changes are applied, the files are known as a prepared backup.
See Also binary log, hot backup, ibbackup_logfile, incremental backup, MySQL Enterprise Backup, prepared backup, restore.

READ COMMITTED
An isolation level that uses a locking strategy that relaxes some of the protection between transactions, in the interest of performance. Transactions cannot see uncommitted data from other transactions, but they can see data that is committed by another transaction after the current transaction started. Thus, a transaction never sees any bad data, but the data that it does see may depend to some extent on the timing of other transactions.

When a transaction with this isolation level performs UPDATE ... WHERE or DELETE ... WHERE operations, other transactions might have to wait. The transaction can perform SELECT ... FOR UPDATE, and lock in share mode operations without making other transactions wait.

SELECT ... FOR SHARE replaces SELECT ... LOCK IN SHARE MODE in MySQL 8.0.1, but LOCK IN SHARE MODE remains available for backward compatibility.
See Also ACID, isolation level, locking, REPEATABLE READ, SERIALIZABLE, transaction.

read phenomena
Phenomena such as dirty reads, non-repeatable reads, and phantom reads which can occur when a transaction reads data that another transaction has modified.
READ UNCOMMITTED

The **isolation level** that provides the least amount of protection between transactions. Queries employ a **locking** strategy that allows them to proceed in situations where they would normally wait for another transaction. However, this extra performance comes at the cost of less reliable results, including data that has been changed by other transactions and not committed yet (known as **dirty read**). Use this isolation level with great caution, and be aware that the results might not be consistent or reproducible, depending on what other transactions are doing at the same time. Typically, transactions with this isolation level only do queries, not insert, update, or delete operations.

See Also **ACID**, **dirty read**, **isolation level**, **locking**, **transaction**.

read view

An internal snapshot used by the **MVCC** mechanism of **InnoDB**. Certain **transactions**, depending on their **isolation level**, see the data values as they were at the time the transaction (or in some cases, the statement) started. Isolation levels that use a read view are **REPEATABLE READ**, **READ COMMITTED**, and **READ UNCOMMITTED**.

See Also **isolation level**, **MVCC**, **READ COMMITTED**, **READ UNCOMMITTED**, **REPEATABLE READ**, **transaction**.

read-ahead

A type of I/O request that prefetches a group of **pages** (an entire **extent**) into the **buffer pool** asynchronously, in anticipation that these pages will be needed soon. The linear read-ahead technique prefetches all the pages of one extent based on access patterns for pages in the preceding extent. The random read-ahead technique prefetches all the pages for an extent once a certain number of pages from the same extent are in the buffer pool. Random read-ahead is not part of MySQL 5.5, but is re-introduced in MySQL 5.6 under the control of the `innodb_random_read_ahead` configuration option.

See Also **buffer pool**, **extent**, **page**.

read-only transaction

A type of **transaction** that can be optimized for **InnoDB** tables by eliminating some of the bookkeeping involved with creating a **read view** for each transaction. Can only perform **non-locking read** queries. It can be started explicitly with the syntax `START TRANSACTION READ ONLY`, or automatically under certain conditions. See Section 8.5.3, “Optimizing InnoDB Read-Only Transactions” for details.

See Also **non-locking read**, **read view**, **transaction**.

record lock

A **lock** on an index record. For example, `SELECT c1 FROM t WHERE c1 = 10 FOR UPDATE;` prevents any other transaction from inserting, updating, or deleting rows where the value of `t.c1` is 10. Contrast with **gap lock** and **next-key lock**.

See Also **gap lock**, **lock**, **next-key lock**.

redo

The data, in units of records, recorded in the **redo log** when **DML** statements make changes to **InnoDB** tables. It is used during **crash recovery** to correct data written by incomplete **transactions**. The ever-increasing **LSN** value represents the cumulative amount of redo data that has passed through the redo log.

See Also **crash recovery**, **DML**, **LSN**, **redo log**, **transaction**.

redo log

A disk-based data structure used during **crash recovery**, to correct data written by incomplete **transactions**. During normal operation, it encodes requests to change **InnoDB** table data, which result from SQL statements or low-level API calls through NoSQL interfaces. Modifications that did not finish updating the **data files** before an unexpected **shutdown** are replayed automatically.

The redo log is physically represented as a set of files, typically named `ib_logfile0` and `ib_logfile1`. The data in the redo log is encoded in terms of records affected; this data is collectively referred to as **redo**. The
passage of data through the redo logs is represented by the ever-increasing **LSN** value. The original 4GB limit on maximum size for the redo log is raised to 512GB in MySQL 5.6.3.

The disk layout of the redo log is influenced by the configuration options `innodb_log_file_size`, `innodb_log_group_home_dir`, and (rarely) `innodb_log_files_in_group`. The performance of redo log operations is also affected by the **log buffer**, which is controlled by the `innodb_log_buffer_size` configuration option.

See Also crash recovery, data files, ib_logfile, log buffer, LSN, redo, shutdown, transaction.

**redo log archiving**

An InnoDB feature that, when enabled, sequentially writes redo log records to an archive file to avoid potential loss of data than can occur when a backup utility fails to keep pace with redo log generation while a backup operation is in progress. For more information, see Redo Log Archiving.

See Also redo log.

**redundant row format**

The oldest InnoDB row format. Prior to MySQL 5.0.3, it was the only row format available in InnoDB. From MySQL 5.0.3 to MySQL 5.7.8, the default row format is COMPACT. As of MySQL 5.7.9, the default row format is defined by the `innodb_default_row_format` configuration option, which has a default setting of DYNAMIC. You can still specify the REDUNDANT row format for compatibility with older InnoDB tables.

For more information, see Section 14.11, “InnoDB Row Formats”.

See Also compact row format, dynamic row format, row format.

**referential integrity**

The technique of maintaining data always in a consistent format, part of the ACID philosophy. In particular, data in different tables is kept consistent through the use of foreign key constraints, which can prevent changes from happening or automatically propagate those changes to all related tables. Related mechanisms include the unique constraint, which prevents duplicate values from being inserted by mistake, and the NOT NULL constraint, which prevents blank values from being inserted by mistake.

See Also ACID, FOREIGN KEY constraint, NOT NULL constraint, unique constraint.

**relational**

An important aspect of modern database systems. The database server encodes and enforces relationships such as one-to-one, one-to-many, many-to-one, and uniqueness. For example, a person might have zero, one, or many phone numbers in an address database; a single phone number might be associated with several family members. In a financial database, a person might be required to have exactly one taxpayer ID, and any taxpayer ID could only be associated with one person.

The database server can use these relationships to prevent bad data from being inserted, and to find efficient ways to look up information. For example, if a value is declared to be unique, the server can stop searching as soon as the first match is found, and it can reject attempts to insert a second copy of the same value.

At the database level, these relationships are expressed through SQL features such as columns within a table, unique and NOT NULL constraints, foreign keys, and different kinds of join operations. Complex relationships typically involve data split between more than one table. Often, the data is normalized, so that duplicate values in one-to-many relationships are stored only once.

In a mathematical context, the relations within a database are derived from set theory. For example, the OR and AND operators of a WHERE clause represent the notions of union and intersection.

See Also ACID, column, constraint, foreign key, normalized.

**relevance**

In the full-text search feature, a number signifying the similarity between the search string and the data in the FULLTEXT index. For example, when you search for a single word, that word is typically more relevant for a row where it occurs several times in the text than a row where it appears only once.
See Also full-text search, FULLTEXT index.

REPEATABLE READ
The default isolation level for InnoDB. It prevents any rows that are queried from being changed by other transactions, thus blocking non-repeatable reads but not phantom reads. It uses a moderately strict locking strategy so that all queries within a transaction see data from the same snapshot, that is, the data as it was at the time the transaction started.

When a transaction with this isolation level performs UPDATE ... WHERE, DELETE ... WHERE, SELECT ... FOR UPDATE, and LOCK IN SHARE MODE operations, other transactions might have to wait.

SELECT ... FOR SHARE replaces SELECT ... LOCK IN SHARE MODE in MySQL 8.0.1, but LOCK IN SHARE MODE remains available for backward compatibility.
See Also ACID, consistent read, isolation level, locking, phantom, transaction.

repertoire
Repertoire is a term applied to character sets. A character set repertoire is the collection of characters in the set.
See Section 10.2.1, “Character Set Repertoire”.

replication
The practice of sending changes from a master database, to one or more slave databases, so that all databases have the same data. This technique has a wide range of uses, such as load-balancing for better scalability, disaster recovery, and testing software upgrades and configuration changes. The changes can be sent between the database by methods called row-based replication and statement-based replication.
See Also master server, row-based replication, slave server, statement-based replication.

restore
The process of putting a set of backup files from the MySQL Enterprise Backup product in place for use by MySQL. This operation can be performed to fix a corrupted database, to return to some earlier point in time, or (in a replication context) to set up a new slave database. In the MySQL Enterprise Backup product, this operation is performed by the copy-back option of the mysqlbackup command.
See Also hot backup, MySQL Enterprise Backup, mysqlbackup command, prepared backup, replication, slave server.

rollback
A SQL statement that ends a transaction, undoing any changes made by the transaction. It is the opposite of commit, which makes permanent any changes made in the transaction.

By default, MySQL uses the autocommit setting, which automatically issues a commit following each SQL statement. You must change this setting before you can use the rollback technique.
See Also ACID, autocommit, commit, SQL, transaction.

rollback segment
The storage area containing the undo logs. Rollback segments have traditionally resided in the system tablespace. As of MySQL 5.6, rollback segments can reside in undo tablespaces. As of MySQL 5.7, rollback segments are also allocated to the global temporary tablespace.
See Also system tablespace, undo log, undo tablespace.

row
The logical data structure defined by a set of columns. A set of rows makes up a table. Within InnoDB data files, each page can contain one or more rows.

Although InnoDB uses the term row format for consistency with MySQL syntax, the row format is a property of each table and applies to all rows in that table.
See Also column, data files, page, row format, table.
row format
The disk storage format for rows of an InnoDB table. As InnoDB gains new capabilities such as compression, new row formats are introduced to support the resulting improvements in storage efficiency and performance.

The row format of an InnoDB table is specified by the ROW_FORMAT option or by the innodb_default_row_format configuration option (introduced in MySQL 5.7.9). Row formats include REDUNDANT, COMPACT, COMPRESSED, and DYNAMIC. To view the row format of an InnoDB table, issue the SHOW TABLE STATUS statement or query InnoDB table metadata in the INFORMATION_SCHEMA.

See Also compact row format, compressed row format, compression, dynamic row format, redundant row format, row, table.

row lock
A lock that prevents a row from being accessed in an incompatible way by another transaction. Other rows in the same table can be freely written to by other transactions. This is the type of locking done by DML operations on InnoDB tables.

Contrast with table locks used by MyISAM, or during DDL operations on InnoDB tables that cannot be done with online DDL; those locks block concurrent access to the table.

See Also DDL, DML, InnoDB, lock, locking, online DDL, table lock, transaction.

row-based replication
A form of replication where events are propagated from the master server specifying how to change individual rows on the slave server. It is safe to use for all settings of the innodb_autoinc_lock_mode option.

See Also auto-increment locking, innodb_autoinc_lock_mode, master server, replication, slave server, statement-based replication.

row-level locking
The locking mechanism used for InnoDB tables, relying on row locks rather than table locks. Multiple transactions can modify the same table concurrently. Only if two transactions try to modify the same row does one of the transactions wait for the other to complete (and release its row locks).

See Also InnoDB, locking, row lock, table lock, transaction.

rw-lock
The low-level object that InnoDB uses to represent and enforce shared-access locks to internal in-memory data structures following certain rules. Contrast with mutexes, which InnoDB uses to represent and enforce exclusive access to internal in-memory data structures. Mutexes and rw-locks are known collectively as latches.

rw-lock types include s-locks (shared locks), x-locks (exclusive locks), and sx-locks (shared-exclusive locks).

• An s-lock provides read access to a common resource.
• An x-lock provides write access to a common resource while not permitting inconsistent reads by other threads.
• An sx-lock provides write access to a common resource while permitting inconsistent reads by other threads. sx-locks were introduced in MySQL 5.7 to optimize concurrency and improve scalability for read-write workloads.

The following matrix summarizes rw-lock type compatibility.

<table>
<thead>
<tr>
<th></th>
<th>S</th>
<th>SX</th>
<th>X</th>
</tr>
</thead>
<tbody>
<tr>
<td>S</td>
<td>Compatible</td>
<td>Compatible</td>
<td>Conflict</td>

<tr>
<td>SX</td>
<td>Compatible</td>
<td>Conflict</td>
<td>Conflict</td>
</tr>
</tbody>
</table>
savepoint

Savepoints help to implement nested transactions. They can be used to provide scope to operations on tables that are part of a larger transaction. For example, scheduling a trip in a reservation system might involve booking several different flights; if a desired flight is unavailable, you might roll back the changes involved in booking that one leg, without rolling back the earlier flights that were successfully booked.

See Also rollback, transaction.

scalability

The ability to add more work and issue more simultaneous requests to a system, without a sudden drop in performance due to exceeding the limits of system capacity. Software architecture, hardware configuration, application coding, and type of workload all play a part in scalability. When the system reaches its maximum capacity, popular techniques for increasing scalability are scale up (increasing the capacity of existing hardware or software) and scale out (adding new servers and more instances of MySQL). Often paired with availability as critical aspects of a large-scale deployment.

See Also availability, scale out, scale up.

scale out

A technique for increasing scalability by adding new servers and more instances of MySQL. For example, setting up replication, NDB Cluster, connection pooling, or other features that spread work across a group of servers. Contrast with scale up.

See Also scalability, scale up.

scale up

A technique for increasing scalability by increasing the capacity of existing hardware or software. For example, increasing the memory on a server and adjusting memory-related parameters such as innodb_buffer_pool_size and innodb_buffer_pool_instances. Contrast with scale out.

See Also scalability, scale out.

schema

Conceptually, a schema is a set of interrelated database objects, such as tables, table columns, data types of the columns, indexes, foreign keys, and so on. These objects are connected through SQL syntax, because the columns make up the tables, the foreign keys refer to tables and columns, and so on. Ideally, they are also connected logically, working together as part of a unified application or flexible framework. For example, the INFORMATION_SCHEMA and performance_schema databases use “schema” in their names to emphasize the close relationships between the tables and columns they contain.

In MySQL, physically, a schema is synonymous with a database. You can substitute the keyword SCHEMA instead of DATABASE in MySQL SQL syntax, for example using CREATE SCHEMA instead of CREATE DATABASE.

Some other database products draw a distinction. For example, in the Oracle Database product, a schema represents only a part of a database: the tables and other objects owned by a single user.

See Also database, INFORMATION_SCHEMA, Performance Schema.

search index

In MySQL, full-text search queries use a special kind of index, the FULLTEXT index. In MySQL 5.6.4 and up, InnoDB and MyISAM tables both support FULLTEXT indexes; formerly, these indexes were only available for MyISAM tables.

See Also full-text search, FULLTEXT index.
secondary index
A type of InnoDB index that represents a subset of table columns. An InnoDB table can have zero, one, or many secondary indexes. (Contrast with the clustered index, which is required for each InnoDB table, and stores the data for all the table columns.)

A secondary index can be used to satisfy queries that only require values from the indexed columns. For more complex queries, it can be used to identify the relevant rows in the table, which are then retrieved through lookups using the clustered index.

Creating and dropping secondary indexes has traditionally involved significant overhead from copying all the data in the InnoDB table. The fast index creation feature makes both CREATE INDEX and DROP INDEX statements much faster for InnoDB secondary indexes.
See Also clustered index, Fast Index Creation, index.

segment
A division within an InnoDB tablespace. If a tablespace is analogous to a directory, the segments are analogous to files within that directory. A segment can grow. New segments can be created.

For example, within a file-per-table tablespace, table data is in one segment and each associated index is in its own segment. The system tablespace contains many different segments, because it can hold many tables and their associated indexes. Prior to MySQL 8.0, the system tablespace also includes one or more rollback segments used for undo logs.

Segments grow and shrink as data is inserted and deleted. When a segment needs more room, it is extended by one extent (1 megabyte) at a time. Similarly, a segment releases one extent's worth of space when all the data in that extent is no longer needed.
See Also extent, file-per-table, rollback segment, system tablespace, tablespace, undo log.

selectivity
A property of data distribution, the number of distinct values in a column (its cardinality) divided by the number of records in the table. High selectivity means that the column values are relatively unique, and can retrieved efficiently through an index. If you (or the query optimizer) can predict that a test in a WHERE clause only matches a small number (or proportion) of rows in a table, the overall query tends to be efficient if it evaluates that test first, using an index.
See Also cardinality, query.

semi-consistent read
A type of read operation used for UPDATE statements, that is a combination of READ COMMITTED and consistent read. When an UPDATE statement examines a row that is already locked, InnoDB returns the latest committed version to MySQL so that MySQL can determine whether the row matches the WHERE condition of the UPDATE. If the row matches (must be updated), MySQL reads the row again, and this time InnoDB either locks it or waits for a lock on it. This type of read operation can only happen when the transaction has the READ COMMITTED isolation level, or when the innodb_locks_unsafe_for_binlog option is enabled. innodb_locks_unsafe_for_binlog was removed in MySQL 8.0.
See Also consistent read, isolation level, READ COMMITTED.

SERIALIZABLE
The isolation level that uses the most conservative locking strategy, to prevent any other transactions from inserting or changing data that was read by this transaction, until it is finished. This way, the same query can be run over and over within a transaction, and be certain to retrieve the same set of results each time. Any attempt to change data that was committed by another transaction since the start of the current transaction, cause the current transaction to wait.

This is the default isolation level specified by the SQL standard. In practice, this degree of strictness is rarely needed, so the default isolation level for InnoDB is the next most strict, REPEATABLE READ.
See Also ACID, consistent read, isolation level, locking, REPEATABLE READ, transaction.

server
A type of program that runs continuously, waiting to receive and act upon requests from another program (the client). Because often an entire computer is dedicated to running one or more server programs (such as a database server, a web server, an application server, or some combination of these), the term server can also refer to the computer that runs the server software.
See Also client, mysqld.

shared lock
A kind of lock that allows other transactions to read the locked object, and to also acquire other shared locks on it, but not to write to it. The opposite of exclusive lock.
See Also exclusive lock, lock, transaction.

shared tablespace
Another way of referring to the system tablespace or a general tablespace. General tablespaces were introduced in MySQL 5.7. More than one table can reside in a shared tablespace. Only a single table can reside in a file-per-table tablespace.
See Also general tablespace, system tablespace.

sharp checkpoint
The process of flushing to disk all dirty buffer pool pages whose redo entries are contained in certain portion of the redo log. Occurs before InnoDB reuses a portion of a log file; the log files are used in a circular fashion. Typically occurs with write-intensive workloads.
See Also dirty page, flush, redo log, workload.

shutdown
The process of stopping the MySQL server. By default, this process cleans up operations for InnoDB tables, so InnoDB can be slow to shut down, but fast to start up later. If you skip the cleanup operations, it is fast to shut down but the cleanup must be performed during the next restart.

The shutdown mode for InnoDB is controlled by the innodb_fast_shutdown option.
See Also fast shutdown, InnoDB, slow shutdown, startup.

slave server
Frequently shortened to “slave”. A database server machine in a replication scenario that receives changes from another server (the master) and applies those same changes. Thus it maintains the same contents as the master, although it might lag somewhat behind.

In MySQL, slave servers are commonly used in disaster recovery, to take the place of a master servers that fails. They are also commonly used for testing software upgrades and new settings, to ensure that database configuration changes do not cause problems with performance or reliability.

Slave servers typically have high workloads, because they process all the DML (write) operations relayed from the master, as well as user queries. To ensure that slave servers can apply changes from the master fast enough, they frequently have fast I/O devices and sufficient CPU and memory to run multiple database instances on the same slave server. For example, the master server might use hard drive storage while the slave servers use SSDs.
See Also DML, master server, replication, server, SSD.

slow query log
A type of log used for performance tuning of SQL statements processed by the MySQL server. The log information is stored in a file. You must enable this feature to use it. You control which categories of “slow” SQL statements are logged. For more information, see Section 5.4.5, “The Slow Query Log”.
See Also general query log, log.
slow shutdown
   A type of **shutdown** that does additional **InnoDB** flushing operations before completing. Also known as a **clean shutdown**. Specified by the configuration parameter `innodb_fast_shutdown=0` or the command `SET GLOBAL innodb_fast_shutdown=0;`. Although the shutdown itself can take longer, that time will be saved on the subsequent startup.
   See Also **clean shutdown**, **fast shutdown**, **shutdown**.

snapshot
   A representation of data at a particular time, which remains the same even as changes are **committed** by other **transactions**. Used by certain **isolation levels** to allow **consistent reads**.
   See Also **commit**, **consistent read**, **isolation level**, **transaction**.

sort buffer
   The buffer used for sorting data during creation of an **InnoDB** index. Sort buffer size is configured using the `innodb_sort_buffer_size` configuration option.

space ID
   An identifier used to uniquely identify an **InnoDB** **tablespace** within a MySQL instance. The space ID for the **system tablespace** is always zero; this same ID applies to all tables within the system tablespace or within a general tablespace. Each **file-per-table** tablespace and **general tablespace** has its own space ID.

Prior to MySQL 5.6, this hardcoded value presented difficulties in moving **InnoDB** tablespace files between MySQL instances. Starting in MySQL 5.6, you can copy tablespace files between instances by using the **transportable tablespace** feature involving the statements `FLUSH TABLES ... FOR EXPORT`, `ALTER TABLE ... DISCARD TABLESPACE`, and `ALTER TABLE ... IMPORT TABLESPACE`. The information needed to adjust the space ID is conveyed in the `.cfg` file which you copy along with the tablespace. See Section 14.6.3.5, “Copying Tablespaces to Another Instance” for details.
   See Also `.cfg` file, **file-per-table**, **general tablespace**, `.ibd` file, **system tablespace**, **tablespace**, **transportable tablespace**.

sparse file
   A type of file that uses file system space more efficiently by writing metadata representing empty blocks to disk instead of writing the actual empty space. The **InnoDB** **transparent page compression** feature relies on sparse file support. For more information, see **InnoDB Page Compression**.
   See Also **hole punching**, **transparent page compression**.

spin
   A type of **wait** operation that continuously tests whether a resource becomes available. This technique is used for resources that are typically held only for brief periods, where it is more efficient to wait in a “busy loop” than to put the thread to sleep and perform a context switch. If the resource does not become available within a short time, the spin loop ceases and another wait technique is used.
   See Also **latch**, **lock**, **mutex**, **wait**.

SQL
   The Structured Query Language that is standard for performing database operations. Often divided into the categories **DDL**, **DML**, and **queries**. MySQL includes some additional statement categories such as **replication**.
   See Chapter 9, **Language Structure** for the building blocks of SQL syntax, Chapter 11, **Data Types** for the data types to use for MySQL table columns, Chapter 13, **SQL Statement Syntax** for details about SQL statements and their associated categories, and Chapter 12, **Functions and Operators** for standard and MySQL-specific functions to use in queries.
   See Also **DDL**, **DML**, **query**, **replication**.

SSD
   Acronym for “solid-state drive”. A type of storage device with different performance characteristics than a traditional hard disk drive (**HDD**): smaller storage capacity, faster for random reads, no moving parts, and with
a number of considerations affecting write performance. Its performance characteristics can influence the throughput of a disk-bound workload.
See Also disk-bound, HDD.

startup
The process of starting the MySQL server. Typically done by one of the programs listed in Section 4.3, “MySQL Server and Server-Startup Programs”. The opposite of shutdown.
See Also shutdown.

statement-based replication
A form of replication where SQL statements are sent from the master server and replayed on the slave server. It requires some care with the setting for the innodb_autoinc_lock_mode option, to avoid potential timing problems with auto-increment locking.
See Also auto-increment locking, innodb_autoinc_lock_mode, master server, replication, row-based replication, slave server.

statistics
Estimated values relating to each InnoDB table and index, used to construct an efficient query execution plan. The main values are the cardinality (number of distinct values) and the total number of table rows or index entries. The statistics for the table represent the data in its primary key index. The statistics for a secondary index represent the rows covered by that index.

The values are estimated rather than counted precisely because at any moment, different transactions can be inserting and deleting rows from the same table. To keep the values from being recalculated frequently, you can enable persistent statistics, where the values are stored in InnoDB system tables, and refreshed only when you issue an ANALYZE TABLE statement.

You can control how NULL values are treated when calculating statistics through the innodb_stats_method configuration option.

Other types of statistics are available for database objects and database activity through the INFORMATION_SCHEMA and PERFORMANCE_SCHEMA tables.
See Also cardinality, index, INFORMATION_SCHEMA, NULL, Performance Schema, persistent statistics, primary key, query execution plan, secondary index, table, transaction.

stemming
The ability to search for different variations of a word based on a common root word, such as singular and plural, or past, present, and future verb tense. This feature is currently supported in MyISAM full-text search feature but not in FULLTEXT indexes for InnoDB tables.
See Also full-text search, FULLTEXT index.

stopword
In a FULLTEXT index, a word that is considered common or trivial enough that it is omitted from the search index and ignored in search queries. Different configuration settings control stopword processing for InnoDB and MyISAM tables. See Section 12.9.4, “Full-Text Stopwords” for details.
See Also FULLTEXT index, search index.

storage engine
A component of the MySQL database that performs the low-level work of storing, updating, and querying data. In MySQL 5.5 and higher, InnoDB is the default storage engine for new tables, superceding MyISAM. Different storage engines are designed with different tradeoffs between factors such as memory usage versus disk usage, read speed versus write speed, and speed versus robustness. Each storage engine manages specific tables, so we refer to InnoDB tables, MyISAM tables, and so on.

The MySQL Enterprise Backup product is optimized for backing up InnoDB tables. It can also back up tables handled by MyISAM and other storage engines.
stored object
A stored program or view.

stored program
A stored routine (procedure or function), trigger, or Event Scheduler event.

stored routine
A stored procedure or function.

strict mode
The general name for the setting controlled by the `innodb_strict_mode` option. Turning on this setting causes certain conditions that are normally treated as warnings, to be considered errors. For example, certain invalid combinations of options related to `file format` and `row format`, that normally produce a warning and continue with default values, now cause the `CREATE TABLE` operation to fail. `innodb_strict_mode` is enabled by default in MySQL 5.7.

MySQL also has something called strict mode. See Section 5.1.10, “Server SQL Modes”. See Also `file format`, `innodb_strict_mode`, `row format`.

sublist
Within the list structure that represents the `buffer pool`, pages that are relatively old and relatively new are represented by different portions of the `list`. A set of parameters control the size of these portions and the dividing point between the new and old pages.
See Also `buffer pool`, `eviction`, `list`, `LRU`.

supremum record
A pseudo-record in an index, representing the gap above the largest value in that index. If a transaction has a statement such as `SELECT ... FROM ... WHERE col > 10 FOR UPDATE;`, and the largest value in the column is 20, it is a lock on the supremum record that prevents other transactions from inserting even larger values such as 50, 100, and so on.
See Also `gap`, `infimum record`, `pseudo-record`.

surrogate key
Synonym name for synthetic key.
See Also `synthetic key`.

synthetic key
An indexed column, typically a primary key, where the values are assigned arbitrarily. Often done using an auto-increment column. By treating the value as completely arbitrary, you can avoid overly restrictive rules and faulty application assumptions. For example, a numeric sequence representing employee numbers might have a gap if an employee was approved for hiring but never actually joined. Or employee number 100 might have a later hiring date than employee number 500, if they left the company and later rejoined. Numeric values also produce shorter values of predictable length. For example, storing numeric codes meaning “Road”, “Boulevard”, “Expressway”, and so on is more space-efficient than repeating those strings over and over.

Also known as a surrogate key. Contrast with natural key.
See Also `auto-increment`, `natural key`, `primary key`, `surrogate key`.

system tablespace
One or more data files (`ibdata files`) containing metadata for InnoDB-related objects (the InnoDB data dictionary), and the storage areas for the change buffer, the doublewrite buffer, and possibly undo logs. Depending on the `innodb_file_per_table` setting, it might also contain table and index data for InnoDB tables. The data and metadata in the system tablespace apply to all databases in a MySQL instance.
Prior to MySQL 5.6.7, the default was to keep all InnoDB tables and indexes inside the system tablespace, often causing this file to become very large. Because the system tablespace never shrinks, storage problems could arise if large amounts of temporary data were loaded and then deleted. In MySQL 5.6.7 and higher, the default is **file-per-table** mode, where each table and its associated indexes are stored in a separate .ibd file. This default makes it easier to use InnoDB features that rely on the Barracuda file format, such as table compression, efficient storage of off-page columns, and large index key prefixes (innodb_large_prefix).

Keeping all table data in the system tablespace or in separate .ibd files has implications for storage management in general. The MySQL Enterprise Backup product might back up a small set of large files, or many smaller files. On systems with thousands of tables, the file system operations to process thousands of .ibd files can cause bottlenecks.

In MySQL 5.6 and higher, the `innodb_undo_tablespaces` defines the number of undo tablespaces for undo logs.

**See Also** Barracuda, change buffer, compression, data dictionary, database, doublewrite buffer, dynamic row format, file-per-table, general tablespace, .ibd file, ibdata file, innodb_file_per_table, instance, MySQL Enterprise Backup, off-page column, tablespace, undo log.
The rows of an InnoDB table are organized into an index structure known as the clustered index, with entries sorted based on the primary key columns of the table. Data access is optimized for queries that filter and sort on the primary key columns, and each index contains a copy of the associated primary key columns for each entry. Modifying values for any of the primary key columns is an expensive operation. Thus an important aspect of InnoDB table design is choosing a primary key with columns that are used in the most important queries, and keeping the primary key short, with rarely changing values.

See Also Antelope, backup, Barracuda, clustered index, compact row format, compressed row format, compression, dynamic row format, Fast Index Creation, file-per-table, .ibd file, index, off-page column, primary key, redundant row format, row, system tablespace, timespace.

table lock
A lock that prevents any other transaction from accessing a table. InnoDB makes considerable effort to make such locks unnecessary, by using techniques such as online DDL, row locks and consistent reads for processing DML statements and queries. You can create such a lock through SQL using the LOCK TABLE statement; one of the steps in migrating from other database systems or MySQL storage engines is to remove such statements wherever practical.

See Also consistent read, DML, lock, locking, online DDL, query, row lock, table, transaction.

table scan
See full table scan.

table statistics
See statistics.

table type
Obsolete synonym for storage engine. We refer to InnoDB tables, MyISAM tables, and so on.
See Also InnoDB, storage engine.

tablespace
A data file that can hold data for one or more InnoDB tables and associated indexes.

The system tablespace contains the InnoDB data dictionary, and prior to MySQL 5.6 holds all other InnoDB tables by default.

The innodb_file_per_table option, enabled by default in MySQL 5.6 and higher, allows tables to be created in their own tablespaces. File-per-table tablespaces support features such as efficient storage of off-page columns, table compression, and transportable tablespaces. See Section 14.6.3.2, “File-Per-Table Tablespaces” for details.

InnoDB introduced general tablespaces in MySQL 5.7.6. General tablespaces are shared tablespaces created using CREATE TABLESPACE syntax. They can be created outside of the MySQL data directory, are capable of holding multiple tables, and support tables of all row formats.

MySQL NDB Cluster also groups its tables into tablespaces. See Section 18.5.12.1, “NDB Cluster Disk Data Objects” for details.
See Also compressed row format, data dictionary, data files, file-per-table, general tablespace, index, innodb_file_per_table, system tablespace, table.

temporary table
A table whose data does not need to be truly permanent. For example, temporary tables might be used as storage areas for intermediate results in complicated calculations or transformations; this intermediate data would not need to be recovered after a crash. Database products can take various shortcuts to improve the performance of operations on temporary tables, by being less scrupulous about writing data to disk and other measures to protect the data across restarts.

Sometimes, the data itself is removed automatically at a set time, such as when the transaction ends or when the session ends. With some database products, the table itself is removed automatically too.
See Also table.

temporary tablespace
The tablespace for non-compressed InnoDB temporary tables and related objects, introduced in MySQL 5.7. The innodb_temp_data_file_path configuration file option defines the relative path, name, size, and attributes for temporary tablespace data files. If innodb_temp_data_file_path is not specified, the default behavior is to create a single auto-extending 12MB data file named ibtmp1 in the data directory. The temporary tablespace is recreated on each server start and receives a dynamically generated space ID. The temporary tablespace cannot reside on a raw device. Startup is refused if the temporary tablespace cannot be created.

The temporary tablespace is removed on normal shutdown or on an aborted initialization. The temporary tablespace is not removed when a crash occurs. In this case, the database administrator may remove the temporary tablespace manually or restart the server with the same configuration, which removes and recreates the temporary tablespace.
See Also temporary table.

text collection
The set of columns included in a FULLTEXT index.
See Also FULLTEXT index.

thread
A unit of processing that is typically more lightweight than a process, allowing for greater concurrency.
See Also concurrency, master thread, process, Pthreads.

torn page
An error condition that can occur due to a combination of I/O device configuration and hardware failure. If data is written out in chunks smaller than the InnoDB page size (by default, 16KB), a hardware failure while writing could result in only part of a page being stored to disk. The InnoDB doublewrite buffer guards against this possibility.
See Also doublewrite buffer.

TPS
Acronym for “transactions per second”, a unit of measurement sometimes used in benchmarks. Its value depends on the workload represented by a particular benchmark test, combined with factors that you control such as the hardware capacity and database configuration.
See Also transaction, workload.

transaction
Transactions are atomic units of work that can be committed or rolled back. When a transaction makes multiple changes to the database, either all the changes succeed when the transaction is committed, or all the changes are undone when the transaction is rolled back.

Database transactions, as implemented by InnoDB, have properties that are collectively known by the acronym ACID, for atomicity, consistency, isolation, and durability.
See Also ACID, commit, isolation level, lock, rollback.

transaction ID
An internal field associated with each row. This field is physically changed by INSERT, UPDATE, and DELETE operations to record which transaction has locked the row.
See Also implicit row lock, row, transaction.

transparent page compression
A feature added in MySQL 5.7.8 that permits page-level compression for InnoDB tables that reside in file-per-table tablespaces. Page compression is enabled by specifying the COMPRESSION attribute with CREATE TABLE or ALTER TABLE. For more information, see InnoDB Page Compression.
See Also file-per-table, hole punching, sparse file.
transportable tablespace

A feature that allows a tablespace to be moved from one instance to another. Traditionally, this has not been possible for InnoDB tablespaces because all table data was part of the system tablespace. In MySQL 5.6 and higher, the FLUSH TABLES ... FOR EXPORT syntax prepares an InnoDB table for copying to another server; running ALTER TABLE ... DISCARD TABLESPACE and ALTER TABLE ... IMPORT TABLESPACE on the other server brings the copied data file into the other instance. A separate .cfg file, copied along with the .ibd file, is used to update the table metadata (for example the space ID) as the tablespace is imported. See Section 14.6.3.5, “Copying Tablespaces to Another Instance” for usage information.

See Also .cfg file, .ibd file, space ID, system tablespace, tablespace.

troubleshooting

The process of determining the source of a problem. Some of the resources for troubleshooting MySQL problems include:

- Section 2.10.2.1, “Troubleshooting Problems Starting the MySQL Server”
- Section 6.2.14, “Troubleshooting Problems Connecting to MySQL”
- Section B.4.3.2, “How to Reset the Root Password”
- Section B.4.2, “Common Errors When Using MySQL Programs”
- Section 14.21, “InnoDB Troubleshooting”.

truncate

A DDL operation that removes the entire contents of a table, while leaving the table and related indexes intact. Contrast with drop. Although conceptually it has the same result as a DELETE statement with no WHERE clause, it operates differently behind the scenes: InnoDB creates a new empty table, drops the old table, then renames the new table to take the place of the old one. Because this is a DDL operation, it cannot be rolled back.

If the table being truncated contains foreign keys that reference another table, the truncation operation uses a slower method of operation, deleting one row at a time so that corresponding rows in the referenced table can be deleted as needed by any ON DELETE CASCADE clause. (MySQL 5.5 and higher do not allow this slower form of truncate, and return an error instead if foreign keys are involved. In this case, use a DELETE statement instead.

See Also DDL, drop, foreign key, rollback.

tuple

A technical term designating an ordered set of elements. It is an abstract notion, used in formal discussions of database theory. In the database field, tuples are usually represented by the columns of a table row. They could also be represented by the result sets of queries, for example, queries that retrieved only some columns of a table, or columns from joined tables.

See Also cursor.

two-phase commit

An operation that is part of a distributed transaction, under the XA specification. (Sometimes abbreviated as 2PC.) When multiple databases participate in the transaction, either all databases commit the changes, or all databases rollback the changes.

See Also commit, rollback, transaction, XA.

U

undo

Data that is maintained throughout the life of a transaction, recording all changes so that they can be undone in case of a rollback operation. It is stored in undo logs either within the system tablespace (in MySQL 5.7 or earlier) or in separate undo tablespaces. As of MySQL 8.0, undo logs reside in undo tablespaces by default.

See Also rollback, rollback segment, system tablespace, transaction, undo log, undo tablespace.
undo buffer
   See undo log.

undo log
   A storage area that holds copies of data modified by active transactions. If another transaction needs to see the original data (as part of a consistent read operation), the unmodified data is retrieved from this storage area.

In MySQL 5.6 and MySQL 5.7, you can use the innodb_undo_tablespaces variable have undo logs reside in undo tablespaces, which can be placed on another storage device such as an SSD. In MySQL 8.0, undo logs reside in two default undo tablespaces that are created when MySQL is initialized, and additional undo tablespaces can be created using CREATE UNDO TABLESPACE syntax.

The undo log is split into separate portions, the insert undo buffer and the update undo buffer.
See Also consistent read, rollback segment, SSD, system tablespace, transaction, undo tablespace.

undo log segment
   A collection of undo logs. Undo log segments exists within rollback segments. An undo log segment might contain undo logs from multiple transactions. An undo log segment can only be used by one transaction at a time but can be reused after it is released at transaction commit or rollback. May also be referred to as an “undo segment”.
See Also commit, rollback, rollback segment, undo log.

undo tablespace
   An undo tablespace contains undo logs. Undo logs exist within undo log segments, which are contained within rollback segments. Rollback segments have traditionally resided in the system tablespace. As of MySQL 5.6, rollback segments can reside in undo tablespaces. In MySQL 5.6 and MySQL 5.7, the number of undo tablespaces is controlled by the innodb_undo_tablespaces configuration option. In MySQL 8.0, two default undo tablespaces are created when the MySQL instance is initialized, and additional undo tablespaces can be created using CREATE UNDO TABLESPACE syntax.

For more information, see Section 14.6.3.3, “Undo Tablespaces”.
See Also rollback segment, system tablespace, undo log, undo log segment.

unique constraint
   A kind of constraint that asserts that a column cannot contain any duplicate values. In terms of relational algebra, it is used to specify 1-to-1 relationships. For efficiency in checking whether a value can be inserted (that is, the value does not already exist in the column), a unique constraint is supported by an underlying unique index.
See Also constraint, relational, unique index.

unique index
   An index on a column or set of columns that have a unique constraint. Because the index is known not to contain any duplicate values, certain kinds of lookups and count operations are more efficient than in the normal kind of index. Most of the lookups against this type of index are simply to determine if a certain value exists or not. The number of values in the index is the same as the number of rows in the table, or at least the number of rows with non-null values for the associated columns.

   Change buffering optimization does not apply to unique indexes. As a workaround, you can temporarily set unique_checks=0 while doing a bulk data load into an InnoDB table.
See Also cardinality, change buffering, unique constraint, unique key.

unique key
   The set of columns (one or more) comprising a unique index. When you can define a WHERE condition that matches exactly one row, and the query can use an associated unique index, the lookup and error handling can be performed very efficiently.
See Also cardinality, unique constraint, unique index.

**V**

variable-length type

A data type of variable length. `VARCHAR`, `VARBINARY`, and `BLOB` and `TEXT` types are variable-length types.

*InnoDB* treats fixed-length fields greater than or equal to 768 bytes in length as variable-length fields, which can be stored off-page. For example, a `CHAR(255)` column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with `utf8mb4`.

See Also off-page column, overflow page.

victim

The transaction that is automatically chosen to be rolled back when a deadlock is detected. *InnoDB* rolls back the transaction that has updated the fewest rows.

**Deadlock detection** can be disabled using the `innodb_deadlock_detect` configuration option.

See Also deadlock, deadlock detection, `innodb_lock_wait_timeout`, transaction.

view

A stored query that when invoked produces a result set. A view acts as a virtual table.

**W**

wait

When an operation, such as acquiring a lock, mutex, or latch, cannot be completed immediately, *InnoDB* pauses and tries again. The mechanism for pausing is elaborate enough that this operation has its own name, the wait. Individual threads are paused using a combination of internal *InnoDB* scheduling, operating system `wait()` calls, and short-duration spin loops.

On systems with heavy load and many transactions, you might use the output from the `SHOW INNODB STATUS` command or *Performance Schema* to determine whether threads are spending too much time waiting, and if so, how you can improve concurrency.

See Also concurrency, latch, lock, mutex, Performance Schema, spin.

warm backup

A backup taken while the database is running, but that restricts some database operations during the backup process. For example, tables might become read-only. For busy applications and websites, you might prefer a hot backup.

See Also backup, cold backup, hot backup.

warm up

To run a system under a typical workload for some time after startup, so that the buffer pool and other memory regions are filled as they would be under normal conditions. This process happens naturally over time when a MySQL server is restarted or subjected to a new workload.

Typically, you run a workload for some time to warm up the buffer pool before running performance tests, to ensure consistent results across multiple runs; otherwise, performance might be artificially low during the first run.

In MySQL 5.6, you can speed up the warmup process by enabling the `innodb_buffer_pool_dump_at_shutdown` and `innodb_buffer_pool_load_at_startup` configuration options, to bring the contents of the buffer pool back into memory after a restart. These options are enabled by default in MySQL 5.7. See Section 14.8.3.5, “Saving and Restoring the Buffer Pool State”.

See Also buffer pool, workload.
workload
The combination and volume of SQL and other database operations, performed by a database application
during typical or peak usage. You can subject the database to a particular workload during performance testing to
identify bottlenecks, or during capacity planning.
See Also bottleneck, CPU-bound, disk-bound, SQL.

write combining
An optimization technique that reduces write operations when dirty pages are flushed from the InnoDB buffer
pool. If a row in a page is updated multiple times, or multiple rows on the same page are updated, all of those
changes are stored to the data files in a single write operation rather than one write for each change.
See Also buffer pool, dirty page, flush.

XA
A standard interface for coordinating distributed transactions, allowing multiple databases to participate in a
transaction while maintaining ACID compliance. For full details, see Section 13.3.7, “XA Transactions”.

XA Distributed Transaction support is enabled by default. If you are not using this feature, you can disable the
innodb_support_xa configuration option, avoiding the performance overhead of an extra fsync for each
transaction.

As of MySQL 5.7.10, disabling innodb_support_xa is not permitted as it makes replication unsafe and
prevents performance gains associated with binary log group commit. The innodb_support_xa configuration
option is removed in MySQL 8.0.
See Also ACID, binary log, commit, transaction, two-phase commit.

young
A characteristic of a page in the InnoDB buffer pool meaning it has been accessed recently, and so is moved
within the buffer pool data structure, so that it will not be flushed soon by the LRU algorithm. This term is used in
some INFORMATION_SCHEMA column names of tables related to the buffer pool.
See Also buffer pool, flush, INFORMATION_SCHEMA, LRU, page.
